Colour functions both to separate and combine areas in the visual field. Like colours tend to represent continuous surfaces. Unlike colours, of course, involve bounding contours and thus tend to segregate areas from each other. While colour in some cases does not directly position areas, it helps determine what areas do or do not belong together. This indirectly has to do with spatial localization. Colour, especially as it pertains to familiar objects, does, however, tend to have properties of localization. Relative distinctness of contours within and bounding objects helps position them. Blurred contours indicate remoteness of objects.

Perception possesses a kind of self-consistency, as has been illustrated in the relations between size, brightness and position, etc. When these are investigated, one factor in the complex seems to be the reference toward which all other factors assume their rightful value. One of the references is the previously illustrated known size, a property possessed by all familiar objects. For example, if a playing card is the sole object illuminated in a dark room, the observer's familiarity with the normal size of a playing card determines the distance at which the card seems to be. Curiously enough, subsequent knowledge of the substitution of undersized and oversized specimens does not materially change the error in perception, at least without the intervention of a learning period.

Although known size is a very common reference toward which all other perceived qualities bear a consistency, it is not always the reference. Under certain conditions the factors of parallax or overlay operate as the primary considerations.

Overlay may be illustrated in the example given in fig. 11.

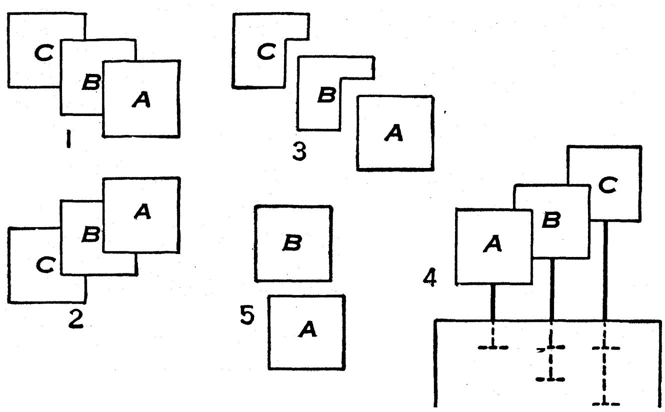

FIG. 11.—OVERLAY AND ELEVATION DETERMINING SPATIAL LOCATION

Square *A* overlays square *B* which in turn overlays C. This may be literal overlay in which B is actually behind *A*, and C is actually behind B in space. In the illustration all three squares lie in one plane for they are part of a two-dimensional drawing. If appropriate portions of squares B and C are removed as in the illustration, the three squares may be set up as cards on rod stands on a table, in which case *A*, instead of being nearest the observer, can be placed farthest away. Card C can be placed in front of B. All that matters is that the three cards be properly lined up with direction of the observer's regard and cues which help to indicate distance are obliterated. One of the main cues of this sort is the position of the rod stands on the table. These can be shielded from view as in 4 of fig. 11. When cards *A*, B and C are not placed so as to overlay one another, the upper of the three generally appears to be farther away. The apparent relative positions of the upper and lower of the three cards is, however, reversible so that the lower card may sometimes appear to be farther away. When the cards are mere pictures of squares in a two-dimensional drawing, relative elevation is a very common factor in producing perspective. However, in three-dimensional situations, sidewise motion of the head will involve parallax, providing sufficient indication for seeing the cards in their true relative distances from the eye regardless of relative elevation. The role of colour is best illustrated in the case of mountains and distant hills. They appear a different colour than near by elevations in land and appear at different distances from day to day depending among other things upon the change in colour. With changes in colour from day to day goes relative indistinctness from haze.

Experimental shifts in brightness will plainly indicate the role of this factor in positioning objects subjectively. All that is needed is to change the brightness on the playing cards under the conditions of presentation described above. If two cards, for instance, are used, the illumination on the one may be dimmed while that on the other may be raised. The two cards will change relative positions. The one whose illumination was lowered will recede, whereas the other one will come nearer to the eye.

The size of the retinal image of an object can be manipulated by three methods—changing the size of the object itself, changing its distance from the eye, and using optical devices involving magnification or diminution. Three-dimensional objects as well as those of two are represented upon the retina in only two dimensions, for it is, in effect, a plane. While the relation between a three-dimensional object and its representation in two dimensions is subject to law, the relations are far from simple, this being in part due to the fact that perceptual processes are involved in the outcome. As previously pointed out, objects of rather fixed conceptual size retain this, regardless of certain changes in the size of the retinal images involved. Manipulations of retinal-image size are interpreted by the individual as manipulations in distance from the individual. This factor comes into play in the use of magnification (in the use of binoculars), the result being that instead of its causing the object to appear larger, it tends to make it appear closer to the observer.

Augmenting the size of the retinal image of an object by bringing the object close to the eye differs from augmentation by instrumental magnification in the effect produced upon the angular relations of the components of the retinal image. Bringing an object closer to the eye (the object retaining its own fixed actual third dimension) enhances the angular relations subtended by the third-dimensional components in the eye. Increasing the image by instrumental magnification of an object at a fixed distance from the eye results in an over-all magnification without an increase in the angles subtended by the third-dimensional components of the object. This diminishes the amount of third dimension relative to the other two. The object, if originally a cube, now looks flatter than a cube.

While many three-dimensional objects tend to appear flattened when magnified by optical means, some of them, which when viewed without magnification are rectilinear, assume what is known as Chinese perspective (see fig. 12). The magnification is two-fold, as is indicated schematically by the dotted lines in fig. 12. The broken lines in the drawing converge at the eye position. The nearer dark-walled cube indicates where the cube is seen when instrumental magnification is employed. The basis for distortion known as Chinese perspective is indicated by the broken lines projected from the magnified cube. Note that the cube after magnification covers more area on the retina, a two-dimensional surface, but does not change shape so as properly to represent an object magnified in the third dimension. The result is that what was rectilinear becomes distorted so that the vertical a representing the more distant edge of the figure is greater than the nearer one b. The cube is now distorted, and becomes an example of Chinese perspective.

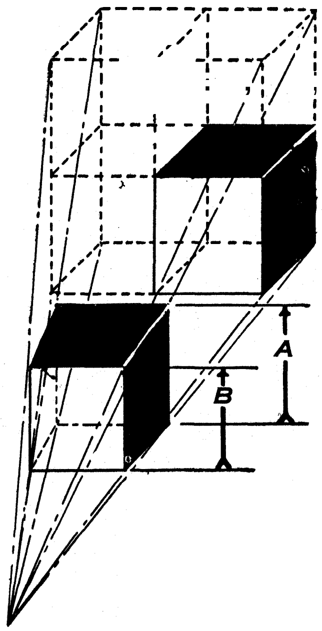

FIG. 12.—CHINESE PERSPECTIVE INSTRUMENTAL MAGNIFICATION OR RETINAL IMAGE

Binocular Vision.—The factors of overlay, etc., operate when only one eye is used and even though they operate in the use of both eyes, they are spoken of as uniocular or monocular factors. The factors peculiar to binocular vision arise from the relations in size, shape and position of the images on the two retinas. The points on the two retinas are classified into those which correspond and those which do not. Corresponding points are the points on the two retinas from which images are projected to the same place in the common visual field. Since the two uniocular visual fields do not fully overlap, the nasal periphery of each retina possesses no corresponding point in the other eye. In all other areas of the retina, each point is physiologically related to a corresponding point in the other eye. The centres of the two foveae are corresponding points, and thus, if an object is looked at directly, the images of the point fixated will fall on them. In cases of squint (cross-eyedness), this is not the case and only seldom is binocular vision possible. Either the image lying off the fovea in one eye is functionally suppressed, or double vision results. When, in some cases of squint, binocular (single) vision is possible. the off-fovea point must function as a corresponding point to the foveal one in the other eye. Noncorresponding points are also called disparate points. Although single vision is possible with disparate points, double vision with corresponding points has not been proved to occur.

To illustrate the operation of the two images in providing cues for space localization, the following will serve Let the individual fixate a square The images of the square are presumably equal in size and fall correspondingly on the two retinas The square is seen directly in front of the individual and in a plane at right angles to the line of regard. If the square is now rotated about its vertical axis so as to be obliquely oriented with regard to the observer, the two retinal images of it will now differ one from the other. If the square is turned so that the left side is farther anay from the eyes than the right side, the shift in the dimensions of the images in the horizontal axis will be as indicated in fig. 13.

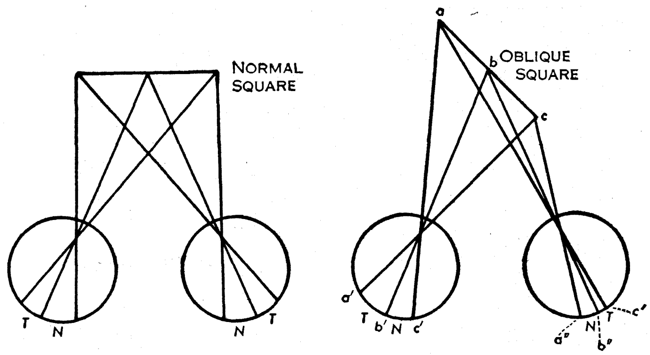

FIG. 13.—SIZE RELATIONS OF THE COMPONENTS OF THE RETINAL IMAGES

Since the surface of the square is more nearly at right angles to the left eye, the image in that eye will be larger than the one in the right eye. Likewise there will be less difference between the nasal and temporal portions of the image in the left eye than in the right. There will be less difference between the temporal portion $a'b'$ (see fig 13) and the nasal portion $b'c'$ in the left eye than between $a''b''$ and $b''c''$ in the right eye. Likewise the over-all image size $a'c'$ in the left eye will be different from $a''c''$ in the right eye Such differences as these in the two retinal images are used by the organism to indicate the spatial orientation of objects. Whereas we have just described some of the image differences which were produced by a specific object of a given size and a given orientation in space, and at a given distance from the eyes. this object is not the only one nhich will produce retinal images of the same specification. The retinal images in the two eyes in the original situation were squares; in the second situation, they were two unequal trapezoids. Any figure which, when properly oriented. will approximate the obliquely oriented square in producing retinal images will tend to function as square. This result is dependent in large part upon the absence of cues in the visual field which would aid in distinguishing the new figure from the square. In a drawing on a sheet of paper normal to the line of regard. a trapezoid can be seen as a square turned obliquely toward the observer. If certain lens systems are interposed between the visual field and the eyes. manipulations in space perception are the result. Lenses not only have what are called power effects, but result in size or magnification effects. Magnification can be produced in all meridians or in one meridian. In the first case, it is called over-all magnification; in the latter, meridional. A refracting medium such as glass or transparent plastic, whose surfaces are parallel (plano) will, when shaped into a curve, produce the necessary refraction to result in the magnification of the image in one meridian; viz, the meridian of the curvature. If this sort of a lens is placed in front of one eye and no lens or a plano lens in front of the other, an experienced distortion of visual space results. The experience is, of course, that of a distortion only by virtue of the fact that known objects no longer possess their original shape, or by virtue of the fact that unknown spatial fields cannot be properly responded to by bodily movements. Objects do not look to be where they can be reached by the hands and feet, etc. While the precise description of the geometry and physiological optics involved in the use of size lenses is too complex to be given here, it can be said in general that experiences produced are those which would result from manipulating the relative sizes and shapes of the two retinal images by moving actual objects (walls, tables, etc ,) toward or away from, or to one side or another, tilting them, or distorting their shapes. There is one gross exception—that the more distant objects appear to be larger and the nearer objects smaller when size lenses are used. This is just the reverse of the resulting appearances of objects in normal naked-eye situations. Since the lenses unequalize the sizes of the two retinal images, the effects have been given the name of aniseikonia, a nord derived from Greek words meaning unequal images. Aniseikonia is of two forms. the laboratory variety, which is produced by size·lenses, and a form occurring clinically with sometimes attendant disturbing symptoms all the way from headaches and gastrointestinal disturbances to feelings that the environment is somewhat unreal.

The **Horopter.**—This is the sum of the points in space that are projected on corresponding points of the two retinas, for any given fixation of the two eyes. Since, by definition. all the points which fall on the corresponding portions of the two eyes are seen as single. all the respective points on the horopter are seen as single. The horopter is an imaginary line, its form depending upon the distance of the fixation point from the eyes. At about two metres. it is theoretically a straight line passing through the fixation point. At a distance considerably less than two metres, the line is concave in the direction of the observer. At distances greater than two metres, the line is convex.

Curiously enough. other than geometrical considerations have to do nith the shape of the horopter. Its shape changes with the level of illumination. with the degree of contrast between objects observed and their backgrounds. Colours also help to determine the end-results. For example, the horopter for red is flatter than for blue. Actually the duration of stimulus exposure used in the determination of the horopter also affects its position.

Visual Perception of Movement.—Response to movement is the most primitive of all visual reactions. An observer may respond to visually presented movement. with only the vaguest apprehension of the direction and extent of the movement and with no appreciation of the size, contours or colour of the moving object.

Most of the other functions of vision, the object reference, localization of objects. attribution of size, contour and distance, may be regarded as bound up in some way with the response to movement. In the course of development, however, they come to have independent status.

The experience of motion is dependent first upon what happens in the retina. Shifts in images on the retina involving certain rates of temporal sequence give rise to the sensation of motion. Such sequences are set up by the images of physical objects which actually move relative to the eye, but it is not only the actual motion of such objects that forms the basis for retinal events leading to the experience of motion. Stationary objects appearing and disappearing at the proper places in the visual field. and at certain critical time relations relative to each other will serve to provide sequences of retinal stimulation adequate to elicit motion perception. The experience of movement induced in this way is called apparent movement, whereas the experience dependent upon physical movement of objects is called real movement.

The experience of movement (real) possesses both lower and upper limits for its elicitation. If the angular movement of an object is 30° per second, its contours are distinct, but if angular movement is considerably below this, no movement is seen. Two successive observations separated by a time interval will serve to indicate that the object has moved, but no direct perception of that movement is possible. The upper range of motion perception involves stages in which the object loses its sharp contours and a limited streaklike effect emerges (14°–21° per second). Finally. the result is a streak across the entire field of vision (116° per second). Under some conditions an object travelling at high rates of angular speed across the field of vision will not be seen even as a streak. It will not be seen at all. The experienced (phenomenal) rate of movement does not bear a fixed relation to actual speed of movement. The size of field through which an object moves is one determinant of this. Other determinants include: (1) geometrical complexity of the field through which an object moves; (2 j the orientation of the object (whether moving in a line with its long axis or its short axis) ; (3) the size of the object and (4) possibly the direction of movement.

Apparent movement can be elicited in many ways. One of the simplest of these is to open and close the eyes alternately while looking in the distance. A near-by object such as a pencil held vertically will move horizontally back and forth. The amount of this motion depends upon which of the two eyes is opened and closed. The dominant eye tends to induce the greater shift in position of the object. Another good example of apparent movement is the experience produced when a lamp is turned on and off while fixating it. As it is turned off. the light it produced does not seem to disappear from all parts of the visual field simultaneously. It disappears last at the lamp itself, having progressively contracted centripetally from the periphery of the field. When the lamp is again turned on, the reverse progression occurs. The light quickly expands centrifugally. Most examples of apparent movement are classified into the following categories:

1. Gamma-movement, the kind just described. It is the expansion and contraction in the visual field elicited by a single stationary object as illumination is raised or lowered at a sufficient rate.

2. Beta-movement. the experience of a single object moving from one place to another when two stationary objects separated in space and time appear and disappear.

3. Delta-movement, a second effect gained from the same objects which produce beta-movement, when they are considerably brighter than the surrounding visual field: and the second object is brighter than the first. Upon the usual presentation of the two objects. beta-movement first occurs. It proceeds from the first to the second objects. Then. since the second object is more intense than the first, a movement in the reverse direction immediately follows. This latter movement is the phenomenon which is called delta-movement.

4. Alpha-movement, the elongation and contraction or other change of an illusory pattern as the appropriate parts of it are exposed in succession. For example, we have in fig. 14 what is known as the Müller-Lyer illusion. Whereas, the two sections of the horizontal line are of equal length as measured physically, they appear unequal. If this figure is presented in two parts, alpha-movement will be seen. Let the lower section including the wings on both ends of the section be presented first. As this is made to disappear, let the upper section be presented. The observer will see the wings change direction and the horizontal line shrink. If the presentation of the two sections is in the reverse order, the line will elongate.

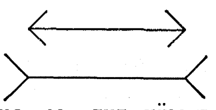

FIG. 14.—THE MÜLLER-LYER ILLUSION.

It was pointed out elsewhere (see *Response to Variable and Intermittent Illumination* above) that motion pictures provide a good example of stroboscopic effect. They also represent a very good example of beta-movement, inasmuch as each successive frame presents certain components in different positions than its predecessor and elicits the experiential effect of motion. When a jumpy effect is created in the movies, it is because of improper timing between the frames for the amount of displacement of the particular objects involved, at least for the amount of absolute illumination or perhaps intensity differential between them and their surroundings. Timing. spatial separation and intensity (and perhaps intensity differential) are crucial in the obtaining of apparent motion that is indistinguishable from the experiential effect elicited by physically moving bodies. As time between successive exposures is lengthened, the spatial separation between objects must be increased. As intensity of bright objects on a dark field is increased their temporal separation must be decreased or their spatial separation increased.

In the case of beta-movement, the experience elicited by the two stationary objects will not always simulate the smooth movement of a single object moving from one position to another. When it does, the motion is called optimal movement. The rules for retaining it, once it exists, were just given. The experienced movement may be confined to one or both of the two objects. This is called part movement and is single part movement if confined to one and dual part movement if it involves both objects. In part movement as the object appears it manifests a sidewise jump. R'hen conditions are not quite right for optimal movement, dual part movement is often quite pronounced.

To understand apparent movement the character of retinal stimulation underlying it must be known. As a beginning, a consideration of what happens on the retina to produce gamma-movement is quite appropriate. A single intense area of illumination, such as an electric lamp, produces not only an image on a restricted part of the retina, but also a veil of stray light over the whole retina. Thus all of the retina participates in the activity of the movement. The region which receives the image of the lamp is most intensely illuminated; and regions surrounding it, least. In other words, a gradient of stimulation is set up. Not only does this gradient exist, but there is also a sensitivity gradient inherent in the retina. The net result is translated into a centre-periphery gradient in latency of retinal response. In terms of the time of sending impulses up the optic nerve. this acts as though the centre of the retina had been stimulated first and then progressively more and more peripheral portions. Granting this, it is perfectly natural to expect to see motion in the instance we have chosen.

Conflicts.—As might be supposed. the cues that the individual gets from the environment do not always harmonize. When it is remembered that all experience is constructed by the organism and that this pertains not only to intellectual deductions but to immediate sensory experience, it is not strange that conflict tends to result. We have already indicated that from the very same physical situation any one of many alternatives is often possible in sensation. This being the case, the task of the organism is to select those alternatives that will fit together to give, at any instant, a self-consistent whole, and to act from instant to instant in such a nay as not to violate a kind of temporal consistency. Notwithstanding, conflict does result. Its most obvious sign is the rapid oscillation between two ways of perceiving something which sometimes occurs. Uncertainty, hesitation and doubt are sometimes experienced by the individual in the act of seeing.

OCULOMOTOR ADJUSTMENTS

General.—The act of seeing is a complex motor process in which each eye must be so adjusted internally as to produce the sharpest retinal image possible. The two eyes must also constantly maintain appropriate positions with reference to each other and to viewed objects. Many movements of the two eyes are spontaneous motions not continually following some specific target (external object in the field of vision) but are instead rotational excursions in obedience to the innervations supplied by the intrinsic features of the nervous organization at the moment. Under such conditions it might be said the movements are spontaneous or free, although during this time the two eyes tend to keep their proper convergent relation. At any instant! any appropriate stimulus factors are able to elicit the individual's attention during which time the eyes are momentarily and intermittently fixed on the objects eliciting this attention. If these objects move relative to the observer, the two eyes follow in such a way as constantly to converge on the area attended to. Eye movements are of the following kinds: idle, spontaneous, exploratory and pursuit. Spontaneous movements of the eyes occur when the individual is not looking at anything in particular. The relative strengths of the innervations of the various eye muscles are determined by differences in balance between several nervous centres. each of which is subject to a different set of influences. Thus eye positions and movements are controlled not only by visual stimuli but also by impulses received from other sources, for instance, from the vestibular nervous centres activated by the organs of equilibrium in the ear. Exploratory movements are those in which the individual is looking to discover or detect something. This may be an unknown something in an unknown position, or it may simply be the unknown material in the task of reading lines of print. In exploratory movements of the latter type, a series of jumps and pauses rather than long sweeps occur. Such movements are called saccadic and bear some relation to speed and comprehension in reading. Pursuit movements are those eye movements which occur in following a moving object in the visual field. The eyes move in such directions as to keep pointed directly at the object of attention.

To effect the proper refraction so that the retinal image of the external object viewed is at its best. the shape of the lens must be properly adjusted. This is called accommodation.

Accommodation, or the Mechanism of Adjustment for Different **Distances.**—When a camera is placed in front of an object. it is necessary to focus it accurately in order to obtain a clear and distinct image on the sensitive plate. This may be done by moving either the lens or the sensitive plate backward or forward so as to place the posterior focal point of the lens on the sensitive plate. For similar reasons, a mechanism of adjustment, or accommodation for different distances. is necessary in the human eye. In the normal eye parallel rays coming from a great distance are focused on the retina. Such an eye is termed emmetropic. Another form of eye is such that parallel rays are brought to a focus in front of the retina. This form is myopic or shortsighted, inasmuch as, for distinct vision, the object must be brought near to the eye. In a third form the focal point, for ordinary distances. is behind the retina, and consequently the rays must be made more convergent by accommodation. This kind of eye is called hypermetropic or farsighted. For ordinary distances, at which objects must be seen distinctly in everyday life, the fault of the myopic eye may be corrected by the use of concave and of the hypermetropic by convex glasses. The concave glass will move the posterior focal point a little farther back, and the convex glass will bring it farther forward; in both cases, however, the glasses may be so adjusted, both as regards refractive index and radius of curvature, as to bring the rays to a focus on the retina, and consequently secure distinct vision.

The imputation that some eyeballs are appropriate, some too short and some too long, for the refractive system of the particular eye is generally made. This is only one way of looking at the matter. Since the lens will accommodate in accordance with the innervation supplied the ciliary body, it can be considered that in myopia, etc., for example, it is the innervation that is inappropriate for the eye as it is. The use of cycloplegics (a kind of eye drops) is a conventional clinical method which attempts to determine the intrinsic relation of lens systems to length of eyeball when the accommodation is relaxed. Some believe that the information gained in this way does not vitiate the idea that the relation between accommodative innervation, focal power of the lens and length of eyeball is a dynamic rather than anatomically referable affair.

From any point 65 m. distant, rays may be regarded as practically parallel, and the point will be seen by the emmetropic eye without any effort of accommodation. This point, either at this distance or at infinity, is called the punctum remotum. In the myopic eye it is much nearer, and for the hypermetropic there is really no such point, and accommodation is always necessary. If an object were brought too close to the eye for the refractive media to focus it on the retina, circles of diffusion causing indistinctness of vision would result, unless the eye possessed some power of adapting itself to different distances. That the eye has the power of accommodation is proved by the fact that, if we attempt to look through the meshes of a net at a distant object, we cannot see both the meshes and the object with equal distinctness at the same time. Again, if we look continuously at very near objects, the eye speedily becomes fatigued. Beyond a distance of 65 m., no accommodation is necessary; but within it, the condition of the eye must be adapted to the diminished distance until we reach a point near the eye which may be regarded as the limit of clear vision for near objects. This point, called the punctum proximum, varies according to the age of the individual. The range of accommodation is thus the distance between the punctum remotum and the punctum proximum.

The mechanism of accommodation has been much disputed. but there can be no doubt it is chiefly effected by a change in the curvature of the anterior surface of the crystalline lens. If we hold a lighted candle in front and a little to the side of an eye to be examined, three reflections may be seen in the eye. The first, a, is erect, large and bright, from the anterior surface of the cornea; the second, b, also erect, but dim, from the anterior surface of the crystalline lens; and the third, *c*, inverted, and very dim, from the posterior surface of the lens, or perhaps the concave surface of the vitreous humour. Suppose the three images to be in the position for distant vision, it will be found that the middle image *b* moves toward a, on looking at a near object. The change

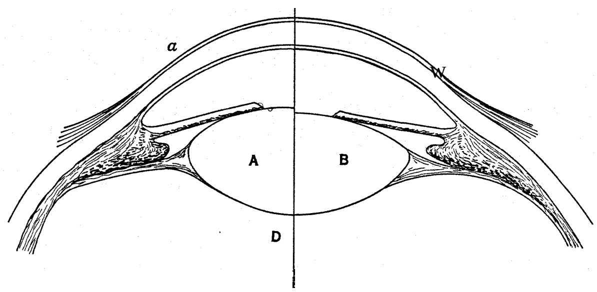

FIG. 1.5.— MECHANISM OF ACCOMMODATION

is caused by an alteration of the curvature of the lens. (See fig. 15.) The changes occurring during accommodation are: (1) the curvature of the anterior surface of the crystalline lens increases, the radius of curvature changing from ten millimetres to a minimum of six millimetres; and (2) the pupil contracts. An explanation of the increased curvature of the anterior surface of the lens during accommodation was thus given by H. von Helmholtz. In the normal condition (that is, for the emmetropic eye) the crystalline lens is flattened anteriorly by the pressure of the anterior layer of the capsule; during accommodation. the radiating fibres of the ciliary muscles pull the ciliary processes for ard, thus relieving the tension of the anterior layer of the capsule, and the lens at once bulges forward by its elasticity.

By this mechanism the radius of curvature of the anterior surface of the lens. as the eye accommodates from the far to the near point, may shorten from ten millimetres to six millimetres. The ciliary muscle, however, contains two sets of fibres, the outer, longitudinal or meridional, which run from before backward, and the inner, circular or equatorial (Müller's muscle). Direct observation of the eye of an animal immediately after death shows that stimulation of the ciliary nerves actually causes a forward movement of the ciliary processes, and there can be little doubt that the explanation above given applies to man.

There is still some difficultyin explaining the action of the equatorial (circular) fibres. Some have found that the increased convexity of the anterior surface of the lens takes place only in the central portions of the lens, and that the circumferential part of the lens is actually flattened, presumably by the contraction of the equatorial fibres. Seeing, however, that the central part of the lens is the portion used in vision, as the pupil contracts during accommodation, a flattening of the margins of the lens can have no optical effect. During accommodation the pupil contracts. and the pupillary edge of the iris, thinned out, spreads over the anterior surface of the capsule of the lens, which it actually touches. This part of the iris, along with the more convex central part of the lens, bulges into the anterior chamber and must thus displace some of the aqueous humour. To make room for this, however, the circumferential part of the iris, related to the ligamentum pectinatum, moves backward very slightly, while the flattening of the circumferential part of the lens facilitates this movement.

Helmholtz succeeded in measuring with accuracy the sizes of the reflected images by means of an instrument termed an ophthalmometer, which he invented. His description of what occurs in accommodation has been attacked a number of times. All opponents of the Helmholtz theory accept the flattened rather than the thickened form of the lens as its resting form. For some theorists, accommodation is not caused by relaxation of the zonula but rather by the direct action of the ciliary muscle on the lens, pressing it together. Some, while subscribing to the Helmholtz zonula-relaxation idea, emphasize the conoidal form of the anterior surface of the lens resulting from the differences in the thickness of the capsule in different parts. Some assign the thickening of the lens in accommodation to the contraction of the ciliary muscle which produces a pressure of vitreous humour against the periphery of the lens tightening the zonula. Another theory postulates contractile fibres within the lens itself, these possessing a similarity to nonstriate muscle fibres, and also sensitive to influences other than by way of ordinary innervation. Still another claims that accommodation is produced by lengthening and shortening of the eyeball itself. Holders of the latter theory point to cases in which accommodation has allegedly occurred in aphakia (absence of the lens). Helmholtz's description continued to be held by most authorities.

Convergence and the Extrinsic Muscles.—The relative positional relations of the two eyes to each other is called convergence. Each eye possesses a centre of rotation. This is slightly behind the centre of the optic axis. Around the centre of rotation there are three principal axes—the anterior-posterior, the vertical and the transverse. In normal oculomotor behaviour the two eyes retain postures so that their axes converge on a point called the fixation point, or point of regard. The lines extending from the centre of rotation to the fixation point are called the lines of regard. The plane defined by these two lines is known as the plane of regard. The referential positions of the eyeballs are as follows:

1. First position. This is defined by erect head posture, the lines of regard directed toward the distant horizon.

2. The second order of positions includes all those involved in moving the eyes around the transverse and horizontal axes. When the eyes rotate around the first, the line of regard is displaced above or below, making with the line representing its former position an angle called the angle of vertical displacement, or the ascensional angle. When the eyeball rotates around the vertical axis, the line of regard is displaced laterally, forming with the median plane of the eye an angle called the angle of lateral displacement.

3. The third order of positions includes all those assumed by the eyeball in performing a rotary movement along with the lateral or vertical displacements. Such movements of rotation are measured by the angle which the plane of regard assumes with the transverse plane, which is called the angle of torsion or angle of rotation.

Normally the movements of the two eyes represent a system so co-ordinated as to direct the two lines of regard toward the common point in space. This is accomplished by six pairs of muscles. When we look at a distant object and the optic axes of the two eyes are virtually parallel, the image of the object falls upon the yellow spots of each retina, and is seen as a single object. An object is always seen as one object if it is imaged on the corresponding points of the two eyes. The four straight or recti muscles of the eye originate in the back of the orbit and are inserted in the front part of the eyeball or its equator. The two oblique muscles pass forward around the eyeball from the nasal side, one to the upper part of the eyeball and the other to the lower, both being inserted on the temporal side. The internal and external recti move the eyes around their vertical axis directing the line of regard to the right or to the left. The superior and inferior recti rotate the eyes around the horizontal axis, raising or lowering the gaze. The oblique muscles rotate the eyes around axes passing through the centre of the eye to the back of the head. These muscles are also responsible for a slight rotation of the eyeballs around the visual axes themselves. Such movements are spoken of as cyclotorsional movements. These muscles operate in pairs under the influence of what is known in physiology as reciprocal innervation.

Convergence and accommodation bear certain relatively fixed relations to each other. For example, when an object approaches the eyes, two things must happen in order that the eyes remain properly adjusted. Convergence must increase and so must accommodation. Any condition which calls for the increase of one without the concomitant change in the other process leads to unsatisfactory results. Failure to maintain the proper relations between accommodation and convergence arises either from the unusualness of the stimulus situation or from the specific characteristics of the visual system of the observer, or both. If the proper convergence does not take place while objects are accommodated for, single objects will be seen as double—as two. This double vision is called diplopia and is not well tolerated by the organism. Sooner or later, what is known as suppression occurs. This is a state in which, although the two eyes do not properly converge on the object of attention, the input from one eye only functions to provide object perception. If the proper accommodation does not occur, the viewed object will be indistinct; it will appear blurred. In addition to the convergence and accommodative mechanisms there is also presumed to be a fusion mechanism. Without the operation of this, many individuals would definitely lose their proper convergence with regard to viewed objects. This is called a state of muscle imbalance, and is detected in a number of ways; one of the simpler ways is to cover one eye while the individual looks at a given object. While the individual continues to regard this object steadily, the second eye is quickly uncovered. It sometimes will be seen that the covered eye quickly changes position as it is uncovered. This is taken to mean that the convergence mechanism was not functioning to hold the covered eye so as to converge on the position to which the uncovered one was directed. Uncovering the second eye supposedly allows the fusion mechanism to begin to operate. This discrepancy between the positions of the eye under the two conditions is one measure of what is called a phoria. Orthophoria is the condition of the binocular system in which no phoria in any direction is demonstrable. Heterophoria is the condition in which one or more phorias exist. If the eye or eyes tend to turn outward, the condition is an exophoria. If inward, it is an esophoria. The eyes may tend to rotate, in which case the condition is one of cyclophoria. They may tend to turn upward or downward in which case the condition is one of hyperphoria or hypophoria, respectively.

The condition of heterophoria is also spoken of as that of latent muscle imbalance. Manifest muscle imbalance is called squint or strabismus.

Pupillary Reflexes and the Iris.—In addition to convergence and accommodation, changes in the size of the pupillary aperture are constantly occurring. The size of the aperture is controlled by the tissue surrounding it and this tissue is called the iris. Strictly speaking, the reflexes involved in controlling pupillary size are iris reflexes rather than pupillary reflexes, for the iris is the tissue constituting the muscles which carry out the necessary mechanical performances.

The iris constitutes a diaphragm which regulates the amount of light entering the eyeball. The aperture in the centre, the pupil, may be dilated by contraction of a system of radiating fibres of involuntary muscle, or constricted by the action of a circular system of fibres, forming a sphincter, at the margin of the pupil. The radiating fibres are controlled by the sympathetic, while those of the circular set are excited by the third cranial nerve. The variations in diameter of the pupil are determined by the greater or lesser intensity of the light action on the retina. A strong light causes contraction of the pupil; with light of less intensity, the pupil will dilate. In the human being, a strong light acting on one eye will cause contraction of the pupil, not only in the eye affected, but also in the other eye. These facts indicate that the phenomenon is of the nature of a reflex action, in which the fibres of the optic nerve act as sensory conductors to a centre in the brain, whence influences emanate which affect the pupil. The centre is in the neighbourhood of the nucleus of the third nerve, beneath the anterior pair of the corpora quadrigemina. On the other hand, the dilating fibres are derived from the sympathetic and it has been shown that they come from the cervical region of the spinal cord. The iris in some animals is directly susceptible to the action of light.

The pupil contracts under the influence of: (1) an increased intensity of light; (2) convergence of the two eyes, as in accommodating for a near object; and (3) such active substances as nicotine, morphia and physostigmine. It dilates under the influence of: (1) a diminished intensity of light; (2) vision of distant objects; (3) a strong excitation of any sensory nerve; (4) dyspnoea; and (5) such substances as atropine and hyoscyamine. The chief function of the iris is to moderate the amount of light entering the eye so as to secure sharpness of definition of the retinal image. This it accomplishes by: (1) cutting off the more divergent rays from near objects; and (2) preventing the error of spherical aberration by cutting off divergent rays which would otherwise impinge near the margins of the lens and would thus be brought to a focus in front of the retina.

As well as manifesting light reflexes and several other specific reflexes not named, the pupil manifests what is called a dark reflex. The dark reflex is a response to very brief intervals of darkness interspersed in otherwise continuous, bright illumination. This would have only academic interest were it not for the fact that some individuals in whom the light reflex has become inoperative still possess a dark reflex, indicating that the nervous paths mediating the two reflexes are not wholly identical.

Whereas constriction in response to light is fairly rapid, dilatation during periods of subsequent darkness is considerably slower.

Pupillary Response to Intermittent Stimulation.—A series of flashes will be followed by the pupil with alternate constriction and dilatation when the flash series does not exceed a rate of almost three per second. As flashes at a rate of one in four or five seconds to three per second are presented, the alternations in the size of the pupil become more and more slight till the pupil no longer follows, but becomes either stationary or irregularly variable. (See fig. 16.) That the stationary state under flash rates of two or three per second is not equivalent to the immobility with steady illumination or with very much faster flash rates has been discovered. Whereas ordinary immobility is a matter of reciprocal innervation, the stationary state here is one in which both the constrictor and the dilator fibres are in contraction more or less simultaneously. Simultaneous tensory activity in both sets of pupillary fibres gives rise to considerable discomfort and is at least part of the basis for discomfort in viewing flickering illumination.

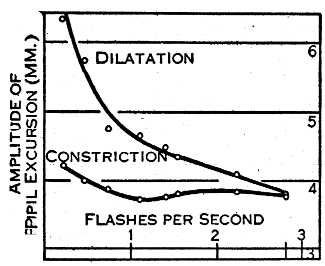

FIG. 16.—CHANGE OF PUPILLARY SIZE AS DEPENDENT UPON FLASH RATE

Differential Nature of Pupillary Response.—A pupillary light reflex is not merely a response to the total quantity of light falling on the whole or any given portion of the retina but is a highly differential response. This is demonstrable in the following way. Let it be arranged so that the two eyes can independently be stimulated. On the one retina let an image of a disk of light in a dark field be formed.

As the intensity of this light is raised from a low level to a fairly high one, the pupils of both eyes (the unstimulated one as well as the one receiving the image) constrict.

Upon reaching the desired maximum of intensity, let the brightness of the disk remain constant, while now applying the same progressive stepwise intensification of a similar image in the corresponding area of the second retina. Whereas it might be expected that the addition to the total amount of light would effectively add to the amount of constriction manifested by the two pupils, such a result is not the case. The initial amount of stimulation applied to the second eye induces, on the contrary, dilatation in both eyes. This result is shown in fig. 17, in which the ordinate represents the diameter of pupillary aperture, and the abscissa the logarithm of the light intensity applied first to one eye and then to the other. The second eye begins to be illuminated at the perpendicular C. It is only after the light in the second eye reaches a considerable fraction of the constant illumination in the first eye that constriction sets in. When both eyes are equally illuminated the combined effect in terms of constriction definitely exceeds the effect elicited by using one eye alone. To obtain this effect the areas on the two retinas need not correspond, nor need the images of the two disks be placed on separate retinas. It is thus evident that the pupils respond differentially rather than to the gross amount of light falling on the two retinas or to the light falling on two separate portions of either one of them. This kind of behaviour parallels very closely perceptual behaviour (brightness discrimination) under the same conditions.

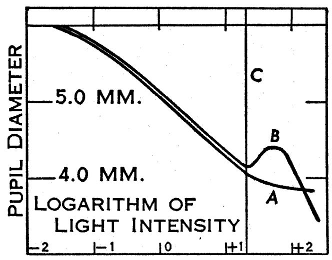

FIG. 17.—THE PUPILLARY REFLEX AS A COMPLEX RESPONSE

A, RESPONSE WHEN TOTAL AMOUNT OF LIGHT IS PRESENTED EXCLUSIVELY TO ONE EYE; *B*, RESPONSE WHEN LIGHT IS VARIOUSLY DISTRIBUTED, THE FIRST PART TO ONE EYE AND THE SECOND PART TO THE OTHER EYE WITH STIMULATION OF THE FIRST EYE CONTINUED

It is known that unequally intense images on the corresponding areas of the two retinas do not sum to give rise to a subjectively brighter surface than does either image alone, but rather give rise to a brightness somewhat between the two. This has long been known as Fechner's paradox. G. T. Fechner found, however, that if the intensities of the images were made equal, the combined effect of the two was a surface of greater brightness than was elicited by stimulating one eye alone.

We also know that a bright object on a dark field is less bright when a similar-sized dim object is in the visual field at the same time than when it exists alone.

Comparing these sensory effects with what was just described regarding pupil behaviour, it is obvious that the sensory and the motor phenomena coincide. See also Index references under "Vision" in the Index volume.

VISIT AND SEARCH, a term for the procedure adopted by a belligerent warship to ascertain whether a merchant vessel is enemy or neutral and, if neutral, whether she is carrying contraband. The vessel's papers are first examined, and if these are in order and no suspicions are aroused she is allowed to proceed on her voyage, a note of examination being entered in her logbook. If inspection of the papers shows the vessel to be hostile or to be carrying contraband or performing services incompatible with neutrality, she is immediately seized; more often there is merely suspicion, in which case she may be searched. The search is carried out by a small party from the belligerent warship in the presence of the master. If the searching officers are satisfied with the results of their investigation the vessel is allowed to proceed; if suspicion still remains she may be brought into port for more thorough search. If she is finally declared innocent and a prize court considers that the suspicion was not reasonable, it may order damages to be paid.

As the size of modern ships makes it impossible to search them thoroughly on the high seas the practice of taking them automatically into port for search became widely recognized. This however caused difficulty between Great Britain and the United States of America in World War I and led to the adoption in 1916 of the navicert system. The navicert, issued by the belligerent's representative in a neutral country. was tantamount to a ship's passport, possession of which ensured in the absence of suspicious circumstances that the vessel would be alloned to proceed on her way. In World War II Great Britain again introduced the navicert system and, as a reprisal for Axis submarine and mine warfare, made it compulsory by an order in council of July 31. 1940. The effect of this order was that any ship not covered by a navicert and proceeding to or from a port whence goods might go to or be exported from enemy territory was deemed to be carrying contraband and was liable to seizure. (X.)

The instructions for the U.S. navy issued in May 1941 and in effect during World War II stated:

48. The belligerent right of visit and search subject to exemptions mentioned in section VII may be exercised outside of neutral jurisdiction upon merchant or private vessels after the beginning of war in order to determine their nationality, the character of their cargo, the nature of their employment, or other facts which bear on their relation to the war.

Such instructions also provided that:

233. Outside neutral jurisdiction, belligerent military aircraft have the right to visit and search. If circumstances make visit and search impracticable, a belligerent militarv aircraft may order a neutral civil craft, subsurface. surface or air, to proceed under escort as directed.

The instructions of the U.S. navy, as well as those of most other maritime states, recognize the exemption from visit and search of neutral merchantmen under convoy.

During World War I the British government developed the practice. continued during World War II. of taking ships or cargoes into British ports and there detaining them for the purpose of general search for evidence of contraband. The practice. said to be justified by the size and seaworthiness of modern vessels, was the subject of objections by the U.S. government during both wars. See also NEUTRALITY. (J. W. Mw.)

VISITATION, an act of visiting, or going to see. a formal visit; also: from biblical phraseology, an act of divine retributive justice.

There are three classes of official visitations: ecclesiastical, charitable and heraldic. Ecclesiastical visitations, originally the periodical journeys of personal inspections to ascertain the temporal and spiritual condition of each parish, form part of the functions of an archbishop, bishop or archdeacon.

In Great Britain all charitable corporations were at law made subject to visitation. If no visitor had been appointed by the founder, the sovereign or his representative was the visitor of all lay, and the church of all ecclesiastical charitable corporations. Under the Charitable Trust acts and the Endowed Schools acts, the board of charity commissioners and the board of education were given certain visitorial powers.

Heraldic visitations (which ceased about 1686) were perambulations made by a king at arms, or other heraldic official with a commission under the great seal, to examine into pedigrees and claims to bear arms. The results of these visitations were entered in visitation books; their admissibility as judicial evidence, however, was questioned on the ground that they merely contained statements obtained from the families to whom they referred (*cf.* D'Arcy de Knayth case, 1901).

VISITING CARD, a card also known as a calling card, bearing the name and sometimes the address. of an individual or a married couple. Visiting cards are used when visiting, to enclose with gifts and flowers, or as an invitation by people in socially active circles, members of the military and diplomatic services and professional people. Cards which include a business address are known as business or trade cards.

The custom of carrying a personal card became popular in Europe in the 18th century. Cards were engraved with classical and allegorical scenes with space left within the design for the caller's signature. Ambassadors, bankers. doctors and prominent citizens who had more frequent use for cards had their names engraved within the design. This was rare and expensive. Cards for business visits ranged from simple printed papers to engraved cards with baroque! rococo or classical style borders. Wares for sale were often listed and illustrated.

Embossed cards with simple classical borders appeared after 1796. During the 19th century visiting cards were decorated nith more elaborate embossing, lace paper borders and hand painting. Messages written on cards were often holiday greetings, leading to the name, "cards of compliment." The first Christmas cards of the 1840s were the same size as the ladies' visiting cards of the decade. Gentlemen's cards were always smaller than ladies'. It nas customary to fold down a corner of a card to express a sentiment. The right-hand bottom corner meant a personal call: the right-hand top corner meant condolence; the left-hand bottom corner meant congratulation.

People in mourning often had solid black cards with the name in white. but this was modified into the use of the black-bordered white card. While professional people usually preferred a simple card, tradesmen utilized every means of graphic reproduction. Thousands of trade cards with elaborate printing and illustration were printed as advertisements rather than as business visiting cards

Cntil World War I the use of cards socially was a highly stylized ritual The telephone and the greeting card (*q.v.*) are partially responsible for its decline. Twentieth century cards are plain nhite cardboard or parchmentlike paper with the name engraved in black ink. Business cards may be printed. Women's cards are approximately $3\frac{1}{4} \times 2\frac{1}{4}$ in.; men's cards are seldom more than $1\frac{1}{2}$ in. deep; children's cards are slightly smaller than those of adults. When the street address is included, it is in the lower right-hand corner. Cards may be left for a friend or client whether or not the caller found him in. They are given to a servant to deliver, put on a card tray, or left in a conspicuous place. Etiquette books define the exact style specifications and uses of cards.

VISITING NURSE. In the United States, public health nurses act as teachers, helpers and friends in homes! clinics, industrial establishments and schools. Public health nursing began in 1877. In many places public health nursing is privately supported; in other places it is a function of the local or state government. Privately supported public health agencies are usually called visiting nurse or public health nurse associations. There are also, however, community nursing services. The workers under the National Red Cross do a considerable amount of public health nursing in rural areas. The public agencies which employ health nurses include boards or departments of health and boards or departments of education. The United States public health service and the United States children's bureau also employ considerable numbers of public health nurses. In many states the state department of health has a supervising nurse who is adviser on public health nursing problems throughout the state. There is also an occasional organization for public health nursing. Much of this work relates particularly to the care of the crippled, maternal and child health and the control of venereal diseases.

The National Organization of Public Health Nursing, in cooperation with the American Public Health association, set up (and periodically revised) standards of appointment for public health nursing positions. There are also minimum requirements for school nurses. In addition to being a graduate registered nurse, a public health nurse must have had special supervised experience or a postgraduate course of at least one year dealing with her specialty. (M. FI.; X.)

In England and Wales a health visitor was defined as a state registered nurse who trained at least six months in midwifery and passed the first examination of the Central Midwives' board, and obtained the health visitor's certificate of the Royal Sanitary institute aiter a course of training lasting six to nine months; or, if she was not a fully trained nurse, underwent a recognized two years' course of training, had at least six months' training in a hospital and passed the first examination of the Central Midwives' board. Training centres were approved by the minister of health for the training of health visitors under memorandum 101 MCW issued in 1925. The syllabus was revised in Jan. 1950. Section 24 of the National Health Service act, 1946, required local health authorities (that is, county councils and county borough councils) to provide a complete health visitor service either by themselves employing health visitors or by making arrangements with voluntary organizations to do so. Duties include visiting persons in their own homes "for the purpose of giving advice as to the care of young children, persons suffering from illness, which includes mental illness, and any injury or disability requiring medical or dental treatment or nursing, and as to the measures necessary to prevent the spread of infection." (E. JN.; X.)

VISSCHER, WILLIAM LIGHTFOOT (1842–1924), U.S. author, was born in Owingsville, Ky., on Nov. 25, 1842. He attended Bath seminary in Owingsville and also Stevenson's academy in Danville, Ky. On the outbreak of the Civil War, Visscher joined the Union army. He enlisted in the Kentucky volunteers and served for more than three years.

In 1868 Visscher was graduated from the University of Louisville (Ky.) law school. He mas admitted to the bar the same year, but never practised law although he served as apprentice to a judge for a few months. The remainder of his life was spent mainly in newspaper work in St. Joseph and Kansas City, Mo.; San Francisco, Calif.; Cheyenne, Wyo.; Denver, Colo.; Portland, Ore.; and Tacoma, Wash. The western U.S. fascinated Visscher and from it he drew heavily for his novels.

He was a public lecturer and dramatic actor for a few years and wrote more than 1,000 poems, the majority of which were published. Visscher's collaboration with William F. ("Buffalo Bill") Cody resulted in *Buffalo* Bill's Own Story (1917). Visscher died in Chicago, Ill., on Feb. 10, 1924.

Among his writings are *Carlisle* of Colorado; Way Out Yonder; Thou Art Peter; Fetch Over the Canoe (1908); Ten Wise Men and Some More (1909) ; Amos Hudson's Motto (1905) ; *A* Thrilling and Truthful History of the Pony Express (1908); Black Mammy (1886); Harp of the South; *Blue* Grass Ballads (1900) ; Chicago, an Epic (1897); Poems of the South (1911); My Lady of the Island; How They Came to Be Statues; Stars of Our Country; and Portraits and Pen-Pictures.

VISTULA, a river of north and central Poland, 677 mi. in length, rises on the northern slopes of the western Beskids, southeast of Cieszyn, flows along the former frontier of East Prussia and flows out to the Baltic sea at the Gulf of Danzig. Main tributaries on the right include the Bug, Dunajec, San and Wisloka rivers; on the left, the Nida, Pilica and Wierzyca. It is connected with the Oder river via the Brda river, the Bydgoszcz canal and the Notec and Warta rivers.

Coal and lumber from Silesia are transported on the Vistula. It was made navigable for small craft as far as Cracow, the river being able to accommodate larger ships up to the mouth of the San river.

During World War I important battles took place on the river. After ihe war the lower part of the river was the dividing line between East Prussia and the Polish corridor.

Before World War I conservancy works had only been carried out on the German part of the river, 138 mi. in length; spur and longitudinal dikes had been built to maintain the water level, thereby facilitating the flow of water at floodtime and also improving navigability.

After the war Poland was too occupied with other matters to carry out improvement works, or even contribute much to the upkeep of the river.

Traffic on the river, consequently, greatly decreased. Later, however. large reservoirs were constructed on the Carpathian tributaries of the river at Roznow and Porembka; thus important steps were taken not only toward efficient regulation of the river itself but also toward the establishment of valuable sources of electrical power. The river is called the Wisła in Polish, Visla in Russian and Weichsel in German.

VITACEAE, a family of cosmopolitan. woody plants, most of them tendril-bearing vines, with 12 genera and about 650 species. The largest genus, which is pantropic, is *Cissus,* containing about 250 species. *Vitis,* with about 60 species, is its one genus of great economic importance, including as it does the European wine grape (V. vinifera), and the North American fox grape (V. labrusca), the parent species of most of the cultivated slip skin American grapes. The Boston ivy (Parthenocissus tricuspidata), cultivated from Massachusetts to Ohio, is native to China and Japan, while the Virginia creeper (*q.v.*) (P. *quinquefolia*) is native to the eastern United States. Leea is a genus of about 100 species, some erect shrubs, others vines, all without tendrils, native to Malaysia and the subcontinent of India.

VITALI, GIOVANNI BATTISTA (c. 1644–1692), Italian violinist and composer, noted for his sonatas for strings. Born in Cremona about 1644, he studied counterpoint under Maurizio Cazzati. From 1666 he served in church positions in Bologna and from 1674 at the court of the duke of Modena.

A prolific composer, he wrote, in addition to sonatas in early forms, dance and vocal music. He is considered to have possibly influenced later development of sonata forms.

He died in Modena on Oct. 12, 1692.

Giovanni Vitali's son, Tommaso Antonio, born at Bologna about 1665, was also an accomplished violinist and composer. He became known principally for his chaconne, which continued to be a standard piece in the violin repertoire of performers in modern times. Tommaso was music director at the court of Modena and from 1706 he was a member of the Bologna Philharmonic academy. He edited a collection of Giovanni's sonatas (1692).

VITALIAN (VITALIANUS), **SAINT** (d. 672), pope from 657 to 672, was consecrated as successor to Eugenius I on July 30, 657. In the Monothelite controversy then raging he refrained from express condemnation of the *Typus* of Constans II (*q.v.*). When Constans visited Rome in 663, the pope received him "almost with religious honours," a deference he requited by stripping all the bronze ornaments of the city—even the tiles of the Pantheon—and carrying them off. Vitalian died about Jan. 27, 672.

His feast day is Jan. 27.

See H. K. Mann, ***The Lives of the Popes in the Early Middle Ages,*** vol i, pt. 2, pp. 1–16 *(1902).*

VITALISM, a school of scientific thought—the germ of which dates from Aristotle—which attempts (in opposition to mechanism and organicism; *qq.v.*) to explain the nature of life as being due to a vital force peculiar to living organisms and different from all other forces found outside living things. This mysterious force (entelechy; *q.v.*) controls form and development and directs the activities of the organism. Vitalism has lost prestige as more and more vital phenomena have been shown to be of chemical and physical nature, and few rigid vitalists are to be found in modern science.

See DRIESCH. HANS ADOLF EDUARD; BIOLOGY: History: *Aristotle* as a Biologist.

VITAL STATISTICS are data on births, deaths, fetal deaths, marriages, divorces, annulments, adoptions, legitimations and notifiable diseases. A vital statistics system includes the collection and preservation of records and reports of these events, and the compilation and analysis of data contained on the records. Individually, the vital record represents evidence of the occurrence of the vital event and of certain facts related thereto. These records are important for many legal and administrative purposes, such as the establishment of citizenship, the right of inheritance, entitlement to benefits and allowances, eligibility for school attendance and military service.

Central vital statistics offices issue certified copies of birth and death certificates to qualified persons on request. Many states of the United States also use the birth registration card or other type of short-form certification of birth facts which does not disclose such information as the occurrence of birth out of wedlock or adoption

Many county and municipal officers also issue copies of vital records which were filed with them prior to the establishment of central registration or passed through their hands before reaching state offices. Collectively, the vital records provide statistics which serve a host of uses, including demographic. genetic and medical research, social welfare and education programs, market analysis and the planning of community facilities.

The subject of vital statistics is treated in a number of separate articles. This article traces the history of vital statistics from church-kept records through the development of the general register office in England and the routine registration of births, deaths and other vital records in Europe and the United States and discusses registration and reporting activities in the United States.

For the theory and application in connection with population, and data on world population, *see* POPULATION; POPULATION ECOLOGY. For the history and modern practices and methods of national censuses *see* CENSUS. (For detailed census figures *see* the POPULATION sections in separate articles on various countries and other political subdivisions.) Movements of peoples are dealt with in MIGRATION. *See* also DEMOGRAPHY; PUBLIC HEALTH and such titles as BIRTH RATE; DEATH RATE; DIVORCE; ILLEGITIMACY; LIFE EXPECTANCY; LONGEVITY; MARRIAGE RATE; SEX RATIO.

History. — Some countries have long-established and highly developed vital statistics systems, while in others, only partial development has occurred. For the origin of vital statistics pertaining to health *see* MEDICINE. HISTORY OF. The earliest known records of vital events were maintained by the church. In England, for example, these records date back to 1538, when the clergy in all parishes were first required to keep a weekly record of christenings, marriages and burials. A beginning was made by the English colonies in America in 1632 when the grand assembly of Virginia passed a law requiring a minister or warden from every parish to appear annually at court on the first day of June and present a register of such events. In 1639 the general court of the Massachusetts Bay colony passed a registration law based on the English precedent but differing in two important respects: the responsibility was placed on government officers rather than on the clergy; and it called for the recording of vital events — births, deaths and marriages — rather than church-related ceremonies, such as baptisms.

The first analytical study based on vital events was made by John Graunt of London in 1662. In 1693 the astronomer. Edmund Halley. applying mathematical techniques, constructed the first scientific life table. About 1800 the Industrial Revolution with the resultant health and social problems stimulated interest in vital and health statistics. As a result, by 1833 births and deaths were routinely registered in France, Belgium. Austria, Prussia. Bavaria, Saxony, the Scandinavian countries, Finland and five cities in the United States.

In 1836 Great Britain enacted a registration law creating a central register office with responsibility for the records and statistics of births, marriages and deaths — by cause — for all of England and Wales.

Birth and death statistics first published by the United States government concerned events in 1850 and were collected by the census method for the entire United States. Beginning in 1900 annual death statistics for a group of states were based on registered events, and beginning in 1915 annual birth data were reported similarly. Beginning with 1933, birth and death statistics included data for the entire country. By 1925 all states were making regular summary reports of notifiable diseases to the federal government.

Registration and Reporting Activities in the United States. — In the United States, vital registration is governed by state laws. Vital records originate with private citizens, members of the families affected by the events, their physicians, funeral directors, clergymen and others. Requirements for filing and penalties are defined by statute. While registration has been the responsibility of the attendant at birth, generally a physician or midwife. newer laws may place the responsibility on hospitals. Each birth must be reported promptly: the reporting requirements vary from state to state, ranging from 24 hours after the birth to as much as 10 days. Certificates must be filed with the local registrar of the birth district. Births to United States citizens in foreign countries are reported to the U.S. department of state.

With regard to the registration of deaths in the United States, the funeral director or person acting as such is responsible for reporting the event. He obtains the data required, other than the cause of death. The latter information is furnished by the physician in attendance, or the coroner. The registration of fetal deaths (infants born dead) is the responsibility of whoever makes final disposition of the fetus, usually the hospital administrator or funeral director.

In most states, marriage licences are issued by town or county clerks who obtain the personal particulars from the applicants. After the marriage is performed, the officiant certifies to the facts of the marriage and sends the record to the official who issued the licence. In most of the states, there is some provision for the local licensing official to send the original marriage record or a copy to the state registrar of vital statistics.

Original divorce and annulment records are, in most states, first filed with the clerk or other official of the court where the decree is granted. Personal particulars are obtained by the clerks from attorneys or petitioners. In many states these records are regularly transmitted to the state vital statistics offices as are records of birth, death and marriage.

Each state is divided into local registration districts for the purpose of collecting vital records. The local and county registrars are responsible for the complete, accurate and timely collection of vital records. These records are permanently filed in vital statistics offices of the state governments.

Through a co-operative arrangement with the individual states, copies of birth, death and fetal death records are sent to the national office of vital statistics, U.S. public health service, for tabulation and publication of national data. This office also promotes more complete and uniform registration throughout the nation, and is the official technical representative of the United States in the advancement of international vital statistics. *See* also references under "Vital Statistics" in the Index volume.

Thompson and P. K. Whelpton, *Population Trends in the Cnited States* (1933); Mortimer Spiegelman, *Introduction to Demography,* Society of Actuaries (1955). (H. L. D.)

VITAMINS are specific organic compounds that are required in the diet in very small amounts (0.005% to 0.00002%). In the absence of sufficient amounts of any one of these substances, growth failure of young animals usually occurs, and specific pathogenic changes recognizable as disease develop in both immature and adult individuals. Naturally occurring diseases in man that result from an insufficient intake of one or more vitamins are termed vitamin deficiency diseases. Beriberi, scurvy, rickets, pellagra, xerophthalmia and pernicious anemia are examples of such diseases.

The vitamins are differentiated from other essential organic dietary ingredients chiefly on the basis of the very small amounts required in the diet. A typical vitamin such as thiamine may comprise 0.001% of an adequate diet, whereas other organic dietary essentials, such as an essential amino acid, are required in amounts at least 1,000 times as great (about 1%).

Deficiency Diseases. — Not until experiments with animals were undertaken near the beginning of the 20th century did the concept become established that the lack of certain dietary constituents could cause disease. This was radical departure from the prevalent idea that all diseases were caused by positive agents. such as bacteria. In 1897 Christiaan Eijkman, working in the Dutch East Indies where a disease known as beriberi was widespread, was able to produce a similar malady in chickens simply by restricting their diet to polished rice, the staple food of the human population. Extracts of the usually discarded rice polishings were found to cure the deficiency disease, and later work showed that the vitamin involved was thiamine (B_1).

Following the demonstration that beriberi is caused by a dietary deficiency, other diseases that resembled certain naturally occurring disorders of mankind and of animals were produced experimentally by feeding various deficient diets.

Thus, A. Holst and T. Frohlich (1912) were able to produce scurvy in guinea pigs by withholding from them fresh plant materials and by feeding them only dried hay and oats. By the use of such a ration it was possible to determine which foods contained the antiscorbutic vitamin (vitamin C or ascorbic acid). If it was present, scurvy was prevented when the food under examination was fed as a supplement to this ration. If the vitamin was absent or present in insufficient amounts, scurvy resulted. In this way the presence of the vitamin in fractions prepared from lemon juice was traced, and the isolation of the antiscorbutic compound, ascorbic acid, was eventually accomplished (C. G. King and W. A. Waugh, 1932).

A similar pattern of events led to the recognition of many of the other vitamins. In more recent years it has been recognized that all classes of living beings—man, microorganisms, plants and animals—require vitamins for growth and well-being. However, the particular ones required in the diet differ from species to species. Thus whole green plants manufacture all the vitamins they require for themselves. In all other classes of living organisms there are many species that require one or more vitamins in the diet, and some that do not. In the latter case, the particular species may, like plants, be capable of making sufficient quantities of it to fulfill its needs, or, in exceptional instances, may have no absolute need for the vitamin in its life processes.

The recognition that bacteria and yeasts may require the same vitamins that man requires greatly facilitated recognition of various vitamins. Approximately half the vitamins now known to be required by animals were discovered originally as substances required for growth of one or another of these microorganisms.

Once the existence of a vitamin is recognized through its effects in permitting growth or curing deficiency disease in a living organism, these effects provide a test or assay method by means of which the vitamin can be isolated as a pure chemical compound from suitable rich source materials. This in turn permits a study of its chemical constitution and eventually its chemical synthesis. Most of the vitamins are now available commercially as synthetic compounds identical in composition and physiological effects with the naturally occurring substances.

Although most of the vitamins are widely distributed in nature, some foodstuffs may be rich sources of one or more vitamins and poor sources of others. Subsequent manufacturing processes may diminish the actual content of one or more of the vitamins. However, some foods are routinely enriched with several of the vitamins to offset these losses, as for example enriched white flour.

Animals that have grown to maturity on diets containing adequate amounts of the vitamins usually require months (with some animals and certain vitamins, even years) to develop signs of deficiency disease when placed on a vitamin-deficient ration. On the other hand, young animals (or adult animals that have grown to maturity with marginal vitamin intakes) have poor vitamin reserves and show deficiency symptoms rather soon when fed vitamin-deficient rations. Both young and old, however. require relatively shorter periods to become deficient in some vitamins than in others. In general the symptoms of a given vitamin deficiency are fairly similar among species, although occasionally one species may show symptoms not manifested by others.

The requirements for vitamins are fairly well established for experimental animals but are only approximate in the case of man. Quantities recommended for human consumption are generally likely to be too high rather than too low. It has been found that in several cases the requirement for a given vitamin can be altered by the amount of some other essential nutrient present. For example, W. A. Krehl, L. J. Teply and C. A. Elvehjem (1945) found that an amino acid, tryptophan, could be substituted for nicotinic acid, a vitamin. This is because part of the former is converted to the latter in the animal body. An example of the opposite effect is the increased requirement for vitamin B_6 that results when a diet high in protein or in methionine is fed to animals.

Vitamins have been classified arbitrarily into fat-soluble and water-soluble groups. The fat-soluble ones are represented by vitamins A, D, E and K, while the water-soluble group consists of the remainder. The water-soluble vitamins other than ascorbic acid are sometimes known collectively as the B-complex.

Determination of the Vitamins in Foods.—Because of the fact that individual foods differ widely in their content of the several vitamins, it is a matter of practical importance to be able to estimate accurately how much of each is present in a foodstuff. This may be done in different ways.

The oldest method for the quantitative determination of a given vitamin is an animal assay. In the making of such an assay, a ration is devised that lacks that vitamin but is otherwise quite adequate. This basal ration plus graded amounts of the material to be tested are fed to some animals (white rats are usually used) while others receive the basal diet plus graded amounts of the pure vitamin. By comparison of the performance of the former with that of the latter, a value for the quantity of vitamin in the unknown can be calculated. Such methods are cumbersome, time consuming and costly. For these reasons they are supplanted by the following procedures whenever the latter are proved to have sufficient specificity; *i.e.*, when it becomes evident that there are no other materials in foods whose effects could be confused with those of the vitamin.

A general method for the determination of vitamin content of foods is based on the fact that various microorganisms need the same vitamins as do the higher animals. The procedure is then the same as in the method of assay. The only difference is that some suitable microorganism is used in place of the rats or other animals. These microbiological methods are useful because they allow the determination of exceedingly minute amounts of the various vitamins, because they are rapid and inexpensive to conduct and because they are generally more precise than animal assays. They were first introduced by E. E. Snell and F. M. Strong in 1939.

Another general method of quantitative determination of a vitamin becomes possible when the chemical structure is elucidated. Then a procedure may be devised that takes advantage of some distinctive chemical property of the vitamin, which sets it apart from other constituents of foodstuffs. Chemical analyses recommend themselves because of their precision, speed and ease of operation.

Vitamin A.—Vitamin A is a fat-soluble alcohol of the formula shown in the diagram. Because of its chemical nature it is readily destroyed by exposure to air and light. It occurs most abundantly in fish and especially in fish-liver oils, and to a considerable extent in butter and in the liver fat of various animals. Vitamin A does not occur in plants, but many vegetables and fruits possess potency because they contain carotenoid pigments that are converted to the vitamin in the body. Most of these yellow and red pigments do not possess this property, but one called p-carotene can serve as a good source of the vitamin. The yellow colour of carrots is caused largely by p-carotene.

Lack of vitamin A in the diet leads to poor growth in young animals, to inability of the eyes to adapt normally to dim light (night blindness) and, as the deficiency progresses. to xerophthalmia and eventual complete blindness. The vitamin is known to function directly in vision as a component of the pigment, visual purple, in the retina. Changes in the skin and in the mucous membranes of the body, best described in general terms as keratinization, are characteristic. Alterations in the growth of bones occur, and these may lead to manifestations such as blindness in calves or deafness in dogs. The reproductive process is specifically interfered with, and this is possibly associated with the alteration that occurs in mucous membranes.

Several closely related compounds that have vitamin A potency are found in animal fats. For example. fresh-water fish oils contain, in addition to vitamin A, a vitamin A_2, which differs from the former by having two fewer hydrogen atoms in the cyclic portion of its structure. It also can form a visual purple.

Vitamin A is reauired in verv small amounts. For example, 4,000 international units of the vitamin or 2.4 mg. of β-carotene per day are said to be sufficient for man.

The existence of vitamin A was first clearly recognized by E. V.

McCollum and M. Davis in 1913 and by T. B. Osborne and L. B. Mendel in 1913; its chemical nature was established by P. Karrer and his associates in 1933.

Vitamin D.—Vitamin D is a fat-soluble alcohol that occurs only in animals but that may arise in dead plant materials when they are exposed to ultraviolet light. The action of such light on ergosterol, on 7-dehydrocholesterol or on certain other sterols leads to the formation of vitamin D. With vitamin D as with vitamin A there are several closely related compounds that possess potency, and any one of these may predominate, or be present exclusively, in a given source. Since the active substance arises by irradiation of various sterols with ultraviolet light, it is not essential that the vitamin be taken in the food because the irradiation of the animal will allow the activation of its sterols. Without such irradiation, the animal must receive food that contains the vitamin. The food may in turn have acquired its vitamin as a result of exposure to light of suitable wave length. Now, although tropical sunlight contains light of the proper wave length to produce activation of sterols, winter sunshine in northern regions of the world, or sunlight that has passed through certain glasses or through clouds, may lack sufficient ultraviolet rays to bring about adequate production of the vitamin in the animal.

Lack of vitamin D leads to the appearance of rickets. In this disease, calcification of bone is retarded and, as a result, such abnormalities as grotesquely bowed legs and malformed skull and chest are produced.

Vitamin D is one of the most active of vitamins from the point of view of the amount required per day. About 10 pg. (400 international units) are considered adequate for a growing child.

Recognition of the therapeutic effects of cod-liver oil and of sunlight in preventing or curing rickets in man was made in the 18th century or earlier. The existence of a vitamin responsible for the effects of cod-liver oil was indicated in experimental animals by E. Mellanby in 1918 and by McCollum in 1922. H. Steenbock, A. F. Hess and M. Weinstock in 1924 demonstrated that the curative effects of ultraviolet light resulted from formation of vitamin D by such irradiation. A pure vitamin D was first isolated from irradiated ergosterol in 1930–31 by large groups of workers in England and in Germany.

Vitamin E or the Tocopherols.—Vitamin E is a fat-soluble phenol found principally in certain plant oils. Wheat-germ oil is a particularly rich source. This vitamin was recognized first by H. M. Evans and K. S. Bishop in 1922, obtained in pure form by Evans and O. H. and G. A. Emerson in 1936, and identified chemically by Karrer, H. Salomon and H. Fritzsche in 1938. Three similar compounds, a-, β- and y-tocopherol, each with vitamin E activity, have been found in nature. Of these, the a-isomer is the most active.

In several species of rodents and in dogs, lack of vitamin E leads to muscular dystrophy. Furthermore, in rats a deficiency results in sterility in the male and leads to failure to bear young in the female. This failure is caused by the death and resorption of the embryos in the later part of the gestational period. In addition to these functions in animals, tocopherols also play a role as antioxidants which retard the rancidification of fats. If these compounds were not present, many vegetable oils would become rancid very rapidly.

Vitamin K.—In 1934 H. Dam showed that when chickens were fed a modified ration they developed spontaneous hemorrhages. This condition subsequently was found to be caused by the lack of a naphthoquinone now known as vitamin K_1. The vitamin present in green leaves mas isolated and shown to have the structure represented in the diagram (R. W. McKee, S. B. Binkley, D. W. MacCorquodale, S. A. Thayer and E. A. Doisy, 1940). Related compounds, both naturally occurring and synthetic, may have activity.

Lack of vitamin K leads to increased clotting time of the blood because of a reduction in the amount of prothrombin. H. A. Campbell and K. Link found a substance, dicumarol, in spoiled sweet clover which causes a drastic increase in clotting time. This effect can be rapidly counteracted by the administration of vitamin K_1.

Ascorbic Acid or Vitamin C.—Vitamin C is a water-soluble, easily oxidizable, carbohydratelike lactone which is necessary in the diet of some animals in order to prevent scurvy. Its structure is shown in the diagram. Only a relatively few species (man, monkeys and guinea pigs) need this vitamin, since most animals can synthesize it themselves. Those which require it in the food depend primarily on fresh fruits, vegetables or other plant materials for their supply of this factor.

Although scurvy was recognized for many centuries, little progress was made in its treatment until the production of the disease in guinea pigs (Holst and Frohlich, 1912), the isolation of the curative agent, ascorbic acid (King and Waugh, 1932), and the elucidation of its nature. A. Szent-Gyorgyi in 1927 isolated ascorbic acid inadvertently without recognizing its vitamin character. Relatively large amounts of this vitamin are required; *i.e.*, an adult man is said to need about 30 mg. per day. The ease of destruction of ascorbic acid by oxidation, especially in neutral or alkaline solution or at elevated temperatures, makes its preservation in foods difficult. Citrus fruits and fresh vegetables and fruits are the best dietary sources of the vitamin.

Thiamine (Vitamin B_1).—Thiamine is a water-soluble nitrogenous basic alcohol which is necessary in the food in order to prevent beriberi. Although this disease results from severe deficiency, less drastic restriction of the vitamin may lead to failure of appetite and to certain types of neuritis. Thiamine is the substance for which the word vitamin was first coined (C. Funk, 1912). The isolation of thiamine absorbed the attention of biochemists for many years until it was finally achieved by B. C. P. Jansen and W. F. Donath in 1926. However, several years elapsed before an improved method of isolation was developed (R. R. Williams and associates) that allowed adequate study of the substance. The problems involved were common to the isolation of many of the vitamins but were magnified by the fact that experience in such matters was lacking since thiamine was the first vitamin to be obtained in pure form. These problems revolve about the exceedingly small amounts present in even the richest sources and the ease of destruction of some of the vitamins.

Thiamine occurs most abundantly in cereal grains and in certain other seeds. Pork is one of the richest animal sources. About 1 mg. per day meets all the needs of an adult human being.

Thiamine functions in some of the enzyme systems by means of which the body converts carbohydrates into energy. In these functions it acts in the form of its ester with pyrophosphoric acid.

Riboflavin (Vitamin B_2).—Riboflavin is a yellow nitrogenous polyhydroxy alcohol, which occurs abundantly in whey and in egg white. Indeed, the greenish-yellow fluorescence of these materials is caused by the presence of this pigment. It was recognized as a vitamin in 1933 (R. Kuhn, P. Gyorgy and T. Wagner-Jauregg).

In addition to failure of growth, the lack of riboflavin leads to changes in the skin and tongue. The eyes frequently are involved. The vitamin is known to function as part of enzyme systems that are concerned with oxidation of carbohydrates and of amino acids. Like thiamine and most other vitamins, it fills its metabolic function not in the free form but as a more complex derivative formed from the vitamin by the organism and containing esterified phosphoric acid derivatives.

Slightly more riboflavin than thiamine is required for the well-being of several species of animals, and it is said that 2 mg. per day will meet the needs of an adult human being adequately. It is widely distributed in both plants and animals, but the richness of diverse materials varies considerably.

Nicotinic Acid (Niacin).—This nitrogenous acid (or its amide) is the water-soluble pellagra-preventative vitamin. J. Goldberger's demonstration that pellagra was a deficiency disease (1925) was followed in 1937 by the identification of nicotinic acid (or its amide) as the vitamin involved (Elvehjem, R. J. Madden, Strong and D. W. Woolley). Pellagra is a disease primarily seen among people who eat large quantities of maize. The dogs and cats owned by pellagrous families may show a similar deficiency disease, which may be cured with the vitamin. Nicotinic acid is one of the most stable of the vitamins, and resists well most cooking or preserving processes. It is widely distributed among plants and animals but, just as with riboflavin, some materials are rich in it while others are poor. On most diets, the requirement of man for nicotinic acid is estimated to be from 5 to 15 mg. per day. However, the amino acid tryptophan can be converted to nicotinic acid by animals, and hence the requirement for the vitamin varies with the amount of this amino acid supplied by the diet. On diets high in good-quality protein, the amount of tryptophan present may be such as to reduce the dietary requirement for nicotinic acid to zero. This explains the early observations of Goldberger that good-quality protein such as that of eggs and milk, both of which are poor sources of nicotinic acid, could prevent or cure pellagra in man.

Like thiamine and riboflavin, nicotinic acid is also a part of enzyme systems concerned with the metabolism of carbohydrates. In these systems, it acts (when combined as cozymase) in catalyzing the oxidation of sugar derivatives.

Pyridoxal, Pyridoxamine and Pyridoxine (Vitamin B_6).—The existence of a vitamin distinct from thiamine and riboflavin that appeared to be an organic base was established in 1936 by T. W. Birch and Gyorgy in experiments with rats. This substance was termed vitamin B,; deficiencies of it led to a disease characterized by severe reddening and erosion of the skin on the ears, nose and paws. A substance that prevented or cured these changes was isolated almost simultaneously in five independent laboratories in 1938. Kuhn and co-workers in Germany and S. A. Harris and K. Folkers in the United States synthesized the compound in 1939; it was named pyridoxine (see diagram).

Snell and co-workers demonstrated in 1942–44 the existence of two additional forms of this vitamin and named these pyridoxal and pyridoxamine. The latter two compounds are more widely distributed than pyridoxine and are responsible for most of the vitamin B_6 activity of natural materials. The vitamin functions as a phosphorylated derivative of pyridoxal and pyridoxamine in the formation and breakdown of amino acids, and hence indirectly of protein, in living tissues.

Up to mid-loth century no human disease had been found to be caused specifically by a deficiency of vitamin B_6 in the food although certain human ailments of obscure origin had been shown to respond to administration of this substance. When such responses had been observed, the lack of sufficient vitamin in the food had not been shown. Although the production of pyridoxine deficiency in animals such as rats: mice, dogs and chickens is readily accomplished, the signs of deficiency depend to some extent on the other constituents of the diet; *e.g.,* the skin lesions in rats may not appear if certain fats are present in the ration. The intensity of the deficiency symptoms and the amount of vitamin B_6 required to prevent them are increased by feeding diets unusually high in protein or in certain amino acids such as methionine. This situation is not unique for pyridoxine deficiency, because a similar dependence of pathology on other constituents of the food is found with several vitamins.

About 1950, vitamin B, deficiency was produced experimentally in man and infants. In infants, the deficiency first manifests itself in a specific type of convulsion that is readily controlled by administration of the vitamin. A large number of cases of such convulsions have been reported in infants fed a processed substitute for human milk. Milk may be marginal in its vitamin B, content, and a portion of this vitamin is destroyed by improper heat treatment. The deficiency is corrected by improved processing procedures.

Pyridoxal, pyridoxamine and pyridoxine are interchangeable in nutrition of animals. although not always in that of microorganisms. Their potency is of the same order as that of thiamine and riboflavin. They are widely distributed in various foodstuffs.

Pantothenic Acid.—This vitamin was first discovered as a growth-promoting substance for yeast by R. J. Williams and collaborators in 1933; it was subsequently discovered independently by others as a growth factor for lactic acid bacteria and as a vitamin for animals. Collaborative studies by R. J. Williams and K. Folkers and their co-workers led to its synthesis in 1940. The compound is a nitrogenous hydroxyacid highly soluble in water but very insoluble in oils.

Pantnthenic acid does nnt occur free in tissues. The nature of the bound forms was clarified through discovery and synthesis by Snell and co-workers during 1947–50 of the compound pantetheine, which contains pantothenic acid combined with thioethanolamine. Pantetheine is required in place of pantothenic acid for growth of some bacteria and is, in turn, a fragment of a larger compound termed coenzyme A. Existence of coenzyme A was first noted by F. Lipmann in 1947 and its structure finally determined during the period 1950–55. In the form of this coenzyme, pantothenic acid promotes a large number of synthetic and degradative reactions in the body that are essential for growth and well-being.

In the absence of pantothenic acid (or its dietary equivalents, pantetheine or coenzyme A), experimental animals fail to grow, show skin lesions and frequently show a graying of the hair. All animals so far studied require the vitamin, but a dietary deficiency sufficiently severe to lead to a clear-cut deficiency disease has not been described in man. Prisoners of war in Japan during World War II, however, were reported to develop subjective symptoms described as "burning feet" that were relieved by administration of pantothenic acid.

The vitamin is widespread in nature and it is not so active, weight for weight, as most other vitamins. For example, a rat needs about ten times as much pantothenic acid as it does of thiamine or of pyridoxine.

Biotin.—This water-soluble nitrogenous acid was first discovered as a nutritive requirement of yeast. Indeed, it was one of the first vitamins to be isolated solely because it was a microbial growth factor, and subsequently to be found necessary for animals. However, after the years 1937–40, the use of bacteria and yeasts in the discovery of new vitamins, and as an aid in their isolation, became common. Biotin was isolated in pure form in 1935 by F. Kogl and B. Tonnies, and its structure was established by V du Vigneaud and his collaborators in 1942, after they had shown that it is required by animals.

The demonstration that biotin is required by certain animals was dependent on the fact (M. A. Boas, 1927) that the addition of uncooked egg white to a diet which is otherwise adequate leads to the production of a disease. This malady is caused by the presence in egg white of a specific protein, termed avidin, which combines with biotin and thus effectively prevents its utilization.

A human need for biotin was not known by the 1950s, possibly for reasons similar to those discussed under previous vitamins. It is a relatively stable substance which is found rather widely distributed in nature. Judged on a weight basis, biotin is one of the most active of the water-soluble vitamins (about 20 times as potent as thiamine for rats or chickens).

Folacin (Folic Acid or Pteroylglutamic Acid).—The existence of a new vitamin that was necessary for growth and for the prevention of anemia in monkeys and chicks and for the growth of various bacteria was demonstrated independently in 1938 by P. L. Day and in 1940 by A. G. Hogan and E. M. Parrott, and by Snell and W. H. Peterson.

Folic acid is a nitrogenous acid the nature of which was established, by Lederle laboratories in 1946, to be xanthopterylmethyl-para-aminobenzoyl glutamic acid. Several related substances that differ from folic acid only in their glutamic acid content have been isolated; their relative potencies in correcting folic acid deficiency in animals and microorganisms differ slightly. They are referred to as polyglutamates of folic acid.

In nature there exists a related group of substances that are derived from folic acid and its polyglutamates by reduction and that may or may not contain a combined formyl group. The first of these to be isolated and synthesized was *folinic* acid (*see* diagram); corresponding modifications of each of the polyglutamates of folic acid presumably occur naturally.

The various compounds of this type are interchangeable in animal nutrition but not always in bacterial metabolism. This vitamin is required for synthesis and breakdown in tissues of a number of important compounds, especially the nucleic acids.

Folic acid or one of its related derivatives is required in the diet of all higher animals studied. However, this requirement is difficult to demonstrate directly with some animals because the vitamin is synthesized by bacteria contained in the intestinal tract and absorbed from there into the body of the host. In such instances, it frequently happens that a deficiency is readily observed in animals fed certain drugs, such as sulfonamides, that interfere with synthesis of this vitamin by intestinal microorganisms. A deficiency of the vitamin in animals leads to anemia and a marked reduction in the number of one type of white blood cells. Some anemias found in human populations, such as the megaloblastic anemia of infancy and nutritional macrocytic anemia, are controlled by administration of the vitamin. An intimate but still poorly understood relationship between folic acid and vitamin B_{12} deficiency also occurs in pernicious anemia. A deficiency of folic acid is also characteristic of the disease sprue. Despite the natural occurrence of deficiency diseases that respond to it, the quantitative requirement for the vitamin is not well established. In chickens and guinea pigs, the amounts required are of the same order of magnitude as those of thiamine.

Vitamin B_{12} **(Cobalamine)**.—Although vitamin B_{12} is one of the most recently isolated and characterized vitamins, its discovery antedates that of many other B vitamins. G. R. Minot and W. P. Murphy found in 1927 that pernicious anemia could be treated successfully with large amounts of whole liver. Much smaller amounts of appropriately purified liver concentrates administered by injection were similarly effective. Over a period of many years pernicious anemia patients were used experimentally to determine the efficacy of purification procedures, and liver concentrates of higher and higher effectiveness were prepared. Finally, in 1948, a crystalline substance that controlled pernicious anemia when extremely small amounts mere administered by injection was isolated by workers in the Glaxo laboratories in England, and at Merck and Company, Inc., in the United States. The substance was called vitamin B_{12} and was shown to be the same as a substance, previously called animal protein factor, required for growth of animals on diets of all-vegetable origin.

Vitamin B_{12} is the most complicated vitamin in structure yet known and is unique in containing a metallic ion, cobalt. It occurs naturally in several closely related forms, all of which are now termed cobalamines because of the presence of cobalt in the molecule. The principal one used for medical purposes is called cyanocobalamin. Its structure was determined in 1956 by a collaborating group headed by A. R. Todd in England and by Folkers in the United States.

So far as known, vitamin B_{12} is not present in higher plants. It is required in the diet of all higher animals studied. It is synthesized by several molds and bacteria, and the ultimate source of the vitamin in liver and animal materials generally appears to be microorganisms of various kinds. Several bacteria that have lost the ability to make the substance for themselves are known; these require minute amounts of it for growth One of these was used as an assay organism during isolation of the vitamin, and all currently used methods of estimation depend upon its ability to promote growth of bacteria that require it. Its exact function in living organisms is unknown, but it clearly functions in some way to permit synthesis of methyl groups of choline and methionine, and in the synthesis of nucleic acid.

Vitamin B_{12} when administered by injection cures pernicious anemia in amounts as small as two millionths of a gram per day. Amounts that are fully curative by injection are without effect if given orally unless they are administered together with preparations from normal human or hog gastric juice. The substance in gastric juice is termed intrinsic factor and was discovered by W. P. Castle in 1934; purified preparations appear to be glycoprotein in nature. Intrinsic factor functions by promoting absorption of vitamin B_{12} through the intestinal wall. It is lacking in the gastric juice of pernicious anemia patients; they develop pernicious anemia even while ingesting a ration that contains adequate vitamin B_{12} for normal persons because, unlike normal persons, they are unable to absorb the vitamin. Thus pernicious anemia can be controlled either by injection of vitamin B_{12} in minute amounts or by oral administration of intrinsic factor with or without added vitamin B_{12}, but not by oral administration of small amounts of the vitamin alone. The condition therefore is not a nutritional deficiency disease produced by lack of the vitamin in the diet. Vitamin B_{12} deficiency from this latter cause is not common, but appears to occur occasionally in strict vegetarians who have persisted in their dietary habits for several years.

Choline.—Before the discovery of vitamin B_{12}, the nitrogenous alcohol choline appeared essential for growth of rats and chicks. Although required in amounts larger than most of the vitamins, it was nonetheless considered as a vitamin by many. The requirement for it largely disappears in animals provided with adequate amounts of the essential amino acid methionine and sufficient vitamin B_{12} to permit synthesis of its methyl groups. For this reason, its status as a vitamin is questionable, although it may promote growth in diets of marginal adequacy. Under conditions where it is required for animal growth, its absence results in hemorrhagic kidneys and an excessive deposition of fat in the liver. The substance is an important component of the metabolically important fatlike substance lecithin.

Choline also functions in the transfer of methyl groups in metabolism.

Inositol.—The vitamin status of inositol, like that of choline, is somewhat in doubt. Its role in nutrition was demonstrated in 1928 by E. V. Eastcott, who showed that it was required for growth of some yeasts. Woolley in 1940 demonstrated an apparent requirement for it by rats and mice. This requirement was not always observed, however, and many purified rations suitable for rat growth do not contain added inositol. Experiments with isotopic glucose have demonstrated its conversion to inositol in animals, hence its synthesis in vivo is possible. On the other hand, most isolated human tissues require the substance for growth in tissue culture (H. Eagle, 1956). It is evident that its nutritional role requires further study. Like choline, inositol occurs in certain lipids.

Miscellaneous.—A number of substances that function similarly to vitamins and are required for growth of various microorganisms are known. They appear not to be required in the diet of animals, so far as now known, and therefore should not be considered as true vitamins. Examples of such substances are lipoic acid, spermine or spermidine, protoporphyrin, cholesterol and several derived forms of the true vitamins such as pyridoxamine phosphate, pantetheine. etc. Such compounds are also required by higher animals, but these have retained the capacity to synthesize them and hence they are not dietary requirements for animals.

VITEBSK, a town of the Byelorussian Soviet Socialist Republic, U.S.S.R. (White Russia). on both banks of the western Dvina (Daugava), and on the railway. in 55° 10′ N., 30° 11′ E. Pop. (1956 est.) 128,000. Industries include the manufacture of glass, agricultural machinery, boots and shoes. sewn goods, sewing needles, spectacles and bristles. There is a large Jewish element in the town.

Vitebsk (Dbesk, Vitbesk and Vitepesk) is mentioned for the first time in 1021, when it belonged to the Polotsk principality. Eighty years later it became the chief town of a separate principality, and so continued until 1320, when it came under the dominion of the Lithuanians. In the 16th century it fell to Poland. Under the privileges granted to the city by the Polish sovereigns it flourished. but soon began to suffer from the wars between Russia and Poland, during which it was thrice taken by the Russians and burned. Russia annexed it finally in 1772. During World War II Vitebsk was captured by the Germans in 1941 and recaptured by soviet troops in the summer of 1944.

VITELLI, VITELLOZZO (?–1502), Italian *condottiere*. Together nith his father, Niccolò, tyrant of Città di Castello. and his brothers, who were all soldiers of fortune, he instituted a new type of infantry armed with sword and pike to resist the German men-at-arms, and also a corps of mounted infantry armed with arquebuses.

Vitellozzo took service with the republic of Florence against Pisa, and later with the French in Apulia (1496) and with the

Orsini faction against Pope Alexander VI. In 1500 Vitellozzo and the Orsini made peace with the pope, and the latter's spn, Cesare Borgia, being determined to crush the petty tyrants of Romagna and consolidate papal power in that province, took the *condottieri* into his service.

Vitellozzo distinguished himself in many engagements, and in 1501 he advanced against Florence, moved as much by a desire to avenge his brother Paolo, who while in the service of the republic had been suspected of treachery and put to death (1499), as by Cesare's orders. In fact, while the latter was actually negotiating with the republic, Vitelli seized Arezzo.

Forced by Borgia and the French, much against his will, to give up the city, he began from that moment to nurture hostile feelings toward his master and to aspire to independent rule. He took part with the Orsini. Oliverotto da Fermo and other captains in the conspiracy of La Magione against the Borgia; but mutual distrust and the incapacity of the leaders before Cesare's energy and the promise of French help brought the plot to naught, and Vitelli and other *condottieri,* hoping to ingratiate themselves with Cesare once more, seized Senigallia (Sinigaglia) in his name. There they were decoyed by him and arrested while their troops were out of reach, and Vitelli and Oliverotto were strangled that same night (Dec. 31, 1502).

VITELLIUS, AULUS (15–69), Roman emperor Jan. 2–Dec. 22, A.D. 69, was born on Sept. 24, A.D. 1j. He was the son of Lucius Vitellius, who had been three times consul and colleague of Claudius as censor. Aulus was consul in 48, and later (perhaps in 60–61) proconsul of Africa. Under Galba, to the general astonishment, at the end of 68 he was chosen to command the army of Lower Germany. His good nature, which was fatal to discipline, made him popular, but he was not ambitious, and was raised to the throne by Valens and Caecina, two commanders of legions on the Rhine. They contrived a military revolt, and early in 69 Vitellius was proclaimed emperor of the armies of Germany at Cologne. He was accepted by the senate after his victory over Otho (*q.v.*), but never by the whole empire. The armies of the east and of the Danube declared for Vespasian, and Vitellius' general Caecina turned traitor. His legions were then defeated before Cremona by the invading general Antonius Primus, and as the victors neared Rome Vitellius meditated abdication. His praetorian guard forbade this and events moved to a tragic climax, during which the capitol of Rome was burned. On the entry of Vespasian's troops Vitellius was dragged from a miserable hiding place and butchered at the fatal Gemonian stairs, crying "Yet I was once your emperor." During his brief administration Vitellius showed indications of a desire to govern wisely. He has a reputation as one of the greatest eaters and drinkers known to history.

VITERBO, a provincial capital and episcopal see of the district of Lazio (Latium), Italy, 54 mi. N.N.W. of Rome, 1,073 ft. above sea level. Pop. (1951) 25,909. It is surrounded by gardens, and enclosed by walls and towers which date partly from the Lombard period. The streets are paved with large lava blocks, of which the town is also built.

The Piazza St. Pellegrino is said to be the best example in the country of a 13th-century piazza. The citadel (Rocca) itself, erected by Cardinal Albornoz in 1345, is now a barrack.

The cathedral, a fine basilica, of the 12th (?) century, with columns and fantastic capitals of the period, originally flat-roofed and later vaulted, with 16th-century restorations, contains the tomb of Pope John XXI, and has a Gothic campanile in black and white stone. Here Pope Adrian IV (Nicholas Breakspear) compelled the emperor Frederick I to hold his stirrup as his vassal.

The church of Sta. Rosa exhibits the embalmed body of that saint, a native of Viterbo, who died in her 18th year after working various miracles and having distinguished herself by her invectives against Frederick II (12j1). Some ruins of Frederick's palace, destroyed after his death, exist. S. Francesco, a Gothic church (1236), contains the fine Gothic tombs of Popes Clement IV and Adrian V, and has an external pulpit of the 15th century. Sta. Maria della Cella is noteworthy for one of the earliest campanili in Italy (9th century). The town hall, with a medieval toner and a 15th-century portico. contains some Etruscan sarcophagi and a few paintings. Close by is the elegant Gothic façade of Sta. Maria della Salute, in white and red marble with many fine scplptures.

The Gothic cloisters of Sta. Maria in Gradi and of Sta. Maria della Verita just outside the town are strikingly beautiful. The latter church contains frescoes by Lorenzo da Viterbo (1469) and an interesting museum.

Viterbo is by some identified with Surrina nova, which is only mentioned in inscriptions, while some place this to the west of Viterbo on the line of the Via Cassia. The Via Cassia was joined there by the Via Ciminia, passing east of the Lacus Ciminius, while a road branched off to Ferentum. It is not an unlikely assumption that there, as elsewhere, the medieval town occupies an Etruscan site. It was fortified by the Lombard king Desiderius. It is the centre of the territory of the "patrimony of Peter." which Countess Matilda of Tuscany gave to the papal see in the 12th century; in the 13th century it became a favourite papal residence.

(T. A.)

VITORIA, FRANCISCO DE (Lat. FRANCISCUS DE VICTORIA) (1483?–1546), one of the greatest of the Spanish theologians, was noted principally for his defense of the rights of the Indians of the new world against the claims of the Spanish throne. He studied at Burgos and after three years teaching at the University of Valladolid (1523–26), became professor of theology at Salamanca in 1526, where he remained until his death. In 1532 he delivered lectures subsequently published under the title, *De Indis et de iure belli relectiones* ("Readings on the Indians and on the Law of War") which, in the course of a defense of the rights of the Indians, set forth certain fundamental principles of the law of nations. One by one he rejected various alleged justifications for the subjection of the Indians, maintaining their rights to the lands they had occupied and their freedom from any compulsion in the acceptance of the Christian religion, and limiting the interposition of the Spaniards to the organization of a government on behalf of the welfare of the Indians. He applied the natural law, derived from right reason to nations as well as to individual men and drew the conclusion that nations in their separate capacities constituted a single commonwealth which possessed an authority to establish laws for the common good. In respect to the form of government of the individual state Vitoria, while preferring monarchy, recognized that the ultimate power of government rested in the people.

His *De Indis et de iure belli relectiones,* with introduction by Ernest Nys, trans. by J. P. Bate, was published in "Classics of International Law Series" (1917).

See James Brown Scott, *The Spanish Origin of International Law,* pt. i, "Francisco de Vitoria and His Law of Nations" (1933).

(C. G. FK.)

VITÓRIA, a city and port of Brazil, capital of the state of Espirito Santo, on the west side of an island at the head of the bay of Espirito Santo. The population of the city in 1950 was 49,735.

The principal streets follow the water line, rising in terraces from the shore, and are crossed by narrow and steep streets. Many buildings are of the colonial type. The entrance to the bay is rather tortuous and difficult, but is sufficiently deep for the largest vessels. The harbour is not large. but is safe and deep, being completely shut in by hills. Large quays, piers, warehouses, etc., facilitate the handling of cargoes.

Vitória is a port of call for coasting steamers and a shipping port in the coffee trade. The other exports are lumber, sugar, rice and mandioca to home ports. A railway starting at Vitoria connects with Rio de Janeiro, 270 mi. to the southwest. Another line runs north and west into the important mineral region of Minas Gerais, for which it provides an outlet.

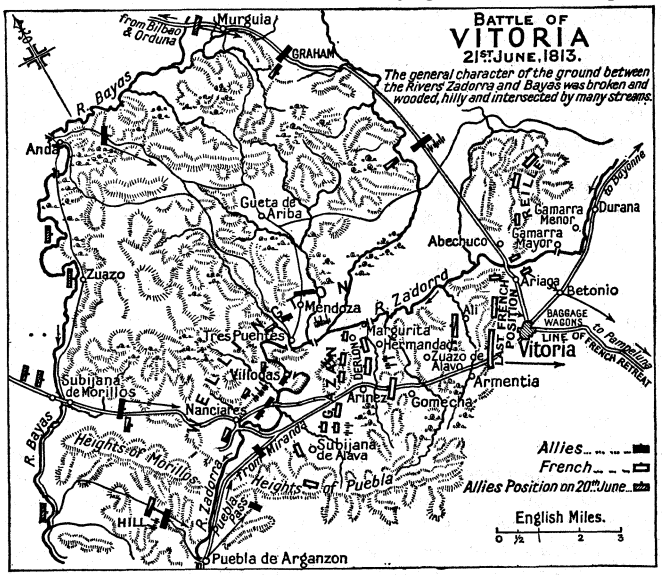
Vitória was founded in 1535 by Vasco Fernandes Coutinho, on the south side and nearer the entrance to the bay, and received the name of Espirito Santo. The old site is still occupied, and is known as Vila Velha (Old Town).

VITORIA, an episcopal city of N. Spain, capital of Álava province; on the Miranda de Ebro-Alsasua section of the Northern railways, among the southern outliers of the Cantabrian mountains, and on the left bank of the river Zadorra, a left-hand tributary of the Ebro. Pop. (1940) 44,341 (mun., 49,752). Vitoria was founded in 581 by Leovigild, king of the Visigoths; but its importance dates from the 10th century. In 1181 Sancho the Wise of Navarre granted it a charter and fortified it. The city is built on a hill 1,750 ft. high, and overlooks the plain of Alava. The cathedral of Santa Maria dates from 1181, but has been considerably spoiled by late additions: the church of San Miguel also dates from the 12th century; it has a beautiful altar, carved in wood by J. Velazquez and G. Hernandez, in the 16th century. Vitoria, from its favourable position on the main lines from Madrid to France and to the port of San Sebastian, is an important centre of trade in wine, wool, horses, mules and hardware. Nationalists captured it in the civil war of 1936–39.

Battle of **Vitoria.**—For the operations which preceded the battle of Vitoria see PENINSULAR WAR. On June 21, 1813, the French army in Spain (about 65,000 men with 150 guns), under King Joseph Bonaparte, held an extended position in the basin of Vitoria, south (with the exception of the extreme right) of the river Zadorra. The left rested on the heights of Puebla, north of the Puebla Pass, and Puebla de Arganzon, through which ran the Miranda-Vitoria-Bayonne road, Joseph's line of communication with France. Thence the line stretched to the ridge of Margarita, the troops so far being under General Gazan, with a second supporting line under D'Erlon between Arinez and Hermandad and a reserve behind Arinez. The right under Reille guarded the Bilbao-Vitoria road.

There were no troops between Hermandad and Ariaga, except a mass of cavalry near Ali. The Zadorra, fordable in certain spots only, was spanned by bridges at Puebla de Arganzon, Nanclares, Villodas, Tres Puentes, Mendoza, Abechuco and Gamarra Mayor, which French guns commanded; but, for some reason, none of these had been destroyed. The faults of the French position and their occupation of it were its extension; that it was in prolongation of and (on the right especially) very close to their line of retreat, so that if the right were driven back this line could be at once seized; that the centre was not strongly held; and that all bridges were left intact.

The Allies (nearly 80,000, with 90 guns), under Wellington, had moved from the river Bayas at daylight to attack Joseph, in



four columns. the right being under Hill (20,000, including Morillos's Spaniards), the right centre and left centre under Wellington (30,000) and the left under Graham (20,000, including Longa's Spaniards). As the columns marched across the intersected country between the Bayas and Zadorra, extending from near Puebla de Arganzon to the Bilbao-Vitoria road, they kept touch with each other; and as they neared the Zadorra the battle opened all along the line soon after 10 A.M. Wellington's instructions to Graham were to undertake no manoeuvre which would separate his column from those on the right; but, with this proviso, to seize the Vitoria-Bayonne road if the enemy appeared decidedly in retreat. Hill after a sharp contest gained the Puebla heights, too weakly held; and pushing through the pass carried the village of Subijana de Alava. The right centre column having reached Villodas, was waiting for Hill to gain further ground, when the bridge at Tres Puentes was observed to be unguarded, probably because it was commanded from the south bank; and, the French attention being now turned towards their flanks, it was surprised and rushed by Wellington with the Light division, supported quickly by cavalry and other troops, who maintained themselves on the south bank. Joseph's centre was partially forced, while his left was hard pressed by Hill; and, fearing that Gazan and D'Erlon might be cut off from Reille, he ordered them to withdraw to a ridge farther back, which they did, holding Arinez in front. Here there was no hard fighting; but, as Wellington had now passed three divisions, many guns and the cavalry (which, however, from the nature of the ground could be but little used) across the Zadorra, Margarita, Hermandad and Arinez soon fell to the Allies.

On the left, Graham, having turned the heights north of the Zadorra with Longa's Spaniards, seized Gamarra Menor close to the Bayonne road. He also with heavy loss carried Gamarra Mayor and Abechuco, but the bridges south of these villages, though more than once taken, were always recaptured by Reille. At length, when a brigade from the Allied centre had been pushed up from Hermandad against Reille's flank, he withdrew from the obstinately defended bridges, and before this Gazan and D'Erlon had also fallen back, fighting, to a third position on a ridge between Armentia and Ali west of Vitoria. Here, at about 6 P.M., they made a last stand, being compelled in the end to yield; and as Graham, having now crossed the bridges, was close to the Bayonne road, the main body of Joseph's army fled by a bad crossroad towards Pampeluna, abandoning artillery, vehicles and baggage (of which an enormous quantity was parked near Vitoria), Reille afterwards joining it through Betonia. The Allies then occupied Vitoria and pursued the French until nightfall. All Joseph's equipages, ammunition and stores, 143 guns, a million sterling in money, and various trophies fell into Wellington's hands, the French loss in men being nearly 7,000, that of the Allies over 5,000, of whom 1,600 were Portuguese and Spaniards. This decisive victory practically freed Spain from French domination. (C. W. Ro.)

VITRÉ, a town of northwestern France, in the department of Ille-et-Vilaine, on-a hill above the left bank of the Vilaine, 24 mi. E. of Rennes by rail. Pop. (1936) 7,298. Vitré belonged in the 10th century to the younger branch of the counts of Rennes. In 1295 it passed to Guy IX, baron of Laval, on his marriage with the heiress, and afterwards successively belonged to the families of Rieux, Coligny and La Trémoille. It was seized by Charles VIII in 1488. Protestantism spread under the rule of the houses of Rieux and Coligny; VitrC became a Huguenot stronghold; and a Protestant church was established, which was suppressed at the revocation of the edict of Nantes in 1685. The estates of Brittany, over which the barons of VitrC and of Léon alternately presided, met here several times. The town largely retains its mediaeval aspect. The ramparts on the north side and on the west, consisting of a machicolated wall with towers at intervals, are still standing. Only one gateway remains of the original 11th century castle; the rest was rebuilt in the 14th and 15th centuries and restored in recent times.

VITRIFIED FORTS, the name given to certain hill-forts of which the defenses consist entirely or to some extent of walls which have been subjected in a greater or less degree to the action of fire. Their form is determined by the contour of the summits which they enclose and generally the plan is simple. The walls vary in size, the vitrified portion being usually confined to a core extending from the top downward, though vitrifaction has been met with on the sides of the wall only, and in one known instance a narrow wall consolidated by vitrifaction was found in the heart of an earthen rampart. As a rule the vitrified mass appears to have been supported by a wall of unvitrified stone built up on one or both faces. No lime or cement has been found in any of these structures, all of them presenting the peculiarity of being consolidated to a greater or less extent by the fusion of the rocks of which they are built. This fusion, caused by the application of intense heat, is not equally complete in the various forts, or even in the walls of the same fort. In some cases the stones are only partially melted and calcined; in others their adjoining edges are fused so that they are firmly cemented together. In many instances pieces of rock are enveloped in a glassy enamel-like coating which binds them into a uniform whole; and at times, though rarely, the entire length of the wall presents one solid mass of vitreous substance.

Some 50 examples have been discovered in Scotland widely distributed. They are also found in Ireland, Lusatia, Bohemia, Silesia, Saxony and Thuringia; in the provinces on the Rhine, especially in the neighbourhood of the Nahe; in the Ucker Lake, in Brandenburg, where the walls are formed of burnt and smelted bricks; in Hungary; and in several places in France. They have not been found in England or Wales.

The following facts may be noted: — (I) The idea of strengthening walls by means of fire is not singular, or confined to a distinct race or area, as is proved by the burnt-earth enclosure of Aztalan, in Wisconsin, and the vitrified stone monuments of the Mississippi valley. (2) Many of the Primary rocks, particularly the schists, gneisses and traps, which contain large quantities of potash and soda, can be readily fused in the open air by means of wood fires—the alkali of the wood serving in some measure as a flux. (3) The walls are chiefly vitrified at the weakest points, the naturally inaccessible parts being unvitrified. (4) When the forts have been placed on materials practically infusible, as on the quartzose conglomerates of the old red sandstone, as at Craig Phadraic, and on the limestones of Dun Mac Uisneachain, pieces of fusible rocks have been selected and carried to the top from a considerable distance. (5) Many of the continental forts are so constructed that the fire must have been applied internally, and at the time when the structure was being erected. (6) Daubrée, in an analysis of vitrified materials taken from four French forts, which he submitted to the Academy of Paris in Feb. 1881, found the presence of natron in such abundance that he inferred that sea-salt was used to facilitate fusion. (7) In Scandinavia, where there are hundreds of ordinary forts, and where for centuries a system of signal fires was enforced by law, no trace of vitrifaction has yet been detected.

Great antiquity has been assigned to these forts, but tool marks indicating the use of iron implements have been found, which would suggest that the structures were in use as late as the early centuries of the Christian era. It has been suggested that they were built as refuges against the Norsemen, and much in the situation and character of the forts favours this supposition. The sites of the Scottish forts are so selected that they not only command what were the favourite landing-places of the vikings, but are the best natural defenses against attacks from the direction of the seacoast. In Saxony and Lusatia the forts are known as Schwedenburgen, and in the Highlands of Scotland as the fortresses of the *Feinne*—designations which also seem to point to an origin dating back to the times of the vikings.

VITRIOL, a name given to certain hydrated sulfates and to sulfuric acid. Blue or roman vitriol is cupric sulfate; green vitriol is ferrous sulfate or copperas; red or rose vitriol is cobaltous sulfate; uranvitriol is a native uranium sulfate and white vitriol is zinc sulfate. Oil of vitriol is concentrated sulfuric acid (*q.v.*).

(J. B. Ps.)

VITRUVIUS (MARCUS VITRUVIUS POLLIO), Roman architect, engineer and author of the celebrated treatise De architectura. Little is known of Vitruvius' life, except what can be gathered from his writings. Although he nowhere identifies the emperor to whom his work is dedicated, it is likely that the first Augustus is meant and that the treatise was conceived after 27 B.C. Since Vitruvius describes himself as an old man, it may be inferred that he also was active during the reign of Julius Caesar. Vitruvius himself tells of a basilica he built at Fanum (now Fano).

De architectura was based on his own experience as well as on theoretical works by famous Greek architects such as Hermogenes (3rd century B.C.). It is divided into ten books, dealing with city planning and architecture in general; building materials; temple construction and the use of the Greek orders; public buildings (theatres, baths); private buildings; floors and stucco decoration; hydraulics; clocks, mensuration and astronomy; and civil and military engines. Vitruvius' outlook is essentially Hellenistic. His wish was to preserve the classical tradition in the design of temples and public buildings, and his prefaces to the separate books of his treatise contain many a pessimistic remark about the glories of contemporary architecture.

Most of what Pliny says in his *Natural* History about Roman construction methods and wall painting was taken from Vitruvius, though unacknowledged. Vitruvius' expressed desire that his name be honoured by posterity was, however, realized. Throughout the classical revival of the Italian Renaissance, his work was the chief authority studied by architects, and his precepts were accepted as final.

Bramante, Michelangelo and Vignola (*qq.v.*) were careful students of Vitruvius.

The best editions of De architectura are those of F. Krohn, "Bibliotheca Teubneriana" (1912) and V. Rose (new ed., 1899); see also H. Nohl, Index *Vitruvianus* (1876). For English translations see those by F. Granger (1931–34) and by M. H. Morgan (1914).

See Carl Axel Boethius, "Vitruvius and the Roman Architecture of His Age" in *Dragma Martino P. Nilsson dedicatum* (1939).

(H. HN.)

VITTEL, a watering place of northeastern France, in the *département* of Vosges, 31 mi. W. of Epinal by rail. Pop. (1954) 4,010. The cold saline and chalybeate waters are bottled and exported in large quantities. They are prescribed in cases of arthritis, dyspepsia, etc.

Vittel is a fashionable resort.

VITTORIA, a town of Sicily in the province of Ragusa, 95 mi. W.S.W. of Syracuse by rail (42 mi. direct), founded in the 17th century. It is a prosperous town in the centre of a fertile district, with the largest wine trade in Sicily. Population (1951) 39,741.

VITTORINO DA FELTRE (VITTORINO RAMBOLDINI or DEI RAMBOLDONI) (1378–1446), Italian educator, the teacher par excellence of the Renaissance, was born at Feltre, in Venetia. About 1396 he entered the University of Padua, where he remained for 20 years as student or teacher. In 1423 he was asked to become tutor to the Gonzaga children, the Gonzagas being then rulers of Mantua. This position he accepted upon the conditions that the school be located at some distance from the court and completely removed from political influence; that he have complete control of the children at all times; and that he be allowed to enroll other children as he saw fit. Both boys and girls from all over Europe attended the school. Like most teachers, Vittorino wrote little, but his pupils picture him as an extremely successful teacher who knew his pupils intimately, loved them, cared for their health and character as well as for their learning, adapted his work to their abilities and used no corporal punishment. He has been called the first modern schoolmaster. His school at Mantua was in essence the world's first boarding school—a place removed from the ordinary influences of life, where the children were watched over, cared for and guarded. It remains a model to the present day.

Vittorino died at Mantua on Feb. 2, 1446.

See W. H. Woodward, *Vittorino da Feltre and Other Humanist Educators* (1905).

(L. CE.)

VITTORIO VENETO, BATTLE OF. This is the title given to the battle or, more truly, campaign in which the Austrian forces on the Italian front were finally overthrown in Oct. 1918. Diaz's plan for the bigger offensive finally decided upon was to concentrate on the Piave front between Pederobba and Fagaré (east of Treviso), to cross the river and break through by way of Conegliano to Vittorio Veneto, dividing the Austrian V. and VI. Armies which held the river line from the sea to Valdobbiadene. The attack was fixed for Oct. 16, but bad weather and a rise of the Piave caused a delay.

Italian Plans.—It was decided to open the action with an attack by the IV. Army (nine divisions) in the Grappa sector, with the double object of drawing the enemy reserves from the Feltre sector and of breaking through in this direction. The attack on the Piave was to be carried out by three armies, the XII., VIII. and X., of which the first and last had been formed specially for this offensive. The XII. Army (one French division and three Italian) was commanded by Gen. Graziani, the commander of the French troops in Italy; and the X. Army (two British divisions and two Italian) by Lord Cavan.

The main drive was to be made by the VIII. Army (14 divisions), attacking from below Pederobba to Ponte della Priula. The XII. Army was to advance northward outside the Piave, while the X. Army was to attack the right wing of the Austrian V. Army and form "a defensive flank to cover and protect the principal manoeuvre of the VIII. Army" (Gen. Diaz's report). On the battle front from the Brenta to Fagaré were massed 41 divisions, 22 in line and 19 in reserve. Against this force the Austrians had 23 divisions in line and immediate reserve, and 10 more divisions within reach. The Piave-Grappa front was divided between two army groups: Boroević's Piave Group (V. and VI. Armies), from the sea to Valdobbiadene, and the newly formed Belluno Group, under Gen. Goglia, from Valdobbiadene to the Brenta. The disposition of the Austrian troops and guns showed a fear for the Grappa positions and a failure to divine the direction of the main Italian attack. In the Grappa sector the Belluno Group had eight divisions in line and three in immediate reserve, while the infantry was backed by some 1,200 guns. The Austrian VI. Army, on the other hand, with seven divisions in line and two in support, had only about 500 guns against a mass of over 2,000. Opposite Lord Cavan's X. Army the right wing of the Austrian V. Army had three divisions in line and one in support.

Allied Attack Opens.—The Italian IV. Army, under Gen. Giardino, attacked at dawn on Oct. 24, and though some headway was made the enemy put up a very stubborn resistance. Already a very fine piece of work had been carried out by British troops of the X. Army, who in the early hours of the same day occupied the northern part of the long shoal island of the Grave di Papadopoli, crossing the main channel in small flat-bottomed boats punted by Italian specialist troops *(pontieri)*, and driving back or capturing the enemy outposts. The general attack should have followed the next night, but a sudden rise in the river, which was coming down in heavy flood at 7m an hour, counselled delay. It was not until the night of Oct. 26, when the southern part of the Grave di Papadopoli had also been occupied by Italian troops of the X. Army, that the bridges began to be thrown across the river 'or the main attack.

The Crossing of the **Piave.**—Eleven crossing points were selected, one at Pederobba for the right wing of the XII. Army, seven on the VIII. Army front, and three for the X. Army, at the Grave di Papadopoli. The XII. and X. Armies threw their bridges successfully, but on the VIII. Army front only two of the seven sets of bridges could be established, both on the north of the Montello. Next day three bridgeheads were established: opposite Pederobba, north of the Montello, and opposite the Grave di Papadopoli. The most important advance was made in the latter sector, where the X. Army succeeded in advancing to a depth of over zm. on a front of about 4m. The British XIV. Corps took 3,500 prisoners and 2,100 were captured by the Italian VI. Corps.

This was the most successful advance of the day. The bridges of the VIII. and XII. Armies were all destroyed during the day. At Pederobba some headway was made, and the troops of the VIII. Army, who attacked towards Sernaglia, gained about a mile. But the right wing of the Army (VIII. Corps) was unable to throw its bridges, and only a detachment of storm-troops reached the left bank. There was a gap of some 6m. between the left wing of the VIII. Army and the British XIV. Corps, which formed the left wing of the X. Army, and the chief move in the general manoeuvre was checked. The VIII. Corps had been detailed to push straight for Vittorio Veneto, and the fact that it had been unable even to start its advance threatened to throw the whole battle out of gear.

No better fortune attended the efforts made on the following night to bridge the river east of the Montello. The swift current and the enemy guns defied all attempts to establish the bridges and the engineers suffered very heavy casualties. In spite of the initial successes, the situation was unsatisfactory, but after the first failure to cross the river east of the Montello, Gen. Caviglia, who commanded the VIII. Army and had the general direction of the attack, had detached the XVIII. Corps from his reserves to pass under the command of Lord Cavan, cross by the X. Army bridges, push north and clear the front of the troops who were held up. The move was entirely successful. The XVIII. Corps under Gen. Basso crossed the river in the early hours of Oct. 28 and attacked northward, while the rest of the X. Army continued its advance.

Position on Oct. 29.—At the close of Oct. 28 the XVIII. Corps had gained nearly 4m. and had crossed the railway north of the Priula bridges. The British XIV. Corps had gone right through the Austrian positions and had patrols out on the Monticano, while the Italian XI. Corps was threatening the enemy troops on the Lower Piave. The bridgehead was 10m. wide and 4m. deep. The XII. Army and the left wing of the VIII. had also made good progress, and at last the VIII. Corps was crossing the river, between Nervesa and Ponte di Priula. The prospects of the following day were bright, for the separation of the Austrian V. and VI. Armies was effected; and the VI. Army, heavily attacked in front, was seriously threatened on its left by Basso's XVIII. Corps.

On the evening of Oct. 29 an Italian flying column entered the town of Vittorio Veneto. The attacking armies had already taken 33,000 prisoners, and the situation of the Austrian troops on the Piave was hopeless. Next day resistance broke down, and the general retirement ordered on the 29th became a complete rout. The troops on Monte Grappa had hitherto held firm against the repeated attacks of the IV. Army, and had made many counter-attacks. But here too, on the night of Oct. 30, a retreat began that was to turn into a flight.

Austrian Collapse and Armistice.—Late on the evening of Oct. 30 the Austrian command announced that in view of the discussions regarding an armistice which were being conducted between Germany and the United States, "our troops fighting on Italian soil will evacuate the occupied region." On the same day the order for a general retreat was given, and that evening, in the Val Lagarina, Gen. Weber von Webernau, commander of the Austrian VI. Corps, made a formal demand for an armistice. Sext day he and his staff were taken to the Villa Giusti, near Padua, and discussions were begun. It was, of course, necessary to communicate with Versailles, where the Allied War Council was discussing a reply to Germany's demand for an armistice.

Meanwhile the fighting continued, and the Austrian armies crumbled away. The Italian VI. and I. Armies attacked in the Trentino, and the III. Army, which had crossed the Piave two days before, was already taking part in the pursuit of Boroević's broken divisions. On the night of Nov. 2–3, although the Armistice was not yet signed, the Austrian command issued an order for the cessation of hostilities. It was at first revoked by the Emperor Charles, but was reissued and reached the front on the morning of Nov. 3. The terms were only agreed on verbally on the afternoon of Nov. 3, and signed at 6 30 P.M.

Conclusion.—When hostilities ceased at 3 P.M. on Nov. 4, Italian troops were far up the Trentino and into Cadore, and to the east the line of the old frontier was passed and the middle waters of the Isonzo were reached. On Nov. 3 Trieste had been occupied from the sea. and half an hour before the expiration of the term fixed by the Armistice an Italian force was landed at Zara. More than 300,000 prisoners had already been counted by the Italians. and the total figure mas in the region of 500,000. A number of troops who had been cut off were allowed to pass the frontier after being disarmed, but not much more than half of the Austro-Hungarian troops on the Italian front reached the territory of the crumbling empire. All material was left behind. including about 7,000 guns. The Austro-Hungarian armies. in spite of bad food and growing depression, began by putting up a stout resistance The troops in the Grappa sector in particular not only resisted firmly but counterattacked nith great vigour, and punished the Italian 4th army very heavily. Giardino lost over 23,000 men. more than three-fifths of the total casualty list. which exceeded 35,000. (W. K. McC.)

VITUS, ST. According to the legend where he is associated with Modestus and Crescentia, by whom he had been brought up, St. Vitus suffered martyrdom at a very early age under the emperor Diocletian. Son of a Sicilian nobleman who was a worshipper of idols, Vitus was converted to the Christian faith without the knowledge of his father, was denounced by him and scourged. but resisted all attacks, on his profession. Admonished by an angel, he crossed the sea to Lucania and went to Rome, where he suffered martyrdom. His festival is celebrated on June 1j. The *Passion* of St. Vitus has no historical value, but his name occurs in the *Martyrologium hieronymianztm.* In 836 the abbey of Coroey, in Saxony, received his relics, and became a very active centre of his cult. In the second half of the 9th century the monks of Corvey, according to Helmold's *Chronica Slavorum,* evangelized the island of Rügen, where they built a church in honour of St. Vitus. The islanders soon relapsed, but they kept up the superstitious cult of the saint (whom they honoured as a god), returning to Christianity three centuries later. At Prague, too, there are some relics of the saint, who is the patron of Bohemia and also of Saxony, and one of the 14 "protectors" *(Nothelfer)* of the church in Germany. Among the diseases against which St. Vitus is invoked is chorea, also known as St. Vitus' dance. (H. De.)

VIVALDI, ANTONIO (1675?–1741), Italian composer and violinist. was the son of Giovanni Battista Vivaldi, a violinist in St. Marks, Venice. Although he was reputed to be one of the finest violinists of his day and is said to have been an influence upon J. S. Bach. Vivaldi suffered neglect until the 20th century when the discovery of many unpublished manuscripts led to a reestimation of his importance.

Vivaldi, known familiarly as *il prete rosso* (the "red priest"), studied under his father and, later, under Giovanni Legrenzi. In 1704 he began his long association with the Conservatory della Pietà in Venice, eventually becoming the concert master and director. The Pietà was a famous music school for girls, and it was there that Vivaldi composed many violin concertos. From the graded difficulty of these it has been assumed that they were used for instruction of his pupils. Most of Vivaldi's fame rests upon his violin concertos, but he also composed concertos for bassoon, flute, oboe, viola d'amore and for various combinations of instruments. In addition, his work contains many operas, concerti grossi and choral works. Bach arranged 16 of the concerti grossi for clavichord, 4 for organ and 1 for clavichords and strings.

In the years 1713–39 Vivaldi produced 39 different operas throughout Italy. Besides writing the music, he often employed the singers and dancers and handled the finances of the companies. Some of the operas contain arias written by other composers; notably, *La Rosmira* (1738) contains an aria by Handel. The operas were uneven in quality, however, some of them having been hastily composed or revised at the whim of Vivaldi's patrons.

VIVALDI, UGOLINO and **SORLEONE,** Genoese merchants connected with the first known expedition in search of an ocean route from Europe to India. According to the contemporary Genoese chronicler Jacopo Doria, Ugolino, with his brother Vadino. was in command of this expedition of two galleys, which he had organized in conjunction with Tedisio Doria, and which left Genoa in May 1291 with the purpose of going to India "by the Ocean Sea" and bringing back goods useful for trade. Planned for commerce, the enterprise also aimed at proselytism, as can be deduced from the presence of two Franciscan friars. In two well-built galleys, Ugolino and Vadino sailed down the bloroccan coast beyond Gozora (Cape Nun), in 28° 47′ N. latitude, after which nothing mas heard of them. From the scanty evidence available. it is not entirely clear whether the brothers aimed at finding the sea route to India by sailing westward or eastnard. although the latter seems more probable. Early in the next century Sorleone, son of Ugolino, is said by a 14th-century Spanish source of doubtful reliability to have undertaken a search for his father and possibly to have penetrated to Mogadoxo on the Somali coast. In 14jj another Genoese seaman, Antoniotto Usodimare, claimed to have met, near the mouth of the Gambia, a descendant of the survivors of the Vivaldi expedition; but this evidence. too, gossesses only limited value.

VIVARINI, the surname of a family of painters of Paduan origin domiciled in the island of Murano (Venice) throughout the 15th century.

ANTONIO VIVARINI, the founder of the family studio, was born c. 1415 and died between 1476 and 1484. His career falls into two parts, in the first of which he worked mainly with his brother-in-law Giovanni d'Alemagna (d. 1450), while in the second he collaborated with his younger brother Bartolommeo. The earliest record of a painting executed jointly by Antonio and Giovanni d'Alemagna dates from 1441. Their main surviving altarpieces are found in the churches of S. Zaccaria (1443–44) and S. Pantaleone, Venice (1444). A large altarpiece executed in 1446 for the Scuola Grande della Carità is in the Xccademia. Venice, and a polyptych of 1448 is in the Brera gallery, Milan. Between 1447 and 1450 the two artists were resident in Padua. The styles of Antonio and Giovanni are not easily distinguished, but Antonio was certainly the dominant partner and ranks as the most important and prolific Venetian artist of the first half of the 15th century. The soft, rounded figures in his heavily ornamented polyptychs are influenced by Gentile da Fabriano and Jacobello del Fiore and. more superficially, by Masolino. The earliest work signed by Antonio and Bartolommeo Vivarini is a polyptych, now in the Bologna gallery, commissioned by Pope Nicholas V in 1450. This is couched in the same idiom as the paintings of Antonio's first period, but in later works. notably polyptychs at Arbe, Dalmatia (1458) and Pausula Marches (1462), the intervention of his more progressive younger brother resulted in the introduction of Renaissance elements into Antonio's style.

BARTOLOMMEO VIVARINI (c. 1432–*c.* 1499) was probably a pupil of his brother Antonio, with whom he collaborated after 1450. Unlike his brother, Bartolommeo was profoundly influenced by Paduan painting in the circle of Squarcione, and from his first dated work (1448) onward reveals a stronger feeling for plasticity and greater formal resource. A painting of St. John Capistrano (Louvre, Paris) of 1459 is typical of his austere and individual style. Contact with the paintings of Mantegna seems to have marked a turning point in Bartolommeo Vivarini's career and is first apparent in an altarpiece of 1464 in the Accademia, Venice. All his most distinguished works date from after this time; among these are altarpieces in SS. Giovanni e Paolo (1473), the Frari (1474) and S. Giovanni in Bragora (1478) in Venice and in the Accademia (1477). His last dated work is a triptych of 1491 at Bergamo, where he seems to have been active in his last years.

ALVISE (or LUIGI) VIVARINI, son of Antonio and nephew of Bartolommeo, was born about 1446 and died between 1503 and 1505. His earliest dated work is an altarpiece at Montefiorentino (Marches) of 1475. To the influence of his uncle Bartolommeo were added those of Antonello da Messina and Giovanni Bellini, apparent in an altarpiece of 1480 in the Accademia at Venice and in many later works. Between 1483 and 148j Alvise was at work in southern Italy, leaving altarpieces at Barletta (1483) and Naples (1485). In 1488 he was employed on paintings for the Sala del Maggior Consiglio of the ducal palace in Venice (lost). His last work, an altarpiece in the Frari begun in 1503, was completed by

Marco Basaiti. The historical importance of Alvise Vivarini has been overrated, and his surviving works reveal him as an imitative artist of lower quality and less originality than Giovanni Bellini or Cima da Conegliano. Some of his best works are his portraits.

VIVEKANANDA (NARENDRANATH DATTA) (1863–1902), Hindu saint and religious leader, founder of the Ramakrishna order, was born on Jan. 12, 1863, in Calcutta. He became a disciple of Ramakrishna (*q.v.*), who fulfilled his requirement for a teacher with direct experience of God whose teachings should not contradict reason. Ramakrishna enabled him to realize oneness with the Godhead and all created beings, subsequently inspiring him to see God in man and to regard service to man as the highest worship. As a wandering monk, Vivekananda discovered spirituality to be the heart of India. But he was appalled by the people's material backwardness, which he felt could be remedied through western science. He came to feel, too, that the west needed India's spiritual insights to control materialistic tendencies. He was thoroughly familiar with the human situation in both east and west. In 1893 Vivekananda represented Hinduism at the World's Parliament of, Religions in Chicago, where he preached the oneness of existence, the divinity of the soul, the nonduality of the Godhead and the harmony of religions.

Vivekananda inaugurated the Vedanta movement in the U.S. and visited England and the continent. On Dec. 9, 1898, he formally dedicated the chapel of the Belur Math, a monastery on the Ganges near Calcutta, which he established as headquarters of the Ramakrishna order, whose twin aims are individual salvation and the giving of "food, education and spiritual wisdom." The monks took up residence at the monastery on Jan. 2, 1899. He asked Indians to cultivate faith in themselves and emphasized renunciation and service as national ideals. Swami Vivekananda's message influenced many of India's leaders in India's national awakening in the 20th century and it became an enduring force in bringing east and west closer together. He died on Jan. 4, 1902, at the age of 39.

VIVES, JUAN LUIS (1492–1540), Spanish humanist, eminent both in the field of educational theory and in psychology, was born in Valencia on March 6, 1492. After studies at Paris (1509–12) he was appointed professor of the humanities at Louvain (1519). Having dedicated his commentary of St. Augustine's *De Civitate Dei* (Basel, 1522) to Henry VIII of England, he went to England in 1523 and was appointed preceptor to Mary, princess of Wales. Taking up residence at Corpus Christi college, Oxford, he was made doctor of laws and gave lectures on philosophy. In 1527, however, he forfeited Henry's favour by opposing the royal divorce from Catherine of Aragon and was imprisoned for six weeks, after which he left England for the Netherlands, to devote himself prolifically to writing. He died at Bruges on May 6, 1540.

The works which brought Vives most fame in his own century were concerned with education. The two letters *De ratione studii puerilis* (the first addressed to Catherine of Aragon, the second to Charles Montjoye) were completed in England in 1523; the *Introductio ad sapientiam* (Eng. trans. by Richard Morison, *An Introduction to Wysedome*, London, 1540) and the *Satellitium sive Symbola* (dedicated to Princess Mary) were both dated from Bruges, where he had gone on a visit, in order to marry, in 1524. His *De institutione feminae Christianae* (Antwerp, 1524; Eng. trans. by Richard Hyrde, *The Instruction of a Christen Wonzan*, 1541) was also dedicated to Catherine of Aragon. His *De disciplinis libri xx* (Antwerp, 1531) contains the seven remarkable books "De causis corruptarum artium" ("On the Decay of Learning") and the five "De tradendis disciplinis" (Eng. trans. by Foster Watson, *On Education*, Cambridge, 1913). The *Exercitationes linguae latinae* (Breda, 1538; Eng. trans. by W. H. D. Rouse, *Scenes of School and College Life*, Oxford, 1931) are dialogues framed to interest schoolboys in Latin. All these works went through many editions.

Vives' claim to be regarded as a pioneer in psychology and in philosophical method rests on his *De anima et vita libri tres* (Basel, 1538), a work which to some extent anticipates that of the great thinkers of the century following his death by its emphasis on induction as a method of philosophical and psychological discovery. In book i Vives abjures the tradition of asking the metaphysical question "What is the soul?" by saying "What the soul is, is of no concern for us to know. What its manifestations are, is of great importance." Likewise in his discussion of the mind he does not refer to the mind's essence but concerns himself with its actions. His central idea is that knowledge is of value only when it is put to use. He then discusses association of ideas, the nature of memory, a proposed law of forgetfulness and the method of recall of an idea; explains the principle of mnemonics; and even touches on animal psychology. In book ii he describes the functions of the *simplex intelligentia* (simple apprehension); and in book iii he examines the emotions or passions.

BIBLIOGRAPHY.—Collected editions of Vives' works include those of Nicolaus Episcopius, 2 vol. (1555), of G. Majansius, 8 vol. (1782–90), and of J. B. Sentandreu (1930 *et seq.*). *See* also J. VIVIANI, RENÉ (1863–1925), French politician, was born at Sidi-bel-Abbès, Algeria, on Nov. 8, 1863. In 1893 he was elected Socialist deputy for Paris and it was not until the close of his life that he left the chamber to enter the senate. In Oct. 1906 he was placed by Clemenceau at the head of the recently created ministry of labour. Viviani was responsible for the law with regard to workmen's pensions. In July 1909 when Briand succeeded Clemenceau as premier, Viviani continued to be minister of labour. In Oct. 1910, in consequence of the attitude adopted by the government in regard to the threatened railway strike, he tendered his resignation. In Dec. 1913 he became minister of public instruction in the Gaston Doumergue cabinet.

In June 1914 Viviani became premier and minister for foreign affairs. He was on his way back from Russia with Poincaré when the Austrian ultimatum was issued against Serbia on July 23. He immediately withdrew the French troops ten kilometres behind the frontier to prove France's pacific attitude. On Oct. 29, 1915, he was succeeded as premier by Briand, in whose government he became minister of justice. After the fall of the Briand cabinet in March 1917 he lived in retirement, but he accompanied Briand to the Washington conference in 1921 as one of the leading French delegates. He died on Sept. 7, 1925. (P. B.)

VIVIANITE, a mineral consisting of hydrated iron phosphate. When unaltered and containing no ferric oxide, the mineral is colourless, but on exposure to the light it very soon becomes of a characteristic indigo-blue colour. Crystals were first found in Cornwall by J. G. Vivian, after whom the species was named in 1817. The mineral had, however, been known earlier as a blue powdery substance, called blue iron-earth, met with in peat bogs, in bog iron ore or with fossil bones and shells. The formula is $Fe_3(PO_4)_2.8H_2O$. It crystallizes in the monoclinic system and the crystals possess a perfect cleavage parallel to the plane of symmetry and are usually bladed in habit; they are very soft, flexible and sectile. Vivianite is prepared artificially by mixing solutions of ferrous sulfate and sodium phosphate.

VIVISECTION: *see* ANIMAL EXPERIMENTATION.

VIZAGAPATAM (correctly VISAKHAPATNAM), a city and district in Andhra Pradesh, India. The city stretches along the coast 380 mi. N.E. of Madras. Pop. (1951) 108,042. The city, or fort, as it is called, is separated from the southern promontory, the Dolphin's Nose, by a small river which forms a bar when it enters the sea. A harbour was opened in 1933. An English factory was established early in the 17th century; it was captured by the French in 1757, but shortly afterward was recovered.

Waltair at the north end of the bay is the seat of Andhra university. Exports include manganese ore, peanuts and sugar.

VISAKHAPATNAM DISTRICT, with an area of 5,200 sq.mi., has a population (1951) of 2,072,698. It is a picturesque and hilly country, but for the most part unhealthful. The main part is occupied by the Eastern Ghats, whose slopes are clothed with luxuriant vegetation and forest trees. The principal crops are rice, millets. pulses and oilseeds, with some sugar cane, cotton, spices and tobacco. Much manganese is mined, and a little limestone, marble and graphite worked.

On the dissolution of the Mogul empire, Visakhapatnam formed part of the territory known as the Northern Circars, which were ceded to the East India company by treaties in 1765 and 1766. The agency was incorporated with the agencies of Ganjam and Godavari into a new division. In 1950 the district was bifurcated, the northern part forming the district of Srikakulam. (S. GL.)

VIZEU or VISEU, a Portuguese episcopal city at the terminus of a branch of the Figueira da Foz-Guarda railway. Pop. (1950) 13.099. The city stands near the ruins of the ancient Vacca, or Cava de Viriato, a Roman military colony founded by Decius Brutus and captured by Viriathus (2nd century B.C.). The administrative district of Vizeu (pop. [1950] 487,182; area 1,937 sq.mi.) coincides with the central and northern parts of the ancient province of Beira (*q.v.*).

VLAARDINGEN, a river port of the Netherlands, in the province of South Holland, on the Maas, 6 mi. W. of Rotterdam by rail. Pop. (1957 est.) 62.188 (mun.). An old town and the seat of a former margraviate belonging to the counts of Holland, Vlaardingen is the centre of the great herring and cod fisheries of the North sea.

VLACHS. The Vlach (Wallach) or Ruman people constitute a distinct division of 'the Latin family of peoples, widely disseminated throughout southeastern Europe, both north and south of the Danube, and extending sporadically from the Bug to the Adriatic. The total number of the Vlachs has been estimated at from 9,000,000 to 11,000,000. Of these the vast majority resided in the former kingdom of Rumania, as enlarged by World War I. South of the Danube, a diminishing number scattered over northern Greece under the name of Kutzo ("lame")-Vlachs, Tzintzars or Aromani. In Serbia this element was preponderant in the Timok valley, and in Istri it was represented by the Cici, who were largely Slavonized, as were entirely the kindred Morlachs of Dalmatia. In Bulgaria Vlachs settled chiefly in the western Rhodopes.

For the physical characteristics of the Vlachs and their historical development. *see* BALKAN PENINSULA: *Ethnology;* RUMANIA. All divisions of the Vlachs. whether inhabitants of Rumania or not. prefer to style themselves *Romani, Romeni, Rumeni* or *Aromani.* The name "Vlach" (Slav *Volokh* or *Woloch*, Greek *Vlachoi*, Magyar *Olóh*, Turkish *Iflók*), which is now used by the Rumans themselves, represents a Slavonic adaptation of a generic term applied by the Teutonic races to all Roman provincials during the 4th and 5th centuries.

The Vlachs claim to be a Latin people in the same sense as the Spaniards or Provençals—Latin by language and culture, and, in a smaller degree. by descent. This claim is generally accepted by ethnologists. The language of the Vlachs is Latin in structure and to a great extent in vocabulary; their features and stature would not render them conspicuous as foreigners in south Italy; and that their ancestors were Roman provincials is attested not only by the names "Vlach" and "Ruman" but also by popular and literary tradition. In their customs and folklore both Latin and Slavonic traditions assert themselves. Of their Roman traditions the Trajan saga, the celebration of the Latin festivals of the Rosalia and Kalendae, the belief in the *striga* (witch), the names of the months and days of the week, may be taken as typical examples. Some Roman words connected with the Christian religion, like *biserica (basilica)* = a church, *botez* = *baptizo, duminica* = Sunday, *preat (presbyter)* = priest, point to a continuous tradition of the Illyrian church. though most of their ecclesiastical terms, like their liturgy and alphabet, were derived from the Slavonic. In most that concerns political organization the Slavonic element is also preponderant, though there are words, like *impărat* = *imperafor*, and *domn* = *dominus*, which point to the old stock. Many words relating to kinship are also Latin. some, like *vitrig (vitricus)* = father-in-law, being alone preserved by this branch of the Romance family.

The centre of gravity of the Vlach people is north of the Danube in the almost circular territory between the Danube, Theiss and Dniester; and corresponds roughly with the Roman province of Dacia, formed by Trajan in A.D. 106. From this circumstance the popular idea has arisen that the Vlachs represent the descendants of the Ronianized population of Trajan's Dacia, which was assumed to have maintained an unbroken existence in Walachia, Transylvania and the neighbouring provinces under the dominion of a succession of invaders. The Vlachs of Pindus, and the southern region generally, were regarded as later immigrants from the lands north of the Danube. In 1871, E. R. Roesler published at Leipzig his *Romanische Studien,* in which he absolutely denied the claim of the Rumanian Vlachs to be regarded as autochthonous Dacians. He laid stress on the statements of Vopiscus and others as implying the total withdrawal of the Roman provincials from Trajan's Dacia by Aurelian, in A.D. 272, and on the nonmention by historians of a Latin population in the lands on the left bank of the lower Danube during their successive occupation by Goths, Huns, Gepidae, Avars, Slavs. Bulgars and other barbarian races. He found the first trace of a Ruman settlement north of the Danube in a Transylvanian diploma of 1222. His conclusions had to a great extent been already anticipated by F. J. Sulzer in his *Geschichte des Transalpinischen Daciens,* published at Vienna in 1781, and at a still earlier date by the Dalmation historian Lucius of Traü in his work *De Regno Dalmatine et Crontiae* (Amsterdam, 1666). They found a determined opponent in J. Jung of Innsbruck, who upheld the continuity of the Roman provincial stock in Trajan's Dacia! disputing from historic analogies the total withdrawal of the provincials by Aurelian; and the reaction against Roesler was carried still further by J. L. Pič, A. D. Xenopol of Jassy, B. P. Hasdeu, D. Onciul and many other Rumanian writers, who maintained that. while their own people north of the Danube represented the original Daco-Roman population of this region, the Vlachs of Greece were similarly descended from the Moeso-Roman and Illyro-Roman inhabitants of the provinces lying south of the river. On this theory the Vlachs occupied almost precisely the same territories in modern times as in the 3rd century. On the whole it may be said that the truth lies between the two extremes. Roesler is no doubt so far right that after 272, and throughout the early middle ages, the bulk of the Ruman people lay south of the Danube.

The earliest Hungarian historians who describe the Magyar invasion of the 9th century speak of the old inhabitants of the country as Romans, and of the country they occupied as *Pascua Romanorum;* and the Russian Nestor, writing about 1100, makes the same invaders fight against Slavs and Vlachs in the Carpathians. So far from the first mention of the Vlachs north of the Danube occurring only in 1222, it appears from a passage of Nicetas of Chonae that they were to be found already in 1164 as far afield as the borders of Galicia; and a passage in the *Nibelungenlied,* which mentions the Vlachs, under their leader Râmunc, in association with the Poles, cannot well be later than 1200.

Nevertheless, through the early middle ages the bulk of the Ruman population lay south of the Danube. It is there that this new Illyrian Romance people first rises to historic prominence. Already in the 6th century. as is shown from the place names such as Sceptecasas, Burgualtu, etc., given by Procopius, the Ruman language was assuming, so far as its Latin elements were concerned, its typical form. In the later campaigns of Commentiolus (587) and Priscus against the Avars and Slavs, the Latin-speaking soldiery of the eastern emperor made use of such Romance expressions as *torna frate!* ("turn, brother!"), or *sculca* ("out of bed") applied to a watch (*cf.* Ruman *a se culca* = Italian *coricarsi* + *ex-[s-]* privative). Next we find this warlike Ruman population largely incorporated in the Bulgarian kingdom, and. if we are to judge from the names Paganus and Sabinus, already supplying it with rulers in the 8th century. The blending and close contact during this period of the surviving Latin population with the

Slavonic settlers of the peninsula impregnated the language with its large Slavonic ingredient. The presence of an important Latin element in Albanian, the frequent occurrence of Albanian words in Rumanian and the remarkable retention by both languages of a suffix article may perhaps imply that both alike took their characteristic shapes in the same region. The fact that these peculiarities are common to the Rumans north of the Danube, whose language differs dialectically from that of their southern brothers, shows that it was this southern branch that throughout the early periods of Ruman history was exercising a dominating influence. Migrations. violent transplantation. the intercourse which was kept up between the most outlying members of the race, at a later period actual colonization and the political influence of the Bulgaro-Vlachian empire! no doubt contributed to propagate these southern linguistic acquisitions throughout that northern area to which the Ruman people was destined almost imperceptibly to shift its centre of gravity.

Byzantium, which had ceased to be Roman and had become Romanic. renewed its acquaintance with the descendants of the Latin provincials of Illyricum through a Slavonic medium, and applied to them the name of Vlach. which the Slav himself had borrowed from the Goth. The first mention of Vlachs in a Byzantine source is about the year 976, when Cedrenus (ii. 439) relates the murder of the Bulgarian tsar Samuel's brother "by certain Vlach wayfarers." at a spot called the Fair Oaks, between Castoria and Prespa. From this period onward the Ruman inhabitants of the Balkan peninsula are constantly mentioned by this name, and there are a series of political organizations and territorial divisions connected with the name of *Vlachia.* A short synopsis may be given of the most important of these, outside the limits of Rumania itself.

Political and Territorial Divisions.—I. The *Bulgaro-Vlach Empire.*—After the overthrow of the older Bulgarian tsardom by Basil "the Bulgar-slayer" (976–102j), the Vlach population of Thrace, Haemus and the Moesian lands passed once more under Byzantine dominion; and in 1185 a heavy tax, levied in kind on the cattle of these warlike mountain shepherds, stirred the Vlachs to revolt against the emperor Isaac Angelus. and under the leadership of two brothers. Peter and Asen, to found a new Bulgaro-Vlachian empire. which ended with Kaliman II in 125;. The dominions of these half-Slavonic, half-Ruman emperors extended north of the Danube over a great deal of what is now Rumania, and it was during this period that the Vlach population north of the river seems to have been most largely reinforced. The 13th-century French traveler Rubruquis speaks of all the country between the Don and Danube as *Asen's* land or *Blakia.*

2. Great *Walachia.*—It is from Anna Comnena, in the second half of the 11th century, that we first hear of a Vlach settlement, the nucleus of which was the mountainous region of Thessaly. Benjamin of Tudela, in the succeeding century, gives an interesting account of this Great Walachia, then completely independent. It embraced the southern and central ranges of Pindus, and extended over part of Macedonia. thus including the region in which the Roman settlers mentioned in the *Acts* of St. Demetrius had fixed their abode. After the Latin conquest of Constantinople in 1204, Great Walachia was included in the enlarged despotat of Epirus. but after passing under the yoke of the Serb emperor Dushan and other Serbian rulers in the 14th century, was finally conquered by the Turks in 1393. Many of their old privileges were accorded to the inhabitants. and their taxes were limited to an annual tribute. Since this period the Megalovlachites have been largely Hellenized, but they are still represented by the flourishing Tzintzar settlements of Pindus and its neighbourhood.

3. Liftle *Walachia* was a name applied by Byzantine writers to the Ruman settlements of Aetolia and Acarnania, and with it may be included "Upper Walachia." Its inhabitants are represented by the Tzintzars of the Aspropotamo and the Karaguni (Black Capes) of Acarnania.

4. The *Morlachs* (*Mavrovlachi*) of the *West.*—These are already mentioned as *Nigri Latini* by the presbyter of Dioclea (c. 1150) in the old Dalmatian littoral and the mountains of Montenegro, Herzegovina and North Albania. Other colonies extended through part of the old Serbian interior, where there is a region called Stara Vlaška or "Old Walachia." The great commercial staple of the east Adriatic shores. the republic of Ragusa. seems in its origin to have been a Ruman settlement. and many Vlach traces survived in its later dialect. Philippus de Diversis, u·ho described the city as it existed in 1440, says that "the various officers of the republic do not make use either of Slav or Italian. with which they converse with strangers, but a certain other dialect only partially intelligible to,us Latins," and cites words with strong Ruman affinities. In the mountains above Ragusa a number of Vlach tribes are mentioned in the archives of that city. and the original relationship of the Ragusans and the nomadic Alpine representatives of the Roman provincials, who preserved a traditional knowledge of the old lines of communication throughout the peninsula, explains the extraordinary development of the Ragusan commerce. In the 14th century the Mavrovlachi or Morlachs extended themselves toward the Croatian borders, and a large part of maritime Croatia and northern Dalmatia began to be known as *Morlacchia.* A Major *Vlachia* was formed about the triple frontier of Bosnia, Croatia and Dalmatia, and a "Little Walachia" as far north as Požega. The Morlachs were Slavonized.

5. Cici of *Istria.*—The extreme Ruman offshoot to the north-west is represented by the Cici of the Val d'Arsa and adjoining Istrian districts. They represent a 15th-century Morlach colony from the isle of Veglia, and had formerly a wider extension to Trieste and the counties of Gradisca and Görz. The Cici almost entirely abandoned their native tongue, which is the last remaining representative of the old Morlach, and forms a connecting link between the Daco-Roman (or Rumanian) and the Illyro- or Macedo-Roman dialects.

6. Rumans *of Transylvania and* Hungary.—As already stated, a large part of the Hungarian plains were, at the coming of the Magyars in the 9th century, known as *Pascua Romanorum.* At a later period privileged Ruman communities existed at Fogaras, where was a *Silva Vlachorum,* at Marmaros, Deva, Hatzeg, Hunyad and Lugos, and in the Banat were seven Ruman districts. Two of the greatest figures in Hungarian history, the 15th-century rulers John Corvinus of Hunyad and his son King Matthias. were due to this element. For its later history see TRANSYLVANIA.

VLADIKAVKAZ, Russian S.F.S.R.: see ORJONIKIDZE.

VLADIMIR, ST. (c. 956–101j). grand duke of Kiev and of all Russia, was the youngest son of Svyatoslav I and his mistress Malushka. In 970 he received Great Novgorod as his appanage. On the death of Svyatoslav in 972, a long civil war took place between his sons Yaropolk and Oleg, in which Vladimir was involved. From 977 to 984 he was in Scandinavia, collecting as many of the viking warriors as he could to assist him to recover Novgorod, and on his return marched against Yaropolk. On his way to Kiev he sent ambassadors to Ragvald, prince of Polotsk, to sue for the hand of his daughter Ragnilda. The haughty princess refused to affiance herself to "the son of a bondswoman," but Vladimir attacked Polotsk. slew Ragvald and took Ragnilda by force. Subsequently (980) he captured Kiev also; slew Yaropolk by treachery, and was proclaimed prince of all Russia. In 981 he conquered the Chervensk cities, the modern Galicia; in 983 he subdued the heathen Yatvyags, whose territories lay between Lithuania and Poland; in 98j he led a fleet along the central rivers of Russia to conquer the Bulgars of the Kama, planting numerous fortresses and colonies on his way. At this time Vladimir was a thoroughgoing pagan. He increased the number of the *trebishcha,* or heathen temples; offered up Christians (Theodore and Ivan, the protomartyrs of the Russian church) on his altars; had 800 concubines, besides numerous wives; and spent his whole leisure in feasting and hunting. He also formed a great council out of his boyars, and set his 12 sons over his subject principalities.

In the year 987, as the result of a consultation with his boyars, Vladimir sent envoys to study the religions of the various neighbouring nations whose representatives had been urging him to embrace their respective faiths. The result is amusingly described by the chronicler Nestor. Of the Moslem Bulgarians of the Volga the envoys reported "there is no gladness among them; only sorrow and a great stench; their religion is not a good one." In the temples of the Germans they saw "no beauty"; but at Constantinople. where the full festival ritual of the Orthodox Church was set in motion to impress them. they found their ideal. "We no longer knew whether we were in heaven or on earth, nor such beauty, and we know not how to tell of it." If Vladimir was impressed by this account of his envoys, he was yet more so by the offer of the emperor Basil II to give him his sister Anna in marriage. In 988 he was baptized at Kherson in the Crimea, taking the Christian name of Basil out of compliment to his imperial brother-in-lam; the sacrament was followed by his marriage with the Roman princess. Returning to Kiey in triumph, he converted his people to the new faith with no apparent difficulty. Crypto-Christians had been numerous in Kiev for some time before the public recognition of the Orthodox faith. The remainder of the reign of Vladimir was devoted to good works. He founded numerous churches, including the splendid *Dẹsyatinnuy Sobor* or "Cathedral of the Tithes" (989), established schools, protected the poor and introduced ecclesiastical courts.

With his neighbours he lived at peace, the incursions of the savage Petchenegs alone disturbing his tranquillity. His nephew Svyatpolk, son of his brother and victim Yaropolk, he married to the daughter of Boleslaus of Poland. He died at Berestova, near Kiev. while on his way to chastise the insolence of his son. Prince Yaroslav of Novgorod. The various parts of his dismembered body were distributed among his numerous sacred foundations and were venerated as relics. The Lniversity of Kiev has rightly been named after the man who both civilized and Christianized ancient Russia. His memory was also kept alive by innumerable folk ballads and legends. With him the Varangian period of Russian history ceases and the Christian period begins.

VLADIMIR, a city and capital of Vladimir *oblast* (formed out of Ivanovo *oblast* in 1944), Russian Soviet Federated Socialist Republic. was known in history as Vladimir-on-the-Klyazma to distinguish it from Vladimir in Volhynia. It is picturesquely situated on the Klyazma and Lybed, in 56° 8' N., 40° 20' E. Pop. (1959) 154,000.

The town is a trading centre on the railway and river between Moscow and Gorki. Factories for knitted goods, fruit juice and bricks were established and oil-pressing and sawmilling industries were developed there. Other industries include the manufacture of plastic products, precision instruments and tractors. Extensive cherry orchards occupy the surrounding slopes; the custom arose of building in each orchard a small watchtower, with cords drawn in all directions to be shaken by the watcher when birds alight.

The citadel stands on a hill and contains two very old cathedrals —the Lspenskiy (restored in 1891). where all the princes of Vladimir were buried, and the Dmitrievskiy (1197; restored in 1834–35). Several churches date from the 12th century.

Vladimir first comes into notice in 1151, when Andrei Bogolyubskiy secretly left Vyshgorod—the domain of his father in the principality of Kiev—and migrated to the newly settled land of Suzdal, where he became (1157) grand prince of the principalities of Vladimir, Suzdal and Rostov. Although Ivan Kalita (1328–41) made Moscow the real head of the *Rus* states, Vladimir remained the coronation city of the grand princes until 1431, and Simeon the Proud. Ivan the Good, Dmitri of the Don and Vasili I were crowned there.

VLADIMIR, a former province of the Russian S.F.S.R., was divided among the Moscow, Yaroslavl, Ivanovo, Gorki and Ryazan regions. It did not coincide with the pre-1917 province of the same name.

VLADIMIRESCU, TUDOR (? –1821), Rumanian popular leader, was a native of Oltenia, of peasant origin but educated among the lesser nobility. He took part in the Serb uprising of 1804. In the Russo-Turkish wars of 1806–12 he led a body of irregular Rumanian troops known as *panduri*, was made a lieutenant in the Russian army and decorated. Having joined the Philiké Hetairia, the Greek revolutionary movement led by Alexander Ypsilanti (q v.), he organized a revolt in Wallachia at the beginning of 1821 to coincide with the Greek rising planned in Moldavia. Vladimirescu brought out his *panduri* even before Ypsilanti had crossed the Prut (Feb. 20, 1821), but the two risings, neither of which received Russian support, soon took on a different character. Vladimirescu's insurrection was at first mainly social, the peasants flocking to his standard against the boyars and indulging in wholesale pillage. but on reaching Bucharest in March he recognized the provisional government and joined forces with the more enlightened boyars to proclaim a Rumanian national crusade, thereupon curbing the excesses of his men. While Ypsilanti aimed at throwing off the Turkish yoke. Vladimirescu was willing to come to an accommodation with the Turks if they would throw out the Phanariotes and set up a national Rumanian government. Ypsilanti, entering Bucharest ten days after Vladimirescu, treated him as a traitor and had him assassinated.

(B. BR.)

VLADIMIR VOLHYNSKIY: *see* WLODZIMIERZ-WOLYNSKI, a town in the province of Volhynia, Poland.

VLADIVOSTOK, a port of Asiatic C.S.S.R.. capital of Primorski *oblast*, Russian Soviet Federated Socialist Republic, in 43° 11′ N., 131" 53' E. It stretches along the northern shore of the Golden Horn, on the slope of a ridge of hills extending westward to Amur bay It is an important city in the far eastern area; its easily accessible harbour, 4 mi. by 1 mi., kept open all the winter by icebreakers, made it the most important naval and commercial centre on the Russian Pacific coast. Pop. (1959) 283,000. A long stone mole for berthing and unloading ships was built at the port, where there are cargo-storage facilities and engineering and repairing yards for ships.

Major exports include timber and lumber. fish, vegetable oils, coal and grain. Industries in Vladivostok the chief base of Soviet whaling flotillas, fishing and crabbing, include fish and food canning and related industries. Airplanes and ships are also built there.

A hydrobiological station was established at Basargin peninsula in 1925. The city became the seat of various research and educational institutions, such as the Pacific Institute of Fisheries and Oceanography and a polytechnic institute.

Muraviev selected the site after the treaty of Aigun (1858) by which the district was ceded to Russia. In July 1860 the first settlers arrived there; the name Vladivostok means "dominator" or "ruler of the east." and the Russians gave concrete evidence of their intention to fulfill that promise when, 12 years later, they established, to the annoyance of Japan, their far eastern naval base there. It also became a major air base and during World Wars I and II was important as a supply port. A railway via Manchuria and the Trans-Baikal district reached the town in 1897, though the final link with the Trans-Siberian was not completed ill 1917. Radio stations and cable connection to Japan were established.

VLAMINCK, MAURICE DE (1876–1958), French painter and writer in the Fauve group, was born in Paris on April 4, 1876. He lived in and near country places most of his life, however, a fact which may account for his rugged and picturesque personality as well as his flair for nature. He became a musician, actor and cyclist as well as painter. His interest in art dates from 1895, with lessons in drawing and study of the Impressionists who were then being shown. During 1899–1900 he gave music lessons for a living and performed as an actor. At the same time he met André Derain, nith whom he shared studio quarters on the island of Chatou. The following year, in company with Derain. he was impressed by the Van Gogh exhibition at Bernheim's Paris gallery; he also met Henri Matisse that year and began to exhibit at the Salon des Indépendants. His first novel. *Grains au vent*, dates from this period (illustrations by Derain); two others were to come later. In 1905, in the famous "Bateau Lavoir" artist group, he met Pablo Picasso and Kees van Dongen. The same year (crucial for the beginning of the Fauve movement) Vlaminck joined with Matisse, Albert Marquet, Derain. Henri Manguin, Georges Kouault, van Dongen, etc., in their group showing at the annual Salon d'Automne, where the term "Fauve" or "wild beast" was first applied to their dynamic, vibrating canvas surfaces with their large bold areas of intense colour applied in a spontaneous, even violent manner. By 1908 Vlaminck gave up this type of painting in favour of the subdued melancholy of the Romantic landscapes.

Vlaminck died Oct. 11. 1958, near Paris.

VLONE (Tosk dialect VLORË; Gheg VLONË; internationally known as VALONA), a seaport of Albania) lies at the northeast end of a gulf which is largely protected by mountains and by the island of Sazan (Saseno), the ancient Saso, and which provides sheltered anchorage under the lee of the Karaburun spit (2,700 ft.). Pop. (1955) 28,212. part Moslem. part Greek Orthodox, with a few Roman Catholics. The port itself is somewhat exposed and lacks breakwaters. Since World War II it has been improved and a new quay constructed. The pleasant, shady town, about 1½ mi. inland, is surrounded by hilly olive groves. The most important export from Vlone, crude oil from the Kucove and Patos oil fields, which were linked by pipeline to the loading point south of the port, was affected by the opening in 1957 of the oil refinery at Cerrik, near Elbasan. The export of natural bitumen from Selenice is also handled by the port. There are a fishing industry and a fish cannery. and olive oil and alcohol factories. Industries set up after World R'ar II included cement making and rice husking. A macadamizedroad links the port with Durres and Tirane.

Vlone (the ancient Avlon or Avlona) played an important part in Greek and Roman times and in the 11th- and 12th-century wars between Normans and Byzantines, and later changed hands between Venetians: Serbs and Turks. On Nov. 28, 1912. Ismail Bey Vlora proclaimed here the independence of Albania. In 1914 the Italians occupied Sazan and later Vlone itself. which they held until 1920, when they withdrew, retaining Sazan, the key to the Otranto strait. Vlone passed again to the Italians when they occupied Albania in April 1939, but, with the rest of the country. Vlone and Sazan reverted to the Albanians with the departure of the German forces in 1944. The historic ruined fortress of Kanine stands on a hill about 2½ mi. S. of the town. (D. R. O.-H.)

VOCATIONAL EDUCATION, or trade or industrial training, is the term applied to instruction that is intended to fit persons for specific industrial or commercial occupations. It may be secured in various ways: (1) learning on the job by the "pickup" method without educational supervision; (2) learning in shop-training departments or vestibule schools maintained by employers; (3) learning as indentured apprentices; (4) learning in trade, technical secondary, continuation or night schools; and (5) learning in shops and schools according to some co-operative arrangement between industrial establishments and the schools.

Vocational education in schools is a relatively modern development. Until the 19th century vocational education, except for the professions, was provided only by apprenticeship. In ancient Greece such instruction was regarded as unworthy of those who would become freemen, and a sharp distinction was drawn between vocational and liberal education. This distinction was perpetuated in the educational practice of western Europe; vocational education continued to be associated with low social status! while schools with classical curriculums were regarded as providing the education "necessary for a gentleman." The growth of industrialization stimulated a new attitude. however, and during the 19th century several leading European nations, notably Germany, began to recognize the importance of vocational instruction in the elementary and secondary schools. (X.)

United States.—Vocational education in the schools of the U.S received its first great stimulation in 1906, when the National Society for the Promotion of Industrial Education was organized for the purpose of extending vocational education throughout the U.S. It was active in securing passage of the Smith-Hughes act on Feb. 23, 1917. This act provided federal aid for public schools offering approved trade and industrial, agricultural and home-making courses of less than college grade to pupils 14 years of age and older. It also made provision for teacher training, civilian rehabilitation and vocational research. Subsequent acts—George-Reed (1929). George-Ellzey (1934). George-Deen (1936), George-Barden (1946)—and other special legislation increased federal appropriations to $28,500.000 annually and extended benefits to Alaska, Hawaii, Puerto Rico and the Virgin Islands.

Federal aids are administered by the U S. office of education through state boards designated by slate legislatures to prepare and develop vocational education programs that meet federal approval. Trade training is offered both through state schools, as in Massachusetts and New Jersey, and in local special vocational schools, vocational high schools or trade and technical schools. In Wisconsin the vocational and adult education program is administered by a state board of vocational and adult education through local boards of vocational and adult education in cities of 5,000 or more.

In industrial centres throughout the country trade apprenticeship is well established. Apprentices receive their practical instruction on their jobs and their related training in apprentice or vocational schools. The bureau of apprenticeship of the U.S. department of labor has developed indentured apprenticeship in co-operation with the states. In the second half of the 20th century there were more than 155.000 apprentices in the U.S and its possessions. The ten leading industrial states together had more than 95,000 of these apprentices.

Compulsory education laws and technological progress have raised the age and general school attainment of young people beginning employment. Industrial needs, too. changed and required an increasing number of technicians. Technical institutes were established to train them. In California, tno-year courses for technicians are offered as terminal courses in the local junior colleges to fill this need. Also, there was an increase in attendance at evening vocational schools on the part of older workers wishing to keep up with the changes occurring in their occupations. (W. F. R)

Great Britain.—In Great Britain the traditional prejudice against vocational training persisted longer than in most other European countries It influenced the opinion not only of adherents of liberal education but also of the workers, who feared that it might be used as a convenient method of recruiting cheap labour. Although in 1895 an important royal commission on secondary education, presided over by Lord Bryce. pleaded strongly for a more sympathetic approach to the education of craftsmen, the new grammar schools. established under the Education act of 1902. adhered to the liberal curriculum. A number of trade and junior technical schools mere established, honever, by local authorities and in 1938 a report of the Consultative Committee on Secondary Education (known as the Spens report) was able to point to the success of these ventures and reaffirm strongly the advocacy of secondary technical education contained in the Bryce report.

When the Spens report was first published the Trades Union congress urged that any move toward specialized training of a vocational character "should be made with great caution and without prejudice to the general education of the child." The success of ministry oi labour training schemes during World War II helped to allay the suspicion of vocational teaching after the age of 15, and there was a much wider recognition of its value to industry and commerce.

The Education act of 1944 made provision for county colleges which all young people who had left school were to attend for a day a week or its equivalent; and it was contemplated that the curriculum would include vocational training. Postwar economic conditions delayed the implementation of this important feature of the act; but in the second half of the 20th century, in addition to nearly 300 secondary technical schools that had become well established, there had been a notable increase of part-time technical education, helped by the increasing readiness of firms to release young workers for a day or half day each week for such training. As against the 40,000 thus released before World War

II, there were more than ten times as many young workers receiving part-time education in this way. Public opinion about vocational training at an appropriate age had changed considerably, and there was a growing acknowledgment of the truth of A. N. Whitehead's dictum that "the antithesis between a technical and a liberal education is fallacious." *See* TECHNICAL EDUCATION; APPRENTICESHIP; ADULT EDUCATION.

VOCATIONAL REHABILITATION: *see* REHABILITATION, MEDICAL AND VOCATIONAL.

VODENA, meaning "city of waters" (Slav. *voda,* "water"), was the medieval name for the town of Edessa (originally ancient Aegae) in Greek Macedonia. *See* EDESSA. (D. M. N.)

VODKA (WODKA), the national distilled alcoholic beverage of Russia and Poland (in Polish the "*w*" has the "*v*" sound). The word means "little water," a diminutive, endearing term. Vodka was first produced in Russia in the 14th century. The spirits from which it was made were obtained from the agricultural product that was most abundant, and cheapest, locally. Wheat, rye, maize, potatoes, sugar beets or a combination of several of these were and still are employed.

In Russia and Poland the producers of vodka, instead of carrying out distilling operations, eventually came to buy highly rectified distilled spirits, which they further rectified by filtration through beds of vegetable charcoal. The purified spirit was next reduced, without being aged, to potable strength with distilled water and then was bottled. This is the traditional method followed today in Russia, Poland and elsewhere. The resultant product is colourless and without any specific flavour or taste. Potable strength in Russia has generally been 80 proof (40% alcohol by volume), although in Poland it is 90 proof (45% alcohol by volume). In both countries, small quantities are bottled at higher proofs. Before World War II, the consumption of vodka was confined almost entirely to Russia, Poland and the Baltic states. After World War II, however, the production and use of vodka increased enormously in other countries, particularly in the United States.

Each producing country or region has developed techniques for processing vodka from the raw materials most easily obtainable locally. In the United States and the United Kingdom great advances have been made in distillation from cereal grains, while in Russia and Poland techniques have been developed in distilling spirits from potatoes. Thus in Russia and Poland potato spirit vodkas are preferred, while in the United States vodka is produced almost entirely from grain spirits. United States federal regulations define vodka as "neutral spirits distilled from any material at or above 190 proof, reduced to not more than 110 proof and not less than 80 proof and after such reduction in proof, so treated . . . (with vegetable charcoal for at least 8 hours) . . . as to be without distinctive character, aroma or taste."

In Poland a product called zubrowka is made by steeping zubrowka grass in vodka. This gives the beverage a light yellowish tinge, an aromatic bouquet and a slightly bitter undertone.

The traditional Russian and Polish method of drinking vodka is neat (*i.e.,* straight) in glasses of about one ounce capacity and ice cold. In other countries, especially the United States, vodka is consumed in mixed drinks of all kinds. Some of the most popular are the screwdriver, a glass of orange juice with a jigger of vodka mixed in; the bloody mary, a glass of tomato juice with vodka; the Moscow mule, ginger beer with vodka added; vodka with tonic; and vodka martini.

See also ALCOHOLIC BEVERAGES, DISTILLED: *Classification of Potable Spirits.* (H. J. GN.)

VOGEL, SIR JULIUS (1835–1899), British colonial statesman, son of Albert Leopold Vogel, was born in London on Feb. 24, 1835, was educated at University College school, London, and emigrated to Victoria during the exciting years which followed the discovery of gold fields there. He became editor of a newspaper at Maryborough, stood for the legislative assembly and was defeated and in 1861 left Victoria, carried in the mining rush to Otago, N.Z., where much gold had just been found. Settling in Dunedin, he bought a half-share in the *Otago Daily Times* and was soon its editor and a member of the Otago provincial council.

He made his paper the most influential in the colony, and was returned to the house of representatives. In 1866 he was head of the Otago provincial executive; by 1869 he had made his mark in the New Zealand parliament and was treasurer in the ministry of Sir William Fox. He brought forward schemes for the construction of trunk railways and other public works. the purchase of land from the Maori tribes and the introduction of immigrants, all to be done with money borrowed in London. For the next six years he was the most powerful man in the colony. In 1875 he was knighted.

In 1874 Vogel. until that time a supporter of the Provincial system, decided to abolish it. In this, with the aid of Sir E. W. Stafford and Sir H. A. Atkinson, he succeeded. In the struggle, however, he broke with many of his old allies, and in 1876 suddenly left New Zealand to take the post of agent-general in London.

The last years of his life were spent in England. He died there, at East Molesey, on March 13, 1899.

VOGELSANG, KARL, FREIHERR VON (1818–1890), Roman Catholic German social reformer, was born at Liegnitz on Sept. 3, 1818. After studying law at Bonn, Rostock and Berlin, he entered the Prussian government service, but after the revolution of 1848 retired to his ancestral estate in Mecklenburg. Becoming a Catholic in 1850, he moved first to Cologne and later to Vienna, contributing to German and Austrian periodicals and newspapers.

Vogelsang's basic views were derived from a mixture of scholasticism and romanticism, the latter as interpreted by Adam Miiller. Condemning capitalism in terms similar to those of socialist writers, he advocated its replacement by a Christian order of society, culminating in a corporative system with self-government of the various socio-economic groups. Interest rates were to be abolished as much as possible. Farmers and artisans were to be organized in co-operatives with legal powers over their members; industrial organization was to follow similar lines, with the workers sharing in the profits. These views bear some similarity to those of the guild socialists. Some of his views were too deeply influenced by the romantic school to be realistic. His numerous articles, however, while more popular than scholarly, exerted great influence, and helped shape the ideas and actions of the Austrian Christian Social party as founded by Karl Lueger. Vogelsang died in Vienna on Nov. 8, 1890.

Vogelsang's more significant writings were edited by Wiard Klopp in *Die sozialen Lehren des Freiherrn von Vogelsang* (1894) and *Leben und Wirken des Sozialpolitikers Freiherr von Vogelsang* (1930). (F. A. Hs.)

VOGLER, GEORG JOSEPH (1749–1814), usually known as Abbé or Abt (Abbot) Vogler, German organist and music theorist, immortalized by Robert Browning's poem, was born in Würzburg on June 15, 1749, and was educated at the Jesuit college there. His father was a violinmaker and he learned to play the violin, organ and other instruments before he was ten, developing for himself an original system of fingering. In 1771 he went to Mannheim, where he composed a ballet for the elector, who sent him to study music in Italy, first at Bologna under Padre Martini (with whom he violently disagreed) and then in Padua with Francesco Vallotti. In 1773 he was ordained priest in Rome, becoming chaplain to the pope, knight of the Golden Spur and member of the academy of Arcadians. Returning to Mannheim in 1775, he was made court chaplain and second *Kapellmeister,* and started his first *Tonschule,* where he taught his own system of harmony, founded on the acoustical theories of Vallotti. In 1780 he followed the electoral court to Munich, where he became chief *Kapellmeister* in 1784, and during 1786–99 he held the post of court conductor in Stockholm, where he opened another school.

During these years, however, his chief work was the development of a simplified organ, based on Giuseppe Tartini's theory of harmonics, which he called the orchestrion. He traveled widely, giving lectures and demonstrations on it, and undertaking commissions to simplify existing organs by introducing free reeds and rearranging the pipes. He made a great reputation with pieces such as J. H. Knecht's "A Pastoral Festival Interrupted by a Storm." In 1807 he settled in Darmstadt at the invitation of the grand duke and opened his most successful school, where C. M. von Weber and G. Meyerbeer were among his pupils. His best works were his Symphony in C and the Requiem Mass, which he finished just before he died at Darmstadt on May 6, 1814; he also wrote several books on harmonics.

VOGT, JOHAN HERMAN LIE (1858–1932), Norwegian geologist and petrologist who pioneered the application of physical chemistry to the study of the origin of igneous rocks and ore deposits, was born at Tvedestrand on Oct. 14, 1858, the son of a physician; his mother was a sister of Marius Sophus Lie (*q.v.*), the celebrated mathematician. He was educated at the University of Christiania (Oslo), taking the diploma of mining engineer in 1880. In 1886 he was appointed professor of metallurgy at Christiania but moved to Trondhjem in 1912 to the chair of mineralogy and geology in the technical high school. He retired from this post in 1928.

His first important work, Studier ***over*** Slugger, appeared in 1884. In this he examined the crystallization phenomena of furnace slags and drew attention to the close resemblance in mineral constitution and texture these artificial products bore to some igneous rocks. His principal work on slags, Die *Silikatschmelzlösungen*, appeared in 1903–04. These studies served as a starting point in his endeavour to work out on broad lines the application of the known laws of solutions to the crystallization of igneous rock magmas, and his pioneer work did much to stimulate experimental research on quantitative lines which has followed. He died in Trondhjem on Jan. 3, 1932. (C. E. T.)

VOGTLAND or VOIGTLAND, a district of Germany, forming the southwest corner of the pre-World War II Land of Saxony and also embracing parts of Thuringia, was bounded on the north by the former principalities of Reuss, on the southeast by Bohemia, and on the southwest and west by Bavaria. Its character is generally mountainous, and geologically it belongs to the Erzgebirge range. It is extremely rich in mineral ores—silver, copper, lead and bismuth. The name denoted the country governed for the emperor by a *Vogt* (bailiff or steward).

VOGÜÉ, EUGENE MELCHIOR, COMTE DE (1848–1910). French author, was born at Nice on Feb 25. 1848. He served in the campaign of 1870, and on the conclusion of the war entered the diplomatic service, being appointed successively attaché to the legations at Constantinople and Cairo and secretary at St. Petersburg (Leningrad). He was almost the first to draw French attention to Dostoievski and his successors. He became a member of the French Academy in 1888. He died in Paris on March 24. 1910.

His works include: *Histoires orientalas* (1879) ; *Portraits du siècle* (1883) ; *Le Fils de Pierre le Grand* (1884) ; *Histoires d'hiver* (1885) ; *Le Roman russe* (1886) ; *Regards historiques et littéraires* (1892) ; *Coeurs russes* (1894) ; *Devant le siècle* (1896) ; *Jean d'Agrève* (1898) ; *Le Rappel des ombres* (1900) ; *Le Maître de la mer* (1903) ; *Maxime Gorky* (1905).

VOGUL (MANSI) are an ethnic minority people living in the northern Ural mountains. According to the Soviet census of 1959, they numbered about 6.000.

The language of the Vogul, and that of their eastern relatives. the Ostyaks (*q.v.;* Khanty), belongs, with Hungarian, to the Ugric group of the Finno-Ugric language family; Vogul and Ostyak are together referred to as Ob-Ugric (see FINNO-UGRIC LANGUAGES).

The Vogul are spread out over an enormous territory: the Khanty-Mansi national district—constructed into a subordinate unit of the Russian Soviet Federated Socialist Republic during World War II out of part of the Omsk region—occupies about 294,000 sq.mi. (The Ostyak-Vogul national district was established in 1930.) The capital is Khanty-Mansiysk, a town situated at the confluence of the Ob and Irtysh rivers.

Since the rivers of this region constitute the principal arteries for surface traffic and are also of dominant importance in Vogul subsistence (fishing), the four principal dialects are identified by the names of the rivers adjacent to which each group is spoken: Northern Vogul by the Sosva; Eastern Vogul by the Konda; Southern Vogul in a small enclave by the lower Tavda; and Western Vogul along three small tributaries of the upper Tavda—the Pelym, Vagil' and Lozva. These dialects differ rather substantially in terms of phonology, morphology and lexical stock, so that mutual intelligibility between, *e.g.,* a Sosva Vogul and a Tavda Vogul is just barely possible.

The Vogul were first mentioned by that name in Russian sources at the end of the 14th century. Throughout their history they were variously exposed to the cultural and political impact of several of their linguistic relatives (the Uralic Samoyeds and Syryenians), Turkic peoples (including the Tatars, who had a profound impact) and the Russians. Their contacts with the latter are millenary, although they have been formally subjected for about 400 years.

The majority of the people fish and hunt, but the Southern Vogul practise animal husbandry and the nomadic Northern Vogul keep reindeer. Vogul dwellings vary according to season from simple tents to more solid winter huts. For transportation they use boats and, in the winter, snowshoes or sleds. Since the middle of the 18th century, the Vogul increasingly became members of the Orthodox Eastern Church.

At the beginning of the 1930s collectivization began in the remote regions inhabited by the Vogul, and efforts were intensified to develop a literature. Although religious tracts were published before 1917 in the Konda dialect, the newly created literary language was based on the Sosva dialect. Since 1932, a number of schoolbooks and other works (folklore collections, children's literature, political pamphlets) appeared in Vogul. Instruction in Vogul schools on the elementary level was (1960s) conducted in the mother tongue. (T. A. SB.)

VOICE is the sound produced by the vibrations of the vocal folds or cords. tno ligaments or bands of fibrous elastic tissue situated in the larynx. It is to be distinguished from speech. which is the production of articulate sounds intended to express ideas. (See SIXGING; PHONETICS; PRONUNCIATION.)

Physiological Anatomy.—The larynx is a valve guarding the entrance to the trachea. In man it is used as the organ of voice. It is situated in the neck where it forms a well-marked prominence in the middle line (see details under RESPIRATORY SYSTEM, ANATOMY OF). It consists of a framework of cartilages, connected by elastic membranes or ligaments. and it contains two important structures knonn as vocal folds or cords. The latter. if brought into apposition, can be blown apart by an expiratory blast of air; a consequent fall in pressure in the trachea allows the folds to come into contact again; repetition of this action allows puffs

FIG. 2.— LIGAMENTS AND CARTILAGES OF THE LARYNX, ANTEROLATERAL VIEW

The cartilages form the framework of the larynx. They consist of three single pieces (the thyroid, the cricoid and the cartilage of the epiglottis) and of three pairs (two arytenoids, two corniculate cartilages of Santorini and two cuneiform cartilages or cartilages of Wrisberg) (see fig. 1 and 2). The epiglottis, the corniculate and cuneiform cartilages and the apexes of the arytenoids are composed of yellow or elastic fibro-cartilage, while the cartilage of all the others is of the hyaline variety, resembling that of the costal or rib cartilages. These cartilages are bound together by ligaments, some of which are seen in fig. 1 and 2, while the remainder are represented in fig. 3. The structures specially concerned in the production of voice are the inferior thyroarytenoid folds, or true vocal folds. These are composed of fine elastic fibres attached behind to the anterior projection of the base of the arytenoid cartilages, *processus vocalis* (see fig. 3) and in front to the middle of the angle between the wings or laminae of the thyroid cartilage. They are continuous with the lateral cricothyroid ligaments which form the *conus* elasticus (see fig. 3).

The cavity of the larynx is divided into an upper and lower portion by the narrow aperture of the glottis or chink between the edges of the true vocal folds, the *rima* glottidis. Immediately above the true vocal folds, between these and the false vocal cords, there is on each side a recess or pouch termed the ventricle of Morgagni, and opening from each ventricle there is a still smaller recess, the laryngeal saccule, which passes for the space of half an inch between the superior vocal cords inside and the thyroid cartilage outside, reaching as high as the upper border of that cartilage at the side of the epiglottis. The upper aperture of the larynx is bounded in front by the epiglottis, behind by the summits of the arytenoid cartilages and on the sides by two folds of mucous membrane, the aryteno-epiglottic folds.

The rima glottidis, between the true vocal folds, in the adult male measures about 23 mm., or nearly an inch from front to back, and from 6 to 19 mm. across its widest part, according to the degree of dilation. In females and in males before puberty the anteroposterior diameter is about 17 mm. and its transverse diameter about 11.5 mm. The membranous vocal folds of the adult male are in length about 15 mm., and of the adult female about

FIG. 3.— SAGITTAL SECTION OF THE LARYNX, RIGHT HALF

11 mm. The larynx is lined with a layer of epithelium which is closely adherent to underlying structures, especially over the true vocal folds. The cells of the epithelium, in the greater portion of the larynx, are of the columnar ciliated variety, and by the vibratory action of the cilia mucus is driven upward; over the true vocal folds, however, the epithelium is squamous. Numerous mucous glands exist in the lining membrane of the larynx, especially in the epiglottis. In each laryngeal pouch there are from 60 to 70 such glands.

Muscles of the Larynx. — The muscles of the larynx forming, with the arytenoid cartilages, the *rima* glottidis, tighten or relax, and approximate or separate the vocal folds. Besides certain extrinsic muscles — sternohyoid, omohyoid, sternothyroid and thyrohyoid — which move the larynx as a whole, there are intrinsic muscles which move the cartilages on each other. These muscles are the cricothyroid, the posterior cricoarytenoid, the lateral cricoarytenoid, the thyroarytenoid, the interarytenoid and the arytenoepiglottidean.

Cricothyroid.—This is a short thick triangular muscle. its fibres passing from the cricoid cartilage obliquely upward and outward to be inserted into the lower border of the thyroid cartilage and to the outer border of its lower horn. When the muscle contracts, the cricoid and thyroid cartilages are approximated.

Thyroarytenoid.—This muscle is divided by anatomists into two parts, one, the internal, lying close to the true vocal cord, and the other, external, immediately within the ala of the thyroid cartilage. Many of the fibres of the anterior portion pass from the thyroid cartilage with a slight curve (concavity inward) to the vocal process at the base of the arytenoid cartilage. They are thus parallel with the true vocal fold, and when they contract the arytenoids are drawn forward if the posticus muscles are relaxed; but if the arytenoid cartilages are braced back contraction of the muscle increases the elasticity of the margins of the glottis. The arrows in fig. 4[C] indicate how the cords are shortened by unopposed contractions of the thyroarytenoid; the external fibres also rotate the vocal processes inward, and thus help in approximating the folds.

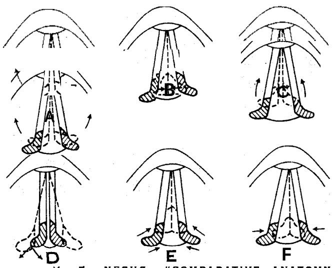
Cricoarytenoids.—The posterior and lateral cricoarytenoid muscles have antagonistic actions and may be considered together. The posterior cricoarytenoids arise from the posterior surface of the cricoid cartilage and, passing upward and outward, are attached to the outer angle of the base of the arytenoid; some fibres arise from the lateral aspect of the cricoid, to be inserted into the body of the arytenoid. On the other hand, the lateral cricoarytenoids arise from the upper border of the cricoid as far back as the articular surface for the arytenoid, pass backward and upward, and are also inserted into the outer angle of the base of the arytenoid before the attachment of the posterior cricoarytenoid. To the inner angle of the triangular base of the arytenoid are attached, as described above, the true vocal folds; and to the outer angle the two muscles in question. The posterior cricoarytenoids draw the outer angles backward and inward, rotating the inner angles, or vocal process, outward; the outermost fibres of the muscles draw the arytenoids away from one another and widen the rima glottidis. This action is opposed by the lateral cricoarytenoids, which draw the outer angle forward and outward, rotate the inner angles inward, and thus approximate the cords. In fig. 4[A] the arrows indicate the direction of action of the lateral cricoarytenoid, and the dotted lines show the positions to which its contraction brings the folds and vocal processes. Fig. 4[D] shows the action of the posterior cricoarytenoid in rotating outward the vocal processes of the arytenoid cartilages.

Interarytenoids.—These pass from the one arytenoid cartilage to the other, and in action these cartilages will be approximated and slightly depressed. In fig. 4[B] the arrows indicate the direction of action of the interarytenoid, while the dotted lines show the positions of the folds and vocal processes on its contraction.

In fig. 4[E] is shown the combined action of unopposed sphincteric muscles, as performed during swallowing; the action of the sphincteric group in phonation, opposed by dilator group of posticus muscles, is shown in fig. 4[F].

Aryteno-Epiglottidean Muscles. — These arise near the outer angles of the arytenoid; their fibres pass obliquely upward, decussate and are inserted partly into the outer and upper border of the opposite cartilage, partly into the aryteno-epiglottic fold, and partly join the fibres of the thyroarytenoids. In action they assist in bringing the arytenoids together, while they also constrict the upper aperture of the larynx.

Voice Registers. — The voice may be divided into the lower or chest register, the higher or head register and the small or falsetto register. Since all the resonators respond to the production of sound at the glottis, these terms are 'misleading. In singing, the voice changes in volume and in quality in passing from one register into another. In the lower registers the membranous vocal folds vibrate, while the arytenoids remain stationary and in apposition. The whole mass of inferior thyroarytenoid fold — consisting of mucous membrane, fatty elastic connective tissue and underlying muscle — vibrates. In the falsetto voice the vocal folds are approximated and the *rima glottidis* is short and of an elliptical shape; only the margins of the inferior thyroarytenoid folds vibrate. The small register is a variant of the falsetto; in it only a part of the membranous glottis is blown open.



V. E. NEGUS, "COMPARATIVE ANATOMY AND PHYSIOLOGY OF THE LARYNX," 1950, WILLIAM HEINEMANN, LTD.

FIG. 4.—ACTION OF INTRINSIC MUSCLES OF THE LARYNX (*see* TEXT)

The pitch of the voice appears to depend on the relation of the elasticity of the glottal margins —as determined by the degree of contraction of the thyroarytenoid muscles—to the pressure of air expelled from the trachea. The pitch can be raised by an increase of the former while the latter remains almost unchanged, or vice versa; probably an increase of elasticity is accompanied by slightly raised air pressure in the changes of pitch in the chest register. In the head register it appears that the innermost fibres only of the thyroarytenoid muscles are in contraction, rise of pitch being produced principally by rise of air pressure.

In 1950 a theory was propounded in France that considered the production of sound at the glottis to be due to rhythmical contraction and relaxation of the marginal muscles, in response to a series of stimuli arriving in the recurrent laryngeal nerves. The fact that a pitch of more than 1,000 cycles per second can be attained presents difficulties, but the authors of the theory explained this as overcome by a diphasic or triphasic method of stimulation. Sir Charles Sherrington demonstrated that if muscles are stimulated more than 67 times per second tetanic contraction is produced; experiments with animals, by means of a piezoelectric transducer or with a selenium cell responding to light shining through the glottis, prove that the thyroarytenoid muscles of the larynx may respond rhythmically to stimuli below a rate of 110 per second, but that above this rate tonic contraction occurs, as is supposed to occur in the usually accepted myoelastic theory of phonation.

Laryngoscopy.—By means of the laryngoscope it is possible to see the condition of the *rima glottidis* and the folds in passing through all the ranges of the voice. In 1807 P. Bozzini first showed that it was possible to see into the dark cavities of the body by illuminating them with a mirror! and in 1829 W. Babington first saw the glottis. In 1855 Manuel Garcia investigated his own larynx and that of other singers, and three years later L. Tiirck and especially J. N. Czermak perfected the laryngoscope. In 1883 Lennox Browne and Emil Behnke obtained photographs of the glottis in the living man. By using the stroboscope B. Oertel, A. Musehold, T. S. Flatau, J. Hegener and G. Panconcelli-Calzia enormously improved the technique of laryngoscopy. The endoscope devised by Flatau and the autophonoscope originated jointly by Panconcelli-Calzia enable extensive observations on the larynx to be carried out while the mouth is closed.

Other apparatus employed for investigating the mechanism of the voice includes the breathing flask of H. Gutzmann, the spirometer, the stethograph and pneumograph (used in connection with the manometer and the phonetic kymograph), all of which are employed for investigating breathing. For observing the action of the vocal folds there have been employed, in addition to the laryngoscope, the strobolaryngoscope and the endoscope, manometric flames, the *Polsterpfeife* of F. Wethlo, resonators, gramophones, microphones and oscillographs. For studying the supraglottal resonators radiograms are taken. Other methods of study are the cathode-ray oscillograph and the piezoelectric transducer.

Action of the Vocal Folds. — The best view of the larynx is obtained with the tongue flat, while attempting to sing the vowel "ee," for this opens out the cavity immediately above the larynx. If the larynx is examined stroboscopically the vocal folds are seen to be alternately opening and closing along the ligamentous portions in the chest notes. In falsetto, part of the glottis is permanently open with the edges of the cords vibrating. In whisper the space between the arytenoids is open. Should this occur during phonation, it constitutes a faulty mechanism producing breathy voice: n-hich is particularly to be avoided in singing.

J. Wyllie affirmed in 1865 that the false vocal cords play the chief part in the closure of the glottis during expiration. Lauder Brunton and J. T. Cash confirmed Wyllie's results and further thought that the function of the false vocal cords was to close the glottis and thus fix the thorax for muscular effort. From the evidence of comparative anatomy, and from observations made on men, it has been demonstrated that in fixation of the thorax, the vocal folds are the important factor. By means of their closure air is prevented from entering the lungs and as the thorax is to a certain extent unable to expand, because of this obstructive mechanism, the ribs tend to come to rest whereby a fixed origin is afforded to the various groups of muscles which move the arms.

The conditions that define the attributes of the human voice are in essentials similar to those of musical instruments in general. The source of energy is the lungs. By them the air is forced under pressure through the glottis causing the vocal folds to move rhythmically, thereby producing a musical note. This musical note is a tone complex of simple harmonic vibrations some of which are modified by the sub- and supraglottal cavities acting as resonators. It is the train of sound waves thus modified. issuing from the mouth. which gives rise to vowels and voiced consonants. Such sound waves can be and sometimes are produced to a limited extent by an indrawn current of air actuating the vocal cords.

To what extent the infraglottal cavities (*e.g.*, the trachea and chest cavity) influence the quality of the glottal note is undetermined. Investigators are however agreed that among the supraglottal cavities the effect of the sinuses (*e.g.*, the maxillary sinus. the ethmoidal cells. sphenoidal sinus and frontal sinus) is negligible owing to their small and variable size, unfavourable positions and minute openings. The expression "sinus tone production" would thus appear to be devoid of justification. Nor can there be any question of directing the voice to a definite point in the buccal cavity. as the dimensions of the mouth cavity, in comparison with the wave length of sound, are too small for reflection to be possible.

Attributes of Voice. — Voiced sounds may be described in terms of their physical constitution and the impression they make on a listener, Their physical description is given in terms of fundamental frequency, harmonic structure and intensity. In the listener, impressions of different kinds are broadly correlated with these physical dimensions. The fundamental frequency of the voiced sound is mainly responsible for the sensation of pitch. the harmonic structure for impressions of quality or timbre, and the intensity of the sound waves for the loudness of the sound.

Fundamental Frequency.—During the production of voice, the vocal folds perform repeatedly a rhythmical opening and closing that gives rise to a musical tone. Each opening of the folds produces a small puft of air or pulse. the repetition rate of which determines the fundamental frequency of the voiced sound. commonly expressed in cycles per second. This frequency depends on the mass, length and elasticity of the folds and on the pressure acting upon them. Increase of pressure in the expiratory air current leads to a rise in the frequency of vibration.

The vocal folds are tightened if the arytenoid cartilages are braced back by contraction of the cricothyroid and posterior crico-arytenoids, and the thyroarytenoids will then give elasticity to the margins of the glottis so that they will recoil after being blown apart. The greater the degree of contraction the higher this elasticity becomes. All the muscles except the cricothyroid (which is innervated by the superior laryngeal) receive nerve filaments from the inferior or recurrent laryngeal branch of the vagus, the fibres being derived from the accessory roots. Both the abductor and adductor nerves come therefore from the inferior laryngeal.

At puberty, the development of the male larynx causes the folds to become more elongated than in women, in the ratio of 3 to 2, so that the male voice is of lower pitch and is usually stronger. During puberty the larynx grows rapidly, and the voice of a boy breaks in consequence of the lengthening of the folds, generally falling an octave or so in pitch.

Castration, performed before puberty, prevents the male growth changes and leaves a high-pitched voice; a eunuch can therefore sing in a treble or soprano range. but with greater power than a woman, owing to his bodily bulk and lung capacity.

In speech, the fundamental frequency ranges from about 80 cycles per second in men's voices to about 400 c.p.s. in women's. The range covered in singing is considerably wider, from about D (74 c.p.s.) in bass voices up to F'" (1.408 c.p.s.) in soprano voices. Exceptional cases are sometimes reported in which singers produce frequencies as low as 44 and as high as 2.048 c.p.s. The ranges of the main types of voice used in music are shown in musical notation in fig. 5.

The Italian soprano Lucrezia Agujari (1743–83) is said to have sung C"". a feat rivaled by Ellen Beach Yaw-Goldthwaite. Dame Nellie Melba ranged from B flat to F'". The lowest note, E below the fourth ledger line in the bass clef (44 cycles per second), is said to have been sung by Gaspard Foster.

Hainzonic *Structure*.—The physical character of voiced sounds is dependent on the wave motions produced by vibration of the vocal folds and on the modifications of these wave motions by the sub- and supraglottal cavities. It is difficult to obtain direct evidence as to the exact form of the sound waves emitted by the larynx, but it can be deduced that this is essentially a pulse wave of approximately triangular wave form; this means that the larynx generates a fundamental frequency (determined by the period of the opening and closing of the vocal folds) and an extended series of harmonic frequencies, each an exact multiple of the fundamental. This frequency complex is radiated from the larynx into the associated cavities and the relative amplitude of the harmonic components is modified by the natural frequency and the resonance characteristics of these cavities. The harmonic structure of voiced sounds can thus be modified by the singer or speaker by changing the disposition of the resonating cavities. The commonest example of such differences in quality or timbre is provided by the production of different vowel sounds. Supposing that the larynx

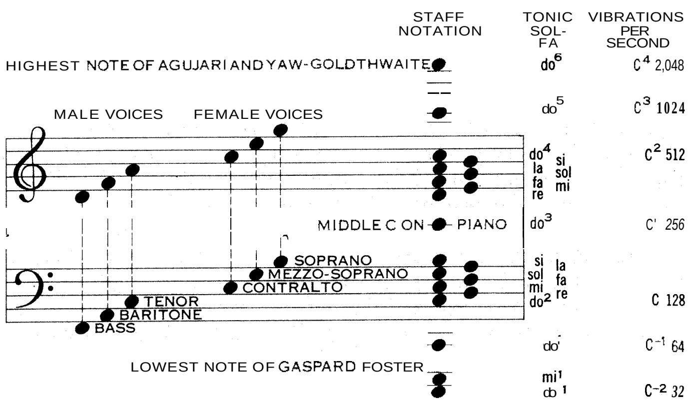


FIG. 5.—COMPASS OF HUMAN VOICE

produces a fundamental frequency of 100 c.p.s. and a long series of harmonics of frequency 200 c.p.s., 300. 400. 500, etc. If the speaker or singer wishes to produce the vowel "a." as in "hard," he disposes the supraglottal cavities so as to allow the greatest amplitude to frequencies in the region of 800–1 200 c.p s. In order to change to the vowel "e." as in "head," he changes the cavities so as to allow greatest amplitude to harmonics in the region of 600–2,000 c p.s. As long as the same disposition of the resonating cavities is maintained, the speaker produces the "same" vowel, even though the fundamental frequency may be changing.

Other differences of quality in voiced sounds, such as that peculiar to a given speaker or singer, are also largely determined by the resonating cavities. Research has indicated, however, that the nature of the larynx tone itself plays an important part in this matter. High-speed pictures of the vocal folds in action, taken by means of a laryngoscope, have provided much information about the modes of vibration of the folds and the time pattern of their movement. The relation between the open phase and the closed phase of the movement, the degree to which the folds are approximated, the manner in which the closure begins and ends, all are known to vary from speaker to speaker and from moment to moment. Since these factors help to determine the sound generated in the larynx, they also affect the harmonic structure of the voiced sound.

Intensity.—The intensity of voiced sounds, like their harmonic structure, is a function both of the action of the vocal folds and of the resonating cavities. The greater the amplitude of movement of the folds, and the longer the period for which they remain open in each cycle, the greater the intensity of the resulting sound. These two features of vocal-fold vibration in turn depend upon the efficiency with which the pressure of air supplied by the lungs is used to set and maintain the folds in vibration. The intensity of the voiced sound will also depend on the amplitude allowed to the various harmonics by the resonating cavities.

The level of energy output during speech or song is relatively low. The mean intensity of conversational voice at three feet from the speaker is about 60 decibles above the common reference level of .0002 dynes per square centimetre; the mean power in speech is hence of the order of 10^{-10} w.

Methods of Investigation.—The principal method of exploring the physical character of voiced sounds is frequency analysis, usually carried out with the aid of electronic filters which allow the passage of frequency components within a certain restricted frequency band and thus permit the registering of the energy level or intensity at any part of the frequency range. Such a filtering device, together with a suitable means of displaying or recording intensity levels, is known as a sound spectrograph. This instrument contains either a bank of filters, each covering a part of the frequency range, or a single adjustable filter which can be made to cover different parts of the range in succession. The voiced sound is applied to the filters, either directly through a microphone and amplifier or from a sound recording, and the intensity level in each filter band at succeeding instants is registered. A common type of sound spectrograph affords a three-dimensional display in which the passage of time is represented on the horizontal axis, the frequency range covered by the analysis on the vertical axis, and variations in intensity are shown by gradations from light to dark in the pattern; a dark trace indicates high intensity level in the filter covering the corresponding section of the frequency range. Often a choice of filter band width is provided; two commonly used values are 45 c.p.s. and 300 c.p.s. If a filter of 45 cycles band width is used, then the total frequency range is divided into sections each 45 cycles wide and the resulting pattern shows variations in the energy level in each section with time. Such an analysis will give the intensity of each separate harmonic for any complex tone having a fundamental higher than 45 c.p.s. This system is commonly used in the study of singing and other musical sounds where good frequency resolution is needed. If a filter band width of 300 c.p.s. is used, then all the energy within each band of 300 cycles is added together and registered. In this case the separate harmonics are not recorded but there is improved time resolution. This type of analysis is often used in the study of speech sounds.

Differences Between Singing and Speech.—The principal physical differences between singing and speech are to be found in the time pattern of variations. In singing, a particular fundamental frequency and a given harmonic structure are maintained for much longer periods than in speech, and changes in intensity are made much more slowly. In speech, the fundamental frequency varies continuously, so much so that it is unusual to find succeeding cycles of vocal-fold movement that occupy exactly the same time. The harmonic structure of speech sounds, too, is changing all the time since the movements of articulation are continuous and hence the cavity shapes are being continuously modified. Intensity changes in speech take place frequently and abruptly and are imposed by the syllabic structure of speech.

Voice Quality in Singing. — The personal taste and experience of the listener must play a large part in any judgments of a singing voice, but since a certain number of singers are widely recognized as of the first rank, it is possible by a physical study of the sounds produced by them to indicate some factors which are important. Two such factors are certain features of harmonic structure and the presence of vibrato. In voices of good quality the higher harmonics, in the range 2,000–6,000 c.p s. or even higher, are generally found to be of considerable intensity and, further, their reinforcement can be controlled by the singer In *mezza-voce* singing the intensity of these harmonics is much reduced, but it is increased in forte passages. Often in singing a phrase or a whole passage in one key, the singer will select and reinforce a particularly high harmonic that fits in well with the key, and will keep this harmonic sounding throughout the phrase or passage despite the changes of fundamental frequency demanded by the melody. This may well be one physical component of what is often referred to as "line" in singing The vibrato in good voices generally consists of regularly repeated fluctuations in fundamental frequency, often accompanied by some fluctuation in intensity. The fluctuations take place very regularly, usually about six or seven times a second. The total change in fundamental frequency varies from singer to singer, but it may produce a change of pitch up to one-quarter tone above and below the true pitch of the note.

Voiced Sounds in Speech. — The main function in speech of the sound produced by the vocal folds is to act as a carrier wave which is modified, or modulated, by the action of the articulatory mechanism. The sound of voice provides the carrying power and the audibility of speech; the intensity of the sound is modulated by the syllabic action of the articulators. Each syllable contains a section of high intensity, the vowel, on each side of which is a section of lower intensity, a consonant. In the production of vowels, the supraglottal cavities provide a relatively open air passage, and during the production of consonants this passage is either partially or completely closed. For certain consonants, the voiced sounds such as "b," "z," "v," etc., the vocal folds continue to vibrate and for others, the voiceless sounds such as "t," "f," "s," etc , the larynx vibration ceases altogether.

One of the main functions of the larynx tone in speech is to convey the intonation of the message. In English, for example, the difference between a statement and a question, between a command and a request, is carried to a great extent in normal speech by variation in the frequency of the vocal-fold vibrations. This is only one illustration of the fact that a speaker's emotional attitude is expressed largely through the larynx tone and particularly through variation in its frequency. In certain languages known as tone languages, which include many Oriental and African languages, variation in larynx frequency may also contribute to semantic distinctions; *i.e.,* the difference between a high and a low pitch in a given word may function very much like the difference between the vowel "i" and the vowel "a," for example.

An important function of the articulatory mechanism. is to change the harmonic structure of the voiced sound produced by the larynx. Each English vowel is characterized by regions of high intensity known as formants. The most important formants are produced by the pharyngeal cavity behind the tongue (formant 1) and by the front mouth cavity (formant 2). The frequency regions for the formants of southern English vowels are given in the table.

Diphthongs are produced by making a rapid movement from one vowel in the direction of another, and in this case there is a marked change of formant frequencies.

Certain English consonants are, from the physical point of view, very similar to vowels and are characterized by formants. These are the sounds "1" and "r," the semivowels "j" and "w" and the nasals "m," "n" and "ng." The last three are articulated with the soft palate in the lowered position and hence they have a prominent third formant provided by the nasal cavity. The remaining consonants require a second sound source in addition to the larynx. In the plosive consonants. "p," "b," "t," "d," "k," "g," the sound is generated by the lips or tongue making a sudden explosive moment; in the fricative consonants, "f," "v," "θ," "ð," "s," "ʃ," "ʒ," "h," the air passage is narrowed at some point to cause audible friction on the passing of air from the lungs.

Artificial Production of Speech Sounds. — There are a number of devices, usually known as speech synthesizers, for the artificial production of speechlike sounds. These are essentially electrical analogues of the human speech mechanism and consist of electronic circuits that provide a pseudolarynx tone, a means of modifying the harmonic structure of this tone and a noise source with which to simulate consonant sounds. The larynx tone generator usually produces a pulse tone of approximately triangular wave form in nhich the pulse rate can be varied over an appropriate range. The tone is then fed into resonant circuits (formant generators) that function as the resonating cavities in speech and change the relative amplitude of the harmonics in the larynx tone, thus giving rise to formants. Noise from the noise generator is either mixed with the larynx tone or used independently to produce consonant sounds. Speech synthesizers provide a highly controllable source of speechlike sounds and are particularly good for determining experimentally the importance of various physical characteristics in the perception and recognition of speech sounds.

TABLE.—*Formant Frequencies of Southern English Vowels*

Vowel symbol	As in	Formant 1 c.p.s.	Formant 2 c.p.s
i:	heed	375	2250
ɪ	hid	425	2125
e	head	500	2000
a	had	700	1850
a:	hard	800	1225
o	hot	625	1000
o:	hoard	500	800
u	hood	450	875
u:	who	375	625
ʌ	hut	750	1250
ə:	herd	550	1350

Substitutes for the Larynx. — Laryngectomized subjects can develop a capacity for producing sounds nhich in essentials resemble normal voice. H Burger and L. Kaiser of Amsterdam first reported a case nhere a pseudolarynx had been developed in the esophagus. The vicarious lung was the stomach. and the lips of the pseudoglottis were actuated by ejecting air mhich had previously been swallowed. The subject could sing, speak and use the telephone. Indeed, vocally, he carried on like a normal person. It is recognized that the esophagus is the receptacle for air and that air is aspirated and not actually swallowed.

Attempts have also been made nith more or less success to supply the voice element in speech by means of vibrating reeds of rubber or thin metal The best known of these devices is the MacKenty-Western Electric Artificial Larynx. By using it the subject is able to direct the expiratory current on to a rubber reed when voicing is required. An electric vibrator, applied to the outer wall of the pharynx. can be used to produce sound in the cavity by forced resonation; the sound is then resolved into articulate speech by the resonators and stops. A somewhat similar vibrator is used to carry sounds directly into the mouth.

The voice of man represents a very great achievement in respect of volume, range and quality. The study of comparative anatomy explains why various changes have taken place in the structure of the mouth, the pharynx and the larynx. the majority designed for purposes other than vocalization; many of these variations have led to reduced efficiency in respiratory exchanges, in olfaction and in deglutition. but they have at the same time benefited man in respect of speech and song.

Comparative anatomy shows at the same time that a very simple apparatus is sufficient for the production of voice and that the remarkable development in the human race is due not chiefly to anatomical structure but rather to increase of intellect.

Man has made the best use of the apparatus available and in return his intelligence has developed to a high degree as a result of his ability to express ideas.

VOILE, a sheer dress material produced from wool, cotton or silk. It is characterized by a light, open and netlike structure based essentially on the principle of the plain calico weave. and produced from warp and weft yarns with an abnormal degree of twist. irrespective of the class of material from which it is spun. The yarn employed may be either single or folded in the warp series or in the weft series, or in both series of threads; and it may be spun with a greater or lesser amount of twist.

VOIT, CARL VON (1831–1908), German physiologist, helped lay the foundations for the modern knowledge of metabolism and nutrition. Born in Amberg, Bavaria, Oct. 31, 1831, he studied with Justus von Liebig and Friedrich Wöhler and was professor of physiology in Munich from 1863 to 1905. He was a founder (1865) of the *Zeitschrift* fur Biologie. Voit raised to a high level the technique of balance studies in which the ingestion and excretion of foodstuffs are determined quantitatively. The painstaking techniques he developed and. the principles he laid down for such studies are still followed. His most important early studies were on nitrogen balance. He and Max von Pettenkofer (*q.v.*) built the first metabolism machine large enough to hold a human being. Using this apparatus they showed that carbon dioxide production is proportional to the rate of muscular activity. They also made the first accurate determination of the energy requirements of man. Such determinations are now generally known in terms of a daily caloric requirement for a given level of activity. Voit died in Munich on Jan. 31, 1908. (P. F. C.)

VOITURE, VINCENT (1597–1648), French writer who exercised a twofold influence on the style of 17th-century literature. Born at Amiens, where he was baptized on Feb. 23. 1597, he completed his education in Paris and early made the acquaintance of the aged Malherbe and J. Guez de Balzac. A regular visitor at the Hôtel de Rambouillet from *c.* 1625, he did much to enliven the proceedings there. Having attached himself to Gaston, duc d'Orléans, he followed him into exile in 1632 and was sent to Spain to negotiate on his behalf. On his return to France, however, in 1634, he was elected to the Académie Française, and in 1636 he composed an eloquent and statesmanlike letter in defense of the cardinal de Richelieu's policy. The government sent him on a state mission to Tuscany in 1638. Voiture died in Paris on May 26, 1648.

Voiture's poems are not without beauty, and his letters are full of witty and subtle allusions that the narrow circle of the Hôtel de Rambouillet could enjoy. These letters were not meant to be printed and so should not be judged as if they were written for the general public. It was Voiture who taught French writers how to combine sentiment and wit, passion and irony, in the manner known as la belle *galanterie.* It was he also who finally succeeded in freeing French poetry from Petrarch's influence. For this he relied partly on the example set by the Hôtel de Rambouillet. partly on his remarkable knowledge of Spanish poetry (G. Lanson. in an article in the *Revue d'histoire littéraire de* France, 1897, shows that he must have read Gbngora, Cristbbal de Castillejo and Hurtado de Mendoza), the characteristics of which he adapted to suit French taste. He was likewise well read in Italian poetry, One of his Best-known sonnets, "La Belle Matineuse," reflects Annibale Caro's influence together with Góngora's.

For the controversy about his sonnet "Uranie" see BENSERADE, ISAAC DE.

Voiture also did much to promote the revival of the old style of ariting exemplified by Clément Marot and the *Amadis* romances. It was he who induced the Parisian salons to write verse in imitation of Marot and to compose chronicles in "old language." This aspect of his work was not a peculiar eccentricity but a reaction against the contemporary tendency to impose a rational and bourgeois outlook on literature. The element of romance is a most important factor in French 17th-century literature, and its survival in the golden age of classicism was due mainly to Voiture.

There is an edition of Voiture's collected works by A. Ubicini, 2 vol. (1853).

See E. Magne, *Voiture et l'Hôtel de Rambouillet,* 2 vol (1929–30); A. Adam, *Histoire de la littérature française au XVIIe siècle,* vol. i (1948) (AE A)

VOIVODE, a title in use among Slavonic peoples, meaning literally, leader of an army (Sl. *voi,* host, army; voditi, to lead; cf, Med. Gr. boebodos) and so applied at various periods and in various eastern European countries to rulers, governors or officials of varying degree. As voda it is best known as the title of the princes of Moldavia and Walachia. In Poland, as *wojewoda* (sometimes latinized as *palatinus*), it is still used as the title of the governor of a province (*wojewodztwo*). In the kingdom of Serbia *vojvod* was the highest military rank.

VOLAPÜK, a constructed language first published in 1880 by a south German cleric. Johann Martin Schleyer (1831–1912). It rapidly gained wide support but the popularity of the language soon declined on account of dissensions among its supporters and the competition of other more easily learned constructed languages; *e.g.,* Esperanto.

Volapiik vocabulary consists largely of English and Romance words, so distorted by phonological simplification that most are not immediately identifiable (*e.g.* Volapiik, "world language" = genitive of vol (Eng. "world") + *pük* (Eng. "speak"). Nouns have four cases marked by suffixes (nom. [zero], accus. -i, gen. -a, dat. -e), plur. -s (*e.g.,* fats, "fathers," gen. *fatas,* etc.). Borrowed words are undeclined, but preceded by an article el (not used with Volapük words) as a case/number marker (*e.g.,* el Edelweiss, *elas* Edelweiss, etc.). Adjectives are derived from nouns by suffixed -ik (gud, "goodness," *gudik,* '(good"), normally undeclined and following their noun. When, however, they precede, they are declined (*e.g., manas* gudik or *gudikas manas,* "of good men"). Numerals are mostly arbitrary monosyllables (*bal,* tel, kil, fol, *lul,* etc.) with suffixes marking ordinals. fractions, etc. Pronominal morphemes (independent, or suffixed as personmarkers to verbs) include informal and formal second person forms (*ol/ols,* "you," sing./plur. informal, *or/ors,* "you," sing./plur. formal) and other complexities. Verbs can carry personal suffixes (*löfob,* "I love," *löfols,* "you love," etc.), six tense prefixes (alofob, "I loved," ilofob, "I had loved," etc.), a passive prefix (palofob, "I was loved") and optative, imperative, conditional, infinitive and participial suffixes.

See also UNIVERSAL LANGUAGE.

VOLCAE, an ancient Celtic people in the province of Gallia Narbonensis, who occupied the district between the Garumna (Garonnej, Cerbenna mons (Cévennes), and the Rhodanus, corresponding roughly to the old province of Languedoc. They were divided into the Arecomici on the east and the Tectosages on the west, separated by the river Arauris (Hérault). The Volcae were free and independent, had their own laws, and' possessed the *ius* Latii. The chief town of the Tectosages was Tolosa (Toulouse); of the Arecomici, Nemausus (Nimes); the capital of the province was Narbo Martius (Narbonne).

VOLCANISM. This article deals with the processes and activity that take place at and are associated with volcanoes, including not only those at the earth's surface but also those associated with volcanic conduits at shallow levels within the earth's crust. They accompany and result from the rise of molten rock, known as magma, or the gases liberated from magma, to the surface of the earth. For discussion of lava flows and pyroclastic rocks, volcanic land forms and the distribution of volcanoes *see* VOLCANO.

ORIGIN OF MAGMA

Although some deep-seated rocks once thought to have resulted from consolidation of magma are now known to form by recrystallization in the solid state (granitization), the existence of magma is unquestionable. At active volcanoes it can be seen issuing from within the earth, sometimes very rapidly and in great quantity. It once was believed that beneath the solid crust, much of the earth is molten. Studies of earthquake waves passing through the earth and of the behaviour of the earth under tidal stresses, however, indicate that the outer 1,400 mi. of the earth is essentially solid. Large bodies of matter with properties like those of liquids as we know them at the surface of the earth must be absent, and magma must be restricted to isolated pockets of relatively small size.

Neither the place nor the manner of origin of magma is known with any certainty. Measurements in wells and mines show that temperature increases with increasing depth within the earth. The rate of increase is not the same at all places. but on an average it is about 1° C. for each 100 ft. Under laboratory conditions volcanic rocks melt at temperatures of 1,000° to 1,500° C., and in nature the presence of gases would be expected to make the melting temperature somewhat lower. Thus, if the rate of temperature increase continues approximately the same at greater depth as in the upper 2 mi., rocks at depths of less than 30 mi. are at temperatures under which they would melt if surface conditions prevailed. However, pressure also increases downward within the earth, and it is believed that this increase of pressure raises the melting point sufficiently so that the rocks remain solid despite the high temperature. Presumably, if in any way the pressure on the hot rocks at depth can be relieved locally, part or all of. the constituents of the rock will melt and form a magma, although the mechanism of such relief of pressure is not clear.

It is generally believed that magma forms at relatively shallow levels in the earth, probably within the upper few tens of miles. Earthquakes preceding some eruptions of Hawaiian volcanoes come from depths of 20 to 25 mi., and suggest that the magma may originate at about that depth. It is interesting that the temperature of erupting Hawaiian lavas is in the range that would be expected at depths of 20 to 25 mi. if the average near-surface temperature gradient continues that far.

The heat within the earth probably is partly residual irom the original formation of the earth. No doubt part of it also is the result of breakdown of radioactive elements within the earth. However, erupting lavas and volcanic gases are not unusually radioactive as compared to other rocks of the earth's surface. It is unlikely that radioactive heat plays a direct part in the generation of magma.

At depth magma may be completely liquid. Commonly, however, it contains suspended grains (phenocrysts) of minerals that have crystallized from it. and it may also contain other solid fragments of rock (xenoliths) torn irom the walls of the enclosing chamber. As it approaches the surface cooling commonly results in further crystallization and an increase in the amount of phenocrysts. Also, as pressure decreases and crystallization progresses, gases that were dissolved in the liquid begin to separate out as bubbles. At that stage the magma consists of three physical phases: liquid melt, solid phenocrysts and xenoliths, and bubbles of gas.

The bubbles of gas are lighter than the enclosing liquid, and rise through it. As they rise, they encounter other bubbles and coalesce with them, so that they increase in size both by expansion as they rise into regions of lesser pressure, and by coalescence. Many of the bubbles reach the top of the magma body and escape from it. either below or at the surface of the earth. However, the escape is impeded by the surface tension and viscosity of the enclosing liquid, and a considerable pressure. of gas in the bubble may be required before the gas can burst its way free. The escape of each tiny bubble thus is a miniature explosion, and the bursting of large high-pressure bubbles from very viscous magma produces violent explosions. During some of the strongest explosions of Asama volcano in Japan, explosive pressures as great as 8,000 lb. per square inch have been calculated. Most volcanic explosions appear. however, to involve lower pressures.

The range of chemical composition of the igneous rocks that result from consolidation of magmas is discussed in the article PETROLOGY, and briefly in VOLCANO. However, the consolidated rock represents only part of the original magma. Most of the gas escapes before consolidation. The chemical composition of the gas phase of magma is not well known, partly because of the extreme physical difficulties encountered in collecting gases directly from the vents of erupting volcanoes. Most of the great cloud of gas poured out during a volcanic eruption consists of steam, but a very large proportion of the steam may come from heating of water in older rocks adjacent to the volcanic conduit, rather than from any deep-seated magmatic source. Thus, during the eruption of Hekla volcano, in Iceland, during 1947–48, and that of Paricutin volcano, Mexico, during the years 1943–52, most of the water in the great eruption clouds appears to have been derived from the body of ground water that saturated the rocks forming the bases of the volcanoes.

The best collections of volcanic gases have been those made by T. A. Jaggar at Kilauea volcano. Hawaii, in 1919. The gases were collected directly from blisters on the surface of the active lava lake. The average composition of 14 samples was: water 70.75%, carbon dioxide 14.07%, carbon monoxide 0.40%, hydrogen 0.33%, nitrogen 5.45%, argon 0.18%, sulfur dioxide 6.40%, sulfur trioxide 1.92%, sulfur 0.10% and chlorine 0.05%. Part of the abundant water may have come irom shallow ground water; and almost certainly some came from near-surface oxidation, by atmospheric oxygen, of hydrogen rising from depth.

Gases trapped in rocks during consolidation resemble in composition those collected at Kilauea, except that chlorine and fluorine commonly are more abundant. Gases liberated at most continental volcanoes also appear generally to be richer in chlorine and fluorine than those of Kilauea. Thus. the great eruption of Katmai volcano, Alaska, in 1912, liberated into the atmosphere such quantities of hydrochloric and hydrofluoric acid that clothes hanging on lines as far away as Chicago were damaged.

PHYSICAL PROPERTIES OF MAGMAS

The temperature of molten lava reaching the earth's surface ranges from about 700° to 1,200° C. At Kilauea the very hot lava issuing directly from the feeding conduits and forming the cores of lava fountains has a temperature (determined by means of optical pyrometers) generally ranging between 1,100° and 1,150° C.. though sometimes dropping as low as 1,050°. The lava lake at Kilauea in 1917 was found by Jaggar to have temperatures ranging from 910° to 1,170°. Similar temperatures were found during the 1938–40 eruption of Nyamlagira, in central Africa. At both places still higher temperatures in the throats of small cones resulted from burning of escaping gases. At Kilauea these temperatures were as high as 1,350°, high enough to cause remelting of the rock in the wall of the throat. The lowest temperature at which Hawaiian basaltic lavas continue to flow appears to be about 700° C.

More siliceous lavas may be erupted at temperatures somewhat lower than 1,000° C.. but the greater violence characterizing these eruptions makes difficult any accurate measurement of the temperature of the lava as it leaves the vent.

The viscosity of Hawaiian lava where it leaves the vent is about 1,000 poises (approximately 100,000 times that of water). As the flows progress down slope the viscosity increases, reaching about 10,000 poises at distances of several miles from the vent. These are among the most fluid of erupting lavas. During the 1947 eruption of Hekla volcano. Iceland, the viscosity of the lavas was about 10,000 poises at the vent, increasing to 500,000 poises and more at the advancing fronts of the flows. More siliceous lavas are even more viscous. Some are so viscous that they can scarcely flow, and pile up around and over their vents to form volcanic domes and spines. (*See* VOLCANO.)

TYPES OF VOLCANIC ERUPTIONS

Some lavas rise to the earth's surface and flow out quietly. at times in great volume. Gas bubbles out of the lava easily and quietly, though great fountains of molten lava may shoot hundreds of feet into the air. Bombs (*see* VOLCANO) falling back to the ground are still fluid, and flatten out on impact to form thin pancakelike masses. There is very little explosion, and pyroclastic material forms only a very small percentage of the total. Most of the material pours out as thin fast-moving lava flows, that may spread to great distances from their vents. Outbreaks of this sort are called Hawaiian-type eruptions. because they are characteristic of the volcanoes of the Hawaiian Islands. The lava flows build broad domical shield volcanoes.

The lava that produces Hanaiian-type eruptions is very fluid and probably always is of mafic composition (basalt and related rocks). The gas content of the erupting magma is low. During eruptions of Kilauea and Mauna Loa, in Hawaii, the total gas content is estimated to be only about 1% by weight.

An interesting, though minor, phase of Hawaiian-type volcanism is the lava lake. The best known example is that which existed in Halemaumau crater, at Kilauea, most of the time during the century from 1823 to 1924. Very fluid lava rose at vents near the centre of the lake, and flowed outward across the lake surface to sink at the edges, and presumably set up a return circulation toward the centre along the lake floor. Permanent fountains of liquid lava marked the vents through which lava rose from depth. From time to time breaking up and foundering of the thin crust that formed on the lake resulted in spectacular displays of secondary fountains, caused by the release of gas trapped in the foundering crusts. A lava lake similar to that formerly occupying Halemaumau crater has been reported to exist in the crater of Nyiragongo volcano, in Belgian Congo. However, lava lakes are not always present at volcanoes of Hawaiian type.

Eruptions of still more fluid magma, probably also poorer in gas than Hawaiian-type eruptions, have produced the flood basalts that cover vast areas in several parts of the world (*see* VOLCANO).

More explosive eruptions appear to result from both greater viscosity of the magma and greater gas content. The larger amounts of gas, unable to escape as readily into the atmosphere, accumulate greater and greater pressure. On escaping, they tear the magma into shreds, and throw them high into the air. Eruptions of only moderately viscous material throw up bombs that are still sufficiently plastic to take on rounded or spindlelike shapes in the air, but which are too completely frozen to flatten out on striking the ground. Ordinarily, the spindle-shaped bombs are accompanied by much more abundant irregularly shaped fragments of cinder. These are called Strombolian-type eruptions, because they are characteristic of much of the activity of Stromboli in Italy. Simultaneously with the pyroclastic ejections from the crater, lava flows may pour out at the foot of the cone, as during the activity of Paricutin volcano in Mexico.

Eruptions of Vulcanian type are still more explosive and throw up many angular blocks that either were already solidified in the crater, or were too viscous to take on rounded shapes in the air. The ejection of blocks typically is accompanied by a great cloud of ash-laden gas. Associated lava flows are short and thick, or may be entirely absent. This type of eruption is named for Vulcano, an island volcano lying north of Stromboli off the west coast of Italy.

There are all gradations from one type of eruption to another, and a single volcano may exhibit activity of different types in successive eruptions, or even at different vents during the same eruption.

Sometimes pressure is relieved on a magma column at considerable depth within the volcanic conduit. A rapid vesiculation (puffing up) of the magma results, and the liberated ash-laden gas rushes up through the conduit with great velocity and volume, corrading (wearing away or abrading) the walls of the conduit and coring out the cone. This occurred, for instance, during the 1906 eruption of Vesuvius, when for about 20 hours a great column of gas rushed forth, rising almost vertically 6 mi. into the air, and boring out an open cylindrical throat 1,500 ft. across within the cone. During the eruption lava flows were poured out on the lower slopes of the volcano and great quantities of fragmental material was hurled out by explosion, but F A Perret has estimated that the weight of gas given off was far greater than that of liquid and solid material. The lavas of Vesuvius are mafic. and of relatively low viscosity. The explosiveness of the eruption illustrates the fact that at least in some instances the abundance of gas may be more important than composition and viscosity of the lava in determining the character of eruption

Probably related in mechanism to the great outrush of gas during the 1906 eruption of Vesuvius are great paroxysmal eruptions that throw out enormous volumes of pumice and ash and commonly are accompanied by the collapse of the summit of the volcanic cone to form a *caldera.* For some reason vesiculation spreads rapidly through great volumes of magma, and the violent expansion tears the escaping magma to bits. The greatest known volcanic eruption of historical times, that of Tambora in Indonesia, in 1815, was of this sort. The explosions blew about 35 cu mi of debris over the surrounding area, and the resultant collapse reduced the height of the mountain from about 13,000 to 9,300 ft. These stupendous eruptions are known as Plinian eruptions, after the elder Pliny, the Roman natural historian who lost his life while investigating the great eruption of Vesuvius that destroyed the city of Pompeii in A D 79.

Certainly resembling in mechanism the Plinian eruptions, and often constituting a phase of them, are glowing avalanches or clouds (from the French, *nuées ardentes)* and froth flows. Glowing avalanches occur also in Pelean eruptions, named for the eruption of Mt. Pelée in Martinique. West Indies, in 1902, and characterized by the growth of a volcanic dome attended by the generation of downrushing, exceedingly mobile avalanches of incandescent material above which rise spectacular convoluting clouds of dust. The froth flows are similarly mobile masses of incandescent pumice and pumiceous ash. Although differing somewhat in mode of origin, the glowing avalanches and froth flows unquestionably are very similar in their mechanism of motion and the cause of their great mobility Each particle in the flows and avalanches. and in the dust clouds that rise above them, is actively liberating gas, and the expanding gaseous envelope is pushing against similar envelopes surrounding neighbouring particles, hence the rapidly expanding and nearly frictionless character of the flow that gives it its great mobility Such flows and avalanches may attain speeds as great as 100 mi. an hour. They are exceedingly destructive, killing all living things in their paths. In 1902 the cloud of incandescent ash accompanying an avalanche of this sort swept down onto the city of St. Pierre, at the foot of Mt. Pelée. and within a few seconds wiped out its entire population of 30,000 persons.

Fumaroles and Solfataras. — Gases continue to issue between eruptions at active and dormant volcanoes, and from slowly cooling thick lava flows. The gases resemble in composition those liberated during eruptions, steam being by far the most abundant. The water probably is very largely of meteoric origin, derived from relatively shallow bodies of ground water or from rain seeping into the rock. Mixed with the steam are other gases Iiberated from underlying magma or from the cooling rock. They include chlorine, fluorine, sulfur, carbon dioxide and small amounts of the common metals and alkaline earths.

The places where these gases are given off are called fumaroles (*q.v.*). The halogen gases (chlorine and fluorine) and the metals are most prominent in the hottest fumaroles, with temperatures of 300° to 600° C. Deposits around them typically include chlorides of iron, aluminum and ammonium. In the cooler fumaroles (100°–200° C.) the sulfur gases predominate and the vents commonly are surrounded by deposits of native sulfur. These sulfur-producing fumaroles are known as solfataras (*q.v.*). Still cooler fumaroles, known as mofettes, may yield largely carbon dioxide. Pools of carbon dioxide accumulating in hollows on the land suriace may form lethal traps for animals. or even humans.

One of the most famous fumarole areas is the Valley of Ten Thousand Smokes (q v.) in Alaska. There, in 1912, a froth flow several hundred feet thick poured down the valley. In the years immediately afterward the surface of the flow was covered with fumaroles (hence the name of the valley). Many of them were very hot. E. G. Zies reported that the gases given off consisted of about 98% water (mostly of meteoric origin), with lesser amounts of hydrochloric, hydrofluoric, and boric acids, and carbon dioxide. Traces of lead, zinc, molybdenum, copper, arsenic, antimony, tin, silver, cobalt, thorium, bismuth, selenium and tellurium were found in the deposits around the fumaroles. Zies computed that during the years 1919–21 about 1,250,000 tons of hydrochloric acid and 200,000 tons of hydrofluoric acid were being discharged into the atmosphere annually from fumaroles in the valley. Activity of the fumaroles gradually diminished, and has now almost ceased.

At the low temperature end, fumaroles grade into thermal (hot) springs and geysers (spouting hot springs).

Pneumatolysis.—Below the earth's surface escaping magmatic gases alter the rocks with which they come in contact. (See GRANITE; PETROLOGY.) New minerals are formed by the addition of such volatiles as boron, chlorine, fluorine and water; and large amounts of silica may be deposited, partly as a replacement of the older rocks (silicification). These changes commonly are associated with the formation of ore deposits (*q.v.*). See also GEOCHEMISTRY. Geochemistry of the Lithosphere.

VOLCANO, an opening in the earth's crust through which molten rock or gases or both reach the surface, and the structure formed by the escape of the material. The structure commonly is a hill or mountain, which may be broadly rounded or may rise in the graceful conical form of a Mt Fuji; or it may be a depression. The form depends largely on the physical conditions of the erupting material and the strength of the eruption. This article deals with the products of volcanic eruptions, the structures built by them and their distribution. For discussion of the processes involved see VOLCANISM.

Molten rock material is known as magma, and rocks formed by its consolidation are called igneous rocks. (*See* PETROLOGY.) Magma appears to originate at comparatively shallow levels within the earth, perhaps most commonly at depths of 10 to 30 mi. It may rise only part way to the surface, congealing within the earth's crust under an insulating cover of other rock and cooling slowly to form coarse-grained rocks such as granite (*q.v.*). These are knoun as intrusive igneous rocks. If, however, it is intruded to very shallow levels, or extruded onto the surface, it cools quickly to form fine-grained rocks such as basalt (*q.v*); or it may be chilled so rapidly that little or no crystallization can take place and volcanic glass results (see RHYOLITE). Igneous rocks formed on the earth's surface are known as extrusive, or volcanic, rocks.

Most of the minerals of igneous rocks are silicates, and the principal chemical component of igneous rocks is silica (SiO_2). The proportion of silica ranges from about 40% to 75% In general, as the proportion of silica decreases that of certain other oxides. notably those of magnesium, calcium and iron. increases. Rocks containing a large proportion of silica are termed siliceous, or acid; those containing a small proportion of silica and large proportions of magnesia and iron oxide are termed mafic, or basic. (See also GEOCHEMISTRY: Geochemistry of *the Lithosphere.*)

The physical properties of magma vary with differences in its chemical composition (including the abundance of gas) and its temperature. Most important is viscosity, on which, together with the abundance of gas, to a large extent depend the behaviour of the intruding or erupting magma, the character of the volcanic eruption and the form of the edifice built by it. In general siliceous magmas are extremely viscous, whereas mafic magmas are comparatively fluid.

LAVA FLOWS

Magma poured out onto the surfaceof the earth forms a lava flow, and the rock produced by its consolidation is known as lava rock, or simply as lava. Several types of lava flows can be recognized, though actually the types are intergradational.

Pahoehoe and Aa Flows.—Mafic lavas such as basalt characteristically form the types of flows known by the Hawaiian names, pahoehoe and aa. Pahoehoe lava flows are characterized by smooth, gently undulating or broadly hummocky surfaces. Locally the thin still-plastic crust of the flow has been dragged and wrinkled, by liquid lava flowing beneath it, into tapestrylike folds and rolls resembling twisted rope or cable. Pahoehoe flows are fed almost wholly internally by streams of liquid lava flowing through natural pipes known as lava tubes formed by freezing of the surrounding lava in less active parts of the flow. As the supply decreases toward the end of the eruption the liquid lava may drain out of the tube, leaving it partly or wholly empty. There are thus formed tunnellike caves that may extend for thousands of feet, or even for miles. Typically, the margin of a pahoehoe flow advances by protruding one small toe after another, so that the movement of the flow front somewhat resembles that of a giant amoeba.

In contrast to pahoehoe, the surface of an aa flow is exceedingly rough, covered with a layer of partly loose, very irregular spiny fragments commonly called clinker. Aa flows are fed principally by rivers of liquid lava flowing in open channels. Typically, such a feeding river forms a narrow band, 25 to 50 ft. wide, along the centre line of the flow, with broad fields of less actively moving clinker on each side of it. Repeated overflows may build narrow walls, or levees, along the edges of the channel. The active portion of the borders and front of the flow is a layer of still pasty incandescent lava beneath the clinker layer, along which the black clinker is passively rafted. At the front of the flow, clinker from the top rolls down and is overridden by the pasty layer, so that the motion of the advancing front resembles that of an endless track on a tractor.

Thin basaltic laval flows generally contain many holes, or vesicles, left by bubbles of gas frozen into the congealing liquid. The vesicles may be filled by deposition of mineral matter from percolating solutions. forming amygdules (from the Greek meaning "almond shaped"); and the lava is then said to be amygdaloidal. Thick flows, which remain hot for long periods, may lose most of their gas before the lava congeals and the resulting rock may be dense, with few vesicles.

Pahoehoe and aa flows may be identical in chemical composition. In fact, it is common for a flow that leaves the vent as pahoehoe to change to aa as it progresses downslope. The reason for the change is not wholly clear in detail, but it is known to be a function of the viscosity of the liquid as related to the amount of internal turbulence. The greater the viscosity, and the greater the stirring of the liquid (as by rapid flow down a steep slope), the greater the tendency for the material to change from pahoehoe to aa. The reverse change does not occur.

Block Lava and Brecciated **Flows.**—Lavas of less mafic (basic) composition commonly form a somewhat different type of flow, known as a block lava flow. These resemble aa in having tops consisting largely of loose rubble, but the fragments in the rubble are less spinose than those of aa and of more regular shape, most of them polygons with fairly smooth sides. Block lava flows are especially characteristic of volcanic rocks of intermediate composition, known as andesites from their widespread occurrence in the Andes mountains.

Flows of more siliceous lava tend to be even more fragmental than block flows. Apparently the escape of gas from the cooling and crystallizing magma causes a series of minute explosions all through the flow, thoroughly shattering the lava into a mass of blocks which, however. are little separated from each other. Brecciated flows of this sort are well exposed along some of the highways crossing the central part of the Sierra Nevada in California.

Sand Flows.—An extension of the same process results in a complete tearing apart of the cooling viscous lava into a mass of predominantly sand-sized shreds of pumiceous glass. These shreds, each surrounded by an expanding cushion of gas, form an exceedingly mobile sand flow or froth flow that may rush downslope to distances of many miles at speeds as great as 100 mi. per hour. They are closely related in mechanism and behaviour to the glowing avalanches (see VOLCANISM). When they come to rest they may be so hot that the glassy fragments become partly, or even largely. melted together, forming what is called welded tuff or ignimbrite. Flows of this sort have formed enormous widespread deposits in New Zealand, Sumatra, western United States and elsewhere, but none has ever been observed actually in process of formation. In 1912 one of these sand flows was erupted in the Valley of Ten Thousand Smokes (*q.v.*), in Alaska, but there were no witnesses to the event.

Volume. — Some lava flows attain great extent and volume. One immense basalt flow in the Columbia river region of northwestern United States is more than 100 mi. long and 50 mi. wide, and has an average thickness of about 400 ft. Thus, its volume is about 400 cu.mi. Lava flows with volumes greater than 0.25 cu.mi. are rare, however. The largest eruptions of Mauna Loa volcano; in Hawaii, have produced flows with volumes of approximately 0.1 cu.mi., covering areas of more than 30 sq.mi. The greatest known flow of historic times was erupted in southern Iceland in 1783. It had a volume of approximately 2.9 cu.mi.

PYROCLASTIC ROCKS

The fragmental products of volcanic explosions are known as pyroclastic (from the Greek *pyr,* "fire," and *klastos,* "broken") rocks. Gas separating out of the magma as it approaches the earth's surface tends to expand and force its nay out of the enclosing liquid. Lavas of high fluidity exert little restraining effect on the gas, which is able to escape freely into the atmosphere, but from lavas of greater viscosity it escapes less readily. In highly viscous lavas the gas in the confined bubbles may attain so high a pressure that when it finally bursts its way free it produces a violent explosion. The explosion expansion of the gas may, in fact, completely disrupt the upper part of the column of rising magma, and eject it onto the earth's surface as a shower of fragments. In general, eruptions of fluid mafic magmas produce only small amounts of pyroclastic material in relation to the volume poured out as lava flows, whereas eruptions of viscous siliceous magmas may consist wholly of exploded material.

Depending on the strength of the explosion and the viscosity and degree of consolidation of the lava, the ejected fragments vary greatly in size, form and consistency. The relatively weak explosions characteristic of mafic magmas throw up showers of material so liquid that much of it is still molten when it strikes the ground. 'These still-molten fragments partly fuse together to form mounds of agglutinate. Less fluid lava forms accumulations of loose fragments of frothy material known as scoria, or cinder, because of its superficial resemblance to the cinder produced by burning coal in a furnace. (Neither volcanic cinder nor volcanic ash are, however, formed by combustion.) Commonly the mild explosions of mafic magma throw out long strings and blobs of liquid material that harden in the air to ribbonlike or droplike forms. The ribbons break up during flight or on striking the ground. Thicker portions of the ribbons often form spindle-shaped masses, or masses resembling in shape a summer squash. Threads of natural spun glass. formed by chilling of filaments of liquid lava drawn out behind blobs thrown out by explosion. are known as Pele's hair, after Pele, the Polynesian goddess of volcanoes.

More violent explosions of more viscous magma produce angular fragments that exhibit little or no evidence of shaping during flight. Some of the angular fragments are derived from a crust of semisolid or solid lava that forms on the top of the liquid, and others are pieces of older rock torn from the walls of the vent. The stronger explosions also produce much larger amounts of fine debris. Extreme vesiculation produces a rock froth knon-n as pumice (*q.v.*), which may be light enough to float readily in water.

Pyroclastic fragments commonly are classified principally on the basis of size. Fragments larger than $1\frac{1}{4}$ in. are known as volcanic bombs if they have rounded outlines acquired during flight, or as blocks if they are angular. Those between $1\frac{1}{4}$ and $\frac{1}{6}$ in. in average diameter are known as lapilli, and material smaller than $\frac{1}{6}$ in. constitutes volcanic ash and dust. When the mixture of volcanic ash and dust becomes lithified into a firm rock, it is called tuff (*q.v.*). Aggregations principally composed of bombs are called agglomerate (*q.v.*), and those of blocks are called breccia (*q.v.*). Cinder may contain fragments of all sizes, from ash to bombs.

A commonly overlooked agent of much importance in volcanic activity is mudflow. During violent eruptions large amounts of ash may accumulate on the slopes of the volcanic cone. and sometimes on nearby mountains. If this ash becomes saturated with water from heavy rains. it may rush down the mountainside at great speed, sometimes as much as 60 mi. an hour, sweeping with it all sorts of debris encountered in its path, and sometimes causing great damage to human property and life. The mudflow comes to rest as a deposit composed of a helter-skelter mixture of ash, blocks of old and new lava rock. tree trunks and other organic matter. Such mudflow deposits are extensive around the bases of many volcanoes, as for instance Mayon, in the Philippines.

VOLCANIC LAND FORMS

Flood **Basalts.**—Fluid mafic lavas usually erupt quietly, with little explosion, and the flows spread to great distances from the vents. In some parts of the earth such flows have been erupted over wide areas from innumerable fissures. These flood basalts have built broad nearly flat accumulations, sometimes called plateaus. although they are not always at high elevations. Such an area is the Columbia river plain east of the Cascade range in Oregon and Washington. There the Columbia river lavas cover an area of about 100,000 sq.mi., and have a volume of about 35,000 cu.mi. This stupendous accumulation consists of hundreds of flows, averaging between roo and zoo it. thick. As mentioned above, some individual flows cover areas of more than 1,000 sq.mi. Just to the east. the Snake river plain is a similar accumulation of somewhat younger lavas. Occasionally broadly rounded mounds on the surface of the plain mark the sources of the latest flows, but mostly the surface is only gently undulating and nearly horizontal. Other areas of flood basalts are in Patagonia, and in the Deccan region of India. A similar mass of nearly horizontal basalt flows once occupied much of the area of the northeastern Atlantic ocean. Remnants of it still can be seen in Scotland and Ireland, the Faeroes and Iceland.

Shield Volcanoes. — Where. instead of being widely scattered, repeated eruptions of fluid lava are concentrated in a restricted area, there results a gently sloping. broadly rounded cone of lava flows known as a shield volcano (because of a supposed resemblance in profile to the round shields of ancient Germanic warriors). Shield volcanoes range in size from small hills, a few tens of feet: high, to the largest individual mountains on earth. Thus Mauna Loa, a typical shield volcano forming part of the Island of Hawaii, has a bulk of about 10,000 cu.mi., and rises 30.000 ft. above its base at the sea floor. Small shield volcanoes may be built wholly by overflows at the summit of the heap, but the bigger ones are formed in large part by eruptions from series of fissures that extend down the flanks of the mountain. Shield volcanoes consist overwhelmingly of lava flows. Rows of spatter cones, formed of agglutinate, and small cinder cones form along the vent fissures and a few thin beds of ash lie between the lava flows, but pyroclastic material makes up at most only a few per cent of the bulk of the mountain.

Shield volcanoes are widely distributed over the earth. The classical examples are in Iceland. The great mountains that project above sea level as the Hawaiian Islands are principally shield volcanoes. Many small shield volcanoes are associated with thin widespread lava flows east of the Cascade range in southern Oregon and northeastern California.

Cinder Cones. — More explosive eruptions of mafic and intermediate lavas commonly build sizeable cinder cones at the heads of the flows. The falling cinder accumulates around the vent, gradually building a conical hill with a bowl-shaped crater at the top, and commonly a gap (breach) at one side through which

Centre left: Eruption in Mokuaweoweo, crater of Mauna Loa, Hawaii, 1940, showing fountains of incandescent lava spouting from the fissure. Such fountains may reach a height of several hundred feet

Centre right: Aerial view of a lateral vent in the Mauna Loa eruption of May 1942

Bottom left: Smooth, or pahoehoe, lava flow (foreground) partially covered by later aa, or clinkery, flow (background). Nyamlagira volcano, Belgian Congo, 1938 eruption

Bottom centre: Ropy surface of pahoehoe flow; Nyamlagira

Bottom right: Lava stream from Mauna Loa approaching village of Hoopuloa, Hawaii, during eruption of 1926. The village was completely destroyed escaped the lava to form the flow. However, the lava does not necessarily escape through a breach in the cone wall, but may pass under the side of the cone in a tunnel established before the cone was built or bored through the cone wall at a later date. The steepness of the outside of the cone is determined by the slope at which the loose cinder can stand in equilibrium. Cinder cones may be only a few tens of feet high, or they may grow to a height of 1,000 ft. or more, like that of Paricutin vblcano in Mexico. They are numerous in nearly all volcanic districts. Although they are composed of loose or only moderately consolidated cinder many of them are surprisingly enduring features of the landscape, because rain falling on them sinks into the highly permeable cinder instead of running off down their slopes to erode them.

Composite Volcanoes. — Most volcanoes consist of alternations of lava flows, poured out from the summit crater or from vents on the flanks of the cone, with layers of cinder, bombs, lapilli and ash. These are known as composite volcanoes. Typically, they form cone-shaped mountains that may be several thousand feet high, and have a volume of several tens of cubic miles. Thus the big composite volcanoes Rainier and Shasta in the Cascade range of northwestern United States rise respectively about 9,000 and 12,000 ft. above their bases, and attain altitudes of more than 14,000 ft. above sea level. Each has a bulk of nearly 100 cu.mi. Some composite volcanoes are graceful cones of unsurpassed beauty and grandeur. Shishaldin, in the Aleutian Islands, is one of these. Others are Mayon, in the Philippines, and Mt. Fuji in Japan. However, the construction of such perfect cones depends on a rarely attained combination of circumstances and most composite cones are far less regular than Fuji or Mayon.

Domes. — Lava reaching the earth's surface may be so viscous that it cannot flow away readily, and piles up around the vent to form a steep-sided mound known technically as'a volcanic dome. Sometimes domes are formed by repeated outpourings of short flows from a summit vent, and sometimes very viscous (but still liquid) lava is pushed up from the vent like a short protrusion of toothpaste from a slightly squeezed tube. Most commonly, however, the initial small extruded mass is gradually expanded by new lava being pushed up into its interior. Fractures forming in the chilled shell of the expanding dome may allow small flows to escape onto its flanks or around its base, but for the most part the growth is simply a slow swelling. As the dome grows the expanding crust breaks up, and pieces of it roll down to form a heap of angular rock fragments (breccia) around its base. Continued crumbling of the shell of the dome may result in a heap of debris that nearly buries the solid portion of the dome.

Domes are widespread in volcanic districts. They may grow in the summit craters of composite cones, in lateral craters, or completely away from any crater. The lava forming them is usually of siliceous character. Domes may attain heights of several hundred feet and diameters of several thousand feet. One of the largest known is the dome that makes up Lassen peak, in Lassen Volcanic National park, California. The Lassen dome is about 2 mi. in diameter at its base and more than 2,000 ft. high, with a volume of about $\frac{2}{5}$ cu.mi. The Chaos crags, just north of Lassen peak, are a row of spectacular domes formed within the last few hundred years. Explosions at the base of one of the domes undermined it and allowed it to collapse, forming the great hummocky landslide deposit known as the Chaos Jumbles.

Spines. — Commonly, lava is squeezed out through breaks in the carapace of the growing dome, much as metal is extruded through dies to make wire. If the lava is sufficiently viscous it forms relatively slender steep-sided projections known as spines. The surface of a dome may bristle with dozens of these spines, a few feet to a few tens of feet high. Rarely, much larger spines are formed. During the 1902 eruption of Mt. Pelée, on the Island of Martinique in the West Indies, a great spine was protruded from a growing dome in the summit crater of the volcano and within a few months rose to a height of nearly 1,000 ft. above the dome (which itself rose nearly 1,000 ft. above the crater floor). However, soon after it reached its maximum height, explosions around its base caused it to collapse. Like the great "needle" of Mt. Pelée, most spines are short-lived, soon crumbling to heaps of angular debris on the surface of the dome.

Craters and Calderas. — Thus far only features of positive relief have been considered, but volcanic land forms may also be negative. The commonest negative form is the crater. In a general sense, all more or less bowl-shaped volcanic depressions may be called craters, but in modern technical literature the term generally is restricted to the smaller depressions, up to about a mile in diameter. Larger depressions are termed *calderas* (meaning "caldron" in Spanish). Most craters are formed by explosion. They are found most commonly at the summit of volcanic cones, but others occur on the flanks of cones, or even wholly unassociated with cones. They may be blasted through the surface of the cone after the latter has been built, but more commonly they are formed over the vent during the formation of the cone. The showers of fragmental material fall back to earth around the vent, gradually building the cone, but directly above the vent the accumulation of material is prevented by the repeated explosions, and a crater in the cone is the result. In spatter cones the welded material stands at high angles, and the crater may have nearly vertical sides; but in cones of cinder or ash the loose material slides in to form the funnel shape typical of craters.

Of the craters not associated with cones, probably the best known are the many small craters blasted by low temperature volcanic explosions in the nearly horizontal nonvolcanic rocks of the Eifel (*q.v.*) region in Germany. Many of these contain beautiful little blue lakes, or *maare,* and the name *maar* has been widely applied to similar explosion craters in flat-lying rocks in other regions. The rim of ejected fragmental material around the crater often is very low and inconspicuous.

Calderas usually, if not always, form by collapse of the top of a volcanic cone or group of cones because of removal of the support formerly furnished by an underlying body of magma. In shield volcanoes of mafic lavas this removal of magma from a chamber beneath the top of the cone may result from eruption at some level low on the cone flank, or simply from intrusion into the lower part of the volcanic structure. The *calderas* of shield volcanoes are relatively small. That of Kilauea, in Hawaii, is 2.5 mi. long, 2 mi. wide and 500 ft. deep.

Larger *calderas* form by collapse of composite volcanoes. These result generally, if not always, from rapid emptying of the underlying magma reservoir by voluminous eruptions of pumice and pumiceous ash, thrown high in the air and scattered over the surrounding countryside or rushing down the slopes of the cone in fiery glowing avalanches. At the end of the eruptions the top of the mountain has disappeared, leaving in its place a great hole. It once was believed that the top of the mountain had been blown away by the explosions, but study of the material thrown out shows that only a little of the vanished part of the cone can be accounted for in that way. Most of it has simply dropped into the void left by the escaping magma. In 1883 Krakatoa (*q.v.*) volcano, in Indonesia, exploded in one of the most violent eruptions of historic times and its collapse formed a *caldera* on the sea floor (accompanied by giant tidal waves that took the lives of thousands of persons on the shores of neighbouring islands).

Other *calderas* are found in most of the major volcanic districts. One of the best known and best studied is that of Crater lake, in Oregon (*q.v.*). There, following the collapse, the great hole in the top of the mountain was gradually filled with water from rainfall and melting snow and renewed eruptions within it poured out lava flows and built the cinder cone of Wizard Island. The Crater lake *caldera* is about six miles in diameter. Probably the largest *caldera* yet described is that in the Jemez (Valle Grande) mountains of northwestern New Mexico, with an average diameter of more than 16 mi.

The term *caldera* generally is reserved for depressions of fairly regular, circular or oval outline. Their shape presumably is governed by the nearly circular horizontal cross section of the underlying body of magma. Other depressions. of markedly angular or irregular outline, also occur in volcanic districts, and commonly are of even larger size than *calderas.* Their angular outlines, and particularly angular re-entrants around their edges. indicate that their shape is governed by pre-existing tectonic structures, such as joints and faults resulting from deformation of the earth's crust, in the underlying older rocks. They therefore are referred to as volcano-tectonic depressions. As in the case of *calderas* of the Crater lake and Krakatoa type, their collapse appears to be at least partly related to the rapid extrusion of voluminous froth flows of siliceous lava, forming extensive deposits of welded tuff. Examples are the Rotorua-Taupo basin in New Zealand, and the basin of Lake Toba in Sumatra. each with an area of over 1.000 sq.mi. and associated with hundreds of cubic miles of welded tuff.

DISTRIBUTION OF VOLCANOES

Probably there is no part of the earth's surface that has not. at some time in the past. been the site of volcanic activity. Indeed, some regions such as the British Isles that we would hardly think of today as volcanic have formerly experienced violent and long-continued volcanic activity.

At present, however, the active and recently active volcanoes are concentrated largely in a great belt encircling the Pacific ocean and a shorter belt extending from the Solomon Islands through New Guinea and Indonesia. The active volcanoes of the Mediterranean region often are regarded as lying on an extension of the latter belt. The greatest concentration of active volcanoes in the world is in Indonesia. where 78 have erupted within historic time and 29 others are still actively giving off gas at fumaroles and solfataras (see VOLCANISM). Of the Indonesian volcanoes probably the best known is Merapi, the "Fire mountain" of central Java, glowing avalanches and mudflows from which have taken thousands of lives. Both the circumpacific and the Indonesian belts of volcanoes correspond with zones of active orogeny, in which the earth's crust has been crumpled and heaved up into mountains during recent geologic times.

Many other active and recently extinct volcanoes are scattered over the earth's surface outside these two main belts. In the Pacific basin they are found in the Hawaiian, Samoan and Galapagos islands; in the Atlantic basin in Iceland, the Azores, the Canary and Cape Verde islands; in the Indian ocean in Réunion, Heard and Kartala islands. The Italian district includes the famous volcanoes Vesuvius, Stromboli and Etna, as well as the one that gave its name to all the rest—Vulcano. Farther east. Santorini lies in the Grecian archipelago. and the less well-known Argaeus and Nimrud are found in the mountains of Asia Minor. Ararat, of Biblical fame, is an extinct volcano. In Africa, volcanoes are associated with the great rift valleys. in which lie lakes Albert, Tanganyika and Rudolf; and others lie near the Red sea, and far to the west in the Cameroons. Even ice-bound Antarctica has its active volcano, Aft. Erebus, on the edge of McMurdo sound.

The continental United States is commonly thought of as immune from volcanic activity, but actually the Cascade range in the northwestern part of the country is part of the circumpacific "ring of fire" and contains many recently extinct volcanoes and several that should be considered active. The tremendous eruption that produced Crater lake occurred only about 6,000 years ago. About a dozen eruptions can be counted in the Cascade range since the early part of the 19th century. The most recent of these, at Lassen peak. California, during the years 1914 to 1917, produced violent explosions, great glowing avalanches, flows of mud and a small lava flow.

VOLCANO ISLANDS (KAZAN-RETTO), three small volcanic islands in the western Pacific ocean, located south of the Bonins and north of the Marianas between 24° and 26° N. and 141° and 143° E. In north-south sequence, they are Kita-Iō-jima (San Alexander). Iō-jima (Sulfur) and Minami-Iō-jima (San Augustine). Unclaimed until the arrival of Japanese fishermen and sulfur miners in 1887. they were claimed formally by Japan in 1891.

Iō-jima (usually appearing in English as Iwo Jima) is the largest (20 sq km.; 11.5 sq.mi) and has a large stretch of level land that was converted into a military airfield during World War II. It was captured from the Japanese by U.S. forces in 1945 after a bloody assault. The few Japanese residents were removed to Japan in 1944. Under the Japanese peace treaty (1951), the U.S. exercises full poner and jurisdiction over the islands, with Japan retaining residual sovereignty. See IWO JIMA. (J. D. EE.)

VOLE, a name employed for several genera of rodents allied to the rats and mice and included in the family Muridae. The two common English forms are better known as the water rat and the short-tailed field mouse. Voles may be distinguished from rats and mice by their small eyes, blunt snouts. stouter build. inconspicuous ears. short limbs and tail and less brisk movements. They also differ in the structure of the cheek teeth. The European field vole (*Microtus agrestis*) is about the size of a mouse and does considerable damage to crops and garden produce. The water vole (*M. amphibius*) is larger, diurnal and aquatic. Largely vegetarian. it will also eat insects. mice and young birds. It is absent from Ireland, but extends from England to China. Numerous other species occur in Europe. north Asia and North America, while fossil voles occur in the Pliocene. (*See* RODENTIA.)

VOLENDAM, a small fishing village of the Netherlands in the province of North Holland. adjoining Edam. It is remarkable for its quaint buildings and the picturesque costume of the villagers, who are of a singularly dark and robust type. Many artists have been attracted to settle here. Volendam had its origin in the building of the great sea dam for the new waterway to Edam in the middle of the 14th century. On the seaward side of the dike are some houses built on piles in the style of lake dwellings. Pop. (1957 est.) 9,477.

VOLGA (Tatar: Etil, Itil or Atel; Finnish: Rsu; in ancient times Rha and Oarus), the longest and most important. river of European Russia, and the longest river of Europe. Its length is 2.293 mi.; its drainage area covers 532,818 sq.mi. and includes middle and eastern Russia. as well as part of southeastern Russia. The Volga rises on the Valdai plateau at a height of 665 ft., in a small spring in 57° 15' N., 32° 30' E., west of Lake Seliger, flows through several small lakes, and after its confluence with the Runa. enters Lake Volga. Below that lake is a dam storing 10,000.000.000 cu.ft. of water, making possible the deepening of the channel as far as the Sheksna during dry periods. After receiving the Sheksna the Volga flows southeast along a broad valley, consisting of a string of former wide lake beds, with a depth of 150–200 ft., in Permian and Jurassic deposits. It receives numerous tributaries from the north including the Unzha (339 mi.). The Oka from the southwest (605 mi.) rises in Orel, near the sources of tributaries of the Don and Dnieper, and receives the Upa, Zhizdra. Ugra, Moskva and Klyazma (left), and the Tsna with the Moksha (right).

The Oka and Volga unite at Nizhniy-Novgorod, and the Volga then enters a broad lacustrine depression which must have communicated with the Caspian in postpliocene times. Its low-water level in this section is only 190 ft. above sea level. and its width ranges from 350 to 1,750 yd. Islands appear and disappear each year after the spring floods. The Sura. bringing a volume of 2,700 to 22.000 cu.ft. per second enters on the right, as do the Svyaga and many smaller tributaries. The Volga then turns southeastward and descends into another lacustrine depression, receiving the Kama, volume 52,500 to 144,400 cu.ft. per second. below Kazan, along which come the products of the Ural mining region. Remains of molluscs still extant in the Caspian occur in this depression and in the lower Kama. The Volga then flows south-southwest, making a great bend at Samara to avoid the Zheguli extension of the Russian plateau. The Volga at Samara is only 54 ft. above sea level. Along the whole of the bend, cliffs fringe the right bank, which the river is constantly undercutting, while from the left bank extends a great plain intersected by former channels of the river. At Volgograd (Tsaritsyn) the river reaches its extreme southwestern limit and is only 45 mi. from the Don. In 1928 the Soviet government accepted estimates for the construction of a canal with sluices on the Don, to link these two rivers; the canal was completed in 1951. The river then turns sharply to the southeast, flowing through the low Caspian steppes. A few miles above Volgograd it sends off a branch, the Akhtuba, which accompanies it to the' sea for 330 mi. Low hills skirt the right bank, but on the left it anastomoses freely with the Akhtuba and often floods the country for 15 to 35 mi.

Efforts are being made to control the Volga there to lessen the annual washing away of fertile alluvial gardens. The delta begins 40 mi. above Astrakhan and contains about 200 mouths. The Volga is constantly eroding its banks, especially during the spring floods, and towns and loading ports are constantly being moved back, consequently the volume of suspended matter deposited on the Caspian shores is great; the level of that sea rises during the Volga floods.

Navigation. — Thereare six sections of the river for navigation. (1) From the Upper Volga dam, 75 mi. from the source, to Tver. There rapids and shallows are numerous, and this part is exclusively used for floating rafts. (2) From Tver to Rybinsk, which is the real head of Volga navigation. In this section the main traffic consists of barges for local trade; to June 20, vessels drawing 2 ft. may use the river, but after that date 1 ft. 9 in. is the maximum possible draft, and the river becomes increasingly shallow, so that navigation may cease altogether. The influence of the Upper Volga dam may give an extra 9 in. of depth. Above Rybinsk the Volga is joined by the Mologa, and at Rybinsk by the Sheksna, which is navigable and which is linked by the Marii and Württemberg canals with the basins of the Neva and Northern Dwina respectively. Fifteen thousand vessels entered the port per annum. (3) From Rybinsk to Nizhniy-Novgorod, 349 mi., the normal draught of vessels is 3 ft. 6 in., but in years of low water, navigation may be completely suspended in July and August. In this section are 30 commercial landing stages and 20 harbours suitable for wintering vessels. (4) From Nizhniy-Novgorod to Kazan, 299 mi., the normal draught is 5 ft. There are 40 commercial landing stages and 40 harbours, only 10 of the latter being really iceproof. (5) Kazan to Volgograd, 938 mi., normal draught 7 ft. There are 37 commercial landing stages and 28 harbours, 6 of which are really safe and iceproof. (6) Volgograd to the Caspian is divided into two parts (i.) Volgograd to Astrakhan, 343 mi. where the navigation is still of the river type and (ii.) Astrakhan to the Caspian, 71 mi., a stretch of nontidal estuary, difficult for navigation, where continuous dredging is necessary to ensure even 8-ft. depth.

The great drawbacks to navigation are (1) the long winter frost, during which the river and its tributaries become sledge routes, the ice lasting from 90 to 160 days; the average date of breakup of ice is April 11 at Tver, the 25th at Kostroma, the 16th at Kazan, the 7th at Volgograd and March 17 at Astrakhan (2) the shallowness of the river during late summer and the frequent formation of islands and their dissolution during flood time.

Fisheries. — The network of shallow and still *limans* or cutoffs in the delta of the Volga and the shallow waters of the northern Caspian, freshened as these are by the water of the Volga, the Ural, the Kura and the Terek, is exceedingly favourable to the breeding of fish, and as a whole constitutes one of the most productive fishing grounds in the world. As soon as the ice breaks up in the delta innumerable shoals of roach (Leuciscus *rutilus*) and trout (*Lucio-trutta leucichthys*) rush up the river. They are followed by the great sturgeon (Acipenser hztso), the pike, the bream and the pike perch (*Leucioperca* sandra). Later on appears the Caspian herring (*Clupea* caspia). which formerly was neglected, but has now become more important than sturgeon; the sturgeon A. *stellatus* and "wels" (*Silurus glanis*) follow, and finally the sturgeon Acipenser giildenstadtii, so much valued for its caviare. In search of a gravelly spawning ground the sturgeon go up the river as far as Sarepta (250 mi.). The lamprey, extensively pickled, the sterlet (*A.* ruthenus), the tench, the gudgeon and other fluvial species also appear in immense numbers.

History. — The Volga was probably known to the early Greeks, though it is not mentioned previous to Ptolemy. According to him, the Rha is a tributary of an interior sea, formed from the confluence of two great rivers, the sources of which are separated by 20° of longitude. The Arab geographers throw little light on the condition of the Volga during the great migrations of the 3rd century, or subsequently under the invasion of the Huns, the growth of the Khazar empire in the southern steppes and of that of Bulgaria on the middle Volga. In the 9th century the Volga basin was occupied by Finnish tribes in the north and by Khazars and various Turkish races in the south. The Slavs, driven perhaps to the west. had only the Volkhov and the Dnieper, while the (Mohammedan) Bulgarian empire, at the confluence of the Volga with the Kama, was so powerful that for some time it was an open question whether Islam or Christianity would gain the upper hand, and Islam is strong in modern Kazan. But, while the Russians were driven from the Black sea by the Khazars, and later on by a tide of Ugrian migration from the northeast, a stream of Slavs moved slowly toward the northeast. down the upper Oka, into the borderland between the Finnish and Turkish regions. After two centuries of struggle the Russians succeeded in colonizing the fertile valleys of the Oka basin; in the 12th century they built a series of fortified towns on the Oka and Klyazma; and finally they reached the mouth of the Oka, there founding (in 1222) a new Novgorod — the Novgorod of the Lowlands, now Nizhniy-Novgorod. The great lacustrine depression of the middle Volga was thus reached; and when the Mongol invasion of 1239–42 came, it encountered in the Oka basin a dense agricultural population with many fortified and wealthy towns — a population which the Mongols found they could conquer, but were unable to drive before them as they had done so many of the Turkish tribes. This invasion checked, but did not stop, the advance of the Russians down the Volga. Two centuries elapsed before the Russians covered the 300 mi. which separate the mouths of the Oka and the Kama and took possession of Kazan.

With the capture of Kazan (1552) the Russians found the lower Volga open to their boats, and eight years afterward they were masters of the mouth of the river at Astrakhan. Two centuries more elapsed before the Russians secured a free passage to the Black sea and became masters of the Sea of Azov and the Crimea; the Volga, however, was their route.

VOLGOGRAD (STALINGRAD until 1961) oblast of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies in the lower Volga region and covers an area of 44,054 sq.mi. Pop. (1959) 1,853,928. Both the Volga and Don cross the oblast. The Volga there has no significant tributaries, but below Volgograd its course is paralleled by its main distributary, the Akhtuba, with a broad flood plain of innumerable old courses and cut-off lakes in between. The northern part of the *oblast* is drained by tributaries of the Don, notably the Khoper, Buzuluk, Medveditsa and Ilovlya. Within the oblast are parts of the Tsymlyansk reservoir on the Don and the Volga reservoir (Volzhskoye Vodokhranilishche) on the Volga. The Volga is flanked on the west by the Volga Uplands, which reach 1,178 ft. in the north. South of Volgograd the line of the upland is continued as the Yergeni. West of the Khoper and Don are further low uplands which represent the extreme southeastern extension of the Central Russian Upland. Between the uplands and again east of the Volga are level plains. The climate is dry and continental; the annual rainfall varies from 14 in. in the west to 12 in. in the east and is irregular, with frequent droughts. Summers are hot, with July average temperatures about 75° F. In early summer scorching sukhovei winds are common. January temperatures average about 15°. Most of the oblast lies in the dry steppe zone, with a natural vegetation of grass and some sage on chernozem soils, and has almost all been plowed. This has given rise to severe soil erosion and gullying, especially on the uplands. Saline soils are common, particularly in the Trans-Volga (Zavolzhye) and the south. Forests occur only as groves on the flood plains; shelter belts have been planted round the Tsymlyansk reservoir.

More than half the population are urban dwellers living in 13 towns and 24 urban districts; over half of these live in the administrative centre of Volgograd. Other towns are small, the largest being Kamyshin (55,000), a river port on the Volga, and Volzhski (67,000), an entirely new town built across the Volga from Volgograd in connection with the barrage. The bulk of the population lives along the rivers and in the northern lowland. Industry is largely concentrated in Volgograd, the other towns being chiefly concerned with processing agricultural products. Petroleum is obtained in the extreme north round Bakhmet'yevka and Zhirnovsk and at Frolovo, northwest of Volgograd, where it occurs together with natural gas. China clays are widespread, as are building sands and glass sands. Salt is obtained from Lake El'ton in the Trans-Volga.

Agriculture is of great importance, but it suffers severely from the climatic conditions and soil erosion. Irrigation is needed but by the early 1960s had been little developed outside the Volga-Akhtuba flood plain and the neighbourhood of the Tsymlyansk reservoir. The waters of the Volgograd reservoir were also intended to serve this purpose. The chief crop is wheat, mostly spring wheat, but there is winter wheat also. Millet, maize (corn) and sunflowers are widely grown, while the *oblast* is part of the main area for mustard in the U.S.S.R. Along the Volga uplands north of Volgograd market gardening (especially fruit, melons and other vegetables) and dairying are well developed. In the south and the Trans-Volga cattle and sheep rearing is important.

The region was occupied in the 5th century by the Finno-Turkic Bulgars, who were in the 10th century driven northward by the Khazars. Later it formed part of the empire of the Tatar Golden Horde, one section of which was incorporated in the khanate of Astrakhan. The Russians in 1557 conquered Astrakhan and in 1589 erected the fort of Tsaritsyn (the present Volgograd), but the real absorption of the region into Russia involved a century of struggle nith the nomads of the Volga. In the reign of Catherine II, the Russian peasants. Cossacks and dissatisfied native tribes rebelled (1773–75) under the leadership of E. I. Pugachev. After the 1917 revolution there was much disorder in the region before it was pacified. It was formerly a *krai* (territory) containing Ralmyk Autonomous *oblnst* until it was created Stalingrad *oblast* in 1936. The Germans occupied part of the area during R'orld War II. (R. A F.)

VOLGOGRAD (TSARITSYN until 1925 and STALINGRAD until 1961), a city and *oblnst* centre of the Russian Soviet Federated Socialist Republic. U.S.S R., stands on the high right bank of the Volga, where its course makes a bend from south-southwest to southeast, 580 mi. E. of Moscow. Pop. (1959) 591.000. Tsaritsyn was established in 1589, soon after the Russian conquest of the banks of the Volga, as a fortress to protect the newly acquired lands. It soon became a major transshipment point for goods portaged across the narrow neck of land which there separates the Volga and Don. Suleiman the Magnificent and Peter the Great both planned to link the rivers by a canal. In 1918. during the Civil War, a major engagement was fought there between the Red and the White armies. which prevented the forces of Adm. A. V. Rolchak and Gen. A. I. Denikin from joining up. The town was named Stalingrad after J. V. Stalin, who organized its defense. One of the decisive battles of World War II took place there, when the Germans, at the limit of their advance, attempted from Aug. 1942 to Feb. 1943 to capture the town and cross the Volga. After bitter fighting in Stalingrad itself, which reduced the city to rubble, the German salient was cut off and an entire army group of 350.000 men annihilated. In 1943 a sword of honour was presented to the "steel-hearted citizens of Stalingrad" by King George VI in token of the homage of the British people. Rebuilt and repopulated after the war, the town's importance greatly increased by the opening (1952) of the Volga-Don canal, immediately to the south, and by the completion (1960) of the giant barrage and 2,500,000-kw. hydroelectric station on the Volga immediately to the north.

Following the denunciation of Stalin, the town was renamed Volgograd in 1961. The modern city and its suburbs extend for nearly 40 mi. along the Volga. Its industries include metallurgy, with the "Red October" steel plant and engineering works, producing tractors, excavators, petroleum equipment and steel cables. There is a large shipyard. Sawmilling and timber-working use logs rafted down the Volga. Building materials produced include cement, ferroconcrete items, bricks, tiles and fireproof materials. Agricultural products of the region provide the raw material for leather and footwear, clothing, canning, jam making. flour milling, brewing, distilling, butter- and fat-making industries. Natural gas, exploited locally from 1953, and by-products from the oil refinery built in 1957 serve as the basis for a new but rapidly growing chemical industry. Railways link Volgograd to Moscow. Saratov, Astrakhan. Krasnodar and the Donets Basin. There are institutes of medicine. civil engineering. teaching, mechanics and municipal economics in the city. (R. A. F.)

VOLHYNIA, formerly a province of Poland. having on the north the province of Polesie, on the west Lublin, on the south Tarnopol provinces, and on the east Russia. It now forms a part of the Volyn *oblast* in the Ukrainian Soviet Socialist Republic, U.S.S.R. Area, 7,683 sq.mi.

It is a plain. washed by the Bug and the tributaries of the Prypet, viz., the Turija. Stochod, Styr, Goryn and Slucz, flowing north from the southern uplands. The north is part of the Polesian forest area, the rest is fertile soil. The chief towns are Luck, Ostróg, Rowno, Dubno, Kowel and Krzemieniec. Pop. (1959) 890,456.

VOLITION, in psychology. *See* FREE WILL; PSYCHOLOGY.

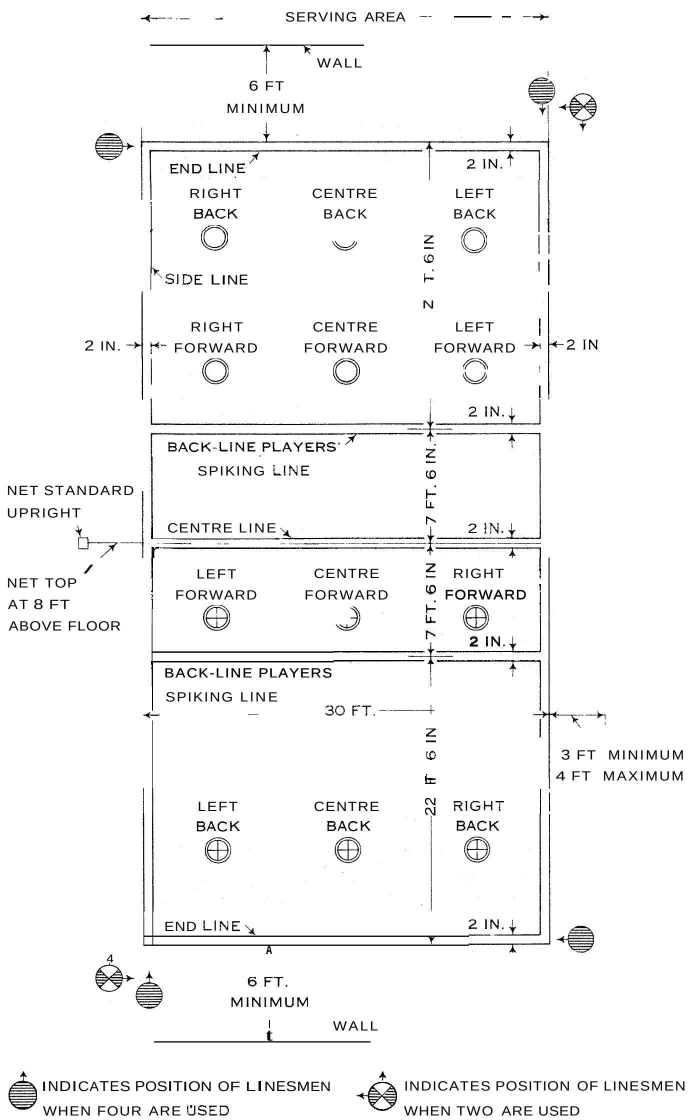
VOLLEYBALL, a game between two teams of players in which a large inflated ball. 26 or 27 in. in circumference, is batted ("volleyed") back and forth across a net, without touching the ground. The game was originated in the United States in 1895 by William G. Morgan while he was physical director at the Young Men's Christian association of Holyoke. Mass. Designed as an indoor sport for businessmen who found basketball too vigorous, it soon proved to have much wider appeal and was introduced into schools, playgrounds and other organizations in the C.S. and foreign countries. World Wars I and II also helped popularize it.

The first rules for the game were written by Mr. Morgan and printed in the first edition of the *Handbook of the Athletic League of the Y.M.C.A.s of North America* (1897). In 1916 rules were issued jointly by the Y.M.C.A. and the National Collegiate Athletic association in the Spalding Blue Cover series. In 1922 the first national U.S. tournament was conducted by the Brooklyn Central Y.M.C.A. of New York.

The United States Volleyball association (U.S.V.B.A.) was formed in 1928 and was recognized as the rules-making governing body in the U.S. The International Volleyball federation was organized in 1947. World volleyball championships (for men in Prague. Czechoslovakia, 1949; for men and women in Moscow, 1952; and in Paris, 1956) did much to standardize and unify playing rules and officiating. In 1957 volleyball was accepted by the International Olympic committee as one of the approved sports for Olympic competition.

The Game.——Volleyball can be played indoors or outside, requires a minimum of space and equipment and can be played by both sexes. The following description is based on the official game as defined in the U.S.V.B.A. rules (the International rules, used in Great Britain, differ only in minor details).

The game is played on a smooth surface on a court 30 ft. wide by 60 ft. long. clearly marked with 2-in. lines. (The lines are placed within the court.) A centre line divides the court into two 30 x 30 ft. spaces. one of which is selected by or assigned to each of the two competing teams. Players may step on but not beyond the centre line. A line $7\frac{1}{2}$ ft. from and parallel to the centre line is marked in each half of the court to indicate the point in front of which a back court player may not stand to drive the ball over the net with great power. (In official U.S.V.B.A. games the drive, "spike" or "kill!' may be performed by players only when they are in the three forward positions. In many recreational games this rule need not apply and the line is therefore omitted from the court.) A tightly stretched net, 3 ft. wide and 32 ft. long, is placed across the court exactly above the centre line; official heights are 8 ft. for men, 7 ft. 6 in. for women and high school students and 7 ft. for younger players. A 2-in. vertical tape marker should be placed across the full width of the net directly above each side boundary line of the court. These markers enable the officials to determine whether served or played balls are legal.



BY COURTESY OF U S VOLLEYBALL ASSOCIATION AND NATIONAL BOARD OF YOUNG MEN S CHRISTIAN ASSOCIATIONS

STANDARD VOLLEYBALL COURT, SHOWING POSITIONS OF PLAYERS. THE COURT IS 60 FT. BY 30 FT.

A minimum space 6 ft. wide around the entire court is needed to permit freedom of action, eliminate hazards from obstructions and allow space for net support posts and the referee's stand. There should be a clear area above the court at least 20 ft. high to permit the ball to be served or received by a team and played across the net without obstruction.

U.S.V.B.A. rules stipulate that the ball should be spherical and have a rubber bladder with a 12-piece laceless leather case or a rubber case, weigh not less than 9 nor more than 10 oz., be inflated to a pressure of not less than 7 nor more than 8 lb. if leather cased or not less than 5 nor more than 7 lb. if rubber cased. It should be balanced to provide smooth flight through the air.

A team consists of six players who take general positions in two rows. Positions in the row closer to and facing the net are left forward, centre forward and right forward. Positions of the second row of players are left back, centre back and right back. (In recreational games where there are more than six on a team, players may be arranged in three rows.) At the start of a match the two team captains draw lots for choice of serve or court. Play is started when the right back of the serving team steps outside his back line and bats the ball with a hand, fist or arm over the net into the opponents' half of the court. The opponents must receive the ball and return it across the net in a series of not more than three contacts with the ball. The ball must not touch the floor, and a player may not touch the ball twice in succession. (This neans that the ball may be returned by a single player or may be played by two or three players in the process of returning it.) A player continues to serve until his team makes an error, commits a foul or completes a game. When the service changes ("side out") the receiving team becomes the serving team and its players rotate clocknise one position; the right forward shifting to the right back position and then serving from any place behind the rear line. Only the serving team can score, points being awarded for errors and fouls of the receiving team such as hitting the ball out of bounds. failing to return the ball, etc. No point is awarded when "side out" is declared. Only one point at a time is scored for a successful play.

A game is won by the team that first scores 15 points or has scored the most points after 8 min. of play, whichever occurs first, provided the ninning team is ahead by 2 or more points. If a winner has not been determined at the end of 8 min., play continues regardless of time until a 2-point lead has been gained by one team. A match is two games out of three.

BIBLIOGRAPHY —*Official Volleyball Guide,* published annually by U.S.V.B A., contains the official rules for the U.S. and Canada, notes on International rules that differ and articles on the game. The Division for Girls and Women's Sports of the American Association for Health, Physical Education and Recreation publishes *Volleyball Guide* biannually Both include bibliographies and lists of audio-visual teaching aids.

VOLNEY, CONSTANTIN FRANÇOIS CHASSEBOEUF, COMTE DE (1757–1820), French savant, was born at Craon (Maine-et-Loire) on Feb. 3, 1757, of good family. He was at first surnamed Boisgirais from his father's estate, but afterward assumed the name of Volney. He spent about four years in Egypt and Syria, and published his *Voyage en Egypte et en Syrie* in 1787, and his *Considérations sur la guerre actuelle des Turcs* in 1788. He was a member both of the States-General and of the Constituent Assembly. In 1791 appeared *Les Ruines,* ou *méditations sur les révolutions des empires,* an essay on the philosophy of history. Volney tried to put his politico-economic theories into practice in Corsica. where in 1792 he bought an estate. He was thrown into prison during the Jacobin triumph, but escaped the guillotine.

In 1795 he undertook a journey to the United States, where he was accused in 1797 of being a French spy sent to prepare for the reoccugation of Louisiana by France. He was obliged to return to France in 1798. The results of his travels took form in his *Tableau du climat et du sol des États-Unis* (1803). He was not a partisan of Napoleon, but, being a moderate man, a savant and a liberal, was impressed into service by him and eventually made a count and put into the senate. At the restoration Volney was made a peer of France. He became a member of the institute in 1795. He died in Paris on April 25. 1820.

VOLO (VÓLOS), a seaport of Greece, on the east coast of Thessaly, at the head of the gulf to which it gives its name. Pop. (1951) 51.144. It is connected by rail nith the Athens-Salonika railway at Larissa (Lárisa). The anchorage is safe, vessels loading and discharging by lighters. The *Kastro* (citadel) marks the site of Pagasae. whence the gulf took the name of Sinus Pagasaeus or Pagasicus. There the Argonautic expedition was said to have sailed. In the 4th century it flourished under the tyrant Jason of Pherae. Two miles south stand the ruins of Demetrias. one of the "Fetters of Greece." founded 290 B.C. by Demetrius Poliorcetes and a favourite residence of Macedonian kings.

VOLOGAESES, or VOLOGASES, the name of five Parthian kings.

VOLOGAESES I, son of Vonones II by a Greek concubine, succeeded his father in A.D. 51. He gave the kingdom of Media Atropatene to his brother Pacorus and occupied Armenia for another brother, Tiridates. This led to a long war with Rome

(54–63), which was ably conducted by the Roman general Corbulo. The power of Vologaeses was weakened by an attack by the nomadic Dahae and Sacae, a rebellion of the Hyrcanians and the usurpation of his son Vardanes II. At last a peace was concluded, by which Tiridates was acknowledged as king of Armenia, but had to become a vassal of the Romans; he went to Rome, where Nero gave him back the diadem; from that time an Arsacid dynasty ruled in Armenia under Roman supremacy. Vologaeses was satisfied with this result and honoured the memory of Nero, though he stood in good relations with Vespasian also, to whom he offered an army of 40,000 archers in the war against Vitellius.

Soon afterward the Alani invaded Media and Armenia; Vologaeses applied in vain for help to Vespasian. It appears that the Persian losses in the east also could not be repaired; Hyrcania remained an independent kingdom. Vologaeses I died in 79/80. His reign is marked by a decided reaction against Hellenism; he built Vologaesocerta (Balashkert) in the neighbourhood of Ctesiphon with the intention of drawing to this new town the inhabitants of the Greek city Seleucia.

VOLOGAESES II appears in history in 1051106 as one of the rival claimants to the throne of the Parthian king Pacorus. He seems to have been able to persist in this claim throughout the reign of Osroes, on whose death in 128/129 the greater part at least of the succession was secured to him. He maintained himself against another rival, Mithradates, and died in 147.

VOLOGAESES III came to the throne in 148. Under him, the unity of the empire was restored, but he was attacked by the Romans under Marcus Aurelius and Verus (162–165). In this war Seleucia was destroyed and the palace of Ctesiphon burned down by Avidius Cassius (164); the Romans even advanced into Media. In the peace, northwestern Mesopotamia was ceded to the Romans. Vologaeses III died in 192. He is probably the king Volgash of the Parsee tradition, preserved in the *Dinkart,* who gathered the writings of Zoroaster.

VOLOGAESES IV first appears in 191 as a rebel against Vologaeses III, whom he succeeded in 192. He was attacked by Septimius Severus in 195, who advanced into Mesopotamia, occupied Nisibis and plundered Ctesiphon (199), but attempted in vain to conquer Hatra; in 202 peace was restored. He died in 2071208.

VOLOGAESES V succeeded his father Vologaeses IV in 2071208. Soon after his accession his brother Artabanus V, the last Arsacid king, rebelled against him and became master of the greater part of the empire. But Vologaeses V maintained himself in a part of Babylonia; his dated coins reach down to A.D. 222/223.

See further PERSIA: *History: The Parthian Empire; N. C.* Debevoise, *A Political History of Parthia (1938).*

VOLOGDA, an *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R. Area 56,178 sq.mi. Pop. (1959) 1,307,000. The *oblasts* of Archangel, Gorky, Yaroslavl, Kalinin and Leningrad fringe it, as does the Karelian Autonomous Soviet Socialist Republic. Much of it was under ice during the Glacial epoch, and it is a region of boulder clay, marsh, lakes and streams. The largest lakes are Kubensk and Lacha, and the rivers include the Sukhona, flowing northwest from Lake Kubensk, and the upper course of the Onega and of the Vaga, both flowing northward, the former into the Arctic ocean and the latter joining the northern Dvina. Nearly half of the region is covered with coniferous forest, densest in the north, and there are vast marshes. The south has been largely cleared of forest and in spite of the poor soil and difficult climatic conditions, crops are raised.

The chief crops are winter rye and oats. Barley, flax, potatoes, summer wheat, grasses, peas and hemp are also grown in small quantities. Cultivation provides 30% of the region's income, stock raising and its dependent industries, 40%. Dairy cattle, of the Kholmogory breed in the north and Yaroslavl in the south, are raised. Horses, sheep and pigs are also raised. Poultry raising was being developed. The timber industry is well developed; there are paper manufactures and cellulose and wood pulp factories. The Sukhona is a navigable waterway linking with the northern Dvina, and there is a canal linking Lake Kubensk with the Sheksna.

Vologda.—Vologda is the chief town of the *oblast,* on the Vologda river above its confluence with the navigable Sukhona river, 59° 14' N., 39° 43' E. Pop. (1959) 138.000. The town has railway and steamer repair yards, manufactures agricultural implements, leather, beer, pottery, glass and cement. It grew rapidly after the railway developed, and numerous local products are exported to Archangel, Leningrad and Moscow.

Its trade is very ancient; it was founded as a colony of Novgorod in 1147, when the fur trade was at its height. The Tatars, in alliance with the prince of Tver, plundered it in 1273, but it soon recovered. Moscow and Novgorod disputed possession of it until 1447, when it was definitely annexed to the former. The opening of Archangel as a port in 1553 made it the chief depot for goods for the north. It was devastated by the Poles in 1613 and by plague in 1648. With the foundation in 1703 of St. Petersburg (Leningrad) trade went via the Baltic and Vologda declined, but developed again after the building of the railway to Archangel.

VOLSCI, ancient Italian people who were prominent in the history of the first century of the Roman republic. They then inhabited the partly hilly, partly marshy district of the S. of Latium, bounded by the Aurunci and Samnites on the S., the Hernici on the E., and stretching roughly from Norba and Cora in the N. to Antium in the S. They were among the most dangerous enemies of Rome, and frequently allied with the Aequi (*q.v.*). From the little town of Velitrae (Velletri) in the Volscian territory, the birthplace of Augustus, comes a very interesting though brief inscription dating probably from early in the 3rd century B.C. It is cut upon a small bronze plate (now in the Naples museum), which must have once been fixed to some votive object.

The name *Volsci* belongs to the -CO- group of tribal names in the centre, and mainly on the west coast, of Italy, all of whom were subdued by the Romani before the end of the 4th century B.C.; and many of whom were conquered by the Samnites about a century or more earlier. They are, from south to north, *Osci, Aurunci, Hernici, Marruci, Falisci;* with these were no doubt associated the original inhabitants of *Aricia* and of *Sidici-num,* of *Vescia* among the *Aurunci,* and of *Labici* close to Hernican territory. The same formative element appears in the adjective *Mons Massicus,* and the names *Glanica* and *Marica* belonging to the Auruncan district, with *Graviscae* in south Etruria, and a few other names in central Italy. With these names must clearly be judged the forms *Tusci* and *Etrusci,* the names given to the Etruscans by the folk among whom they settled. The Samnite and Roman conquerors tended to impose the form of their own group-name, namely the suffix -NO-, upon the tribes they conquered; hence the *Marruci* became the *Marrucini,* the *Arici* became *Aricini.* The conclusion suggested is that these -CO- tribes occupied the centre and west coast of Italy at the time of the Etruscan invasion; whereas the -NO- tribes only reached this part of Italy, or at least only became dominant there, long after the Etruscans had settled in the peninsula.

In the name *Volsci,* the older form *Volusci* contains the word meaning "marsh," since the change of *velos-* to *volus-* is phonetically regular in Latin. The name *Marīca* ("goddess of the salt-marshes") among the Aurunci also appears on the coast of Picenum and among the Ligurians; Stephanus of Byzantium identified the Osci with the Siculi who were kinsmen of the Ligures. In marshy places this *-co-* or *-ca-* suffix is used. Besides the *Aurunci, dea Marica* and *intempestaeque Graviscae* (Virg., *Aen.*, x, 184), we have the *Ustica cubans* of Horace *(Odes,* i, 17, 11), the *Hernici* in the Trerus valley, *Satricum* and *Glanica* in the Pomptine marshes. *See* ITALIC DIALECTS.

VOLSINII, an ancient town of Etruria, Italy. The older Volsinii occupied in all probability the isolated tufa rock, so strongly defended by nature, upon which in Roman times stood the town which Procopius calls Ourbibentos *(Urbs vetus,* the modern Orvieto). It had, and needed, no outer walls, being surrounded on all sides except the southwest by abrupt tufa cliffs; but a massive wall found by excavation on the southwest side of the town may have belonged to the acropolis. An Etruscan temple of the 4th century B.C. stood near the northeast extremity of the plateau. It measured 72 by 54 ft. and had three *cellae;* and at the foot of the hill on the north a large Etruscan necropolis was found dating from the 5th century B.C. The tombs, constructed of blocks of stone and arranged in rows divided by passages, often had the name of the deceased on the façade. Many painted vases, etc., were found; some were placed in the Museo Civico at Orvieto. Tombs with paintings were also found at Settecamini to the southwest of the town on the way to Bolsena. Volsinii was reputed the richest of the 12 cities of Etruria. Wars between Volsinii and Rome are mentioned in 392, 308 and 294 B.C. Zonaras states that the city was destroyed by Fulvius Flaccus in 265-264 B.C. and removed elsewhere, though the old site continued to be inhabited. The new city was certainly situated on the hills on the northeast bank of the Lake of Bolsena (*Lacus Volsiniensis*), 12 mi. W.S.W. of Orvieto, where many important antiquities were found.

See P. Perali, *Orvieto Etrusca* (Rome, 1928), who proposes to identify Orvieto with the ancient *Fanum Voltumnae*.

VOLSTEAD, ANDREW J. (1860–1947), U.S. congressman, born in Goodhue county. Minn. He was admitted to the bar in 1884 and then set up his practice at Granite Falls. Minn. Volstead was a member of the 58th to 67th congresses (1903–23), 7th Minnesota district. He was the author of the Farmers' Co-operative act and of the Volstead act. the first step in the struggle to enforce the 18th amendment to the constitution regarding the prohibition of intoxicating liquors. The Volstead act was passed Oct. 18. 1919, over the president's veto. Its most drastic feature, and the one most criticized. was the definition of intoxicating liquors as beverages containing "one-half of one per centum or more of alcohol by volume." Volstead was active as a legal adviser in the enforcement of prohibition until the amendment u-as repealed in 1933. Volstead died Jan. 20, 1947.

VOLTA, ALESSANDRO GIUSEPPE ANTONIO ANASTASIO (1745–1827), Italian physicist, celebrated as a pioneer of electrical science, after whom the "volt" is named, was born at Como on Feb. 18, 1745. He was successively appointed a teacher of physics at Como (1774) and to the newly founded chair of physics at Pavia in 1779. In 1777 and again in 1782 he journeyed through Switzerland. France, Germany. Holland and England, and became acquainted with many scientific celebrities. In 1791 he received the Copley medal of the Royal society. In 1801 Napoleon called him to Paris to show his experiments on contact electricity. and a medal was struck in his honour. He was made a senator of the kingdom of Lombardy. In 181j the emperor of Austria made him director of the philosophical faculty of Padua. In 1819 he retired and settled in his native town. where he died on March 5, 1827. A statue was erected to his memory at Como. For Volta's electrical work and his place in the history of discovery, see ELECTRICITY; also VOLTMETER.

VOLTA, the largest river of the Guinea coast west of the Niger, with a length of 710 mi. Its mouth and most of its basin are in Ghana. It has two main upper branches, the Black Volta and the White Volta: both rising in the grassy plateau country of French West Africa north of the coastal forest belt. The Black Volta rises in about 11° N., 5° 10′ W., flows northeast to about 13° N., and then turns south. From about 11° N. to 9° N. it forms the boundary between Ghana and the Ivory Coast. After turning eastward it is joined by the White Volta at about 1° W., 8° 40′ N. It then flows southeast across a wide lowland basin to its junction with the Oti and from there southward to break across the coastal range near the river port of Akuse. Thence it runs eastward to the head of its delta.

The whole Volta system has had a complex history. All three of the main rivers — the Black Volta, White Volta and Oti — have cut back across the plateau escarpment and captured streams formerly flowing to the middle Niger. The alternation of well-graded reaches in wide valleys with rapids in narrow defiles, and the frequent abrupt changes of direction, all point to the composite character of the river.

The Volta rivers are little used for transport. Water levels vary greatly in accordance with the seasonal rainfall. Heavy surf breaks on a bar across the main mouth and this prevents the entry of any but shallow-draft vessels. Rapids just above Akuse limit navigation to about 50 mi. below that point. Work was begun in 1954 on the new port of Tema, 40 mi. W. of the mouth, which, when completed, would be the port for the eastern region, and would also handle imported raw materials and the aluminum for export from the Volta River project. This major scheme, first proposed in 1938, to use the Volta waters for power production, was under active consideration in the late 1950s. The dam at Ajena 70 mi. upriver from the sea and 45 mi. from Tema could impound, at a level of 250 ft., a lake 225 mi. long and covering over 3,000 sq.mi., and would produce a generating capacity estimated at 660,000 kw. Kine-tenths of this would be used in an aluminum smelter treating bauxite from the western regions Surplus power would be available for industrial and private purposes and for rail traction, and uater for much-needed irrigation. In 1956 a steel arch bridge over the Volta was completed at Adomi, linking the Eastern Region and Trans-Volta Togoland. It has a span of 805 ft. and carries a two-lane roadway and footpaths. (T. HER)

VOLTAIRE (the pen name for FRANÇOIS MARIE AROUET) (1694–1778), was born on Nov. 21, 1694, at Paris, and mas baptized the next day. His father was François Arouet, a notary; his mother was Marie Marguerite Daumart or D'Aumard. Both father and mother were of Poitevin extraction. but the Arouets had been for two generations established in Paris. the grandfather being a prosperous tradesman. François was the fifth child of his parents. Little is known of the mother, who died when François was only seven years old. She pretty certainly was the chief cause of his early introduction to good society, the abbé de Chbteauneuf (his sponsor in more ways than one) having been her friend.

The abbé instructed him early in belles-lettres and deism, and Franqois showed when still a child a faculty for facile verse making. At the age of ten he was sent to the Collège Louis-le-Grand, which was under the management of the Jesuits, and remained there till 1711. It was his whim, as part of his general liberalism, to depreciate the education he received: but it seems to have been a sound and good education. Nor can there be much doubt that the great attention bestowed on acting — the Jesuits kept up the Renaissance practice of turning schools into theatres for the performance of plays both in Latin and in the vernacular — had much to do with his lifelong devotion to the stage. It must have been during his earliest school years that the celebrated presentation of him by his godfather to Ninon de Lenclos took place, for Ninon died in 1705. She left him 2,000 fr. "to buy books with."

In Aug. 1711, at the age of 17, Franqois returned home, and the usual battle followed between a son who desired no profession but literature and a father who refused to consider literature a profession at all. For a time Franqois submitted, and read law at least nominally. The abbé de Châteauneuf died before his godson left school, but he had already introduced him to the famous and dissipated coterie of the Temple. His father tried to break him off from such society by sending him in the suite of the marquis de Châteauneuf, the abbé's brother, to The Hague. There he met a certain Olympe Dunoyer ("Pimpette"), a girl apparently of respectable character and not bad connections, but a Protestant, penniless, and daughter of a literary lady whose literary reputation was not spotless. His father stopped any idea of a match by procuring a lettre de *cachet*, which, however, he did not use. François, who had been sent home, submitted. and for a time pretended to work in a Parisian lawyer's office; but he again manifested a faculty for getting into trouble — this time in the still more dangerous way of writing libellous poems — so that his father was glad to send him to stay for nearly a year (1714–15) with Louis de Caumartin, marquis de Saint-Ange, in the country. When he returned to Paris, he was forthwith introduced to a less questionable and even more distinguished coterie than Vendôme's, to the famous "court of Sceaux," the circle of the beautiful and ambitious duchesse du Maine. It seems that he lent himself to the duchess's frantic hatred of the regent Orléans, and helped to compose lampoons on that prince. At any rate. in May 1716 he was exiled, first to Tulle, then to Sully. Allowed to return, he again fell under suspicion of having been concerned in the composition of two violent libels and on May 16, 1717, was sent to the Bastille. He there recast Oedipe, began the Henrzade and determined to alter his name. Ever after his exit from the Bastille in April 1718 he was known as Arouet de Voltaire, or simply Voltaire, though legally he never abandoned his patronymic. Probably the name is an anagram on "Arouet le jeune," or "Arouet l. j."

A further "exile" at Chbtenay and elsewhere succeeded the imprisonment, and though Voltaire was admitted to an audience by the regent and treated graciously he was not trusted. *Oedipe* was acted at the Théâtre Français on Nov. 18 of the year of release. It had a run of forty-five nights, and brought the author not a little profit. With these gains Voltaire seems to have begun his long series of successful financial speculations. But in the spring of next year the production of Lagrange-Chancel's libels, entitled the *Philippiques,* again brought suspicion on him. He was informally exiled, and spent much time with Marshal Villars, again increasing his store of "reminiscences." He returned to Paris in the winter, and his second play, *Artémire,* was produced in February 1720. It was a failure. In December 1721 his father died, leaving him property (rather more than four thousand livres a year), which was soon increased by a pension of half the amount from the regent. In return he offered himself as a secret diplomatist to Dubois.

His visiting espionage, as unkind critics put it—his secret diplomatic mission, as he would have liked to have it put himself—began in the summer of 1722, and he set out for it in company with a certain Madame de Rupelmonde, to whom he as usual made love, taught deism and served as an amusing travelling companion. He stayed at Cambrai for some time, where European diplomatists were still in full session, journeyed to Brussels, went on to The Hague, and then returned. The *Henriade* had got on considerably during the journey. During the late autumn and winter of 1722–23 he abode chiefly in Paris, taking a kind of lodging in the town house of M. de Bernières, a nobleman of Rouen, and endeavouring to procure a "privilege" for his poem. In this he was disappointed, but he had the work printed at Rouen nevertheless, and spent the summer of 1723 revising it. In November he caught smallpox and was very seriously ill. The book was privately printed in the spring of 1724. His third tragedy, *Mariamne* was a failure. The regent had died shortly before, not to Voltaire's advantage; for he had been a generous patron. Voltaire had made, however, a useful friend in another *grand seigneur,* as profligate and nearly as intelligent, the duke of Richelieu, and with him he passed 1724 and the next year chiefly, recasting *Mariamne* (which was now successful), writing the comedy of *L'Indiscret,* and courting the queen, the ministers, the favourites and all who seemed worth while. The end of 1725 brought a disastrous close to this period of his life. He was insulted by the chevalier de Rohan, replied with his usual sharpness of tongue, and shortly afterwards, when dining with the duke of Sully, was called out and bastinadoed by the chevalier's hirelings, Rohan himself looking on. Nobody would take his part, and at last, nearly three months after the outrage, he challenged Rohan, who accepted the challenge, but on the morning appointed for the duel Voltaire was arrested and sent for the second time to the Bastille. He was kept in confinement a fortnight, and was then packed off to England in accordance with his own request. Voltaire revenged himself on the duke of Sully for his conduct towards his guest by cutting Maximilien de Béthune's name out of the *Henriade.*

Voltaire's visit to England lasted about three years, from 1726 to 1729. George II., who succeeded soon after his arrival, was not fond of "boetry," but Queen Caroline was, and international jealousy was pleased at the thought of welcoming a distinguished exile from French illiberality. The Walpoles, Bubb Dodington, Bolingbroke, Congreve, Sarah, duchess of Marlborough, Pope, were among his English friends. He made acquaintance with, and at least tried to appreciate, Shakespeare. He was much struck by English manners, was deeply penetrated by English toleration for personal freethought and eccentricity, and gained some thousands of pounds from an authorized English edition of the *Henriade,* dedicated to the queen. But he visited Paris now and then and gained full licence to return in the spring of 1729.

He was full of literary projects, and immediately after his return he is said to have increased his fortune immensely by a lucky lottery speculation. The *Henriade* was at last licensed in France; *Brutus,* a play which he had printed in England, was accepted for performance, but kept back for a time by the author; and he began the celebrated poem of the *Pucelle,* the amusement and the torment of a great part of his life. At the end of 1730 *Brutus* did actually get acted. Then in the spring of the next year he went to Rouen to get *Charles XII.* surreptitiously printed, which he accomplished. In 1732 another tragedy, *Ériphile,* appeared, with the same kind of halting success which had distinguished the appearance of its elder sisters since *Oedipe.* But at last, on the 13th of August 1732, he produced *Zaïre,* the best (with *Mérope*) of all his plays, and one of the ten or twelve best plays of the whole French classical school. Its motive was borrowed to some extent from *Othello,* but that matters little. In the following winter the death of the comtesse de Fontaine-Martel, whose guest he had been, turned him out of a comfortable abode. He then took lodgings with an agent of his, one Demoulin, in an out-of-the-way part of Paris, and was, for some time at least, as much occupied with contracts, speculation and all sorts of means of gaining money as with literature.

In the middle of this period, however, in 1733, two important books, the *Lettres philosophiques sur les Anglais* and the *Temple du goût* appeared. Both were likely to make bad blood, for the latter was, under the mask of easy verse, a satire on contemporary French literature, especially on J. B. Rousseau, and the former was, in the guise of a criticism or rather panegyric of English ways, an attack on everything established in the church and state of France. The book was condemned (June 10th, 1734, the copies seized and burnt, a warrant issued against the author and his dwelling searched. He himself was safe in the independent duchy of Lorraine with Emilie de Breteuil, marquise du Chbtelet, with whom he began to be intimate in 1733. The château of Cirey, a half-dismantled country house on the borders of Champagne and Lorraine, was fitted up with Voltaire's money and became the headquarters of himself, of his hostess, and now and then of her accommodating husband. Many pictures of the life here, some of them not a little malicious, survive. It was not entirely a bed of roses, for the "respectable Emily's" temper was violent, and after a time she sought lovers who were not so much *des cérébraux* as Voltaire. But it provided him with a safe and comfortable retreat, and with every opportunity for literary work. In March 1735 the ban was formally taken off him, and he was at liberty to return to Paris, a liberty of which he availed himself sparingly.

At Cirey he wrote indefatigably and did not neglect business. The principal literary results of his early years here were the *Discours en vers sur l'homme,* the play of *Alzire* and *L'Enfant prodigue* (1736), and a long treatise on the Newtonian system which he and Madame du Chbtelet wrote together. In the first days of his sojourn he had written a pamphlet with the title of *Treatise on Metaphysics.* Of metaphysics proper Voltaire neither then nor at any other time understood anything, and the subject, like every other, merely served him as a pretext for laughing at religion with the usual reservation of a tolerably affirmative deism. In March 1736 he received his first letter from Frederick of Prussia, then crown prince only. He was soon again in trouble, this time for the poem of *Le Mondain,* and he at once crossed the frontier and then made for Brussels. He spent about three months in the Low Countries, and in March 1737 returned to Cirey, and continued writing, making experiments in physics (he had at this time a large laboratory), and busying himself with iron-founding, the chief industry of the district. The best-known accounts of Cirey life, those of Madame de Grafigny, date from the winter of 1738–39; they are somewhat spiteful but very amusing, depicting the frequent quarrels between Madame du Chbtelet and Voltaire, his intense suffering under criticism, his constant dread of the surreptitious publication of the *Pucelle* (which nevertheless he could not keep his hands from writing or his tongue from reciting to his visitors), and so forth. Frederick, now king of Prussia, made not a few efforts to get Voltaire away from Madame du Châtelet, but unsuccessfully, and the king earned the lady's cordial hatred by persistently refusing or omitting to invite her. At last, in September 1740, master and pupil met for the first time at Cleves, an interview followed three months later by a longer visit. .Brussels was again the headquarters in 1741, by which time Voltaire had finished the best and the second or third best of his plays, *Mérope* and *Mahomet*. *Mahomet* was played first at Lille in that year; it did not appear in Paris till August next year, and *Mérope* not till 1743. This last was, and deserved to be, the most successful of its author's whole theatre. During these years much of the *Essai sur les moeurs* and the *Siècle de Louis XIV*. was composed. He also returned, not too well-advisedly, to the business of courtiership, which he had given up since the death of the regent. He was much employed, owing to Richelieu's influence, in the fêtes of the dauphin's marriage, and was rewarded, through the influence of Madame de Pompadour on New Year's Day 1745 by the appointment to the post of historiographer-royal, once jointly held by Racine and Boileau. In the same year he wrote a poem on Fontenoy, he received medals from the pope and dedicated *Mahomet* to him, and he wrote court *divertissements* and other things to admiration. But Voltaire, who had been for years the first writer in France, had been repeatedly passed over in elections to the Academy. He was at last elected in the spring of 1746, and received on the 9th of May. Then the tide began to turn. His favour at court had naturally exasperated his enemies. He had various proofs of the instability of his hold on the king during 1747 and in 1748. He once lay in hiding for two months with the duchesse du Maine at Sceaux, where were produced the comedietta of *La Prude* and the tragedy of *Rome sauvke*, and afterwards for a time lived chiefly at Lunéville; here Madame du Chbtelet had established herself at the court of King Stanislaus, and carried on a liaison with Saint-Lambert, an officer in the king's guard. In 1749 she died after the birth of a child.

After Madame du Chbtelet's death Voltaire had some idea of settling in Paris, but mischief was the very breath of his nostrils. He went on writing satiric tales like *Zadig*. He engaged in a foolish and undignified struggle with Crébillon *père* (not *fils),* a rival set up against him by Madame de Pompadour, but a dramatist who, in part of one play, *Rhadamiste et Ze'nobie,* has struck a note of tragedy in the grand Cornelian strain, which Voltaire could never hope to echo. *Semirame* (1748), *Oreste* (1750) and *Rome sauvée* itself were all products of this rivalry.

All this time Frederick of Prussia had been continuing his invitations. Voltaire left Paris on June 15, 1751, and reached Berlin on July 10. It is certain that at first the king behaved altogether like a king to his guest. He pressed him to remain; he gave him (the words are Voltaire's own) one of his orders, twenty thousand francs a year, and four thousand additional for his niece, Madame Denis, in case she would come and keep house for her uncle. His residence in Prussia lasted nearly three years. It was quite impossible that Voltaire and Frederick should get on together for long. Voltaire was not humble enough to be a mere butt, as many of Frederick's led poets were; he was not enough of a gentleman to hold his own place with dignity and discretion; he was constantly jealous both of his equals in age and reputation, such as Maupertuis, and of his juniors and inferiors, such as Baculard D'Arnaud. He was greedy, restless, and in a way Bohemian. He tried to get D'Arnaud exiled, and succeeded. He got into a quite unnecessary quarrel with Lessing. He had not been in the country six months before he engaged in a discreditable piece of financial gambling with Hirsch, the Dresden Jew. He was accused of something like downright forgery—that is to say, of altering a paper signed by Hirsch after he had signed it. The king's disgust at this affair (which came to an open scandal before the tribunals) was so great that he was on the point of ordering Voltaire out of Prussia, and Darget the secretary had no small trouble in arranging the matter (February 1751). Then it was Voltaire's turn to be disgusted with an occupation he had undertaken himself—the occupation of "buckwashing" the king's French verses. However, he succeeded in finishing and printing the *Sibcle de Louis XIV.,* while the *Dictionnaire philosophique* is said to have been devised and begun at Potsdam. But Voltaire's restless temper was brewing up for another storm. In the early autumn of 1751 La Mettrie, one of the king's parasites, and a man of much more talent than is generally allowed, horrified Voltaire by telling him that Frederick had in conversation applied to him (Voltaire) a proverb about "sucking the orange and flinging away its skin," and about the same time the dispute with Maupertuis, which had more than anything else to do with his exclusion from Prussia, came to a head. Maupertuis got into a dispute with one Konig. The king took his president's part; Voltaire took Konig's. But Maupertuis must needs write his *Letters,* and thereupon (1752) appeared one of Voltaire's most famous, though perhaps not one of his most read works, the *Diatribe du Docteur Akakia.* Even Voltaire did not venture to publish this lampoon on a great official of a prince so touchy as the king of Prussia without some permission, and if all tales are true he obtained this by another piece of something like forgery—getting the king to endorse a totally different pamphlet on its last leaf, and affixing that last leaf to *Akakza.* Of this Frederick was not aware; but he did get some wind of the *Diatribe* itself, sent for the author, heard it read to his own great amusement, and either actually burned the ms. or believed that it was burnt. In a few days printed copies appeared. Frederick put Voltaire under arrest for a time. After repeated reconciliations followed by fresh difficulties Voltaire at last left Potsdam on the 26th of March, 1753. It was nearly three months afterwards that the famous, ludicrous and brutal arrest was made at Frankfort, on the persons of himself and his niece, who had met him meanwhile. The whole situation was at last put an end to by the city authorities, who probably felt that they were not playing a very creditable part. Voltaire left Frankfort on July 7, and travelled to Colmar.

Voltaire's second stage was now over in his sixtieth year. He had been, in the first blush of his Frankfort disaster, refused, or at least not granted, permission even to enter France proper. At Colmar he was not safe, especially when in January 1754 a pirated edition of the *Essai sur les moeurs,* written long before, appeared. Permission to establish himself in France was now absolutely refused. Nor did an extremely offensive performance of Voltaire's—the solemn partaking of the Eucharist at Colmar after due confession—at all mollify his enemies. His exclusion from France, however, really meant exclusion from Paris and its neighbourhood. In the summer he went to Plombières, and after returning to Colmar for some time journeyed in the beginning of winter to Lyons, and thence in the middle of December to Geneva. Voltaire had no purpose of remaining in the city, and almost immediately bought a country house just outside the gates, to which he gave the name Les Délices. He was here practically at the meeting-point of four distinct jurisdictions—Geneva, the canton Vaud, Sardinia and France, while other cantons were within easy reach; and he bought other houses dotted about these territories, so as never to be without a refuge close at hand in case of sudden storms. At Les Délices he set up a considerable establishment, which his great wealth made him able easily to afford. He kept open house for visitors; he had printers close at hand in Geneva; he fitted up a private theatre in which he.could enjoy what was perhaps the greatest pleasure of his whole life—acting in a play of his own, stage-managed by himself. His residence at Geneva brought him into correspondence (at first quite amicable) with the must famous of her citizens, J. J. Rousseau. His *Orphelin de* la *Chine,* performed at Paris in 1755, was very well received; the notorious *La Pucelle* appeared in the same year. The earthquake at Lisbon, which appalled other people, gave Voltaire an excellent opportunity for ridiculing the beliefs of the orthodox, first in verse (1756) and later in the (from a literary point of view) unsurpassable tale of *Candide* (1759). All was, however, not yet quite smooth with him. Geneva had a law expressly forbidding theatrical performances in any circumstances whatever. Voltaire had infringed this law already as far as private performances went, and he had thought of building a regular theatre, not indeed at Geneva but at Lausanne. He undoubtedly instigated D'Alembert to include a censure of the prohibition in his *Encyclopédie* article on

"Geneva," a proceeding which provoked Rousseau's celebrated Lettre *à D'Alembert sur les* spectacles. As for himself, he looked about for a place where he could combine the social liberty of France with the political liberty of Geneva, and he found one.

At the end of 1758 he bought the considerable property of Ferney, on the shore of the lake, about four miles from Geneva, and on French soil. Many of the most celebrated men of Europe visited him there. In spite of these interruptions he wrote much and conducted an immense correspondence, which had for a long time once more included Frederick, the two getting on very well when they were not in contact. Above all, he now, being comparatively secure in position, engaged much more strongly in public controversies, and resorted less to his old labyrinthine tricks of disavowal, garbled publication and private libel. The suppression of the *Encyclopédie,* to which he had been a considerable contributor, and whose conductors were his intimate friends, drew from him a shower of lampoons directed now at "l'infâme" (see infra) generally, now at literary victims, such as Le Franc de Pompignan, or Palissot or at Fréron, an excellent critic and a dangerous writer, who had attacked Voltaire from the conservative side, and at whom the patriarch of Femey, as he now began to be called, levelled the farce-lampoon of *L'Écossaise.*

Here, too, he began that series of interferences on behalf of the oppressed and the ill-treated which is an honour to his memory. Volumes and almost libraries have been written on the Calas affair, and we can but refer here to the only less famous cases of Sirven (very similar to that of Calas, though no judicial murder was actually committed), Espinasse (who had been sentenced to the galleys for harbouring a Protestant minister), Lally (the son of the unjustly treated but not blameless Irish-French commander in India), D'Étalonde (the companion of La Barre), Montbailli and others.

In this way Voltaire, who had been an old man when he established himself at Ferney, became a very old one almost without noticing it. The death of Louis XV. and the accession of Louis XVI. excited even in his aged breast the hope of re-entering Paris, but he did not at once receive any encouragement, despite the reforming ministry of Turgot. A much more solid gain to his happiness was the adoption, or practical adoption, in 1776 of Reine Philiberte de Varicourt, a young girl of noble but poor family, whom Voltaire rescued from the convent, installed in his house as an adopted daughter, and married to the marquis de Villette. Her pet name was "Belle et Bonne," and nobody had more to do with the happiness of the last years of the "patriarch" than she had. It is doubtful whether his last and fatal visit to Paris was due to his own wish or to the instigation of his niece, Madame Denis. At the end of 1777 and the beginning of 1778, he had been carefully finishing a new tragedy—Zrhne—for production in the capital. He started on Feb. s, and five days later arrived at the city which he had not seen for 28 years.

He was received with immense rejoicings, not indeed directly by the court, but by the Academy, by society and by all the more important foreign visitors. About a fortnight after his arrival, age and fatigue made him seriously ill, and a confessor was sent for. But he recovered, scoffed at himself as usual, and prepared more eagerly than ever for the first performance of *Irène,* on March 16. At the end of the month he was able to attend a performance of it, which was a kind of apotheosis. He was crowned with laurel in his box, amid the plaudits of the audience, and did not seem to be the worse for it. He even began or proceeded with another tragedy—Agathocle—and attended several Academic meetings. But such proceedings in the case of a man of eighty-four were impossible. To keep himself up, he exceeded even his usual excess in coffee, and about the middle of May he became very ill. On May 30, the priests were once more sent for—to wit, his nephew, the abbé Mignot, the abbé Gaultier, who had officiated on the former occasion, and the parish priest, the curé of St. Sulpice. In a state of half-insensibility he petulantly motioned them away, dying in the course of the night. The result was a difficulty as to burial, which was compromised by hurried interment at the abbey of Scellières in Champagne, anticipating the interdict of the bishop of the diocese by an hour or two. On July 10, 1791 the body was transferred to the Pantheon, but during the Hundred Days it was once more, it is said, disentombed, and stowed away in a piece of waste ground. His heart, taken from the body when it was embalmed, and given to Madame Denis and by her to Madame de Villette, was preserved in a silver case, and when it was proposed (in 1864) to restore it to the other remains, the sarcophagus at Sainte Genevibve (the Pantheon) was opened and found to be empty.

In person Voltaire was not engaging, even as a young man. His extraordinary thinness is commemorated, among other things, by the very poor but well-known epigram attributed to Young, and identifying him at once with "Satan, Death and Sin." In old age he was a mere skeleton, with a long nose and eyes of preternatural brilliancy peering out of his wig. He never seems to have been addicted to any manly sport, and took little exercise. He was sober enough (for his day and society) in eating and drinking generally; but drank coffee, as his contemporary, counterpart and enemy, Johnson, drank tea, in a hardened and inveterate manner. It may be presumed with some certainty that his attentions to women were for the most part platonic; indeed, both on the good and the bad side of him, he was all brain. Conversation and literature were, again as in Johnson's case, gods of his idolatry. He was good-natured when not crossed, generous to dependents who made themselves useful to him, and indefatigable in defending the cause of those who were oppressed by the systems with which he was at war. But he was inordinately vain, and totally unscrupulous in gaining money, in attacking an enemy, or in protecting himself when he was threatened with danger. Voltaire's works, and especially his private letters, constantly contain the word "l'infiime" and the expression (in full or abbreviated) "écrasez l'infiime." This has been misunderstood in many ways—the mistake going so far as in some cases to suppose that Voltaire meant Christ by this opprobrious expression. No careful and competent student of his works has ever failed to correct this gross misapprehension. "L'infâme" is not God; it is not Christ; it is not Christianity; it is not even Catholicism. Its briefest equivalent may be given as "persecuting and privileged orthodoxy" in general, and, more particularly, it is the particular system which Voltaire saw around him, of which he had felt the effects in his own exiles and the confiscations of his books, and of which he saw the still worse effects in the hideous sufferings of Calas and La Barre.

Works.—Vast and various as his work is, its vastness and variety are of the essence of its writer's peculiar quality. The divisions of it have long been recognized, and may be treated regularly.

The first of these divisions in order is the theatre. Between fifty and sixty pieces (including a few which exist only in fragments or sketches) are included in his writings, and they cover his literary life. It is at first sight remarkable that Voltaire, whose comic power was undoubtedly far in excess of his tragic, should have written many tragedies of no small excellence in their way, but only one fair second-class comedy, *Nanine.* His tragedies, on the other hand, are works of extraordinary merit in their own way. Zaire, among those where love is admitted as a principal motive, and Mkrope, among those where this motive is excluded and kept in subordination, yield to no plays of their class.

As regards his poems proper, of which there are two long ones, the Henriade and the Pucelle, besides smaller pieces, of which a bare catalogue fills fourteen royal octavo columns, their value is very unequal. The Pucelle is extremely desultory; it is a libel on religion and history. But it is amusing. The minor poems are as much above the Pucelle as the Pucelle is above the Henriade. It is true that there is nothing, or hardly anything, that properly deserves the name of poetry in them—no passion, no sense of the beauty of nature, only a narrow "criticism of life," only a conventional and restricted choice of language, a cramped and monotonous prosody, and none of that indefinite suggestion which has been rightly said to be of the poetic essence. But there is immense wit, a wonderful command of such metre and language as the taste of the time allowed to the poet, a singular if somewhat artificial grace, and great felicity of diction.

The third division of Voltaire's works in a rational order consists of his *prose romances* or *tales.* In these admirable works more than in any others that the peculiar quality of Voltaire—ironic style without exaggeration—appears. That he learned it partly from Saint Evremond, still more from Anthony Hamilton, partly even from his own enemy Le Sage, is perfectly true, but he gave it perfection and completion. If one especial peculiarity can be singled out, it is the extreme restraint and simplicity of the verbal treatment. Voltaire never dwells too long on this point, stays to laugh at what he has said, elucidates or comments on his own jokes, guffaws over them or exaggerates their form. The famous "pour encourager les autres" is an typical example, and indeed the whole of *Candide* shows the style at its perfection.

The fourth division of Voltaire's work, the *historical,* is the bulkiest of all except his correspondence, but it is far from being among the best. The small treatises on Charles XII. and Peter the Great are indeed models of clear narrative and ingenious if somewhat superficial grasp and arrangement. The so-called *Siècle de Louis XIV.* and *Siècle de Louis XV.* (the latter inferior to the former but still valuable) contain a great miscellany of interesting matter, treated by a man of great acuteness and unsurpassed power of writing, who had also had access to much important private information. But even in these books defects are present, which appear much more strongly in the singular olla-podrida entitled *Essai sur les moeurs,* in the *Annales de l'empire* and in the minor historical works. These defects are an almost total absence of any comprehension of what has since been called the philosophy of history, the constant presence of gross prejudice, frequent inaccuracy of detail, and, above all, a complete incapacity to look at anything except from the narrow standpoint of a half-pessimist and half self-satisfied *philosophe.*

To his own age Voltaire was pre-eminently a poet and a philosopher; the unkindness of succeeding ages has sometimes questioned whether he had any title to either name, and especially to the latter. His largest *philosophical* work, at least so called, is the curious medley entitled *Dictionnaire philosophique,* which is compounded of the articles contributed by him to the great *Encyclopédie* and of several minor pieces. No one of Voltaire's works shows his anti-religious or at least anti-ecclesiastical animus more strongly. The various title-words of the several articles are often the merest stalking-horses, under cover of which to shoot at the Bible or the church, the target being now and then shifted to the political institutions of the writer's country, his personal foes, etc., and the whole being largely seasoned with that acute, rather superficial, common-sense, but also commonplace, ethical and social criticism which the 18th century called philosophy. The book ranks perhaps second only to the novels as showing the character, literary and personal, of Voltaire; and despite its form it is nearly as readable.

In general *criticism* and *miscellaneous* writing Voltaire is not inferior to himself in any of his other functions. Almost all his more substantive works, whether in verse or prose, are preceded by prefaces of one sort or another, which are models of his own light pungent *causerie;* and in a vast variety of nondescript pamphlets and writings he shows himself a perfect journalist.

There remains only the huge division of his *correspondence,* which is constantly being augmented by fresh discoveries, and which, according to Georges Bengesco, has never been fully or correctly printed, even in some of the parts longest known. In this great mass Voltaire's personality is of course best shown, and perhaps his literary qualities not worst. His immense energy and versatility, his adroit and unhesitating flattery when he chose to flatter, his ruthless sarcasm when he chose to be sarcastic, his rather unscrupulous business faculty, his more than rather unscrupulous resolve to double and twist in any fashion so as to escape his enemies,—all these things appear throughout the whole mass of letters.

When sympathy and dislike are both discarded or allowed for, he remains one of the most astonishing, if not exactly one of the most admirable, figures of letters. His great fault was an inveterate superficiality. But this superficiality was accompanied by such wonderful acuteness within a certain range, by such an absolutely unsurpassed literary aptitude and sense of style in all the lighter and some of the graver modes of literature, by such untiring energy and versatility in enterprise, that he has no parallel among ready writers anywhere. Not the most elaborate work of Voltaire is of much value for matter; but not the very slightest work of Voltaire is devoid of value in form. In literary craftsmanship, at once versatile and accomplished, he has no superior and scarcely a rival.

Bibliography.—For the many editions of Voltaire's works, *see* G. Bengesco, *Bibliographie de Voltaire* (4 vols., Paris, 1882–90). For Voltaire's life and works, *see* the essays of Thomas Carlyle and of Lord Morley (1872); M. Desnoiresterres, *Voltaire et la société française* (1867); F. Espinasse, *Voltaire* (1882) with bibliography; J. Churton Collins, *Voltaire in England* (1886); J. R. Lounsbury, *Shakespeare and Voltaire* (1902); G. Lanson, *Voltaire* (1906); F. Caussy, *Voltaire, seigneur de village* (1912); A. S. Hurn, *Voltaire et Bolingbroke* (1915); G. M. C. Brandes, *F. de Voltaire* (1916); J. M. Robertson, *Voltaire* (1922); R. Aldington, *Voltaire* (1925); A. Bellesort, *Essai sur Voltaire* (1925); F. Vezinet, *Autour de Voltaire* (1925); C. B. Chase, *The Young Voltaire* (1926); E. Henriot, *Voltaire et Frédéric II.* (1927). Recent English versions of Voltaire's shorter writings are: *Zadig and other romances* (trans. A. I. Woolf and W. S. Jackson, 1926); *Candide and other romances* (trans. R. Aldington, 1927); V. Thaddeus, *Voltaire, Genius of Mockery* (1928); Alfred Noyes, *Voltaire* (1936).

VOLTERRA (anc. *Volaterrae*), a town and episcopal see of Tuscany, Italy, in the province of Pisa, from which it is 51 mi. by rail S.E., and 35 by road W.N.W. from Siena. Pop. (1936) 11,704 (town); 20,638 (commune). It stands on a commanding olive-clad eminence 1,785 ft. above sea-level, with a magnificent view over mountains and sea (the latter some 20 m. distant), and is surrounded by the massive remains of its ancient walls of large, roughly-rectangular blocks of stone, some 4½ m. in circuit, enclosing an area which must have been larger than was actually needed for habitation. Tombs of the later Villanova period (end of the 9th century B.C.) have been found within its circuit, but only at the north-west extremity. Here the clay of which the hill is formed is gradually giving way, causing landslips and the collapse of buildings, notably of the abbey church of S. Salvatore (1030) and SS. Giusto e Clemente. The mediaeval town occupies only the southern portion of this area. The most important relic of its Etruscan period is the Porta dell' Arco, an archway 20 ft. high, the corbels of which are adorned with almost obliterated heads. Volterra contains many picturesque mediaeval towers and houses. The Palazzo dei Priori (1208–57), containing the picture gallery, is especially fine, and the Piazza Maggiore in which it stands most picturesque. The museum contains a valuable collection of Etruscan antiquities, especially cinerary urns from ancient tombs of alabaster, with the figure of the deceased on the lid, and reliefs from Greek myths on the front. They belong to the 3rd and 2nd centuries B.C. The cathedral, enlarged and adorned by Pisan artists in 1254, has a fine pulpit of that period, and on the high altar are sculptures by Mino da Fiesole; it contains several good pictures. The sacristy has fine carvings. The baptistery (1283) has a font by Andrea Sansovino, and a ciborium by Mino da Fiesole. Both these buildings are in black and white marble. S. Francesco has frescoes of 1410, and S. Girolamo terra-cottas by Giovanni della Robbia and pictures. The inhabitants are chiefly employed in the manufacture of vases and other ornaments from alabaster found in the vicinity.

Volaterrae (Etruscan *Velathri)* was one of the most powerful of the 12 confederate cities of Etruria. During the war between Marius and Sulla it withstood the latter's troops for two years in 82–80 B.C. In the 12th and 13th centuries it enjoyed free institutions; in 1361 it fell under the power of Florence. It rebelled, but was retaken and pillaged in 1472.

See C. Ricci, *Volterra* (Bergamo, 1905); R. MacIver, *Villanovans and Early Etruscans* (Oxford, 1924) 63–65. (T. A.)

VOLTMETER, an instrument which indicates the difference of the electric potential between its terminals on a scale graduated in volts. Legally, the (international) volt is the electromotive force which produces a current of one (international) ampere in a resistance of one (international) ohm. This volt is equal to $1{\cdot}00049 \times 10^8$ absolute C.G.S. units. Voltmeters are always connected in parallel across the points whose potential difference is required to be measured, and, since it is essential not to disturb this potential difference, they must have a high resistance so that they may pass only a very small current. They may be divided into two classes: (1) electrostatic: (2) electrokinetic. Electrostatic voltmeters depend for their action on the fact that when two conductors are at different potentials they attract each other with a force which varies as the square of the potential difference between them. Such voltmeters have the advantage of possessing an infinite resistance, but they are not very suitable for the measurement of small voltages (*e.g.*, 100 volts). Electrokinetic voltmeters are simply high resistance galvanometers, and measure potential differences in terms of the minute currents which pass through them when they are connected to the points whose potential differences are required. (See INSTRUMENTS, ELECTRICAL MEASURING.)

VOLTURNO, a river of central Italy, which rises in the neighbourhood of Alfedena in the central Apennines of Samnium, runs south as far as Venafro, and then southeast. After a course of about 75 mi. it receives, about 5 mi. E. of Caiazzo, the Calore. The united stream now flows west-southwest'past Capua (ancient Casilinum), where the Via Appia and Latina joined just to the north of the bridge over it, and so through the Campanian plain, with many windings, into the sea. The direct length of the lower course is about 31 mi., so that the whole is slightly longer than that of the Liri, and its basin far larger (2,106 sq.mi. with a length of 109 mi. in a straight line and a discharge of 40 cu.m. per second at the mouth). The river has always had considerable military importance. and the colony of Volturnum (no doubt preceded by an older port of Capua) was founded in 194 B.C. at its mouth on the south bank by the Romans; it is now about one mile inland. A fort had already been placed there during the Roman siege of Capua, in order. with Puteoli, to serve for the provisioning of the army. The river was navigable as far as Capua.

On Oct. 1, 1860, the Neapolitan forces were defeated on the south bank of the Volturno, near S. Maria di Capua Vetere, by the Piedmontese and Garibaldi's troops, a defeat which led to the fall of Capua.

VOLUNTEERS, a general term for soldiers who are not professionals and are not permanently embodied under arms in times of peace. The idea of a large organized volunteer force seems to have originated in England at the time of the Militia bill of 1757, which was amended in 1758 to allow the militia captains to accept volunteers instead of the ordinary militiamen who were compulsorily furnished pro rata by each parish. In 1778 the volunteers were still voluntary substitutes for militiamen, though formed in separate companies of the militia unit, but volunteer corps soon began to form themselves independently of the militia.

These volunteers, disbanded in 1783, were promptly revived when the French Revolutionary Wars produced a new enemy. When the danger of invasion was at its height the force numbered 380,000 men, or $3\frac{1}{2}\%$ of a population that already kept up a regular army and a militia In 1808 was formed the local militia, in which enlistment and training were both stricter and better defined, and the greater part of the volunteers transferred themselves to this body. By 1812 the local militia reached a strength of 215,000 as against the 70,000 of the remaining volunteers. With the general peace of 1814 almost all these forces disappeared. After an interval of nearly half a century the warlike attitude of France caused British citizens once more to arm for the protection of their country.

The enrollment of the volunteer force took place at first under the old statute (44 Geo. III). The main provisions of that act, however, were found inapplicable to the altered conditions under which invasion was now possible. A new act (Volunteer act, 1863) was soon passed, the most important provision of which was that expected invasion should constitute a sufficient reason for the sovereign to call out the volunteers, in lieu of the old condition, which required the actual appearance of the enemy. This was modified in 1900 during the South African War by a further enactment allowing the authorities to call out the volunteers at times of "imminent national danger and great emergency." In 1907–08 the whole force was recast and organized along with the yeomanry (*q.v.*) into the new territorial force.

See TERRITORIAL ARMY.

The United States until World War I depended largely upon volunteers in case of national emergency. In the War of 1812 volunteers. rangers and militia numbered 471.622 as against 56,032 regulars. In the Mexican War a call for 50,000 volunteers was quickly responded to, but lack of food and transportation caused thousands of volunteers to be left behind or sent home. In the Civil War, both sides started with the volunteer system and later began conscription (q v.). The chief difficulties about the volunteer system were the short enlistment terms and the fact that the law gave the governors of states the right to appoint the officers of volunteer regiments. In the Spanish-American War the president was authorized to call out volunteers for a two-year term. Under this act about 220,000 volunteers were raised; together with 60,000 regulars, they formed the United States army during the war. The Volunteer Army bill of April 25. 1914, stipulated that all officers were to be appointed by the president.

In World War I the United States definitely abandoned the volunteer system and resorted to a selective draft. Nevertheless the Selective Service act permitted voluntary enlistment by persons between 18 and 40, and left enlistment freely open to persons registered for the draft, provided that such registrants had not yet been called up for examination by their local boards. Regulations issued Dec. 15, 1917, however. prohibited voluntary enlistment for draft registrants. In Aug. 1918 further volunteering of any kind ceased by order of the war department. Down to that time voluntary enlistments in the various army components had numbered 877.458, while the total for the navy and marine corps was 490,418. In 1940 the approach of World War II raised the question of a peacetime draft in congress, and a Selective Service bill became law on Sept. 16.

During World War II, in order to promote the most effective mobilization and to eliminate waste of manpower arising from disruptive recruitment, volunteer recruitment ceased by executive order on Dec. 5, 1942. This order provided that no male person who had reached 18 years but mas under 38 years of age should be inducted into the enlisted personnel of the armed forces, except under provisions of the Selective Training and Service act of 1940, as amended. Involuntary inductions began in Nov. 1940 and totaled approximately 950,000 before war was declared in Dec. 1941. Total inductions from Nov. 1940 to Oct. 31, 1946, were 10,110,104. Approximately 66% of those who served in the armed forces during World War II were registrants inducted through selective service. Among the remainder, a large proportion were influenced to enlist or seek commissions because of their liability to be drafted.

The passage by congress of the Selective Service act of 1948 was unprecedented, as the United States never before had had compulsory military service in peacetime. The act provided for the operation of selective service on a limited scale and was utilized as a partial source of manpower during the Korean war of 1950–53. Under joint agreement of the armed forces, registrants could volunteer for enlistment provided they had not received their preinduction notice from selective service.

The Reserve Forces act of Aug. 9, 1955, provided for the enlistment of volunteers in the reserve components of the armed forces, Males 17 to $18\frac{1}{2}$ years of age were, with written parental consent at age 17 years, permitted to enlist for a special six months' active duty training. This training period was followed by three years of attendance at weekly reserve unit assemblies and at two-week annual summer camps, with consequent draft deferment. High school student volunteers, upon enlistment, were deferred automatically from reporting for the six months' training duty until graduation or attainment of the age of 20 years. The older volunteers who enlisted were six-year enlistees with 24 months' active duty training and consequent reserve unit membership and deferment. Critical specialists, over $18\frac{1}{2}$ years of age, certified as such by selective service, were enrolled for eight years to be served after completion of three months' training duty. These persons were deferred from the draft during the period of their enlistment.

Volunteers as Political Weapons. — In the 1950s the use of "volunteers" as political factors in international relations came to the fore. During 1950–53 hundreds of thousands of volunteers of the Chinese People's Republic substantially aided the North Korean communists in combat against the United Nations forces in the Korean conflict. In the Suez crisis of 1956, the U.S.S.R. offered volunteer soldiers and airmen to help Egypt in the struggle against Israel, Britain and France. This overt threat of Soviet intervention was averted by the United Nations security council's prompt sending to Egypt of a hastily improvised police force composed of soldiers of certain other member nations.

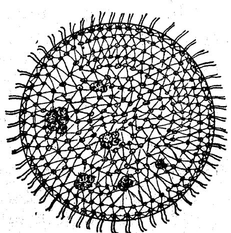
VOLUSENUS, FLORENTIUS [FLORENCE WOLSON, or WOLSEY, in later writers WILSON, though in letters in the vernacular he writes himself VOLUSENE] (*c.* 1504–*c.* 1547), Scottish humanist, was born near Elgin about 1504. He studied philosophy at Aberdeen, went to Paris, and became tutor to Thomas Wynter, reputed son of Cardinal Wolsey. He paid repeated visits to England, where he was well received by the king, and, after Wolsey's fall, he acted as one of Cromwell's agents in Paris. In Paris he knew George Buchanan, and found patrons in Jean, Cardinal de Lorraine and Jean du Bellay. He was to have gone with Du Bellay on his mission to Italy in 1535, but illness kept him in Paris. As soon as he recovered he set out on his journey, but stopped at Avignon, where Sadolet made him master in the school at Carpentras. Volusenus paid frequent visits to Lyons, probably also to Italy, where he had many friends, perhaps even to Spain. In 1546 he set out to return to Scotland, but died at Vienne in Dauphiné in 1546 or early in 1547. Volusenus was a great admirer of Erasmus, but he criticized the purity of his Latin and also his philosophy. His own philosophy is Christian and Biblical rather than classical or scholastic. He takes an independent view of Christian ethics and ultimately reaches a doctrine as to the witness of the Spirit and the assurance of grace which breaks with the traditional Christianity of his time and is based on ethical motives akin to those of the German reformers. His linguistic studies embraced Hebrew, Greek and Latin. His reputation rests on the beautiful dialogue, *De Animi Tranquillitate,* first printed by S. Gryphius at Lyons in 1543. From internal evidence it appears to have been composed about that time, but the subject had exercised Volusenus for many years. The dialogue shows Christian humanism at its best, and the verses which occur in it and the poem which concludes it give Volusenus a place among Scottish Latin poets, but it is as a Christian philosopher that he attains distinction.

The dialogue was reissued at Leyden in 1637 by the Scots writer David Echlin, whose poems, with a selection of three poems from the dialogue of Volusenus, appear, with others, in the famous Amsterdam collection *Delitiae Poetarum Scotorum hujus aevi,* printed by Blaev in 2 vol. in 1637. Later editions of the dialogue appeared at Edinburgh in 1707 and 1751 (the latter edited by G. Wishart). All the reissues contain a short life of the author by Thomas Wilson, advocate, son-in-law and biographer of Archbishop Patrick Adamson. Supplementary facts are found in the letters and state papers of the period, and in Sadolet's *Letters.*

VOLVOX, fresh-water, chlorophyll-bearing colonial organisms assigned by zoologists to the Mastigophora (Protozoa), by botanists to the Chlorophyceae (Algae). (*See* ALGAE: *Classification.*) In different species, the hollow colony ranges from ellipsoidal to spherical, measures about 0.25 to 3.0 mm. and contains approximately 500 to 50,000 flagellates.



ADAPTED FROM HYMAN, "THE INVERTEBRATES" (MCGRAW-HILL)

VOLVOX MAGNIFIED 60 TIMES

Each flagellate is covered with a cellulose layer and an outer gelatinous matrix. Except in *V. aureus,* the matrix is discontinuous so that interfaces, usually hexagonal, are visible externally. Asexual colonies contain biflagellate somatic cells and 8 to 60 reproductive cells (gonidia), which produce daughter colonies. In sexual colonies, developing ova or spermatozoa replace gonidia.

Volvox thus illustrates differentiation of somatic and reproductive cells, a phenomenon considered significant in tracing evolution of higher animals from Protozoa. In certain species, somatic flagellates appear to be joined by cytoplasmic strands.

In temperate climates *Volvox* thrives in the spring and apparently disappears in late summer or autumn, passing the winter as an encysted zygote. In the spring, excystment occurs as the zygote develops into a first-generation colony. The young colony turns itself inside out (inversion) so that the anterior ends of the component flagellates face outward. At maturity, daughter colonies are produced. These colonies, and often one or more succeeding generations, reproduce asexually, but sooner or later (*e.g.,* fourth or fifth generation) gametes are developed. Separate colonies yield spermatozoa and ova in heterothallic species, male colonies usually being smaller than females. Each colony produces both ova and spermatozoa in homothallic species, spermatozoa being liberated before ova reach maturity. Fertilization results in zygotes, each of which encysts. Released after death of the colony, zygotes sink to the bottom. Thick-walled zygotes, formed late in the season, serve as winter resting stages. (R. P. H.)

VONDEL, JOOST VAN DEN (1587–1679), Dutch poet, was born at Cologne, Ger., on Nov. 17, 1587. His father, a hatter, was an exile from Antwerp on account of his Anabaptist opinions; but he returned to Holland when Joost was about ten years old, and settled in Amsterdam, where he carried on a hosiery business. Joost was the eldest son and was expected to succeed to his father's shop. He was early introduced to the chamber of the Eglantine, however, and devoted most of his time to poetry and study.

When the elder Vondel died he married Maaiken de Wolf, and seems to have left the management of his affairs in her capable hands. He read the French contemporary poets, and was especially influenced by the *Divine Sepmaine* of Guillaume du Bartas; he made some translations from the German; he was soon introduced to the circle gathered in the house of Roemer Visscher, and with these friends began to make a close study of classical writers. His first play, *Pascha of de Uyttocht der Kinderen Israels uit Egypte* (1612) marked the beginning of a long and brilliant literary career. (*See* DUTCH LITERATURE.) After the production of his political drama of "Palamedes, or Murdered Innocence" (1625), which expressed his indignation at the judicial murder of Johan van Oldenbarneveldt in 1619, Vondel was forced to go into hiding, but the Amsterdam magistrates eventually satisfied themselves with exacting a small fine. In the following years he issued a number of satires against the extreme Calvinists, and he entered into close relationship with Hugo Grotius. Vondel had long been attracted by the aesthetic side of the Roman Catholic Church, and this inclination was perhaps strengthened by his friendship with Marie Tesselschade Visscher, for the Visscher household had been Catholic and liberal. Tesselschade's husband died in 1634; Vondel's wife died in 1635; and the ties between the two were strengthened by time. Vondel eventually showed his revolt against the Calvinist tyranny by formally embracing the Roman Catholic faith in 1640. The step was ill-received by many of his friends, and Pieter Hooft forbade him the hospitality of his castle at Muiden. In 1657 his only surviving son, who was entrusted with the hosiery business, mismanaged affairs and had to take ship for the Netherlands Indies, leaving his father to face the creditors. Vondel had to sacrifice his small fortune, and became a government clerk. He was pensioned after ten years' service, and died on Feb. 5, 1679.

The more important of his 32 dramas are: *Hierusalem Verwoest* ("Jerusalem Laid Desolate") (1620); *Palamedes, of Vermoorde onnooselheyd* ("Palamedes, or Murdered Innocence") (1625); *Gijsbreght van Aemstel* (1637); *De Gebroeders* (1640), the subject of which is the ruin of the sons of Saul; *Joseph in Egypten* (1640); *Maria Stuart, of gemartelde majesteit* (1646); the pastoral of *De Leeuwendalers* (1648); *Lucifer* (1654); *Salmoneus* ("Solomon") (1657); *Jephtha* (1659); *Koning David in Ballingschap* ("King David in Banishment"), *Koning David hersteld* ("King David Restored") and *Samson* (1660); *Batavische Gebroeders,* the subject of which is the story of Claudius Civilis (1663); *Adam in Ballingschap* ("Adam in Exile") (1664), after the Latin tragedy of Hugo Grotius. He also wrote translations from the tragedies of Seneca, Euripedes and Sophocles; didactic poems, and much lyrical poetry besides what is to be found in the choruses of his dramas. His complete works were edited by Van Lennep. 12 vol. (1850–69). A bibliography (1888) was published by J. H. W. Unger, who revised Van Lennep's edition in 1888–94. *Lucifer* was translated into English verse by L. C. van Noppen (1898).

Baumgartner, S. J. (1882); by C. Looten (1889); by J. A. Alberdingk Thijm (*Portretten van Joost van den Vondel* [1876]); chapters on Vondel, pp 133–325, in W. J. A. Jonckbloet's *Geschiedenis der nederlandsche letterkunde,* vol. iv (1890); A. J. M. H. Schillings, *Vondel en de regeerders van Amsterdam (1917)*; J. F. M. Sterck, *Oorkonden over Vondel en zijn kring (1918)*; A. J. Barnouw, *Vondel (1925).*

VONIER, ANSCAR (1875–1938), Benedictine abbot of Buckfast abbey, England, a prominent theologian, author and preacher, was born Nov. 11, 1875. in Ringschnait. Ger. He was educated in Germany, France and England before becoming a Benedictine at Buckfast (1893), where he was ordained to the priesthood (1898). After receiving his doctorate in philosophy (1900) at St. Anselm's, Rome, he taught at both Buckfast and St. Anselm's. When he was not yet 31 years old. Vonier was elected (1906) abbot of Buckfast, and immrdiately began his greatest work, the total reconstruction of the abbey church. The work was done by the monks themselves—usually five or six of them—and took 25 years (1907–32). After 32 years as abbot, Vonier died at Buckfast, Dec. 26. 1938.

He wrote 15 books. *The Human Soul and Its Relations With Other Spirits* (on the soul's nature, origin and destiny), *The Spirit and the Bride* (on the Holy Spirit) and *The Personality of Christ* (on the mystery and significance of the Incarnate Word) are some of his best works, but the most important was *A Key to the Doctrine of the Eucharist,* mhich explains his theory of the sacrifice of the Mass. His collected works were published in three volumes in 1952–53. Vonier was at his best, however, as a preacher. Although not a polished speaker, he was most effective because of his clarity, his doctrinal solidity and especially his sincerity.

See Ernest Graf, *Anscar Vonier, Abbot of Buckfast (1957).*

(T. G. O'C.)

VONNOH, ROBERT WILLIAM (1858–1933), C S. portrait and landscape painter, was born in Hartford, Conn , Sept. 17, 1858. He studied art at the Massachusetts Normal Art school and taught there after his graduation (1879–81). In 1881 he went to Paris. where he was a pupil of Gustave Boulanger and Jules Lefebvre at the Académie Julian. He returned to the United States and taught at the Cowles Art school, Boston, 1884–85; at the Boston Museum of Fine Arts school, 1885–87; and in the schools of the Pennsylvania Academy of the Fine Arts, Philadelphia, 1891–96, and again, 1918–20. He received the Proctor portrait prize of the National Academy of Design (1904), as well as a number of other medals and awards for his work. He is represented in the Pennsylvania Academy of Fine Arts, the Metropolitan Museum of Art, New York city, and in numerous other galleries. His portraits are generally considered to excel his other paintings, although some of his landscapes are highiy regarded. He died at Nice, France, Dec. 28, 1933.

His second wife. BESSIE POTTER VONNOH (1872–1954), a sculptress, aas born in St. Louis, Mo., Aug. 17, 1872. and studied sculpture under Lorado Taft. She became a member of the National Sculpture society (1898) and of the National Academy of Design (1921). She is represented in the Art institute, Chicago, the Metropolitan Museum of Art, New York city, and elsewhere.

VONONES (on coins ONONES), the name of two Parthian kings. VONONES I, eldest son of Phraates IV, was in Rome as a hostage when. on the assassination of Orodes II (*c* A.D. T), the Parthians applied to Augustus for a new king of the house of Arsaces. Augustus sent them Vonones, who. however, could not maintain himself: educated as a Roman, he was despised as a slave of the Romans.

Another Arsacid, Artabanus (I1 or III, depending on the interpretation of Trogus Pompeius, xli; *cf.* N. C. Debevoise, *Political History of Parthia,* Chicago, 1938, p. 16. n. 66), connected with the powerful Dahae and king of Atropatene, was invited to the throne and. after an initial defeat. expelled Vonones. The coins of Vonones (m-ho always used his proper name) date from A.D. 8–12. those of Artabanus II begin in A.D. 10. Vonones fled into Armenia and became king there. But Artabanus demanded his deposition, and Augustus, not wanting a Parthian war, removed Vonones into Syria, where he was kept in custody. When he tried to escape. A D. 19, he was killed by his guards.

VONONES II, governor of Media. succeeded King Gotarzes in A.D 51 (perhaps they were brothers), but died after a few months and was succeeded by his son Vologaeses I.

VOODOO (VODUN, a god or spirit, from the Fon language of Africa) is the name of the religion practised in poverty-ridden rural areas of Haiti. Developed by slaves brought to the island by the French during the late 17th to early 19th centuries, Voodoo has the basic features of African religion. especially that of the people of Dahomey. It also has ingredients from native West Indian cults and employs bits from Roman Catholic liturgy, sacraments and sacramentals, despite the opposition of the church. Parallel religions of African origin are Santería in Cuba, Obeah in Jamaica and Orisha in Brazil. Long presented by journalists as cannibalistic, sexually orgiastic and sorcery-ridden, Voodoo has been studied more sympathetically since the 1920s by anthropologists, musicologists and interpreters of folk dance, as well as by psychical researchers interested in the apparent clairvoyance and mediumship of its priests. As a religion. Voodoo has been characterized by modern observers in terms varying from "decadent superstitious syncretism" to "authentic expression of divine archetypes in pure and classic form."

Central to Voodoo is the worship of *loa,* chiefly divine beings of the African pantheon but also ancestors who have been deified. Since most Voodooists are practising Roman Catholics who view their total religious life as a unity, the *loa* are loosely identified with various saints. Each *loa* has its ceremonial colour, its day of the week, its ritual invocations and songs, its sacred emblem to be drawn on the ground and above all its characteristic behaviour when possessing a devotee (*see* POSSESSION). For in Voodoo services the divine beings are expected to select subjects to put into unconscious trance, and then to be incarnated briefly in them for styiized dance, supernatural counsel, feats with fire, feasting and on special occasions the acceptance of animal sacrifices (chickens. goats and bulls). Unlike African practice, which has each person susceptible of possession by only one divine being nhich claims him for a lifetime. Voodoo practice allows an individual's possession by various *loa* at different times, although those of his family inheritance dominate. Guidance and aid from the *loa* may be further sought through dreams and through the mediumship of adepts: in domestic Voodoo, an elder of the family; in cult society Voodoo, an initiated and divinely called male *hungan* or female *mambo.* These latter figures are the centres of voluntary autonomous congregations which they serve as priest, counselor, healer, political guide and lodge-master, with the aid of their acolytes. Each such leader provides the congregation with a sanctuary. though it be only a shed, where there may be celebrated nighttimes after work the elaborate prescribed rites, accompanied by sacred drums beating in intricate rhythms. Such congregational worship is public, but Voodoo also has its traditions of private magic supposedly worked by sorcerers, including the use of curse charms, the creation of zombis or living dead, and the bloodsucking of werewolves; one of the functions of the *loa* is supposedly to protect the faithfui from these.

(Ha. H. B.)

VOORHEES, DANIEL WOLSEY (1827–1897), U.S. lamyer and politica1 leader. was born in Butler county, O., on Sept. 26, 1827, of Dutch and Irish descent. During his infancy his parents removed to Fountain county, Ind., near Veedersburg. He graduated at Indiana Asbury (now De Pauw) university, Greencastle, Ind., in 1849; was admitted to the bar in 1850, and began to practise in Covington, whence in 1857 he removed to Terre Haute. From 1858 to 1860 he was U.S. district attorney for Indiana. In 1861–66 and in 1869–73 he was a Democratic representative in congress; and in 1877–97 he was a member of the U.S. senate.

During the Civil War he seems to have been affiliated with the Knights of the Golden Circle, but he was not so radical as Vallandigham and others. He was a member of the committee on finance throughout his service in the senate, and his first speech in that body was a defense of the free coinage of silver and a plea for the preservation of the full legal tender value of greenback currency, though in 1893 he voted to repeal the silver purchase clause of the Sherman act. He had an active part in bringing about the building of the congressional library.

He was widely known as an effective lawyer, especially in jury trials. In allusion to his unusual stature he was called "the Tall Sycamore of the Wabash." He died in Washington, D.C., on April 10, 1897.

Some of his speeches were published under the title *Forty Years of Oratory* (2 vol.. 1898), edited by his three sons and his daughter, with a biographical sketch by T. B. Long.

VORARLBERG, the most westerly *Bundesland* of Austria, with an area of 1,005 sq.mi.

Physical Geography. — The southern boundary is formed by the limestone range of the Rhatikon Alps (Scesaplana. 9,734 ft.) and part of the crystalline Silvretta massif (Piz Buin, 10.879 ft.). North of the Kloster valley the dolomitic limestone builds the western end of the Lechtal Alps, rising above 8,850 ft., which merge, beyond the Walser valley, into the heights of the Bregenzerwald. The southern slopes of these are of dolomite and more than 6.500 ft. in height but northward the limestone is replaced by the softer sandstones, marls and conglomerates of the Flysch zone with a general softening of the landscape. In this region, near Bregenz, lignite occurs, but elsewhere power is obtained from the mountain streams, rich in falls and fed by plentiful annual precipitation (80 in.).

The climate in the Rhine valley, sheltered and mild, influenced by the foehn (south wind), suits vine and fruit cultivation and its influence stretches far up the fertile tributary valley of the Ill. Of the total area about 88% is productive land but of this 30% is occupied by forests and only 3½% is cultivated ground, the remainder being natural or artificial pasture. Cattle rearing and the production of milk are therefore important and in this respect Swiss influence is more evident than elsewhere in Austria. So, too, the industrial development of Vorarlberg reflects Swiss contacts, for the manufacture of textiles, particularly cotton goods, has grown with the advantage of cheap power. The building of the Arlberg railway (1880–84) effected a considerable strengthening of the economic and political interests of Vorarlberg with the remainder of Austria.

The population is Roman Catholic and German in speech (95%), although in the 17th century Ladin, a Rhaeto-Romance language, was generally spoken. Vorarlberg had 145,000 inhabitants in 1910 and 193,657 in 1951. More than one-third live in the four towns of the province (1951 census): Bregenz (cap.) 20,277; Dornbirn, 22,532; Feldkirch 15,115; Bludenz 10,178.

History.—Vorarlberg is a modern name for the various counties or lordships in the region which the Habsburgs (after they secured Tirol in 1363) succeeded in purchasing or acquiring — Feldkirch (1375, but Hohenems in 1765 only), Bludenz with the Montafon valley (1394), Bregenz (in two parts, 1451 and 1523) and Sonnenberg (1455). After the annexation of Hohenems (its lords having become extinct in 1759), Maria Theresa united all these lordships into an administrative district of Hither Austria, under the name Vorarlberg, the governor residing at Bregenz. In 1782 Joseph II transferred the region to the province of Tirol. The lordship of Blumenegg was added in 1804, but in 1805 all these lands were handed over, by virtue of the peace of Pressburg, to Bavaria, which in 1814 gave them all back, save Hoheneck. In 181j the administrative arrangements were made which lasted until 1918.

After World War I the population voted by a great majority for union with Switzerland (May 11, 1919), but neither the Helvetic government nor the Allies lent encouragement to this transfer of allegiance. Vorarlberg became one of the nine Austrian *Bundeslander*. From April 1938, when Austria was annexed to Germany, Vorarlberg with Tirol formed a *Gau*, but in 1945 it became an Austrian *Bundesland* again.

See N. Krebs, *Die Ostalpen und das heutige Österreich* (Stuttgart, 1928); A. Helbok, *Geschichte Vorarlbergs von der Urzeit bis zur Gegenwart* (1927).

VORONEZH, a region *(oblast)* of the Russian Soviet Federated Socialist Republic. bounded on the south by the Ukrainian Soviet Socialist Republic. U.S S R., and the Kamensk *oblast,* on the east by the Balashov *oblast,* on the north by the Lipetsk *oblast* and on the west by the Kursk *oblast.*

Voronezh occupies the southern slopes of the central Russian plateau (450–700 ft.), and its surface is hilly and intersected by deep ravines in the west, where two ranges of chalk hills separated by the broad Don valley run north and south. East of the Don river is a low plain through which flow the Voronezh and the Bityug. its two left-bank tributaries. Glacial clays with erratic boulders and lacustrine clays and sands cover much of the area. There is an abundant supply of chalk and kaolin clay for pottery. The magnetic anomaly existing in Kursk extends into the southwest of Voronezh and indicates the presence of deep-seated iron ore beds. The soils are mainly black earth formed on loess; they vary in character from the rich black earth with a high humus content of the southern "feather-grass" steppe through the meadow steppe of the centre to the *lyesostep* of the north. This latter is black earth on which forest spread with moister conditions; the forest disappeared, through reckless cutting, and the black earth there was reduced in humus quantity to 4% to 6%. Tree cutting had a disastrous effect in the west and centre for the spring streams frequently washed away fields and roads.

Until World War I Voronezh was mainly an agricultural area and only 6% of its population was urban. Factory industries mere few and included flour milling, oil pressing, distilling, brickmaking, leather- and ropeworks. From 1928 the region was included in the Soviet industrialization program and by 1940 it had many engineering and chemical plants. Its area then was 26,400 sq.mi. and its population was 3,551.009.

In Jan. 1955 the Voronezh region lost about one-fourth of its area when its eastern and northern parts were respectively included in the new regions of Balashov and Lipetsk reducing the total land area to 20,232 sq.mi. The number of Voronezh *rayons* or districts was reduced from 84 to 49. The population in 1959 was 2,363,000 and the chief towns were Voronezh, Liski, Ostrogozhsk, Buturlinovka and Rossosh.

Voronezh, the capital of the region, is situated on the navigable Voronezh river, 15 mi. N. of its confluence with the Don, in 51° 42' N., 39° 10' E. The site was occupied in the 11th century by a Khazar town, deserted during the 14th and 15th centuries. The Russians built a fort there in 1586, which was burned by the Tatars in 1590, but rebuilt. Peter the Great, using the then abundant oak forests of the region, built a flotilla of boats for the conquest of Azov. The town was destroyed by fire in 1703, 1748 and 1773, but each time arose again. In 1897 it had a population of 84,146, which grew to 326,836 in 1939, and 454,000 in 1959. Before World War I the city of Voronezh had a foundry, three distilleries and a few steam-powered flour and oil mills. In 1940 it had ten times more industrial workers than in 1914. It also had 12 institutions of higher education, including a university, which was opened in 1915, during World War I, when the University of Tartu or Dorpat (now in Estonia) was transferred to Voronezh. During World War II Voronezh was occupied by the Germans from July 7, 1942, to Jan. 25, 1943, and the front line ran through the city, along the Voronezh river. The fighting reduced the town to ruins. It was reconquered by Col. Gen. F. I: Golikov and by 1953 Voronezh was entirely rebuilt. (K. SM.)

VORONOFF, SERGE (SERGHEI VORONOV) (1866–1951), Russian-born French surgeon known for his studies in grafting of glands, was born at Voronezh on July 10, 1866. He served as chief surgeon of the Russian hospital in France during World War I, much of his surgery being devoted to bone grafting. In 1921 he became director of experimental surgery at the Collège de France, Paris. where he carried out experiments in grafting glands into sheep. with a view to improving their physique and the quality of their wool. Voronoff attracted world attention nith his claim to have rejuvenated elderly men by transplantation of young human or monkey testicular tissue *(see* REJUVENATION). In 1937 he claimed in a report to the Société de Pathologie Comparée that intelligence and physical gronth of backward children could be improved by grafts of thyroid glands of monkeys

Among his published works were *Life, a Study of the Means of Restoring Vital Energy* (1921); *The Study of Old Age and My Method of Rejuvenation* (1926); and *Conquest of Life* (1932).

Voronoff, who had become a French citizen in 1897, died at Lausanne, Switz., on Sept. 1, 1951.

VORONTSOV or WORONZOFF, the name of a Russian family, various members of which are distinguished in Russian history.

MIKHAIL ILLARIONOVICH VORONTSOV (1714–1767), Russian imperial chancellor, was the first to become prominent. At the age of 14 he was appointed a Kammer junker at the court of Elizabeth Petrovna. whom he materially assisted during the famous coup d'état of Dec. 6, 1741, uhen she seized the Russian throne. In Jan. 1742 he was married to Anna Skavronskaya, the cousin of the empress, and in 1744 he was created a count and vice-chancellor. His jealousy of Count Aleksey Bestuzhev-Ryumin (1744–58) induced him to participate in Count Lestocq's conspiracy against that statesman.

The empress' affection for him (she owed much to his skilful pen and still more to the liberality of his rich kinsfolk) saved him from the fate of his accomplices, but he lived in a state of semieclipse during the domination of Bestuzhev-Ryumin. On the disgrace of Bestuzhev-Ryumin, Vorontsov was made imperial chancellor in his stead.

Though well meaning and honest, Vorontsov as a politician was singularly timorous and irresolute, and always took his cue from the court. Thus, under Elizabeth he was an avowed enemy of Prussia and a warm friend of Austria and France; yet he made no effort to prevent Peter III from reversing the policy of his predecessor. Yet he did not lack personal courage, and he endured torture rather than betray his late master after the revolution of July 9, 1762. He greatly disliked Catherine II, and at first refused to serve under her, though she reinstated him as chancellor. When he found that the real control of foreign affairs was in the hands of Nikita Panin, he resigned from his office (1763).

To judge from Vorontsov's letters, he was a highly cultivated man.

ALEXANDER ROMANOVICH VORONTSOV (1741–1805), Russian imperial chancellor, nephew of the preceding and son of Count Roman Vorontsov, represented Peter III for a short time at the court of St. James's. Catherine II made him a senator and president of the department of trade; but she never liked him, and ultimately (1791) compelled him to retire from public life. In 1802 Alexander I summoned him back to office and appointed him imperial chancellor.

The Vorontsovs had always insisted on the necessity of a close union with Austria and Great Britain, in opposition to Panin and his followers, who had leaned on France or Prussia until the outbreak of the revolution made friendship with France impossible. Vorontsov was also an implacable opponent of Napoleon. The rupture with Napoleon in 1803 is mainly attributable to him. He retired in 1804.

His "Memoirs of My Own Times" (Rus.) was printed in vol. vii of the *Vorontsov Archives.*

SEMEN ROMANOVICH VORONTSOV (1744–1832), Russian diplomatist, brother of Alexander Romanovich, distinguished himself during the first Turkish War of Catherine II at Larga and Kagula in 1770. In 1783 he was appointed Russian minister at Vienna, but in 1785 was transferred to London where he lived for the rest of his life.

During Catherine's second Turkish War he contributed to bring about the disarmament of the auxiliary British fleet which had been fitted out to assist the Turks, and in 1793 obtained a renewal of the commercial treaty between Great Britain and Russia. Subsequently, his policies profoundly irritated the empress. On the accession of Paul he was raised to the rank of ambassador extraordinary and minister plenipotentiary, and received immense estates in Finland.

Neither Vorontsov's detention of the Russian squadron under Makarov in British ports nor his refusal, after the death of Bezborodko, to accept the dignity of imperial chancellor could alienate the favour of Paul. It was only when the emperor himself began to draw nearer to France that he began to consider Vorontsov as incompetent to serve Russia in England, and in Feb. 1800 all the count's estates were confiscated. Alexander I on his accession at once reinstated him, but ill-health and family affairs induced him to resign his post in 1806.

MIKHAIL SEMENOVICH VORONTSOV (1782–1856) Russian prince and field marshal, son of the preceding, spent his childhood and youth with his father in London.

During 1803–04 he served in the Caucasus under Tsitsianov and Gulyakov. He served in the campaigns of 1805–07 against Napoleon, against the Turks in 1809–11 and nith Bagration's army in 1812. In 1814, at Craonne, he brilliantly withstood Napoleon in person. He was the commander of the corps of occupation in France from 181j to 1818. In 1823 he was appointed governor general of New Russia, as the southern provinces of the empire were then called. He was the first to start steamboats on the Black sea (1828).

The same year he succeeded the wounded Menshikov as commander of the forces besieging Varna. which he captured on Sept. 28. In the campaign of 1829 he took measures to prevent the spread of the plague from Turkey to Russia. In 1844 Vorontsov was appointed commander in chief and governor of the Caucasus with plenipotentiary powers. For his brilliant campaign against Shamyl, and especially for his difficult march through the dangerous forests of Ichkerinia, he was raised to the dignity of prince. By 1848 he had captured two-thirds of Daghestan. and the situation of the Russians in the Caucasus, so long almost desperate, was steadily improving. In the beginning of 1853 Vorontsov retired. He was made a field marshal in 1856, and died the same year at Odessa.

VOROSHILOV, KLEMENTIY EFREMOVICH (1881–), Soviet army officer and government official, was born at Verkhneye. Ekaterinoslav (later Dnepropetrovsk) province, Ukraine, on Jan. 23. 1881, the son of a workman. .

He joined the Russian Social Democratic party in 1903, and in 1906 was a delegate to the Stockholm congress of the Bolsheviks. He spent most of the period from 1907 to 1914 in prison or exile. In 1918 he organized the 5th Ukrainian Red army which marched from Lugansk to Tsaritsyn (later Stalingrad). He defended Tsaritsyn against A. I. Denikin's White Russian army and from that period dated his devotion to Joseph Stalin. who was the political commissar on the front. In 1919 Voroshilov became a member of the Ukrainian Communist government and commander of the 14th army in the Ukraine. In 1921 he was appointed commander of the North Caucasian military area and in Rlay 1924 commander of the Moscow military area. In the meantime he continued to rise in the party organization: in 1921 the 10th congress elected him a member of the central committee and from Jan. 1926 he was a member of its Politburo. From 1925 to 1940 he was a deputy chairman of the council of people's commissars (from 1946 of ministers) and from July 1941 a member of the five-man State Defense committee.

One of the most successful field commanders in the civil war, Voroshilov, who never received military training as a staff officer, did-badly in June–Sept. 1941 as commander of the northwestern (Leningrad) front. On Jan. 21. 1945, he signed the armistice with Hungary on behalf of the Allied (Soviet) command, and up to March 1946 was chairman of the Allied Control commission in Budapest.

In Oct. 1952 the 19th congress of the Communist party of the Soviet Union re-elected him to its central committee, which two days later elected him a member of its presidium. On March 6, 1953, after Stalin's death. Voroshilov was appointed chairman of the presidium of the supreme soviet of the U.S.S.R., a function equivalent to that of the head of state.

Voroshilov continued as "president" of the U.S.S.R. after Georgi M. Malenkov, Stalin's successor. was replaced (Feb. 1955) as chairman (premier) of the U.S.S.R. council of ministers by Nikolai A. Bulganin; and after Bulganin was in turn replaced (March 1958) by Nikita S. Khrushchev. In May 1960 Voroshilov resigned at the age of 79 and was replaced by Leonid I. Brezhnev.

VOROSHILOVGRAD (formerly known as LUGANSK), a city of the Ukrainian Soviet Socialist Republic, on the small Lugan river. 10 mi. from its confluence with the northern Donets. in 48° 35' N., 39° 19' E. It is situated on the railway in the Lugan mining district of the Donets, which consists of the Lisichansk coal mining region and the Gorodishche anthracite mines. Coal was known to exist in the time of Peter the Great, but was not worked until 1795, when an Englishman. Gascoyne. established the town's first ironworks for supplying the Black sea fleet. Its distance from the sea proved a difficulty and the works were closed until the Crimean War, when shot, shell and gun carriages were again produced. After 1923 the town developed rapidly and its population in 1956 was estimated at 251,000 as against 34.175 in 1900. Industries developed there include smelting, engine building and enamel works, the manufacture of timber saws and ball bearings and flour milling and brewing industries. During World War II Voroshilovgrad was occupied by German forces, 1941–43...

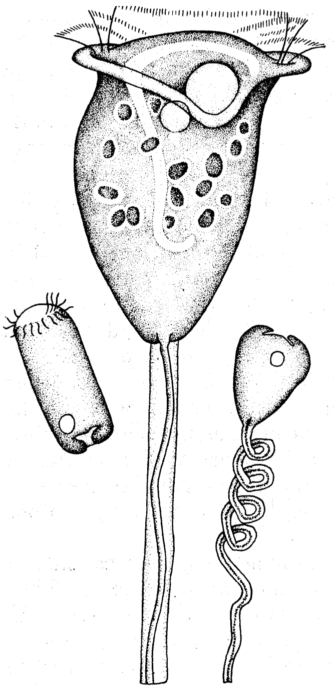
VÖROSMARTY, MIHÁLY (1800–1855), Hungarian poet, a leading figure of Hungarian literary life during the era of reforms (1825–49). Born on Dec. 1, 1800, at Nyék, into a family of impoverished nobles, he soon had to provide for himself. From the age of 15 as a schoolboy and later while studying law, he supported himself by private tutoring. He first attempted to write poetry during his school days and he never ceased to write. In 1825 he published an epic. written in hexameters. *Zalán futása*, describing the conquest of Hungary by Árpád, and the defeat of Zalán who had previously ruled the country. The epic. in ten cantos, has great artistic merit but its resounding success was caused also by the general patriotic upsurge of the period which clamoured for a work describing the glorious past of the nation.

Vorosmarty belonged to the group of writers led by Károly Kisfaludy, and he was a regular contributor to the literary periodical *Aurora*. In 1828 Vorosmarty became the full-time editor of a well-known magazine: the *Tudományos Gyűjtemény*, and his is the curious privilege of being the first Hungarian man of letters to make a living — admittedly a modest one — out of literature.. Vorosmarty's influence and fame was steadily growing, but he had little practical sense and what influence he exerted was through the authority of his genius and the unpretentious integrity of his character. In 1830 he became the first member of the newly founded Hungarian academy. Vorosmarty mas the best dramatist of his time. His early work was strongly influenced by German and French romantic drama but in 1830 he produced a really great work, *Csongor és Tünde*, a symbolic fairy-tale. He married late, in 1843, and his wife Laura Csajághy inspired some beautiful poems, among which *A merengőhöz* ("To a day-dreamer," 1843) is outstanding. Having achieved fame, reasonable material comfort and a happy marriage Vorosmarty was in a position to look forward to a contented old age, when the War of Independence (1848–49) shattered his life. An ardent partisan of Kossuth, he embraced the national cause and became a member of parliament. During the repression which followed, Vorosmarty had to go into hiding and lived with his three children in great misery. His personal misfortune and the tribulation of his country affected his mind and though he was still able to produce some splendid poems, such as *Vén cigány* ("The Old Gypsy." 1854), he was unable to continue his former activity. He died at Pest on Nov. 19, 1855.

Vorosmarty played a most important part in the development of Hungarian literature. By purifying it from overwhelming classical and German influence, he made it national not only in language but also in spirit. His ardent love of Hungary pervaded all his works as it directed all his life. It was with him that literature in Hungary became really Hungarian and, at the same time, reached maturity. (Ds. SR.)

VORTEX: *see* WHIRLPOOL.

VORTICELLA, the generic name of protozoa identified by a bell-shaped or cylindrical body with a conspicuous wreath of cilia on the oral end and a contractile unbranched stalk on the aboral end, usually without cilia between the oral and aboral ends. Vorticellas are very cosmopolitan. They eat bacteria and small protozoa, live in fresh and salt water, often in clusters attached to aquatic plants, surface scum, submerged objects or various aquatic animals. Although often found in clusters, each vorticella's stalk is fastened independently. The stalk consists of an external sheath that contains a fluid and a spirally arranged contractile thread. In its contracted condition the stalk-thread is shortened and the sheath is coiled like a corkscrew.



AFTER NOLAND AND FINLEY, "TRANSACTIONS." AMERICAN MICROSCOPICAL SOCIETY (1931)
VORTICELLA ONE-CELLED ANIMAL FOUND IN PONDS
Greatly magnified. Adult (centre) and immature forms

Vorticellas reproduce by longitudinal fission and conjugation. After fission, one of the two animals keeps the original stalk; the other grous a temporary wreath of cilia at the aboral end, detaches itself and migrates. Propelled by the temporary cilia, the migrant chooses a place for attachment, grows a stalk and loses the temporary cilia. In conjugation one small special migrant (microconjugant) finds a special attached *Vorticella* (macroconjugant) and the two conjugants amalgamate completely, forming one organism in a sexlike union that eventually leads to fission.

C. G. Ehrenberg wrote the modern description of *Vorticella* in 1838. The first description, 1676, was by Anthony van Leeuwenhoek. Later August Johann Rösel (1755) and C. Linnaeus (1767) described vorticellas. Approximately 200 species are known. They belong to the family Vorticellidae but may be called peritrichs. Their close peritrich relatives, *Carchesium* and *Zoothamnium*, are occasionally mistaken for vorticellas. (H. E. F.)

VOSGES, an upland *département* of eastern France, formed in 1790 chiefly by territory previously belonging to Lorraine, together aith portions of Franche-Comté and Champagne, and bounded north by Meurthe-et-Moselle. northeast by Bas-Rhin, east by Haut-Rhin, southeast by the territory of Belfort, south by Haute-Saône, nest by Haute-Marne and northwest by Meuse. Pop. (1954) 372,523; area 2,279 sq.mi. The Vosges mountains form a natural boundary on the east, their highest French eminence, the Hohneck, attaining 4,465 ft. The Monts Faucilles traverse the south of the department in a broad curve declining on the north into elevated plateaus, on the south encircling the upper basin of the Saône. This chain, dividing the basins of the Rhône and the Rhine, forms part of the European watershed between the basins of the Mediterranean and Atlantic. The Moselle and the Meuse, tributaries of the Rhine, have the largest drainage areas in the department; a small district in the northwest sends its waters to the Seine, the rest belongs to the basin of the Rhône. The Moselle rises in the Col de Bussang in the extreme southeast, and in a north-northwesterly course of about 70 mi. in the department receives the Moselotte and the Vologne on the right; the Mortagne and Meurthe on the right and the Madon on the left bank also belong to this department though they join the Moselle outside its borders.

The elevation and the northward exposure of the valleys make the climate severe, and a constant dampness prevails, owing both to the abundance of the rainfall and to the impermeability of the subsoil. The minter average temperature reduced to sea level is 34° to 35°, the summer average temperature being 66° to 68°. The rainfall varies from 28 in. to 60 in., according to the altitude. Arable farming flourishes in the western districts where wheat, oats, beetroot, tobacco, hops, potatoes and hemp are largely grown. The vine is cultivated on the river banks, to best advantage on those of the Moselle. Pasture is abundant in the mountainous region, where cheese-making is carried on to some extent, but the best grazing is in the central valleys. Forests, which occupy large tracts on the flanks of the Vosges, cover about one-third of the department, and are a principal source of its wealth. Sawmills are numerous in the Vosges and the manufactures of furniture, sabots, brushes and wood-working in general are prominent industries. The department has mines of lignite and stone quarries of various kinds. There are numerous mineral springs, notably those of Contrexéville, Plombières, Vittel, Bains-les-Bains, Martigny-les-Bains and Bussang. Metal goods are made, but the manufacture of textiles is the chief industry, comprising the spinning and aeaving of cotton, wool, silk, hemp and flax, and the manufacture of hosiery and of embroidery and lace, Mirecourt (pop. [1954] 4,619), which also makes musical instruments, being an important centre for the two last. The department forms the diocese of St. Dié (province of Besançon), has its court of appeal and educational centre at Nancy, and belongs to the district of the XX army corps. It is divided into three arrondissements of Épinal, the capital, Neufchâteau and St. Dié, with 29 cantons and 532 communes.

VOSGES, a mountain range stretching along the west side of the Rhine valley, from Basel to Mainz, a distance of 150 mi. They are similar to and closely associated with the Black Forest. The ranges are similar in geological formation and are portions of the same structural unit, for the Rhine valley which separates them lies in a rift valley of Tertiary age. In addition both have fine forests on their lower slopes, above which are open pasturages and rounded summits of a uniform altitude; both have a steep fall to the Rhine and a gradual descent on the other side. The Vosges in their southern portion are mainly of granite, with some porphyritic rocks, and a red sandstone (occasionally 1,640 ft. thick) which on the western versant is named "grès Vosgien."

Orographically the range is divided into four sections: the Grandes Vosges (62 mi.), extending from Belfort to the Col de Saales; the Central Vosges (31 mi.), between the latter and the Col de Saverne; the Lower Vosges (30 mi.) from thence to the source of the Lauter; and the Hardt Mts. (*q.v.*). The rounded summits of the Grandes Vosges are called "ballons." The departments of Vosges, Haute Saône, and Haut-Rhin and Belfort territory meet at the Ballon d'Alsace (4,094 ft.). Then northward the average height of the range is 3,000 ft., the highest point, the Ballon de Guebwiller (Gebweiler), or Sultz, rising east of the main chain to 4,672 ft. The Col de Saales is 1,824 ft. high. The central section is both lower and narrower than the Grandes Vosges, Mont Donon (3,307 ft.) being the highest summit. The Rhine and Marne Canal and the Paris-Strasbourg railway traverse the Col de Saverne. There are motor roads over the passes of Bussang (Remiremont to Thann), the Col de la Schlucht (3,737 ft.) (Gérardmer to Munster), the Bonhomme (St. Dié to Colmar) and the pass from St. Dié to Ste. Marie-aux-Mines. The Lower Vosges are a sandstone plateau ranging from 1,000 to 1,850 ft. high, and are crossed by the railway from Hagenau to Sarreguemines, defended by the fort of Bitche.

The annual rainfall is much higher and the mean temperature much lower in the western than in the eastern versants while on the latter the vine ripens to a height of 1,300 ft.; but its only rivers here are the Ill and other shorter streams. The Moselle, Meurthe and Saar all rise on the Lorraine side. Moraines, boulders and polished rocks testify to the existence of glaciers which formerly covered the Vosges. The lakes, surrounded by pines, beeches and maples, the green meadows which provide pasture for large herds of cows, and the fine views of the Rhine valley, Black Forest and snow-covered Swiss mountains combine to make the district picturesque.

VOSS, JOHANN HEINRICH (1751–1826), German poet, remembered chiefly for his translations of Homer. was born at Sommersdorf in Mecklenburg on Feb. 20, 1751, the son of a farmer. After some time as a private tutor, he went to Gottingen in 1772 at the invitation of H. C. Boie (*q.v.*), whose attention he had attracted by poems contributed to the *Gottinger Musenalmanach.* Here he studied theology (briefly) and philology, and became one of the leading spirits of the famous *Gottinger Hainbund.* In 1775 Boie handed over to him the editorship of the *Gottinger Musenalmanach,* which he continued to issue for several years. In 1777 he married Boie's sister Ernestine. From 1778 to 1802 Voss was headmaster of schools. first at Otterndorf, Hanover (where he began to translate the *Odyssey),* then at Eutin; but he found the work uncongenial and gave it up, living as a private scholar in Jena. In 1805 he moved to Heidelberg where he mas given a professorship in classical philology, which allowed him to devote himself to his translations. An ardent rationalist, he waged an exasperated and embittered struggle against the younger romantics (Arnim. Brentano, Creuzer) and against his childhood friend F. L. Stolberg, a convert to Roman Catholicism. He became more and more lonely and died on March 29, 1826, in Heidelberg.

Voss published his collected poems in 1802. As a lyricist he wrote mainly songs, odes, elegies and pastoral idylls in the style of Klopstock and the ancients. His idyll *Luise* (1795), which portrays with naturalistic ease the life of a country pastor's family, inspired Goethe to write *Hermann and Dorothea.* Voss is chiefly famous. however, for his translations. The *Odyssey* (1781) and *Iliad* (1793), particularly, achieved permanent importance. Voss was regarded by Goethe and other German poets as an authority on classical metres; but his pedantic regard for the niceties of form and language led him in his later translations to strain his medium on behalf of exactitude. His classical authors included Virgil (1789 ff.), Ovid (1798) and Horace (1806). He also translated *A Thousand and One Nights* (1781–85) and, with his sons Heinrich and Abraham, Shakespeare's plays (1818–29).

J. H. Voss's *Sämtliche poetische Werke* came out in 1835 (new ed. 1850). A good selection, with biography, is in A. Sauer, *Der Gottinger Dichterbund,* vol. 1 (*Kürschner's Deutsche Nationalliteratur*, vol. 49, *1887).* His *Briefe* have also appeared, 4 vol. (1829–33).

H. *Voss an F. G. Klopstock* (letters, 1954). (FH. W. W.)

VOSSIUS (Voss), **GERHARD JOHANN** (1577–1649), German classical scholar and theologian, was the son of Johannes Voss. a Dutch Calvinist pastor, and was born in a village near Heidelberg, where his father had found refuge. But Voss was unwelcome among the Lutherans, and returned with his son to Holland. Gerhard was educated at the university of Leyden, where he became the lifelong friend of Hugo Grotius, and studied classics, Hebrew, church history and theology. He was rector (1600–14) of the high school at Dort, and then director of the theological college at Leyden (1614–19). He came under suspicion of heresy, and escaped expulsion from his office only by resignation (1619). In 1618 he had published his history of Pelagian controversies, which his enemies considered favoured the views of the Arminians or Remonstrants. In 1622, however, he was appointed professor of rhetoric and chronology, and subsequently of Greek, in the university. He declined invitations from Cambridge, but accepted from Archbishop Laud a prebend in Canterbury cathedral without residence, and went to England to be installed in 1629, when he was made LL.D. at Oxford. In 1632 he left Leyden to become professor of history in the newly founded Athenaeum at Amsterdam.

Vossius died on March 19, 1649.

Vossius was amongst the first to treat theological dogmas and the heathen religions from the historical point of view. His principal works are *Historia Pelagiana sive Historiae de controversiis quas Pelagius eiusque reliquiae moverunt* (1618); *Aristarchus, sive de arte grammatica* (1635 and 1695; new ed. in two vols., 1833–35); *Etymologicum linguae Latinae* (1662; new ed in two vols, 1762–63); *Commentariorum Rhetoricorurn oratoriarum institutionum Libri VI* (1606 and often); De *Historicis Graecis Libri III* (1624); *De Historicis Latinis Libri III* (1627); *De Theologia Gentili* (1642); *Dissertationes Tres de Tribus Symbolis, Apostolico, Athanasiano et Constantinopolitano* (1642). Collected works published at Amsterdam (6 vols., 1695–1701).

VOTING: see ELECTORAL SYSTEMS; VOTING BEHAVIOUR.

VOTING BEHAVIOUR. This term deals with the people's choice—why do people vote as they do? In most of the democratic countries of the west, large numbers of citizens eligible for the ballot do not vote at all, and the decision to support one candidate rather than another is by no means based simply and directly on individual consideration of the political issues involved. Most research on the topic centres on the social and psychological factors underlying voting decisions. Although it mainly reflects U.S. practice in presidential elections, such research does perhaps provide some insight into voting behaviour generally.

According to the traditional view of voting as presented in classical texts of democratic theory, inspired by the political views of the 18th-century Enlightenment, the voter is supposed to be interested in politics and to express that interest by broad, continuous and critical attention to the flow of electoral news and talks in the communication mediums. He is supposed to be well informed on campaign issues, events and personalities; to give impartial, rational consideration to the issues at hand; to judge political proposals in the light of general principles dictated by the public interest; and to discuss political matters with his fellow voters so that a wide popular debate on the issues will be held, led by the candidates themselves. The key words used to describe the voter in political theory are such terms as informed, interested, rational, principled. That is what the voter is supposed to be like; what is he really like?

Influence of Social Status.—First, as to the basis of voting: people's votes are closely tied to their social position. In this way, the vote serves as the political projection and expression of a country's social fabric. In the United States in the second half of the 20th century, there were three major factors of a sociological character that affected the vote decision:

1. Ecological, *i.e.,* environmental differences in viewpoint, reflecting the distinctive regional outlooks of, for instance, the south or New England or such residential differences as the suburb against the metropolis.

2. Socioeconomic status, under which are included such characteristics as class, occupation, income level and class identification (*i.e.,* the voter's feeling as to what class he belongs to, regardless of where "objective" criteria place him). There is, however, substantial deviation between the class-predicted vote and actual vote. Substantial numbers do not vote with their class—and there are probably more deviants from the "labour vote" than from the corresponding "business vote."

3. Ethnic or "minority" characteristics such as race, nationality and, importantly, religion. This factor receives less overt attention, possibly because of its greater social sensitivity. The plain fact is that the two-party vote in the U.S., at least in national elections, can be closely tied to the ethnic identification of the voters. This is true not only of Negro-white differences but also differences in voting behaviour between native born and foreign born, between groups of diverse national origin and finally between Protestants on the one hand and Catholics and Jews on the other. Indeed, there is good reason to believe that the influence of religion on vote—simply in the sense of religious membership or identification—is stronger than the class or socioeconomic difference. If there is a "class vote" in the U.S. there is a "religious vote" as well.

But that is not the whole story. In part, such political differences by strata, whatever their historical origins, are sustained by the day-to-day personal relations in the family, in the work place and among friends. First, there is a hereditary vote—the child following the politics of the parents—and there is near unanimity on political questions inside the family, within as well as between generations. Similarly, there is high political agreement among friends and among co-workers. In short, the typical voter is encapsulated in a congenial and harmonious atmosphere in which political preferences are communicated to him informally and indirectly in a socially reinforcing manner.

In addition, there is the continuity provided by the "party habit," *i.e.,* the tendency to go along with the same selection made earlier, partly as a way of justifying one's preceding vote decisions.

Small wonder, then, that voting preferences are usually quite stable. Most voters do not change their minds during a presidential campaign, and large numbers do not change from one election to the next. It typically requires a substantial change in one's social position, either relatively or absolutely, to effect a major change in vote—for example, for the society, a depression that stirs up the political situation enough to challenge the preferences of many; for the group, a politically tinged event such as regional unemployment or the threat of racial desegregation; for the individual, an upward movement in occupational mobility that involves shifts in residence, friendships, standards of living and social judgment.

Shifts in Party Allegiance.—But some people do change their votes; who are they? Evidence suggests that they are the less partisan-minded voters who are relatively indifferent to the above considerations, or are subject to conflicting group claims on their loyalty. Certainly only a minority in the United States are highly interested, by any reasonable definition, in the political scene in normal times, and the most partisan individuals are precisely the people who change their votes least frequently and with greatest difficulty. The less interested are the less partisan, and as such they are less likely to have their vote based solidly on the types of characteristics noted above; they may be subject to social cross pressures on their vote, having a foot in each camp, so that the outcome of the election means less to them. For example, wealthy members of an ethnic group may be under such cross pressures: their wealth may incline them in one direction and their ethnic status in the other. Their personal associations tend to be in the same situation, and so reinforce the conflict. There are always a number of people so situated that the election results are seen by them to be of little personal consequence. They are the people who tend not to follow the progress of the campaign in newspapers and on television or radio; who are most influenced by their personal contacts with friends and party workers; who are least concerned about the issues of the campaign; and who settle their vote late in the campaign.

Thus voting behaviour creates a striking spectacle in which the most interested and most knowledgeable are the least open to persuasion, most of them knowing well ahead of the campaign, long before either candidates or platforms are selected, how they will vote.

On the other hand, those most subject to change are the least involved and the most likely to shift their preference on frivolous grounds.

Issues.—As to the content of politics, the important issues appear to be of two kinds—what have been called "position" issues and "style" issues. The former are typically of an economic sort, having to do with taxation, farm prices, labour-management relations and similar matters; that is, they are tied quite clearly to the socioeconomic position of the voter and they appeal to him, and have consequences for him, in that connection. Style issues deal more with matters of political taste, *e.g.,* civil liberties, prohibition, immigration, intergroup relations or government corruption; they are more likely to be tied to ethnic and regional considerations. Style issues are probably more likely to be crucial when position issues are quiescent, and the great historical issues, like slavery, contain elements of both.

At any given time, only a few issues are really in contention insofar as public attitudes are concerned. The adherents of opposing sides actually agree on a large number of matters of political importance—what the issues are, what is likely to happen, what criteria to judge by, what the rules of the political game are. The partisans differ on those issues that happen to be in the "political gateway" at the moment, for example, the rich man-poor man issues of the New Deal era. But neither the electorate, nor probably the system, can handle more than a few issues at any given time in a large and heterogeneous country.

U.S. Presidential Campaigns.—Now how does a brief presidential campaign in the U.S. reflect this view of the basis of voting, the stability of political preferences, and the content of the political program?

The campaign defines which issues shall be prominent, and even dominant, and each side seeks to get its definition accepted rather than its opponent's. One effect of this effort is that partisans increasingly agree with their own candidate by resolving "inconsistent" opinions in favour of the central party opinion, and even by misperceiving the candidates' positions on subsidiary issues in order to bring them into harmony with one's own preferences. Thus over-all, the campaign organizes many small disagreements into one big disagreement, namely, which party shall hold power. What starts as a mass of diverse opinions, with cleavages running every which way in the electorate, is organized by the campaign into a single basic difference of opinion between the two sets of party supporters.

The campaign reinforces the faithful: it recharges the interest of the already convinced and provides them with the political rationale currently active. The partisan tends to select his own side's material from that provided by communications mediums. Thus, the campaign not only reguarantees his basic vote but also transforms many partisans into effective personal campaigners within their own circles. The campaign brings into action the latent votes of those predisposed to one or the other side through their social identifications and associations; it thus "brings out" the vote, but only in a particular direction. It converts the doubtful, who, though few, often carry the balance of power in close elections.

The campaign has the polarizing effect of promoting consensus within social groups and cleavage between them. Under its impact, people come to agree more with people like themselves, in socioeconomic or ethnic terms, and to disagree more with people on the other side.

Thus, it is seen, the foundations of American political parties are in social groups with inter- and intragenerational solidarity, and political interests and social traditions reinforce one another by means of the campaign.

In summary, as it has been said,

The usual analogy between the voting "decision" and the more or less carefully calculated decisions of consumers or business men or courts may be quite incorrect. For many voters political preferences may better be considered analogous to cultural tastes—in music, literature, recreational activities, dress, ethics, speech, social behavior. Consider the parallels between political preferences and general cultural tastes. Both have their origin in ethnic, sectional, class, and family traditions. Both exhibit stability and resistance to change for individuals, but flexibility and adjustment over generations for the society as a whole. Both seem to be matters of sentiment and disposition rather than "reasoned preferences." While both are responsive to changed conditions and unusual stimuli, they are relatively invulnerable to direct argumentation and vulnerable to indirect social influences. Both are characterized more by faith than by conviction and by wishful expectation rather than careful prediction of consequences. . . . (Bernard Berelson *et al., Voting, a Study of Opinion Formation in a Presidential Campaign,* pp. 310–311, Chicago: University of Chicago Press, 1954.)

Implications for Democratic Theory.—Finally, what are the implications of this description of voting behaviour for the political theory of democracy? Some of the "requirements" for the democratic citizens were noted above, yet we find that taken by and large the citizens do not fulfill the standards. Substantial proportions of the electorate are not particularly interested in political matters, or well informed on them. They vote their class or regional or even religious interests rather than "the public interest." There is often little that is specifically political in the considerations that lead to their vote; the decision often arises out of a pervasive group understanding rather than a process of ratiocination. Indeed, it can be said that for many citizens the decision as to how to vote is not really an individual matter at all but a kind of collective decision in which a whole group of people, from the family to the social stratum, work their way to a final position without much conscious and deliberative thought.

This image of voting violates traditional ideals of democratic participation, yet the system works. What can be said about this seeming discrepancy?

The political philosophy we have inherited has given more consideration to the virtues of the typical citizen of the democracy than to the working of the system as a whole . . . Liberal democracy is more than a political system in which individual voters and political institutions operate. For political democracy to survive, other features are required: The intensity of conflict must be limited, the rate of change must be restrained, stability in the social and economic structure must be maintained, a pluralistic social organization must exist, and a basic consensus must bind together the contending parties. (Berelson *et al., ibid.)*

The classical tradition, in this view, demanded political virtue of the citizen in too extreme, too doctrinal and too general a form. What is required is a voting population that is not homogeneous but heterogeneous in its political quality. For example, as the system requires conciliation of opposing interests, it is facilitated by the people who are indifferent to political matters and thus provide a cushion between the partisans. As the system requires stability, it is furnished by the voters with strong party loyalties. As the system requires flexibility, it is facilitated again by the low-interest changers.

The need for heterogeneity arises from the contradictory functions we expect our voting system to serve. We expect the political system to adjust itself and our affairs to changing conditions; yet we demand too that it display a high degree of stability. We expect the contending interests and parties to pursue their ends vigorously and the voters to care; yet, after the election is over, we expect reconciliation. We expect the voting outcome to serve what is best for the community; yet we do not want disinterested voting unattached to the purposes and interests of different segments of that community. We want voters to express their own free and self-determined choices; yet, for the good of the community, we would like voters to avail themselves of the best information and guidance available from the groups and leaders around them. We expect a high degree of rationality to prevail in the decision; but were all irrationality and mythology absent, and all ends pursued by the most coldly rational selection of political means, it is doubtful if this system would hold together.

In short, our electoral system calls for apparently incompatible properties—which, although they cannot all reside in each individual voter, can (and do) reside in a heterogeneous electorate. What seems to be required of the electorate as a whole is a distribution of qualities . . . (Berelson *et al., ibid.)*

In this way the countless acts of voting behaviour performed by millions of individual voters add up to a working political system.

VOTING MACHINES, devices that record and count votes cast in an election. Each voting machine is a complete polling booth and is surrounded with curtains to insure privacy. The entire list of candidates and referendum questions appears on the face of the machine in much the same way as on a paper ballot. Wear each candidate's name and near each question there is a pointer that the voter may move into position to indicate his preference. All machines also provide space for write-in votes. Within the machine are counters that record and count the votes for each candidate and question.

In using a voting machine the voter first steps into the booth and either pulls a lever or flips a switch that closes the curtains around him and simultaneously "opens" the machine to record his vote. He then moves the levers adjacent to the names of the candidates he wishes to support and the questions he wishes to vote on. If he makes a mistake or changes his mind while he is still in the booth he may raise any of the levers that he has moved and vote for a different candidate. When finished. he reverses the main lever or snitch; this returns the pointers to their original position, opens the curtains and registers his vote Each candidate's total vote accumulates throughout the election so that the final count is ready the moment the polls close and can be dispatched to central headquarters immediately. Each voting machine is inspected by the election officials before the voting begins and is sealed after the polls have closed and the total vote has been recorded.

A MODERN VOTING MACHINE WITH VERTICAL LISTING

Though voting machines have been used in Brazil. Cuba and the Netherlands, the United States is the only country in the world that has used them extensively. It is the only large and wealthy nation with enough elections of the right type to make their manufacture and use practical from an economic standpoint. Voting machines are most useful when the ballot lists many offices to be filled and many proposals to be voted on, though an extremely long ballot may exceed the capacity of the machines. In Great Britain, because of the short ballot and infrequent elections, voting machines have not found favour. In the United States, where a federal system is combined with the separation of powers, short terms of office, nomination by direct primaries and the exercise of local self-government. there is a multitude of elections. Nominal filing fees, the tradition of the long ballot and the availability of the initiative and referendum insure an even greater number of candidates and issues. And the system of majority representation permits the use of a voting machine of basically simple design.

Chief among the advantages claimed for voting machines are the folloning: (1) The results of an election are instantly available in every precinct. (2) The count is accurate. (3) The possibility of fraud or error is greatly reduced. (4) Because of the lessened opportunity for fraud or error, recounts are seldom called for and. when necessary, may be completed quickly and at little cost. (5) The machine prevents the voter from spoiling his ballot either by putting an "X" in the wrong place or by voting for more candidates than the law allows. (6) Over a period of years, election costs can be considerably reduced. partly through savings in the printing of tons of paper ballots and partly through economies resulting from the need for fewer election officials. Net savings are usually sufficient to amortize the cost within from 12 to 15 years. long before the expiration of the life of the machines.

Yet objections to the use of voting machines are raised. Those nho oppose their use point out that the initial cost is substantial—$1 500 to $1.800 for each machine. To this original cost must be added the expense of storage and, unless they are stored at the polling places. the cost of transporting them to and from the polling places at election time. The machines may reduce the possibility of fraud and error but. it is argued, they do not entirely eliminate it. It is also argued that machines discourage voting. Many voters. it is said. are reluctant to use the machines because they are unfamiliar with their operation and distrustful of them. In some elections, particularly primaries, there may be so many parties and candidates to be voted on that they cannot all be listed on the machines. In such cases paper ballots must be used instead of the machines. Some difficulty also arises in adapting machines to elections based on complicated systems of proportional representation (*q.v.*) nherein the voter may indicate a series of preferences rather than absolute choices. Machines can be designed to record and measure such preferences but their greater complexity, plus the limited market for them. has thus far made their manufacture commercially impracticable. Further difficulties arise in making provision for absentee voters to use voting machines.

Historical Background.— The first use of voting machines in the United States occurred in Lockport, N.Y., in 1892, when the Jacob H. Myers machine was used. Four years later voting machines were used in Rochester, N.Y. Although they were successful. the early machines developed slowly. chiefly because some nere defective in manufacture or were improperly installed and serviced. In some states the legality of voting machines was questioned on the ground that the state constitutional requirement that voting be "by ballot" meant that a paper ballot must be used. With rare exceptions, the courts rejected this line of argument.

During the first decade of the 20th century the various companies engaged in the production of voting machines were combined into a single firm in Jamestown. N.Y., known since 1923' as the Automatic Voting Machine company. This firm had the field to itself until the expiration of certain basic patents in 1929 opened the way a few years later for the Shoup Voting Machine company, the only other firm in the business.

It was estimated that approximately 100,000 machines manufactured and sold by these two companies were used in the election in Nov. 1960. Available in several sizes and operated either electrically or manually, they attained their most economical use in precincts having approximately 450 voters. The two makes have many similarities but it is perhaps worth noting that the older and more widely used Automatic machine employs horizontal listing and has its counters located in back while the Shoup models use vertical listing, after the manner of the paper ballots-used in most states. and have their counters in front directly under the names of candidates.

The use of voting machines in the U.S. depends upon state legislative action specifying conditions for their use and setting forth requirements the machines must meet. The machines are normally required to give the voter the same opportunities for choice allowed by the secret paper ballots. Use of machines, usually made optional nith local authorities, is mandatory in New York, Rhode Island. Connecticut. Delaware. Maryland and Louisiana. As of 1960, only Idaho, South Dakota and Alaska had made no provision for them. In that year it was estimated that about 60% of all U.S. voters cast their votes on machines.

See Spencer D Albright, *The American Ballot (1942)*; *The Book of the States* (biennial). (J. A. V.)

VOTKINSK, a town in the Udmurt Autonomous Soviet Socialist Republic, Russian Soviet Federated Socialist Republic, U.S S.R., on a tributary of the Kama river in 57° 5′ N., 53° 55' E. Pop. (1959) 59.000. It manufactures agricultural machinery and has railway and shipbuilding yards; it is the terminus of a branch railway

VOUET, SIMON (1590–1649), French painter, who established in France a modern baroque style of decorative painting, was born in Paris on Jan. 9, 1590. He formed his style in Italy, where he lived from 1612 to 1627 He began as a follower of Caravaggio in Rome but tended to use ampler, more idealized forms in the 1620s. The Sacchetti "Allegory of Intellect, Memory and Will" (1625) exemplifies this latter phase.

He returned to Paris in 1627 at the request of Louis XIII, who named him his first painter, and thereafter Vouet secured almost all the important commissions there, dominating the city artistically for 15 years and exercising an enormous influence. A new bourgeois class now had the means to build expensive town houses and wanted an artist able to manage large decorative schemes. Vouet supplied what nas needed. Engravings and surviving panels show that he had carefully studied Italian illusionistic ceiling decorations; for example, his work in the Château Chilly derived from Guercino's "Aurora"; that at the Hôtel Séguier (completed 1640) from S'eronese.

Vouet's original contribution was a baroque flourish and unity of organization. His other principal undertakings were in the Hôtel Bullion and Richelieu's palace at Rueil. He died in Paris on June 30, 1649.

His religious paintings of the early 1630s, for example, the "St. Charles Borromeus" (Brussels), show him to have been an artist with as developed a baroque style as any of his contemporaries in

Europe except Rubens—a style tempered, however, with characteristically French restraint. The "Madonna" in the Ashmolean museum, Oxford, and the "Diana" at Hampton Court palace well illustrate his soft, smooth and idealized modeling, his sensuousness, his use of bright colours and also his debilitating facility. See also PAINTING: France: 17th and 18th Centuries.

See Anthony Blunt, *Art and Architecture in France 1500–1700* (1953). (M. W. L. K)

VOW, a special obligation which a person voluntarily takes upon himself beyond and above regular religious duties and ceremonial, and often separate from them. A vow is usually taken in view of extraordinary circumstances and involves putting forth unusual effort or refraining from doing some usual actions. Its purpose is to overcome certain dangers, to ensure particular benefits or to serve as a means of spiritual self-discipline. The special intensity of practice and the individual voluntary character of a vow set it off from regular religious observances, such as the Christian observance of Lent and Moslem keeping of Ramadan (holy month), even though these are seasons of self-denial. If a person voluntarily binds himself to additional self-denial or duties during these seasons, however, such measures could be called vows.

Vows are to be found in almost all religious traditions. The Old Testament records many vows, among them that of Jephthah to sacrifice the first living being from his house to greet his return if God would grant him victory in battle (Judg. xi, 30–31). Hindus individually often vow special fasting or offerings to priests and gods on their sacred days.

It is common in Buddhism for laymen to take upon themselves some of the extra practices of monks, such as eating no solid food after midday and avoiding worldly entertainment for a day, week or month.

In addition to these there is also the long-term or even lifetime vow, particularly among special religious sects or orders. Among the Hebrews the Nazirites vowed not to cut their hair nor drink wine, sometimes for life (Num. vi). A Roman Catholic priest vows himself to chastity, and vows of chastity, poverty and obedience are taken in Roman Catholic religious orders and congregations. A Hindu sadhu (holy man) may vow never to lie donn to sleep. The Buddhist monk gives up all personal possessions except a few living necessities, begs his food and devotes himself to meditation and study. These are organized patterns of religious living; yet persons enter them voluntarily and live in them a life of erfort or self-denial, much beyond the standard required of ordinary believers. Hence such a life may be called a life of vow-fulfillment.

See also MONASTICISM. (W. L. KI.)

VRATSA, the capital of the district of Vratsa, Bulg., on the northern slope of the Stara Planina and on a small subtributary of the Danube. Pop. (1556) 26,582. Vratsa is an archiepiscopal see. Wine, leather and gold and silver filigree are manufactured, and there is a school of sericulture.

VRSAC (VERSEC), a town of Serbia, in the province of the Vojvodina, Yugos. Population (1961) 31,551, comprising Serbs, and Magyars. It is famous for its red wines and brandy. Large quantities of maize are grown in the district and some wheat and oats. There are flour mills and distilleries in the town, which also manufactures distilling and general mill machinery. It has a handsome church and is the seat of a Greek Orthodox bishop. During the revolution of 1848–49 the Hungarians defeated the Serbs there in 1848 and were themselves defeated and the town occupied by the Austrians in 1849.

During World War II the town, after the German invasion of Yugoslavia in 1941. was again under Hungarian control.

VUILLARD, JEAN EDOUARD (1868–1940), French artist, born in Cuiseaux, France, became famous for his paintings of French gardens and interiors.

In later years he painted the portraits of public men, including Camille Chautemps and Yvon Delbos.

His paintings were exhibited throughout Europe, and there were occasional exhibitions of them in the United States. His works were acquired by the Metropolitan Museum of Art in New York city and by museums of Buffalo, N.Y., and Cleveland, O.

Vuillard died in La Baule, France. on June 21, 1940.

VULCAN, the Roman god of fire (Volcanus), particularly in its destructive aspects as volcanoes or conflagrations. It is very doubtful that he was properly a deity of smiths, but poetically he is given all the attributes of the Greek Hephaestus (*q.v.*) and Virgil gives an elaborate description of his workshop (*Aeneid,* book viii, lines 416 ff.). His worship in Italy is undoubtedly very ancient. At Rome he had his own priest (*flamen*) and a festival on Aug. 23, the Volcanalia, which was marked by a rite of unknown significance. the heads of Roman families threw small fish into the fire, perhaps an appeasement offeringof creatures normally beyond the god's reach. The celebration took place in the Volcanal (area Volcani) in the northwest corner of the forum where fishermen brought fresh fish from the Tiber to sell on the occasion.

A second festival of Vulcan is indicated in the calendars on May 23.

He was invoked to avert fires, as his epithets Quietus and Mulciber (fire allayer) and his associations with Stata Mater, Ops Opifera and the Nymphae suggest. Since he was a deity of destructive fire his temples were properly located outside the city. As the city of Rome grew to embrace the Volcanal, a newer shrine including a temple was built in the Campus Martius outside the walls sometime before 214 B.C.

Vulcan was particularly revered at Ostia, where his was the principal cult.

VULCANIZATION: see RUBBER: PRODUCTION AND MANUFACTURE; TIRE.

VULCI, an ancient town of Etruria, about 10 mi. N.W. of Tarquinii. The circuit of the walls measures about 4 mi., and scanty traces of them and of Roman buildings within them still exist. The Ponte della Badia over the Fiora, a bridge with a main arch of 66-ft. span, 98 ft. above the stream, is also Roman. An aqueduct passes over it.

About 1½ mi. above a dam was built for a hydroelectric plant to provide at least 6,000 h.p. The former wealth of the town is mainly proved by the discoveries made in its extensive necropolis—Greek vases, bronzes, etc.—many of which are now in the Vatican.

In 1828–56 more than 15,000 tombs were opened. These were entirely subterranean, but some of the chamber tombs were later re-examined and cleared. There is one great tumulus, the Cuccumella, and a few smaller ones. The frescoes from the François tomb, illustrating Greek and Etruscan myths, were preserved in the Museo Torlonia at Rome. Vulci was one of the 12 cities of Etruria. Coruncanius triumphed over the people of Vulsinii and Vulci in 280 B.C.

See S. Gsell, *Fouilles* dans *la nkcropole de Vulci* (Paris, 1891), for the excavations of 1889 (with copious references to earlier publications); Bendinelli in *Notizie degli Scavi,* p. 342 *et seq.* (1921).

VULGATE, a Latin version of the Bible prepared in the 4th century by St. Jerome and so called from its common use in the Roman Catholic Church (see BIBLE: Translations).

VULPIUS, CHRISTIAN AUGUST (1762–1827), German author, was born at Weimar on Jan. 23. 1762, and was educated at Jena and Erlangen. In 1790 he returned to Weimar, where Goethe. who had entered into relations with Vulpius' sister Christiane Vulpius (1765–1816), whom he later married. obtained employment for him. There Vulpius began. in imitation of Christian Heinrich Spiess. to write a series of romantic narratives. Of these, about 60 in number, his Rinaldo Rinaldini (1797), the scene of which is laid in Italy during the middle ages, was considered the best.

In 1797 Vulpius was given an appointment at the Weimar library, of which he became chief librarian in 1806. Me died at Weimar on June 25, 1827.

VULTURE, the name applied to a group of birds whose best-known characteristic is that of feeding on carrion. The American forms belong to the family Cathartidae and include the condor (*q.v.*), the California condor *(Gymnogyps californianus)*, the king vulture (*Sarcoramphus papa)* with a gaudily coloured head, the turkey buzzard or turkey vulture *(Cathurtes aura)* and the black buzzard, black vulture or carrion crow (*Coragyps atratus)*, the last two being familiar birds in southern United States. They resemble the European vultures in habits.

Old world vultures belong to the hawk family (Accipitridae). The cinereous vulture *(Aegypius monachus)* inhabits tropical and subtropical zones from the Straits of Gibraltar to China. The Egyptian vulture or pharaoh's hen (*Neophron percnopterus*), which ranges over most of Africa and thence to India, is a remarkably foul feeder. Numerous other species are known from Africa and southern parts of Europe and Asia.

Vultures have the head and neck bare of feathers. They locate food by sight rather than scent. When one circling bird descends to a corpse, others see and quickly follow. Vultures, gorged with food, are often unable to take flight. (G. F. Ss.)

VYATKA, R.S.F.S.R.: *see* KIROV.

VYAZMA, a town of the Russian Soviet Federated Socialist Republic, U.S.S.R.. in Smolensk *oblast,* at 55° 11' N., 34° 19′ E., at the confluence of the Berba and Vyazma rivers. It is a railway junction and has leather, oil pressing and match factories.

In the 11th century Vyazma was a trade centre linked with Narva on the Gulf of Finland. It was captured by Lithuania in the 15th century, but later became Russian. From 1611 to 1634 it was under Polish rule. Population (1956 est.) 26,700.

VYCPÁLEK, LADISLAV (1882–), Czech composer, was born at Vrsovice, near Prague, Feb. 23, 1882. One of the most serious and intellectual of modern composers, he leaned strongly toward mysticism and sacrificed both colour and euphony where necessary to polyphonic requirements.

His cantata Of *the Last Things of Man* (1921) may be described as a spiritual protest against the materialism that prevailed after World War I. It is based on Moravian folk music and consists of choruses and soprano and bass solos. Other works include a string quartet, opus 3; several sets of songs, among which were *Forebodings and Visions, Festivals of Life, In God's Palm* and *The Awakening;* Moravian folk songs and ballads and pianoforte pieces. Vycpalek joined the staff of the library of Prague university in 1907 and was appointed keeper of the music department in 1922, from which post he retired in 1942.

VYRNWY (FYRNWY), an artificial lake or reservoir in the northwest of Montgomeryshire, north Wales, 825 ft. above sea level. The lake, largest in Wales, is 5 mi. long and nearly 1 mi. wide. It was constructed in 1880–90 to supply Liverpool with water by damming the Vyrnwy river, a tributary of the Severn.

VYSHNI VOLOCHEK, a town of the Russian Soviet Federated Socialist Republic in the Kalinin *oblast,* in 57° 38' N.. 34° 33' E., on the Moscow-Leningrad railway and on the Vyshnevolotsk navigation system, constructed by Peter the Great in 1703–09 to connect the upper Volga with the Neva. The Mariinsk system largely superseded it. Sawmilling became the chief industry in this forested district, but textile, glass and brewing industries also were established there. Pop. (1956 est.) 60,000.

W THIS letter, as its name implies, was the letter *u* or *v*, which were identical until comparatively recent times, doubled and used by the Norman scribes to represent the English bilabial semivowel (modern *w*), which had previously been represented in the Saxon hands by a runic letter. The sound did not occur in the Romance languages. Latin had possessed it, but it had passed in imperial times into the voiced labial spirant (modern *v*). A separate symbol was thus required to represent the English sound, and the French preferred the doubling of one of their own letters to the use of the rune.

(B.F.C.A.; J.W.P.)

WA, a tribe inhabiting northeast Burma, between the Salween and the Nam Hsin rivers. They claim to be autochthonous and may represent the aborigines of northern Thailand and of Indo-china; old records and travelers (*e.g.*, McLeod in 1837) speak of them as the original inhabitants. Their village sites are still found covered with jungle. The people are short and dark. and may have Negrito blood in them. though speaking a Mon-Khmer language. They are popularly divided into wild and tame. The wild Wa are head hunters. Outside every village is an avenue of huge oaks. Along one side is a line of posts facing toward the path with skulls fitted into niches, cut sometimes in front sometimes behind the post. when there is a hole in front, through which the skull is visible. Skulls must be added annually if the crops are to be good; those of distinguished and pious men are the most efficacious. and head hunting (*q.v.*) takes place during the sowing season. Villages are high on the slopes of hills, usually on a knoll or spur. The only entrance is through a tunnel 30 to 100 yd. long, of which there are usually two at opposite sides of the village, about 5 ft. high. and so narrow that two persons cannot pass freely. sometimes winding slightly to prevent gunfire; the path is studded with pegs to prevent a rush. Tattooing is occasional only; divination is performed with chicken bones; dogs are eaten; polygamy is permitted. monogamy prevails and the tame Wa have five clans presumably exogamous.

See Scott & Hardiman. *Gazetteer of Upper Burma, etc.* (1900).

WAALS, JOHANNES DIDERIK VAN DER (1837–1923), Dutch physicist: who was awarded the 1910 Nobel prize in physics for his researches on the equations of conditions of gases and fluids, was born at Leiden, Nov. 23. 1837. A self-taught man who took advantage of the opportunities offered by the University of Leiden. he first attracted notice in 1873 with his treatise *Over de continuiteit van den gas-en vloeistoftoestand* ("On the Continuity of the Liquid and Gaseous State"), by which he gained his doctor's degree. He taught physics at various schools, and in 1877 he was appointed professor of physics in the University of Amsterdam, a post which he retained until 1907. Van der Waals built up a kinetic theory of the fluid state, he combined the determination of cohesion in Laplace's theory of capillarity with the kinetic theory of gases, and this led to the conception of the continuity of the liquid and gaseous states. Using this as a starting point he arrived at an equation of state which gave an explanation of critical phenomena and fitted in very well with the experimental observations of Andrews on carbon dioxide. Continuing this work he tried to arrive at an equation which would be the same for all substances. He eventually did this by using the values of the volume, temperature and pressure divided by their critical values. This led van der Waals to his statement of the "law of corresponding states" which enabled Sir James Dewar and Kammerlingh Onnes to determine the necessary data in the liquefaction of the permanent gases. He also discovered the law of binary mixtures. He died in Amsterdam on March 9, 1923. *See* also LIQUEFACTION OF GASES.

WABASH RIVER. The largest southward-flowing tributary of the Ohio river. the Wahash river rises in Grand lake in western Ohio. It follows a generally westward course across Indiana and eventually swings southward near the western boundary of the state. The total length of the Wabash is 475 mi.; for the last 200 mi. it serves as the boundary between Indiana and Illinois.

The Wabash drains an area of slightly more than 33.000 sq.mi. and has a number of important tributaries. The largest left-bank tributary is the White river, which drains a large portion of southern Indiana. The right-bank tributaries include the Little Wabash, Embarrass. Tippecanoe and Vermillion rivers. At Mt. Carmel, Ill. (75 mi. above the mouth of the river). the average rate of flow is 27.650 cu.ft. per second. The flow rate rises to a maximum of 127,000 cu.ft. per second in February and declines to a minimum of 3,990 in October.

During the 18th century the Wabash was well-known to the French in America, and it served them as an important transportation link between Louisiana and Quebec. After the War of 1812 the Wabash basin was rapidly developed by settlers from the eastern states and from Europe, and the river continued as an important artery of trade, both for flatboats and river steamers. River navigation almost completely disappeared after the coming of the railroads in the 1850s. Only the lower 75 mi. of the river is now utilized for barges carrying petroleum, sand and gravel.

The Wabash basin contains some of the richest commercial grain and livestock farm land in the American midwest. and its cities are well-known manufacturing and service centres. The most important communities on the river are Terre Haute, Lafayette and Vincennes.

Cities and industries located along the river's banks use the Wabash for water supply purposes. (R. R. D.)

WACE, ROBERT (?) (1100?–1175?), Anglo-Norman chronicler, was born in Jersey. He studied at Caen; he became personally known to Henry I, Henry II and the latter's eldest son Prince Henry; from Henry II he received a prebend at Bayeux and other gifts. Except for these facts he is known to us only as the author of two metrical chronicles in the Norman-French language Of these the earlier in date is the *Romun de Brut,* completed in 1155, which is said to have been dedicated to Eleanor of Aquitaine (ed. A. J. V. Le Roux de Lincy, 2 vol., Rouen. 1836–38). This is a free version of the Latin *Historia Britonum* by Geoffrey of Monmouth, in rhyming octosyllables; it was rendered into English, shortly after 1200, by Layamon, a Mass priest of Worcestershire, and is also largely used in the rhymed English chronicle of Robert Mannyng. Wace's second work, the *Roman de Rou,* written between 1160 and 1174, has a less fabulous character than the *Brut,* being a chronicle of the Norman dukes from Rollo to Robert Curthose. It has been ably dissected by Gustav Korting (*Über die Quellen des Roman de Rou*, Leipzig. 1867), who shows that it is mainly based upon Dudo and William of Jumièges. There is also reason for thinking that Wace used the *Gesta regum* of William of Malmesbury. Where Wace follows no ascertainable source for the material in his chronicles he must be used with caution. Undoubtedly he used oral tradition; but he also seems in various instances to have given free play to his imagination.

The *Roman* de Rou is written in rhyming octosyllables, varied by assonanced alexandrines. It has been edited by F. Pluquet (2 vol. and supplement, Rouen, 1827–29) and more completely by H. Andresen (2 vol., Heilbronn, 1877–79). (H. W. C. D.)

WACHSMUTH, CHARLES (1829–1896), U.S. paleontologist, born in Hanover, Germany. Sept. 13, 1829. In 1865 he paid a visit to Europe, where he decided to devote all his energies to the elucidation of the crinoidea, and did so with signal success. He made further extensive collections, and, together with Frank Springer (1848–1927), he published a series of papers on their studies of crinoids, also an extensive monograph on the *Revision of the paleocrinoida* (1879–86). After Wachsmuth's death on Feb. 7, 1896, appeared *The North American Crinoidea Canzerata* (2 vol. and atlas, 1897).

WACKENRODER, WILHELM HEINRICH (1773–1798), German writer, the fellow student of Ludwig Tieck (q *v.*) at Erlangen and Gottingen. Wackenroder inspired his friend with his own enthusiasm for the art of the middle ages. They aent to Berlin in 1794, and after the breach with Nicolai there in 1796, to Dresden The relation between medieval art and religion is the theme of Wackenroder's *Herzensergiessungen eines Kunstliebenden Klosterbruders* (1797). His early death, in 1798, was a great blow to his friend, who completed Wackenroder's fragmentary works.

See Wackenroder's *Werke und Briefe,* ed., in 2 vol., by F. von der Leyen (1910); P. Koldewey, *Wackenroder und sein Einfluss auf Tieck* (1904).

WACO, a city in north-central Texas, U.S., and seat of McLennan county, is situated on the former site of a Hueco Indian village, about 94 mi. S. of Dallas. Waco was an important Brazos river crossing on cattle trails after the Civil War. Originally an agricultural centre, it still depends partly on crops and livestock but a strong diversified industry has been added, including tire and glass manufacturing and smaller industries. It is a key highway hub for national and state roads. Settled in 1849 and incorporated in 1856, Waco adopted manager-commission government in 1924.

Baylor university, the largest Southern Baptist college, with medical branches at Dallas and Houston. moved to Waco in 1886–87 from Independence, Tex.. where it had been chartered in 1845 by the republic of Texas. Baylor's Armstrong-Browning library is noted for its collection of Robert and Elizabeth Browning lore Paul Quinn college, Texas' first Negro college, was established at Waco in 1872.

A violent tornado devastated Waco the afternoon of May 11, 1953. killing 114 persons, injuring 597 and doing more than $40,000 000 worth of property damage. The U.S. 12th air force headquarters, James Connally base and a U.S. Veterans' mental hospital are in Waco. Cameron park, 680 wooded acres, is one of the state's largest. A $2,000 000 Masonic Memorial temple is the site of annual Grand Lodge of Texas sessions. A steel-cable suspension bridge over the Brazos, opened in Jan. 1870. is still in use. Lake Waco, formed in 1923 by damming the Bosque river, is a popular recreational area just west of the city. Yearly weather temperatures vary considerably, but the mean annual average is about 67° F. and rainfall averages 30 to 35 in.

The population of Waco was 97,808 in 1960, an increase of 15.5% over 1950; that of the Waco standard metropolitan statistical area comprising McLennan county was 150.091, an increase of 15.3%. For comparative population figures *see* table in **TEXAS**: *Population.* (T. E. T.)

WAD, a black, earthy mineral consisting mainly of hydrated manganese dioxide, has been of importance as an ore of manganese. It varies considerably in chemical composition, and contains different impurities, often in large amount. A variety containing much cobalt oxide is called asbolite. while lampadite is a cupriferous variety. It is very soft, readily soiling the fingers, and may be considered as an earthy mixture composed chiefly of pyrolusite or psilomelane (*qq.v.*). It results from the decomposition of other manganese minerals and is often deposited in marshes ("bog manganese") or by springs. The name wad is of uncertain origin, and has been applied also to graphite.

WADAI, a region of north central Africa, is bounded north by the Sahara and east by Darfur province of Sudan, West and southwest it extended to Kanem and Bagirmi and southeast to Dar Runga. Formerly an independent Mohammedan sultanate, it was conquered by the French in 1909–10 and now forms part of the Republic of the Chad. By the French it was divided into the departments of Wadai and Batha. Total area about 91.000 sq.mi. Population (1951 est. natives only): Wadai, 461.400; Batha, 329,900.

Physical **Features.**—Wadai is for the most part a flat, dreary plain, about 1,500 ft. in altitude, part of the clay zone which covers much of the basin of Lake Chad. It is, however, traversed by ranges of hills nhich rise another 1,000 ft., and east and north is encircled by mountains—part of the ranges which stretch in a rough semicircle from Tibesti to Darfur. In the northeast Dar Tama rises to a plateau of 2.500 to 3,000 ft., with the peak of Niéré reaching 3,937 ft. The plains are mostly bush covered, but in places this gives way to long grass, with parklike regions in the west. The surface is often sandy, but there are considerable areas of black-cotton soil. To the south and east the land rises, and there are large forests, which, northward along the Darfur frontier, thin down to scrub. The northern region, bordering the Sahara, is semiarid, though much of it, watered by intermittent streams, affords good pasturage. There, on the northwest confines of Wadai, are remarkable sand ridges of fantastic shape—hollow mounds, pyramids. crosses, etc., which are characteristic of the Libyan desert. There are also sandstone rocks of varying colours—red, blue, pink, white, black—presenting the aspect of ruined castles, ramparts and churches. In the extreme northeast are some intermittent streams. with an easterly flow. There the Wadi Homr, in 16" N., marks the limit of vegetation—beyond, northward. is absolute desert. South of it are many similar wadis, their banks covered with thick thorn bush. And 75 mi. S. of Wadi Homr is a lake, 2 mi. long by 500 yd. wide, called Undur. This desert lake dries up for half the year. Apart from this northeast region, the country forms part of the Chad drainage area. The streams which rise in the northeastern districts, of which the Batha (more than 300 mi. long) is the largest, flow west, the Batha ending in a depression, about 200 mi. E. of Lake Chad, called Lake Fittri. Another stream, the Wadi Rime, with a more northerly course, goes in the direction of Chad, but ends in swamps in the clayey soil. The rivers of Dar Runga—a forested district south of Wadai proper—flow westward toward the Shari, but, save the Bahr Salamat. none reaches it. About 100 mi, above the Salamat-Shari confluence is Lake Iro. joined to the Salamat by a short channel.

The flora includes timber trees, numerous dum palms. mimosa, acacia, the tamarind, and many kinds of grasses. The cotton plant grows wild. and a species of wild coffee tree reaches 50 to 60 ft. and yields excellent berries. Among animals are large herds of gazelle; baboons are common. and elephants are found in the forest. Ostriches are found in the north, where the lion is also occasionally seen. Of birds, the most conspicuous are cranes (white, black and crested); storks are also common in some regions. Of domestic animals. the camel is common in the northern district, elsewhere the bull is used for transport. Horses, cattle, sheep and goats are numerous. Caterpillars are sometimes a plague, and there are visitations of locusts.

Inhabitants and Trade.—The inhabitants consist of Negroid and Negro tribes. Arabs, Fula, Tibbu and half-castes. The Maba, the dominant race, are said to be of Nubian origin; they live chiefly in the northeastern district, and in the days of the sultanate were allied with the Arab tribes, known in Wadai as Zoruk (dark) and Homr (red).

The capital, Abeshr, in the northeast, set on a plain surrounded by hills, is a town of two-storied mud brick buildings with flat, battlemented roofs and a fine market square. From Abeshr a caravan route crosses the Sahara via the Kufra oases to Bengasi in Cyrenaica. Another route, on the pilgrim way from west Africa to Mecca, goes east through Darfur to Khartoum. Maize, millet, cotton and indigo are cultivated, and cloth is woven. There is also an industry in leather goods. Ivory and ostrich feathers used to be taken to Tripoli by the desert route, together with small quantities of coffee and other produce. This trade has greatly decreased. There is a trade in cattle, horses and coffee with the Republic of the Sudan, with the regions to the south and with Nigeria.

Until the French conquest, Wadai mas a great centre of the slave trade. Slaves were obtained by raiding and in the form of tribute from Bagirmi, Kanem and other countries once dependent on Wadai.

History.—Wadai early became a meeting ground of Negro and Arab culture. Eastern influences and the Mohammedan religion ultimately obtained predominance, though the sovereignty of the country reverted to the Negro race. It was sometimes tributary to and sometimes the overlord of the neighbouring countries, such as Bagirmi and Kanem. It was made known to Europe by the writings of the Arab geographers, but it was not until Nachtigal's visit in 1873 that accurate knowledge of the land and people was obtained. About 1640 a Maba chieftain named Abd-el-Kerim conquered the country, driving out the Tunjur, a dynasty of Arabian origin. Thereafter Wadai suffered from many civil and foreign wars. The Senussi brotherhood, introduced by Mohammed Sherif, sultan from 1838 to 1858, gained a dominant position in Wadai.

In the last decade of the 19th century the French advancing from the Congo made their influence felt in Wadai, and by the Anglo-French declaration of March 21. 1899 Wadai was recognized as within the French sphere. Tnat state was then torn by civil wars. The Sultan Ibrahim was murdered in 1900, and Ahmed Ghazili became sultan. He ordered one of his rivals, the Emir Acyl, to be blinded, whereupon Acyl fled westward and entered into friendly relations with the French. A few months later (Dec. 1901) Ahmed was dethroned. With Doud Murra, who then became sultan, the French endeavoured to come to an understanding, and in Nov. 1903 the Wadaians agreed to recognize the possession of Bagirmi, Kanem, etc., by France. However, in the spring of 1904, acting, it is believed, at the instigation of the Senussi, the Wadaians attacked French posts in the Shari region and carried off many slaves. Intermittent fighting continued for years. It resulted in strengthening the position of the French and of their ally Acyl, and in 1908 Doud Murra, again, it is stated, at the instigation of the Senussi, proclaimed the *jihad*. His army was split up under *aguids* (feudal lords), and was beaten in detail.

By 1912 Wadai had been completely pacified by the French and the once powerful sultanate was abolished, though the sultans of the petty states, such as Dar Tama, between Wadai and Darfur retained their authority under French protection. In the years 1913 and 1914 a terrible famine caused immense loss of life. Col. Jean Tilho says "the population of Wadai, put by Nachtigal at more than 2,000,000 in 1872, had fallen to 300,000 when I went that way [in 1917]." Abeshr then "retained few traces of its ancient splendour," though it was later gradually rebuilt by the French. Wadai was but little affected by Senussi activity during World War I. The occupation of Darfur by the Sudan government in 1916 led to better order in the borderlands, and to the demarcation of the frontier in 1923. The French had rigorously suppressed slave trading, but other trade gradually increased, especially with the Sudan.

WADDINGTON, WILLIAM HENRY (1826–1894), French statesman, was born at St. Remi-sur-l'Avre (Eure-et-Loir) on Dec. 11, 1826. He was the son of a wealthy Englishman who had established a large spinning factory in France and had been naturalized as a French subject. After receiving his early education in Paris, he mas sent to Rugby, and thence to Trinity College, Cambridge. He undertook travels in Asia Minor, Greece and Syria, the fruits of which were published in two *Mémoires,* crowned by the Institute, and in his *Mélanges* de *numismatique et de philologie* (1861). His other archaeological works include the *Fastes de l'empire romain,* and editions of Diocletian's edict and of Philippe Lebas's Voyage *archéologique* (1868–1877). He was elected in 1865 a member of the Académie des Inscriptions et Belles-Lettres.

After standing unsuccessfully for the department of the Aisne in 1865 and 1869, Waddington was returned by that constituency at the election of 1871. He was minister of public instruction in the short-lived cabinet of May 19, 1873, and in 1876, having been elected senator for the Aisne, he was again entrusted by Dufaure with the ministry of public instruction. His most important project, a bill transferring the conferment of degrees to the state, passed the Chamber, but was thrown out by the Senate. He continued to hold his office under Simon, with whom he was overthrown on seize *mai* 1877. (See SIMON, JULES FRANÇOIS.)

Waddington was minister of foreign affairs under Dufaure and a French plenipotentiary at the Berlin Congress. He obtained, from Lord Salisbury, a promise that Great Britain in return for Cyprus would allow France a free hand in Tunis. Early in 1879 Waddington succeeded Dufaure as prime minister but held office only by sufferance of Gambetta, and had to retire in December. In 1883 he accepted the London embassy, which he continued to hold till 1893, showing an exceptional tenacity in defence of his country's interests. He died on Jan. 13, 1894. His wife, an American lady, whose maiden name was Mary A. King, wrote some interesting recollections of their diplomatic experiences—Letters of *a* Diplomatist's Wife, *1883–1900* (New York, 1903), and Italian Letters (London, 1905).

WADE, BENJAMIN FRANKLIN (1800–1878), American statesman, was born near Springfield, Mass., on Oct. 27, 1800, of Puritan ancestry. He was reared on a farm, receiving little systematic education, and in 1821 he removed with his family to Andover, in the Western Reserve of Ohio. In 1825 he began the study of law at Canfield, was admitted to the bar in 1827, and began practice at Jefferson, Ashtabula county, where from 1831 to 1837 he was a law partner of Joshua R. Giddings, the anti-slavery leader. From 1851 until 1869 he was a member of the U.S. Senate, first as an anti-slavery Whig and later as a Republican. In the Senate Wade was from the first an uncompromising opponent of slavery, his bitter denunciations of that institution and of the slaveholders receiving added force from his rugged honesty and sincerity. His blunt, direct style of oratory and his somewhat rough manners were characteristic. After the outbreak of the Civil War he was one of the most vigorous critics of the Lincoln administration. He advocated the immediate emancipation and arming of the slaves, the execution of prominent southern leaders, and the wholesale confiscation of Confederate property. In 1864, with H. W. Davis (*q. v.*), he secured the passage of the Wade-Davis Bill (for the reconstruction of the southern States), the fundamental principle of which was that reconstruction was a legislative, not an executive, problem. This bill was passed by both houses of Congress, just before their adjournment, but President Lincoln withheld his signature. Soon afterward (Aug. 5) Wade and Davis published in the New York Tribune the famous "Wade-Davis Manifesto," a vituperative document impugning the President's honesty of purpose and attacking his leadership.

As long as President Johnson promised severe treatment of the conquered South, Wade supported him, but when the President definitively adopted the more lenient policy of his predecessor, Wade became one of his most bitter and uncompromising opponents. In 1867 he was elected president *pro tem* of the Senate, thus becoming acting vice president. He voted for Johnson's conviction on his trial for impeachment, and for this was severely criticized, since, in the event of conviction, he would have become president; but Wade's whole course before and after the trial would seem to belie the charge that he was actuated by any such motive. After leaving the Senate he resumed his law practice He died at Jefferson, O., on March 2, 1878.

See A. G. Riddle, *Life of Benjamin F. Wade* (Cleveland, O., 1886).

WADE, GEORGE (1673–1748), British field-marshal, was the son of Jerome Wade of Kilavally, Westmeath, and entered the British army in 1690. He was present at Steinkirk in 1692, and in 1695 he became captain. In 1702 he served in Marlborough's army, earning particular distinction at the assault on the citadel of Liége. After service in Portugal, Minorca, and Spain, Wade, as major-general, was military governor at home during the Jacobite rebellion of 1715. He twice detected important Jacobite conspiracies, and on the second occasion procured the arrest of the Swedish ambassador in London, Count Gyllenborg. In 1719 he was second in command of the land forces in the "conjunct" military and naval expedition to Vigo. In 1724 he was sent to the Highlands where he began the system of metalled roads which is commemorated in the lines—

> Had you seen these roads before they were made,
> You would lift up your hands and bless General Wade.

Wade superintended the construction of 40 stone bridges and with great tact. disarmed the clans. In 1742 he was made a privy councillor and lieutenant general of the ordnance, and in 1743 field marshal. In this year he commanded the British contingent in Flanders, and was associated in the supreme command with the duke d'Aremberg, the leader of the Austrian contingent. The campaign, as was to be expected when the enemy was of one nation, superior in numbers and led by Saxe, was a failure, and Wade, who was 70 years of age and in bad health, resigned the command in March 1744.

King George II promptly made him commander in chief in England. and in that capacity Field Marshal Wade had to deal with the Jacobite insurrection of 1745, in which he was utterly baffled by the perplexing rapidity of Prince Charles Edward's marches. On the appointment of the duke of Cumberland as commander in chief of the forces, Wade retired. He died on March 14, 1748.

WADELAI, a village in the British protectorate of Uganda on the west bank of the Nile. 1 mi. N. of the mouth of the Ora river. It was first visited by Lieut. H. Chippindall, an assistant of C. G. Gordon, in March 1875. Now largely abandoned, it was a much disputed place during the mahdi rebellion. In 1885 Emin Pasha made it his fortified headquarters (the old perimeter trench may still be seen in an air photograph).

For three years Wadelai was the headquarters of the Egyptian Equatorial province. After Emin Pasha's withdrawal with Sir Henry Stanley in 1889. Wadelai remained under the control of the mutinous troops commanded by Fadi el Mula Bey, who eventually enlisted in Belgian service. Following the Anglo-Belgian agreement of May 12, 1894. Wadelai became a station of the Congo Free State; in 1910, a year after the death of King Leopold II, ruler of the Congo Free State, it was incorporated into the Anglo-Egyptian Sudan, and in 1914 it was finally transferred to Uganda. (H. A. WF.)

WADHWAN, a town in Zalawad district, Bombay state, India; pop. (1951) 23,381. It is a manufacturing and railway centre approximately 60 mi. N.E. of Rajkot and about 100 mi. W.N.W. of Baroda.

The petty state of WADHWAN (area 242 sq.mi.; pop., 1941, 50,915). of which the town was capital. was within the Eastern Kathiawar subagency of the combined Baroda, Western India and Gujarat states agency prior to its absorption into the state of Saurashtra on Feb. 15, 1948, and part of Bombay state in 1956.

WADI HALFA or HALFA, a town of Sudan on the right bank of the Nile. About 6 mi. above the town is the second cataract, and on the west bank of the Nile opposite Wadi Halfa are the ruins of the ancient Egyptian city of Buhen. Wadi Halfa is the northern terminus of the Sudan railway and the southern terminus of a steamboat service on the Nile, which, running to Shellal (Aswan), connects there with the Egyptian railways. Pop. (1956) 11,006.

WAFER. A thin flat cake or biscuit. As articles of stationery, wafers consist of thin, brittle, adhesive disks. used for securing papers together and for forming a basis for impressed official seals.

These wafers are made of a thin paste of very fine flour, baked between wafer irons over a charcoal fire till the thin stratum of paste becomes dry and brittle and the flour starch is partly transformed into glutinous adhesive dextrin. The cake is cut into round disks with suitable steel punches.

WAFER ASH (Ptelea trifoliata), a small North American tree of the rue family (Rutaceae, *q.v.*), called also shrubby trefoil and hop tree! found from New Tork and southern Ontario to Nebraska and south to Florida, Arizona and Mexico, and often planted for ornament.

While often shrubby, the plant sometimes grows to a height of 2j ft. and bears strong-smelling, long-stalked trifoliate leaves and greenish-white flowers in dense clusters. The somewhat hoplike fruit is a nearly orbicular samara with a membranous, netted-veined wing. about three-quarters of an inch broad.

WAGER: see GAMBLING AND BETTING.

WAGES. Wages are the remuneration for the expenditure of effort in the production of goods and services. In precise economic terminology, wages are the price of labour. The effort of the wage earner may be physical, mental or a combination of the two; it may be under another's direction or may be of a managerial and decision-making character. But whatever his specific occupation, the wage earner supplies some form of human contribution to production, and wages are the reward for this contribution. If wage earnings of individuals are added together in order to obtain the total wage bill of an economy, the resulting total determines how much of the national product goes to labour and how much is available, by implication, to the other factors of production — natural resources (land) and capital.

Because all except the most rudimentary economies exhibit specialization and differentiation in the kinds and amounts of labour contributed by the various individual wage earners, there are wide differences in the wage rates received by individual workers. The wage structure of a national economy — the schedule of wage payments within it—is thus highly complex.

Not only is any given national wage structure characterized by conspicuous wage differences, but these differences themselves vary from country to country and within a given country over a period of time. Such variation may be ascribed in part to differences in technology and methods of production as well as to differences in the composition of the total output of the economy. Job classifications which are significant in one economy are often found to be unimportant in another that is in a different stage of technological advancement.

Wages represent the major if not the sole source of money income for a large portion of wage earners. The wage structure of an economy, therefore, is one important determinant of the distribution of income prevailing in it.

The general level of wages can be taken as a useful estimate, at least, of the average economic well-being. Similarly the differentials in the wage structure: which determine the way in which the total labour income is distributed among its recipients. correspond approximately to differences in living standards. Viewed in this light, wages have social as well as economic implications by virtue of their impact on the welfare and conditions of life of wage earners.

A distinction is frequently made between money and real wages. The term "money wages" refers to the amount in dollars and cents, or other appropriate monetary units, that workers receive. The term "real wages" refers to the quantity of goods and services that can be purchased with money wages. Thus real wages involve a relationship between money wages and the retail price level or the cost of living.

THEORIES OF WAGES

The general level of real wages in an economy depends on three factors: the size of the total national product; the portion of the product accruing to labour; and the size of the labour force. These three wage determinants are not independent, however, and a major point of difference between various wage theories lies in their varying premises as to the interrelations between the basic factors.

All economic theories are conditioned, moreover. by the institutions of the economy in which they are conceived, and wage theories in particular are derived in part from the role that wages play in the functioning of the economy.

Pre-19th-Century Theories. — The wage theory of St. Thomas Aquinas, a leading representative of medieval thought, was a natural outgrowth of his philosophy of 'a static society characterized by rigid class structure. The "just wage" of St. Thomas was included in his general concept of "just prices" and indeed was developed as a central element in it. In this doctrine customary practice played the dominant role, and competitive forces were for the most part excluded. Thus the just wage was defined as that which permitted its recipient to live in a manner appropriate to his position in society. Although this doctrine was associated with a social organization based on status, its implication that the worker's cost of living should be a first charge on production had an interesting echo in the minimum-wage legislation of the 20th century.

In the tradition-oriented society envisaged by St. Thomas, wages had a single function — that of distributing income. The type of work an individual performed, as well as his place of work, was largely predetermined by his birth.

In a dynamic economy, however, wages have a second function — that of allocating labour to the various occupations and productive enterprises. As employers bid for labour and as workers seek employment, pressures are created that produce alterations in the wage structure. The effects of such pressures were discernible even in the middle ages, despite the fact that custom, guild rules and city and state regulations were important wage determinants in that period.

The mercantilists — economists who flourished in the period of commercial development and the emerging nation-states — were more preoccupied with commerce and the balance of trade than with wages. Wages entered their writings primarily as a cost of production, and the low-wage doctrine which they tended to espouse was linked with their emphasis on the importance of maintaining favourable positions in foreign trade.

The physiocrats — 18th-century economists credited with introducing the doctrine of *laissez* faire — emphasized agriculture as the natural economic activity of man. Such physiocrats as François Quesnay and Anne Robert Jacques Turgot believed that the landless labourer was in so unfavourable a bargaining position relative to the employer that his wage would never far exceed the level of bare subsistence.

Adam Smith, the greatest and most influential advocate of a free-enterprise economy, did not develop a precise theory of wages. Instead, he anticipated in the Wealth of Nations (1776) a variety of later theories. Wages depend. he said in effect, on supply and demand, on the competition of workers for jobs and of employers for labour. This competition presumably is desirable, as a manifestation of the pursuit of individual self-interest through which members of society are led "as by an invisible hand" to make the greatest contribution to the national wealth. Thus by piecing together various passages of the Wealth of Nations one discovers a foreshadowing of the doctrine that wage rates established by competition lead to an optimum allocation of labour. But this was implied only, for Smith also asserted that in the bargaining bet een employers and labour the advantage lies almost invariably with the employer. He pointed, also, to the propensity of employers to unite in attempts to reduce wages.

Subsistence Theory of Wages. — The earliest of the modern wage theories, the subsistence theory, was also the gloomiest. In its most stark and primitive form, it stated that real wages tend to hover about the bare minimum required for physical subsistence. The subsistence theory had already appeared in the writings of the mercantilists — Thomas Mun, for example — as well as in those of some of the physiocrats. It remained for David Ricardo, an English economist, to formulate the theory precisely and in an internally logical fashion.

Ricardo deduced the subsistence theory of wages from the population theories of a contemporary, Thomas Robert Malthus. Malthus had maintained that population, if unchecked, tends to double itself about every 25 years, while food supply, produced under conditions of diminishing returns, increases more slowly.

In Ricardo's view any increase in real wages could be only temporary. With higher wages, living standards would rise and population would expand proportionately. The increase in the supply of labour would again push wages down to the point of bare subsistence. Thus in the long run all temporary gains in real wages would be wiped out by an increase in the amount of labour. The subsistence theory held sway for a number of years. Its pessimistic conclusions caused Thomas Carlyle to speak of "the dismal science of economics."

Malthus and Ricardo lived at a time early in the Industrial Revolution when population in western countries was growing at an extraordinarily rapid rate and when technological development was in its infancy. Later trends proved conclusively that their premises have no general validity. Population did not continue to increase at the predicted rate. technological advance led to greatly increased productivity and real wages rose substantially. The Ricardian thesis may contain more than a grain of truth, however, when applied to some of the less-industrialized areas of the world.

Though Ricardo formulated a blunt statement of the subsistence theory, he—as well as Malthus — also advanced a suggestion which sensibly attenuated it. He implied that, in countries where expanding productivity had permitted workers to become accustomed to a standard of living above that required for physical subsistence, the birth rate might tend to adjust itself to this fact,

The subsistence theory in its unmodified form recurred, however, in the works of Karl Marx, whose intellectual debt to Ricardo was considerable. Marx, however, regarded the subsistence theory not as universally valid but as descriptive of wages under capitalism. Ferdinand Lassalle, another important 19th-century figure in the development of socialist thought, likewise enunciated this doctrine, which he termed the "Iron Law of Wages" under capitalism.

Wages Fund Doctrine. — Around the middle of the 19th century, as the subsistence theory approached the end of its vogue, the wages fund doctrine was developed. It became prominent in the writings of John Stuart Mill and his contemporaries. The doctrine was to some extent an outgrowth of the concept of capital developed by Nassau William Senior. He regarded capital as abstinence from consumption, and as providing the fund from which employers advance wages to labourers.

The wages fund doctrine held that the total amount available for wages is constant in the short run. Thus the average wage of workers is determined by this constant fund divided by the number of workers. In its simplest form, the doctrine held that the wage fund or total wage bill is predetermined by the money that employers of labour set aside for wages.

It was believed that in the long run the wage fund would increase in proportion to the growth of capital. A larger amount of savings and investments would lead to a larger predetermined wage fund and therefore to higher wages.

The wages fund doctrine was never as clear-cut as the subsistence theory of wages. Given its premises, the subsistence theory was valid. In contrast, the wages fund doctrine as expressed by its proponents was full of ambiguities, and the meanings of its terms were frequently unclear.

It was not until the end of the 1860s. however, that the doctrine was seriously questioned. Among the writers who attacked it were William Thomas Thornton, a British economist, and Francis Amasa Walker, a U.S. economist, both of whom criticized the theory on technical grounds.

Another reason for the vigorous criticism of the theory was that it provided little hope of raising wages through union activities. If there was indeed a predetermined wage fund, the only hope of improving the lot of labour lay in patiently awaiting either the accumulation of capital or a decrease in the number of workers among whom the fund was divided.

At a time when labour unrest was conspicuous in England, this conclusion of the theory could not fail to attract attention. Mill himself recanted the wages fund theory in 1869 in a famous review of Thornton's book, On Labour. This action contributed to the decline of the theory's influence.

It must be conceded, however, that there is a germ of truth in the wages fund doctrine. Wages are certainly related to productivity, and availability. of capital is one factor determining productivity. The fatal weakness of the doctrine, however, lay in its failure to show that there is a determinate wage fund. It failed to establish any inevitable quantitative relationship between a wage fund and the amount of capital or between the total national product and the proportion of the product that goes to labour.

Marginal Productivity Theory. — The subsistence theory of wages and the wages fund doctrine each focused attention on a single determinant of wages — labour supply and demand, respectively. The marginal productivity theory, on the contrary, was an ambitious attempt to explain not only the general level of wages but the entire wage structure of a highly competitive economy in terms of the interaction of supply and demand. Developed toward the end of the 19th century, it gained such general acceptance among economists that it practically replaced all other wage theories. The 20th century, however, witnessed a considerable revolt against both its applicability and the conclusions following from it. Even so, it remained a widely held theory of wages; for one reason, because its most severe critics were not able to offer an acceptable alternative.

Rudiments of the theory can be found in the writings of several precursors, notably in those of the German economist, Johann Heinrich von Thunen. which appeared in 1826 but attracted little notice. More importantly. the theory rests on general methods of marginal analysis that were the contribution of the Austrian school of economists in the last half of the 19th century. A well-rounded statement of the marginal productivity theory of distribution to all productive factors, including labour, was first developed toward the end of the 19th century by the British economist, Philip Henry Wicksteed. and by the U.S. economist, John Bates Clark.

In its treatment of supply, the marginal productivity theory embodies elements that are common to all 20th-century wage theories, as follows: The supply of labour to an economy depends on the number of individuals who want to work and are available for work, the efficiency of workers and the hours of employment. Each of these factors is subject to substantial long-run variations. On the basis of available data, however, it appears unlikely that the total labour supply at any time is significantly altered by changes in the general wage structure. On the other hand, the supply of labour to a firm, an occupation, an area or an industry is closely related to the prevailing wage structure. In describing this relationship, economists use the term "mobility." Labour mobility is the tendency for workers to move from job to job in response to relative advantages in the terms of employment. If labour is highly mobile, differences in wages between two firms, all other things being equal, cause workers to move from the low-wage to the high-wage firm until the differentials are eliminated. Wage differences, however, are not the sole factor that may induce worker movement. Differences in working conditions or in the ease or attractiveness of jobs may also account for worker behaviour which is characterized by mobility.

On the other hand, purely random movement is not so characterized. It must be emphasized that mobility is not gauged by the amount of movement, but by the degree to which existing job differences call forth worker movement.

The distinguishing characteristics of the marginal productivity theory appear in the analysis of the demand for labour. The analysis begins by considering the individual business firm, the basic productive unit in the economy. The largest and most significant portion of labour is hired by firms which produce goods and services for sale to consumers or to other producers. The demand for labour on the part of such employers exists because of the value of labour's contribution to the output of the firm.

In the simplest case, it is assumed that the firm can sell all its output at a certain price—a price independent of the amount produced by the single firm. Furthermore, it is assumed that the firm can hire any amount of the type of labour it requires at a certain rate—a rate on which its own decision has no effect.

Given these assumptions, the theory predicts the amount of labour a firm will employ. The familiar law of diminishing returns plays an essential role. This law, applied to labour, states that (all other things remaining equal) the net addition to total output which is obtained by hiring an additional employee decreases, at least beyond a certain point, as the number of employees increases. Here enters the marginal product from which the theory derives its name. The "marginal physical product" is the addition to the total output of the firm which is obtained by employing one additional worker (more rigorously, an additional unit of labour). All other elements in the production process are assumed to be held constant. The value of the marginal product is the value of this additional output.

Assuming that the employer behaves in such a manner as to obtain maximum profits—an assumption which underlies all analyses of this type—then it is clear that he will continue to hire additional labour so long as the revenue produced by the addition of a worker exceeds the cost—determined by the wage rate—of hiring him. The law of diminishing returns leads to the conclusion, however, that the employer will not continue to hire more workers indefinitely.

Though each additional worker increases the total product, the increase in output becomes smaller, as more and more workers are added. The law of diminishing returns predicts. in other words, that the marginal physical product, and therefore the value of the marginal product, decreases as the number of workers increases. Hence eventually the cost of hiring an additional worker will exceed the revenue gained by doing so.

It must be emphasized that the marginal productivity theory, as applied to the firm, does not yield the wage the typical employer will pay, but rather the amount of labour he will hire at a given wage. The higher the wage, the less labour he will employ. A decline in wage rates will produce an increase in the amount of labour hired (and in output); an increase in wage rates will have an opposite effect.

In order to generalize on this conclusion to embrace the entire economy, it is necessary to make several simplifying assumptions in addition to the ones already made: that no firm, by its own decisions, can affect the price of the commodities it sells or of the labour it hires. It must also be assumed that labour is completely mobile and that employers and employees have knowledge on which to judge their best interests. These assumptions are bracketed together under the term "perfect competition." Under such conditions it is possible to develop a logical theory to explain the wage rates that will prevail in the economy as a whole.

The total demand for any given type of labour will be the aggregate demand of employers and will be related to the wage rate. At the same time, the number of workers available will vary directly with the wage rate. Supply and demand, in other words, each depend on the wage rate—the one rising, the other falling as the wage rate rises. At a certain wage the supply of labour offered exactly matches the amount of labour hired. In the absence of barriers to the free operation of competitive forces, this rate will actually obtain.

Under conditions of perfect competition, the equilibrium wage structure has two essential properties. First it "clears the market" in the sense that there is no unemployment or underemployment (employment at a rate below that obtained by other individuals possessing the same skills). Furthermore, it is associated with an allocation of labour which is the most efficient possible—given the existing income distribution and schedule of consumer wants. It must be emphasized that no moral or ethical properties are ascribed to this rate—the wage rate is simply part of the total price structure in the economy and has in the last analysis no more ethical content than the system of consumer demand underlying the entire edifice.

It has never been maintained, even by the most fervid devotees of this economic doctrine, that the rigid assumptions of perfect competition are actually fulfilled in any existing economy. However, some economists have made two claims. First, the theory is said to yield results that approximate reality with fair accuracy. Wage rates, it is claimed, do not deviate far in most instances from those which the theory would predict. Second, it is asserted that in instances where wages above competitive levels have been established by union pressure, law or other means, a misallocation of labour has resulted.

The original marginal productivity analysis was modified and enriched by the development in the early 1930s of techniques for analyzing certain cases in which the conditions of perfect competition do not prevail. The theory of imperfect or monopolistic competition was evolved almost simultaneously by Joan Robinson in England and Edward H. Chamberlin in the United States. It furnished insight into two situations—referred to in technical writings as monopsony and oligopoly—in nhich wages may be increased—all other things remaining equal—without an attendant decline in employment.

Monopsony occurs when a single employer (or a group of employers acting in formal or informal collusion) exercises control over the labour market sufficient to influence wage rates by his own policies. Roughly speaking, such control reduces the effect of employer competition for labour as an upward pressure on wages. Monopsony might be present, for example, where one employer hires the major portion of the labour force in a community and where movement of workers from the area is difficult.

Oligopoly exists where a few large firms produce the entire output of a commodity. Under such circumstances each firm must expect that its decisions as to output and price will cause a reaction on the part of its competitors. In consequence, the relationship between the wage rate and the volume of employment ceases to be well defined.

Criticisms of the Marginal Productivity Theory.—Like the wages fund doctrine, the marginal productivity theory admits the possibility that steady increases in real wages may occur as a result of increasing productivity. On the other hand, it offers little satisfaction to those who seek to raise the general level of wages above that which would result from the operation of competitive forces at any particular time. For it asserts that the payment of wages above the competitive level to any part of the labour force must carry with it the certainty of unemployment, misallocation of labour or both.

Ever since the theory emerged, there has been considerable interest in wage raising via minimum-wage legislation and union organization. To accept the marginal productivity theory without reservations is in effect to renounce the aspiration to alter wage rates through either of these channels. It is not, therefore, surprising that there have been vociferous criticisms of the theory. These generally take three forms.

First, the assumptions of the theory are sometimes challenged. It is asserted, for example, that not all business conduct can be interpreted in terms of profit maximization. It is also asserted that the marginal product is technically difficult if not impossible to determine in substantial sectors of the economy. Moreover, it is pointed out that business decisions are not predicated on present prices but on estimates of the future.

Second, some critics of the theory believe that wage rates not only are affected by productivity but that they affect it in ways not incorporated in the marginal productivity theory. Increased wages may make employees more efficient, for example. They may, moreover, make employers more efficient. A wage increase which occurs because of government regulation or union intervention may "shock" an employer into introducing improved techniques of production rather than reducing his labour force. This is particularly true where competitive forces are not very strong.

Third, the applicability of the theory in a dynamic economy is questioned by a number of critics. It is maintained that in such an economy market forces are subject to rapid change. Other things may not remain the same, and consequences predicted by the theory may fail to materialize.

Bargaining Theory of Wages.—The labour market, in marginal productivity analysis, is regarded as the market for a factor of production and as amenable to the general techniques appropriate to the study of such markets. According to the bargaining theory of wages, on the contrary, the labour market can be understood only by a careful consideration of those elements which distinguish wage determination from the determination of other prices in the economy.

Traces of the bargaining theory—like most others—are discernible in Adam Smith. Thornton, too, in attacking the wages fund doctrine asserted that the power of employers to combine easily and the inability of most workers to postpone accepting employment even at unfavourable terms are factors acting to depress wages. In 1898 John Davidson developed at some length a theory that wages are the result of bargaining between employers and employees and that no simple principle of economic analysis is capable of explaining this process adequately.

Exponents of the bargaining theory believe that there can at best be described upper and lower limits between which the rate for a given type of labour must lie. Within this range, the precise wage paid is said to depend on the relative bargaining power of labour and employers. The greatest weakness of the bargaining theory of wages lies in its failure to define the limits precisely or to estimate the range between them. The upper limit becomes simply that rate above which the employer will refuse to hire a certain group of workers, the lower limit the rate below which workers refuse to work. Supply and demand analysis appears thus to enter by the back door, so to speak, in the formulation of the limits. Because, however, the theory supposes a range between the limits, a range created essentially by the various impediments to perfect competition, there is room for workers to raise wages or for employers to lower them, depending on which has superior bargaining power.

The bargaining theory offers a powerful theoretical justification for union organization. For the theory admits the possibility that wages may be increased without untoward effects on employment, and it suggests that such an increase may actually be possible if labour is able to augment its bargaining strength. Moreover, the theory embraces the possibility of achieving desirable results through minimum-wage legislation.

Purchasing Power Theory.—The purchasing power theory of wages is one not of wage determination but rather of the relation of wages to the level of economic activity. That wages affect consumer demand for goods is easy to perceive. The lower an individual's income. the greater tends to be the proportion of it that goes toward consumption. Thus, higher wages received by lower income groups will tend to increase consumer demand. This fact was long used by unions as an argument for high wages.

The argument, however, that low wages might lead to depression did not achieve professional status until the British economist John Maynard Keynes developed his general theory of the business cycle during the 1930s. Keynes attributed the business cycle to an unbalance between three quantities: consumption, savings and investment.

Certain followers of the Keynesian analysis, by highlighting consumption, gave additional substance to the purchasing power theory. Even so, the theory did not gain universal acceptance. Debate continued to prevail, for example, as to whether a suitable wage policy during depression would be to raise wages in order to increase buying and stimulate employment or to lower them in order to decrease costs and stimulate employment.

Most economists agreed, however, that although the wage level may affect economic activity it is only one among several factors which do so. Also it is recognized that in the presence of strong unions, wage reduction might not be a feasible political expedient even if clearly justified on economic grounds.

TRENDS IN WAGE LEVELS IN THE UNITED STATES

The history of the United States has been characterized by an enormous expansion in productivity and a rising level of real wages. The increase in real wages has not been steady, however. During the period from the Revolutionary War to around 1820 price increases appear to have offset increases in money wages to keep real wages at about a stationary level.

Between 1820 and 1850, on the other hand, there was an overall increase in real wages of around 40%. Further advances occurred from 1860 to 1890, so that by 1890 real wages stood at more than twice the 1820 level.

Paul H. Douglas, in his monumental study of real wages, estimated that real hourly earnings for industry as a whole increased about 40% between 1890 and 1926—an increase in excess of 1% per year. Here again, however, the increases did not occur uniformly. Real wages were almost constant between 1890 and World War I, and most of the increase in real hourly earnings occurred after 1917. The years from 1890 to 1926 witnessed a substantial shortening in the length of the work week, the average standard week in industry as a whole declining from 58.4 hours to 49.8. It is therefore not surprising that the rise in average weekly earnings was less than that in hourly wages.

For the period from 1914 to 1955, average real hourly earnings in manufacturing increased about 215%. Real weekly earnings in the same period rose by 160%. Real weekly earnings more than doubled between 1933 and 1955. They advanced rapidly during the latter years of the 1930s, during World War II and again during the years around 1950. In only a few years—mainly during the early 1930s and immediately following World War II—did they fail to rise.

It is interesting to compare figures in wage trends with closely related data on productivity. Using 1850 as a base, output per man-hour, measured in constant prices, had more than doubled by 1900 and had increased by more than five times by 1950 Over this century, the total annual production of goods and services multiplied twenty-fivefold. At the same time, the aggregate of man-hours worked in 1950 was less than five times as great as that of 1850.

These figures suggest one conclusion of great significance. So long as productivity continues to increase, this trend in itself permits and justifies a steady increase in real wages. It must be recalled, however, that the figures cited deal with total productivity and represent contributions to total output of all factors of production together.

The total amount of wages paid in an economy depends not only on the size of the total product but on the proportion of the product which goes to labour. Over the years, this proportion displayed only small variation. It increased a little in depression years, but on the whole the annual wage income remained around two-thirds of the total national income.

The substantial increase in real wages resulted from an increase in the total product rather than in labour's proportionate share of the product.

Wage Differentials.—Wages in a modern industrial economy differ from person to person and from one locality and region to another, both within the same occupational level and among occupations. Wage differentials. that is. differences in remuneration received by the various wage earners, are of many kinds and stem from a number of causes.

Some differentials in wages would be expected to occur under assumptions of perfect competition. Of this character are differentials resulting from subjective worker preferences as to types of employment. Jobs differ markedly in their characteristics. Some involve dirt, noise, high temperature, monotony, hard physical labour, irregular employment, low social prestige or other undesirable features. For such work, a higher wage rate may be necessary to attract labour from more desirable jobs requiring similar skills. Wages, in other words, are only one element of a job, and some wage differentials have the effect of equalizing the desirability of various types of work requiring the same type of labour. Moreover, wage earners are not all identical in talents, skills and efficiency. Thus the supply of labour to various occupations is not the same. This fact is sufficient to explain why high wages tend to go to those possessing talents which are valued highly by society but are relatively rare. Even within the same occupational classification variations in individual efficiency give rise to differences in remuneration.

Both the foregoing types of wage differentials would be expected to occur and persist under the conditions of perfect competition. In a perfectly competitive economy, furthermore, some temporary differentials might occur because economic adjustments do not take place instantaneously. A wage differential between two jobs with identical characteristics, for example, might exist by virtue of a transition reflecting a change in production methods or consumer demand. though in the long run the differential would be expected to be eliminated through the interaction of market forces.

In contrast, it appears that some wage differentials can be interpreted only by taking into account deviations from competitive conditions. Lack of labour mobility is a paramount factor in many such instances. A few examples are sufficient to suggest the effects of barriers to mobility. Regional differences in wage rates may be traced in part to the reluctance or inability of individuals in low-wage communities to leave their homes and seek work elsewhere or to their lack of knowledge regarding the existence of better job opportunities. Wages in specialized skills and professions may be maintained at levels above competitive rates by restrictions on the number of individuals admitted to training for such occupations. The traditionally low wage level of women has undoubtedly been partly the result of restrictions on the type of work open to them.

It is an interesting fact that, by mid-20th century, the upward trend in real wages in the United States had been accompanied by some shifts in differentials. Though all groups had shared in the advances in real income, the relative position of workers in various sections of the economy had not remained constant.

Differentials between skilled and unskilled labour declined during the first half of the 20th century. According to one estimate, the wage rates of skilled factory workers averaged about twice as much as the rates for unskilled labour in 1907. By 1947 the ratio had declined to one and a half. Tending also to narrow the spread in average wage rates has been the increase in assembly-line production, which has increased the number of semiskilled workers and decreased the relative significance of the highly skilled and unskilled.

In average earnings for various industries for the period from 1929 to 1950, some tendency toward a narrowing of industrial differentials is observable. A number of low-wage industries made unusually large gains, while remuneration in some high-wage industries advanced at less than the average rate.

Notable gains in average annual earnings were made, for example, in water transportation and highway freight transportation, both of which had been low-wage industries prior to World War II; the percentage gains in air transportation, with comparatively high prewar earnings, were considerably less. With some exceptions, wages in typical white-collar industries tended to advance less rapidly than did those for manufacturing and manual labour. On the other hand, most manufacturing industries exhibited relatively uniform gains over this period.

Changes in the relative wage positions of industries are difficult to interpret. In some cases technological advances alter the composition of the labour force in such a way as to account for a wage trend which fails to conform to the national average. The economic status of the industry also may be an important factor.

During the 20th century, wages of agricultural labour remained characteristically low as compared with those of urban employees, even when allowance is made for the difference between rural and urban living costs. In 1920, a peak year for farm earnings in the early decades of the century, average weekly farm wages were less than half the full-time weekly wages of factory workers. In 1929 hourly earnings of farm labourers averaged 42% of earnings in manufacturing. The depression period of the 1930s saw a decline in this ratio—between 1933 and 1940 hourly earnings of employees in agriculture were approximately one-fourth of those in manufacturing. By 1946, however, hourly wages on farms had risen enough to average 46% of factory workers' earnings. These figures can be explained in part by the fact that migration from farm to city tends to decline when unemployment is high, creating a greater supply of rural labour which tends to depress wages. The depressed level of prices of agricultural commodities which persisted until World War II is also a relevant factor.

Regional differentials have formed a noticeable feature of the wage structure of the United States. Average wages in the south have lagged behind those of other sections, while in the far west a high-wage tendency has existed.

Data accumulated in the late 1940s indicated that although the relation between wages in the south and those of other sections had varied considerably over the period 1907 to 1946, the relative position of southern workers at the end of this period was approximately the same as at the beginning. A widening of the differential associated with the depression of the 1930s had been offset by an opposite trend in later years. There are great variations within regions, however. and comparisons for specific localities or specific occupations show that the average north-south differential does not prevail consistently throughout the various segments of the economy.

A correlation exists between the earnings of individuals and such personal characteristics as age. sex and race. Earnings tend to be lowest in the earliest and latest years of a worker's productive life. Earnings of women average lower than those of men, and of Negroes lower than of white workers. In large part, however, these facts represent not differentials in pay for identical jobs, but differences in employment opportunities and in regularity of employment.

Modern Wage Structures.— In describing wage structures of modern firms a distinction is usually made between primary or basic wage rates and supplementary wages. Basic wage rates are those paid for work performed during normal working periods. The majority of basic wage rates are defined in terms of a time unit—hour, day, week, month or, less frequently, year. Often the term salary is used to denote earnings computed on the basis of a weekly or longer time unit. For a substantial number of wage earners compensation is defined in terms not of time units but of output, under various types of incentive systems.

Supplementary wage payments are premium payments, over and above applicable basic rates, for work performed during hours outside a normal working day or week. Such payments are commonly made for work done on Saturday, Sunday or holidays, for night work or for a work day in excess of 8 hours or a work week in excess of 40 hours.

From the standpoint of the individual employee, premium wage payments for undesirable schedules compensate for the discomfort or inconvenience of such schedules. When an enterprise operates on a multiple-shift or seven-day week basis, supplementary wage payments equalize the position of the variously scheduled employees. When labour is scarce, these payments are inducements for workers to offer their services on night shifts, holidays and week ends.

From the standpoint of the employer, premium payments increase production costs. They have the effect, therefore, of discouraging production outside the normal work day and work week.

Wage payments in goods, as food, use of employer-owned housing or the like, are sometimes found. They are probably of greatest significance in agriculture, although even there they are not, on the average, a large fraction of total wages.

Pension and insurance benefits of various types, payments for holidays and vacation periods not worked and dismissal wages are part of the total compensation received by many mage earners. The prevalence and importance of these so-called "fringe benefits" greatly increased during and following World War II. Like wages, payments of this type represent labour costs to employers.

Time Wage Rates.—Time wage rate structures, in which wage payments are based on time intervals, are the commonest form of basic wage structure. All companies have at least some employees paid on a time rate basis, and in many enterprises this is the sole method of compensation.

There are three major types of time wage systems: personal wage rate structures; job title rate structures; and job evaluation systems.

Under personal wage rate structures, wage rates apply to persons rather than to jobs. In the personnel records of companies using such systems, wage rates are established according to named employees. Such informal and individualized wage structures are particularly prevalent in small firms. They are appropriate in enterprises where management can be familiar with the requirements of each job and the capabilities of each worker.

Job title rate structures assign wage rates by referring to names of jobs—machinist, carpenter, janitor, for example. Frequently there are refinements within each classification for different levels of proficiency and experience. In firms using this type of wage rate structure, job titles are characteristically those that have evolved by usage in the plant or in the labour market.

In contrast, where job evaluation wage rate systems prevail jobs are analyzed and defined in terms of basic attributes and requirements. Scientific job analysis is thus the essence of job evaluation. It assumed increasing importance in the United States after the 1920s.

There are a variety of possible systems. of varying complexity, for developing evaluated wage rate structures. Most of them, however, have a number of common features. A set of evaluation factors is the basis for the job analyses. The factors depend on the types of work covered by the system. Among those typically used are: mental development; accuracy; dexterity; responsibility for equipment; responsibility for the work of others; physical effort; visual effort; physical discomfort; and accident hazard. In establishing a job evaluation system, evaluation factors are subdivided into degrees, and weights are attached to the various degrees of each factor. Each job to be evaluated is then analyzed on the basis of these factors. The analysis of the requirements and content of the job, taken in conjunction with the weights assigned to the factors, furnishes a means of grouping jobs in labour grades. The wage rate for a given job depends on the labour grade associated with it.

Job evaluation is a method not for setting the general wage level for a firm, but for evolving a rational wage structure within a given general wage level. The choice of a general wage level depends, among other things, on the financial position of the firm. its present and potential position within the industry, the number and qualities of employees desired, the anticipated bargaining reactions of union representatives (if the concern is unionized), the type of competition characteristic of the local labour market and, most important, the actual wage rate levels existing in competitor plants and in the labour market as a whole.

After the general wage level has been selected, the job evaluation system is brought to conform with this policy by assigning wage rates to a few key jobs occurring at various points in the job range. These rates are assigned in reference to the firm's general wage policy and the going rates in the labour market. The remaining jobs are then assigned wage rates in conformance with the rates for key jobs.

A particular labour grade may be assigned a single rate or a rate range. In the latter case, an employee's wage lies somewhere within the range for his job classification. Some companies provide for automatic progression within this range; others for increases within the range based on merit.

Incentive Wage Rates.—The essential characteristic of an incentive wage rate structure is that payment depends on output rather than work time. Such wage structures have been introduced into the production phases of a variety of manufacturing industries and have been used in some extractive industries.

Taking into account all forms of incentive mage payments—piecework, bonus and commission—it was estimated in 1952 that about a fourth of all employees in the United States received wages in this form. Commonly the incentive wage is based on the individual worker's output. although occasionally group incentives are used. In general, there appears to be a tendency for incentive workers to receive higher earnings than those on time rates in the same occupations.

If incentive wages are to be successfully employed in manufacturing, certain conditions must exist. First, the process of production must be substantially standardized, uniform and repetitive. Raw materials and productive equipment must be uniform and must be maintained at adequate levels. Under these circumstances, variation in output can be assumed to be primarily attributable to variations in worker effort. Second, output must be measurable and homogenous. Third, the production cycle must be relatively brief. Finally, incentives must be applied with caution where costly raw materials or delicate machinery create the possibility that more will be lost through spoilage and waste than will be gained through increased speed of production.

Modern incentive plans commonly provide for a guaranteed minimum hourly rate which constitutes a "floor" below which hourly earnings cannot fall. Compensation increases above the minimum in direct proportion to increase in output. Production standard3 used in arriving at the guarantee and the incentive rates are usually based on motion and time analysis of the job. The normal time for the production of a unit of output is determined, in other words, by analyzing the various operations necessary to produce the unit. However. production standards determined in this way are based on concepts of "the average worker," "normal work speed and effort" and "normal working conditions." Hence the determination of standard production time inevitably involves human judgment and cannot be purely objective.

Effect of Labour Organization **on** Wage Rates.—In the absence of labour organization, wages are determined unilaterally by employers on the basis of considerations noted in the preceding section. In unionized firms (or where a group of firms act as a unit in dealing with a union) wages are arrived at through collective bargaining negotiations between representatives of labour and management. Collective bargaining may involve proposals which are made solely for strategic purposes. However, the real positions — as opposed to possible strategic positions — of employer and union are formulated at least in part with reference to conditions of supply and demand. The employer is willing to pay at least enough to attract labour of suitable kinds and amounts. The wage demanded by the union is ordinarily not so high as to produce the danger of substantial unemployment in the firm.

The determination of the wage in the range between these positions depends in part on the skill of the negotiators. Moreover, since wages are only one issue in collective bargaining, the agreement may be influenced by settlements on nonwage issues. Most important are the varied factors — public opinion, government action. financial reserves of each party and the like — which determine the relative strength of labour and management in the event of a strike. For although the overwhelming majority of labour-management agreements are reached without a work stoppage, the possibility that failure to agree may lead to a strike is the driving force that impels the bargainers to seek agreement.

In addition to bargaining within the range between the employer offer and the union demand, labour may attempt to influence conditions of supply and demand to change the bargaining range.

As to supply. effective avenues of influence are limited. The demand for immigration restriction, which was one of the major political planks of the American Federation of Labor prior to the 1920s, was unquestionably related to a desire to restrict labour supply. Similarly certain licensing laws have the effect of limiting supply in some occupations. It is doubtful, however, whether conditions of labour supply can be appreciably affected in the short run except through legislation.

Some unions have endeavoured to increase the demand for union-made goods by advertising campaigns, boycotts imposed on competing nonunion products and similar techniques. A different method of increasing the demand for labour has also been used — that of imposing limitations on output of individual workers through some form of union-set productive standards. For the most part. however, these and other techniques of influencing demand are adopted not primarily as a means of achieving wage gains but to make more jobs available at times when employment declines.

Efforts to evaluate the actual impact of unions on wage rates are hampered by the difficulty of separating the effects of various factors. Statistical data can give information as to relative levels of union and nonunion wages, but they give no satisfactory evidence as to whether or not the differentials occurring are attributable to union activity.

Douglas found that during the 1890s and the early years of the 20th century union wages were considerably above those of the labour force as a whole. Since unionism was concentrated primarily in skilled trades at that time, however. the significance of his findings is difficult to assess. From around 1914 through the 1920s union wages in manufacturing rose no more rapidly than did nonunion wages. Only in the highly organized building trades did unionists make gains appreciably above the general average. Douglas concluded that the effect of a union is to raise wages at the time organization becomes effective, after which time advances tend to be at approximately the general rate.

Studies in the late 1940s showed that in partially unionized industries wages in nonunion plants tended to lag behind those in union plants, although within each industry differentials for various occupations were not consistent.

Detailed analyses of the studies, however, show that it is difficult to isolate the effect of unionization because regional and other differences enter. The general advance in real wages from 1939 to 1948, for example. showed no close correlation between the wage rise by industries and the extent of unionization. Increases above average were obtained in bituminous coal mining, which is highly organized, but also by unorganized domestic and agricultural workers.

Some economists have considered collective bargaining as a factor tending to increase wage rigidity in periods of rapid price adjustments. They base this view on the fact that collective wage bargains run for a prescribed period of time. However, wages tend generally to be "sticky" over the business cycle, in the sense that turns in their movement lag behind alterations in employment and price levels.

The total effect of unions on wages cannot be estimated entirely by studying contrasts between union and nonunion workers, since the presence of widespread unionization may affect the position of labour as a whole. For example. employers of nonunion labour may follow union wage patterns in an effort to avoid organization. On the other hand, if union-achieved rates are so high as to curtail employment in some occupations, a larger supply of labour to other occupations may depress wages there.

Finally, a discussion of the impact of unions on wages is incomplete without reference to political questions. Contemporary unions exert political pressures not only to win desired legislation on wages and collective bargaining but to influence national economic policy as well. Thus union espousal of a price stabilization program during World War II and the Korean war undoubtedly influenced the trend of real wages. In short, the economic position of labour as a whole may be affected not only by the direct wage-determining activities of unions but by their effect on national economic policy as well.

Wage Regulations. — The earliest wage regulations in the United States were maximum wage laws, enacted during the colonial period by town and colonial governments in an effort to prevent labour shortages from pushing wages upward. In their purpose these laws resembled enactments which were in effect in England in the same period.

Indeed, wage-fixing laws of this character came into being in England in the 14th century, when the Black Death had decimated the labour force, and persisted until the beginning of the 19th century. The early wage laws in the United States had little effect, and they disappeared. as did those of England, with the Industrial Revolution and the ascendancy of the principles of *laissez faire*.

Late in the 19th century there began a movement for a different type of wage legislation, the setting of minimum standards to prevent wages from sinking below the subsistence level. This movement, which led to government action at about the same time in England, Australia and New Zealand, was essentially social and humanitarian in character. Its spokesmen emphasized such costs of poverty as illness: crime and social disorganization.

The first minimum-wage law in the United States was enacted by Massachusetts in 1912. In the course of the next decade 14 states took similar action. All the laws applied solely to women or to women and children. This may be attributed partly to the fact that the wages of women tended to be lower than those paid to men, and partly also to the view that the health and well-being of women and children are of especial importance to society. On the latter ground it was believed that the regulation of the wages of women would be upheld by the courts as a proper exercise of the constitutional powers of the states.

In 1923, however, the supreme court declared minimum-wage laws to be unconstitutional. Not until 1937 was this decision reversed. By 1956 minimum-wage laws were in effect in 30 states as well as in Alaska, the District of Columbia, Hawaii and Puerto Rico. The laws of most jurisdictions applied only to women or to women and minors. although in a few instances their coverage extended to men as well.

State minimum-wage laws have displayed much variation, not only as to coverage and effectiveness of administration but also as to the way in which the minimum wage is determined. In some states, the law establishes a flat minimum, applicable to all covered workers, with exceptions permitted only for those whose inexperience or physical disability justify special lower rates. In the majority of states, however, the rate for each covered industry is set separately by a commission or wage board. The wage levels established by the various states have also been far from uniform. The trend during the early 1950s was toward a minimum of 75 cents an hour, but many states had minima far below this figure for some or all covered occupations.

Federal regulation of wages was embodied in the Fair Labor Standards act of 1938, sometimes called the Wages and Hours law. This act, which dealt with wages, hours and child labour, covered most employment in interstate commerce and in the production of goods for interstate commerce. Employees in agriculture and in certain other specified industries were excluded, however. Originally the act's wage provisions were aimed at the establishment of a 40-cent an hour minimum wage.

By subsequent amendments to the act, the minimum wage was increased to 75 cents an hour in 1949 and to $1 in 1956. Wages below the statutory minimum might be authorized for learners or apprentices and also for certain handicapped individuals. Except during periods of emergency, as during World War II and the Korean war, direct governmental regulation of general wage levels was not adopted in the United States.

States also commonly regulated methods of wage payment and similar matters. Typical instances were measures forbidding the payment of wages in scrip, requiring that wages be paid at least every two weeks or specifying in some manner the place of payment. Related in purpose to such legislation were mechanics lien provisions, which reinforced the common-law doctrine that workmen have a prior claim on an employer's property for wages due. Prevalent also were laws concerning the garnishment of wages. These usually restricted the percentage of future wages which might be assigned to creditors. Compensation for work on public contracts has also been subject to government regulation.

TRENDS IN THE UNITED KINGDOM

The distinction between a wage and a salary was, by the middle of the 20th century, being less sharply drawn than it once had been. The board of trade at successive censuses of industrial production asked firms to classify employees as "operatives" or as "administrative, technical and clerical employees." Administrative, technical and clerical staff includes: directors, managers, superintendents and works foremen; research, experimental, development, technical and design employees (other than operatives); draftsmen and tracers; and travellers and office (including works office) employees. Operatives include all other classes of employees, and these are the wage earners in industry. Outside industry, the official statisticians tried to apply a comparable classification. whence the description "wage" is given to the earnings of operative workers in transport such as drivers and conductors and to those of storemen. warehousemen, porters, messengers, postmen, waiters, cooks and domestic servants; moreover, in 1953 shop assistants, who had been classified as receiving a salary, were reclassified as wage earners on the ground that their work was not administrative, technical or clerical. The classification therefore depends not on the frequency of payment or on the size of income, but on occupation.

Formerly a salaried worker in contrast with a wage earner tended to receive his or her pay irrespective of the number of hours worked, being paid in periods of holiday or absence through sickness but receiving no additional pay for extra effort or for working overtime. Hence salaries fluctuated less than wages. Presumably this was why the commissioners of inland revenue used to obtain half-yearly information from firms about the earnings of any manual workers within the income-tax ranges, whereas the earnings of the salaried workers were assessed annually. That distinction, however, disappeared in 1944 with the introduction of pay-as-you-earn income tax.

Furthermore, under the pre-1948 insurance schemes against unemployment, sickness and old age, manual workers had to contribute no matter what their incomes were, but salaried workers earning more than a specified amount (£250 a year up to 1940 and £420 a year subsequently) did not contribute anything or become entitled to benefits. After the introduction of the national insurance scheme with universal insurance, that distinction too disappeared. Thus as a result of changes in the 1940s the inland revenue and the national insurance authorities ceased to make any distinction between wages and salaries or to issue any statistics from which any such distinction could be derived.

Sources and Scope of Statistics.—The principle source of statistics about wages in the United Kingdom is the ministry of labour and, for the period before the establishment of the ministry of labour in 1917, the board of trade, which from 1893 had maintained a labour department. So far as the number of wage earners is concerned, complete information is primarily provided by the occupational records of the censuses of population taken in 1951, in 1931 and at ten-year intervals before that; however, for the manufacturing and other industries covered by the census of production more frequent information is available. Early information about wages can best be extracted from A. L. Bowley's Wages and Income in the C'nited Kingdom Since 1860 (1937).

Official statistics are of two types, the one relating to recognized rates of pay, the other to money receipts by wage earners (before deduction of national insurance contributions and income tax); the former are called wage rates and the latter earnings.

The information about recognized rates of pay applies almost entirely to minimum and standard rates which have been the subject of collective agreements, arbitration awards or legislation. Such rates are a good guide, but in times of active trade many wage earners can earn substantially more than the agreed rates: for example. in the spring of 1956 adult males in the coal-mining industry were averaging £14 15*s.* a week when the quoted rate—the national minimum weekly wage inclusive of the value of certain allowances in kind—was £9 0*s.* 6d. a week for underground workers aged 21 years and over; and in the engineering industry. where the agreed rates were about £8 8s. a week for skilled workers and £7 2s. a week for labourers (though varying somewhat according to area), the average earnings for adult males were £12 12*s.* a week.

The agreed rates of pay are recorded in a volume called Time Rates of *Wages* and *Hours of* Labour, published annually after 1946 but infrequently before then and including only two editions between 1915 and 1946 (those of 1920 and 1929). Details of changes in such rates are recorded monthly in the Ministry of *Labour Gazette*. It is from such information that the official index number of wage rates is derived.

The information about earnings is obtained as a result of special inquiries undertaken by the ministry of labour every six months after 1941. Before 1941 such surveys were only made at irregular intervals, including July 1940 and Oct. 1938 (which serves as a base for measuring increases after the outbreak of World War II). Surveys were also made in 1886, 1906, 1924, 1928, 1931 and 1935, the results normally showing average earnings in the week of inquiry in the industry covered and distinguishing males and females always and adults and young workers in 1935 and subsequently. After 1938 the figures for individual industries were combined to give averages for groups of industries and for all industry by weighting according to the estimated number of wage earners in each individual industry (the results are summarized in Tables V and VI).

The average for all industry is therefore variable with the distribution of personnel among the several industries and might conceivably increase without any change in rates in any of the industries if workers were transferred from low-paid to higher-paid industries. These returns also indicate the average number of hours worked in the week.

The statistics are incomplete. They are collected on a voluntary basis in the industries covered and do not cover all industries. For some of the industries excluded (*e.g.,* coal mining, the dock service, agriculture and the railways) information is available elsewhere; but for most of the service industries, including distribution, catering establishments, entertainments and sport, there is a dearth of statistics.

Variation of Earnings.— *In* general the only information has been about average weekly earnings and we have very little knowledge of the variation in earnings within industries. The wage census for *1938* recorded individual earnings, and hence some information about the spread of earnings in that year is available.

The average earnings for men in *1938* were *69s.* a week; one-quarter of the number of men earned less than *55s. 9d.;* and one-quarter more than *80s. 6d.* This indicated that a spread of about *24s. 9d.* a week (or 36% of the average) covered half of the number of male wage earners. For women workers the spread of earnings about the average of *32s. 6d.* a week was relatively greater, one-quarter of their number earning less than *25s.* and one-quarter more than *38s. 7d.*, so that a range of *13s. 7d.* (or 42% of the average) covered half the number of women workers.

The variation between workers in *1938* was relatively less than it had been in 1906 when ranges of *45%* of the average for men and 49% for women covered half the total of workers. There is some evidence that the relative variations in *1886* were smaller than in 1906.

During the first half of the 20th century the proportion of wage earners on piecework increased for men and decreased for women as follows: for men, the number on piecework was 18% of the total of male wage earners in 1906, still 18% in *1938* but 24% in 1947; for women, the corresponding figures were 59%, then 46%, then 39%. The decrease for women was apparently partly associated with the rapid growth of employment of women in industries other than textiles. *(See* R. B. Xnsworth, article in the *Statistical Society Journal,* 1949.)

The Period 1795–1914.—The earliest general investigation into wages in the United Kingdom was the inquiry of *1886,* and the study of movements before that date depends on scattered accounts, which can only be pieced together with great difficulty and some uncertainty (at least till *1850,* after which date records are more numerous). Table I exhibits the wages in some of the occupations for which records can be traced back to an early date, together with some more recent figures for comparison. With the great rise of prices during the Napoleonic wars wage rates increased by more than 50%, reaching a maximum in *1815;* during the next 15 or 20 years there was an irregular fall, and then wages were nearly stationary till about 1850, at a height about one-third above that of 1790–95. If the movements of money wages are compared with those of prices, it becomes evident that a considerable advance was made in real wages between *1815* and 1850.

**Trade-union or other agreed rates* †As *estimated* by G. H. *Wood in the Statistical Journal,* p. 135 (1910) with *some adjustment of dates.*

Prices began to rise soon after 1850, culminated after some fluctuations in 1873 and then fell rapidly till in *1880* they were near the level of *1850* again. During these *30* years it is computed that wage rates in specific occupations rose about 30%, but because of the relative increase of numbers in the better-paid occupations the average wages of all men rose more than 40% and reached about *24s.* weekly.

It is probable that prices moved faster than money wages till *1860* and that wages gained on prices till *1870,* and in the next decade real wages made rapid progress (at the cost of some unemployment) as prices fell. Prices continued to fall irregularly till about *1895* and then rose with some interruptions till, at the outbreak of war in 1914, the level of *1880* and of *1850* was again approximately reached.

Money wages rose from *1886* to 1890, from *1896* to 1900 and, after a slight fall, from 1911 to 1914. Throughout the period of falling prices real wages rose considerably. but from 1900 to 1914, or even from *1895* to 1914, it is doubtful whether money wages rose as fast as prices. Some statisticians, indeed, have computed that real wages fell perceptibly in the *1j* or 20 years before World War *I;* but in this connection the figures given in Table II may be borne in mind.

TABLE *11.—Average Weekly Wages of Fully Employed Men in Great Britain, 1795–1914*

Item	1795	1850	*1880*	1902	1914
Actual wage . . .	13s. 6d.	17s.	24s.	*29s.*	32s.
Real wage (1914 prices)	8s. 6	17s.	24s.	32s.	32s.

The Period After 1914.—Table II indicates that prices in 1914 approximated to prices both in *18jo* and in *1880* so that from *1850* to 1914 money wages were a tolerable measure of real wages. After 1914 price increases associated with two major wars were not balanced by corresponding decreases and the problem of allowing for the decreased value of money became important. Prices rose rapidly from 1914 to 1920, then fell rapidly throughout *1921* and *1922* until they were at a level about 75% higher than they had been in 1914. They rose rapidly again from 1939 and continued to rise until in *1952* they were about 120% higher than they had been in *1938.* Yet from the viewpoint of the United Kingdom in 1953 one is impressed by the stability of money wages in the period *between* the wars.

Index numbers of wage rates recorded the same value in 1937 that they had recorded in 1924 after having been about 7% lower in 1933. Table III, based on A. L. Bowley's index of wage rates and on the ministry of labour's official cost-of-living index. illustrates the course of wages from 1914 to *1938.* Some typical rates are given in Table IV. which is derived mainly from the 22nd *Abstract* of *Labour Statistics* (1937).

**For December in 1918 and in 1920 (when prices were changing substantially) and for the average month in the subsequent years.*

The economy settled down after World War I with real wages about 10% higher in 1924 than they had been in 1914. It was after 1924 that it was common to speak of the rigidity of the wage structure, meaning that wage rates moved too slowly to reflect the needs of an economy in which prices were falling and in which, after 1929, unemployment rose to more than 20% of the insured population in the years from 1931 to 1933 inclusive. This period did not represent all loss to the wage earners, for throughout the period prices were falling more rapidly than wage rates. so that the real wages of those who remained employed rose rapidly. In 1933 real wages were about 15% better than they had been in 1924.

The striking improvement in real wages between 1924 and 1933 is what one expects in an economy with rigid wage rates and falling prices. What perhaps was equally striking was that the improvement was not lost in the subsequent period of rising prices following 1933, a period of recovery from depression and increased employment. Wage rates increased every year from 1934 to 1938 about as fast as the cost of living rose.

The United Kingdom therefore entered World War II with a wage structure that had increased real wages by about 25% or 30% in the 25 years from 1914. This improvement was not entirely due to increased productivity: it was greatly helped partly by the ability to buy the requisite imports with a smaller volume of exports and partly by the income from overseas investments that had been made during the 20 years preceding 1914, which years however had themselves by contrast seen little if any improvement in real wages.

*Aged 21 years and over. †Aged 18 and over

For the period from 1939 to 1947 the official cost-of-living index is an unsatisfactory measure of price increases. This index was based on working-class standards as they had been before World War I and was calculated. especially for food. on a small number of commodities, the prices of which served to indicate the general level of prices. So long as prices were uncontrolled and not subsidized, prices in the index had tended to move in a way not greatly dissimilar from that of other prices. Rut when, in World War II, commodities in the official index were subsidized and other commodities taxed, the cost-of-living index was lower than the cost of maintaining the standard to which wage earners had become accustomed. In this article, therefore, to evaluate real wages from 1938 until the introduction of the new and satisfactory index of retail prices in 1947, the index calculated by R. G. D. Allen and published in the London and Cambridge Economic service's bulletin has been used.

Early in World War II wage rates lagged behind prices, but by the end of the war that lag had ended. Wage rates, however, were by now an inadequate indication of wages. With full employment, the withdrawal of wage earners into the armed forces and the need to attract workers into new types of employment, the opportunities for exceeding the minimum or recognized rates of pay increased. Earnings rose more rapidly than either wage rates or prices and became a more realistic measure of wages than were wage rates. One must remember, however, that greater effort and longer hours were often required to obtain these greater earnings. In July 1944 weekly earnings of adult males reached a peak that they were not again to reach until mid-1947. This pause in the increase of earnings of men was associated with a decrease in the intensity of work and a spurt in wage rates, especially in 1946, the year following the end of the war. Increases granted in that year are officially estimated to have increased the national wage bill by £3,000,000 a week. It looked for a while as if the position were going to resemble that of the period immediately after World War I, when in 1919 wage increases put up the weekly wage bill by £2,500,000. (See Tables V and VI.)

In fact the pattern of wage rates in 1919 and later was not followed after 1946. For each of the four years 1947 to 1950 the increase in the weekly wage bill was about £1,000,000 or £2,000,000 a week compared with an increase of £5,000,000 in 1920, a decrease of £6,000,000 in 1921 and of £4,000,000 in 1922. After World War II the United Kingdom avoided a rapid inflation and subsequent deflation such as had followed World War I. Nevertheless, whereas after World War I a period of near stability in wage rates had been achieved in five years, that is by 1923, after World War II the inflation became chronic and was continuing unabated after ten years. There were record increases in wage rates of £6,500,000 a week in 1951 and of £6,600,000 in 1956 with increases in the intervening years averaging £4 000,000 a week. Stability was still not in sight and annual demands for wage increases by trade unions were recognized parts of the industrial pattern.

The substantial increases in wage rates in 1946 were followed by reductions in the number of hours nhich constituted the normal working week. These reductions typically reduced hours from 47 or 48 to about 44 a week and were the first substantial changes made since 1919 (likewise a date shortly after the end of war), when hours were reduced from about 53 to 48 a week. The reduction, however, in the number of hours to make up a recognized week's work was not associated with a corresponding reduction in the number of hours actually worked. That had already fallen from a wartime peak of 53 to between 47 and 48 by Jan. 1946, that is, before the reduction in normal hours and it remained between 46 and 49 for the whole of the period up to 1956. The reduction proved to be a way, not of giving wage earners more leisure, but of giving them more money income by counting some of the hours customarily being worked as overtime, attracting additional rates of pay. It is typical to reckon the first two hours overtime in any day as if it aere two and a half hours, and further hours as if each were one and a half hours.

Table VII shows that real

earnings early in 1956 were markedly higher than before the war, the apparent improvement having taken place in two stages, the first during the war; then after a period of relative stability there was further marked improvement after 1952.

The changes in wage rates were achieved with little industrial strife and negligible unemployment. After World War I industrial disputes caused an annual loss of 50,000,000 working days in the three years 1919 to 1921, 162,000,000 in 1926 (the year of the coal stoppage and general strike) and an annual loss of 7,000,000 in the three years 1929 to 1931. In contrast, the annual loss in the ten years from 1946 averaged less than 2,000,000 working days, which is about the same as in the best years between the wars.

For two reasons the picture of earnings and wage rates so far

TABLE VII.—*Index Numbers, 1938–56*

Year	Retail prices	Wage rates	Earnings men	Real wage rates	Real earnings
1938	100	100	100	100	100
1940	117	112	129	96	110
1942	137	131	161	96	117
1944	145	144	181	99	125
1946	154	163	175	106	114
1948	175	177	197	101	113
1950	185	186	215	100	
1952	221	218	2j6	99	
1954	232	238	292	103	126
1956	254	274	343	108	135

Retail prices from the *Bulletin* of the London and Cambridge Economic service; wage rates from the ministry of labour, covering men and women and including workers in agriculture, coal mining and on the railways; earnings of adult males covered by the ministry of labour's half-yearly inquiry; real wage rates and earnings obtained by division with the index of retail prices.

presented needs modifying: during World War II wage earners became for the first time substantial payers of income tax; and there were some important changes in relative positions not indicated by measures of average change.

When indirect taxation is changed, prices change as well and the calculated index of real wages automatically allows for the change. There is no such automatic correction when income tax is changed and, therefore, an allowance might specifically be made as soon as wage earners become substantial payers. At average earnings of 1938 a single man paid about 2% of his income in tax and a married man paid nothing. At average earnings of 1944 or 1945 a single man paid 22% of his income as tax, a married man without children 14%, with one child 9% and with two children 3%; allowing for these substantially modifies the picture of a wartime increase in real earnings, especially for single men. By 1950 the burdens of income tax for men had fallen: at the average earnings level, to about 10 % of income for the single man, 5% for the married man without children and 2% for the married man with one child, the man with two dependent children not paying anything, and since 19jo the burden as a proportion of the average man's wage has remained substantially unchanged. Table VIII attempts to make allowances for changes in income tax.

TABLE VIII.—*Index Numbers of Real Earnings, 1938–56*

Year	Not allowing for income tax	Allowing for income tax			
		Single man	Married, no child	Married, 1 child	Married, 2 children
1938	100*	100	100	100	100
1944	125*	100	107	114	121
1950	116*	106	110	114	116
1952	116*	107	111	115	116
1954	126*	115	118	123	
1956	135*	120	128	131	

*As given in Table VII (last column). The 1956 figures are provisional.

It is to be noticed that the increases in income tax during the war years took away much of the apparent improvement in real earnings, especially for single men and married men without dependent children, but reductions in income tax which took place between 1946 and 1950 were for all groups studied except those with two children, sufficient to remove the deterioration otherwise apparent between 1944 and 1950. After 1950 changes in the level of income tax had little further influence on earnings at the average level. Persons with incomes above the average received by wage earners suffered proportionately more from the wartime increases in income tax and generally benefited proportionately more from the subsequent reductions.

The other reason for modifying the situation already presented is a tendency for agricultural workers and coal miners to gain relatively to workers in other industries and, within industries, for the unskilled to gain relatively to craftsmen. Earnings per-man-shift worked at coal mines (including allowances in kind), which had averaged 11*s.* 8*d.* in 1938, averaged 52*s.* 10*d.* in 1955. Similarly, whereas in 1938 the average of minimum rates for agricultural workers was 34s. 6d. a week during Jan.–Aug. 1956, the national minimum of 135*s.* was raised in Sept. 1956 to 141*s.*

The tendency for unskilled workers in industry to gain relatively to the skilled was the result of flat-rate increases being given to all workers to compensate for rises in the cost of living, and though there had been sporadic attempts by skilled workers since the war to obtain increased differentials, the movement had not gone far by the late 1950s. In 1929 engineers in London received 39% more than their labourers; in March 1956 they received only 18% more. Likewise in 1929 builders in large towns had 32% more than their labourers; in 1956 only 13% more. Further examples could be given to show that the increase in wage rates after the outbreak of World War II was such that craftsmen benefited less than labourers and might in some cases be worse off in real terms than they had been.

Wages as a Cost of Production.— Wages, primarily considered as a major source of most individual incomes are also part of the cost of production of almost all goods and services. Table IX attempts to show wages in relation to the total cost of production. It shows that in 1955 wages represented 40% of all costs of production and including salaries 60%. In addition many other costs are in fact analogous to wages, as for example much of the income of self-employed persons. The reason for the low proportion that wages represent of the cost of agricultural production is that there are many working farmers whose income is not called a wage because they are self-employed and much the same applies to the income of many small shopkeepers. If one adds to this the fact that total cost is recorded before allowing for depreciation of durable equipment, the large extent to which general wage increases must produce almost proportionate increases in prices and therefore have little influence in real terms will be realized.

Table IS shows that in 1955 wages and salaries represented a slightly higher proportion of national income than in 1950, and there is some evidence that this is part of a process continued from 1938 However! the change certainly has been slow and if allowance had been made for the costs of maintaining the increased volume of capital equipment, it would be less than Table IX indicates.

Summary.— There was a striking improvement in real wages in the quarter-century before World War II. During the war there was further improvement in earnings, largely associated with increased intensity of work and mostly taken away by increased taxation. After the war real wages continued to improve, rather slowly at first but with gathering momentum in the period from 1952 to 1956. The rapid improvement before 1939 was helped by the reduction in foreign lending compared with the period before 1914, by the improvement in the terms of trade and by the income from investments made in previous periods, but it was hindered by a less than full employment of the United Kingdom's economic resources. After the war there was a full utilization of economic resources. full employment and marked increases in industrial production, but much of the increased production was absorbed in compensating for the reduction in real income from overseas investments and the deterioration in the terms of trade. The wage earner had the benefit of full employment, and where she desired it his wife was able to obtain work also. But by 1956 the experience of the worker was that from 1938 or from 1945 increases in money earnings of the order of 6% or 7% a year meant what seemed to them modest increases in real income. They were, therefore. demanding annual increases automatically, making restoration of monetary stability difficult. It seemed, in 1956, that they looked upon an annual increase in the same way that in the period of nage rigidity between World Wars I and II they looked upon unchanged incomes—as something that could only be sacrificed at risk to real standards. And. with full employment, they obtained these annual increases. (H. S. BR.)

WAGES BOARDS: see INDUSTRIAL RELATIONS.

WAGGA WAGGA: see RIVERINA.

WAGNER, COSIMA (1837–1930), was born in Bellagio, Italy, on Dec. 25, 1837. She was the illegitimate daughter of Franz Liszt (*q.v.*) and the Countess Marie d'Agoult. In 1857 she married Hans Von Bulow (*q.v.*), one of the outstanding conductors of his time and a favourite pupil of Liszt, but though she encouraged him in his work and remained devoted to him throughout her life, their marriage proved far less than she had hoped for. She bore him two daughters whom she called Daniela and Blandina. The two daughters subsequently born to Cosima—Isolde (1865) and Eva (1867) were Richard Wagner's children. In 1868, Cosima with her four daughters left Bülow and went to live with Wagner in Triebschen where she came to know Friedrich Nietzsche on whom she made a lasting impression. Wagner and Cosima were finally married in 1870. In that year, too, on the occasion of the first anniversary of the birth of their son Siegfried (1869–1930), Wagner composed the Siegfried *Idylle* as a surprise for Cosima. With the passing of Wagner (1883), she took upon herself the management of the Bayreuth festivals, of which she was art director until 1908 when her son took over. To this self-imposed task, she applied her characteristic energies and her continued devotion to the works of Wagner's genius. She was the moving force behind the festival plays both in commercial and social matters, influencing the selection of repertoire, artists and style of presentation. She died in Bayreuth, in total blindness, on April 1, 1930. Cosima was not only the wife of Wagner, his close coworker, but a woman of great gifts and enormous energies. Part of her published diaries and letters convey a vivid impression of her strong and fascinating personality. That she was sometimes unhappy with Wagner was no doubt true. But their marriage was one of singular mutual enrichment and for Cosima the realization of perfect womanhood.

WAGNER, HONUS (JOHN PETER WAGNER) (1874–1955), U.S. baseball player, one of the first five men elected to the Baseball Hall of Fame at Cooperstown, N.Y., and generally considered the greatest shortstop in U.S. baseball history. The "Flying Dutchman," as he was called, led the Iiational league in batting eight times and established records for the greatest number of doubles and triples.

Born Feb. 24, 1874, at Mansfield (now Carnegie), Pa., Wagner, who stood 6 ft. tall and weighed 200 lb., joined Louisville (then in the National league) in 1897 and went to the Pittsburgh Pirates in 1900. He was past 40 when he retired in 1917. Wagner, who appeared in two world series, had a batting average of .329 for 21 seasons and stole a total of 720 bases.

Honus Wagner died in Carnegie, Pa., on Dec. 6, 1955.

(J. D. McC.)

WAGNER, (WILHELM) RICHARD (1813–1883), German dramatic composer and theorist, was born at Leipzig on May 22, 1813. That year his father, a minor civil servant, died and his mother married Ludwig Geyer, a painter and a singer-actor. The artistic and theatrical background of Wagner's early years (several elder sisters became opera singers or actresses) was a main formative influence. Impulsive and self-willed, he was a negligent scholar at the Kreuzschule, Dresden, and the Nicolaischule, Leipzig; but under the inspiration of Beethoven, Mozart, Weber, Shakespeare, Goethe and Schiller, he taught himself the piano and composition and wrote a five-act verse-trageay. At 17 he had a crude overture performed at the Leipzig theatre.

A Hoffmannesque romantic youth, he was attracted by the glamour of German student life. Not having matriculated. he enrolled at Leipzig university as a second-class student and, although he lived wildly, he applied himself earnestly to composition. Owing to his impatience with all academic techniques, he spent a mere six months acquiring a groundwork with Theodore Weinlig, cantor of the Thomasschule, but his real schooling was a close personal study of the scores of the masters, notably the quartets and symphonies of Beethoven. His own Symphony in C was performed at the Leipzig Gewandhaus concerts in 1833. On leaving the university that year, he spent the summer as operatic coach at Wurzburg, where he composed his first opera. Die Feen (The Fairies). As with all his subsequent works, the libretto, after a fantastic tale by Carlo Gozzi, was his own. The opera being refused at Leipzig. he sought employment and became conductor to a provincial theatrical troupe from Magdeburg. impelled by having fallen in love at first sight with one of the actresses, Wilhelmine (Minna) Planer (1809–66).

The next six years he spent struggling as a provincial conductor of third-rate opera companies in Magdeburg, Konigsberg and Riga, striving idealistically to raise standards and incurring enormous debts owing to his poor pay and careless expenditure. In 1836, at Konigsberg, he directed a single disastrous performance of his second opera, Das Liebesverbot ("The Ban on Love," after Shakespeare's Measure for Measure). Later in the same year and in the same city he married Minna Planer. In 1839, fleeing from his creditors in Riga, he assayed his long-cherished plan to conquer Paris. German opera composers were without honour in their native country, which preferred French and Italian models; and Wagner, precociously convinced of his coming greatness, thought a dazzling success in Paris would win him recognition at home.

His three years in Paris were disastrous. Despite Meyerbeer's recommendation, he could not break into the closed circle at the Opéra. Living with the colony of poor German artists, he staved off starvation by means of musical journalism and hack work. Nevertheless in 1840 he completed Rienzi (after Bulwer-Lytton's novel) ; and in 1841. his technique having profited from his hearing of the music of Berlioz, he composed his first representative opera. Der *fliegende Holländer* (The Flying Dutchman), based on the old legend. He offered Rienzi to Dresden, where it was accepted.

In 1842. aged 29, he gladly returned to Dresden, where Rienzi was triumphantly performed on Oct. 20. Next year The Flying *Dutchman* (produced at Dresden, Jan. 2, 1843) was less successful, owing to its innovatory style and method. But he was appointed *Hofkapellmeister* at the court opera, a post that he held until 1849. On Oct. 19, 1845, *Tannhäuser* (based. like all his future works, on Germanic legends) was coolly received but soon proved a steady attraction; after this, each new work achieved popularity with the public, despite persistent hostility from many critics. For the next 20 years, however, Wagner was not to present any further new works. He completed Lohengrin in 1848 but his projected administrative and artistic reforms alienated the court opera authorities; and, his mind having turned to ideas of social regeneration, he became embroiled in the Gerinan revolution. He wrote inflammatory articles and took an active part in the Dresden uprising of 1849. When this failed he fled from Germany with a price on his head, unable to attend the first performance of Lohengrin at Weimar, given by his friend Liszt on Aug. 28, 1850.

Until 1858 Wagner lived in Zurich. composing, writing treatises and conducting (he directed the London Philharmonic concerts in 1855 with great success). Having already studied the Siegfried legend and the Norse myths as a possible basis for an opera. and having written an operatic "poem." *Siegfrieds Tod,* in which Siegfried was conceived as the new type of man who would emerge after the successful revolution he had hoped for. Wagner now cogitated intensely concerning revolution, social and artistic. From 1849 to 1852. he wrote his basic prose works: *Die Kunst und die Revolution (Art and Revolution), Das Kunstwerk der Zukunft (The Art Work of the Future). Eine Mitteilung an meine Freunde (A Communication to My Friends)* and *Oper und Drama (Opera and Drama).* The latter adumbrated a new. revolutionary type of musical stage work—the vast work. in fact, on which he was engaged. By 1852 he had added to the poem of *Siegfrieds Tod* three others to precede it, the whole being called *Der Ring des Nibelungen (The Ring of the Nibelung)* and providing the basis for a tetralogy of musical dramas: *Das Rheingold (The Rhinegold); Die Walküre (The Valkyrie); Der junge Siegfried (Young Siegfried),*later called simply *Siegfried;* and *Siegfrieds Tod (Siegfried's Death),*later called *Götterdämmerung (The Twilight of the Gods).*

By 1857 Wagner's style had been enriched by the stimulus of Liszt's discoveries and he had composed *The Rhinegold, The Valkyrie* and two acts of *Siegfried.* But he now suspended work on *The Ring:* the impossibility of mounting this colossus within any foreseeable future was enforcing a stalemate on his career and led him to project a "normal" work capable of immediate production. Also his optimistic social philosophy had yielded to a metaphysical, world-renouncing pessimism. nurtured by his discovery of Schopenhauer's philosophy. The outcome was *Tristan und Isolde* (1857–59). of which the crystallizing agent was his hopeless love for Mathilde Wesendonk (the wife of a rich friend and patron). which led to separation from his wife Minna.

Life in Zurich had become too embarrassing, and Wagner completed *Tristan* in Venice and Lucerne. In 1860 he went to Paris. where the following year sumptuous productions of a revised version of *Tannhäuser* were a fiasco. owing to scandalous riots by a powerful clique. But in 1861 an amnesty allowed him to return to Germany: from there he went to Vienna, where he heard *Lohengrin* for the first time. He remained in Vienna three years, enjoying enthusiastic recognition. traveling widely as conductor and awaiting a projected production of *Tristan.* As this failed to materialize, owing to the artists' bewilderment over its revolutionary style, Wagner began a second "normal" work, the comedy-opera *Die Meistersinger von Nürnberg (The Mastersingers of Nürnberg).* But by 1864 his lavish expenditure and inveterate habits of borrowing and living on others had brought him to financial disaster: he had to flee from Vienna to avoid imprisonment for debt. *The Ring* was still incomplete and *Tristun* apparently unperformable. He had powerful enemies. largely because of his own bad dealing. which arose from blind artistic self-centredness and a sense of persecution. He was without a penny; and he arrived in Stuttgart, a man of 51 without a future. almost at the end of his tether.

Something like a miracle saved him. He had always made loyal friends, owing to his fascinating personality, his towering genius and his artistic integrity. Now a new friend, of the highest influence. came to his rescue. In 1863 Louis II (*q.v.*), a youth of 18, ascended the throne of Bavaria. He was a fanatical admirer of Wagner's art and. having read the poem of *The Ring* (published the year before with a plea for financial support), he invited Wagner to Munich to complete the work there.

The king set him up in a villa. and during the next six years there mere successful Munich productions of all of Wagner's representative works to date, including the first performances of *Tsistan* (1865), *The Mastersingers* (1868), *The Rhinegold* (1869) and *The Valkyrie* (1870,—all directed by the first great Wagner conductor. Hans von Bülow. At first a new theatre at Munich was projected for this purpose. with a music school attached. but this came to nothing because Wagner raised a storm by his way of living. Not only did he constantly run into debt despite his princely salary but he also attempted to interfere in the government of the kingdom. In addition. he entered into relations with von Bulow's wife, Cosima (the daughter of Liszt; 1837–1930). She bore him three children. Isolde (1865–1921), Eva (1867–1942) and Siegfried (1869–1930), before her divorce in 1870 and her marriage to Wagner in the same year, his first wife Minna having died in 1866. For all these reasons. Wagner ceased to live in Munich as early as 1865. But he never forfeited the friendship of the king, nho set him up at Triebschen on the Lake of Lucerne whence he paid lengthy visits to Munich to supervise the productions of his works The year 1870 saw the appearance of his profound essay *Beethoven.*

In 1869 Wagner had resumed work on *The Ring,* which, in keeping with his later views, he now brought to its world-renouncing conclusion. It had been agreed with the king that the tetralogy should be first performed in its entirety at Munich. but Wagner broke the agreement, convinced that a new type of theatre must be built for the purpose. Having discovered a suitable site at Bayreuth he toured Germany, conducting concerts to raise funds and encouraging the formation of societies to support the plan. In 1872 the foundation stone was laid In 1874 Wagner moved into a house at Bayreuth that he called Wahnfried (Peace from Madness), and that year he completed *The Ring.* The whole vast project was eventually realized, in spite of enormous difficulties, artistic. administrative and financial. The king. who had provided Wahnfried for Wagner, made him a gift of 100 000 talers. and mortgages were raised that were later paid off by the royalties on Wagner's works. *The Rzng* received its triumphant first performance in the new Festspielhaus at Bayreuth on Aug. 13. 14, 16 and 17. 1876. (*See* also BAYREUTH.)

Wagner spent the rest of his life at Wahnfried, making several visits to Italy. and one to London in 1877 to give a successful series of concerts. During these years he composed his last work. the sacred festival drama. *Parsifal*, begun in 1877 and completed and produced at Bayreuth in 1882; and he dictated to his wife his autobiography. *Mein Leben* (My *Life*) He died of heart failure. at the height of his fame. in Venice on Feb 13. 1883 aged 69. He was buried in the grounds of Wahnfried in the tomb he had himself prepared; a few days later. King Louis rode to Bayreuth alone at dead of night to pay his personal tribute. Since then. the Festspielhaus has staged yearly festivals of Wagner's works except during World War II; it is worth mentioning that he himself intended it also to present the works of any outstanding German composers nho might follow him.

These are merely the main events of Wagner's life. which cannot be adequately summarized since it was crammed with intense and variegated activity. His inexhaustible energy went not only into his work but also into innumerable friendships, enmities and love affairs. into various far-reaching projects that he abandoned and into sporadic political activity; and most of the countless separate happenings of his life were surrounded by tortuous intrigue.

Development.—Wagner's development. achievement and influence can only be understood by accepting his own view that he was not simply a composer but a musical dramatist. Music never interested him for its own formal sake but only as emotional and psychological expression It is significant that he first taught himself composition to provide music for his boyhood verse-tragedy, and that the conception that eventually materialized as *The Rzng* originally presented itself as an alternative between a poetic drama concerned with Fredrick I Barbarossa and a musical drama on the Siegfried legend. Apart from certain jejune youthful efforts, he composed no purely formal instrumental works; his whole significant *oeuvre* is musicodramatic. Nevertheless, his search for the utmost depth. subtlety and precision in the musicodramatic expression of feeling resulted in a radical revolution of compositional technique that crucially affected the development of music as an art in itself.

Wagner's slow and erratic development, from the crudest tyro to a supremely original master creator is unique. beginning with the poorest technical equipment, he achieved greatness by sheer persistent force of artistic imagination and hard-won experience. However his early incapacity should not be exaggerated. he made a considerable step forward from the gauche Symphony in C of his 20th year to the opera *Dze Feen* of his 21st The latter is a really professional work; and in using the fantastic-legendary atmosphere and style of the new romantic German opera so newly founded by Weber and continued by Marschner, Wagner was already following his ordained path, since his primary achievement was to bring this tradition to a magnificent climax and thus to set Germany on the operatic map once and for all. The crucial deficiency of *Die Feen* is its lack of any personal musical style. On the other hand, an additional section for an aria in Marschner's *Der Vampyr,* written the same year, reveals Wagner's individuality clearly, since it develops a vivid thematic complex that later became a main element in *The Ring.*

His two subsequent operas were not an advance but a diversion along a false path. Acutely aware of the provincialism of German opera (and with one eye on Paris), he wrote *Das Liebesverbot,* a clumsy plagiarism of Bellini and Donizetti, and *Rienzi,* a grandiose attempt at opera in the manner of Meyerbeer and Gasparo Spontini. The former was so much wasted energy, but in the latter he learned something about constructing a musical stage work on the vast scale he was to adopt later. But it was in his comparatively compact next opera that his personality was first defined. Homesick in Paris and disillusioned with his false gods, he composed *The Flying Dutchman,* in which his mature romantic German style clearly emerged. If the subsidiary parts of. the work followed conventional models, the main dramatic situations showed a Wagner who had hitherto appeared only in the music added to the *Vampyr* aria. The essence of this new style was the symphonic expression of aspects of the unconscious linked with the characters portrayed symbolically on the stage.

In *Tannhäuser* and *Lohengrin* Wagner developed this style on the large scale he had broached in *Rienzi.* The sheer scope of these works—the building of rnusicodramatic climax on climax—is masterly. Nevertheless, as before, Wagner was only his true self in the symphonic handling of the main situations. In the subsidiary parts he was now worse off than before: having abandoned conventional models, he handled the supporting action in an amateurish, four-square, semirecitative style that he himself was later to smile at. And even at the great climaxes he sometimes used vulgar material, which is recognizable early Wagner but bears little relation to his definitive style. The trouble was that he wanted to reject as mere artifice all conventional methods of operatic construction and to extend dramatic and pyschological development over a whole work by means of a continuous symphonic web; but he had not yet discovered a way to do this. The three early operas contain much deadwood of his own or others' devising.

It was during his period of cogitation over social theory that he found the way at last. Theoretically, in *The Art Work of the Future,* and autobiographically, in *A Communication to nay Friends,* he projected a revolutionary type of musical stage work that he specified in full in *Opera and Drama.* This treatise analyzed intellectually the art form toward which he was moving creatively in building *The Ring.* Basing himself on the romantic-socialistic doctrine of the "natural man," and looking forward to the imminent creation of a socialist state in which this concept would flourish, he prophesied the disappearance of opera as artificial entertainment for an elite and the emergence of a new kind of musical stage work for the people, expressing the self-realization of free humanity. This new type of work was later to be called "music drama," though Wagner never used this term but preferred simply "drama." It was intended as a return to the Greek drama as Wagner understood it—the public expression of national and human aspirations in symbolic form by enacting racial myths and using music for the full expression of the dramatic action.

Wagner's emphasis on opera as drama merely resumed and developed the ideas of Monteverdi and Gluck; but in propounding the revolutionary conception he had been striving for in his three previous works he went much further. He envisaged the disappearance of the old operatic type, with its libretto provided by a hack versifier as an opportunity for the composer to make a "set-piece" opera out of purely musical forms separated by recitative. Briefly put, the new art form would be created by a single artist, who would write a poetic drama that should find full expression as a musical drama when it was set to a continuous vocal-symphonic texture. This texture would be woven from basic thematic ideas. called *Leitmotive* (singular, *Leitmotiv)* or "leading motives": these would arise naturally as expressive vocal phrases sung by characters at crucial emotional points of the drama and would then be developed by the orchestra as "reminiscences" in accordance with the expressive need of the dramatic and psychological development of the action. *(See* also LEITMOTIV.)

This conception found full embodiment in The *Ring,* except that the leading motives did not always arise as vocal utterances but were often introduced by the orchestra to portray characters, emotions or events in the drama. With his use of this method, he rose immediately to his amazing full stature: his style became unified and deepened immeasurably, and he was able now to fill his works from end to end with intensely characteristic music. Except for moments in *The Rhinegold,* the old weaknesses, formal and stylistic, vanished altogether and with them disappeared the last vestiges of the old "opera." Wagner's works now fulfilled his new conception literally, except in two respects. First, whereas in *The Rhinegold* and *The Valkyrie* the symphonic development of the motives was largely explanatory of the drama, Wagner used it with much greater subtlety from *Tristan* onward. The impact of Schopenhauer's theory of the supremacy of music among the arts (brilliantly developed in Wagner's own essay *Beethoven)* led him to tilt the expressive balance of musical drama more toward music: the motives ceased to remain neatly identifiable with their dramatic source but worked with greater psychological complexity, in the manner of free association. Secondly, for the comedy of *The Mastersingers* Wagner incorporated into his new conception certain of the old "operatic" elements (aria, quintet, etc.)

Achievement.—Wagner's creation of his own type of musical drama was a fantastic singlehanded achievement, considering the scale and scope of his art. His method was to condense the confused mass of material at his disposal—the innumerable conflicting versions of the legend chosen as a basis—into a taut dramatic scheme; and in this scheme. as in his model, the *Oresteia* of Aeschylus, the stage events are few but crucial. the main part of the action being devoted to the working out of the characters' psychological motivation?. The "poem"—the verbal drama—he laid out with musical structure in mind so that it formed a natural basis for large-scale musical forms comprising detailed musical-emotional development.

In setting the poem he used his mastery of construction on the largest scale. which he had learned from studying Beethoven, to keep the broad outlines clear while he consistently developed the leading motives to mirror every shifting nuance of the psychological situation. Criticism of these motives as arbitrary, factual labels shows a complete misunderstanding of Wagner: he called them "carriers of the feeling" and, owing to their essentially emotional character, their pliability and Wagner's resource in alternating, transforming, combining and intermingling them, they do function as the subtle expression of the changing feelings, conscious or unconscious, behind the dramatic symbols.

The result of these methods was a new art form, of which the distinguishing feature was a profound and complex symbolism working on three indivisible planes—dramatic, verbal and musical. The vital significance of this symbolism is being more and more realized, though its involution of layer beneath layer of meaning has hardly begun to be explored. Through all the various stages of Wagner criticism—the opposition to him as a "modernist" in his lifetime, the heavy-handed exegesis of his philosophy during the high Wagnerian period (1880–1914) and the ill-informed abuse of his art when reaction set in between World Wars I and 11—Wagner's complex interrelation of dramatic. verbal and musical symbolism has not been approached with anything like the thoroughness it deserves.

Wagner's symbolic art was a fundamental contribution to the stream of thought and feeling passing from Paul Feuerbach, through Schopenhauer and Nietzsche, to modern depth psychology. The common theme of all his mature works. except *The Mastersingers,* is the romantic concept of "redemption through love"; but this element, used rather naïvely in the three early operas. became, in the later musical dramas, a mere catalyst for much deeper complexes of ideas on various levels. In *The Ring* there are at least five interwoven strands of overt meaning concerned with German nationalism, international socialism, the philosophy of Schopenhauer. Buddhism and Christianity. (Wagner sketched a dramatic scheme for a Buddhist musical drama, *Die Sieger* [*The Victors*], and for a Jesus von *Nazareth*, neither of which he completed.) On another level, there is a prophetic treatment of some of the dominant themes of depth psychology: power complex arising from sexual inhibition, incest, mother-fixation and Oedipus complex. (*See* also PSYCHOANALYSIS.)

Tristnn stands in a line of symbolism extending from the themes of "night" and "death" explored by such German romantic poets as Novalis, through the Schopenhauerian indictment of life as an evil illusion and the renunciation of the will to live, to the modern psychological insight into the relationship between eroticism and the death wish. *The Mastersingers* stands apart as a work in which certain familiar themes are treated on a purely conscious plane with mellow wisdom and humour: the impulsiveness of youth and the resignation of age, the ecstasy of youthful love. the value of music itself as an art. But in Wagner's last work, *Parsijal*, the symbolism returns on a deeper level than before He has been much criticized for this strongly personal treatment of a religious subject, which mingles the concepts of sacred and profane love; but in the light of modern knowledge. his insight into the relationship between religious and sexual experience can only seem much in advance of his time. The themes of innocence and purity, sexual indulgence and suffering, remorse and sexual renunciation are treated with a peculiar subtle intensity and depth of compassion that explore deeply into the unconscious and make *Parsifal* in some ways the most visionary of all Wagner's works.

Influence.—Wagner's influence, as a musical dramatist and a composer. was a powerful one. Later operatic composers mere greatly indebted to him—not only the many who adopted his methods more or less implicitly. like Richard Strauss or the few who turned them to entirely personal account. like Debussy, but even those who rejected his conception and continued the older type of "set-piece" opera. Although few have been able to follow him in providing their own verbal basis. all significant opera composers have profited from his reform in the matter of giving dramatic depth. continuity and cohesion to their works. "Music drama" is dead but musical drama is still fully alive.

In the purely musical field. Wagner's influence was even more far-reaching. He de eloped such a wide expressive range thst he was able to make each of his works inhabit a unique emotional world of its own; and. in doing so. he raised the melodic and harmonic style of German music to its highest emotional and sensuous intensity. It was this intensity that caused him to bestride the late 19th century like a Colossus: the subsequent history of music, apart from the nationalist schools and the development of the traditional symphony by composers like Sibelius and Shostakovich, stems entirely from him, either by extension of his discoveries or reaction against them. There was. of course his immediate effect on late romantics like Richard Strauss in Germany and like Bruckner and Mahler both of whom exploited his gains in the field of the gigantic Austrian symphony; but his influence was far more widespread than this. The sensuous and symbolic content of his works profoundly affected artists of all kinds in France and impelled Debussy, partly by subtilization and partly by rejection, to evolve his own elusive sensuous, symbolic and epoch-making art Moreover, Wagner's persistent modulation without perfect cadences and his intensive development of German chromaticism, notably in *Tristan*, was later carried further by Schoenberg to the point where it led to the crucial breakthrough into atonality (see HARMONY) And on the negative aide, the psychological intensity of his music caused a violent reaction that resulted in the fierce abstract intellectualism of the theory and practice of the neoclassic school headed by Stravinsky. Wagner was the great turning point of western music, representing at once the final romantic culmination of the old tonal system and the source of the new music of our time.

See also references under "Wagner, (Wilhelm) Richard" in the Index volume.

BIBLIOGRAPHY.—For a realistic but sympathetic analysis of Wagner's phenomenally complex character, the reader should consult Ernest Newman, *The Life of Richard Wagner,* 4 vol. (1933–47), which unravels the tangled skein meticulously. Against this work should be checkrd all the preceding, unreliabie accounts of Wagner's life and personality, including Wagner's own in *Mein Leben*. 2 vol. (1911), and the official German and English biographies by C. F. Glasenapp, *Das Leben Richard Wagners*, 6 vol. (1894–1911), and W. A. Ellis, *Life of Richard Wagner*, 6 vol. (1900–08). Even Newman is not absolutely final in every last detail. since certain sources (notably the letters of Wagner published as the Burrell collection, 1951) were not available to him.

Wagner's own prose works were translated into English by W. A. Ellis, 8 vol. (1892–99). The best analytical introduction to Wagner's stage works, with exhaustive accounts of which they are based. is Ernest Newman's *Wagner Operas* (1949, republished with the title *Wagner Nights,* 1950). A penetrating and detailed study of Wagner's development as a musical dramatist, in close connection with his changing theories, is Jack Stein's *Richard Wagner and the Synthesis of the Arts* (1960). A. O. Lorenz, in *Das Geheimnis der Form bei Richard Wagner,* 4 vol. (1924–1933), provided a schematic bar-by-bar analysis of the musical construction of *The Ring, Tristan. The Mastersingers* and *Parsifal*. There is no book on Wagner's influence, operatic or purely musical; and the studies that attempt to interpret the symbolism of Wagner's works should all be approached with caution.

(D. V. C.)

WAGNER-JAUREGG, JULIUS (1857–1940). Austrian psychiatrist. was born at Wels in Upper Austria on March 7. 1857. He was awarded the 1927 Nobel prize in medicine and physiology for his introduction of malaria treatment for general paralysis. After graduating doctor of medicine at the University of Vienna in 1880 he worked first in the department of experimental pathology and internal medicine and then in the psychiatric clinic. In 1859 he was appointed professor of psychiatry and neurology at the University of Graz, and in 1893 was called to the corresponding chair at Vienna and to the directorship of the university hospital for nervous and mental diseases. He held these posts for 35 years, acquiring an international reputation as a psychiatrist, and retired in 1928.

Cases in which sufferers from nervous or mental disease had shown considerable improvement after contracting a febrile infection had been recorded from early times, but these empirical observations had never been followed up systematically. As early as 1587 Wagner-Jauregg proposed that nature's experiment should be imitated by deliberately producing an infectious disease. and he stressrd the advantages uf malaria as a disease that could be interrupted at will by means of quinine. In 1890 he attempted to induce fever by the injection of tuberculin and other foreign proteins, and it was not until 1917 that he actually inoculated cases of progressive paralysis with tertian malaria. The result was a striking improvement in the prognosis of a disease which had hitherto been regarded as incurable.

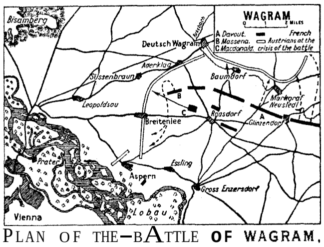
Although the treatment of general paralysis was later greatly modified by the introduction of chemotherapeutic and antibiotic agents. Wagner-Jauregg's work remained of importance. Earlier in his career he had made contributions to other branches of medicine, especially concerning cretinism and other thyroid diseases. He died in Vienna on Sept. 27. 1930. (W. J. BP.)

WAGON or WAGGON, a large four-wheeled vehicle for the carriage of heavy loads, drawn by two or more horses. This is the general English use of the term, where it is more particularly confined to large vehicles used in the carrying of agricultural produce. It is also used of uncovered heavy rolling stock for freight on railways. (*See* RAILWAY.) In the U.S. the term is applied also to lighter vehicles, such as are used for express delivery, police work. etc.. and to various forms of four-wheeled vehicles used for driving, to which the English term "cart" would be given.

WAGRAM or DEUTSCH WAGRAM, a village of Austria in the plain of the Marchfeld, $11\frac{1}{2}$ mi. N.E. of Vienna. Pop. (19.51) 3.996. It gives its name to the battle of July 5 and 6. 1809, in which the French army under Napoleon defeated the Austrians under the archduke Charles.

On the failure of his previous attempt to pass his army across the Danube at Aspern (*see* ASPERN-ESSLING, BATTLE OF; NAPOLEONIC CAMPAIGNS), Napoleon set himself to concentrate around Vienna and the island of Lobau not only his own field forces but also every man, horse and gun available from Italy and south Germany for a final efiort. Every detachment was drawn in within 48 hours' call, his rearward communications being practically denuded of their covering troops. The island of Lobau itself was converted practically into a fortress, and more than 100 guns were mounted on its banks to command the Austrian side of the stream. Giving up. in face of this artillery. the direct defense of the riverside, the Austrians formed in a great arc of about 6-mi. radius extending from the Bisamberg, overlooking the Danube, in the west, to Markgrafneusiedl on the east. From this point to the Danube below Lobau a gap was left for the deployment of the archduke Johann's army from Pressburg 35 mi. distant. This army. however, arrived too late. The total front, therefore, was about 12 mi, for 120,000 men, which could be reduced to about 6 mi. by a forward march of a couple of hours.

Meanwhile Napoleon replaced the temporary bridges over the main stream by means of two solid structures, protecting them by palisades of piles and floating booms, and organized an armed flotilla to command the waterway. On the island itself preparations were made to throw three bridges across the Lobau arm of the stream opposite Aspern and Essling. and seven more on the right, facing east between Gross Enzersdorf and the main river. For several days previous to the great battle the French had sent across small detachments; hence when, on the afternoon of July 4, an advanced guard was put over near Gross Enzersdorf, the attention of the Austrians was not particularly attracted and they did not interfere. Under cover of this detachment Napoleon's pontoniers made the seven bridges. Long before daylight on July 5 the troops began to stream across, and about 9 A.M. the three corps destined for the first line (Davout. Oudinot and Masséna) had completed their deployment on a front of about 6.000 yd. and were moving forward to make way for the second line (Eugène and Bernadotte) and the third line (Marmont, Bessikres's cavalry and the guard). About noon the general advance began, the French opening outward like a fan to obtain space for manoeuvre.



PLAN OF THE BATTLE OF WAGRAM, JULY 5–6, 1809

The Austrians held a strong position along the line of the Russbach from Wagram to Markgrafneusiedl with their left, while their right was held ready for a counterattack intended to roll up the French attack from left to right when the proper moment should come. The movements of the great French masses in the confined space were slow, and although the French left under Masséna pushed the Austrians back beyond Leopoldsau and Süssenbrunn, the main attack on the line of the Russbach did not declare itself till 8 P.M.; the corps did not attack simultaneously, and failed altogether to make any serious impression on the Austrian position. But, hearing of the success of his left wing on the Russbach, the archduke determined to anticipate the French next morning on that side, and four corps were directed upon Masséna, who had bivouacked his troops overnight on the line Leopoldsau-Sussenbrunn-Aderklaa. the latter, a strongly built village. forming, as it were, a bridgehead to the passages of the Russbach at Wagram. Another corps with a strong cavalry force was also directed to pivot round Markgrafneusiedl and to attack Davout on his right; on this flank also the arrival of the archduke Johann was expected later in the day.

The Austrian movements were somewhat ill connected; nevertheless, by 11 A.M. Masséna's detached left division had been driven back almost to Aspern, and hi's right. though aided by Bernadotte, had failed to recapture Aderklaa, from which the Austrians had driven his advanced posts early in the morning. The situation for the French looked serious, for their troops were not fighting with the dash and spirit of former years. But Napoleon was a master in the psychology of the battlefield. and he knew that on the other side things were much the same. He therefore sent orders for a great counterstroke. Davout on the right was to press his attack on Markgrafneusiedl and roll up the Austrian left flank, Oudinot, next him. mas simply to engage the enemy on the heights with artillery fire for the time being. The capture of Markgrafneusiedl was to be the signal for the main blow against the Austrian centre by Eugene's two corps (under Macdonald and Grenier), which were then moving up. Meanwhile Masséna was to move laterally across the front to aid his isolated division in guarding the threatened left flank. The gap thus left was covered by a line of guns, soon raised to a total of 104, which prepared the advance of the 5th corps (Macdonald) through the gap on Sussenbrunn, followed by the guard and reserve cavalry.

Macdonald formed his 30.000 men in a gigantic hollow square —two lines, each of four deployed battalions. closed up so that the whole was six ranks deep, while the remainder of the infantry marched behind in column on either flank, and cavalry closed the rear. The Austrian round shot cut swaths through this dense square, whose trail appeared one mass of dead and dying, creating a terrible impression on all who saw it. It had shrunk so much from losses. and still more from stragglers. that it came to a halt in a sandpit a mile short of Siissenbrunn. When reinforced, both directly and by divisions launched to attack Aderklaa and Breitenlee on its flanks, Macdonald resumed his advance and reached his objective. At the same time Napoleon had ordered forward Oudinot to cross the Russbach between Baumdorf and Wagram and to strike the joint of the Austrian line at Wagram. The Austrian left centre had been weakened by reinforcements sent to the left, hard pressed by Davout, and by stretching to cover the gap on the other side. This weakening enabled Oudinot to gain Wagram, while Davout had also made headway. With the penetration near Wagram, the Austrian army mas split. and learning that the archduke Johann could not arrive until evening the archduke Charles at about 2:30 P.M. ordered a general retreat, the main part westward and the left wing northward.

The French had seen more of the slaughter than their adversaries, and except for the emperor and Davout all seem to have been completely shaken. Even in Davout's command: always the steadiest in danger, the limit of endurance had been passed, for when, at about 5 P.M., the advanced patrols of the archduke Johann's force appeared on their flank, panic on a scale previously unknown in the *grande armée* seized the right wing, and Napoleon had to confess that no further advance was possible for several days.

Berndt (*Zahl im Kriege*) gives the following figures: French 181,700 (including 29,000 cavalry) and 450 guns engaged, of whom 23,000 men were killed and wounded, 7,000 missing; Austrians. 128.600 (including 4,600 cavalryj and 410 guns engaged. losses 19.110 killed and wounded and 6,740 missing.

WAGTAIL, the popular name for birds of the subfamily Motacillinae, which, together with the Anthinae (see PIPIT), form the passerine family Motacillidae.

The pied wagtail is almost confined as a breeding species to the British Isles. It constitutes a good example of a species owing its origin to isolation. It is represented on the continent by the white wagtail (*M. alba*), of which it is a subspecies. Three other species occur in England, but the subfamily with several genera and many species ranges over the old world, except Australia and Polynesia, while Asiatic species reach northwest America.

Wagtails are long-tailed, generally particoloured birds. frequenting streams and stagnant water and feeding on seeds, insects, worms, small molluscs and crustaceans. The nests are made of moss, grass and roots. with a lining of hair and feathers; four to six eggs are laid, bluish-white or brown, with yellow marks.

WAHHABI, the name of a puritan movement within Islam. Wahhabis or *Ikhwan* (brothers) purport to follow in detail the practice of the Prophet, and regard as infidels all who do otherwise. Their enemies are the enemies of the true faith and their every campaign is therefore a jihad (holy war), death in which is a sure passport to paradise. Another feature of these communities is the complete elimination of all tribal distinctions. The old pastime of tribal raid and counterraid is discountenanced. The blood feud is no more. In the matter of doctrine the Wahhabis (*Ikhwan*) differ from their fellow Moslems in rejecting a large mass of tradition which they regard as unauthentic. Like all Moslems they regard the Koran as the word of God and therefore the foundation of their social code, but there is admittedly much in the Koran and much not in it which from the earliest days of Islam required explanation or consideration. Such matters were freely dealt with by the Prophet in conversation or in his practice, the records of which were collected in the form of traditions of the Prophet, which, being generally handed down by word of mouth, with time grew in volume. *See* ARABIA: *History*.

WAHOO *(Euonymus atropurpureus)*, a small North American tree of the staff tree family (Celastraceae), known also as burning bush, found from New York to Montana and southward and sometimes planted for ornament. The handsome fruit, ripening in October and persisting until midwinter, is a deeply lobed capsule with smooth purple valves which split apart at maturity, disclosing large seeds covered with a scarlet aril. *See* CLIMEING BITTERSWEET; SPINDLE TREE.

WAINEWRIGHT, THOMAS GRIFFITHS (1794–1852), English journalist and subject painter, was born at Chiswick in Oct. 1794. He contributed to various magazines and painted pictures some of which were exhibited at the Academy. Because of his extravagant habits, Wainewright's affairs became deeply involved. In 1830 he insured the life of his sister-in-law in various offices for a sum of £18,000, and uhen she died, in December of the same year, payment was refused by the companies on the ground of misrepresentation. Wainewright retired to France, where he was seized by the authorities as a suspected person and imprisoned for six months. He had in his possession a quantity of strychnine, and it was afterward found that he had poisoned not only his sister-in-law but also his uncle, his mother-in-law and a friend. He returned to London in 1837 but was arrested on a charge of forging, 13 years before, a transfer of stock, and was sentenced to exile for life. He died in Tasmania in 1852.

The *Essays and Criticisms* of Wainewright were published in 1880, with an account of his life, by W. Carew Hazlitt; and the history of his crimes suggested to Dickens his story of *Hunted Down* and to Bulwer-Lytton his novel of *Lucretia*.

WAINWRIGHT, JONATHAN MAYHEW IV (1883–1953), U.S. army officer, achieved fame as the hero of Bataan and Corregidor in the defense of the Philippines early in World War II (*q.v.*). Born on Aug 23, 1883, at Walla Walla, Wash., Wainwright grew up on army posts along the western frontier where his father had served in the wars against the Indians. Like his father he attended the U.S. Military academy, West Point, N.Y., and on his graduation in 1906 was commissioned a second lieutenant of cavalry. His career thereafter followed the usual pattern — service with troops, attendance at army schools and slow promotions. During World War I, when he rose to the temporary rank of lieutenant colonel, he served as adjutant of the training camp at Plattsburg, N.Y., and later saw action in France during the St. Mihiel and Meuse-Argonne offensives. He remained in Germany with the army of occupation until Oct. 1920. Promoted to major in 1920, he reached the rank of brigadier general 8 years later when he became commander of the 1st cavalry brigade. In Sept. 1940 he was promoted to major general and sailed for Manila to assume command of the Philippine division. There, on March 11, 1942, when Gen. Douglas MacArthur departed for Australia, Wainwright took over command of all U.S. forces in the Philippines, in a situation that was already hopeless. At Corregidor on May 6 he was forced to surrender to the Japanese. From that time until Aug. 1945 General Wainwright was a prisoner of war in Formosa and Manchuria. Rescued in time to participate in the surrender ceremony aboard the U.S. battleship "Missouri," he returned to the United States in September to be greeted with a hero's welcome and to receive the medal of honour. His book, *General Wainwright's Story* (1946), was edited by R. Considine. Wainwright retired from the army Aug. 31, 1947, and died Sept. 2. 1953.

See Louis Morton, *The Fall of the Philippines, "U.S. Army in World War II Series"* (1953). (L. MN.)

WAITE, MORRISON REMICK (1816–1888), seventh chief justice of the Gnited States, was born in Lyme, Conn.. on Nov. 29, 1816. He graduated from Yale college in 1837 and studied law in the office of his father, Henry M. Waite, a justice of the supreme court of Connecticut. In 1838 he moved to Maumee City, O., where he was subsequently admitted to the bar and began the practice of law. In 1850 he moved to Toledo, where he developed a substantial practice in railroad and other corporate matters. Although he was a Whig and later a Republican, he was not so active in politics as many of his predecessors and successors on the supreme court. Waite first achieved national prominence in 1871 in the "Alabama" arbitration (*q.v.*) at Geneva, Switz., where he served as one of the U.S. counsel with William M. Evarts and Caleb Cushing. He was serving as chairman of the Ohio constitutional convention in Jan. 1874 when Pres. U. S. Grant appointed him to the supreme court. He served as chief justice until his death, which occurred on March 23, 1888.

In general it may be said that the Waite court represented a reaction against the extreme nationalist movement which followed the close of the Civil War, and the significant contribution of his court was the tendency to uphold state powers against claims that the 14th amendment or the commerce clause had invalidated the state action. The extent of the economic and social problems which came before the court in this period is illustrated by the fact that before the beginning of Waite's term only 30 cases involving the commerce clause of the constitution had reached the court (five in the era of the Marshall court), and at the close of Waite's tenure the number had increased to 158. In Waite's term he gave the opinion of the court in more than 1,000 cases.

Waite in many cases held that the privileges and immunities of citizens of the United States mere not increased by the 14th amendment, and that the amendment did not give congress extensive power to protect civil rights (*see* CIVIL LIBERTIES). While Waite represented a movement to uphold the power of the states, statements by him, first in *Munn* v. *Illinois*, 94 U.S. 113 (1877), later in *Stone* v. *Farmer's Loan and Trust Co.*, 116 U.S. 307 (1886), that a state cannot "do that which . . . amounts to taking of private property for public use . . . without due process of law" were used by subsequent supreme courts as the basis of asserted power of the supreme court to invalidate state police power (*q.v.*) regulations of private property. In one of the few cases in which Waite invalidated a state act, *Hall* v. *De Cuir*, 95 U.S. 485 (1878), a Louisiana reconstruction statute which required all carriers to give equal accommodation without discrimination on account of race or colour was involved. This statute was held unconstitutional as a "direct burden" upon interstate commerce and therefore a matter for national regulation. In 1945 this case served to invalidate a Virginia statute requiring interstate carriers to separate races (*Morgan* v. *Virginia*, 328 U.S. 373 [1945]).

Waite's most famous case was *Munn* v. *Illinois*, one of a group of six cases known as the Granger cases, involving legislation growing out of the Populist movement in Illinois and other states, principally in the midwest, to fix maximum rates to be charged by grain elevators and railroads. The suits instituted to test the validity of these laws charged that state laws providing for rate fixing constituted deprivation of private property "without due process of law" under the 14th amendment. Waite borrowed a phrase from Lord Chief Justice Sir Matthew Hale in 17th-century England (Hale, *De Portibus maris*) to hold that when a business or private property was "affected aith a public interest" it was subject to regulation. The chief justice said that where business was subject to regulation, then "for protection against abuses by legislatures, the people must resort to the polls, not to the courts." Without doubt the basic significance of this case was the establishment of the idea, foreign to much of the economic thinking of the time, that private property was subject to legislative regulation. Waite's loose use of the phrase borrowed from Lord Hale was in later cases turned to a contrary purpose so that no regulation was permitted unless the business was in the nature of a public utility. It was not until 1934 (in *Nebbia* v. *New York*, 291 U.S. 502 [1934]—New York milk cases) that the supreme court returned to Waite's own idea of the legislative power — private property could be regulated whenever the court could find that the legislature sought to fulfill a public interest.

Another of Waite's decisions, *Reynolds* v. *United States*, 98 U.S. 145 (1878), which attracted notoriety at the time and was considered with renewed interest in the second half of the 20th century, concerned religious freedom. The question was whether the religious belief of a Mormon must be accepted as a justification for a criminal act (polygamy) because the 1st amendment forbids congress to pass a law which shall prohibit free exercise of religion. Subsequent interest in the case stemmed from its extended discussion of the meaning of the constitutionally protected religious freedom. Waite held that congress could make polygamy by a Mormon a criminal act, for he drew a distinction between freedom to believe, which was protected, and freedom to practise certain acts which were not protected by the constitution against legislative acts.

The 14 years of Waite's chief justiceship are sometimes a forgotten period in constitutional history or are treated as a time in which the chief justice is described as a weak or insignificant leader. Yet Waite and his court established or confirmed many of the accepted principles of U.S. constitutional jurisprudence. Waite also attempted to establish a conception of the office of chief justice which would take it out of politics. He stopped consideration of his name for the presidency because he thought such consideration would detract from the prestige of the court, and he refused for similar reasons to serve on the electoral commission (*q.v.*) in the Hayes-Tilden controversy.

See Bruce Raymond Trimble, *Chief Justice Waite, Defender of the Public Interest (1938)*; Felix Frankfurter, *The Commerce Clause Under Marshall, Taney and Waite* (1937). (A. DM.)

WAITS, the itinerant musicians who paraded the streets at night at Christmas time (A.S. *wacan,* to "wake" or "watch"). The waits of the 14th and 15th centuries were watchmen who sounded horns or even played a tune to mark the hours. The book of household expenses of Edward IV (1478) provides for "a wayte. that nyghtely from Mychelmas to Shreve Thorsdaye pipe the watch within this courte fowere tymes; in the somere nightes three tymes."

Besides "piping the watch" and guarding the palace against thieves and fire, this wait had to attend at the installation of knights of the Bath. London and all the chief boroughs had their corporation waits from the early 16th century. In 1582 Dudley, earl of Leicester, wrote to the corporation of London asking that a servant of his should be admitted to the city waits. The London waits played before the mayor during his annual progress through the streets and at city dinners.

In the 18th and early 19th century the ordinary street watchman serenaded householders at Christmas time, calling round on Boxing day to receive a gratuity for their tunefulness. When in 1829 their place as guardians of the city's safety was taken by police, private individuals kept up the custom.

WAKATSUKI, REIJIRO (1866–1949), Japanese statesman, graduated in law at the Imperial university of Tokyo in 1892, when he also entered the civil service. He was nominated crown member of the house of peers in 1911, and was minister of finance in 1912 and in 1914–15, and also minister of home affairs in 1924–26. He succeeded Viscount Kato as prime minister and leader of the Kensei-kwai party in 1926. He desired to broaden the basis of his cabinet by including members of the Seiyuhonto party, but failed, and was compelled to reconstitute his ministry (June 1926). exclusively with members of the Kensei-kwai party. Later on, he succeeded in obtaining the support of the Seiyuhonto party, thus securing a majority in the chamber. During the autumn of 1926 proceedings against students accused of communism caused considerable unrest. But the real cause of his fall on April 16, 1927, was the failure of the Suzuki firm. Later, the Kensei-kwai and Seiyuhonto united to establish a new party, Minseito, on June 1, 1927. Wakatsuki transferred the leadership to Hamaguchi, co-operating with Tokonami, the leader of Seiyuhonto. A few years later, on April 14, 1931, he again was selected to head a cabinet, but his tenure lasted only a few months, until Dec. 12. He died near Ito, Japan, Nov. 21, 1949.

WAKE, "waking" or watching round a corpse before burial (A.S. *wacan,* to "wake" or "watch"); in the wider sense, a vigil kept to commemorate the dedication of the parish church. This religious wake consisted in an all-night service of prayer and meditation in the church. These services, termed *Vigiliae* by the church, appear to have existed from the earliest days of Anglo-Saxon Christianity. Each parish kept the morrow of its vigil as a holiday. Wakes soon degenerated into fairs; people from neighbouring parishes came to join in the merrymaking, and the revelry and drunkenness became a scandal. In 1445 Henry VI tried to suppress markets and fairs on Sundays and holy days.

Side by side with these church wakes there existed the custom of "waking" a corpse. The custom, as far as England was concerned, seems to have been older than Christianity, and to have been at first essentially Celtic. Doubtless it had a superstitious origin, the fear of evil spirits hurting or even removing the body. The Anglo-Saxons called the custom lich-wake or like-wake (A.S. *lic,* "a corpse"). With the introduction of Christianity the offering of prayer was added to the vigil. As a rule the corpse, with a plate of salt on its breast, was placed under the table, on which was liquor for the watchers. These private wakes soon tended to become drinking orgies. With the Reformation and the consequent disuse of prayers for the dead the custom of waking became obsolete in England, but survived in Ireland.

WAKEFIELD, EDWARD GIBBON (1796–1862), British statesman, prime mover in colonizing New Zealand, was born in London on March 20, 1796. Wakefield was for a short time at Westminster school. He eloped at 20 with Eliza Susan Pattle, the orphan daughter of a merchant in the far east trade. Her relatives became reconciled to the match and procured Wakefield a secretary's appointment in the British legation at Turin. He resigned this post in 1820, upon the death of his wife and then spent some years in Paris. In 1826 he decoyed Ellen Turner, the daughter of a wealthy manufacturer, from school by means of a forged letter and induced her to believe that she could only save her father from ruin by marrying him. She accordingly accompanied him to Gretna Green. where they went through a ceremony of marriage. His wife's relatives pursued them to France and persuaded her to leave him. He was tried with his confederates at Lancaster assizes (March–May 1827), convicted and sentenced to three years' imprisonment in Newgate. The marriage, which had not been consummated, was dissolved by parliament.

Wakefield turned his attention while in prison to colonial affairs and acutely detected the main causes of the slow progress of the Australian colonies in the enormous size of the landed estates and the reckless methods of allocation of land. He proposed the sale of land in small quantities at a sufficient price, and the employment of the proceeds as a fund for promoting immigration. These views were expressed with extraordinary vigour in his *Letter From Sydney* (1829), published while he was still in prison, but composed with such graphic power that it has been continually quoted as if written in Australia. After his release, Wakefield produced a tract on the *Facts Relating to the Punishment of Death in the Metropolis,* with a vivid picture of the condemned felons in Newgate and another on incendiarism in the rural districts, with an equally powerful exhibition of the degraded condition of the agricultural labourer.

He soon, however, became entirely engrossed with colonial affairs and having impressed John Stuart Mill, Col. Robert Torrens and other leading economists with the value of his ideas. became the motive force behind the South Australian company, by which the colony of South Australia was ultimately founded. In 1833 he published anonymously *England and America,* a work primarily intended to develop his own colonial theory outlined in the appendix entitled "The Art of Colonization." The body of the work is fruitful in seminal ideas, though some statements may be rash.

In 1837 the New Zealand association was established, as a result of Wakefield's efforts. Scarcely, however, was this great undertaking fairly begun when he accepted a post on Lord Durham's staff on the latter's appointment as lord high commissioner in Canada (*see* DURHAM, JOHN GEORGE LAMBTON, 1ST EARL OF). The "Public Lands and Emigration" section of the Durham report embodied Wakefield's ideas and he is said to have been the means by which the report mas given prematurely to the public through *The Times,* to prevent its being tampered with by the government. He certainly acted in this spirit a few months later, when in May 1839, understanding that the authorities intended to prevent the dispatch of emigrants to New Zealand, he hurried them off on his own responsibility, thus compelling the government to annex the country just in time to anticipate a similar step on the part of France (*see* NEW ZEALAND: *History*). In 1846 Wakefield. exhausted by work, was struck down by apoplexy and spent more than a year in complete retirement, writing during his gradual recovery his *Art of Colonization.*

The management of the company had meanwhile passed into the hands of others, whose sole object was to settle accounts with the government and wind up the undertaking. Wakefield seceded, and joined Lord Lyttelton and John Robert Godley in establishing the Canterbury settlement as a Church of England colony. A portion of his correspondence on this subject was published by his son as *The Founders of Canterbury* (Christchurch, 1868). In 1854 he appeared in the first New Zealand parliament as extra-official adviser of the acting governor, a position which excited great jealousy, and as the mover of a resolution demanding the appointment of a responsible ministry. In that year Wakefield's health broke down. He spent the rest of his life in retirement, dying at Wellington on May 16. 1862.

Wakefield was a man of large views and lofty aims and in private life displayed the warmth of heart which commonly accompanies these qualities. But he hesitated at nothing necessary to accomplish an object and the conviction of his untrustworthiness gradually alienated his associates and left him politically powerless. Excluded from parliament by the fatal error of his youth, he was compelled to resort to indirect means of working out his plans by influencing public men. But for a tendency to paradox, his intellectual powers were of the highest order.

WAKEFIELD, a city and a municipal, county and parliamentary borough in the West Riding of Yorkshire, Eng. Pop. (1951) 60,371. Area 8.3 sq.mi. Lying on the Calder river at the eastern edge of the Pennines, it became the meeting place of the lowlanders with the people of the dales and thus developed as a market. It is still an agricultural centre and is also a focus of rail and road routes from all parts of Yorkshire and the headquarters of the county council of the West Riding. Textiles and coal account for about hali the local employment, and there are chemical and engineering industries, brewing and a considerable traffic in grain. The Aire and Calder Navigation canal connects it with the Humber ports.

The name (Wacafeld in Domesday) probably denotes the site of the annual festivals or woke plays, and the town became noted for its miracle plays and, more recently, for its music festival. Wakefield was the chief place in a large estate belonging to Edward the Confessor and was still a royal manor in 1086. Shortly afterward it became a baronial liberty, extending into Lancashire and Cheshire. In 1204 the lord of the manor received a grant of a three days' fair at Wakefield, and as early as 1231 the town seems to have had some form of burghal organization. By 1308 it had a wool market; about 1470, foreign cloth weavers, chiefly Flemings, began to settle there; and by 1500 Wakefield was the centre of the district. During the 18th century it became noted for the manufacture of woolen stuffs. In 1342 rights of toll were granted to repair the bridge over the Calder, and a chantry chapel was built alongside it; the chapel was drastically restored in 1847, its ancient façade now being at Kettlethorpe hall; and a modern bridge was built beside the old one in 1933. The town was attacked and taken by Lord Fairfax in 1643 but Sandal castle, south of the river, was not taken until 1644; it was dismantled in 1648.

Down to 1832 Wakefield was under the superintendence of a constable appointed by the steward of the lord of the manor, but in that year the town was enfranchised and now the borough returns one member. In 1848 a charter of incorporation was granted; in 1888 the town was created a city; and in 1915 it became a county borough.

In 1888 the bishopric of Wakefield was formed, almost entirely from that of Ripon. The diocese includes about one-seventh of the parishes of Yorkshire and covers a small portion of Lancashire. The cathedral is the ancient parish church of All Saints, rebuilt in 1329, whose crocketed spire (247 ft.) is the highest in Yorkshire. The Queen Elizabeth Grammar school was founded in 1591, and among its scholars was John Radcliffe (1650–1714), iounder of the Radcliffe observatory and library at Oxford. George Gissing was also a native of Wakefield. The city has a museum and an art gallery.

The battle of Wakefield (1460) was fought near Sandal castle, a monument marking the spot where Richard Plantagenet fell.

WAKEFIELD ESTATE, Westmoreland county, Va., the site of George Washington's birthplace, was purchased by his father in 1718. The original house, situated between Bridges creek and Popes creek, where George Washington spent the first three or four years of his childhood, was accidentally burned during the Revolutionary War, and no description of it has survived. The memorial mansion, built in 1931 by the Wakefield National Memorial association, therefore represents a Virginia plantation house of the 18th century but is not a restoration. The estate and the memorial mansion were donated to the United States in 1931 and became the George Washington Birthplace National monument. (E. M. RY.)

WAKE ISLAND, an atoll in the central Pacific ocean 2,302 mi. W. of Honolulu and 1,987 mi. S.E. of Tokyo. It consists of three low lying (altitude 21 ft.) islets, Wilkes, Peale and Wake ($2\frac{1}{2}$ sq.mi. in all), lying in a horseshoe shape on the reef, separated by narrow, shallow channels and enclosing a lagoon 44 mi. long and 2 mi. wide. It was probably seen by the Spanish explorer Mendaña in 1568 and was visited by the British Capt. William Wake in 1796; its position (latitude 19° 16' N., longitude 166° 39' E.) was fixed by the U.S. exploring expedition under Lieut. Charles Wilkes in 1841. It was formally claimed by the U.S. in 1899 to be used as a cable station and was placed under naval jurisdiction in 1934. In 1935 a commercial airline established a seaplane base and hotel there for overnight stops on transpacific flights to Guam and the Philippines.

In 1941, recognizing the strategic location of Wake, the U.S. navy began the construction of an air and submarine base which was about half completed at the time of the Pearl Harbor attack. At this time the atoll was commanded by Comdr. W. S. Cunningham, U.S.N.; the marine defense force of about 447 men was under Maj. James P. S. Devereux and there were about 1,100 civilian workers on the atoll. The Japanese first attacked Wake with 36 bombers at noon on Dec. 8, 1941 (Wake time), a few hours after the Pearl Harbor assault. A Japanese naval task force, including cruisers, destroyers and transports, appeared on Dec. 11, but was repulsed with considerable loss by the coast defense guns and aircraft, Thereafter, however, the Japanese had the atoll under almost continuous air attack, and a U.S. relief force failed to reach the area before the Japanese returned on Dec. 23 with a much more powerful force. In the predawn hours they succeeded in putting about 1,000 troops ashore and after five hours of fierce resistance the island commander surrendered when the situation had become manifestly hopeless. Altogether 1,616 Americans were captured and most of them were evacuated to China and Japan. The Japanese fortified the atoll heavily, but repeated attacks by U.S. aircraft during the remainder of the war devastated it completely. The Japanese garrison surrendered on Sept. 4, 1945, and the U.S. immediately constructed a naval air base there for the use of planes en route from Hawaii to Japan. Commercial planes began to use the atoll again on Nov. 25, 1945. Wake was the scene on Oct. 15, 1950 (Wake time), of an important conference between Pres. Harry S. Truman and Gen. Douglas MacArthur (*q.v.*) regarding the situation in Japan, Korea and the far east generally. Placed under the control of the Civil Aeronautics administration, Wake continued to serve as a stopping point for military and commercial planes flying the North Pacific. (J. H. K.)

WAKE-ROBIN, a name given to various wild flowers of the genus *Trillium* of North America and Asia, and also applied to the cuckoopint of Europe and north Africa. *See* CUCKOOPINT; TRILLIUM.

WAKSMAN, SELMAN ABRAHAM (1888–), U.S. microbiologist and biochemist; won the Nobel prize in physiology and medicine in 1952 for the discovery of streptomycin (*q.v.*). One of the world's foremost authorities on soil microbiology and on antibiotics derived from microorganisms of the soil; his most important contributions were in the characterization and classification of the *Actinomyces,* which include many antibiotic-producing organisms. Waksman and his pupils and co-workers discovered and described many new species and also characterized the antibiotics which they produce. Outstanding among them were streptomycin. first described in 1944, the first important specific agent effective in the treatment of human tuberculosis, and neomycin, reported in 1949, extensively used in treating numerous infectious diseases of man, animals and plants.

Waksman was born July 22, 1888, in Priluka, Russia. He emigrated to the United States in 1910 and became a naturalized citizen in 1916. He received his B.S. and M.S. degrees in agriculture at Rutgers university and his Ph.D. in biochemistry at the University of California. With only brief interludes, his teaching and research were all at Rutgers. There he became professor of soil microbiology in 1930, professor and head of a newly organized department of microbiology in 1940 and director of its institute of microbiology, which he established in 1949. He also organized a division of marine microbiology at Woods Hole Oceanographic institute and served as consultant and adviser to many governmental institutions and commercial organizations. In addition to scientific papers and books: he wrote an autobiography My *Life with the Microbes* (1954). (M. FD.)

WALACHIA or **WALLACHIA,** a former principality of southeastern Europe, constituting after its union with Moldavia on Nov. 9, 1859, a part of Rumania (*q.v.*).

WALAFRID STRABO (or Strabus, *i.e.*, "squint-eyed") (d. 849). German monk and theological writer, was born about 808 in Swabia. He was educated at the monastery of Reichenau, near Constance, where he had for his teachers Tatto and Wettin. Then he went on to Fulda, where he studied under Hrabanus Maurus before returning to Reichenau, of which monastery he was made abbot in 838. There is a story—based, however, on no good evidence—that Walafrid devoted himself so closely to letters as to neglect the duties of his office, and so was expelled from his house; but, from his own verses, it seems that the real cause of his flight to Spires was that he espoused the side of Lothair I (*q.v.*) on the death of Louis the Pious in 840. He was, however, restored to his monastery in 842, and died on Aug. 18, 849, on an embassy to his former pupil, Charles the Bald.

Works.—Of his theological works the most famous is the exegetical compilation which, under the name of *Glosa ordinariu* or the *Glosa,* remained for about 500 years the most widespread and important quarry of medieval biblical science, and even survived the Reformation, passing into numerous editions as late as the 17th century. The oldest known copy, in four folio volumes, is almost entirely Walafrid's work and gives us his method. In the middle of the pages is the Latin text of the Bible; in the margins are the "glosses," consisting of a very full collection of patristic excerpts in illustration and explanation of the text. An *Expositio quutuor Evangeliorum* is also ascribed to Walafrid.

Of interest also is his *De exordiis et incrementis rerum ecclesiasticarum* written between 840 and 842. It deals with ecclesiastical usages, churches, altars, prayers, bells, pictures, baptism and the Holy Communion. Walafrid shows no trace of belief in transubstantiation as taught by his famous contemporary Radbertus.

Walafrid's chief historical works are the rhymed *Vita sancti Galli* and a much shorter life of St. Othmar, abbot of St. Gall (d. 759). A critical edition of them by E. Dummler is in the *Monzimenta Germaniae hist. Poetae Latini*, ii, p. 259 ff. (1884). Walafrid's poetical works also include a short life of St. Blaithmaic, a high-born monk of Iona, murdered by the Danes in the first half of the 9th century; a life of St. Mammas; and a *Liber de visionibus Wettini*.

Many of Walafrid's other poems are, or include, short addresses to kings and queens (Lothair, Charles, Louis, Pippin, Judith, etc.) and to friends.

His most famous poem is the *Hortulus,* dedicated to Grimald. It is an account of a little garden that he used to tend with his own hands, and is largely made up of descriptions of the various herbs he grew there and their medicinal and other uses.

WALCOTT, CHARLES DOOLITTLE (1850–1927), U.S. paleontologist and geologist, noted principally for work on the Cambrian faunas of North America. He was born in New York Mills, N.Y., March 31 and became interested in fossils as a boy. After selling a collection to Harvard university he became assistant (1876) to James Hall, state geologist of New York. He studied the geology and paleontology of New York, eastern Canada, Ohio and Indiana. In 1879 he became assistant geologist on the newly organized U.S. geological survey. In 1883 he was appointed paleontologist of the U.S. survey and honorary curator of the National museum. His interest in Cambrian paleontology carried him to all parts of the west, all of the Appalachian states, eastern and western Canada and Wales. These studies and his search for Pre-Cambrian fossils continued throughout the remainder of his life in spite of continuous administrative duties.

Walcott published about 300 scientific papers and books. The most notable are on the appendages of trilobites, paleontology of the Eureka (Nev.) district, Cambrian faunas of North America, fauna of the Olenellus zone, Cambrian correlations, fossil medusae, Cambrian brachiopods, Cambrian geology and paleontology (5 vol.) and Cambrian faunas of China. Although Walcott never attended college he received 12 honorary degrees, four from European universities, and many other honours. He died in Washington, D.C., Feb. 9, 1927. (J. M. WR.)

WALD, LILLIAN D. (1867–1940), **U.S.** sociologist, nurse and social worker, who originated municipal school nursing, was born in Cincinnati, O., on March 10, 1867. She graduated (1891) from the New York hospital training school for nurses. In 1893 she founded the internationally known Henry Street settlement for social services and later expanded it into a nurses' training centre. She began the work of the school nurse in New York city in 1902 and planned the district nursing service of the American Red Cross. Vitally interested in the promotion of child welfare, Miss A'ald was active in promoting the establishment of the federal children's bureau in 1912. She served the cause of public welfare on several national and international commissions and conferences, notably in the 1919 series at Cannes, Zürich and Washington; was chairman of the American Union Against Militarism; one of the organizers of the National Women's Trade Union league; and represented the public from 1910 on the joint board of sanitary control of certain trades. Her books include *The House on Henry Street* (1915) and *Windows on Henry Street* (1934). She died on Sept. 1, 1940, in Westport, Conn.

WALDECK, a *kreis* and former state of Germany, between Westphalia and Hesse-Nassau. Once a principality and from Nov. 1918 to March 1929 a republic and constituent state of the Weimar republic, it was, on April 1, 1929, amalgamated with Prussia at the request of its people. It has an area of 420 sq.mi., covered with hills, which culminate in the Hegekopf (2,766 ft.). The centre is the plateau of Corbach. The chief rivers are the Eder and the Diemel, flowing into the Weser. Pop. (1950) 91,925.

Oats is the principal crop, but rye, potatoes and flax are also grown, and fruit cultivated. There are mines, slate and stone quarries. Manufactures are retarded by isolation from railways. The old capital was Arolsen (pop. 5,759 in 1950).

WALDECK-ROUSSEAU, PIERRE MARIE RENÉ (1846–1904), French statesman, remembered for his legalization of trade unions, for his pacification of the Dreyfus affair and for his Associations law, was born at Nantes on Dec. 2, 1846. Having studied law at Poitiers and in Paris, he practised as a barrister at Saint-Nazaire from 1870 and at Rennes from 1873 to 1879, when he was elected to represent Rennes in the chamber of deputies. A supporter of Léon Gambetta, he first distinguished himself with a report to the committee on the reform of the judiciary (1880). Re-elected deputy in 1881, he was minister of the interior in Gambetta's cabinet (Nov. 1881–Jan. 1882) and again in Jules Ferry's (Feb. 1883–March 1885). To these years belong his circular to the prefects warning them against appointing the nominees of deputies instead of those of the government to offices in the *de'partements* (1881); and the celebrated *loi Waldeck-Rousseau* of 1884, which legalized the formation of trade unions (with certain restrictions).

From 1885 to 1889 Waldeck-Rousseau sat as deputy for Ille-et-Vilaine. He did not stand for re-election to the chamber in 1889 or in 1893, but continued practising as a barrister in Paris (where he was enrolled as one in 1886); and in 1893 he defended Gustave Eiffel in the trial at the climax of the Panama scandal. In 1894, however, he became senator for the *département* of Loire. He stood as candidate for the presidency of the republic in 1895, but withdrew in order to allow Félix Faure an absolute majority.

On the fall of Charles Dupuy's ministry in June 1899, during the agitation about the proposed retrial of Alfred Dreyfus (*see* FRANCE: History), Waldeck-Rousseau was invited to form a cabinet. He assembled a coalition of "republican defense," another "union of the left," comprising at one extreme Gen. G. A. A. de Gallifet and at the other Alexandre Millerand, the first Socialist to hold office under the third republic (this appointment was the occasion of a split in the French Socialist party). When Dreyfus was again found guilty at his retrial, the government promptly advised Pres. Émile Loubet to grant him a pardon. To restore the rule of law and to put an end to the disorders provoked by the "nationalist" factions ("plebiscitary republicans" and monarchists), Waldeck-Rousseau had recourse to procedure under the law of 1875, whereby the senate could be transformed into a high court to try cases of treason: the result was the condemnation of Paul Déroulède (*q.v.*) and his supporters in Jan, 1900. Waldeck-Rousseau could thereafter maintain order without displays of force, relying on the senate and manipulating the groups in the chamber of deputies. The amnesty of Dec. 1900, against further prosecutions in the Dreyfus affair, was chiefly the result of his advocacy.

The most important measure of the later period of Waldeck-Rousseau's administration was the Associations law of July 1, 1901. This on the one hand abolished all restrictions on the right of association for licit purposes but on the other withheld this freedom from religious congregations, for which specific authorization by statute was required. In the debating preceding enactment Waldeck-Rousseau avoided extreme anticlericalism; and in 1903 he emerged from retirement to protest against the interpretation that Emile Combes was putting on the law in refusing on principle to authorize any religious associations.

The elections of April–May 1902 returned a majority favourable to the government; and surprise was felt when Waldeck-Rousseau resigned on June 3, 1902. He died on Aug. 10, 1904.

WALDEN, PAUL (1863–1957), Russian chemist who won international fame by his discovery in 1897–99 of the phenomenon known as the "Walden inversion," was born at Rosenbeck castle near Riga in the district of Livonia, on July 26 (new style; July 14, old style), 1863. He studied at the universities of Riga, Leipzig and Munich, and was successively professor of chemistry at Riga, St. Petersburg, Moscow, Rostock and, after Rostock was burned in 1942, guest professor at Tiibingen. In 1912 he was delegate to the International Congress of Applied Chemistry, New York, and in 1927–28 visiting professor at Cornell university, Ithaca, N.Y.

The Walden inversion is a chemical reaction in which a reversal of the rotatory power of an optically active compound takes place. It indicates that the mechanism of substitution does not involve the simple replacement of one group by another, but probably the loosening of all groups and atoms followed by a rearrangement. Walden's later researches were concerned mainly with the electrical properties of solutions, but his publications covered a wide range. As a noted historian of chemistry, his best-known work is *Geschichte der Chemie* (1947; 2nd ed., 1950). He died in the village of Gammertingen near Sigmaringen, Ger., Jan. 24, 1957. His "Notes From the Life of a Chemist" was translated into English by R. E. Oesper, *J. Chem. Educ.*, 28:160 (1951). (W. J. BP.)

WALDENBURG (Polish WALBRZYCH), a town in Wroclaw, Poland, in former German Silesia. Waldenburg, which became a town in 1426, lies in the centre of the productive coal district of the Waldenburger Gebirge, a branch of the Sudetic chain. Among other industrial establishments are machine, brick, wire, furniture, porcelain and earthenware factories and a china-painting establishment; there are also numerous flax-spinneries and linen factories in the neighbourhood. It was incorporated into Poland in 1945. Pop. (1960) 117,100.

WALDENSES. The Waldensian valleys lie to the southwest of Turin, in the direction of Monte Viso, being fertile and well wooded. The principal town near the valleys is Pinerolo (Pignerol). Just to its southwest there opens the chief Waldensian valley, the Val Pellice, watered by the stream of that name with the capital, Torre Pellice.

SECTS OF THE MIDDLE AGES

The name Waldenses was given to the members of an heretical Christian sect which arose in the south of France about 1170. The history of the sects of the middle ages is obscure, because the earliest accounts of them come from those who were concerned in their suppression. Later apologists of each sect reversed the process. In early times these sectaries produced little literature of their own; when they produced a literature at the beginning of the 1jth century they attempted to claim for it a much earlier origin. Hence there is confusion on every side. The polemical conception which has done much to perpetuate this confusion is that of the historical continuity of Protestantism from the earliest times. According to this view the church was pure and uncorrupt till the time of Constantine, when Pope Sylvester gained the first temporal possession for the papacy, and so began the system of a rich, powerful and worldly church, with Rome for its capital. Against this secularized church a body of witnesses silently protested; they were always persecuted but always survived, till in the 13th century a desperate attempt was made by Innocent III. to root them out from their stronghold in southern France. Persecution gave new vitality to their doctrines, which passed on to Wycliffe and Huss, and through these leaders produced the Reformation in Germany and England.

But, so far as can now be discovered the heretical sects of the middle ages rested upon a system resembling Manichaeism which was imported into Europe from the East. (*See* MANICHAEISM.) The Manichaean system of dualism, with its severe asceticism, and its individualism, which early passed into antinomianism, was attractive to many minds in the awakening of the 11th century. Its presence in Europe can be traced in Bulgaria soon after its conversion in 862, where the struggle between the Eastern and Western churches for the new converts opened a way for the more hardy speculations of a system which had never entirely disappeared, and found a home amongst the Paulicians (*q.v.*) in Armenia. The name of Cathari (*q.v.*), taken by the adherents of this new teaching, sufficiently shows the Oriental origin of their opinions, which spread from Bulgaria amongst the Slavs, and followed the routes of commerce into central Europe. The earliest record of their presence there is the condemnation of ten canons of Orleans as Manichees in 1022, and soon after this we find complaints of the prevalence of heresy in northern Italy and in Germany. The strongholds of these heretical opinions were the great towns, the centres of civilization, because there the growing sentiment of municipal independence, and the rise of a burgher class through commerce, created a spirit of criticism directed against the worldly lives of the clergy.

The system of Catharism recognized two classes of adherents, *credentes* and *perfecti*. The *perfecti* only were admitted to its esoteric doctrines and to its superstitious practices. To the ordinary men it seemed to be a reforming agency, insisting on a high moral standard, and upholding the words of Scripture against the traditions of an overgrown and worldly church. It may be said generally that Catharism formed the abiding background of mediaeval heresy. Prevailing discontent, in conflict with authority generally ended by borrowing something from Catharism. The result was that in the beginning of the 13th century there was a tendency to class all bodies of heretics together.

WALDENSIAN SECT

Most of these sects were stamped out before the period of the middle ages came to a close. The Waldenses, under their more modern name of the Vaudois, survived into the 19th century in the valleys of Piedmont, and have been regarded as at once the most ancient and the most evangelical of the mediaeval sects. It is, however, by no means easy to determine their original tenets, as in the 13th and 14th centuries they were a body of obscure and unlettered peasants, hiding themselves in a comer, while in the 16th century they were merged in the Reformation.

Already in the 9th century there were many protests against the rigidity and want of spirituality of a purely sacerdotal church. Thus Berengar of Tours (999–1088) upheld the symbolic character of the Eucharist and the superiority of the Bible over tradition. The Paterines in Milan (1045) raised a protest against simony and other abuses of the clergy, and Pope Gregory VII. did not hesitate to enlist their Puritanism on the side of the papacy and make them his allies in imposing clerical celibacy. In France, at Embrun, Peter de Bruys founded a sect known as Petrobrusians, who denied infant baptism, the need of consecrated churches, transubstantiation, and masses for the dead. A follower of his, a monk, Henry, gave the name to another body known as Henricians, who centred in Tours. The teachers of these new opinions were men of high character and holy lives, who in spite of persecution wandered from place to place, and made many converts from those who were dissatisfied at the want of clerical discipline which followed upon the struggle for temporal supremacy into which the reforming projects of Gregory VII. had carried the church.

It was at this time (1170) that a rich merchant of Lyons, Peter Waldo, sold his goods and gave them to the poor; then he went forth as a preacher of voluntary poverty. His followers, the Waldenses, or poor men of Lyons, were moved by a religious feeling which could find no satisfaction within the actual system of the church, as they saw it before them. Like St. Francis, Waldo adopted a life of poverty that he might be free to preach. He had a translation of the New Testament made into Provencal, and his preachers explained the Scriptures. Pope Alexander III., who had approved of the poverty of the Waldensians, prohibited them from preaching without the permission of the bishops (1179). Waldo answered that he must obey God rather than man. He was excommunicated by Lucius III. in 1184.

DIVISIONS OF WALDENSIAN BELIEF

The earliest definite account given of Waldensian beliefs is that of the inquisitor Sacconi about 1250. (D'Argentré, *Collectio judiciorum de novis erroribus,* i. 50, etc.) He divides them into two classes; those north of the Alps and those of Lombardy. The first class hold (1) that oaths are forbidden by the gospel, (2) that capital punishment is not allowed to the civil power, (3) that any layman may consecrate the sacrament of the altar, and (4) that the Roman Church is not the Church of Christ. The Lombard sect went farther in (3) and (4), holding that no one in mortal sin could consecrate the sacrament, and that the Roman Church was the scarlet woman of the Apocalypse, whose precepts ought not to be obeyed, especially those appointing fast-days. This account sufficiently shows the difference of the Waldenses from the Cathari: they were opposed to asceticism and had no official priesthood; at the same time their objection to oaths and to capital punishment are closely related to the principles of the Cathari.

These opinions were subversive of the system of the mediaeval church, and were viewed with disfavour by its officials. The earliest known document proceeding from the Waldensians is an account of a conference held at Bergamo in 1218 between the ultramontane and the Lombard divisions, in which the Lombards showed a greater opposition to the recognized priesthood than did their northern brethren. (Preger, *Beiträge zur Geschichte der Waldensier*)

ATTEMPTS AT SUPPRESSION

The spread of these heretical sects led to resolute attempts at their suppression. The crusade against the Albigensians could destroy prosperous cities and hand over lands from a heedless lord to one who was obedient to the church; but it could not get rid of heresy. The revival of preaching, which was the work of the order of St. Dominic, did more to combat heresy, especially where its persuasions were enforced by law. The work of inquisition into cases of heresy proceeded slowly in the hands of the bishops, who were too busy with other matters to find much time for sitting in judgment on theological points about which they were imperfectly informed. The greatest blow struck against heresy was the transference of the duty of inquiry into heresy from the bishops to Dominican inquisitors. The secular power, which shared in the proceeds of the confiscation of those who were found guilty of heresy, was ready to help in carrying out the judgments of the spiritual courts. Everywhere, and especially in the district round Toulouse, heretics were keenly prosecuted, and before the continued zeal of persecution the Waldenses slowly disappeared from the chief centres of population and took refuge in the retired valleys of the Alps. There, in the recesses of Piedmont, where the streams of the Pellice, the Angrogne, the Clusone and others cleave the sides of the Alps into valleys which converge at Susa, a settlement of the Waldensians was made who gave their name to these valleys of the Vaudois. In the more accessible regions north and south heresy was exposed to a steady process of persecution, and tended to assume shifting forms. Among the valleys it was less easily reached, and retained its old organization and its old contents. Little settlements of heretics dispersed throughout Italy and Provence looked to the valleys as a place of refuge, and tacitly regarded them as the centre of their faith. At times attempts were made to suppress the sect of the Vaudois, but the nature of the country which they inhabited, their obscurity and their isolation made the difficulties of their suppression greater than the advantages to be gained from it. However, in 1487 Innocent VIII. issued a bull for their extermination, and Alberto de' Capitanei, archdeacon of Cremona, put himself at the head of a crusade against them. Attacked in Dauphine and Piedmont at the same time, the Vaudois were hard pressed; but luckily their enemies were encircled by a fog when marching upon their chief refuge in the valley of the Angrogne, and were repulsed with great loss. After this Charles II., duke of Piedmont, interfered to save his territories from further confusion, and promised the Vaudois peace. They were, however, sorely reduced by the onslaught. Scattered bodies of Waldenses in Germany influenced, and afterwards joined, the Hussites and the Bohemian Brethren.

The last step in the development of the Waldensian body was taken in 1530, when two deputies of the Vaudois in Dauphin6 and Provence, Georges Morel and Pierre Masson, were sent to confer with the German and Swiss Reformers. A letter addressed to Oecolampadius gives an account of their practices and beliefs at that time, and shows us a simple and unlettered community, which was the survival of an attempt to form an esoteric religious society within the mediaeval church. It would appear that its members received the sacraments of baptism and the holy communion from the regular priesthood, at all events sometimes, but maintained a discipline of their own and held services for their own edification, largely dependent on the work of itinerant preachers. After giving an account of themselves they asked for information about several points in a way which showed the exigencies of a rude and isolated society, and finally they said that they had been much disturbed by the Lutheran teaching about freewill and predestination, for they had held that men did good works through natural virtue stimulated by God's grace, and they thought of predestination in no other way than as a part of God's foreknowledge. Oecolampadius gave them further instruction, especially emphasizing the wrongfulness of their outward submission to the ordinances of the church: "God," he said, "is a jealous God, and does not permit His elect to put themselves under the yoke of Antichrist." The result of this intercourse was an alliance between the Vaudois and the Swiss and German Reformers. A synod was held in 1532 at Chanforans in the valley of the Angrogne, where a new confession of faith was adopted, which recognized the doctrine of election, assimilated the practices of the Vaudois to those of the Swiss congregations, renounced for the future all recognition of the Roman communion, and established their own worship no longer as secret meetings of a faithful few but as public assemblies for the glory of God.

THE VAUDOIS AND PROTESTANTISM

Thus the Vaudois ceased to be relics of the past, and became absorbed in the general movement of Protestantism. This was not, however, a source of quiet or security. In France and Italy alike they were marked out as special objects of persecution, and the Vaudois church has many records of martyrdom. The most severe trial to which the Vaudois of Piedmont were subjected occurred in 1655. The Congregation de Propaganda *Fide* established, in 1650, a local council in Turin, which exercised a powerful influence on Duke Charles Emmanuel II., who ordered that the Vaudois should be reduced within the limits of their ancient territory. Fanaticism took advantage of this order; and an army. composed partly of French troops of Louis XIV., partly of Irish soldiers who had fled before Cromwell, entered the Vaudois valleys and spread destruction on every side. They treated the people with horrible barbarity, so that the conscience of Europe was aroused, and England under Cromwell called on the Protestant powers to join in remonstrance to the duke of Savoy and the French king. The pen of Milton was employed for this purpose, and his famous sonnet is but the condensation of his state papers. Sir Samuel Morland was sent on a special mission to Turin, and to him were confided by the Vaudois leaders copies of their religious books, which he brought back to England, and ultimately gave to the university library at Cambridge. Large sums of money were contributed in England and elsewhere, and were sent to the suffering Vaudois.

By this demonstration of opinion peace was made for a time between the Vaudois and their Persecutors; but it was a treacherous peace, and left the Vaudois with a hostile garrison established among them. Their worship was prohibited, and their chief pastor, Leger, was obliged to flee, and in his exile at Leyden wrote his *Histoire générale* des *églises vaudoises* (1684). The revocation of the edict of Nantes in 1685 began a new period of persecution, which aimed at entire extermination. This was found so difficult that the remnant of the Vaudois, to the number of 2,600, were at last allowed to withdraw to Geneva. But the love of their native valleys was strong among the exiles, and in 1689 one of their pastors, Henri Arnaud, led a band of 800 men to the reconquest of their country. His first attempts against the French were successful; and the rupture between Victor Amadeus, duke of Savoy, and Louis XIV. brought a sudden change of fortune to the Vaudois. They were recognized once more as citizens of Savoy, and in the war against France which broke out in 1696 the Vaudois regiment did good service for its duke. The peace of Utrecht saw the greater part of the French territory occupied by the Vaudois annexed to Savoy, and, though there were frequent threatenings of persecution, the idea of toleration slowly prevailed in the policy of the house of Savoy. The Vaudois, who had undergone all these vicissitudes, were naturally reduced to poverty, and their ministers were partially maintained by a subsidy from England, which was granted by Queen Anne. The 18th century, however, was a time of religious decadence even among the Alpine valleys, and the outbreak of the French revolution saw the Vaudois made subjects of France. This led to a loss of the English subsidy, and they applied to Napoleon for an equivalent. It was granted, and their church was organized by the state. On the restoration of the house of Savoy in 1816 English influence was used on behalf of the Vaudois, who received a limited toleration. From that time onwards the Vaudois became the objects of much interest in Protestant countries. Large sums of money were collected to build hospitals and churches among their valleys, and they were looked upon as the possible centre of a Protestant church in Italy. Especially from England did they receive sympathy and help. An English clergyman, Dr. Gilly, visited the valleys in 1823, and by his writings on the Vaudois church attracted considerable attention, so that he was enabled to build a college at La Torre. Moreover, Dr. Gilly's book *(A* Visit to the Valleys of Piedmont), chancing to fall into the hands of an officer who had lost his leg at Waterloo, Colonel Beckwith, suggested an object for the energies of one who was loth at the age of twenty-six to sink into enforced idleness. Beckwith visited the valleys, and was painfully struck by the squalor and ignorance of a people who had so glorious a past. He settled among them, and for thirty-five years devoted himself to promoting their welfare. During this period he established no fewer than 120 schools; moreover he brought back the Italian language which had been displaced by the French in the services of the Vaudois church, and in 1849 built a church for them in Turin. He lived in La Torre till his death in 1862, and the name of the English benefactor is still revered by the simple folk of the valleys

BIBLIOGRAPHY.—Modern critical study starts with J. J. Dollinger, *Beiträge zur Secktengeschichte des Mittelalters* (1890) and E. Combo, *Histoire des Vaudois (1898). See* also *H.* Lea, *History of the Inquisition in the Middle Ages;* J. Chevalier, *Mémoires sur les Hérésies en Dauphiné* (1890).

WALDERSEE, ALFRED, COUNT (1832–1904), Prussian field marshal, first campaigned in 1866 as aide-de-camp to General of Artillery Prince Charles of Prussia, being present at Königgrätz. In the Franco-German War he was at Metz and joined the staff of the grand duke of Mecklenburg-Schwerin against Chanzy's army on the Loir. In 1881 Waldersee became Moltke's principal assistant at Berlin He succeeded Moltke as chief of the general staff in 1888; during the Boxer insurrection in China in 1900 he commanded the joint forces, but arrived too late for the fighting before Peking. He died on March 5, 1904.

WALDO, SAMUEL LOVETT (1783–1861), U.S. painter, who was extremely prolific in his production of competent but unexceptional portraits, was born in Windham, Conn., April 6, 1783. After working in Hartford, Conn., and Charleston, S C., he went in 1806 to London. In 1809 he returned to New York and was a conspicuous figure in the city's art life until his death there on Feb. 16, 1861. He became an associate of the National Academy of Design in 1847.

Among Waldo's many works, which are exhibited in a number of U S. galleries, are a series of portraits of the early mayors of New York, now in the New York city hall; a portrait of Peter Remsen. in possession of the New York Historical society; and a portrait of Andrew Jackson and a self-portrait, in the Metropolitan Museum of Art.

In 1820 Waldo began a collaboration with his student William Jewett (1792–1874). For nearly 40 years they jointly produced and signed a vast number of portraits.

WALDSTEIN, FERDINAND, COUNT (1762–1823), youngest son of Graf Waldstein und Wartemburg von Lux, was born on March 24, 1762. At Bonn, Beethoven received encouragement from Waldstein, to whom he dedicated his opus 53, known as the "Waldstein" sonata. A theme of Count Waldstein's also served for a set of 12 variations for piano duet, written by Beethoven in 1791 or 1792. Waldstein died on Aug. 29, 1823.

WALENSEE, also called the Lake of WALLENSTADT, a Swiss lake. It is formed by the Seez river, which now enters the lake at its eastern end. Near its western end the Linth has been diverted through the Escher canal (completed in 1811) into the lake, from which it soon again issues in order, by means of the Linth canal (completed in 1816), to flow into Lake Zürich. The Walensee has an area of 9.3 sq.mi. It is 492 ft. deep, and its surface is 1,375 ft. above sea level. On the northern shore rises the seven-peaked range of the Churfirsten (7,566 ft.). On the south side are the crags of Mürtschenstock (8,008 ft).

WALES. The principality of Wales (Cymru, Gwalia, Cambria) in Great Britain has an area of 7,476 sq.mi. and had in 1961 a population of 2,196,943.

Its maximum length from north to south is 136 mi., while its breadth varies between 92 mi from St. David's head to the English border near Crickhowell and 37 mi. in central Wales between Aberystwyth and the Shropshire boundary.

Structure and Physical **Features.**—Wales is a hill country composed almost entirely of Palaeozoic rocks much dissected by deep valleys. The highland mass culminates in the Snowdon massif in the northwest, where Snowdon itself (3,561 ft.) is the highest mountain in England and Wales. Carnedd Dafydd (3,427 ft.) and Carnedd Llewelyn (3,485 ft.) are also specially marked. The whole of this country is mountainous, with bare slopes deeply worn by ice action above 2.000 it. The mountain line tapers out southwestward to the peninsula of Lleyn which has some spectacular peaks of crystalline rock and ends in the Isle of Bardsey (Ynys Enlli)—the isle of the saints. The Snowdon country is interspersed with lakes. Those in the valley bottoms—long and deep—show evidence of glacial as well as of structural origin. They contrast markedly with the rounder, darker lakes in the mountain cirques. To the northwest of the Snowdon country is the island of Anglesey (Ynys Mon), a remnant of a very ancient land mass.

It is now a worn-down peneplain showing in its drainage pattern a well-marked Caledonian trend. Some of the northeast to southwest valleys have been drowned in recent geological times to form the picturesque Menai strait separating the island from the mainland. To the south and east of the Snowdon massif the country is still highland approximately at about 2,000 ft., but it is less mountainous in character in the Harlech dome, the Arenig moorlands, the Berwyn mountains and the Wiraethog moorlands. Sometimes, however, as in southern Merioneth, peaks like Cader Idris (2,927 ft.) represent once more true mountain scenery.

Still farther to the eastward and southward there stretches a vast plateau of crumpled grits and shales in an endless succession of rounded hills from Denbighshire around to north Pembrokeshire. Plynlymon (2,468 ft.) is among the higher points of this central moorland. The region is covered to a great extent by boulder clay, giving a cold, wet subsoil with many bogs and consequently able to support only a small population.

This crescentic plateau of pre-Carboniferous rocks is followed to the southeastward by the country of the Old Red Sandstone and the coal measures. This region is more varied in relief with outstanding hills of sandstone like Radnor forest (2,163 ft.) or the steep scarp of the Brecknock (Brecon) Beacons (2,907 ft.), the Black mountains or the volcanic rocks of the Breidden. The coal-measure country has become very distinct from the rest of Wales in many respects, whether we consider the belt on the English border in Flint and Denbigh or the great coal field of south Wales. The latter is oval in form, becoming narrower at its western end in Pembrokeshire. Geologically it is a syncline within which the hard bands of Pennant grit stand out above the deeply incised valleyways. Numerous streams flow across the southern coal field in long, narrow steep-sided valleys that limit possibilities of settlement and communication. Many of the resulting problems, both industrial and social, have been very difficult. *(See* RHONDDA.) To the south of the coal field is the lower plateau country known as the vale of Glamorgan. This has Triassic and Liassic rocks with much fertile soil.

The south coastal plain of Wales is broken by the sea, giving Carmarthen and Swansea bays. The north Wales coast line is low westward from the Dee estuary, but Great Ormes head, a peninsula of Carboniferous limestone, stands out, as does the igneous rock of Penmaenmawr farther west. The coasts of Lleyn are rocky as many of the mountain lines die away to the sea. In Cardigan bay especially, former low ridges between the valleys run out to sea as partly submerged causeways. They are known locally as *sarnau.*

Southwest Wales sends out hard, resistant bands of old rock to form numerous headlands, the softer rock between being worn away to form small bays in the coast of north Pembrokeshire. In south Pembrokeshire is a coast with the great submerged valley or ria of hlilford Haven. There are evidences of subsidence along the south Wales coast in the west; submerged forests are uncovered at Amroth.

The rivers of Wales may be said to fan out to sea from the interior highland mass. In the north are the Clwyd and the Conway; on the west the Dwyryd, Mawddach, Dovey (Dyfi), Rheidol, Ystwyth and Teifi; and on the south the eastern and western Cleddau, the Taf, Towy, Loughor, Nedd (Neath), Taff and Wysg (Usk). It is these radiating valleys, or, rather, those of them which are most shut off from English influences working from the eastward along the coastal plains, that are the special homes of the Welsh heritage. The interior highland mass is drained also by rivers which fall to the lowlands of the English border—the Dee, Severn and Wye—and these valleys have offered opportunities for contacts between the English and Welsh ways of life for generations. (E. G. Bow.)

Flora and Fauna.—The flora is a somewhat impoverished version of the British flora in general: thus 1,100 flowering plants are recorded as native to Wales as against about 1,600 for Great Britain as a whole. The following species are confined in Britain to Wales: lesser whitebeam (*Sorbus minima*), rock cinquefoil (*Potentilla rupestris*), yellow whitlow grass (*Draba aizoides*), cotoneaster (*Cotoneaster integerrima*), mountain spiderwort (*Lloydia serotina*) and the grass *Mibora minima.*

The vegetation reflects the mountainous nature of the country and its westerly climate and consequent prevalence of leached soils, and the range of natural or seminatural vegetation types is very wide. Moisture-loving species such as ferns and bryophytes are found almost throughout in greater abundance than in England.

The proportion of grassland is relatively high, nearly two-thirds, as compared with less than 40% in England. Monmouthshire, with nearly 13% of woodland, was relatively well afforested even before World War I; since that time, and in consequence of the rise of state forestry, artificial plantations have increased very considerably in most parts of Wales, and the landscape in certain districts is becoming increasingly dominated by coniferous trees. (H. A. He.)

The remoter parts of Wales shelter some mammals and birds extinct or rare elsewhere in Britain. Thus the polecat is fairly common in central Wales though hardly known elsewhere, and the pine marten occurs in a few places; among birds, a few pairs of kites represent the sole British survivors, and the rare chough breeds inland as well as at some coastal sites.

The vole of the Pembrokeshire island of Skomer is differentiated as a subspecies from the mainland bank vole. Grassholm, off Pembrokeshire, is the home of one of the largest gannet colonies in Europe, and other sea and shore birds occur in the numbers that might be expected in a country with about 600 mi. of varied coast line. There are bird observatories on Skokholm and Bardsey Islands. Large beds of cockles on parts of the south Wales coast support a flourishing cockle fishery. Fresh-water fishes peculiar to Wales are the gwyniad of Bala lake and the Llanberis char. Among insects, the beautiful beetle *Chrysolina cerealis,* confined to one small area of Snowdon, and the moths Ashworth's rustic and Weaver's wave. also known in Britain only from the hilly regions of north Wales, may be regarded as faunal relicts. (C. Mn.)

HISTORY

The earliest traces of man in Wales are known from the caves at Paviland in Gower, Coygon in Carmarthenshire and Pontrewydd in Flintshire. The earliest signs of occupation refer to a time when man became a cave dweller. 4s pine forests spread with the return of a somewhat milder climate after the Glacial period. Wales was inhospitable to early man, especially as the only flint available was that derived from the debris of the ice sheets on the shores of the Irish sea. People appear to have drifted to Wales, finding forest-free spots on the windswept tops of the lower moorland and along the shore where in several places occur flint chipping floors with implements of early type but unknown date. Among the early immigrants in Wales were people of Old Stone Age stock whose descendants still live in remote moorland areas such as Plynlymon and the Black mountain region of Carmarthenshire. These people have dark hair and eyes, long, high-ridged heads, big eyebrows and rather prominent mouths. A very much larger element in the Welsh population are the little dark people with dark hair and eyes and rather long heads and slender build. These represent early drifts from southwest Europe by land and sea, presumably in Neolithic times. Wales, with its volcanic rocks in the northwest and the southwest, was more attractive to people who had learned the art of polishing stone, and the principality has yielded many beautiful examples of polished stone axes. A proportion of the population on coastal patches in southern Glamorganshire, northwestern Pembrokeshire, Ardudwy and elsewhere belong to a type with broad heads, strong jams, very dark hair and often a strong, tall build. Similar people occur on many of the coastal patches of southwestern and western Europe and represent emigrants or traders of the early ages of metal. In several, though not in all, cases this type occurs in regions with megalithic monuments, and these are important in the projecting peninsulas of northwest and southwest Wales.

The stone circle seems to have been of special significance in west Wales and the stones of the inner circle and horseshoe at Stonehenge (*q.v.*) were taken from the Prescelly mountains. (See H. H. Thomas, "The Source of the Stones of Stonehenge," *Antiquaries Jour.*, vol. iii, p. 239, 1923.) The arrival of large numbers of Beaker folk at the dawn of the age of metal in Yorkshire and East Anglia does not seem to have influenced Wales to any great extent, although there are evidences of their culture along the south Wales coastal plain and in the north. Central Merioneth has yielded many examples of the broad-headed, fair, tall type with arched skull and deep-set eyes that is associated with Beaker burials in England and on the continent. The movement of Bronze swordsmen through western Europe to Britain and Ireland in the later Bronze Age is thought by some to be responsible for the spread of the Gaelic languages now surviving in Ireland, the Isle of Man and northwest Scotland. This movement apparently had relatively little influence in Wales. The expansion of the La Tène culture from the continent to Britain in the last centuries B.C. is usually associated with the spread of Brythonic Celtic speech, the foundation of the Welsh language. The western aspect of this culture—Iron Age B as it is known in Britain—entered Wales just before or during Roman times and was closely associated mith the western sea routes. The newcomers appear to have strengthened the Nordic, or tall, fair, long-headed elements in the population, and it is to this period that we can ascribe many hilltop fortresses that guard the lower slopes of the Welsh moorlands. It is thought that the builders of these hilltop camps maintained fairly peaceful relations with the Romans, and in Cardiganshire their influence was strong where the traces of Roman work are weak.

Roman Wales.—Wales was won for the Roman empire by S. Iulius Frontinus and Gnaeus Iulius Agricola. The former was legate in Britain from A.D. 74 to 78, during which time he crushed the Silures, the warlike tribesmen of southeastern Wales. Farther west were the Demetae, of the country round Carmarthen; they were probably subdued at the same time. Agricola's first act, upon his arrival in 78, was to conquer the Ordovices of mid-Wales; in the same campaign, he attacked the tribes of the northwest, crossed the Menai strait and completed the conquest of Anglesey, from which C. Suetonius Paulinus had been recalled 18 years earlier. The island had been the stronghold of the druids and throughout its history has held an exceptional position as an area of great fertility (hence known as *Mon mam* Cymru, "Mona, the mother of Wales"), defended from attack by a rampart of mountains. Wales was effectively held throughout the period of the Roman occupation of Britain, but always as a part of the imperial frontier and by purely military measures. Two of the three legions quartered in the island after 120 held the portals. The 20th was stationed at Deva, the modern Chester, known to the Welsh ever since as Caerlleon, the 2nd Augustan at Isca, also known to later times as Caerllion and Caerleon. From the two legionary stations roads ran west to smaller forts such as Segontium (Caernarvon), Canovium (Caerhun), Cardiff and Gelligaer; roads and forts of the same type were built in the interior. Some of these forts, perhaps, served only a temporary purpose, but it is clear from the absence in Wales (save around Cardiff and Newport) of Roman towns and country houses that the region had no settled civil life of the type found in eastern Britain. Excavations, notably at Dinorben near Abergele, have shown that the natives, while not uninfluenced by Roman culture, lived for the most part an independent and semibarbarous life and still occupied the rude stone and earthen hill forts of their ancestors. The survival of Welsh, a Celtic language akin to Gaulish, supports this conclusion and that it should contain a large number of Latin loan words is natural. (See BRITAIN: Roman Britain.)

Irish and Saxon.—In the age following the abandonment of Britain by the Roman empire, the two outstanding features are the conflict between the Brythonic and the Goidelic elements and the rapid conversion of the country to the Christian faith. It is beyond doubt that, in the 5th century, western Wales was occupied by an Irish-speaking people; the traditions on the subject have been confirmed by the discovery of Ogham inscriptions, especially in Pembrokeshire and Carmarthenshire. Whether these Goidels were aboriginal or invaders from Ireland is still an open question; in either case, they were overborne by Brythonic conquerors from the east and their language became extinct. Tradition ascribed the Brythonic triumph in Gwynedd (northwest Wales) to a leader from north Britain named Cunedda, whose posterity became kings of various districts from Cardigan to Denbigh. As to the coming of Christianity, there is nothing to associate it with Roman rule in Wales. Yet, in the middle of the 6th century, it is to be gathered from the De *Excidio* of Gildas (the one British work of this epoch which has survived) that the British princes who had risen to power on the ruins of the old order were Christians and, if lawless and licentious, yet amenable to the influence of the church. He mentions especially Maglocunus, the Maelgwn Gwynedd of Welsh tradition, lord of Anglesey and Snowdonia and great grandson of Cunedda, as having at one time forsworn his realm and become a monk. Monasticism, in fact, was the movement which wrought the transformation; Wales was converted by the monks, the "sancti" of Gildas, to which company belonged Dewi, who became in Norman times the patron saint of Wales, St. David.

While these events were taking place, the eastern side of Britain was being occupied by English settlers. Wales was not, at first, greatly affected, for the flight of the defeated Britons into the mountains of the west is legend and not history. But at the beginning of the 7th century a new problem arose, which resulted directly from the Saxon conquests. When hugustine, after the conversion of Kent, strove to establish relations with the British clergy, he met with unexpected opposition and failed in his purpose. The differences were merely the result of the long separation between the Celtic and the continental churches; they did not affect doctrine, but .concerned such practical questions as the true date of Easter. Nevertheless, they were sufficient to bring about a schism, which was still violent in the time of Bede; the Welsh Church did not accept the Roman Easter until 768, when it finally gave way at the instance of Elfodd, who was bishop in north Wales. By this time, secular life in Wales had also come to feel the full force of the English impact. The victories of Wessex, notably that of Deorham in 577, had parted the Welsh of Gwent and Glamorgan from their brethren in Somerset, Devon and Cornwall; in the north, the efforts of Cadwallon of Gwynedd, who fell in 633/634 in battle with Oswald of Northumbria, did not avail to maintain British ascendancy in that region, with the result that, in the 8th century, having lost Chester, Shrewsbury and Hereford to the Mercians, the Welsh were confined to the mountainous tract in the west which has ever since been their home. It was Offa (757–796) who definitely marked the boundary by the dike which bears his name, a "travelling" earthwork connecting the mouth of the Clwyd with the Wye above Hereford and shown by place names to have been for centuries the actual frontier between the two races.

Wales bore the full brunt of the attacks of the Northmen. Its monasteries, distributed along the coast and often set, as was the manner of the Celts, on lonely islands, suffered grievously. St. David's was often in peril, but contrived to keep up a tradition of learning, of which the leading representative in the 9th century was Asser, the friend and biographer of Alfred of Wessex. It does not appear, however, that the pirates made any substantial settlement on Welsh soil; they were held at bay by the gallant Rhodri the Great (844–877). founder of the princely houses of Gwynedd and Deheubarth (south Wales) and ruler of all Wales save Dyfed (the land of the Demetae), Brecon, Gwenr and Glamorgan. Many Scandinavian place names are still found on the coastal patches, especially in south Pembrokeshire and south Glamorganshire. Through all the confusion of the next 150 years, a time of conflict with the Northmen and with the Mercians, as well as of internal strife, the line of Rhodri maintained itself in its two branches in north and in south \Vales. It produced one remarkable man in Howel the Good (910–950), a scion of the southern line, who married the heiress of Dyfed, journeyed to Rome in 928 and is styled "king of all the Welsh." His position enabled him to undertake a reform of Welsh law, for which posterity gratefully remembered him; the representative gathering which met at Whitland (Y Ty Gwyn ar Daf) to receive the new code is without a parallel in the early annals of Wales, and "the law of Howel," amplified and re-edited by generation after generation of Welsh legists. became the standard of tribal and personal relations throughout the country. In its precision and subtlety, it has been held to be the greatest intellectual achievement of mediaeval Wales.

The Norman Conquest.—On the eve of the Norman Conquest, there was a striking outburst of activity under one of the ablest of Welsh princes. Gruffydd ap Llewelyn (1039–63) was not of the ruling dynasty, yet he succeeded in making himself master of the whole of Wales—a position never reached by any Welsh chieftain in later times. He owed his power to his success against the Mercians, whom he drove out of their villages in the neighbourhood of Prestatyn, Mold, Wrexham. Oswestry, Montgomery, Knighton and Radnor. Later, he formed an alliance with Aelfgar and Mercia against the Normans whom Edward the Confessor had posted at Hereford (1055); on Aelfgar's death. he was exposed to the hostility of Harold Godwinson and by him was overthrown. His meteoric career made a great impression in England and led to the question of Wales being envisaged there as one of national defense. When William I had completed the subjugation of the English he attacked this problem with his usual insight and, as a first measure. set up the three earldoms of Chester, Shrewsbury and Hereford to protect the realm from the ravages of the Welsh. Further, he encouraged his followers to win land for themselves in north Wales. and to such good purpose that in 1098 the earls of Chester and Shrewsbury had almost conquered Anglesey. In that year, however, the Normans discovered their weakness in sea power. without which the island could not be held; the attempt to subjugate Gwynedd was abandoned. Progress in south Wales had been slower; the Conqueror had there recognized the claims of Rhys ap Tewdwr (1078–93), who had stepped into the dominant position in the south through the signal victory of Mynydd Carn (1081), won in comradeship with Gruffydd ap Cynan of Gwynedd. On the death of Rhys, however, the floodgates were opened and Korman adventures swept irresistibly over the southern area.

During the reign of Henry I the Welsh problem appeared to have been settled. The Norman hold upon south Wales was complete, extending even to the bishopric of St, David's, and the line of Rhys ap Tewdwr was almost forgotten. Powys, the region between Chester and Machynlleth, kept its independence under the posterity of Bleddyn ap Cynfyn (d. 1075), but it was much enfeebled by the quarrels of the reigning house. The weak spot in the Korman system was Gwynedd; there, behind the shelter of the Snowdonian range, Gruffydd ap Cynan (1081–1137) was able to rebuild from humble beginnings the edifice overthronn by William I and William II. No sooner was the king's hand removed by death than a revolt broke out against the foreign power, in which the leaders were Gruffydd's sons, Owain and Cadwaladr, backed by the renewed strength of Gwynedd. The reign of Stephen marks a general revival of energy among the Welsh, who profited to the full by the English civil war; Gwynedd, Powys and Deheubarth became strong principalities under the respective leadership of Owain Gwynedd (1137–70), Madog ap Maredudd (1132–60) and Rhys ap Gruffydd (1135–97). It was thus a hard task which Henry II had before him when he strove in Wales, as elsewhere, to re-establish the conditions of his grandfather's rule; temporary success against Owain in 1157 and against Rhys in 1163 was followed by virtual defeat in 116j, when storms drove him back from the Berwyn moorlands before he had encountered the united forces of the Welsh. The Becket quarrel and his Irish schemes induced him to reconsider his policy; he now resolved upon an alliance nith Rhys ap Gruffydd, whom events had made not only master of most of south Wales, but also beyond question the leading Welsh prince. The pact between Henry and Rhys, concluded in Sept. 1171, was observed until the king's death and bore fruit in the assistance given by the Welsh to the crown in the rebellion of 1173–74. Bard and chronicler alike sound the praises of "the Lord Rhys," who is also well known from the writings of his relative, Gerald of Barry (Giraldus Cambrensis). The authentic history of the eisteddfod begins with the festival he held in Cardigan in 1176; he was also the liberal patron of the Cistercian movement, and supported Archbishop Baldwin, when in 1188 he made a tour of Wales to preach the crusade.

The Power of **Gwynedd.**—After Rhys's death, the primacy of Wales reverted to Gwynedd. A grandson of Owain. Llewelyn ap Iorwerth (1194–1240), ousted his rivals in that district and proved his quality by the capture of Mold from the English (1199). He had two external opponents to fear, the ruler of southern Powys and the English king. From Gwenwynwyn (1195–1216) he wrested his dominions and, with northern Powys in vassalage, he remained arbiter of north Wales until his death. John was. at first, friendly, but the inevitable struggle came in 1211 and, having survived this ordeal, Llewelyn was able to cooperate, first with the pope and then with the insurgent barons, in the humiliation of the king. His services were recognized in the Great Charter and he profited by the situation to carry his arms into south Wales, where he became overlord of the descendants of the Lord Rhys and aided them in the destruction of Norman castles. Under Henry III he was one of the magnates of the English realm, wedded to a half-sister of the king, an ally of the feudal party, attacked in vain by Hubert de Burgh in 1228.

Llewelyn's son, David (1240–46), struggled to retain his father's position, but died before the issue was finally determined. He left no heir, and Gwynedd passed to his young nephews, against whom Henry III had no difficulty in asserting the royal power. In 1255, however, Llewelyn ap Gruffydd defeated his brothers at Bryn Derwin and prepared to repeat the triumphs of his grandfather. Seizing the opportunity afforded by the baronial revolt, he found himself lord in a few years of as wide a territory as his great namesake; even the fall of his ally, Earl Simon, did not check his progress, and by the treaty of Montgomery (1267) he was recognized as prince of Wales (the first official appearance of the title) and suzerain of the other Welsh chieftains. When Edward I succeeded, he was at the height of his power, but, misjudging the situation, he soon lost all; resistance in 1277 led to the forfeiture of everything save western Gwynedd and his title; a second rebellion in 1282 resulted in total overthrow and death in a chance encounter not far from Builth (Dec. 11).

The English Conquest.—In both his wars with Llewelyn the Last. Edward had won his victory by the use of sea power against Gwynedd. He had realized that it was only thus that Wales could be crippled. namely by a final blow at the vulnerable danger spot. The dynasty was disposed of by the execution of David, Llewelyn's brother, in 1283. But it was in a quite limited sense that Wales was conquered at this time. Llewelyn's dominions were brought by the statute of Rhuddlan (1284) under the direct rule of the crown; they were divided into counties, furnished with crown officials and protected by new castles and boroughs at Caernarvon, Conway, Beaumaris, Criccieth and Harlech. But the old marcher lordships, baronial preserves where the lords ruled as little kings and royal writs did not run, mere not interfered with; indeed, their number was increased and new franchises arose around Denbigh, Ruthin, Wrexham and Chirk. Even the loyalist princes of Powys and the vale of Towy were left undisturbed and among the smaller Welsh landowners the changes were far fewer than might have been supposed. Indeed, in many respects the new Wales differed little from the old. It was still a land of small, independent states. each governed by its own customs and inhabited by a Welsh-speaking population, among whom the old Welsh culture flourished. Edward was no friend to marcher privileges, in 1291 he brought the lords of Brecon and Glamorgan to book for exercising the right of private war, and in 1301 he revived the principality of Wales in the person of his son, seemingly in order to create a Welsh authority which could bridle the barons. But tradition was more potent than the royal will; under the weak rule of Edward II Wales became the battleground of baronial factions and, when Edward III in 1343 again created a prince of Wales, it was with a less ambitious purpose; the Black Prince was hardly more than the chief Welsh landlord, the master of Welsh archers and lancemen who fought mith distinction under him at Crécy and Poitiers.

There had been revolts of the Welsh under Rhys ap Maredudd of Dryslwyn (1287), Madog ap Llewelyn of Meirionydd (1294) and Llewelyn Bren of Senghenydd (1316). But, in the course of the 14th century, resistance died down; even Anglesey, that ancient focus of liberty. produced defenders of the crown such as the Penmynydd family, ancestors of the Tudors, and Sir Howel of the Horseshoes. men who never forgave the murderers of Edward II. The country was growing more prosperous and a thriving trade sprang up at ports like Rhuddlan, Beaumaris, Haverfordwest and Carmarthen. It is therefore startling to find, at the opening of the 15th century, Wales convulsed by a new revolt, more widespread than any of its predecessors.

Owen Glendower (*q.v.*) was the direct male representative of the line of northern Pomys, with claims through his mother to the lands of the Lord Rhys, At the accession of Henry IV he held a portion of this inheritance on the banks of the Dee and of the Teify. When in 1400 he broke into rebellion, it was mainly to vindicate personal wrongs. But Henry underestimated both his hereditary prestige and his high abilities, with the result that Owen's power grew from year to year and he was ere long emboldened to proclaim himself independent prince of Wales. The capture of his enemy Reginald Grey gave him financial resources: that of Edmund Mortimer a valuable ally. He concluded a treaty with Charles VI of France, won the castles of Harlech and Aberystwyth, held parliaments of his subjects and exercised in a large part of Wales the powers of a ruling prince. The downfall of his friends, the Percys, at Shrewsbury (1403) was not fatal to the movement; more serious was the failure of the French at Woodbury Hill (1405) and the loss of the two castles (1408–09). As the difficulties of Henry IV gradually disappeared, Owen's cause became hopeless and he died in hiding c. 1416. He has never ceased to be the darling hero of Welsh popular tradition.

The Glendower movement left Welsh society in ruins and during the rest of the century recovery was but slow. Disorder returned with the Wars of the Roses, in which Welshmen such as Owen Tudor (d. 1461) and William Herbert, earl of Pembroke (d. 1469), were deeply involved. It was a Tudor who at last brought peace alike to England and Wales on the field of Bosworth (148j), with a large Welsh following who reckoned that they had avenged in this victory the wrongs of foreign rule.

Union With England,— Under Henry VII and during the first 25 years of the next reign. Wales, whether old principality or feudal marches, was administered by a prerogative council; the Court of the lord president in the marches of \Vales, an amalgam (of pre-1485 Yorkist origin) of the prince of Wales' council with the council of the earls of March; its seat was usually at Ludlow, the *caput* of the great Mortimer territories. But later a group of acts of parliament (those of 1j36 and 1542 being the most important), loosely known today as the Acts of Union, replaced this dominion status by an incorporation of all Wales in the realm of England. The hitherto unshired march ground was now divided into five new shires (including Monmouth, which, however, was left awkwardly suspended between Wales and England, through inconsistencies in the wording of the acts); the 13 shires and their boroughs were between them to return 27 members to parliament. March jurisdiction disappeared (though not the manorial courts); henceforth the common law of England alone was to be valid in Wales. But, for convenience, 12 of the shires (excluding Monmouth, this time) were grouped into four circuits, whose business was to be taken by special judges not drawn from the Westminster bench. There were also to be special chancery and exchequer courts for Wales. This mechanism, the king's great sessions in Wales, lasted till 1830. The shires were to have justices of the peace and quarter and petty sessions. The council at Ludlow was not only continued, but was even recognized by statute (1542) and further given appellate and first-instance jurisdiction. As no line of demarcation was drawn between its executive functions and those of the magistracy, or between its judicial functions and those of the great sessions, each could during the next century be played off against the other. However. the council was shorn of many of its powers in 1641 and, though revived in 1660, was finally abolished in 1689. The fixed pattern then emerges: great, quarter and petty sessions as the judicial mechanism, quarter sessions as the main administrative organ. The justices of the peace governed Wales in local matters, right down to the Local Government acts of 1888.

The New **Squirearchy.**—With the extension of English law to Wales, the old Welsh law of land inheritance (already obsolete in many parts of Wales) disappears, except for local vestiges (disguised as copyhold tenures) which could be found even in 1918. Primogeniture and entail together fostered the growth of a landlord class, which indeed had begun to arise in Wales as far back as the age of the princes but nas now reinforced by the advent of "new men" nho fished successfully in the troubled waters of the times. The landlords would naturally furnish justices of the peace and members of parliament. Moreover, though really large estates (by English standards) were not numerous in Wales, estates in general would now devolve en bloc, in many cases enhanced by grants and purchases of monastic lands and of crown lands alienated by royal necessities.

It is true that, even before the disasters of the Commonwealth period, the effort to emulate the material standards of their English compeers tended to involve the Welsh squires in difficulties which neither speculation nor screwing up rents nor marrying English heiresses availed to remove. Yet, for all that, the squirearchy ruled the roost. The smaller freeholders (then numerous) were indeed economically independent within their own limits, but the rise of the squires depressed them in the social scale. Of old, they had been the social and cultural equals even of the greater gentry, for they too had bonedd, "gentle blood," as the old Welsh way of life regarded it. But now the increasing disparity of material conditions and the monopoly of public officeby the squires opened a gulf between the two. Disinherited younger sons of squires either sought their fortunes in England or abroad or were given by the head of their house a meed of freehold land (or a family living). with which they dropped into the freeholder class, or took a tenant farm on the family estate. Most of the tenantry, burdened with rising rents and infringed leases, sank into poverty — though not into pauperism, for the Elizabethan poor law was to be a dead letter in most parts of Wales until the 18th century. There was as yet hardly any middle class. Professional men clung to the skirts of the great. Towns were few and small. most of them mere pawns in the rivalry of the gentry for the control of parliamentary representation.

The Welsh Language After the **Union.**—By the act of 1536 (not modified in this particular till the Welsh Courts act, 1942), English became the official language of the court and of public business. The consequences, though indirect and long term, were important. It was not that the gentry then, or even before a long time, ceased (or could afford to cease) to be Welsh speaking; even late in the 18th century a magnate here and there took pride in his native language and in its literature. But the act led to an early stratification of the gentry and ultimately to a cleavage between the gentry as a whole and their social inferiors. The largest landowners, whose official duties and social aspirations assimilated them with their fellows in England, were Anglicized at a fairly early date. The lesser squires (with whom we may group the upper beneficed clergy) moved more slowly — monoglot Welshmen indeed even they could hardly remain. with their grammar-school and university or inns-of-court education. Even the freeholders were affected. The 17th- and early 18th-century dissenting ministers (mostly freeholders), though ministering in Welsh, corresponded and kept their church records in English (not to speak of eking out their stipends by keeping little schools in which English was taught), and so did the 18th-century leaders of Welsh Methodism, nearly all of them clergymen. The masses were only sporadically literate even in Welsh, though literacy reached a lower social stratum than it did in contemporary England. They kept up a fairly vigorous folk literature in Welsh, though the classical poetry which had of old depended upon the patronage of the gentry declined as these drifted from the ancient moorings. Any extensive Anglicization of the masses was hardly possible before the English-speaking immigrations of the 19th century and the compulsion of the Education act of 1870. Even so, Welsh, until the great dislocations that followed World War I, remained the language most familiar to more than 40% of a population that had quadrupled between 1801 and 1911.

The Protestant Reformation.—The official discouragement of Welsh was countermined by the government's own action. For a Protestant government had to provide its Welsh-speaking subjects with a Welsh prayer book (1567, rev. 1621) and a Welsh Bible (1588, rev. 1620). The work of the Welsh Bible in preserving the literary language from extinction and the spoken language from crumbling into a congeries of patois cannot be exaggerated, though it should be remembered that, until literacy became much more widespread, the stately biblical diction and style could be propagated, even after the pocket Bible of 1630 appeared, for the most part only through the people's hearing Bible and prayer book read in church. Protestaptism was also promoted among the reading classes by books in Welsh written or translated by clergymen or laymen of the upper class who still clung to the old literary tradition. On the other hand, learned and patriotic Roman Catholics in exile strove to provide counterpropaganda in Welsh, in the teeth of government censorship.

The rate of the genuine acceptance of the Reformation by the Welsh people cannot be measured, with our insufficient data. In a sense, the masses must still have largely hankered after the old faith, even at the end of Elizabeth's reign, but they were not vocal, and outward conformity seems by 1603 to have been pretty complete. The ruling classes as a whole had found it desirable to support the new religion. Quite apart from the profit which the dissolution of the religious houses had brought them, loyalism was ingrained in them. Further, the menace to the long Welsh coast line from Spain, either directly or through Ireland (a country not loved in Wales), was always at hand to stiffen them. Their tenantry, schooled by agelong tribal tradition, would make little demur. There was, of course. always a declared minority of Roman Catholic recusants to be found in all classes; Jesuit and other missions were active; there were Welsh Roman Catholic martyrs both in Elizabethan times and in the time of Titus Oates; and there were whole pockets (chiefly in the northeastern and southeastern corners) of Roman Catholicism sheltered by gentry of the old faith. Indeed. there was a marked increase of recusancy in Wales under James I.

Nonetheless, the story is one of decline—slow at first, much more rapid after 1679—until Irish immigration in the 19th century brought substantial numerical increase. And it is certain that by the middle of the 17th century the Anglican Church was deeply ensconced in the hearts of the people. whose countryside poets stoutly championed it against papist and puritan alike.

Puritanism, indeed, in the sense of inconformity, was for a long time far rarer in Wales than was recusancy, although, if we judge by their writings, the Elizabethan propagators of Protestantism in Wales were rather "leftist" in their views (always of course within the Anglican order) and although the earl of Essex's conspiracy of 1601 was supported not only by the men of his own lands in southern Pembrokeshire but also by men in eastern Denbighshire. Indeed, these two latter regions (together with eastern Monmouthshire) were precisely the parts of Wales in which the later inconformity showed its head. It should be noted that they were mostly of English speech and influenced by Cheshire or Shropshire. or by the City of London either directly or through Bristol. The first dissenting congregation in Wales was at Llanfaches (1639), on the Monmouthshire border. In the hinterland, apart from the Bristol channel ports, only an occasional freeholder or squireen was attracted by puritanism. With the Civil War came deliberate puritan propaganda. first by itinerant preachers, then (1650) under an Act for the Propagation of the Gospel in Wales, whose commissioners strove to purge Wales of inactive or "malignant" clergymen, to replace these by "godly" ministers, and to redistribute the endowments of the church, setting up also a system of puritan grammar schools. The plan naturally collapsed in 1660, to the great joy of most Welshmen. But one important and permanent result of the act is often overlooked: it had spread dissent, however thinly, over all the Welsh-speaking parts of Wales. and the penal laws of Charles II failed to stamp it out. Dissent had by 1688 set up county organizations, and these by 1715 had crystallized into more than 70 local congregations. Even though dissent in 1715 accounted for barely more than 5% of the population, it was there, organized for further advance.

Politics After the Union.—Politics in the modern sense hardly affected the homekeeping Welshman before the 19th century. The ruling class (about 100 families), from which members of parliament were drawn, had indeed its internal rivalries, but contested elections were infrequent. Only on occasion would a recalcitrant group of squires challenge those in possession; what was at stake was prestige and power within the shire rather than any larger issue. Once elected, the Welsh members, down to 1642, mostly acted as a body, a "Welsh interest," often as an official Welsh committee of the house on matters affecting Wales. In general politics they were stoutly loyalist, but very far from being uncritical of authority. Under Charles I they strongly expressed their dissatisfaction with excessive taxation, arbitrary uses of prerogative and mishandling of foreign affairs, but they vented their disapproval upon the king's favourites and advisers, not upon the king's own head, and when it became clear that the left wing of the Long parliament was bent on wholesale encroachments upon the king's authority, the Welshmen pulled out. Only 7 out of the 27 took the parliamentary side in 1642, and only in southern Pembrokeshire, eastern Denbighshire and eastern Montgomeryshire did parliament find much armed support. In Wales outside these areas there was indeed no real civil war but only, at first, a parliamentary attempt to contain Wales (the king's recruiting ground) and then a parliamentary invasion of Wales. Despite the shocking mishandling of loyalist Wales by royalist commanders, Wales, harried by parliamentary committee after committee and then by majors general, welcomed the Restoration well-nigh unanimously.

But the Restoration could not wholly restore. Welsh members no longer acted as a body, and a few of them are found in the ranks of the later Country party. Further. a certain amount of sequestration and a greater amount of forced sales of land to meet fines had crippled many landowners. The greatest (especially the most prudent during the troubles) could weather the storm with some prospect of recovery, but the smaller, clinging in spite of their losses to "gentle" standards of life, gradually sank with diminished lands into the freeholder class or sold out and turned to the law or to commerce. The county families (with estates enlarged by buying out their less fortunate fellows) became a caste of about 50 families. More and more, as the 18th century wore on, these monopolized the parliamentary seats. A striking example is that of the Williams-Wynn family, which held Montgomeryshire till 1880—far down in a newer era—and lost its Denbighshire seat only in 1886. The politics of these men, whose dependents were still tribally docile, concerned Wales hardly at all. The atavistic spurt of Jacobitism among some of them was of no practical importance.

Popular Education and the Methodist Movement.—A great impulse in the field of popular education (not that Wales had ever been totally devoid of this) was given by the charity-school movement of the Society for the Promotion of Christian Knowledge (1699), continuing the experiment of Thomas Gouge's Welsh trust (c. 1672–81). The S.P.C.K. not only printed a considerable number of Welsh Bibles, prayer books and other religious literature in Welsh but also founded about 95 schools all over Wales. But the movement was completely transformed in the hands of Griffith

Jones (1683–1761), rector of Llanddomror in Carmarthenshire, and of his coadjutor and successor Bridget Bevan (*née* Vaughan, 1698–1779). Their work. begun about 1737. took the form of establishing circulating schools with itinerant teachers who camped for three or six months in a locality and then moved on to fresh ground. During Jones's lifetime, more than 158,000 learners of all ages passed through his schools—possibly one-third of the population. The effect was a mass production of literacy in Welsh. intended by him solely to promote Bible reading. But obviously the spread of literacy was bound to have wider effects in the future.

The Welsh Methodist movement, initiated independently in 1735 by Howel Harris (1714–73) and by Daniel Rowland (1713–90), was not. as is too often assumed, a revolt against abuses in the established church. It is true that, crippled as it had been at the Reformation by wholesale alienation of monastic tithes and hampered after 1714 (and for that matter till 1870) by the practice of appointing English bishops (often absentees) to the Welsh dioceses, the church was not, in the 18th century. at the peak of its efficiency. But the root of Methodism was "enthusiasm," a thing suspect in the eyes of the educated, whether lay or clerical and whether Anglican or dissenting. Eloquent preaching spread the movement primarily among the masses. A network of small religious groups (societies), organized in a quasi-Presbyterian framework. consolidated it; and the Bible reading made possible by the schools of Griffith Jones (no Methodist) helped to transform the mass of small tenantry, rural labourers and the increasingly numerous industrial workers into a literate, articulate and potentially critical public.

For a long time there was no thought (except in a few instances) of cecession from the established church; indeed, though the evangelical wing of Welsh dissent had at first co-operated with the Methodist leaders. they were on not too good terms after 1742 or so. Secession. when it did at last come, came through the force of circumstances. Authority in the established church had increasingly hardened toward the new movement; clerical recruits to it became fewer and fewer; the parish clergy frequently refused communion to hlethodists; and many Methodists would no longer communicate in their parishes. preferring to await a Methodist clergyman's visits. After the death of the older clerical leaders. such as Daniel Rowland and the hymnist William Williams (1717–91), this became a grave difficulty. On the other hand. the greater lay preachers, men not only of eloquence but also of ability and force of character, could not see why the sacramental office should be denied them. Thomas Charles (1735–1814), a clergyman who was now the acknowledged leader and organizer of the movement. for some time resisted the seceding tendency but was finally convinced. In 1811 Methodism began to ordain its ministers. At one stroke the Calvinistic Methodist "connection" within the church became a dissenting denomination. Dissent (the older dissent itself had grown slowly down to 1775 but had since acquired considerable momentum) now greatly outnumbered Anglicanism in Wales. though it was not till after 1843 that Methodist dissent swung over to political Radicalism.

The 19th and 20th Centuries.— The 19th century was to witness the political sequel of the Methodist secession, of the cleavage (linguistic. religious and economic) between the landlords and their tenantry (a tenantry now literate and beginning to be provided with journalism in Welsh) and of the new rivalry between landed and industrial interests. Successive Reform acts extended the franchise, and by 1886 the parliamentary representation of Wales had been almost monopolized by the Liberal-Radical party and a "Welsh interest," indeed an officially styled Welsh party, had reappeared in the commons. Its program was in general that of English Radicalism, but differences of emphasis and of priority in application led the Welsh party to pursue a course which can quite fairly be labelled nationalist. Welsh agrarian grievances (manifested. for example, in 1839–44 in a sort of *Jacquerie* known as the Rebecca riots and again in the "tithe war" of 1886–91) tended to be elbowed out of priority by the antiestablishment urgency of Welsh dissent. One form of this was the demand for popular education of all grades freed from Anglican association—primary schools (especially after 1870), then secondary schools (1889) and finally the federation of university colleges (the first of which dated from 1872) into a national university (1893). A national museum and a national library came in 1907. Piecemeal attacks upon the ascendancy of the established church culminated in 1919 in the disestablishment and disendowment of the Anglican Church in Wales; as a corollary that church, now known as the Church in Wales, became an autonomous province. But all these were achievements of a new middle class which had developed in Wales during the 19th century and was now providing Wales with members of parliament in lieu of the old squire members. It was a class which had recoiled from Chartism and from the infant trade-union movement. In the end, therefore, Welsh Radicalism ceased to attract that working-class vote which had enabled it to realize so much of its program; the workers, at first in south Wales and afterward in north Wales too, went over to political Labour; and by the 1950s Welsh Liberalism had suffered almost total parliamentary eclipse. One of its unrealized aspirations (1886), home rule for Wales, became the watchword of a new Welsh Nationalist party (1924) which, however, had not made much headway at the polls by the middle of the 20th century.

World War I and. much more. World War II led to considerable upheaval in Wales. For example, large-scale English immigration and Welsh emigration seriously imperilled the Welsh language, which in the 1950s was not spoken by much more than 20% of the people. Yet the awareness of nationhood (whether Welsh-speaking or not) was, if anything, sharpened. In April 1949 the Labour government established the advisory council for Wales; in Oct. 1951 the Conservative government included a minister for Welsh affairs in the cabinet (the home secretary); from Jan. 1957 the position of minister for Welsh affairs was held by the minister of housing and local government, and in December of that year a minister of state for Welsh affairs was appointed.

The cry for home rule was not confined to the Nationalist party proper. Strenuous efforts. moreover. were made to check the disuse of Welsh. Quite apart from the sympathy of the ministry of education toward the use and teaching of Welsh in the schools, these efforts were strongly supported by Urdd Gobaith Cymru (the League of Welsh Youth), by Undeb Cymru Fydd (the New Wales union) and by the council (1937) of the Eisteddfod (*q.v.*), all three nonparty and undenominational.

POPULATION

In 1961 the total population of Wales and Monmouthshire was 2,640,632. The sparse numbers of inhabitants in the rural areas and the intensive crowding of the southern coal field made the distribution of population very uneven. All the towns with the highest population figures (1961) are in the south Wales coal field: Cardiff (256,270). Swansea (166.740): Rhondda (100.314). Merthyr Tydfil (59.008) and Port Talbot (50.223). Other large towns are (1951 population) Pontypool (42,703). Barry (40,990). Aberdare (40.932). Pontypridd (38.633). Gelligaer (36,169), Caerphilly (35,189), Llanelly (34,476) and Neath (32.254).

Since the 16th century Monmouthshire, although geographically in Wales, has been regarded as part of England. It is still largely peopled by Celts many of its place names are Welsh and for legislative and administrative purposes it is usually linked with Wales, while the bishopric of Monmouth is within the Church in Wales. For administration of justice, honever, Monmouthshire is part of the Oxford assize circuit.

TABLE I —*Area and Population of Wales*

County	Area (sq mi.)	Population			
		1871	1901	1951	1961
Anglesey (Ynys Mon)	276.2	51,040	50,606	50,637	51,700
Breconshire (Brycheiniog)	733.5	59,901	54,213	56,484	55,544
Caernarvonshire (Arfon)	569.1	106,121	125,649	124,074	121,194
Cardiganshire (Ceredigion)	692.7	73,441	61,078	53,267	53,564
Carmarthenshire (Caerfyrddin)	919.8	116,710	135,328	171,742	167,736
Denbighshire (Dinbvch)	668.9	105,102	131,582	170,699	173,843
Flintshire (Flint)	255.8	76,312	81,485	145,108	149,888

Total	7,476.3	1,218,135	1,714,800	2,172,339	2,196,943

Religion.— Classical references to religious cults in pre-Roman Britain have been the pretext for much conjecture as to the nature of the pre-Christian religions of Wales. All that can be said is that the island of Anglesey seems to have had a tradition of special sanctity. The post-Roman centuries were characterized by a revival of prehistoric conditions in the west and although Christianity reached there very early the salient feature is its close associations with the previously existing traditions. The church of Yspytty Cynfyn in north Cardiganshire is built within what was once a stone circle and observers have recorded many circular churchyards in Wales. The spread of the Celtic saints or preachers of Christianity from Ireland to Wales, Cornwall, Brittany and many parts of the continent helped to make St. David's important. It stands at the convergence of a number of routes from little landing places on a storm-washed peninsula. The itinerant Celtic saints established many small cells or churches in Wales, many of which still bear the founder's name in their dedication. From the 7th century onward the power of the Roman Church grew and the older Welsh traditions were brought nominally under its sway. The attempts of Giraldus Cambrensis in the 12th century to gain ecclesiastical independence for Wales are an echo of the marked individuality of the Celtic traditions.

Among pilgrim routes to Santiago de Compostela (*q.v.*) the maritime one from Ireland via Wales. Cornwall and Brittany was important, and it seems to have been also a survival or revival of a prehistoric route of trade. By the Renaissance the Roman Church had gathered into itself and assimilated all the earlier ritual, and the Anglican Church did not replace it completely in rural Wales. The strongholds of Anglicanism were in the small castle-towns of the coastal plains. The mass of the population of moorland Wales long retained its mediaeval ideas. Early Puritanism appeared in those regions that had the closest associations with the English plains and particularly in those regions that had specialized in weaving. Such districts attracted refugees from the continent.

Radnorshire became an early centre of the Quakers and Baptists, Montgomeryshire of the Independents, while in the weaving centres of the south Wales coastal plains early Puritanism was developed especially by the Independents and the Baptists, who seem to have been specially selected for persecution and whose early chapels are in several cases in remote spots. They seem to have entered regions in southwest Wales (*e.g.*, northwest Pembrokeshire) that were sparsely populated in the middle ages, a movement that seems to have been associated with the introduction of root crops. The Methodist revival of the 18th century, mainly through the influence of the Welsh language, affected chiefly the moorland regions of Wales. Henceforth the country was predominantly Nonconformist.

An honourable exception to the absentee or indifferent English prelates of this period is to be found in Thomas Burgess. bishop of St. David's, whose exertions were the chief cause of the foundation in 1822 of St. David's college at Lampeter, an institution erected to provide a better and cheaper education for intending young Welsh clergymen. It was not until 1870 that, by Gladstone's appointment of Joshua Hughes to the see of St. Asaph, the special needs and claims of the Welsh Church were officially recognized. Thus between 1811 (the year of the Methodist secession) and 1832 (the date of the Reform bill), the number of dissenting chapels had risen from 945 to 1.428. In 1870, the dissenting bodies were supporting two quarterly, six monthly and ten weekly papers. all published in the vernacular. A result was the Sunday Closing act of 1881 and the Welsh Intermediate Education act of 1889. In 1893 Lord Rosebery's cabinet appointed the Welsh Land Tenure commission, whose report, published in 1896, did much to exonerate the squirearchy from charges of extortion and sectarian oppression.

In 1914 the Bill for the Disestablishment and Disendowment of the Church of England in Wales was passed. It provided that the secularized portion of the endowment of the church should be applied to specified national purposes, mainly educational. and a financial amendment in the direction of compensation to the church was passed in 1919.

Cnder a new constitution (1922) the supreme authority of the Church in Wales was vested in a governing body, representative of the clergy and laity. The area that came under the jurisdiction of this body became known as the province of Wales. with an archbishopric established for the time being at St Asaph. The province is practically coterminous with Wales and Monmouthshire. with the exception of a few border parishes which under the Welsh Church act voted themselves out of the Church in Wales. Six dioceses are comprised within the ecclesiastical province of Wales: Bangor in the northwest, St. Asaph in the northeast, St. David's in the southwest. while the populous area of the southeast is shared between Llandaff, Monmouth and Swansea and Brecon (including the almost entirely rural counties of Brecon and Radnor).

Roman Catholicism is still strong here and there in the border counties, especially Flintshire. In most cases it survives in' conjunction with mediaeval landed families. After the last half of the 19th century it flourished exceedingly in the south Wales industrial regions. especially among the immigrants of Irish descent. In 1898 a bishop with the title of Menevia (Latin form of St. David's) was appointed for the Roman Catholic community in all Wales except the counties of Glamorgan and Monmouth; these latter (and Herefordshire) were included in the archbishopric of Cardiff, which was founded in 1916. After the expulsion of the religious orders from France in 1903 several communities of French monks and nuns took up their abode in the principality.

The majority of the followers of the Methodist revival movement of the 18th century in Wales form the Calvinistic Methodist Church of Wales, known also as the Presbyterian Church of Wales by virtue of an act of parliament passed in 1927. While its churches are strongholds of the Welsh language, many use English in the services. It is organized under the *Cymanfa Gyfredinol* (general assembly), which meets annually and elects a moderator. There are two *Cymdeithasfa* (synods), representing respectively the north and south of the country. The individual churches are grouped into a *Cwrdd Dosbarth* (district meeting), and the latter into a large unit, the *Cwrdd Misol* (presbytery). In addition to the presbyteries in Wales, there are three of the Welsh body in England: in London, Manchester and Liverpool.

Other followers of the Methodist revival are members of the Methodist Church in Wales (formerly the Wesleyan Methodist Church), an integral part of the Methodist Church in England; Welsh candidates for this branch of the ministry are trained in English Methodist theological colleges.

The Independents and Baptists each have an Undeb (union) for Wales; the former is part of the Congregational Cnion of England and Wales, and the latter is within the Baptist Union of

Great Britain. (E. G. Bow.; X.)

University.—The Cniversity College of Wales was founded at Aberystmyth in 1872; that of South Wales and Monmouthshire at Cardiff in 1883; and that of North Wales at Bangor in 1884. On Nov. 30, 1893. the constituent colleges were incorporated by royal charter as the University of Wales. nith Lord Aberdare (d 1895) as its first chancellor. The university was reorganized nith a supplemental charter in 1920 when the fourth constituent college was founded at Sn ansea.

There are 2j8 members of the governing body. appointed representatives of county and county borough councils in Wales and Monmouthshire being in a majority of one over the other representatives which include those chosen by the lord president of the council. 12 each appointed by the colleges and the Welsh National School of Medicine. the Guild of Graduates. the national museum and the national library The local authorities contribute financially by the levy of special rates for the purpose. All the main branches of cultural and scientific education are catered for and special attention is given to Celtic studies agriculture metallurgy and engineering The national school of medicine is at Cardiff

Extramural studies have been vigorously developed throughout Wales. In addition to the regular financial support received froin local authorities there were liberal private benefactions during the earlier part of the 20th century. The total number of students grew from a few hundred in 1872 to more than 5,000 in 1953.

ECONOMIC AND INDUSTRIAL CONDITIONS

Wales and Monmouthshire form approximately one-seventh of England and Wales. Half of the land reaches an altitude of 600 ft. above sea level, while half of this exceeds 1,000 ft. This enabled the inhabitants to maintain a distinct political existence for centuries after the English lowlands had become subject to one authority. It was not until the 19th century that the traditional isolation of Wales began to be profoundly affected by the development of railways. World competition became operative. to the embarrassment of local industries previously protected by the isolation of the local market.

Agriculture.—Largely because of its climate Wales is primarily a dairy-farming country. Essentially it is also a country of small farms. the great majority of the total holdings being less than 150 ac Even so. the farming industry plays a more important part in the economy of the country as a whole than it does in England.

During the period of World War II Welsh agriculture undernent a virtual revolution. increasing production to such effect that it contrived to feed Wales to a greater extent than ever before and at the same time to supply parts of England.

One of the outstanding achievements of the Welsh livestock industry was to increase its milk production on a substantial scale so that by 19j2 there nere more than 315,000 cows and heifers in milk. an advance of 14% on the 1939 total. In the same period temporary grass acreage had risen by 81%. The output of milk continued to increase during the mid-1950s.

Other striking advancec up to 1952 nere the doubling of the tillage acreage, the increase in cattle. pigs and poultry by 10% and the making good of the severe losses caused by the disastrous 1946–47 winter. Substantial increases were maintained in sheep, pigs and cattle during 1956–57.

Much is attributable to a big increase in use of machines. Whereas in 1939 only one farmer in 1j in Wales had a tractor by 1953 the average was one tractor per farm and there was a further increase in tractors of about 30% during 1953–56.

In the early 1950s advance in production appeared to have been halted. but by mid-1953 Welsh agriculture was forging ahead again. Up to Aug. 31. 1953, government grants had been paid to hill farmers to cover 1 458 improvement schemes costing £465,805. The total number of cattle and calves in 1953 was the highest since records were first kept in 1867, each subsequent year showing a slight increase.

Many of the large farms in the Welsh lowlands employ paid labourers but in the uplands the work is done for the most part by family labour. The total of those engaged in agriculture and horticulture in Wales in 1957 was 41.800. Agriculture in Wales made marked progress after the application of scientific methods to all branches of farming, in nhich the Lniversity colleges at Bangor and Aberystwyth. with the support of the ministry of agriculture. rendered invaluable service Agricultural co-operative societies first established in Wales in 1901, multiplied rapidly after World War I. and in 1922 a Welsh agricultural organization society was founded Small mixed holdings of the average size of 47 ac are characteristic of Wales, and the small farmers were quick to grasp the advantages provided by the co-operative purchasing of foodstuffs. etc. The independent Welsh Farmers' union, founded in 1918, was later merged in the National Farmers' union.

The total forestland in Wales increased from 106,909 ac. in 1939 to 189.116 ac in 19j6 h noteworthy change after 1939 nas the big proportion of derelict woodland acquired for replanting by the Forestry coinmission. which was 50% of the total in 1953 compared with only 10% in 1939. During 1939–56 total workers increased from 800 to 3,290.

The Industrial Revolution in Wales.—In 1801 Wales and Monmouthshire had a population of 587,245, fairly evenly distributed over the land. since the vast majority of the people were engaged in agriculture or in related occupations. As the Industrial Revolution developed. and particularly after 1841. the rural exodus. accompanied by the decay of many industries nhich had supplemented the earnings of agriculture. led to an enormous concentration of population in the iron- and coal-producing valleys of southeast Wales. According to the 1951 census. 62 6% (1 627,-696) of the population of Wales and Monmouthshire (2,598,67j) uas concentrated in the two counties of Glamorgan (1,202,581) and Monmouth (425 11j).

Trade unionism has long been a potent force in south Wales. The first important organization of miners and ironworkers was the Cnion club and after its suppression in 1831 there came into existence a secret society. the Scotch Cattle. whose symbol was a bull's head and horns.

In the 1860s the Amalgamated Association of Miners, a rival to the National Miners' union gained much support in Wales nhere. from 187j there was constant agitation against the sliding scale payment of wages. Following a strike in 1898 the sliding scale was abolished and the South Wales Miners' federation was organized This body, later affiliated nith the Miners' Federation of Great Britain, latterly the National Cnion of Mineworkers, continued to be proinineint in the trade-union movement. (*See* Ness Ednards' *History of the South Wales Miners' Federation,* 1938.)

South **Wales.**—*Coal.*—Because of the high quality of the coal and its proximity to tidal waters. from 1881 the south Wales coal field was the chief coal-exporting region of the norld However the narrow mining valleys present unusual difficulties. for the level ground is occupied by surface norks and the hillsides are used as waste tips The same causes which gave Welsh coals their superiority also made mining in this area more costly and dangerous than in any other part of Britain. Welsh coal is dry and fiery, and the fine coal dust is a constant source of danger. Loose-jointed coal and loose or rotten roof. more frequent in south Wales mines than elsewhere. are responsible for nu- accidents accompanied loss of life. The incidenre of dust disease by the 1930s and 1940s had vere in any British coal field. but scientific dust suppression and

combative measures later caused considerable improvement. For these reasons, the output per man is less than the average for the rest of Britain

After World War I the demand for Welsh coal decreased greatly, both at home and abroad. Although the population and the industrial power equipment increased substantially, economies in the utilization of coal lessened consumption in the United Kingdom. The Welsh coal export trade fell off because of the development of coal resources abroad and the increased use of fuel oils, coupled with heavy import duties, drastic quotas and the subsidizing of industries. In 1938 there were 136,000 miners employed in the south Wales coal field, as compared with 168,000 in 1928 and nearly 250,000 in 1913. There were 119,600 persons employed in the coal mining industry in 1956. The output of coal in 1928 was 43,300,000 tons, but by 1938 the figure had fallen to 35,300,000 tons. South Wales continued, however. then to be the premier coal exporting area in the United Kingdom. Coal exports fell still further after World War II and drastic reorganization was called for when the industry became nationalized in 1947. The total output of salable coal from south Wales pits in the first year of nationalization was 22,288,000 tons and by 1952 this had risen to 23,730,000 tons, an average production maintained annually since. Opencast production in south Wales in 1947 yielded 842,600 tons and by 19j6 the total was 1,640,000 tons. In the north Wales coal field the average production of salable coal rose to 2,300,000 tons between 1948 and 1956.

The National Coal board's plans for south Wales provided for a capital expenditure of about £100,000,000 in the period 1950 to 1965. There were seven administrative areas in the coal field in 1953, each of which had a major project in hand or planned where horizon mining methods would be concentrated on for improved haulage, ventilation and output. Most of the remaining 140 pits would also be modernized.

Industries — Prior to 1870 the leading place in the economic development of south Wales was held by the iron industry. Along the northern edge of the coal field plentiful and readily accessible supplies of coal, iron ore and limestone occurred in close proximity. Consequently, in the first half of the 19th century a narrow upland tract, extending for about 20 mi. from Pontypool and Blaenavon to Hirwaun, nith its chief centre at Merthyr-Dowlais, became the greatest iron-producing region in the world. The invention of processes for the large-scale manufacture of steel and the resulting demand for richer and purer iron ores than those found in the coal field caused many of those works to be closed or to be transferred to the seaboard, where imported iron ore could be treated.

At one period \Vales enjoyed a virtual world monopoly in the manufacture of tin plate. Of 77 such works in Britain in 1875

there were 57 situated in south Wales. The industry was hard hit by the U.S. McKinley tariff in 1890 but recovered through the willingness of both employers and workers to make sacrifices and by the capturing of new markets in eastern Europe. The manufacture of heavy steel products (such as rails, sleepers [ties]. ship plates and girders) is carried on at Port Talbot, Cardiff and Ebbw Vale. The works at Cardiff, completed in 1936. were then the most modern of their type in Great Britain, and those at Ebbw Vale replaced the old steelworks, closed after World War I.

During World War II most of the old-type tin-plate works ceased production and were used for storing war material; and their workers were dispersed in munition factories all over the country. It became clear after the war that the Welsh tin-plate industry would have to be thoroughly modernized if it was to hold its own in the world markets. Accordingly four leading companies pooled plans and resources and formed the Steel Company of Wales which in four years laid down a steel strip plant at Margam, Port Talbot, the most up-to-date of its kind in Europe, which. when in full production, would employ 8,400 men and attain a weekly output of 3,500 tons of rails and 22,800 tons of steel strip and plate.

To complete the modernization scheme an extensive cold reduction plant capable of converting 7,000 tons a week of Port Talbot strip was built at Llanelly and started production in 1952, while in 1956 a similar modern plant was completed at Velindre, near Swansea. This enterprise, involving capital outlay of about £100,000,000, was expected to restore the supremacy of Welsh tin plates in the intensified battle for world trade.

Although by the mid-1950s there was some decrease in home demand for certain steel products. Welsh steel output continued to rise gradually. In west Wales the long-foreseen closure of the old tin-plate handmills caused unemployment. Major developments were being carried out at several major steelworks during the mid-1950s.

Copper ores were shipped from all parts of the world to Swansea for smelting and refining in the 19th century, but because of the lessened copper content of ores and the increasing cost of freights, smelting came to be conducted in close proximity to the copper mines. and the industry disappeared in Wales. However, a copper manufacturing industry still remained. In the years following World War I many works were closed down, but though export trade was affected by economic, financial and political conditions in foreign countries, the industry was continued at Landore, Llanelly and Port Talbot.

Copper sulphate, a by-product of copper manufacturing, was exported mainly to France and Italy for the purpose of spraying in vineyards. Copper-nickel sulphide ores smelted in Canada to a kind of Bessemer matte are shipped to Swansea for refining. The principal by-products of the nickel-manufacturing process, copper sulphate, nickel sulphate and nickel ammonium sulphate, are put to a variety of uses.

Spelter (zinc) is produced in Swansea from sulphide ores imported mainly from Australia and used chiefly in the making of alloys. brass and bronze and in the manufacture of galvanized iron. General engineering industries in Wales include iron and brass founding. the manufacture of railway material and patternmaking; wire, wire netting and wire rope are also made. In 1922 an oil refinery was built at Llandarcy, between Neath and Swansea, for treating crude petroleum imported through Swansea by the Anglo-Iranian Oil company.

A new industrial revolution occurred in Wales after World War II with the government-stimulated settlement of new industries in areas that had been severely hit. especially in south Wales, by the trade slump in the interwar period.

By the end of June 1953 new factories and extensions of existing factories had provided 137,000 new jobs of which 109,000 had been created after the end of the war in 194j. A total of 453 factory projects were completed. An example of the expansion of new industries was the progress of the toymaking trade with 3j firms regularly employing 3,000 workers in Wales and exporting their products to all parts of the world in competition with traditional toymakers on the continent. Despite restrictions on capital investment several extensions of government-financed factories were carried out in the mid-1950s.

While a number of small manufacturing firms on trading estates closed under the economic stress of 19jj–56, the general trend in Wales was toward further expansion. The Suez canal crisis focused attention on the deepwater anchorages of Milford Haven where oil interests were planning harbourage for enlarged tankers to berth and for crude oil to be pumped through a pipeline to the refinery at Llandarcy (Glamorgan). By 1957 plans were prepared for extending Milford docks and an iron ore terminal was also envisaged. The main south Wales ports combined their efforts to try and gain new general cargo traffic to offset the loss of coal trade.

SCENES IN WALES

PHOTOGRAPHS (TOP LEFT, CENTRE LEFT, BOTTOM LEFT. BOTTOM RIGHT) E. W. TATTERSALL, (TOP RIGHT, CENTRE RIGHT) MUSTOGRAPH its economic life to Lancashire and the Midlands than to south Wales, for east-to-west routes are far more practicable than north-to-south in Wales. The north Wales coal field lies in the counties of Flint and Denbigh and extends for about 40 mi. from south to north along the Dee valley. Although extensive, it is far less rich and varied in its output than the south Wales field. The coal obtained is used chiefly for domestic purposes and for gas manufacture, the cannel coal of Flintshire (around Leeswood, Hope and hlold) being specially reputed for its gas-producing qualities. Fire clay, which is mined along with the coal, is used in the brick and tile industries at Ruahon. Cefn, Rhosllanerchrugog and near Mold. Production figures for north Wales after nationalization were: from the mines in 1947, 2,038,446 tons, opencast. 83,909 tons; in 1952, 2,226,100 tons and 215,222 tons respectively.

Industries.—The first ironworks in Wales n-as established at Bersham. near Wrexham. in 1701, but the ore mined from the coal measures of North Wales became almost exhausted before the close of the 19th century. However. as in south Wales, the manufacture of steel from imported ores became a considerable industry. and galvanized iron and tin plates are made at several places. Extensive developments took place from 1948 onward at the Shotton steelworks, putting them in line with the latest production methods.

The chief centre of the fine chemical industry in Wales is at Ruahon. and around Holywell and Flint are important paper and artificial silk industries. Although the mining of lead and zinc declined, it was still being carried on at Halkyn during World War II. Holywell is the centre of the woollen industry of north Wales, fine imported wools being employed in preference to the coarser local product. Wales produces the best slates in the world, but the industry has been struggling following the end of World War II.

Chief centres of the slate-quarrying industry are Bethesda, Llanberis, Nantlle and Festiniog in the counties of Caernarvon and Merioneth, all districts faced with economic eclipse in the 1950s.

Efforts were continuing in the mid-1950s to attract new industries to depressed areas in north Wales, in Anglesey and Caernarvonshire.

(1937). (J. C. G. J.)

WALEWSKI, ALEXANDRE FLORIAN JOSEPH COLONNA, Comte (1810–1868), French politician and diplomatist, was born at Walewice near Warsaw on May 4, 1810, the son of Napoleon I and his mistress Marie, Countess Walewski. At the age of 14 Walewski refused to enter the Russian army, escaping to London and thence to Paris. where the French government refused his extradition to the Russian authorities. Louis Philippe sent him to Poland in 1830, and he was then entrusted by the leaders of the Polish revolution with a mission to London. After the fall of Warsaw he took out letters of naturalization in France and entered the French army, seeing some service in Algeria. In 1837 he resigned his commission and began to write for the stage and for the press.

The accession of Louis Napoleon to power ill France guaranteed his career. He was sent as envoy extraordinary to Florence. to Naples and then as ambassador to London. where he announced the coup d'état to Palmerston (*q.v.*). In 1855 Walewski became minister of foreign affairs, and acted as French plenipotentiary at the congress of Paris next year. When he left the foreign office in 1860 it was to become minister of state. an office which he held until 1863. Senator from 1855 to 1865, he entered the *corps législatif* in 1865 and was installed, by the emperor's interest. as president of the chamber. A revolt against his authority two years later sent him back to the senate. Walewski died on Oct. 27, 1868.

WALKER, FRANCIS AMASA (1840–1897), U.S. economist and statistician. a leader in modernizing and broadening the character and scope of economics in the Anglo-U.S. world, was born at Boston, Mass., on July 2, 1840. His father, Amasa Walker (1799–1875), also a distinguished economist. was the author of The *Science* of *Wealth,* a widely popular textbook. As superintendent of the United States censuses of 1870 and 1880, Francis Amasa Walker expanded the coverage of the census so that it would mirror the nation's development. He exerted his influence as a teacher first at Yale college (1873–81) and then. while president of the Massachusetts Institute of Technology. Cambridge. He was the author of outstanding treatises. notably *The Wages* Question (1876), *Money* (1878) and Political *Economy* (1883). He was president of the American Statistical association (1883–97) and of the American Economic association (1885–92). He died Jan. 5, 1897.

Walker was a decisive influence in discrediting the previously generally accepted wages-fund doctrine. He also effectively stressed the importance of the entrepreneur (as distinct from the capitalist) as the organizer of industry. His controversial studies on immigration invigorated the analysis of population trends.

See James P. Munroe, *A Life of Francis Amasa Walker* (1923). (J. Dn.)

WALKER, FREDERICK (1840–1875), English painter and illustrator, was born in Marylebone, London, May 26, 1840. He studied at Leigh's academy, the British museum and the Royal academy schools, and in 1858 apprenticed himself to J. W. Whymper, the wood engraver. His mature work (particularly illustration which, however, he practically gave up after about 1866) was influenced by his friend J. E. Millais, and especially by the latter's Tennyson drawings of 1857. For another close friend, W. M. Thackeray, he illustrated *The Adventures of Philip* (1861–62) and *Denis Duval* (1860–63) in the *Cornhill* magazine. His first oil, "The Lost Path," was shown at the Royal Academy in 1863, but "Bathers" (Royal Academy. 1867) began the series of his most popular pictures in which, like A. Legros at this time, he turned to a socially-minded realism ("The Plough," 1870; "At the Bar," 1871), sometimes painting like J. F. Millet ("Mushroom Gatherers," *c.* 1868). Walker was elected associate of the Royal Academy in 1871. He died at St. Fillans, Perthshire, June 5, 1875.

WALKER, GEORGE (1618?–1690), hero of the siege of Londonderry, son of George Walker, rector of Kilmore and chancellor of Armagh (d. 1677). In the Irish war of 1688. Walker, though in Holy Orders and advanced in years. raised a regiment for the defense of Dungannon. However, Robert Lundy, the acting governor of Londonderry, ordered the abandonment of the place on March 14, 1689.

On the approach of the enemy (April 13) Walker hurried to Londonderry to inform Lundy, but mas unable to convince him of his danger. He returned to his men at Lifford, where, on the 14th, he took part in a brush with the enemy, afterward following the retreat of the army to Londonderry. The town was in great confusion. and Walker found the gates shut against him and his regiment. He was forced to pass the night outside, and only entered the next day "with much difficulty and some violence upon the Centry." Immediately on his arrival he urged Lundy to take the field and refused the demand to disband his own soldiers. On April 17 Lundy determined to give up the town to James, and called a council from which Walker and others were excluded. But the next day the king and his troops, who had advanced to receive the surrender, were fired upon from the walls contrary to Lundy's orders, and the arrival of Capt. Adam Murray with a troop of horse saved the situation. Lundy was deprived, and allowed to escape in disguise. On April 19 Walker and Maj. Henry Baker were chosen joint governors. Walker commanded 15 companies (900 men) and to him also was entrusted the supervision of the commissariat. He showed great energy, courage and resource throughout the siege, and led several successful sallies. At the close of the siege, which lasted 150 days, the town was at the last extremity; but on July 30 Walker preached the last of the sermons by which he had helped to inspire its defense. An hour later ships were seen approaching, and the town was relieved.

Walker was received by William and Mary at Hampton court on Aug. 9. 1689. He was nominated to the bishopric of Londonderry, but was shot at the Boyne, July 1. 1690.

WALKER, HENRY OLIVER (1843–1929), U.S. painter, known mainly for his murals, was born at Boston, Mass., on May 14, 1843. He was a pupil of Léon Bonnat in Paris. Walker at first painted the figure and occasional portraits, but later he devoted himself almost exclusively to mural decoration.

His paintings, symbolizing lyric poetry. for the Library of Congress. Washington. D.C., and his decorations for the appellate courthouse in New York city, the enlarged statehouse at Boston. the Essex county courthouse at Newark. N.J.. and the capitol at St. Paul. Minn., are among his most important works. He died in Belmont. Mass.. on Jan. 14, 1929.

WALKER, HORATIO (1858–1938), U.S.-Canadian painter. whose subjects were most often taken from Canadian peasant life. was born at Listowel. Ont., on May 12. 1858. \t7hen he was a child his family settled at Rochester, N.Y. Although entirely self-taught, he became a distinguished painter of animals. the figure and landscape. His pictures show the influence of Troyon and Millet. mainly in their feeling for largeness of composition, in solidity of painting and in the choice of themes. Walker was a member of the National Academy of Design, New York city, and of the American Water Color society. Among the several U.S. galleries that exhibit his works are the City Art museum. St. Louis. Mo. ("Milking, Evening" and "Woodcutters"), and the Albright gallery. Buffalo, N.Y. ("Prodigal Son").

WALKER, OBADIAH (1 616-1699), master of University college, Oxford, was born at Darfield, near Barnsley, Yorkshire, and was educated at University college. Oxford, becoming a fellow and tutor. In 1638 he was deprived of his academic appointments. but he returned to Oxford at the restoration of 1660. In June 1676 he was elected to the headship of University college. Xfter the accession of James II Walker declared himself a Catholic, being partly responsible for the tactless conduct of James in forcing a quarrel with the fellows of Magdalen college. Mass was said in his residehce, and later a chapel was opened in the college for Roman Catholic worship. He died on Jan. 21, 1699.

WALKER, ROBERT (fl. 1641–1660?), English portrait painter, much employed by the parliamentarians. His portraits of Oliver Cromwell (National Portrait gallery, London. and elsewhere), "Henry Ireton" and "John Lambert" (National Portrait gallery!, "Colonel Hutchinson" and "Mrs. Hutchinson" (Milton park, Northants), and "The Marquess of Hertford" (1656, Syon house, Middlesex) show a slavish dependence on Van Dyck (a plagiarism with which he was reproached by his contemporaries), an impersonal use of paint and no sense of colour. There is. however, a dour sincerity in the heads, and such portraits on a smaller scale as his self-portraits (at Belvoir: Ashmolean museum. Oxford; and Hampton court) or the "John Evelyn" (1648; Evelyn collection. Christ Church, Oxford) are native portraits of some character. He painted copies of some of the Titians in the collection of Charles I. He appears in the records of the Painter Stainers company between 1641 and 1652 and he may have survived until after the Restoration.

See E. Waterhouse, *Painting in Britain, 1530 to 1790* (1953). (O. M.)

WALKER, ROBERT JOHN (1801–1869), U.S. senator, secretary of the treasury and governor of the Kansas territory, was born on July 19, 1801 at Northumberland, Pa. He was graduated from the University of Pennsylvania in 1819 at the head of his class, and was soon thereafter admitted to the bar. He early associated himself with the Republican-Democratic party and played a prominent part in organizing a Jacksonian movement in the state. In 1825 he married Mary Bache, great granddaughter of Benjamin Franklin, and the next year moved to Natchez, bliss., to join his brother in the practice of law. Speculation in public lands, however; soon absorbed his attention, and by assisting squatters and small bidders to secure plots at low prices he gained a popularity that opened the nay to a public office.

In 1835 Walker won a seat in the U.S. senate, where he quickly gained a reputation as a ready speaker and an ardent supporter of Democratic party measures. He was particularly active in moves to secure land legislation favourable to the actual settler and to the nevi-er states. He opposed Whig efforts to increase the tariff and to distribute proceeds from the sale of public lands to the states. He kept a firm hold on his own state by supporting the moves to repudiate the huge debt contracted by extravagant internal improvements and excessive bank loans. He was re-elected to the senate in 1841.

Always a promoter and expansionist in temper, Walker early became interested in Texas. He sponsored the senate bill of 1837 for the recognition of Texas independence, and worked closely with Pres. John Tyler for annexation. In Jan. 1844 he wrote a long letter to friends in Kentucky setting forth the great benefits to be derived from annexation and the grave dangers of permitting Texas to fall into British hands. Widely circulated throughout the United States. this letter played an important part in forcing the Texas question into the presidental campaign of that year and in giving James K. Polk the presidency. For Walker's services Polk named him secretary of the treasury.

In his first annual report as secretary, Walker advocated a reduction of the tariff to a revenue basis, and then framed the administration bill for that purpose. The report was hailed as a "classic of free-trade literature," and the passage of the "Walker tariff" played an important part in preparing British public opinion for acceptance of a compromise settlement of the Oregon boundary. Walker also won acclaim by establishing a warehouse system for handling imports and for his part in the creation of the department of the interior.

Out of office in 1849, Walker remained in Washington practising law and promoting land and railroad schemes. Pres. Franklin Pierce offered him the mission to China but a misunderstanding occurred and he resigned immediately after acceptance. He had again resumed his business activities when Pres. James Buchanan implored him to accept the governorship of the Kansas territory. It was a difficult assignment but, given assurance that the administration would back him in permitting the people of the territory to decide the slavery issue for themselves. Walker accepted. In Kansas he attempted to secure the co-operation of the free-soil forces by promises of fair elections and assurance that "climate not politics" would decide the issue. The inference that climate forbid slavery antagonized the south and frightened the administration. Walker's rejection of fraudulent votes in Kansas elections and his refusal to accept the Lecompton constitution brought his recall and his break with the Democratic party.

During the Civil War Walker served the treasury department abroad, selling federal bonds and undermining Confederate credit by linking Jefferson Davis with Mississippi repudiation—a thing which he himself had supported and which Davis had opposed. Xfter the war he continued his law practice and played some part in pushing the Alaska purchase bill through congress.

See for the best study of Walker, H. D. Jordan, "A Politician of Expansion," *Miss. Valley Hist. Rev.*, xix, 362–381 (Dec. 1932); W. E. Dodd, "Robert J. Walker, Imperialist,!' Chicago Literary Club *Papers* (1914). (Ay. Cn.)

WALKER, WALTON HARRIS (1889–1950), U.S. army officer, who commanded United Nations and Republic of Korea ground troops during the Korean war, was born in Belton, Tex., on Dec. 3, 1889, and graduated from the U.S. Military academy in 1912. He served with Funston's Veracruz expedition in 1914 and commanded a machine-gun battalion in France during World War I. During World War II Walker commanded the 4th armoured corps (later redesignated the 20th corps), and organized the vast desert training centre in California. With Gen. George S. Patton's 3rd army in Europe, he achieved outstanding offensive success by aggressive employment of co-ordinated infantry and armoured units. His 20th corps, the "ghost corps," liberated Chartres and Verdun, fought at Metz, helped reduce the Saar-Palatinate pocket and captured Erfurt and Weimar.

Walker was commanding the 8th army in Japan when the North Koreans invaded South Korea in 1950, and he was promptly appointed ground commander in Korea. His skillful defense of the Pusan perimeter prevented the expulsion of UN forces and made it possible for Gen. Douglas MacArthur to outflank and rout the North Koreans by the amphibious landing at Inchon. Walker's 8th army pushed to the Manchurian border, but entry into the conflict of Chinese Communist forces necessitated withdrawal. He died in an automobile accident near Seoul, Dec. 23, 1950, and was posthumously promoted to full general. (&!IN. BN.)

WALKER, WILLIAM (1824–1860), U.S. adventurer, was born in Nashville. Tenn., on May 8, 1824. He graduated at the University of Nashville in 1838, and in 1843 received his M.D. from the University of Pennsylvania. Later he studied law and was admitted to the bar in New Orleans. On Oct. 15, 1853, he sailed from San Francisco with a filibustering force for the conquest of Mexican territory. He landed in lower California, and on Jan. 18, 1854, proclaimed this and the neighbouring state of Sonora an independent republic. Starvation and Mexican attacks led to the abandonment of this enterprise, and Walker resumed his journalistic work in California. On May 4, 1855, with 56 followers, Walker sailed for Nicaragua, having been invited by one of the belligerent factions to come to its aid. In October Walker seized a steamer on Lake Nicaragua belonging to the Accessory Transit company, a U.S. corporation engaged in transporting freight and passengers across the Isthmus, and was thus enabled to surprise and capture Granada and make himself 'master of Nicaragua. Peace was then made; Patricio Rivas, who had been neutral, was made provisional president, and Walker secured the real power as commander of the troops. At this time two officials of the Accessory Transit company determined to use Walker as their tool to get control of that corporation, then dominated by Cornelius Vanderbilt. They advanced him funds and transported his recruits from the United States free of charge. In return Walker seized the property of the company, on the pretext of a violation of its charter, and turned over its equipment to the men who had befriended him.

On May 20, 1856, the new government was formally recognized at Washington by Pres. Franklin Pierce. Walker managed to maintain himself against a coalition of Central American states, led by Costa Rica, which was aided and abetted by agents of Cornelius Vanderbilt, until May 1, 1857, when, to avoid capture by the natives, he surrendered to Commander Charles Henry Davis, of the U.S. navy, and returned to the United States In Nov. 1857 he sailed from Mobile with another expedition, but soon after landing at Punta Arenas he was arrested by Commander Hiram Paulding of the U.S. navy, and had to return to the United States as a prisoner on parole. On his arrival he was released by order of Pres. James Buchanan.

After several unsuccessful attempts to return to Central America, Walker finally sailed from Mobile in Aug. 1860 and landed in Honduras. There he was taken prisoner by Capt. Salmon, of the British navy, and was surrendered to the Honduran authorities. He was executed Sept. 12, 1860.

See Walker's own narrative, accurate as to details, *The War in Nicaragua* (1860) ; also W. V. Wells, *Walker's Expedition to Nicaragua* (1856) ; C. W. Doubleday, *Reminiscences of the "Filibuster" War in Nicaragua* (1886) ; J. J. Roche, *The Story of the Filibusters* (1891), revised and reprinted as *Byways of War* (1901); and W. O. Scroggs, *Filibusters and Financiers* (1916) (W. O S)

WALKER, WILLIAM HULTZ (1869–1934). U.S. chemical engineer who made important contributions to the development of methods for manufacturing acetate rayon and for waterproofing fabrics, was born in Pittsburgh, Pa., April 7, 1869. After receiving a B.S. degree from Pennsylvania State college in 1890 and M.A. and Ph.D. degrees from Gottingen, Ger., in 1892, he taught chemistry for two years at Pennsylvania State college and then in 1894 became a professor at Massachusetts Institute of Technology. He organized the institute's department of chemical engineering in 1905, the research laboratory of applied chemistry in 1907 and the school of chemical engineering practice in 1916. He remained on the institute's staff until 1921.

From 1900 through 1905, Walker and A. D. Little operated a partnership as consulting chemists. Walker's work resulted in many discoveries and inventions. including the methods for producing rayon and waterproofing fabrics. *(See* SYNTHETIC FIBRES: *History.)* During World War I, Walker did important work on poison gases and the production of helium while in charge of the chemical service section of the U.S. army and the Edgeworth arsenal. Walker was associate editor of the *Journal of Industrial and Engineering Chemistry* and received many professional, academic, military and civilian honours. He died July 9, 1934, near Seabrook, N.H. (W. E. HD.)

WALKING, as a recreational activity distinct from competitive sport, is a pleasant method of promoting physical fitness, especially among those whose occupations are sedentary. It combines a natural means of exercise with the advantage of economy, for it requires no special equipment. Since the walker can adjust the length and duration of his exercise to suit his wishes, it does not impose physical strain except perhaps on those who undertake walking among hills or mountains.

Many persons choose walking, mainly on weekends or holidays, as a solitary form of relaxation, but youth clubs and other groups arrange rambles or hikes. The normal length of the walk undertaken is from 7 to 12 mi. for a half-day or from 12 to 20 mi. for a full day. These organized rambles, in which the desire for exercise is combined with a love of the countryside, are held in the country districts surrounding large towns and follow a route previously decided upon by the leader or a specially chosen route published in a newspaper or magazine.

For those who follow the pastime regularly and intensively, there are associations established in some countries, such as the Ramblers' association in Great Britain and the Wilderness society in the United States. These encourage walking and protect the interests of their members by making representations to preserve footpaths, bridle paths and rights of way in parkland, common land and recognized open spaces in areas of natural beauty against the encroachment of builders, local authorities and national undertakings. They also help walkers to obtain hostel accommodation, and by exchange of information and services enable those of one country to pursue their activities in others. The Appalachian Trail conference, with the aid of its member organizations in 14 states, maintains campsites and a trail more than 2.000 mi. long from Mt. Katahdin in Maine to Mt Oglethorpe in Georgia; it publishes information on conditions of the camps and trail. (J. C. G. C.)

Walking Races. — These races are tests of speed and endurance in walking, either over a measured distance or in a set period of time Walking is often called the "heel and toe" sport because the early method of judging the fairness of competitors laid emphasis on these as points of contact with the ground.

As a healthful form of recreation walking races have no superior, for the contestant derives all the benefits of complete and prolonged muscular exercise accompanied by stimulation of the heart and lungs. A competitive span of 20 years is quite normal among devotees, while some have won world honours in their mid-40s.

Walking is used as a test of fitness, notably in England, where it is embraced in the duke of Edinburgh's scheme for boys, in Sweden and in the Netherlands. In Sweden it was made a national fitness test in the early 1930s and by 1960 about 3,000,000 Swedish men. women and boys possessed the time qualification badge. The Nijmegen marches in the Netherlands, organized by the Dutch League of Physical Culture, are open to the world in both civilian and military categories. The test comprises four separate days' consecutive walking over distances up to 35 mi. each day, with about 12,000 persons taking part.

There have been some remarkable results in both speed and endurance: V. Hardmo of Sweden covered 2 mi. in 12 min. 45 sec. and D. J. Thompson of England covered the 53 mi. from London to Brighton in 7 hr. 35 min. 12 sec. The study of walking mechanics has made its contribution to these results, especially the part played by the hips in extending the length of stride while keeping the rate of energy used very low. This allows the average race walker to stride $\frac{4}{7}$ of his standing height without the necessity of lifting his body weight.

Thk shortest racing distance in common usage is that of 1 mi., popular in the United States for indoor meets but in other countries mainly used for junior competitions. The longest annual event is from Paris to Strasbourg, a distance of 312 mi.; this nonstop race is usually won in a time around 70 hr.

The popularity of nalking as a sport dates from the latter part of the 19th century, although chronicles of single walking feats go back many decades. Between 1850 and 1870 it was mainly professional and many a record was made as the result of a staked wager. Sometimes it was man versus horse, with the man invariably winning if the duration was great enough. Notable walkers of those days mere C. Westhall, W. Perkins, H. Thatcher, J. H. Hocking and J. W. Raby. In England, organized control of walking came when the Amateur Athletic club introduced a 7-mi. event into their championships of 1866, won in the time of 59 min. 32 sec. by J. G. Chambers. His name is perpetuated on the vase named for him and still awarded to the winner of that event.

In the 1870s and 1880s a number of U.S. handicap and distance events were held, a feature of that era being a six-day (144-hr.) go-as-you-please race in the Gilmore gardens in New York city. The men walked rapidly as long as they could, rested or napped, then returned to walk again; the competitor who covered the longest distance at the end of the week was the winner.

Walking races were first part of the Olympic games in 1908 when the British walkers G. E. Larner and E. J. Webb finished first and second in both 3.500-m. and 10-mi. events. Only once after that was a short-distance walk included—in 1920 when one of 3.000 m. mas tried. No walk was included in 1928 because of judging difficulties, but in 1932 a longer distance of 50.000 m. was won by T. W. Green of Great Britain. This distance remained, but the 10.000 m reintroduced in 1948 was superseded by one of 20,000 m. on a closed road circuit. Italy, Sweden and the U.S.S R. in turn dominated these walking races. For complete record of Olympic walking races, see OLYMPIC GAMES.

The United States developed outstanding performers in W. Milhalo, W. Chisholm and Henry Laskau, but these set up no recognized amateur records. However, Milhalo turned professional in 1952 and in four years established 59 world professional records, nearly all of which were better than the comparable amateur standards. Among them was the feat of walking 140 mi, in 24 hr. (H. H. W.)

WALKING FERN (Camptosorus *rhizophyllus*), a small fern notable for its curious method of producing new plantlets at the tips of the leaves or fronds that touch ground. It is native to, but not common in, the eastern United States, where it is found mostly on limestone outcroppings. The bluish-green, spear-shaped fronds are 4 to 12 in. long and are, unlike the popular conception of fern leaves, undivided; they arise from a short, erect or ascending rootstock Colonies of these ferns are sometimes seen growing on mossy boulders.

WALKLEY, ARTHUR BINGHAM (1855–1926), English dramatic critic, son of Arthur Hickman Walkley, was born at Bristol on Dec 17, 1855. He was educated at Warminster school, Balliol and Corpus Christi colleges, Oxford. In 1877 he entered the post office in a junior capacity, rising to become assistant secretary in 1911. He was dramatic critic to the Star, the Speaker and the Tinzes.

His criticism was none the less serious for being shrewd and witty, and was given greater value by his determination "that his work was the creative art of letters not the writing of news." Two volumes have been published of his collected Times articles. He died at Brightlingsea, on Oct. 7, 1926.

WALL, RICHARD (1694–1778), diplomat and minister in the Spanish service, belonged to a family settled in Waterford. Debarred from public service at home as a Roman Catholic, he served in an Irish regiment—probably—of the Spanish army during the expedition to Sicily in 1718. Appointed secretary to the duke of Liria, his knowledge of languages, his adaptability, his Irish wit and self-confidence made him a favourite not only with the duke of Liria, but with other Spanish authorities. He became known to Jose Patiño, minister to Philip V, and was sent by him on a mission to Spanish America. In 1747 he was employed in the peace negotiations at Aix-la-Chapelle, and in 1748 was named minister in London, where he was popular. A partisan of an English alliance, his views recommended him to the favour of Ferdinand VI (1746–59), whose policy was resolutely peaceful. From 1752–64 he was minister of foreign affairs at Madrid. Charles III (1759–88) continued Wall in office, but the king's close relations with the French branch of the House of Bourbon made Wall's position very trying: as a foreigner he was suspected of favour to the English. Charles, however, detested changing his ministers and Wall only extorted leave in 1764 by feigning a disease of the eyes. He was given a handsome allowance and a grant for life of the crown land near Granada, which afterward became Godoy's and finally, the duke of Wellington's.

See Coxe, *Memoirs of the Kings of Spain of the House of Bourbon* (1815) ; *Documentos inéditos para la historia de España,* **vol. xciii.** (1842 *et seq*).

WALLABY (BRUSH KANGAROO) : see KANGAROO.

WALLACE, ALFRED RUSSEL (1823–1913), British naturalist famous for his joint communication with Charles Darwin on the origin of species by natural selection, was born at Usk, Monmouthshire, on Jan. 8, 1823. After leaving school he worked as a land surveyor and architect. About 1840 he began to take an interest in botany, and began the formation of a herbarium. In 1844–45, while an English master in the Collegiate school at Leicester, he met Henry W. Bates (*q.v.*), through whose influence he became interested in beetles, and with whom he went in 1848 on an expedition to the Amazon. In March 1850 the two naturalists separated, and each wrote an account of his travels and observations. Wallace's Narrative of Travels on the Amazon *and* Rio Negro was published in 1853. On his voyage home the ship was burned and his collections lost, except those which he had dispatched beforehand. In 1854–62 he made a tour in the Malay archipelago. His *The* Malay Archipelago appeared in 1869. The chief parts of his vast insect collections eventually passed into the Hope collection of the University of Oxford and the British museum. Wallace divided the Malay archipelago into a western group of islands, which in their zoological affinities are oriental. and an eastern, which are Australian. The oriental Borneo and Bali are respectively divided from Celebes and Lombok by a narrow belt known as "Wallace's Line," on the opposite sides of which the indigenous Mammalia are as widely divergent as in any two parts of the world. Wallace originated his theory of natural selection during these travels.

Origin **of** Species.—In Feb. 1855, staying at Sarawak in Borneo, he wrote an essay "On the Law Which Has Regulated the Introdpction of New Species" (*Ann.* and *Mag. Nat. Hist.*, 1855. p. 184). He states the law as follows: "Every species has come into existence coincident both in time and space with a pre-existing closely-allied species." For three years, so he tells us, "the question of how changes of species could have been brought about nas rarely out of my mind." Finally, in Feb. 1858, during a severe attack of intermittent fever at Ternate. in the Moluccas, he began to think of Thomas R. Malthus' Essay on *Population* (see MALTHUS, THOMAS ROBERT), and, to use his own words, "there suddenly flashed upon me the idea of the survival of the fittest." The theory was thought out during the rest of the ague fit, drafted the same evening, written out in full in the two succeeding evenings and sent to Darwin by the next post. Darwin in England at once recognized his own theory in the manuscript essay sent by the young and almost unknown naturalist in the tropics, then a stranger to him. "I never saw a more striking coincidence." he wrote to Sir Charles Lyell (*q.v.*), on the very day, June 18, when he received the paper: "if Wallace had my manuscript sketch written out in 1842, he could not have made a better short abstract! Even his terms now stand as heads of my chapters."

Under the advice of Lyell and Sir Joseph Hooker (*q.v.*), the essay was read, together with an abstract of Darwin's own views, as a joint paper at the Linnean society on July 1, 1858. The title of Wallace's section was "On the Tendency of Varieties to Depart Indefinitely From the Original Type." The "struggle for existence," the rate of multiplication of animals, and the dependence of their average numbers upon food supply are very clearly demonstrated, and the following conclusion nas reached: "Those that prolong their existence can only be the most perfect in health and vigour; . . . the weakest and least perfectly organized must always succumb."

The difference between Lamarck's theory (see LAMARCKISM) and natural selection is very clearly pointed out. "The powerful retractile talons of the falcon and the cat tribes have not been produced or increased by the volition of those animals; but among the different varieties which occurred in the earlier and less highly organized forms of these groups, *those always survived longest which had the greatest facilities for seizing their prey.* Neither did the giraffe acquire its long neck by desiring to reach the foliage of more lofty shrubs, and constantly stretching its neck for the purpose, but because any varieties which occurred among its antetypes with a longer neck than usual *at once secured a fresh range of pasture over the same ground as their shorter-necked companions, and on the first scarcity of food were thereby enabled to outlive them."* Wallace also alluded to the resemblance of animals, and more especially of insects, to their surroundings, and pointed out that "those races having colours best adapted to concealment from their enemies would inevitably survive the longest."

Natural Selection.—In 1870 Wallace's two essays, written at Sarawak and Ternate, were published with others as a volume, *Contributions to the Theory of Natural Selection.* In the additional essays, the new theory was applied to the interpretation of certain classes of facts. In this and other works, Wallace differed from Darwin on certain points. Thus the two concluding essays contend that man has not, like the other animals, been produced by the unaided operation of natural selection, but that other forces have also been in operation. Here may be seen the influence of Wallace's convictions on the subject of spiritualism. He expressed his dissatisfaction with the hypothesis of "sexual selection" by which Darwin sought to explain the conspicuous characters which are displayed during the courtship of animals. The expression of his opinion on both these points of divergence from Darwin will be found in *Darwinism* (1889).

Darwin died before the controversy upon the possibility of the hereditary transmission of acquired characters arose over the writings of August Weismann (*q.v.*), but Wallace freely accepted the general results of the German zoologist's teaching, and in *Darwinism* presented a complete theory of the causes of evolution unmixed with any trace of Lamarck's use or disuse of inheritance, or the comte de Buffon's hereditary effect of the direct influence of surroundings. *Tropical Nature and Other Essays* appeared in 1878, and was later republished combined with the 1871 *Essays.* His *Geographical Distribution of Animals* appeared in 1876 and *island Lzfe,* a supplement to it, in 1880.

Miscellaneous **Works.**—Wallace published *Miracles and Modern Spiritualism* in 1875 (new ed., 1896), in which he gives the experimental reasons for his beliefs. which were in no way connected with revealed religion. In 1882 he published *Land Nationalization,* in which he argued the necessity of state ownership of land, a principle which he had originated long before the appearance of Henry George's work. In *Forty-five Years of Registration Statistics* (1885) he maintained that vaccination is useless and dangerous. Wallace also published an account of what he held to be the greatest discoveries as well as the failures of the 19th century, *The Wonderful Century* (1898; new ed., 1903). His later works include *Studies, Scientific and Social* (1900), *Man's Place in the Universe* (1903), *The World and Life* (1910) and *Social Environment and Moral Progress* (1912). He published his autobiography, *My Life,* in 1905 (new ed., 1908). Possessed of a bold and original mind, his activities radiated in many directions, apparently rather attracted than repelled by the unpopularity of a subject. A nontheological Athanasius, he had the truest missionary spirit.

Wallace was married in 1866 to the eldest daughter of the botanist William Mitten, of Hurstpierpoint, Sussex. In 1910 he received the Order of Merit. Wallace died at Broadstone, Dorset, on Nov. 7, 1913.

WALLACE, SIR DONALD MACKENZIE (1841–1919), British author and journalist, was born on Nov. 11, 1841. He was educated at the universities of Glasgow, Edinburgh, Berlin and Heidelberg and at the École de Droit. Paris. When 28 years of age he was invited by a friend to visit Russia, and became so much interested that he remained there six years. His *Russia* (1877) had a great success, and was at once recognized as a classic. Mackenzie Wallace acted as correspondent of the *Times* (London) in St. Petersburg (Leningrad), Berlin and Constantinople, and after the battle of Tell-el-Kebir (1882) in Egypt. From 1884 to 1889 he was in India as private secretary to the viceroy, Lord Dufferin, and to his successor, Lord Lansdowne. From 1891 to 1899 he was director of the foreign department of the *Times.* In 1899 he undertook the editorship of the new volumes (issued in 1902 as the 10th edition) of the *Encyclopedia Britannica.* Wallace died at Lymington, Hampshire, on Jan. 10, 1919.

WALLACE, HENRY AGARD (1888–), 33rd vice-president of the United States, was born in Adair county, Ia., Oct. 7, 1888. After graduating from Iowa State college, Ames, in 1910, he joined the staff of *Wallace's Farmer.* This magazine had been founded by his grandfather and was later edited by his father, who served as secretary of agriculture under President Harding and President Coolidge. Wallace studied farm prices, produced the first corn–hog ratio charts and forecast the farm price collapse of 1920. His experiments with higher yielding corn strains resulted in major advances in plant genetics.

Wallace, formerly a Republican, shifted to the Democratic party in 1928, and edited *Wallace's Farmer and Iowa Homestead* from 1929 to 1933. As secretary of agriculture under Pres. Franklin D. Roosevelt from 1933 to 1940, he helped formulate and administer the Agricultural Adjustment acts to conserve the soil, store reserves, control production and raise farm prices.

He was President Roosevelt's choice for vice-president in 1940. As vice-president, Wallace became Roosevelt's good-will ambassador in Latin America and also traveled in the far east. During World War II he assumed many emergency duties in addition to the vice-presidency. After being passed over for renomination as vice-president in 1944, Wallace became secretary of commerce in 1945 and continued in that position under Pres. Harry S. Truman. But his plans for revitalizing the department were overshadowed by his criticisms of the Truman administration's "get tough" policy with the Soviet Union and his warnings against getting into an atom bomb race with the Russians.

Wallace left the Truman cabinet in 1946 and became editor of the *New Republic.* He resigned this position late in 1947 to become the Progressive party candidate for president. He campaigned for closer co-operation with the U.S.S.R.; urged that the United Nations administer all foreign aid; favoured reduction of armaments; and opposed universal military training. He got more than one million popular votes but no electoral votes. Later he broke with the Progressive party and returned to private life.

Wallace was a prolific writer. His best known works are *Sixty Million Jobs* (1945), which called for governmental action to supplement private enterprise; *The Century of the Common Man* (1943); and *America Must Choose* (1934).

Bibliography.—Russell Lord, *The Wallaces of Iowa (1947)*; Karl M. Schmidt, *Henry A. Wallace: Quixotic Crusade, 1948* (1960); Dwight Macdonald, *Henry Wallace, the Man and Myth* (1948). (T. Ss.)

WALLACE, LEWIS (Lew) (1827–1905), U.S. army officer and author, was born at Brookville, Ind.. April 10, 1827. He abandoned law in Indianapolis to recruit volunteers for the Mexican War, and served in 1846–47. In the Civil War he served with the Union forces and attained the rank of major general of volunteers. He served as president of the courts of inquiry that investigated the conduct of Gen. D. C. Buell and condemned Henry Wirz, commander of the Confederate prison at Andersonville, Ga. He was also a member of the court that tried the persons charged with conspiracy against Pres. Abraham Lincoln. He resigned from the army in 1865 and resumed the practice of law. He was governor of New Mexico territory (1878–81) and minister to Turkey (1881–85). He died at Crawfordsville, Ind., Feb. 15, 1905. His literary reputation rests upon three historical romances: *The Fair God* (1873), a story of the conquest of Mexico; *Prince of India* (1893), dealing with the Wandering Jew and the Byzantine empire; and his greatest popular success. *Ben Hur* (1880), a tale of the coming of Christ, which was translated into several languages and made into a play and a motion picture. *Lew Wallace: An Autobiography* was published in 1906.

WALLACE, SIR RICHARD (1818–1890), English art collector and philanthropist whose name is perpetuated by the famous collection at Hertford house, Manchester square, London, was born in London on June 21, 1818. A natural son of Viscount Beauchamp, later the 4th marquess of Hertford, and Agnes Jackson, née Wallace, he was educated in Paris and, after the 3rd marquess' death in 1842, acted as confidential secretary to the 4th marquess, assisting him in the formation of his magnificent art collections. In 1870 Lord Hertford died, leaving Wallace heir to the bulk of his large fortune, his unentailed property and his entire art collections. The part of these collections that eventually went to form the celebrated museum at Hertford house owes its character to both men. Lord Hertford assembled most of the superb French 17th- and 18th-century furniture and minor arts, the old masters and the modern French paintings, to which Wallace added the armour and the medieval and Renaissance objects of art. In 1871 he was created a baronet for his services to the English community during the siege of Paris. He was a British commissioner at the Paris exhibition of 1878 and also a trustee of the National gallery, the National Portrait gallery and a governor of the National Gallery of Ireland. He sat in parliament for Lisburn, Ire., from 1873 to 1885, when he retired to Paris, where he died on July 20, 1890. His wife, who died in 1897, bequeathed to the British nation those sections of the art collections, then housed on the ground and first floors of Hertford house, which form the Wallace collection.

See General Guide to the Wallace Collection (1958). (F. J. B. W.)

WALLACE, SIR WILLIAM (*c.* 1270–1305), the popular national hero of Scotland, is believed to have been the second son of Sir Malcolm Wallace of Elderslie and Auchinbothie, in Renfrewshire. The only authority for the events of his early life is the metrical history of Blind Harry, who lived about two centuries later than Wallace, during which a considerable body of legend had probably gathered round the name. At the same time he professes to follow as his "autour" an account that had been written in Latin by John Blair, the personal friend and chaplain of Wallace himself. Blair's account has perished.

In his boyhood, according to the usual accounts, he resided for some time at Dunipace, in Stirlingshire, with an uncle, who is styled "parson" of the place. His education was continued at Dundee, where he made the acquaintance of John Blair. On account of an incident that happened at Dundee—his slaughter of a young Englishman named Selby, for an insult offered to him—he is said to have been outlawed, and so driven into rebellion against the English. He gradually gathered round him a body of desperate men whom he led in various attacks upon the English. Several of the more patriotic nobles—including the steward of Scotland, Sir Andrew Moray, Sir John de Graham, Douglas the Hardy, Wishart, bishop of Glasgow, and others—joined him. An attack was made upon the English justiciar, Ormsby, who was holding his court at Scone. The justiciar himself escaped, but many of his followers were captured or slain. The burning of the Barns of Ayr, the quarters of English soldiers, in revenge for the treacherous slaughter of his uncle, Sir Ronald Crawford, and other Scottish noblemen, followed.

The success of these exploits induced the English king to send an army, under the command of Sir Henry Percy and Sir Robert Clifford, against the insurgents. The English came up with Wallace at Irvine, when all Wallace's titled friends left him and made submission to Edward, except the ever faithful Sir Andrew Moray. The treaty of Irvine by which these Scottish nobles made submission, is printed in Rymer's *Foedera.* It is dated July 9, 1297, and is the first public document in which the name of Sir William Wallace occurs. Wallace retired to the north, and although deserted by the barons was soon at the head of a large army. In a short time he recovered almost all the fortresses held by the English to the north of the Forth. He had begun the siege of Dundee when he heard that an English army, led by the earl of Surrey and Cressingham the treasurer, was on its march northward.

Battle of Stirling.—Leaving the citizens of Dundee to continue the siege of the castle, he made a rapid march to Stirling. Encamping in the neighbourhood of the Abbey Craig—on which now stands the national monument to his memory—he watched the passage of the Forth. After an unsuccessful attempt to bring Wallace to terms, the English commander, on the morning of Sept. 11, 1297, began to cross the bridge. When about one half of his army had crossed, and while they were still in disorder, they were attacked with such fury by Wallace, that almost all—Cressingham among the number—were slain, or driven into the river and drowned. Those on the south side of the river were seized with panic and fled tumultuously, having first set fire to the bridge. The Scots, however, crossed by a ford, and continued the pursuit as far as Berwick. Sir Andrew Moray was killed.

Its results were important. The English were everywhere driven from Scotland. To increase the alarm of the English, as well as to relieve the famine which then prevailed, Wallace organized a great raid into the north of England, in the course of which he devastated the country to the gates of Newcastle. On his return he was elected guardian of the kingdom. In this office he set himself to reorganize the army and to regulate the affairs of the country. His measures were marked by much wisdom and vigour, and for a short time succeeded in securing order, even in the face of the jealousy and opposition of the nobles.

Battle of Falkirk.—Edward was in Flanders when the news of this successful revolt reached him. He hastened home, and at the head of a great army entered Scotland in July 1298. Wallace slowly retired before the English monarch, driving off all supplies and wasting the country. The nobles as usual for the most part deserted his standard. Edward, compelled by famine, had already given orders for a retreat when he received information of Wallace's position and intentions. The army, then at Kirkliston, was immediately set in motion, and next morning (July 22, 1298) Wallace was brought to battle in the vicinity of Falkirk. After an obstinate fight the Scots were overpowered and defeated with great loss. Among the slain was Sir John de Graham, the bosom friend of Wallace, whose death, as Blind Harry tells, threw the hero into a frenzy of rage and grief. The account of his distress is one of the finest and most touching passages in the poem. With the remains of his army Wallace found refuge for the night in the Torwood—known to him from his boyish life at Dunipace. He then retreated to the north, burning the town and castle of Stirling on his way. He resigned the office of guardian, and betook himself again to predatory warfare against the English.

Betrayal.—At this point his history again becomes obscure. He is known to have paid a visit to France, with the purpose of obtaining aid for his country from the French king. This visit is narrated with many untrustworthy details by Blind Harry; but the fact is established by other and indisputable evidence. When in the winter of 1303–1304 Edward received the submission of the Scottish nobles, Wallace was expressly excepted from all terms. A price was set upon his head, and the English governors and captains in Scotland had orders to use every means for his capture. On Aug. 5, 1305 he was taken—as is generally alleged, through treachery—at Robroyston, near Glasgow, by Sir John Menteith, carried to the castle of Dumbarton, and thence conveyed in fetters and strongly guarded to London. He reached London on the 22nd of August, and next day was taken to Westminster Hall, where he was impeached as a traitor by Sir Peter Mallorie, the king's justice. To the accusation Wallace made the simple reply that he could not be a traitor to the king of England, for he never was his subject, and never swore fealty to him. He was found guilty and condemned to death. The sentence was executed the same day with circumstances of unusual cruelty.

For bibliography *see* the article in the *Dict. Nat. Biog. The* principal modern lives are James Moir's (1886), and A. F Murison's (1898). (A. F. Hu.; X.)

WALLACE, WILLIAM VINCENT (1812–1865), Irish composer, was born at Waterford, Ireland, on Mar. 11, 1812. He led a roving and adventurous career in Australia, the South Seas, India, and S. America. In 1845 he settled in London and in November of that year his opera *Maritana* was played at Drury Lane theatre with great success. This was followed by *Matilda of Hungary* (1847). *Lurline* (1860), *The Amber Witch* (1861), *Love's Triumph* (1862), and *The Desert Flower* (1863). He also composed for the piano He died on Oct 12. 1865.

WALLACH, OTTO (1847–1931), German organic chemist awarded the Nobel prize in chemistry in 1910 for his pioneer uork on the structure of asoxy and alicyclic compounds. was born at Konigsberg, March 27, 1847. An early student of literature and art, he was attracted to chemistry by Friedrich Wöhler at Göttingen and August Wilhelm von Hofmann at Berlin. He was an assistant to Hermann Wichelhaus in Berlin and Friedrich August Kekulé at Bonn. In 1889 he was appointed director of the Chemical institute at Gottingen where he remained until his retirement in 191j. At Bonn, where Wallach taught pharmacy. he became interested in the structure of ethereal oils such as camphene. citrene, carvene, eucalyptene and related terpenes with the empirical formula $C_{10}H_{16}$. There were many of these oils which were thought at that time to be different since they occurred in a variety of plants. Utilizing common reagents such as hydrogen chloride and hydrogen bromide, Wallach by 1895 had laid the foundations for the carbon skeleton of the terpenes and characterized the differences between the structure of similar compounds. JVallach was not so much a theorist as an analyst who proved that many terpenes thought to be different were the same. By 1901, 100 papers by Wallach reported the painstaking work which formed the basis of subsequent research to determine the structure of complex naturally occurring organic substances. He wrote *Terpene und Kampfer* (1909; 2d ed.. 1914). His accuracy as an analyst was proved by synthesis of the molecules whose structure he had determined. He died Feb. 26, 1931, at Gottingen. (V. Bw.)

WALLACK, a famous family of British-U.S. actors and theatre managers. William Wallack, the founder of the family. was a leading player at Astley's amphitheatre in London. Henry John Wallack (1790–1870), his son, was born in London and appeared at Astley's at an early age. In 1819 he made his U.S. debut in Baltimore. then returned to England and played the Covent Garden theatre for several years, returning to the U.S. in 1837 to manage the first Wallack's theatre. He died in New York in 1870.

James William Wallack (1795–1864), second son of William and brother of Henry. was born in London. Aug. 24. 1795. Beginning his acting career in 180; at the age of 12, he spent the next decade chiefly at the Drury Lane theatre in London. Between 1818 and 1852 he crossed and recrossed the Atlantic. playing alternate engagements in London and New York. He became manager of the National theatre in New York in 1837 and remained there until the theatre burned two years later. For a time he managed Niblo's Gardens, and in 183'2 took over Brougham's Lyceum. renaming it Wallack's. In 1861 he built another theatre at 13th and Broadway. He died on Dec. 25, 1864.

James William Wallack II (1818–1873) was born in London on Feb. 24, 1818, the son of Henry John and nephew of James William. He played at the Covent Garden theatre under his father, and in 1837 he joined his uncle's company at the National theatre in New York. He was outstanding in tragedy and melodrama. His best roles were Fagin, Macbeth. Richard III and Iago. In 1865 he became a member of Wallack's Stock company, under his cousin Lester. He died near Aiken. S.C., on May 24. 1873.

Lester Wallack (1820–1888), christened John Johnstone Wallack, an outstanding actor, playwright and manager of the 19th century. was born in New Tork city on Jan. 1. 1820, the son of James William Wallack I. He made his first New Tork stage appearance in 1847 in Dion Boucicault's *Used Up*, and after several years of apprenticeship became an actor in his father's company. In 1861 he succeeded to the management of Wallack's theatre. His play *Rosedale; or, The Rifle Ball* was a considerable success in 1863. In 1882 he opened the New Wallack's theatre and until his retirement in 1887 managed both theatres. His productions were noted for their polish. A spectacular benefit was held in his honour in 1888, when Edwin Booth, Lawrence Barrett, Joseph Jefferson. Helena Modjeska and other stars performed *Hamlet*. Wallack died on Sept. 6, 1888, at his home near Stamford. Conn. His memoirs, *Memories of Fifty Years*, were published in 1889. (S. W. H.)

WALLASEY, a municipal, county and parliamentary borough. Cheshire. Eng., 20 mi. N.W. of Chester by road. Pop. (1951) 101,369. Area 9.2 sq.mi. It covers the northeast tip of the Wirral peninsula, at the mouth of the Mersey river. A system of ferries connects it with Liverpool, for many of whose workers it is a dormitory suburb.

The borough includes the seaside resort of New Brighton, and the whole of its water frontage (7 mi.) is skirted by a promenade. Except in the south, where the borough adjoins Birkenhead docks, there is little industry, the area being almost entirely residential. The church of St. Hilary, a foundation of the 10th century, was rebuilt in 1759 and again in 1858 after a fire. Wallasey was incorporated in 1910, became a county borough in 1913 and a parliamentary borough in 1918.

WALLA WALLA, a city of southeastern Washington, U.S., 120 mi. S.W. of Spokane; the seat of Walla Walla county. The name was the Indian place name and means "place of many waters." Marcus Whitman, a Congregational missionary, established a mission in the locality in 1836 which became a way station on the Oregon trail until Nov. 29. 1847, when Whitman, his wife and several other members of the mission were massacred. In the succeeding Indian wars the site became a base of military operations and Ft. Walla Walla was begun in 1856. A settlement developed around the fort and in 1862 the town was laid out and incorporated. During the 1870s and early 1880s it was the largest city in the territory; bypassed by transcontinental railroads, it lost first place to Seattle by 1883 and fell behind Spokane by 1890. Stock raising. grain growing and pea canning (established by 1932) are leading industries. Branch-line railroads, good highways and excellent airport facilities make up for lack of mainline railroad service. Improvements on the nearby Columbia and Snake rivers have expanded hydroelectric power and provided slack water for barge transport. Educational facilities include Whitman college. a private college established in 183'9. and Walla Walla college, a Seventh-day Adventist institution founded in 1892 at College Place, a suburb. There is also a civic orchestra and a little theatre group. For comparative population figures *see* table in Washington: *Population.* (H. J. De.)

WALL CREEPER (*Tichodroma muraria*), a small, nonmigratory bird of the family Certhiidae. It inhabits rocky ravines and cliff faces as well as stone structures from central Europe to southern China. The total length is about 6½ in., including the short tail and slender curved bill. Although the upper parts are mainly grayish with the throat and breast black in summer and white in winter (young are like winter adults), the rounded wings have distinctive brilliant red coverts. The wall creeper has a desultory fluttering flight, spending most of its time climbing about rock faces, boulders or stonework. searching the crevices for insects. It nests well back in crevices, usually laying four eggs. (R. S. Pr.)

WALLENSTEIN (properly Waldstein). **ALBRECHT WENZEL EUSEBIUS VON,** duke of Friedland, Sagan and Mecklenburg (1583–1634). German soldier and statesman. was born at Hermanice (Hermanitz on the Elbe) in Bohemia. on Sept. 24. 1583. After the death of his parents he was sent to the Jesuit college of nobles at Olmütz. after which he professed the Roman Catholic faith. In 1599 he went to the University of Altdorf, which he had to leave in consequence of some boyish follies. Next he studied at Bologna and Padua and visited many places in southern and western Europe. While in Padua he gave much attention to astrology. and during the rest of his life he never wavered in the conviction that he might trust to the stars for indications as to his destiny. For some time Wallenstein served in the army of the emperor Rudolph II in Hungary. which was commanded by a methodical professional soldier. George Basta. His personal gallantry at the siege of Gran won for him a company without purchase. In 1606 he returned to Bohemia. and in 1609 he married an elderly widow, Lucretia von Vičkov (née Rekesch von Landeck), whose great estates in Moravia he inherited after her death in 1614. His new wealth enabled him to offer 200 horse, splendidly equipped. to the archduke Ferdinand for his war with Venice in 1617. Wallenstein commanded them in person. and from that time he enjoyed both favour at court and popularity in the army.

In the disturbances which broke out in Bohemia in 1618 and proved to be the beginning of the Thirty Years' War. advances were made to Wallenstein by the revolutionary party; but he preferred to associate himself with the imperial cause, and he carried off the treasure chest of the Moravian estates to Vienna, part of its contents being given him for the equipment of a regiment of cuirassiers. At the head of this regiment Wallenstein won great distinction under Buquoy in the war against Mansfeld. He was not present at the battle of the White Mountain (1620), but he did brilliant service as second-in-command of the army which opposed Gabriel Bethlen in Moravia, and recovered his estates which the nationalists had seized. The battle of the White Mountain placed Bohemia at the mercy of the emperor Ferdinand, and Wallenstein turned the prevailing confusion to his own advantage. He secured the great estates belonging to his mother's family, and the emperor sold him on easy terms vast tracts of confiscated lands. He was allowed to form his possessions into a territory called Friedland, and he was raised in 1622 to the rank of an imperial count palatine, in 1623 to that of a prince. In 1623 he made another wealthy marriage, with Isabella Katharina Harrach. In 1624 he was made duke of Friedland. Meantime he fought with skill and success against Gabriel Bethlen, and so enhanced his reputation at the dark moment when Vienna was in peril and the emperor's general Buquoy dead on the field of battle. He was not only the detached visionary with vast ambitions, but also the model ruler of his principality. He placed the administration of justice on a firm basis, founded schools and developed agriculture, mining and manufactures.

When the war against the Bohemians had become a widespread conflagration. Ferdinand found he had no forces to oppose the Danes and the northern Protestants other than the army of the Catholic league, which was controlled not by him but by Maximilian of Bavaria. Wallenstein saw his opportunity and early in 1626 he offered to raise not a regiment or two, but a whole army for the imperial service. After some negotiations the offer was accepted. the understanding being that the troops were to be maintained at the cost of the countries they might occupy. Wallenstein's popularity brought great numbers of recruits to his standard He soon found himself at the head of 30.000 (not long afterward of 50,000) men. For the campaigns of this army in 1625, 1626 and 1627, against Mansfeld. the northern Protestants and Gabriel Bethlen, see THIRTY YEARS' WAR.

Having established peace in Hungary. Wallenstein proceeded, in 1627, to clear Silesia of some remnants of Mansfeld's army; his outlay in the conduct of the war was to be taken into account in the conclusion of the bargain with the emperor whereby he eventually became duke of Sagan (Feb. 1628). He then joined Tilly in the struggle with Christian IV, and afterward took possession of the duchy of Mecklenburg, which was granted to him in Jan. 1628 in reward for his services, the hereditary dukes being displaced on the ground that they had helped the Danish king. He failed to capture Stralsund, which he besieged for several months in 1628. This important reverse caused him bitter disappointment, for he had hoped that by obtaining free access to the Baltic he might be able to make the emperor as supreme at sea as he seemed to be on land. It was a part of Wallenstein's scheme of German unity that he should obtain possession of the Hanseatic towns, and through them destroy or at least defy the naval power of the Scandinavian kingdom, the Netherlands and England. This plan was completely frustrated by the resistance of Stralsund. Moreover the emperor's Edict of Restitution (1629) not only rallied against him all the Protestants but brought in a great soldier and a model army, Gustavus Adolphus and the Swedes.

At the same time the victory of the principles of the league involved the fall of Wallenstein's influence. By his ambitions, his high dreams of unity and the incessant exactions of his army, he had made for himself a host of enemies. He was reported to have spoken of the arrogance of the princes, and it appeared probable that he would try to bring them, Catholics and Protestants alike. into rigid subjection to the crown. Again and again the emperor was advised to dismiss him. Ferdinand was very unwilling to part with one who had served him so well; but the demand was pressed so urgently in 1630 that he had no alternative, and in August Wallenstein was removed from his command.

Wallenstein accepted the decision calmly, gave his army to Tilly, and retired to Gitschin (Jicin), the capital of his duchy of Friedland. There, and at his palace in Prague, he lived in an atmosphere of mysterious magnificence, the rumours of which penetrated all Germany.

Gustavus Adolphus had landed in Germany, and it soon became obvious that he was formidable. Tilly was defeated at Breitenfeld and on the Lech, where he received a mortal wound, and Gustavus advanced to Munich. while Bohemia was occupied by his allies the Saxons. The emperor entreated Wallenstein to come once more to his aid. Wallenstein at first declined; he had, indeed, been secretly negotiating with Gustavus Adolphus, in the hope of destroying the league and its projects and of building his new Germany without French assistance. However, he accepted Ferdinand's offers, and in the spring of 1632 he raised a fresh army as strong as the first within a few weeks and took the field. This army was placed absolutely under his control, so that he assumed the position of an independent prince rather than of a subject. His first aim was to drive the Saxons from Bohemia—an object which he accomplished without serious difficulty. Then he advanced against Gustavus Adolphus, whom he opposed near Nuremberg and dislodged after the battle of the Alte Veste. In November came the great battle of Liitzen (*q.v.*), in which the imperialists were defeated. but Gustavus Adolphus was killed.

To the dismay of Ferdinand, Wallenstein made no use of the opportunity provided for him by the death of the Swedish king, but withdrew to winter quarters in Bohemia. In the campaign of 1633 much astonishment was caused by his apparent unwillingness to attack the enemy. He was in fact preparing to desert the emperor. In the war against the Saxons he had offeredthem as terms of peace the revocation of the edict. Religious toleration and the destruction of the separatist regime, as well as not inconsiderable aggrandizements for his own power. formed his program, so far as historians have been able to reconstruct it. and. becoming convinced from Ferdinand's obstinacy that the edict mould never be rescinded. he began to prepare to "force a just peace on the emperor in the interests of united Germany." With this object he entered into negotiations with Saxony. Brandenburg. Saeden and France. He had vast and vague schemes for the reorganization of the entire constitutional system of the empire, with himself as supreme authority.

Irritated by the distrust excited by his proposals and anxious to make his power felt, he at last assumed the offensive against the Snedes and Sasons, winning his last victory at Steinau on the Oder in October. He then resumed the negotiations. In December he retired with his army to Bohemia. fixing his headquarters at Pilsen. It had been suspected in Vienna that Wallenstein was playing a double part, and the emperor, encouraged by the Spaniards at his court. anxiously sought for means of getting rid of him. Wallenstein was well aware of the designs formed against him, but displayed little energy in his attempts to thwart them. This was due in part, no doubt, to ill-health, in part to the assurances of his astrologer, Battista Seni.

His principal officers assembled around him at a banquet on Jan. 12, 1634, when he got them to sign a declaration to the effect that they would remain true to him. On Feb. 19 a second paper was signed; but on this occasion the officers' expression of loyalty to their general was associated with an equally emphatic expression of loyalty to their emperor.

On Jan. 24 the emperor had signed a secret patent removing him from his command, and imperial agents had been labouring to undermine Wallenstein's influence. On Feb. 7 two of his officers, Octavio Piccolomini and Johann Aldringer, had intended to seize him at Pilsen, but finding the troops there loyal to their general. they had kept quiet. But a patent charging Wallenstein and two of his officers with high treason, and naming the generals who were to assume the supreme command of the army, was signed on Feb. 18 and published in Prague.

Wallenstein realized the danger and, on Feb. 23, accompanied by his most intimate friends and guarded by about 1,000 men, he went from Pilsen to Eger. hoping to meet the Swedes under Duke

Bernhard. After the arrival of the party at Eger, Col John Gordon, the commandant, and Col. Walter Butler and Maj. Walter Leslie agreed to rid the emperor of his enemy. On the evening of Feb. 25 Wallenstein's supporters Christian Ilow, Wilhelm Kinsky. Adam Trczka and his master of the horse. Heinrich Neumann, were received at a banquet by the officers and then murdered. Butler, Capt. Walter Devereux and a number of soldiers hurried to the house where Wallenstein was staying and broke into his room. He was instantly killed by a thrust of Devereux's partisan.

WALLER, EDMUND (1606–1687), English poet, was born on March 9, 1606. the eldest son of Robert Waller of Coleshill and Anne Hampden. his wife. Early in his childhood his father moved to Beaconsfield. Waller was educated at Eton and King's College, Cambridge. He left without a degree, and it is believed that in 1621 he sat as a member for Agmondesham (Amersham) in the last parliament of James I. Clarendon says that Waller was "nursed in parliaments." In that of 1624 he represented Ilchester, and in the first of Charles I. Chipping Wycombe. The first act by which Waller distinguished himself, however, was his surreptitious marriage with a wealthy ward of the Court of Aldermen, in 1631. He was brought before the Star Chamber for this offence, and heavily fined. After bearing him a son and a daughter at Beaconsfield, Mrs. Waller died in 1634. It was about this time that the poet was elected into Falkland's "Club."

It is supposed that about 1635 he met Lady Dorothy Sidney, eldest daughter of the earl of Leicester, who was then eighteen years of age. He formed a romantic passion for this girl, whom he celebrated under the name of Sacharissa. She rejected him, and married Lord Spencer in 1639. In 1640 Waller was once more M.P. for Amersham; later, in the Long Parliament, he represented St. Ives. Waller had hitherto supported the party of Pym, but he now left him for the group of Falkland and Hyde. An extraordinary and obscure conspiracy against Parliament, in favour of the king, which is known as "Waller's Plot," occupied the spring of 1643, but on May 30 he and his friends were arrested. In the terror of discovery, Waller was accused of displaying a very mean poltroonery, and of confessing "whatever he had said, heard, thought or seen, and all that he knew . . . or suspected of others." Waller was called before the bar of the House in July, and made an abject speech of recantation. His life was spared and he was committed to the Tower, whence, on paying a fine of £10,000, he was released and banished the realm in Nov. 1643. He married a second wife, Mary Bracey of Thame, and went over to Calais, afterwards taking up his residence at Rouen.

In 1645 the *Poems* of Waller were first published in London, in three editions. Many of the lyrics were already set to music by Henry Lawes. In 1646 Waller travelled with Evelyn in Switzerland and Italy. During the worst period of the exile Waller managed to "keep a table" for the Royalists in Paris, although in order to do so he was obliged to sell his wife's jewels. At the close of 1651 the House of Commons revoked Waller's sentence of banishment, and he was allowed to return to Beaconsfield, where he lived very quietly until the Restoration.

In 1655 he published *A Panegyric to my Lord Protector,* and was made a Commissioner for Trade a month or two later. He followed this up, in 1660, by a poem *To the King, upon his Majesty's Happy Return.* Being challenged by Charles II. to explain why this latter piece was inferior to the eulogy of Cromwell, the poet smartly replied, "Sir, we poets never succeed so well in writing truth as in fiction." He entered the House of Commons again in 1661, as M P. for Hastings, and Burnet has recorded that for the next quarter of a century "it was no House if Waller was not there." His sympathies were tolerant and kindly, and he constantly defended the Nonconformists. One famous speech of Waller's was: "Let us look to our Government, fleet and trade, 'tis the best advice the oldest Parliament man among you can give you, and so God bless you." After the death of his second wife, in 1677, Waller retired to his house called Hall Barn at Beaconsfield. In 1661 he had published his poem, *St. James' Park;* in 1664 he had collected his poetical works; in 1666 appeared his *Instructions to a Painter;* and in 1685 his *Divine Poems.* The final collection of his works is dated 1636, but there were posthumous additions made in 1690. He died at Hall Barn, with his children and his grandchildren about him, on Oct. 21, 1687.

Waller's lyrics were at one time admired to excess, but with the exception of "Go, lovely Rose" and one or two others, they have greatly lost their charm. His fancy was plain and trite. He made writing in the serried couplet the habit and the fashion. It was this regular heroic measure which was carried to so high a perfection by Dryden and Pope.

The only critical edition of Waller's *Poetical* Works is that edited, with a careful biography, by G. Thorn-Drury, in 1893. (E. *G.;* X.)

WALLER, SIR WILLIAM (*c.* 1597–1668), English soldier, son of Sir Thomas Waller, lieutenant of Dover, was educated at Magdalen hall, Oxford, and served in the Venetian army and in the Thirty Years' War. He was knighted in 1622 after taking part in Sir Horace Vere's expedition to the Palatinate. In 1640 he became member of parliament for Andover. He supported the parliament when the Great Rebellion broke out in 1642. As colonel he captured Portsmouth. Farnham. Winchester and other places; and in 1643 as major general he operated around Gloucester and Bristol (*see* CIVIL WAR, *ENGLISH*), winning a victory at Highnam and capturing Hereford He then opposed the advance of Sir Ralph Hopton and the royalist western army, and though defeated at Lansdown (near Bath) he shut up the enemy in Devizes. However. Hopton and a relieving force from Oxford completely defeated Waller's army at Roundway Down, many reproaching Essex, the commander in chief, for allowing the Oxford royalists to turn against Waller. The Londoners, who had called him "William the Conqueror." raised a new army, but the forces nere distinctly local. and resented long marches and hard work far from their own counties. At the first siege of Basing house they mutinied in face of the enemy, and their gallantry at critical moments, such as the surprise of Alton in Dec. 1643 and the recapture of Arundel in Jan 1644. only partially redeemed their general bad conduct. Waller himself. a general of the highest skill, "the best shifter and chooser of ground" on either side, was, like Turenne, at his best at the head of a small and highly disciplined army.

Though successful in stopping Hopton's second advance at Cheriton (March 1644), he was defeated by Charles I in the war of maneuver ahich ended with the action of Cropredy Bridge (June) ; and in the second battle of Newbury in October his tactical success at the village of Speen led to nothing His last expeditions were made into the west for the relief of Taunton, and in these he had Cromnell as his lieutenant general. By this time the confusion in all the armed forces of the parliament had reached such a height that reforms were at last taken in hand. The original suggestion of the celebrated New Model army came from Waller (July 2, 1644). Simultaneously came the Self-Denying ordinance, nhich required all members of parliament to lay down their military commands. Waller had already requested to be relieved—and his active military career came to an end. Henceforth, embittered. he was constantly engaged, as presbyterianism waned in parliament, in opposing both the Independents and the army politicians: and after the death of Charles I he supported the presbyterian-royalist opposition to the Commonwealth. He was several times imprisoned between 1648 and 1659 He promoted the final negotiations for the restoration of Charles II and sat in the Convention parliament. He died on Sept 19, 1668

See A à Wood, *Athenae Oxonienses,* ed by P Bliss, vol iii, p 812 (London, 1813–20), and two partial autobiographies, "Recollections by General Sir William Waller" (printed in *The Poetry of Anna Matilda,* London, 1788) and *Vindication of the Character,* etc. (London, 1793).

WALLINGFORD, a municipal borough in the Abingdon parliamentary division of Berkshire. Eng , on the Thames. $14\frac{1}{2}$ mi. N.W. of Reading by road. Pop. (1961) 4,829. Area 1.2 sq.mi. It is a residential town and a resort for Thames boating. From the earliest times the ford was important and there are traces of the earthworks which surrounded the town and which have been attributed to Alfred the Great (c. 878). Traces have also been found of Bronze Age occupation; there was a Romano-British settlement, and the motte of the Norman castle can still be identified. Wallingford castle. one of the last to hold out for Charles I, nas demolished during the Commonwealth. The church of St.

Leonard retains pre-Conquest and Norman work. The bridge, rebuilt in the 19th century, incorporates parts of the 13th-century bridge. Though burned by Sweyn in 1006, Wallingford was the most important borough in Berkshire at the time of the Domesday survey. The town suffered greatly from the Black Death, and its decline was accelerated by the building, in the early 1 jth century, of two bridges near Abingdon, which diverted the main road bet\\-een London and Gloucester from Wallingford. The earliest charter, given by Henry II (11 j5), was confirmed and enlarged by Henry III in 1267 and by Philip and Mary in 1557–58. The governing charter until 1835 was that given by Charles II in 1663.

WALLINGTON: *see* BEDDINGTON AND WALLINGTON.

WALLIS, JOHN (1616–1703), an English mathematician, one of the greatest of Isaac Newton's precursors, was born at Ashford, Kent, on Nov. 23, 1616. In 1632 he entered Emmanuel college, Cambridge, where he distinguished himself in many branches of learning. About eight years later he gained a fellowship at Queens' college, Cambridge. He was ordained in 1640, and shortly afterward he exhibited his skill in an entirely different direction by deciphering a number of cryptic messages from royalist partisans which had fallen into the hands of the parliamentarians. Wallis was a prominent member of that body whose interest in the new experimental science led to the formation of the Royal society in 1660. His interest in mathematics began in 164;. when a copy of William Oughtred's *Clavis Mathematicae* came into his hands. His complete mastery of this work gave unmistakable evidence of his mathematical strength. .\bout this time, despite the fact that he had incurred the lasting hostility of the parliamentarians by signing the remonstrance opposing the king's execution. Wallis was elected to the vacant Savilian professorship of geometry at Oxford in 1649. This appointment marked the beginning of a period of intense mathematical activity which lasted almost without interruption until the closing years of his life. A chance perusal of the works of E. Torricelli, in which B. Cavalieri's method of indivisibles was freely used to effect the quadrature of certain curves, stimulated his interest in the age-old problem of the quadrature of the circle, and led to the publication of his *Arithmetica Infinitorum* in 1656. In this work he extended Cavalieri's law of quadrature to embrace negative and fractional exponents, and by a long, complicated chain of reasoning he established the relation: $\frac{4}{\pi} = \frac{3.3.5.5.7.7.9.9.11.11...}{2.4.4.6.6.8.8.10.10.12...}$

This work proved a great inspiration to Newton, a fact which he readily acknowledged.

In 1657 there appeared his *Mathesis Universalis*, a somewhat elementary work whose chief value lies in its account of the development of notation. In 1657–58 Wallis was appointed *Custos Archivorum* to the Cniversity of Oxford. The appointment of a Cambridge man to this office did not meet with universal approval, and there mere many who were ready to attrihute Wallis' rapid advancement to a decided inclination to trim his sails to the prevailing political winds. His next work of importance was the *Mechanica, sive Tractatus de Motu* (3 parts, 1670–71), which refuted many of the errors regarding motion which had persisted since Archimedes and, moreover, gave a definite and permanent meaning to many of the constantly occurring terms such as force and momentum.

Though he was approaching his 70th year, Wallis published in 168j his *Treatise of Algebra,* an important contribution to the study of equations. However, the historical section is of little value since Wallis was never able to recognize the genius of the mathematicians on the continent. Against Descartes he was particularly severe. Wallis' life was embittered by a number of quarrels of which the one with Hobbes was the most profitless (*see* HOBBES, THOMAS). He died at Oxford on Oct. 28, 1703.

See J. F. Scott, *The Mathematical Work of John Wallis (1616–1703)* (1938). (J. F. ST.)

WALLON, HENRI ALEXANDRE (1812–1904), French historian and statesman, was born at Valenciennes on Dec. 23, 1812. Wallon succeeded Guizot as professor at the Sorbonne in 1846. Returning to politics in 1871 he immortalized himself by carrying his proposition for the establishment of the republic with a president elected for seven years, and then eligible for re-election, which, after violent debates, was adopted by the assembly on Jan. 30, 1875. "My proposition," he declared, "does not proclaim the republic; it creates it." Upon the establishment of the republic, Wallon became minister of public instruction, and effected many reforms, but his views were too conservative for the majority of the assembly, and he retired in May 1876. He had been chosen a life senator in Dec. 1875. Returning to his historical studies, Wallon produced four works of great importance, though less from his part in them as author than from the documents which accompanied them: *La Terreur* (in *Correspondant,* 1880–73; in book form, 1873); *Histoire du tribunal révolutionnaire de Paris avec le journal de ses acts* (6 vol., 1880–82); *La Révolution du 31 mai et le fédéralisme en 1793* (2 vol., 1886); *Les Réprésentants du peuple en mission et la justice révolutionnaire dans les départements* (5 vol., 1888–90). He also published a number of articles in the *Journal des savants;* for many years he wrote the history of the Académie des Inscriptions (of which he became perpetual secretary in 1873) in the collection of *Memoirs* of this academy. He died at Paris on Nov. 13, 1904.

WALLOON LITERATURE. Walloon is a Romance dialect, belonging to the same group as the Picard, Lorrain and Francian, of which the latter, under the name of French, has had such a notable development. The several varieties of Walloon are spoken in the southern part of Belgium, in that region generally called "Wallonie" (from a word coined about 1858), of which Likge is the chief centre of dialectal literature.

This literature has its historical monuments. To the northeast belong the cantilena of *Eulalie,* one of the oldest Romance texts (11th century), *Li Ver del Juïse* (the Last Trial), the *Dialogues du Pape Grégoire* (the Dialogues of Pope Gregory), commentaries on *Job, Lent Sermons* and the *Poème Moral.* There are also the delightful song fable of *Aucassin and Nicolette,* one of the masterpieces of the middle ages, and the copious, but somewhat fastidious chronicles of Jean le Bel, Jacques de Hemricourt, Jean d'Outremeuse and Jean de Stavelot. Lastly, the edition by J. Cohen, in 1920, of the *Mystères et Moralités du XIV^e S.,* has enriched the ancient literary patrimony of the Walloon country.

The two Nativities to be found in Cohen's edition are undoubtedly the ancestors of *Noels Wallons* (ed. by Doutrepont in 1909), which are still alive in the popular minds. It may be objected that those works were not written in the dialect spoken by the people at that time, but in a literary language of Picard rather than of French character. However, their dialectal features reveal the anonymous origin of the texts.

We must wait till the beginning of the 17th century before we can find works written in dialect. The three oldest texts written in the dialect of Likge are an *Ode,* dated 1620, a *Sonnet,* dated 1622, and a *Morality,* dated 1623. They were published in 1921 by Jean Haust. A pasquinade on *Women and Marriage* (ed. Jean Haust, 1925) is, unfortunately, undated, but might be assigned to about 1600. Of the 17th and 18th centuries we possess, in all, some 50 lyrical pieces; complaints of peasants about the devastations caused by foreign soldiers, speeches on the topics of the time, satires against the affectations of women, pamphlets about political troubles or religious controversies, humorous compliments on the occasion of a clerical promotion, et~. Their literary value is, on the whole, rather mediocre. An exception must be made, however, for the lyrical satire. *Les Ewes di Tongue* (the Waters of Tongres, 1700), by Lambert Rickmann, perhaps the best Walloon satire in existence, of astonishing verve, rich in somewhat gross but striking images.

In the middle of the 18th century, four comic operas mere composed. They constitute the so-called *Théâtre Liégeois* (ed. Bailleux, 1854). A literary circle used to meet at Chevalier S. de Harlez's; its members (canons, deans, lords and rich bourgeois) amused themselves by writing burlesques, and a composer of great talent, Jean Noel Hamal, provided a lively and picturesque music to the libretti written by his friends. The performance achieved a tremendous success. The four plays in question are entitled *Li Voyedje di Tchaudfontaine* (the Journey to Chaudfontaine), a delightful farce (edit. Haust, 1924); *Li Ljîdjwes Egadî* (the Enlisted Liégeois), a touching picture of local customs; *Li Fiesse di Houte-s'i-Ploût* (the Festival of H.), a village idyll with a somewhat weak plot; and above all, the most original piece of the collection, *Les Hypocondes* (the Hypochondriacs), a diverting picture of the whims and torments of imaginary invalids who go to Spa to drink the waters. A farce in two acts entitled *Li Mâlignant* (the Malevolent) closes this first series, which, although really remarkable for its local colour and veracity, is naturally deprived of high moral feeling.

The revolution of 1789 and the troubles it brought inspired numerous patriots of Liége with popular and satirical songs. Albin Body edited more than 250 of these, but they are now forgotten, with the exception of a song against *The Prussians,* written by the lawyer, J. J. Velez (1817), the popularity of which was revived by World War I.

Few names deserve notice in the first half of the 19th century. Among these may be mentioned *Li Copareye* (1822) by Ch. N. Simonon, which celebrates the ancient clock-tower of the Cathedral of Saint-Lambert and the glorious deeds of the history of Liége; *Li Ktapé Manedje* (the Disordered Household), 1830, by H. J. Forir, a lively satire of the confusion produced in the commonwealth by carelessness and improvidence; *Li Pantalon Trawé* (the Torn Trousers) 1839, by Ch. Du Vivier, an epos, in a few stanzas, of the fighter of 1830, the humble soldier who served under different régimes without any personal profit; *Li Bourgoyne* (1846) by Jos. Lamage, a bacchic song which still enjoys popularity among the Walloon population.

A touching elegy *Leyiz-m'plorer* (Let Me Cry), 1854, and a graceful idyll *L'avez-v'-veyou passer?* (Did you see her pass?) 1856, revealed in Nicolas Defrecheux a true poet. The Walloon people were delighted to hear their patois express such sincerity so delicately. In 1856 the *Société Liégeoise de Littérature Wallonne* was founded. It grouped intellectuals, scholars, writers and folklorists into a kind of small provincial academy, held yearly competitions and published "Bulletins" and "Annuaires."

In 1857 it awarded a prize to *Li Galant dil Servante,* a play written by André Delchef, which opens the revival of the Walloon stage. In 1884, the Société awarded a prize to *Tîtâ l' Periquî,* by Edouard Remouchamps, a play which, because of its caustic vein and the admirable manner in which it was acted, led to a prodigious development of Walloon literature.

But everqwhere the spoken dialect is losing ground to French; the dialect is considered as vulgar, especially in the Hainaut district, along the French frontier. However, the written dialect is used more than ever before. In nearly all villages, dramatic societies perform Walloon plays. In more important centres, writers are grouped in societies which award prizes and publish papers and periodicals: at Tournai, the *Théâtre* of Arthur Hespel, and the *Cabaret Wallon;* at Mons, the *Ropïeur* and its circle; at La Louvière, the *Mouchon d'Aunias;* at Charleroi, the *Association Littéraire;* at Namur, the society *Les Rèlis* and its organ *Le Guetteur Wallon;* in Liége, the *Société de Littérature Wallonne,* the *Caveau Liégeois,* the *Auteurs Wallons,* the *Wallonne* and many others; and so at Verviers, at Malmedy, etc. Liége hss two theatres which, every night, perform Walloon plays before a fairly large audience; humour and wit is their chief feature, except when such writers as Henri Hurard or Louis Lekeu, helped by excellent native actors, offer important plays. Poetry includes joyful songs, satirical pasquinades, sentimental ballads, and descriptive or narrative poems. Such works as *Li Panèd Bon Diu* (the Bread of God) by Henri Simon, the somewhat nostalgic poems of Joseph Yriendts, the love elegies of Emile Wiket, the lyrics of Martin Lejeune, Louis Lagauche, Marcel Launay, Jean Wisimus and many others, combine a real respect for style and prosody with true poetic feeling. Fiction has produced interesting works, such as the *Houlot* (1888) by D. D. Salme. *La Famille Tassin* (1900) by Ad. Tilkin, and the delicate *Solia d'Amour* (1928) by Joseph Laubain. Let us also mention *Cadet* by Jean Lejeune, who, with wonderful realism, relates incidents in the life of a rabbit, *Li Brak'nî* (the Poacher) by Joseph Calozet, a masterpiece that reminds the reader of the rustic stories of George Sand, and the tales *Pou Dire à l'Eschrienne* (Hearth Tales), to mention only a few. Walloon literature to-day is most vivid, and it is to be hoped that, like Gaelic literature, it will remain popular in its inspiration.

WALLPAPER. Wallpaper first came into general use in Europe during the last quarter of the 17th century, and the name "paper hangings" which was then given to the product is a significant indication of its real origins. In an English publication issued by John Houghton, fellow of the Royal society, in 1699, it is stated that in Surrey at that time paper hangings were sometimes known as "Paper Tapistry." and this description aptly fitted what was, in fact, a practical and cheap substitute for the more costly decorative hangings favoured by the wealthy. It is interesting to note that even at this early date paper hangings were being sold in rolls, for Houghton refers to this as follows: "but there are some other done by Rolls in long sheets of a thick Paper made for the Purpose whose sheets are pasted together to be so long as the Height of a Room. . ."

It is often assumed that the Chinese were the inventors of wallpaper, but there is no evidence that wallpaper, as such, was in general use in the far east earlier than the time of its introduction to Europe. From the very beginning wallpaper was regarded as a cheap substitute for tapestry hangings, painted cloths, leather and wood paneling, and because it so closely imitated these and other forms of mural decoration its use was quickly established and its development assured.

In discussing origins it should be borne in mind that wallpaper, so-called, was used on occasion soon after the introduction of papermaking to Europe during the latter part of the 15th century. It is known, for example, that the early letterpress printers were responsible for some of the decorated sheets found *in situ* and dating from the early part of the 16th century. The remains of one decorated sheet printed in the black printers' ink of the period was found in 1911 on the ceiling of the master's lodge at Christ's college, Cambridge. This proved to be the work of a printer, Hugo Goes of Beverley and York, who had used the back of a proclamation of Henry VIII for the purpose. Another paper, of heraldic design, found adhering to the wattle and daub of a room at Besford court, Worcester, is known to have been printed about 1550. Similar discoveries of the kind, all pointing to a capricious use of the printing press and to a tendency to widen its scope, are noted in a paper by Hilary Jenkinson in the *Antiquaries' Journal,* vol. 5, no. 3 (July 1925). These decorated sheets. printed by nood blocks, were readily acceptable as linings for boxes, chests and cupboards, and the use of such papers as hangings for walls was simply the outcome of expediency and human ingenuity.

The distinction between the 16th- and 17th-century lining papers and the true wallpapers of the same period is an important one. The characteristic most typical of the latter is that the design should be capable of "repeat" when sheets were pasted in juxtaposition on the wall. The principle of repeating patterns mas understood by textile printers as early as the 14th century. and the idea is probably of much earlier origin. Throughout its long history wallpaper has been closely linked with textiles whether printed, painted, woven or embroidered. The Christ's college, Cambridge, example (*see* above) is distinguished by a woodcut motif (a pomegranate) similar in character to those found in medieval velvet hangings of Italian origin; other papers belonging to the Tudor period are printed with designs imitating the "black-work" embroidery to be seen in garments worn by persons of quality in the time of Elizabeth I. Contemporary with these are the lining papers and the wallpapers containing some kind of heraldic ornamentation.

It is difficult to establish which ivas the first European country to invent and use ivallpaper. The claims of France. Germany and England each have some validity, and each is based on indisputable grounds according to the nationality of the historian concerned. It can be said with reasonable certainty, however, that the English and continental letterpress printers of the 16th century played an important part in developing an idea which had already been anticipated in the production of the painted cloths and painted papers of a still earlier period.

The sort of paper hangings available when their manufacture was in its infancy are enumerated in an advertisement published by Edward Butling, stationer of Southwark, London, about 1690 (Bagford collection, British museum). Here it is stated that Edward Butling "maketh and selleth all sorts of Hangings for Rooms in Lengths or in Sheets, Frosted or Plain: also a sort of Paper in Imitation of Irish Stich and several other sorts, viz: Flock-work [*see* below] Wainscot, Marble, Damask. . ." It concludes by announcing that the business sells "all sorts of Stationary wares." It is understandable that the stationers should be associated with the beginnings of wallpaper, but a link of even greater significance is to be found in the London paper-hanging makers of the late 17th century whose predecessors were leather gilders (makers, among other items, of decorated leather hangings for rooms) who turned over to the production of the cheaper hangings made of paper as soon as the latter commodity was available in sufficiently reliable quantity and quality.

Flock Papers.—Pre-eminent among the earliest wallpapers were the flock papers which reproduced the rich texture of the medieval silk and velvet hangings. Flock papers were being made in England and France during the 17th century, and the Painters Stainers' company in London claimed "flock-work" (*cf.* Butling advertisement, above) among their monopolies as early as 1626. The art of flocking on cloth was practised in the middle ages to make coarse cloth look finer than it was in fact, but its application to paper was not widely adopted until the latter part of the 17th century because the roughly made paper was not always tough enough to withstand the weight of the flock material. It is possible that Samuel Pepys was referring to a flock paper when he used the term "counterfeit damask" to describe the hangings in his wife's closet. The flock used in making these papers originally consisted of powdered wool, which was scattered over paper on which the design had previously been drawn, or printed in a slow-drying adhesive or varnish. (Most 18th-century encyclopaedias describe this process in detail, and a full description is also found in R. Dossie's *Handmaid to the Arts* [1758] and J. Beckmann's *A History of Inventions and Discoveries,* trans. by W. Johnston, 4 vol. [1797].) Flock was sometimes used to enrich the already liberally decorated leather hangings, which were popular in Germany and the Netherlands throughout the first half of the 18th century. Flock papers formed a prominent part of the stbck in trade of some of the earliest wallpaper makers and dealers in London, and have been a deservedly popular form of paper-hanging ever since. At one time they were known on the continent as *papiers d'Angleterre,* but toward the end of the 18th century the French surpassed the English in quality and design and the latter did not regain supremacy till the early part of the 19th century. Many important mansions in various parts of the world contain rooms hung with flock wallpaper, and manufacturers today, besides producing by improved processes flock papers for modern use, can at short notice meet demands for the replacement of originals that have been damaged or destroyed.

Chinese Papers.—Contemporary with the flock papers were the painted Chinese papers which first began to arrive in Europe toward the end of the 17th century. They were generally described as "India" papers, the name "India" being applied to various goods and *objets d'art* originating in the far east which were brought over in ships of the Dutch, French and English East India companies. Most of these papers were produced specially for the European market and were often made up in sets of 25 rolls, each 12 ft. long by 4 ft. wide. The absence of repeat and the studied dissimilarity of detail as between one length and another gave them a unique quality which was much prized by those who possessed a room decorated and furnished in the fashionable oriental style. Because of their beauty and costliness a far larger number of original Chinese papers have survived the years than might be expected. They may be seen in museums and also in many of the larger houses throughout the world. In England particularly fine examples may be seen at Temple Newsam, Leeds; Nostell priory, Yorkshire; and Woburn abbey, Bedfordshire. The importation of Chinese papers, as already mentioned, commenced during the late 17th century, and European wallpaper makers were quick to imitate them, though indifferently well for the most part. Many of the finest *chinoiserie* papers were produced by etched plates or wood blocks, the colour being introduced by hand or stencil.

The 18th century saw the development of wallpaper manufacture far beyond the expectations of the early makers. It is true that the first wallpapers justified themselves on the score of novelty and cheapness and also because they so cleverly reproduced the appearance of more costly hangings; more significant is the fact that they made an irresistible appeal to the wealthy and fashionable sections of society both in England and on the continent. The early 18th-century makers, already experts in their craft, were in touch with persons of taste, and these valuable contacts provided a necessary stimulus to the development of style and design. The use of wallpaper by Horace Walpole at Strawberry Hill, Twickenham, and Madame de Pompadour's interest in Chinese and English wallpapers are cases in point. Wallpaper's suitability proclaimed itself by its adaptability, its novelty and its delightful appearance, and the varied types that were obtainable—embossed papers, chintz patterns, flocks, satin grounds, stripes and verditer papers to mention but a few varieties—added still further to its popularity.

Papier-Mâché and "Long" Paper.—The 18th-century wallpaper maker. in England particularly, was a specialist in hanging his products to the best advantage, and many elaborate schemes of wallpaper decoration were devised and carried out by him. It is not generally known that he was also noted for his skill in making papier-mâché. Thomas Mortimer states in *The Universal Director* (1763): "Most if not all [the paper-hanging makers] are also manufacturers of Papier Maché ornaments for Looking Glass and Picture Frames." The papier-mâché side of the English wallpaper makers' business was of considerable importance, including elaborate ornaments for ceilings, cornices and moldings, all very necessary for the decoration of rooms. Count Friedrich von Kielmansegge, in his *Diary of a Journey to England in the Years 1761–1762* (1902), writes, "To the ceilings papier maché has been added uhich looks like stucco. This material is said to be in general use in London and I should never have taken it for what it really is." An act was passed in 1712 which imposed a duty of one penny (increased two years later to $1\frac{1}{2}d.$) on every square yard of paper "printed, painted or stained"—a very inconvenient measure for the paper stainer, entailing the presence in the works of the excise officer who had to stamp each sheet with an appropriate cipher. The tax persisted with little alteration until 1836.

The manufacture of wallpaper in America began about 1750, and it is likely that it was introduced there by English craftsmen. At this time England was not only meeting domestic demand but exporting consignments to America and other parts of the world.

From the middle of the 18th century onward great efforts were made to satisfy the growing demand for wallpaper, and all kinds of experiments were instituted to increase the volume of production. Thomas Fryer of London obtained a patent in 1764 for a new method of printing with engraved cylinders, and a London stationer, Jacob Bunnett, in 1786 claimed to have perfected a machine capable of printing "ten times as many pieces [of wallpaper] in as short a time as one piece is now printed by the common method." William Palmer, also of London, in 1829 patented a hand-operated mechanical block-printing device, etc. But inventive progress was hampered by the lack of a "continuous" sheet of paper, which was not produced by papermakers until 1801–07, when the Fourdrinier papermaking machine was perfected at Two Waters mill, Hertfordshire, by Henry and Sealy Fourdrinier. With "long" paper in plentiful supply and the principle of calico printing in mind, success was achieved at last by a Darwen, Lancaster, firm of calico printers, C. H. and E. Potter, who commenced the manufacture of machine-printed wallpaper in 1840. English machine-

printed papers were made in ever-increasing quantities from that date, but the production of hand-printed papers was never discontinued: in fact, the latter form an important range of present-day collections.

Design.—Such is the broad outline of wallpaper's history and origins; now a word about design. Because of its ephemerality and its acceptance as a substitute for more expensive hangings, wallpaper cannot have attracted the finest designers in the early stages of its appearance in Europe. But the middle of the 18th century saw the rise of a number of artists and craftsmen of international repute in this field of industrial art: Jean Papillon (1661–1723), wood engraver and paper stainer of Paris; John Baptist Jackson, printer in chiaroscuro of Battersea; John Sherringham of Chelsea (the Wedgwood of paper stainers); the Eckhardt brothers. Francis Frederick and George, of Chelsea, makers of hand-painted silk hangings and etched wallpapers, whose business enjoyed royal patronage; and Jean Baptiste Réveillon of Paris, whose designs were superbly drawn and produced. Many wallpapers of this period, all made by hand. have survived, and many have a dignity and authority characteristic of this golden age of design But French supremacy of design and execution reached its zenith at the turn of the century and during the early part of the 19th century, at mhich period the flock papers and distemper-coloured papers of Réveillon and the panoramic decorations of Joseph Dufour and other Parisian makers were unique. By this time wallpaper was developing rather less commendable complications of design than the French panoramic or *paysage* types, and the moldings, columns, capitals and similar architectural themes which it now imitated even called for special experience in hanging, especially in relation to the direction in which the light penetrated into the room. A large variety of hand-printed borders was available, and all kinds of finishes were used, such as embossing, varnishing or spangling with mica dust or metallic powders.

The early 19th century saw the first experiments to perfect a reliable nashable paper which involved the use of varnish or japan gold size and turpentine and most likely detracted from the general appearance of the product.

Overembellishment was a feature of those wallpapers which were to have a wide popular appeal, a factor which unfortunately persisted up to comparatively recent times. The Gothic revival in England nas responsible for some of the worst forms of wallpaper design which A. W. N. Pugin resolutely excluded from his papers used in certain rooms in the new houses of parliament. Owen Jones, author of *The* Grammar of Ornament (1856), favoured a flat formality of design, and many of his wallpapers are severely conventional in character. William Morris' wallpaper designs, printed by Jeffrey and Co., Islington, made their first appearance in 1862. The importance of this artist-craftsman in the history of paper hangings lies in his insistence on, and rediscovery of, good design and colour. His work and that of Walter Crane and their followers, both in England and elsewhere. brought a new appreciation of the possibilities of wallpaper. It was in the branches of machine production that a fresh stimulus was most needed, however, and here the Morris traditions were neglected until the end of the century when they were revived on the European continent through the *Jugend* style and art *nouveau.*

It has been said that nothing remarkable in mallpaper design was achieved after William Morris. but this, like most generalizations, is not entirely true Many competent artists contributed to the variety and versatility of nallpaper during the 20th century, and in England men such as Walter Crane, C. F. A. Voysey and Heywood Sumner were still actively at work for the industry in its opening decade. The first half of the 20th century was notable for violent economic and social changes—World Wars I and II not only interrupted nallpaper production but forcibly introduced people to the meaning of austerity; hence those years were comparatively less eventful in the matter of wallpaper design than those of the preceding half-century. Yet during the period Edward Bawden, John Aldridge and Graham Sutherland were among those artists of international standing whose designs were put into production. Others came into prommence at the time of the British Wallpaper exhibition held in London in 1945. Perhaps the most remarkable and, from the design standpoint, regrettable feature about wallpaper is that manufacturers have always tried to produce something for everybody's taste instead of adopting smaller, more selective ranges of design. With the stimulus of the Festival of Britain in 1951 and other similar exhibitions to give new incentives, wallpaper design of the 1950s, like that of many articles in common use, became influenced by the so-called contemporary trend mhich at least encouraged a more imaginative feeling for colour and pattern. This new appreciation of the value of colour and pattern became noticeable in many departments of interior decoration, and the simplicity of line characterizing the furniture perhaps led to the use of good pattern and colour in the background against which this furniture was to appear. In the mid-1950s there were signs that manufacturers were anxious to stimulate a new perception of colour and to provide opportunities for the consideration of scale and proportion. The wallpaper collections included large-scale patterns suitable for schoolrooms, lecture halls, hotels and even places of entertainment. Some of these wallpapers, too large in repeat to be printed by machine, were being produced by screen printing, and these augmented wallpapers which had already been so•widely used for exhibition and general display purposes.

Outstanding among modern wallpaper designers have been Ben Rose, Marion Dorn, Donald K. Soderlund, John R. Denst and Irving Sherman in the United States; Elsbeth Kupferoth and Margret Hildebrand in Germany; Bent Karlby in Denmark; Stig Lindberg in Sweden; Robert and Roger Nicholson, Lucienne Day, etc., in England.

Wallpaper, along with many other commodities, came, during the 1950s, within the popular "do-it-yourself" movement which swept the western world on both sides of the Atlantic and gave new zest to the instinct for homemaking which the high cost of skilled labour was checking. With the issue of detailed instructions, demonstrations and films, manufacturers of wallpaper banished most of the drudgery associated with home decorating.

Apart from the use and development of screen printing, the production of both hand- and machine-printed goods has undergone little material change for many years. Research in all branches of manufacture is rigorously pursued, however, one result being the discovery of new finishes to enhance appearance and durability. In England the larger manufacturers' productions comply with standards laid down by the British Standards institution (B.S. 1248/1954).

WALLQVIST, OLAF (1755–1800), Swedish statesman and ecclesiastic, was ordained in 1776, became doctor of philosophy in 1779, court preacher to Queen Louise Ulrica in 1780 and bishop of Växjö in 1787. His preaching had attracted the attention of Gustavus III, who placed him at the head of the newly appointed commission for reforming the ecclesiastical administration.

His political career began during the mutinous riksdag of 1786, when he came forward as one of the royalist leaders. At the stormy riksdag of 1789 it was very largely because of his co-operation that the king was able to carry through the Act of Union and Security (see SWEDEN: History). During the brief riksdag of 1792, as a member of the secret committee, Wallqvist rendered the king essential services. Indeed Gustavus III during his last six years mainly depended upon Wallqvist and his colleague Carl Gustaf Nordin, who subordinated their private enmity to the royal service.

During the G. A. Reuterholm (*q.v.*) administration, Wallqvist was kept remote from court. In 1800 he was recalled to the political arena, but he died on April 30. (R. N. B.)

WALLSEND, a municipal (1901) and parliamentary (1913) borough of Northumberland, Eng., 4 mi. E.N.E. of Newcastle on the north bank of the Tyne about 5 mi. from the North sea. Pop.

(1951) 48,678. Area 5.3 sq.mi. On the site of the Roman military camp *Segedunum* at the eastern end of Hadrian's wall (from which comes its name), it was an agricultural village until the 16th century. when glassmaking and saltmaking were begun. By the end of the 18th century these had been superseded by shipbuilding (from 1759), coal mining and marine engineering. particularly steam turbines. which from 1894 were developed in Wallsend. The chemical trade grew up between 1854 and 1898 when the coal pits were flooded. and other industries include the making of gangways, ropes, mining equipment, plywood and plastics. Though forming with Newcastle (west) and Tynemouth (east) 12 mi. of unbroken industrial building along Tyneside. Wallsend possesses six parks and open spaces and a village green.

WALL STREET, a street in the lower part of New York city on which or near which are concentrated the chief financial institutions of the United States. It corresponds to the London financial district in Threadneedle. Throgmorton and Lombard streets, and is rivalled only by that centre in its importance as an international money market. The street itself is narrow and short, extending only about seven blocks from Broadway to the East river, and the financial houses occupy only the upper or western half of the street. The Wall street financial district. however. extends several blocks north and south of the street and also includes an area west of Broadway. Even before the Civil War the street was recognized as the financial capital of the country, and most of the major banking houses have sought to maintain headquarters there, amidst the offices of insurance companies. railway corporations, steamship, iron, coal and copper companies and several hundred other large industrial corporations. Companies with securities listed on the New York Stock exchange maintain at least a transfer office conveniently near. Besides the New York Stock exchange there are in the neighbourhood the American Stock exchange. Cotton exchange. Coffee exchange. Metal exchange. Produce exchange and lesser exchanges. The district is the headquarters of most brokerage firms. Private hankers are also established in the street, the famous house of J. P. Morgan and Co. occupying its own building at the corner of Wall and Broad streets.

Wall street owes its name to Peter Stuyvesant, who in 1652, as governor of the little Dutch settlement of New Amsterdam, ordered a palisade built on the site to protect the town from feared invasions of the English. The last of the wall was removed in 1699, and both sides of the street were quickly built up. The street was famous in the political life of the country after the Revolution when for a brief period the governmental offices of the city, state and nation were all located there. At the old Federal building, on the site of the present Subtreasury building, George Washington in 1789 was first inaugurated president. and there the first United States congress met.

See F. T. Hill. *The Story of a Street* (1908), for history, and S. S. Pratt, *The Works of Wall Street,* 3rd ed. (New York, 1921), for an anaylsis of the financial activities.

WALMER, a watering place of Rent. Eng. Pop. (1931) 5,324. It was transferred to the borough of Deal in 1935. Lower Walmer. the portion most frequented by visitors. extends northward along the coast so as to be contiguous with Deal. Upper Walmer is a short distance inland, and below it Walmer castle lies close to the sea. This was a blockhouse built for coast defense by Henry VIII. but it became the official residence of the lords warden of the Cinque Ports. It ceased to be the official residence in 1905, when the prince of Wales (afterward George V) was appointed lord warden, and the public was given access to those rooms which possess historical associations with former holders of the office. such as the duke of Il'ellington, who died there in 1852, William Pitt and others. Walmer is a member of the Cinque Port of Sandwich.

WALMISLEY, THOMAS ATTWOOD (1814–1856), English musician. was born in London on Jan. 21, 1814. He was the eldest son of Thomas Forbes Walmisley (1783–1866), a well-known organist and composer of church music and glees. Thomas Attwood, his godfather, taught him composition. He became organist at Trinity and St. John's colleges. Cambridge. in 1833, and in 1836 was made professor of music in the University. He died at Hastings on Jan. 17, 18j6. His Cathedral *Music* was edited aiter his death by his father, and published in 1857. Some fine examples of his work are to be found in the D minor and B flat evening services. He was one of the first Englishmen to recognize the greatness of Bach's *Mass in B Minor*.

See the article by A. D. Coleridge in *Grove's Dictionary of Music and Musicians,* 5th ed. (London, New York, 1955) ; Edmund Fellowes, *English Cathedral Music* (London, Toronto, 1941).

WALNUT, the common name for the genus *Juglans*, which is widely known throughout the world because of the nuts and timber it produces. About 17 species are recognized, although some are distinguished only by their fruits, and in some cases there are intermediate forms hard to classify. Walnut plants, among the noblest of all hardwoods. may live for several centuries and become huge trees from 100 to 150 ft. tall with proportionate spread of crown and with trunk diameters of 4 to 6 ft. Sometimes growth is in bush or shrub form. but this is believed attributable more to environmental factors than to species limitation. All walnuts furnish food for many forms of wildlife; some produce nutritious. wholesome and palatable food for man. The product of one, the Persian walnut. is of greater importance as a food crop than that of any other nut tree outside the tropics. It and the eastern black walnut together furnish two of the world's most valuable and popular woods, used in making furniture and gunstocks and in interior decoration.

Persian Walnut.—The Persian (English) walnut, *Juglans regia,* is a large-growing tree, attaining heights of more than 100 ft. and trunk diameters of j or 6 ft. The bark is light to whitish in colour and very smooth while young. but it becomes gray and fissured with advanced age. The leaves are glossy and yellowish-green; there are from j to 0 leallets as a rule hut sometimes as many as 11 or 13. The surface is glossy and the margins are entire. The nut hulls are also smooth and glossy and about † in. in thickness. The nuts are of straw colour and the shells of varying thickness. sometimes being thick. hard and bony; in the case of nuts grown for market. the shells are thin enough to break easily with a light stroke of a hammer.

This walnut has been under cultivation for so many centuries and in so many countries that there is much uncertainty as to its exact place of origin and dates of introduction. One opinion is that the original home was in the mountains of western and northern China. Another view is that it was native throughout much of southeastern Europe, east to the Himalayas, and that it was carried from there to China. where it is cultivated to a wide extent and sometimes is naturalized to altitudes in excess of 8,000 it. It is little cultivated in Japan, although it has Iong been grown there to some extent.

Some authorities are uncertain that this walnut was in England before 1562, which appears to be the earliest date at which its presence there is definitely recorded. Others contend that it must have been taken there during the Roman occupation. A.D. 43 to 410. During modern times, production in that country has been of slight importance. Following World War I, increased planting in England and Wales was advocated. This was supported by the East Malling Research station, which then instituted a general investigation to determine the best varieties, rootstocks and methods of culture.

There is no certainty as to when this walnut was first taken to North America, although it is logically assumed to have been introduced by colonists during the 17th century. Environmental conditions in neither eastern nor southern regions of the United States are favourable for its commercial development. While there are many sites in the eastern states where the trees may grow well and bear good nuts with considerable regularity for several decades or even. in rare cases. a century or longer, the great majority of all that are planted perish before reaching bearing age. Stocks from Europe. the U.S.S.R. and China have been tried many times, only to fall short in so far as adaptability for commercial production was concerned. There are scattered trees throughout the general region between Long Island and Iiorfolk, Va., on the east and Wisconsin and Arkansas on the west.

An attempt to establish the Persian walnut in the eastern states was inaugurated in 1923 by P. C. Crath of Toronto. Ont., who as a retired Presbyterian missionary in Poland personally made selections from the hardiest and choicest trees in localities of the Carpathian mountains with which he had long been intimately familiar. Thousands of his trees were later planted in Ontario: western British Columbia and throughout the northern United States. By mid-century a fair percentage was reported to he giving promise of value for home planting in many localities where others had failed.

Cultural methods of the old world and new world differ radically. in harmony with economic necessity. In the former. where farm units are small and the primary object is to produce food for the home and a small surplus for sale to obtain money with which to purchase family necessities, trees are used in a general utility capacity. In some regions there are sizable orchards. but throughout most of Europe and Asia planting is mainly in conjunction with other crops or along farm borders, highways and about home grounds. The trees are often scattered about the fields in such manner that the landscape greatly resembles any typical pastoral view of eastern Cnited States. Prunings and dead branches serve as faggots for fuel.

The trees are headed high—18 to 20 ft.—in order to develop maximum length of trunk and also that they may interfere as little as possible with other crops to which the land is devoted. Important production is not expected in less than 20 years from the time of planting. On the whole. production is mainly from seedling trees, although there have been many grafted trees in France since probably before 1800. When for any reason these high-headed trees are cut, if fairly sound, the long trunks have value for furniture making.

It is on the Pacific coast of the United States, where the annual crops in the 1950s were about 70,000 tons for California and 7,000 for Oregon, that the industry of both producing and marketing Persian walnuts is conducted most intensively. Established in the first place (during the latter half of the 19th century) by able pioneers and later encouraged by state and federal research agencies and motivated by a strongly organized co-operative. the California Walnut Growers association, walnut growing there has long been on a plane rarely attained by any agricultural industry.

Secrets of successful walnut culture in California and the Pacific northwest call for strict use of well-chosen varieties including suitable pollinizers; trees grafted on stocks of the same walnut species: spacing the trees at not less than 60 ft. each way (12 to the acre): fertile soil; regular use of soil improvement crops; fertilization and irrigation as necessary; spraying or dusting to control pests and diseases; heading the trees low so as to provide shade for the trunks and thus lessen the danger of sunscald and also to bring about full bearing in 10 to 12 years; orchard heating in frosty areas; harvesting the nuts as soon as about 10% of the hulls have broken open; treating the nuts immediately with ethylene gas or with what is known as the "water sweat" process in order to loosen the hulls; and prompt hulling and drying (preferably by dehydration). The nuts are later graded with extreme care as to type and size. bleached so as to bring all to a common. bright. attractive colour, and each nut is stamped to show its brand designation. All that do not attain tlie required standard for sale "in-shell" are rated as "culls" and sold in the "shelled" condition; that is. as kernels. During years of overproduction. surplus nuts are also shelled.

The leading varieties are Placentia, Franquette. Payne. Eureka, Mayette and Concord.

The official estimates of the annual production of nuts, in short tons. for the five-year period 1948–52, were lor the United States 76,320 tons; Italy 22.440 tons; France 16.920 tons: Turkey 8,580 tons: Balkan countries 10,640 tons. Other important countries of production are China. India. Chile and Australia.

Other Species of Walnut.— The eastern biack walnut. J. *nigra,* is the largest groner of the genus. and heights to 150 ft. and trunk diameters to 6 it. were not unusual in tlie original virgin forests of the northeastern United States. Its native range included practically all regions where soil conditions were favourable, from lower New England, southern Ontario and southeastern Minnesota on the north to central parts of Georgia and the gulf states, westward to San Antonio. Tex. It was most abundant from the mountain valleys of western Pennsylvania, the Virginias and North Carolina. westward through the basin drained by the Ohio and Mississippi rivers to eastern Kansas and Nebraska. Outside this general region. there are many small districts where it has always grown equally well. What is believed to have been the largest walnut tree of any species ever recorded grew near Lake Erie in western New Tork. This tree was said to have been 150 ft. tall and to have had a trunk girth of 36 ft. It was 80 ft. to the first limbs and was 5 ft. through at that point. It was blown over during a gale in April 1822. The largest tree of the species known in later times overlooked Chesapeake bay, a feu. miles south of Annapolis. Md. In 1941 its girth at breast height was 19 ft. 9 in. and its estimated height 100 ft.

It is as a timber tree that this walnut is best known tliroughout the world. The value of its lumber together with its beauty and nobility -in an ornamental capacity so impressed the American colonists that it became one of the first new world introductions to be established in Europe; it is known to have been taken there during the 17th century. Its abundance. the ease with which it could be worked with carpenter's tools. its freedom from warping and checking. together with its lasting qualities when exposed to weather or in contact with soil, led to its use in countless ways. Farm residences, barns, bridges. railroad ties. canoes, boats and even ships were sometimes made of this wood. Because of the beauty of its grain. it is a great favourite in making furniture, pianos. organs, sewing machines. caskets and many other products. From early times, it has been the preferred wood for making gunstocks in the Cnited States.

Export of black walnut logs to Europe, chiefly to England and Germany. in both of which countries the lumber was iong used for both civilian and military purposes. constituted a heavy drain on the total supply. During World War I this wood served a vital end as material for making propellers for military planes, first in England and later in the United States. The extent to which it was used in making gunstocks during World War II resulted in the greatest drain on the supply that the country ever experienced. This led to the launching. late in 1943, by the American Walnut Manufacturers association of Chicago. Ill.. of a national campaign to stimulate *walnut* tree *planting* about the *entire* country. wherever soil and economic conditions might appear favourable.

Beginning with the first propagation of the Thomas variety in Pennsylvania about 1880. this species began slowly to work its way into U.S. orcharding. During the next third of a century, small numbers of grafted Thomas trees were planted in widely scattered gardens of many states. mainly to be lost sight of. Concerted interest began to show results in the way of commercial numbers of grafted trees from nurseries soon after the organization in 1910 of the Northern Nut Growers association. Inc. Other varieties were soon brought to light. largely as a result of cash prize contests conducted by that association for the best entries of seedling nuts. By the 1950s many hundreds of seedling black walnut trees had been top-worked with scions from the new selections, and there were a number or' orchard plantings ranging in size from a few trees each to 1.000 or more. These n-ere in various states. especially Pennsylvania. Michigan, Indiana, Illinois: Iowa and others south to the Carolinas and Arkansas.

Varieties which in the 1950s n-ere considered of greatest promise were: Adams. Allen. Creitz. Cresco. Edmunds. Edras. McMillen, Myers, Ohio. Sifford. Snyder. Stabler, Stambaugh. Tasterite. Ten Eyck, Thomas. Todd and Wiard.

Kernels of this walnut are a much-favoured product in making ice cream and candies and. to some extent. sweet breads. Together with kernels of the butternut, a close relative. also indigenous to the eastern Cnited States. the kernels not only add body to such food products but retain their flavour during the cooking process to a remarkable degree. The salt. oi walnut kernels in many parts of the country annually returns many thousands of dollars to rural communities. Shelling is largely by use of hand-power lever machines. although in a few instances motor-driven machines are used in small factories.

The Arizona black walnut, *J. major,* is a tree of medium size, reaching its maximum height at about 50 ft. and its greatest diameter of trunk at about 4 ft. It occurs at altitudes of 1,500 to 6,000 ft. in alluvial plains and mountain valleys of Arizona and New Mexico, southward to Durango. Mex. Its leaves are sometimes as much as a foot long and its leaflets typically 9 to 13 in number, although occasionally there are 17 or 19. The margins are distinctly serrate. The nut is edible but too small to be of value. The tree is seldom planted except in botanical gardens.

The (southern) California black walnut, J. *californica,* is a peculiar tree in that it seldom develops a trunk oi more than a few feet but puts out many branches from near the ground to form a rather bushy-appearing crown. Its maximum height is about 50 it. The nut is too small to have economic value. Stumps are reported to have been dug and sold by the pound to good advantage ior use by veneer concerns. One stump is said to have weighed joo lb. The tree is planted very little. In dry calcareous soils, this species oiten becomes a mere shrub of but a few feet in height.

The Hinds (northern California) black walnut, *J. hindsi,* is much the more valuable of the two species of *Juglans* indigenous to Caliiornia. Its usual maximum height is 50 to 60 ft. and its greatest trunk diameter about 3 ft. It is said, however, that in certain localities there are specimen trees 100 it. or more in height with diameters of 44 to 48 in. The tree is much used in roadside planting in northern Caliiornia and as an ornamental both there and in northwestern Oregon. Hinds walnuts are about equal in size to those of eastern black, and to an important extent they are shelled and the kernels sold readily to confectioners. Trees of this species formerly were, but no longer should be, used as rootstocks for propagating grafted varieties of the Persian walnut; graft union failures result.

The wood of this walnut, although the grain is somewhat coarse, takes a high polish, and to the limited extent that trees are available for cutting, the lumber is used in a manner similar to that of the eastern and Persian walnuts. There are a few clons, but these are little propagated.

The heartnut or cordate walnut, J. *sieboldiana cordiformis,* a native of Japan, is a small or medium-sized tree, rarely attaining heights of more than 50 ft. or trunk diameters greater than 2 ft. In moderately severe regions of the north temperate zone, it grows rapidly and tends to develop a broad-spreading, low crown with luxuriant foliage, considered by some as tropical in aspect. While it is normally precocious, and under favourable conditions may bear moderately for several decades, it is rarely prolific. It usually has 13 to 15 leaflets per leaf and yields its fruits in racemes of five to nine each. The nut is small, heartlike in shape, sharply pointed at the apex, flattened on the sides, and rounded at the base and grooved from the middle of the sides to the apex. When placed on a block and tapped with a hammer, either on an edge or on the end, the shell readily splits into halves along the sutures, and although this is crosswise to the kernel, it enables it to be extracted without injury. Several varieties have been made available by U.S. nurserymen ior limited use in garden planting. The best known of these are Bates, Fodermaier, Lancaster, Stranger, Walters and Wright.

The Siebold walnut, J. *sieboldiana,* a variant form of heartnut, differing irom it only in fruit, has been planted in the United States to about the same extent. As a tree, its habits and features are identical. Seedlings of either are likely to produce nuts of the other or of an intermediate type which might be classified either may. Siebold walnuts arc larger than heartnuts, being irom one to two inches long. They are roundish at the base and conical from below the middle to the apex. The shell is smooth to the hand but distinctly fissured; it is hard and difficult to crack so as to release the kernels except in particles. The kernel greatly resembles that of butternut in appearance, texture and flavour, except that it is usually milder.

It is said that in Japan both this and heartnut trees are used as sources of lumber for gunstocks and furniture. Neither has indicated special possibilities in such capacity under U.S. conditions. However, both make very satisfactory ornamentals in the northeastern states, where growth and longevity are both better than in the south. Neither has been found commercially profitable in the United States, since the nuts do not compete well with others on the market. Their most satisfactory use is as decorative trees and as producers of nuts for the home table. Both iorms hybridize readily with Persian walnut and butternut.

The Texas black walnut, *J. rupestris,* is a shrubby or small-growing tree, rarely attaining more than 30 ft. in height or a trunk diameter greater than 30 in. The leaves are 9 to 12 in. long and the leaflets 13 to 23 in number, slender and with finely serrate margins. The nuts are small, roundish, thick-walled and of little value, although sweet. The tree commonly occurs on limestone soils, especially along streams of western Texas, southwestern Oklahoma and southeastern New Mexico. Wood from the largest stumps and butt log cuts makes a beautiiul veneer and is much prized.

Miscellaneous Walnuts.— Other native walnuts of the new world which received little world attention include the Argentine black walnut, *J. australis;* the Bolivian black walnut, *J. boliviana;* the Colombian black walnut, *J. columbiensis;* the Ecuador walnut, J. *honorei;* the Cuban walnut, *J. insularis;* and the Guatemalan walnut, *J. mollis.* In the United States there are a number of hybrid forms, of which none bears evidence of promise for either nut or timber production. Both the California and Hinds walnuts hybridize freely with the eastern black; the Persian with any black or with butternut, and also with the heartnut. Some of these have been regarded as having potential value for forestry plantings, but none has been so used. The costs of procuring suitable seed in quantity and the expense of securing land suitable for walnut trees of any kind are effective barriers against growing hybrid walnut trees in quantity for timber production. The term "Claro" is applied to wood oi any hybrid walnut grown in California.

There are three walnuts in northeastern China, much alike, which are recognized as being separate species. These are the Cathay walnut, *J. cathayensis;* the Manchu walnut, *J. mandshurica;* and one which appears to have no common name, *J. stenocarpa.* None is believed to offer special inducement to practical planters, except possibly in cold regions having a maritime climate.

WALPOLE, HORATIO or Horace (1717–1797), English politician and man of letters, 4th earl of Orford—a title to which he only succeeded at the end of his life—\\,as born in London on Sept. 24, 1717. He was the youngest of the five children of the 1st earl of Orford (Sir Robert Walpole) by Catherine Shorter, but by some scandalmongers Carr, Lord Hervey, has been called his father.

He was educated at Eton, where he formed what was known as the "Quadruple Alliance" with Thomas Gray, Richard West and Thomas Ashton, and became very intimate with Henry Seymour Conway, George Augustus Selwyn and the two Montagus; and at King's college. Cambridge.

Walpole was returned to parliament in May 1741 for the Cornish borough of Callington. He retired from parliament, probably because his success in political life had not equalled his expectations. but he continued until the end of his days to follow and to chronicle the acts and the speeches of both houses of parliament. Through his father's influence he had obtained three lucrative sinecures in the exchequer, and for many years (1745–84) he enjoyed a share, estimated at about £1,500 a year, of a second family perquisite. the collectorship of customs. He acquired in 1747 the lease and in the next year purchased the reversion of the villa of Strawberry Hill: near Twickenham, on the banks of the Thames. He established a printing press there, which he called Officina Arbuteana. where many of the first editions of his own works were printed. His nephew, the reckless 3rd earl. died on Dec. 5, 1791, and Walpole succeeded to the peerage, but he never took his place in the house of lords. All his life long he was a victim of the gout, but he lived to extreme old age and died unmarried. in Berkeley square, London, on March 2. 1797. All Walpole's printed books and manuscripts were left to Robert Berry and his two daughters, Mary and Agnes, and Mary Berry edited the five volumes of Walpole's works which were published in 1798.

The pen was ever in Horace Walpole's hands, and his entire compositions would fill many volumes. His *Castle of Otranto* (1764) is the prototype of the romantic novel. The *Mystevious Mother* (1768) is the least bad of tragedies when tragedy was at its worst. Walpole's antiquarian works merit praise. The volume of *Historic Doubts on the Life and Reign of King Richard the Third* (1760), one of the earliest attempts to rehabilitate a character previously stamped with infamy, showed acuteness and research. A work of more lasting reputation is *Anecdotes of Painting in England* (1st ed., 4 vol., 1762–71). A cognate volume, also based on the materials of Vertue, is entitled the

Catalogue of Engravers Born and Resident in England (1763), also often reprinted. As a senator himself, or as a private person following at a distance the combats of St. Stephen's, Walpole recorded in a diary the chief incidents in English politics. If he was sometimes prejudiced, he rarely distorted the acts of those whom he disliked; and his prejudices, which lie on the surface, were mainly against those whom he considered traitors to his father. These diaries extend from 1750 to 1783, and cover a period of momentous importance. The *Memoirs of the Last Ten Years of the Reign of George II.* was edited by Lord Holland (1846); its successor, *Memoirs of the Reign of King George III.*, was edited by Sir Denis Le Marchant (4 vols., 1845), and re-edited in 1854 by G. F. Russell Barker; the last volumes of the series, *Journal of the Reign of George III. from 1771 to 1783*, were edited and illustrated by John Doran (2 vols., 1859), and were edited with an introduction by A. F. Steuart (London, 1909). To these works should be added the *Reminiscences* (2 vols., 1819), which Walpole wrote in 1788 for the Misses Berry. But Walpole was above all a letter-writer. His correspondents were numerous and widespread, but the chief of them were William Cole (1714–1782), the clerical antiquary of Milton; Robert Jephson, the dramatist; William Mason, the poet; Lord Hertford during his embassy in Paris; the countess of Ossory; Lord Harcourt; George Montagu, his friend at Eton; Henry Seymour Conway (1721–1795) and Sir Horace Mann. The *Letters* were published at different dates, but the standard collection is that by Mrs. Paget Toynbee (1903–1905), and to it should be added the volumes of the letters addressed to Walpole by his old friend Madame du Deffand (4 vols., 1810). A selection has been edited by W. S. Lewis (New York and London, 1926). Walpole has been called "the best letter-writer in the English language." His political estimates are more acute than his literary ones.

Abundant information about Horace Walpole will be found in the *Memoirs* of him and of his contemporaries edited by Eliot Warburton (1851), J. H. Jesse's *George Selwyn and his Contemporaries* (4 vols., 1843–44) and the extracts from the journals and correspondence of Miss Berry (3 vols., 1866); also *Horace Walpole and his World*, by L. B. Seeley (1884) and Austin Dobson, *Horace Walpole* (1890). It would be unpardonable to omit mention of Macaulay's sketch of Walpole's life and character. *See* also P. Yvon, *Horace Walpole, 1717–97. Essai de biographie psychologique et littéraire* (1924), and *Horace Walpole as Poet* (Paris, 1924); H. B. Wheatley in *Cambridge History of English Literature*, vol. 10 (1913); D. M. Stuart, *Horace Walpole* in *English Men of Letters* (1927).

WALPOLE, SIR ROBERT: *see* ORFORD, ROBERT WALPOLE, 1ST EARL OF.

WALPURGIS (WALPURGA or WALBURGA), **SAINT** (d. *c.* 780), English missionary to Germany, was born in Sussex at the beginning of the 8th century. She mas the sister of Wunnibald, first abbot of Heidenheim. She went about 750 with some other nuns to found religious houses in Germany. Her first settlement was at Bischofsheim in the diocese of Mainz, and two years later (754) she became abbess of the Benedictine nunnery at Heidenheim in the diocese of Eichstatt. On the death of Wunnibald in 760 she succeeded him in his charge also! retaining the superintendence of both houses until her death. Her relics were translated to Eichstätt, where she was laid in a hollow rock, from which exuded a kind of bituminous oil afterward known as Walpurgis oil. and regarded as of miraculous efficacy against disease. The cave became a place of pilgrimage, and a church was built over the spot. Walpurgis is commemorated at various times, but principally on the 1st of May, her day taking the place of an earlier heathen festival marking the beginning of summer. She is regarded as the protectress against magic arts.

WALRAS, LÉON (1834–1910), French economist and author of a classical work on pure economics, was born at Évreux. son of the economist Auguste Walras. After twice failing the entrance examination to the Bcole Polytechnique in Paris for lack of adequate preparation in mathematics, he entered the Bcole des Mines in 1854. In 1858 he was convinced by his father that he should pursue economics, and he obtained the chair of political economy in the faculty of law of the Academy of Lausanne. Switz., in 1870. His outstanding work, *Éléments d'économie politique pure* (1874–77; English translation in 1954, from the edition of 1926, by William Jaffe, titled *Elements of Pure Economics)*, was a pioneering comprehensive application of mathematical analysis to the case of general economic equilibrium under a "regime of perfectly free competition"; that is, a conceptual solution of the problem of the equilibrium of prices, quantities of products and the productive factors. In his other important publications, *Théorie mathématique de la richesse sociale* (1883) and *Études d'e'conomie politique appliquée* (1898), Walras presented reforms that he conceived to be necessary for the effective functioning of the system of free enterprise, notably land nationalization and modification of the gold standard. (J. DN.)

WALRUS (MORSE) (*Odobenus rosmarus)*, a large marine mammal allied to the seals. Characterized by the prolongation, in both sexes, of the upper canine teeth into tusks, which may reach a length of 2 ft., the adult walrus measures about 10 or 11 ft. and is a heavily-built animal. The head is rounded, the eyes small, external ears absent. The short broad muzzle bears on each side a group of stiff, bristly whiskers. The tail scarcely projects beyond the skin. The fore limbs are only free from the elbow and the fore flipper is broad, flat and webbed. The hind limbs, free from the heel, are fan-shaped. The skin is covered with short, rufous hair, which becomes very scanty in old animals. There are deep folds on the shoulder.

The walrus inhabits the northern circumpolar region in small herds. It prefers the coastal portions or ice floes and feeds largely on bivalve mollusks which it digs up from the bottom of the sea with its tusks. Normally inoffensive and affectionate, when attacked the walrus can use its tusks with terrible effect and the herd usually combine against an enemy. Its principal foe, apart from man, is the polar bear, and its flesh is an important article of food to the Eskimo and Chukchi. Commercially the walrus is valuable for its oil, its hide and its ivory. The Pacific walrus, with longer and more slender tusks, has been separated as *O. r. divergens.* Like the Atlantic form, its numbers have been much reduced within recent years. Fossil walruses are known from the late Tertiary of the U.S., England, France and Belgium.

WALSALL, a municipal, county and parliamentary borough of Staffordshire, Eng., 6 mi. E. of Wolverhampton. Pop. (1961) 117,836. Area 13.7 sq.mi. The old town stands on a ridge and is dominated by the 15th-century church of St. Mafthew in the centre, On the northeast is a 90-ac. arboretum. Manufactures include leather goods, machine tools, chemicals and aircraft parts. Coal, limestone and ironstone are mined nearby. Queen Mary's school is a foundation of 1554 and there was educated John Hough (1651–1743), president of Magdalen college, Oxford, and bishop of Oxford, Lichfield and Worcester. Walsall was the scene of the charitable work of Sister Dora (Miss Pattison) who died there in 1878 and whom a statue and a stained glass window in St. ~ ~ t thew's commemorate. Walsall (Waleshale) was given in 996 to the church of Wolverhampton. It was a royal manor in the time of Edward the Confessor, but later passed to the Bassets and the Beauchamps. Henry VIII gave it (1538) to Dudley, afterward duke of Northumberland. Charters were granted by Henry II in 1159 and by Henry IV, Charles I (1627, which laid the foundations of municipal self-government) and Charles II (1674, by which the town was governed until 1835). The roll of mayors dates back to 1377 and the first mention of a town clerk is in 1660. It had a merchant guild in 1390; in the 17th century it was known for its manufacture of iron goods and nails; in the 18th century the staple industry was the making of chapes and shoe buckles. Three annual fairs are held, two were granted in 1399, and the Tuesday market was granted in 1417 to Richard Beauchamp, earl of Warwick. Walsall was not represented in parliament till 1832; it returned one member until 1955 when the borough mas divided into two.

WALSH, THOMAS JAMES (1859–1933), U.S. lawyer and senator, was born in Two Rivers, Wis., on June 12, 1859.

In 1912 he was elected U.S. senator from Montana, going to the Senate without previous experience in public office. He was re-elected in 1918 and in 1924. He was five times a delegate to the Democratic national convention previous to 1924, in which year he presided as chairman of the convention. In 1924 he was offered the vice-presidency on the ticket with John W. Davis, but he declined. He was even more seriously spoken of in 1928 as the only strong alternative candidate to Alfred E. Smith, but before the convention met he signified his desire not to be considered. In the Senate he became an outstanding figure. His speeches, replete with facts and packed with close reasoning, made him a formidable adversary in debate. As an expert lawyer he was constantly called upon for advice. He aided in drafting the Prohibition and Woman-Suffrage amendments to the Constitution, and was also author of that part of the Federal Reserve Act which requires national banks to subscribe for stock in the Federal Reserve banks. He also formulated the case against the seating of Senator Truman H. Newberry, of Michigan. He is chiefly noted, however, for the tireless tenacity with which he prosecuted the investigation of circumstances surrounding the illegal leasing of Government oil reserves during Harding's Administration. His energetic although unsuccessful struggle in 1928 to secure a Senate investigation of power companies earned him Roosevelt's first choice for Attorney General. Unfortunately his death on March 2nd closely followed the wide popular approval of the preliminary announcement of his appointment.

WALSH, WILLIAM JOHN (1841–1921), Roman Catholic divine, was born in Dublin Jan. 30, 1841. Educated in Dublin and at St. Patrick's college, Maynooth, in 1867 he was appointed professor of dogmatic and moral theology at Maynooth. In 1878 he became vice-president of the college and in 1881 succeeded Dr. Russell as president. Dr. Walsh served on several committees and commissions. He was partly responsible for the appointment of the commission to enquire into the working of the Queen's Colleges, and he became a member of the senate of the university. In 1885 he was summoned to Rome by the Pope and given the appointment of archbishop of Dublin. This office he continued to hold till his death in Dublin, on April 9, 1921. Dr. Walsh was a commissioner for education in Ireland (1891) and, a member (1908) of the Dublin statutory commission which established the Catholic National University, with himself as chancellor. In politics he was a Nationalist, but he strongly opposed compromise with the British Government, and after the rebellion of 1916 he supported the Sinn Feiners.

Dr. Walsh's published works include *A Plain Exposition of the Irish Land Act of 1881* (1881); *The Queen's Colleges and the Royal University* of *Ireland* (1883–84); *The Irish University Question* (1890).

WALSINGHAM, SIR FRANCIS (*c.* 1530–1590), English statesman, was the only son of William Walsingham, common serjeant of London (d. March 1534), by his wife Joyce, daughter of Sir Edmund Denny of Cheshunt. Francis matriculated as a fellow-commoner of King's college, Cambridge, of which Sir John Cheke was provost, in Nov. 1548; and he studied there amid strongly Protestant influences until Michaelmas 1550, when he appears to have gone abroad to complete his education. Returning in 1552 he was admitted at Gray's Inn on Jan. 28, 1553, but in 1555–56 he was at Padua, where he was admitted a "consiliarius" in the faculty of laws. Walsingham was twice married; in Jan. 1562 to Anne (d. 1564), daughter of George Barnes, lord mayor of London, and to Ursula, daughter of Henry St. Barbe and widow of Sir Richard Worsley. By his second wife Walsingham had a daughter who married firstly Sir Philip Sidney, secondly Robert Devereux, 2nd earl of Essex, and thirdly, Richard de Burgh, earl of Clanricarde.

Walsingham sat in Elizabeth's first and second parliaments for Banbury, and was attached to the party of Cecil. In 1567–70 he was supplying Cecil with information about the movements of foreign spies in London. Ridolfi, the conspirator, was committed to his custody in Oct. 1569. In the summer of 1570 he was, in spite of his protestations, designated to succeed Norris as ambassador at Paris. Walsingham was the ablest of the new men whom Cecil, having triumphed over the older aristocracy, brought to the front.

Embassy to Paris.—An essential element in the new policy was the substitution of an alliance with France for the old Burgundian friendship. The affair of San Juan de Ulua and the seizure of the Spanish treasure-ships in 1568 had been omens of the inevitable conflict with Spain; Ridolfi's plot and Philip II.'s approaches to Mary Stuart indicated the lines upon which the struggle would be fought; and it was Walsingham's business to reconcile the Huguenots with the French Government, and upon this reconciliation to base an Anglo-French alliance which might lead to a grand attack on Spain, to the liberation of the Netherlands, to the destruction of Spain's monopoly in the New World and to making Protestantism the dominant force in Europe. Walsingham threw himself heart and soul into the movement. He was the anxious fanatic of Elizabeth's advisers; he lacked the patience of Burghley and the cynical coolness of Elizabeth. He supplied the momentum which was necessary to counteract the caution of Burghley and Elizabeth; but it was probably fortunate that his headstrong counsels were generally overruled by the circumspection of his sovereign. He would have plunged England into war with Spain in 1572, when the risks would have been infinitely greater than in 1588, and when the Huguenot influence over the French Government, on which he relied for support, would probably have broken in his hands.

Walsingham, however, was an accomplished diplomatist, and he reserved these truculent opinions for the ears of his own Government, incurring frequent rebukes from Elizabeth. In his professional capacity, his attitude was correct enough; and, indeed, his anxiety for the French alliance and for the marriage between Elizabeth and Anjou led him to suggest concessions to Anjou's Catholic susceptibilities which, came strangely from so staunch a Puritan. Although a defensive alliance was concluded between England and France in April 1572, the French Government perceived that public opinion in France would not tolerate an open breach with Spain in Protestant interests. The massacre of St. Bartholomew ruined all such hopes.

He was recalled in April 1573, and eight months later he was admitted to the privy council and made joint secretary of State with Sir Thomas Smith. He held this office jointly or solely until his death; in 1577 when Smith died, Dr. Thomas Wilson was associated with Walsingham; after Wilson's death in 1581 Walsingham was sole secretary until July 1586, when Davison began his brief and ill-fated seven months' tenure of the office. After Davison's disgrace in Feb. 1587 Walsingham remained sole secretary, though Wolley assisted him as Latin secretary from 1588 to 1590. He was also returned to parliament at a by-election in 1576 as knight of the shire for Surrey in succession to Charles Howard, who had become Lord Howard of Effingham, and he was re-elected for Surrey in 1584, 1586 and 1588. He was knighted on Dec. 1, 1577, and made chancellor of the order of the Garter on April 22, 1578.

State **Secretary.**—As secretary, Walsingham could pursue no independent policy; he was rather in the position of permanent under-secretary of the combined home and foreign departments, and he had to work under the direction of the council, and particularly of Burghley and the queen. He continued to urge the necessity of more vigorous intervention on behalf of the Protestants abroad, though now his clients were the Dutch rather than the Huguenots. In June 1578 he was sent with Lord Cobham to the Netherlands, mainly to glean reliable information on the complicated situation. In Aug 1581 he was sent on a second and briefer mission to Paris. Its object was to secure a solid Anglo-French alliance against Spain without the condition upon which Henry III. insisted, namely a marriage between Elizabeth and Anjou. The French Government would not yield, and Walsingham came back, followed by Anjou, who pressed his claims in person. Walsingham's last embassy was to the court of James VI. in 1583, and here his vehement and suspicious Protestantism led him astray. Elizabeth and Burghley were inclined to try an alliance with the Scottish king, and the event justified their policy, which Walsingham did his best to frustrate, although deserted on this occasion by his chief regular supporter, Leicester.

For the rest of his life Walsingham was mainly occupied in detecting and frustrating the various plots formed against Elizabeth's life. He raised the English system of secret intelligence to a high degree of efficiency. At one time he is said to have had in his pay 53 agents at foreign courts, besides 18 persons whose functions were even more obscure. Some of them were double spies, sold to both parties, whose real sentiments are still conjectural; but Walsingham was more successful in seducing Catholic spies than his antagonists were in seducing Protestant spies, and most of his information came from Catholics who betrayed one another. The most famous of the plots frustrated by Walsingham was Anthony Babington's, the discovery of which enabled him to bring pressure to bear upon Elizabeth to ensure Mary's execution. Walsingham died deeply in debt on April 6, 1590.

See K. Stahlin, *Sir Francis Walsingham und seine Zeit* (Heidelberg, 1908, etc.) ; and C. Read, *Mr. Secrrtary Walsingham and the policy of Queen Elizabeth* (3 vols., 1925).

WALSINGHAM, THOMAS (d. c. 1422), English chronicler, was probably educated at the abbey of St. Albans and at Oxford. He became a monk at St. Albans, where he appears to have passed the whole of his monastic life except the six years between 1394 and 1400 during which he was prior of another Benedictine house at Wymondham, Norfolk. At St. Albans he was in charge of the scriptorium, or writing room, and he died about 1422. Walsingham's most important work is his *Historia Anglicans,* covering the period between 1272 and 1422. Some authorities hold that Walsingham himself only wrote the section between 1377 and 1392, but this view is controverted by James Gairdner in his *Early Chroniclers of Europe* (1879).

His most important works are *Historia Angliae brevis,* edit. by H. T. Riley (1863–64) ; *Chronicon Angliae,* edit. Sir E. M. Thompson (1874); *Gesta Abbatum Monasterii S. Albani,* edit. by T. H Riley (1867–69); *Ypodigma Neustriae,* edit. by T. H. Riley (1876).

WALTER, BRUNO (1876–1962), conductor, was born in Berlin, Ger., on Sept. 15, 1876. In 1893 he began to conduct operas at the Cologne opera house. He was chorus master, 1894–95, and conductor. 1895–96. of the opera house in Hamburg. He later held various posts, including that of conductor of the Vienna opera, 1901–12, and served as guest conductor in many of the music centres of the world. He was musical adviser to the Philharmonic-Symphony Society of New York, 1947–49. In 1938 he became a French citizen and in 1946 a United States citizen. He died on Feb. 17, 1962, in Beverly Hills, Calif.

See his autobiography, *Theme and Variations* (New York, 1946).

WALTER, HUBERT (d. 1205), chief justiciar of England and archbishop of Canterbury, was a relative of Ranulf de Glanvill, the great justiciar of Henry II., and rose under the eye of his kinsman to an important position in the Curia Regis. In 1184 and in 1185 he appears as a baron of the exchequer. He was employed, sometimes as a negotiator, sometimes as a justice, sometimes as a royal secretary. He received no clerical promotion from Henry II., but Richard I. appointed him bishop of Salisbury, and by Richard's command he went with the third crusade to the Holy Land. He gained the respect of all the crusaders, and acted as Richard's principal agent in all negotiations' with Saladin, being given a place in the first band of pilgrims that entered Jerusalem. He led the English army back to England after Richard's departure from Palestine; but in Sicily he heard of the king's captivity, and hurried to join him in Germany. In 1193 he returned to England to raise the king's ransom. Soon afterwards he was elected archbishop of Canterbury and made justiciar. He was very successful in the government of the kingdom, and after Richard's last visit he mas practically the ruler of England. He had no light task to keep pace with the king's constant demand for money. He was compelled to work the administrative machinery to its utmost, and indeed to invent new methods of extortion. To pay for Richard's ransom, he had already been compelled to tax personal property, the first instance of such taxation for secular purposes. The main feature of all his measures was the novel and extended use of representation and election in government.

His chief measures are contained in his instruction to the itinerant justices of 1194 and 1195, in his ordinance of 1195 for the conservation of the peace, and in his scheme of 1198 for the assessment of the carucage. The justices of 1194 were to order the election of four coroners by the suitors of each county court. These new officers were to "keep," *i.e.,* to register, the pleas of the crown, an important duty hitherto left to the sheriff. The juries, both for answering the questions asked by the judges and for trying cases under the grand assize, were to be chosen by a committee of four knights, also elected by the suitors of each county court for that purpose. In 1195 Hubert issued an ordinance by which four knights were to be appointed in every hundred to act as guardians of the peace, and from this humble beginning eventually was evolved the office of justice of the peace. His reliance upon the knights, or middle-class landowners, who now for the first time appear in the political foreground, is all the more interesting because it is this class who, either as members of parliament or justices of the peace, were to have the effective rule of England in their hands for so many centuries.

In 1198, to satisfy the king's demand for money, Hubert demanded a carucage or plough-tax of five shillings on every ploughland (carucate) under cultivation. This was the old tax, the Danegeld, in a new and heavier form and there was great difficulty in levying it. To make it easier, the justiciar ordered the assessment to be made by a sworn jury in every hundred, and one may reasonably conjecture that these jurors were also elected. Hubert negotiated a peace with Scotland in 1195, and in 1197 another with the Welsh. But the carucage was not a success, and the Great Council refused to equip a force of knights to serve abroad.

In 1198 Hubert, who had inherited from his predecessors in the primacy a fierce quarrel with the Canterbury monks, gave these enemies an opportunity of complaining to the pope, for in arresting the London demagogue, William Fitz Osbert, he had committed an act of sacrilege in Bow Church, which belonged to the monks. The pope asked Richard to free Hubert from all secular duties, and he did so, thus making the demand an excuse for dismissing Hubert from the justiciarship. On May 27, 1199, Hubert crowned John, making a speech in which the old theory of election by the people was enunciated for the last time. He also took the office of chancellor and cheerfully worked under Geoffrey Fitz Peter, one of his former subordinates. In 1201 he went on a diplomatic mission to Philip Augustus of France, and in 1202 he returned to England to keep the kingdom in peace while John was losing his continental possessions. In 1205 he died. Hubert was an ingenious, original and industrious public servant, but he was grasping and perhaps dishonest.

See W. Stubbs, *Constitutional History,* vol. i. (1897); Miss K. Norgate's *England under the Angevin Kings,* vol. ii. (1887) ; W. Stubbs, preface to vol. iv. of Roger of Hoveden's *Chronicle* ("Rolls" series, 1868–71).

WALTER, JOHN (1738/9–1812), founder of *The Times* newspaper, London, was born in 1738/9, probably in London, and from the death of his father, Richard Walter (about 1755/6), until 1781 was engaged in a prosperous business as a coal merchant. He played a leading part in establishing a Coal Exchange in London; but shortly after 1781, when he began to occupy himself solely as an underwriter and became a member of Lloyd's, he over-speculated and failed. In 1782 he bought from one Henry Johnson a patent for a new method of printing from "logotypes" (*i.e.,* founts of words or portions of words, instead of letters), and made some improvements in it. In 1784 he acquired an old printing office in Blackfriars, which formed the nucleus of the Printing-house Square of a later date, and established there his "Logographic Office." At first he only undertook the printing of books, but on Jan. 1, 1785 he started a small newspaper called *The Daily Universal Register,* which on reaching its 940th number on Jan. 1, 1788 was renamed *The Times.*

The printing business developed and prospered, but the newspaper at first had a somewhat chequered career. In 1789 Walter was tried for a libel in it on the duke of York, and was sentenced to a fine of £50, a year's imprisonment in Newgate, to stand in the pillory for an hour and to give surety for good behaviour for seven years; and for further libels the fine was increased by £100, and the imprisonment by a second year. On March 9, 1791, however, he was liberated and pardoned. In 1799 he was again convicted for a technical libel, this time on Lord Cowper. He had then given up the management of the business to his eldest son, William, and had (1795) retired to Teddington, where he died on Nov. 16, 1812. In 1759 he had married Frances Landen (died 1798), by whom he had six children, In 1803 William Walter transferred the sole management to his younger brother, John.

JOHN WALTER (2) (1776–1847), who really established the great newspaper of which his father had sown the seed, was born on Feb. *23,* 1776, and was educated at Merchant Taylors' school and Trinity college, Oxford. He found *The Times* one of a number of unconsidered journals whose opinions counted for little. He left it in 1847 a great organ of public opinion, deferred to and even feared throughout Europe, consulted and courted by cabinet ministers at home and in intimate relations with the best sources of independent information in every European capital. On taking over the management in *1803,* he signalized the new spirit of the direction by his opposition to Pitt, which cost him the withdrawal of government advertisements and the loss of his appointment as printer to the customs and exposed him to the not too scrupulous hostility of the official world. He let the government do its worst and held on his way. From about 1810 he delegated to others editorial supervision (first to Sir John Stoddart, then to Thomas Barnes and in *1841* to J. *T.* Delane), though never the supreme direction of policy. In *1832* Walter, who had purchased an estate called Bear Wood in Berkshire, was elected to parliament for that county, and retained his seat till 1837. In 1841 he was returned to parliament for Nottingham, but was unseated next year on petition. He died in London on July *28,* 1847.

JOHN WALTER (3) (1818–94), his eldest son, was born at Printing-house square in 1818, and was educated at Eton and Exeter college, Oxford, being called to the bar in 1847. On leaving Oxford he took part in the business management of *The Times,* and on his father's death became sole manager, though he devolved part of the work on Mowbray Morris. It was under him that the successive improvements in the printing machinery, begun by his father in *1814,* at last reached the stage of the Walter press in 1869, the pioneer of modern newspaper printing presses. In 1847 he was elected to parliament for Nottingham as a moderate Liberal, and was re-elected in 1852 and in 1857. In 1859 he was returned for Berkshire and, though defeated in 1865, was again elected in 1868 and held the seat till he retired in 1885. He died on Nov. 3, 1894, and was succeeded by Arthur Fraser Walter (1846–1910), his son. A. F. Walter remained chief proprietor of *The Times* till 1908, when it was converted into a company. He then became chairman of the board of directors, and on his death was succeeded in this position by his son John, who entered *The Times* office in 1898 and was chairman of the directors from 1910 to 1923. John Walter's son, Hubert Walter (b. 1870), joined the staff in *1894* and acted as special representative in Paris and elsewhere. (For changes in the management of *The Times* after 1908 see NEWSPAPER: *United Kingdom.)* (H. C.; X.)

WALTER, LUCY (*c.* 1630–1658), mistress of the English king Charles II and mother of the duke of Monmouth (*q.v.*), was born at Roch castle, near Haverfordwest. Her home having been captured and burned by the parliamentary forces in *1644,* Lucy Walter found shelter first in London and then at The Hague. There, in 1648, she met Charles, possibly renewing an earlier acquaintance. Their intimacy lasted with intervals till the autumn of *1651,* and Charles claimed the paternity of a child born in *1649,* whom he subsequently created duke of Monmouth.

WALTER, THOMAS USTICK (1804–1887), one of the architects of the U.S. Capitol, was important especially for the quality and influence of his designs based upon ancient Greek models. He was born in Philadelphia, Pa., on Sept. 4, 1804, and served variously as professor of architecture at the Franklin institute, Philadelphia, engineer for the harbour at La Guaira, Venez. (1843–45), and president of the American Institute of Architects (1876–87), which in 1857 he had helped to found. His style was formed in part by two brief periods of employment in the Philadelphia office of the architect William Strickland. In 1833 Walter was selected to design the main building of Girard college in Philadelphia, and the form which he finally gave to Founders' hall remains unsurpassed as an example of Greek Revival architecture. Its designer is better known, however, for the additions which he made to the U.S. Capitol in Washington, D.C., and especially for the massive cast-iron dome with which he replaced the earlier low wooden one (1855–63). Illustrative of Walter's rare use of styles other than the Greek Revival is the Gothic design of the Philadelphia county prison (Moyamensing) with its Egyptian debtors' wing *(1835).* His last years were spent in the architectural office of John McArthur, Jr., where he is assumed to have had some part in the design of the Philadelphia city hall. He died in Philadelphia on Oct. *30, 1887.*

WALTER OF COVENTRY (fl. 1290), English monk and chronicler, who is known only through the historical compilation which bears his name, the *Memoriale fratris Walteri de Coventria.* The author of the *Memoriale* lived in the reign of Edward I and mentions the homage done to Edward as overlord of Scotland (1291). Since the main narrative extends only to *1225,* the *Memoriale* is emphatically a secondhand production. Rut for the years 1201–25 it is a faithful transcript of a contemporary chronicle, the work of a Barnwell canon.

The Barnwell annalist is the most valuable authority for the Barons' War. He is less hostile to John than are Ralph of Coggeshall, Roger of Wendover and Matthew Paris. He praises the king's management of the Welsh and Scottish wars; he is critical in his attitude toward the pope and the English opposition; he regards the submission of John to Rome as a skillful stroke of policy. The constitutional agitation of *1215* does not arouse his enthusiasm; he passes curtly over the Runnymede conference, barely mentioning Magna Carta. (H. W. C. D.)

WALTHAM, a city of Massachusetts, U.S., in Middlesex county, is on the Charles river *10* mi. W. of Boston. The area was first settled in 1636, set off from Watertown (*q.v.*) and incorporated as a town in *1738,* and chartered as a city in 1884. The five-foot waterfall in the centre of town was used to grind flour in the 17th century; in *1788* a paper mill was established there. In 1813 Francis Cabot Lowell used the site for the Boston Manufacturing company's power mill, the first in the U.S. to process raw cotton into cloth under one roof. For many years the American Waltham Watch company (established in *1854)* was one of the largest in the world, and it played an important part in the city's progress. Watchmaking was largely superseded by the manufacture of electronic equipment and precision instruments. A mental hospital, a sanatorium and a school for the mentally ill are there. The first U.S. training school for nurses was started in Waltham in *1885.* The city is the site of Brandeis university (founded in 1947) and the provincial houses of two Roman Catholic orders. The town's most famous resident was Nathaniel Prentiss Banks (*q.v.*). The city, which is part of the Boston standard metropolitan statistical area: had a population of *55,413* in 1960 and 47,187 in 1950. For comparative population figures see table in MASSACHUSETTS: *Population.* (SA. S.)

WALTHAM HOLY CROSS, a market town and urban district in the Epping parliamentary division of Essex, Eng., between the Lea and Epping forest, 13 mi. N.E. of London bridge. Pop. *(1951) 8,201.* Its former name, Waltham Abbey, was derived from the abbey built by Harold in *1060.* The abbey church replaced an earlier one made to hold a miraculous cross found at Montecute in Somerset. Henry II refounded the abbey in *1177.* Henry III frequently stayed at Waltham abbey. Most of the abbey church was demolished at the dissolution, but the nave was retained and now forms the parish church. The tower was built (1556–58) from remains of the old building. Of the monastic buildings there remain only a bridge, gateway and other fragments. The district contains greenhouses, producing tomatoes, cucumbers and out-of-season fruits and flowers. The manufacture of fertilizers and plastics also provides employment. A government high-explosive factory was later devoted to research.

WALTHAMSTOW, a municipal and parliamentary borough of Essex, Eng., and a northeastern suburb of London. Pop. (1951) *121,135.* Area *6.8* sq.mi. Lying on the eastern side of the Lea valley, it has large reservoirs for London's water supply. The church of St. Mary was built in 1535. Besides other old brasses it contains effigies of Sir George Monoux (d. *1543)* and Anne, his wife. Walthamstom has several educational institutions. such as the Sir George Monoux grammar school and the South West Essex technical college and school of art. There is a local history museum and a William Morris gallery with a collection of his works. In the reign of Edward the Confessor Walthamstow belonged to Waltheof, son of Siward, earl of Northumbria, and passed in 1309 to Guy de Beauchamp, earl of Warwick. The town, incorporated in 1929, returns two members to parliament. Though the area is largely residential, there are industries, including engineering.

WALTHARIUS, a Latin poem founded on German popular tradition, relates the exploits of the west Gothic hero Walter of Aquitaine. Our knowledge of the author. Ekkehard, a monk of St. Gall, is due to a later Ekkehard (Ekkehard IV, d. 1060), who gives some account of him in the *Casus Sancti Galli* (cap. 80). The poem is said to have been by Ekkehard I (d. 973) 'in his schooldays for his master-Geraldus. If so, he must have possessed precocious powers. *Waltharius* was dedicated by Geraldus to Erchanbald, bishop of Strasbourg (*fl.* 965–991), but mss. were in circulation before that time. Ekkehard IV stated that he corrected his namesake's Germanisms. The poem was probably based on epic songs now lost.

Walter was the son of Alphere, ruler of Aquitaine, which in the 5th century was a province of the west Gothic Spanish kingdom. On Attila's invasion the western princes are represented as offering tribute and hostages. Gibich. here described as a Frankish king, gave Hagen as a hostage in place of his son Gunther; the Burgundian Heririh, his daughter Hiltegund; and Alphere, his son Walter. Hagen and Walter became brothers in arms, fighting for Attila. while Hiltegund was put over the queen's treasure. Presently Gunther succeeded his father and refused the tribute. whereupon Hagen fled from Attila's court. Walter and Hiltegund, who had been betrothed in childhood. also escaped, taking with them a great treasure. The story of their flight forms one of the most charming pictures of old German story. At Worms, however, the treasure excited the cupidity of Gunther. Taking 12 knights, among them the reluctant Hagen, he overtook them at the Wasgenstein (Vosges). Walter engaged the Nibelungs one at a time, until all were slain but Hagen, who held aloof and was only persuaded by Gunther on the second day to attack his comrade. Luring Walter from the strong position of the day before, Gunther and Hagen attacked. All three were incapacitated, but their wounds were bound up by Hiltegund.

The essence of the story is the series of single combats. The incoherences make it likely that many changes have been introduced in the legend. *Thidreks Saga* makes the story more probable by representing the pursuers as Huns. Probably Hagen was originally the father of Hiltegund, and the tale was a variant of the saga of Hild in *Skaldskaparmál*. Hild. daughter of King Hogni, was carried off by Hedinn. The fight between father and lover only ceased at sundown, to be renewed on the morrow, since each evening Hild raised the dead by her incantations. This is obviously a mediaeval variant of the ancient myth of the struggle between light and darkness.

Bibliography.—*Waltharius* was first edited by Fischer (Leipzig, 1780). Later and more critical editions are by Jacob Grimm (*Lat. Gedichte des Mittelalters*, Göttingen, 1838); R. Peiper (1873); V. Scheffel and A. Holder (Stuttgart. 1874); German translations by F. Linnig (Paderborn, 1885), and H. Althof (Leipzig, 1896). *See* also Scheffel's novel of *Ekkehard* (Stuttgart, 1887). The A.S. fragments of *Waldere* were first edited by G. Stephens (1860), afterwards by R. Wülker in *Bibl. der angel-sachs. Poesie* (Cassel, 1881); by F. Holthausen in *Göteborgs Hogskolas Årsskrift* (vol. v, 1899), with autotype reproductions of the two leaves which have been preserved. *See* also A. Ebert, *Allg. Gesch. der Lit. des Mittelalters im Abendlande* (Leipzig, 1874–87); R. Koegel, *Gesch. der deutschen Literatur bis zum Ausgange des Mittelalters* (vol. i, pt. ii, Strashourg, 1897); M. D. Larned, *The Saga of Walter oj Aquitaine* (Baltimore. 1892); B. Symons. *Deutsche Heldensage* (Strasbourg, 1905). With *Waltharius* compare the ballads "Earl Brand" and "Erlinton" (F. J. Child, *English and Scottish Popular Ballads*, i, 88 *seq.*); and *see* R. W. Chambers, *Widsith* (1912).

WALTHEOF (d. 1076), earl of Northumbria. was a son of Earl Siward of Northumbria. Too young to succeed to the northern earldom when his father died in 1055, he was afterward appointed by King Edward to an earldom in the midlands, comprising the shires of Huntingdon, Northampton, Bedford and Cambridge: He submitted at first to King William. but joined the Danes when they invaded Yorkshire and stormed York in 1069. Received again into William's favour, he was granted his father's Xorthumbrian earldom in 1072, and married to Judith, the king's niece. In 1075 he joined the conspiracy against the king arranged by the earls of Norfolk and Hereford; but soon repenting of his action he confessed his guilt to Archbishop Lanfranc, and then to William, who was in Normandy. Returning to England with William, he was arrested. As an Englishman, subject to a law which regarded treason as a capital crime, he was condemned to death and beheaded on St. Giles's hill near Winchester on May 31, 1076. Weak and unreliable in character. Waltheof, like his father, is said to have been a man of immense bodily strength. Devout and charitable, he was regarded by the English as a martyr, and miracles were said to have been worked at his tomb at Crowland. The earl left three daughters. the eldest of whom, Matilda, brought the earldom of Huntingdon to her second husband. David I, king of Scotland.

See E. A. Freeman, *The Norman Conquest*, vol. ii, iii and iv (Oxford, 1870–75); F. M. Stenton, *Anglo-Saxon England*, 2nd ed. (Oxford, 1947); R. H. Hodgkin, *A History of the Anglo-Saxons*, 2 vol., 3rd ed. (Oxford, 1953).

WALTHER VON DER VOGELWEIDE (*c.* 1170–*c.* 1230), the most celebrated of mediaeval German lyric poets. For all his fame, Walther's name is not found in contemporary records, with the exception of a solitary mention in the travelling accounts of Bishop Wolfger of Passau—"Walthero cantori de Vogelweide pro pellicio V. solidos longos"—"To Walther the singer of the Vogelweide five shillings to buy a fur coat," and the main sources of information about him are his own poems and occasional references by contemporary Minnesingers. It is clear from the title *hêr* (Herr, Sir) these give him, that he was of noble birth; but it is equally clear from his name Vogelweide (Lat. *aviarium,* a gathering place or preserve of birds) that he belonged not to the higher nobility, who took their titles from castles or villages, but to the nobility of service (*Dienstadel*), humble retainers of the great lords, who in wealth and position were little removed from non-noble free cultivators. For a long time the place of his birth was a matter of dispute, until Professor Franz Pfeiffer established beyond reasonable doubt that he was born in the Wipthal in Tirol, where, not far from the little town of Sterzing on the Eisak, a wood—called the Vorder- und Hintervogelweide—preserves at least the name of his vanished home.

Tirol was at this time the home of several noted Minnesingers; and the court of Vienna, under the enlightened duke Frederick I. of the house of Babenberg, had become a centre of poetry and art. Here it was that the young poet learned his craft under the renowned master Reinmar the Old, whose death he afterwards lamented in two of his most beautiful lyrics; and in the open-handed duke he found his first patron. This happy period of his life, during which he produced the most charming and spontaneous of his love-lyrics, came to an end with the death of Duke Frederick in 1198. Henceforward Walther was a wanderer from court to court in many Germanic countries, singing for his lodging.

For material success in this profession he was hardly calculated. His criticism of men and manners was scathing; and even when this did not touch his princely patrons, their underlings often took measures to rid themselves of so uncomfortable a censor. Thus he was forced to leave the court of the generous duke Bernhard of Carinthia (1202–1256); after an experience of the tumultuous household of the landgrave of Thuringia he warns those who have weak ears to give it a wide berth; and after three years at the court of Dietrich I. of Meissen (reigned 1195–1221) he complains that he had received for his services neither money nor praise. Walther was, in fact, a man of strong views; and it is this which gives him his main significance in history, as distinguished from his place in literature. From the moment when the death of the emperor Henry VI. (1197) opened the fateful struggle between empire and papacy, Walther threw himself ardently into the fray on the side of German independence and unity. Though his religious poems sufficiently prove the sincerity of his catholicism, he remained to the end of his days opposed to the extreme claims of the popes, whom he attacks with a bitterness which can only be justified by the strength of his patriotic feelings. His political poems begin with an appeal to Germany, written in 1198 at Vienna, against the disruptive ambitions of the princes:—

Crown Philip with the Kaiser's crown
And bid them vex thy peace no more.

He was present, on Sept. 8, at Philip's coronation at Mainz, and supported him till his victory was assured. After Philip's murder in 1209, he "said and sang" in support of Otto of Brunswick against the papal candidate Frederick of Staufen; and only when Otto's usefulness to Germany had been shattered by the battle of Bouvines (1212) did he turn to the rising star of Frederick II., now the sole representative of German majesty against pope and princes. From the new emperor his zeal for the empire at last received recognition; and a small fief in Franconia was bestowed upon him, which, though he complained that its value was little, gave him the home and the fixed position he had so long desired. That Frederick gave him an even more signal mark of his favour by making him the tutor of his son Henry VII., is more than doubtful. Walther's restless spirit did not suffer him to remain long on his new property. In 1217 we find him once more at Vienna, and again in 1219 after the return of Duke Leopold VI. from the crusade. About 1224 he seems to have settled on his fief near Wiirzburg. He was active in urging the German princes to take part in the crusade of 1228, and may have accompanied the crusading army at least as far as his native Tirol. In a beautiful and pathetic poem he paints the change that had come over the scenes of his childhood and made his life seem a thing dreamed. He died about 1230, and was buried at Wiirzburg, after leaving directions, according to the story, that the birds were to be fed at his tomb daily.

Historically interesting as Walther's political verses are, their merit has been not a little exaggerated. Of more lasting value are the beautiful lyrics, mainly dealing with love, which led his contemporaries to hail him as their master in song (*unsers* sanges meister). He is of course unequal. At his worst he does not rise above the tiresome conventionalities of his school. At his best he shows a spontaneity, a charm and a facility which his rivals sought in vain to emulate. His earlier lyrics are full of the joy of life, of feeling for nature and of the glory of love. Greatly daring, he even rescues love from the convention which had made it the prerogative of the nobly born, and puts the most beautiful of his lyrics—Unter der linden—into the mouth of a simple girl.

A certain seriousness, which is apparent under the joyousness of his earlier work, grew on him with years. Religious and didactic poems become more frequent; and his verses in praise of love turn at times to a protest against the laxer standards of an age demoralized by political unrest. Throughout his attitude is healthy and sane. He preaches the crusade; but at the same time he suggests the virtue of toleration, pointing out that in the worship of God

Christians, Jews and heathen all agree.

He fulminates against "false love"; but pours scorn on those who maintain that "love is sin." In an age of monastic ideals and loose morality there was nothing commonplace in the simple lines in which he sums up the inspiring principle of chivalry at its best:—

Swer guotes wibes liebe hbt
Der schamt sich ieder missetât.[1]

The Gedichte were edited by Karl Lachmann (1827). This edition of the great scholar was re-edited by M. Haupt (3rd ed., 1853). Walther *v.* d. Vogelweide, edited by Franz Pfeiffer, with introduction and notes (4th edition, by Karl Bartsch, Leipzig, 1873). Glossarium *zu* d. Gedichten Walther's, *nebst* e. *Reimverzeichnis,* by C. A. Hornig (Quedlinburg, 1844). There are translations into modem German by B. Obermann (1886), and into English verse Selected poems of Walter *von* der Vogelweide by W. Alison Phillips, with introduction and notes (London, 1896). The poem Unter der Linden, not included in the latter, was freely translated by T. L. Beddoes (Works, 1890), more closely by W. A. Phillips in the Nineteenth Century for July 1896 (ccxxxiii. p. 70). Songs and Sayings contains English translations of Walther's poems, by F. Belts (1917). Leben *u.* Dichten *Walther's* von der *Vogelweide,* by Wilhelm Wilmanns (Bonn, 1882), is a valuable critical study of the poet's life and works. (W. A. P.)

[1]He who has the love of a good woman
Is ashamed of every misdeed.

WALTON, ERNEST THOMAS SINTON (1903–), Irish physicist, was awarded, jointly with Sir John Douglas Cockcroft. the 1951 Nobel prize for physics for fundamental work on "the transmutation of atomic nuclei by artificially accelerated' atomic particles." Walton was born on Oct. 6, 1903, at Dungarvan. County Waterford, Ire. He was educated at the academies at Banbridge (County Down) and Cookstown (County Tyrone) and in the Methodist college. Belfast. In 1922 he entered Trinity college. Dublin, and in 1927 he went to Trinity college. Cambridge. where he worked with Cockcroft under Lord Rutherford in the Cavendish laboratory. He held in turn an 1851 Overseas Research scholarship (1927–30), a senior research award of the Department of Scientific and Industrial research (1930–34) and the Clerk Maxwell scholarship in Cambridge university (1932–34). In 1946 he was elected Erasmus Smith's professor of natural and experimental philosophy in the University of Dublin. In 1932 in collaboration with Cockcroft he disintegrated the nucleus of the lithium atom by bombarding it with protons, artificially accelerated in an electric field of high potential. The products of disintegration proved to be helium nuclei and thus there had been a transmutation of lithium into helium. In 1938 Walton was awarded the Hughes medal by the Royal society. (D. McK.)

WALTON, IZAAK (1593–1683), English writer. author of The Compleat Angler, was born at Stafford on Aug. 9, 1593; the register of his baptism gives his father's name as Jervis, and nothing more is known of his parentage. He settled in London as an ironmonger, and at first had one of the small shops, 7½ ft. by 5 ft., in the upper story of Gresham's Royal Burse or Exchange in Cornhill. In 1614 he had a shop in Fleet street, two doors west of Chancery lane. There, in the parish of St. Dunstan's, he gained the friendship of John Donne, then vicar of that church. His first wife, Rachel Floud, great-great-niece of Archbishop Cranmer, died in 1640. He married again soon after, his second wife being Anne Ken—the pastoral "Kenna" of The Angler's Wish—stepsister of Thomas Ken, afterward bishop of Bath and Wells. After the royalist defeat at Marston Moor, he retired from business. He had bought some land near his birthplace, Stafford, and he went to live there; but. according to Wood. spent most of his time "in the families of the eminent clergymen of England. of whom he was much beloved"; and in 16jo he was again living in Clerkenwell.

In 1653 came out the first edition of his famous book, *The* Compleat Angler. His second wife died in 1662, and was buried in Worcester cathedral church, where there is a monument to her memory. One of his daughters married Hawkins, a prebendary of Winchester. The last 40 years of his long life seem to have been spent in ideal leisure and occupation, the old man traveling here and there, visiting his "eminent clergymen" and other brethren of the angle, compiling the biographies of congenial spirits and collecting here a little and there a little for the enlargement of his famous treatise. After 1662 he found a home at Farnham castle with George Morley, bishop of Winchester, to whom he dedicated his Life of George Herbert and also that of Richard Hooker; and from time to time he visited Charles Cotton in his fishing house on the Dove. He died in his daughter's house at Winchester on Dec. 15, 1683, and was buried in the cathedral. It is characteristic of his kindly nature that he left his property at Shalford for the benefit of the poor of his native town.

Walton hooked a much bigger fish than he angled for when he offered his quaint treatise, The Compleat Angler, to the public. There is hardly a name in English literature, even of the first rank, whose immortality is more secure or whose personality is the subject of a more enthusiastic cult. The Compleat Angler, dedicated to his friend John Offley, was published in 16j3, but Walton continued to add to its completeness in his leisurely way for a quarter of a century. Later editions appeared during his lifetime, in 1655, 1661, 1668 and 1676. In the 1676 edition the 13 chapters of the original had grown to 21, and a second part was added by his brother angler Charles Cotton, who took up "Venator" where Walton had left him and completed his instruction in fly-fishing and the making of flies.

Walton did not profess to be an expert with the fly; the fly-fishing in his first edition was contributed by Thomas Barker, a retired cook and humorist, who produced a treatise of his own in 1659; but in the use of the live worm. the grasshopper and the frog "Piscator" himself could speak as a master. The famous passage about the frog—often misquoted about the worm—"use him as though you loved him, that is, harm him as little as you may possibly, that he may live the longer"—appears in the original edition. The additions made as the work grew were not merely to the technical part; happy quotations, new turns of phrase, songs, poems and anecdotes were introduced as if the leisurely author, who wrote it as a recreation, had kept it constantly in his mind and talked it over point by point with his numerous brethren. There were originally only two interlocutors in the opening scene, "Piscator" and "Viator"; but in the second edition, as if in answer to an objection that "Piscator" had it too much his own nay in praise of angling, he introduced the falconer, "Auceps," changed "Viator" into "Venator" and made the new companions each dilate on the joys of his favourite sport.

Although *The Compleat Angler* was not Walton's first literary work, his leisurely labours as a biographer seem to have grown out of his devotion to angling. It was probably as an angler that he made the acquaintance of Sir Henry Wotton, but it is clear that Walton had more than a love of fishing and a humorous temper to recommend him to the friendship of the accomplished ambassador. At any rate, Wotton, who had intended to write the life of John Donne and had already corresponded with Walton on the subject, left the task to him. Walton had already contributed an *Elegy* to the 1633 edition of Donne's poems, and he completed and published the life, much to the satisfaction of the most learned critics, in 1640. Sir Henry Wotton dying in 1639, Walton undertook his life also; it was finished in 1642 and published in 1651. His life of Hooker was published in 1662, that of George Herbert in 1670 and that of Bishop Sanderson in 1678.

The Lives of Dr. John Donne, Sir Henry Wotton, Mr. Richard Hooker, Mr. George Herbert, etc., was published in 1670. This, together with the life of Robert Sanderson, was edited by George Saintsbury in 1927. All these subjects were endeared to the biographer by a certain gentleness of disposition and cheerful piety; three of them at least—Donne, Wotton and Herbert—were anglers. Their lives were evidently written with loving pains, in the same leisurely fashion as his *Angler,* and like it are of value less as exact knowledge than as harmonious and complete pictures of character. Walton also rendered affectionate service to the memory of his friends Sir John Skeffington and John Chalkhill, editing with prefatory notices Skeffington's *Hero of Lorenzo* in 1652 and Chalkhill's *Thealma and Clearchus* a few months before his own death in 1683. His poems and prose fragments were collected in 1878 under the title of *Waltoniana.*

The best-known old edition of the *Angler* is J. Major's, 2nd ed. (1824, repr. 1927). A facsimile of the first edition was reprinted in 1928 by A. and C. Black. The book was edited by Andrew Lang in 1896, and various modern editions have appeared. The standard biography is that by Sir Harris Nicolas, prefixed to an edition of the *Angler* (1836). There are notices also, with additional scraps of fact, annexed to two American editions, Bethune's (1847) and Dowling's (1857). An edition of Walton's *Lives,* by G. Sampson, appeared in 1903. *See* also T. Westwood, *The Chronicle of the "Compleat Angler" of Izaak Walton and C. Cotton* (1864); S. Martin, *Izaak Walton and His Friends* (1903); E. Marston, *Thomas Ken and Izaak Walton* (1908); R. B. Marston, *Walton and Some Earlier Writers on Fish and Fishing* (1909).

WALTON AND WEYBRIDGE, an urban district (1933) in the Esher parliamentary division of Surrey, Eng., on the right bank of the Thames about 15 mi. W.S.W. of London. Pop. (1951) 38,112. Area 14.1 sq mi. The district is bounded by the Thames, Wey and Mole rivers, and rises to about 200 ft. at St. George's hill. It is mainly residential. but there is some market gardening, and large aircraft works are beside the former motor track at Brooklands, Weybridge. Electrical and dental equipment and plastics are also made. Walton church (St. Mary) has late Norman features and contains Elias Ashmole's memorial to the astrologer William Lilly, some fine brasses, and statuary by F. L. Chantrey and L. Roubiliac. The scold's bridle (1632) is one of the earliest examples in England. The Tudor manor house was occupied by John Bradshaw. president of the court that tried Charles I.

Many prehistoric implements have been dredged from the Wey and the Thames near Weybridge and on St. George's hill is a Bronze Age camp. In 1537 Henry VIII built Oatlands palace and until its demolition by Oliver Cromwell it was a residence of Elizabeth I, James I and Charles I. In 1790 the duke of York bought the estate from the duke of Newcastle and lived there until 1822.

WALTON-LE-DALE, an urban district in the Preston South parliamentary division of Lancashire, Eng., on the tongue of land betneen the Darwen and the Ribble. 2 mi. S.E. of Preston. Pop. (1951) 14,709. Area 7.4 sq.mi. The church of St Leonard was originally built in the 11th century Roman remains have been found. The manor of Walton was granted by Henry de Lacy about 1130 to Robert Banastre. It afterward passed to the Langtons and about 1592 to the Hoghtons of Hoghton. Walton was the principal scene of the battle of Preston (1648) where the royalists lost the Ribble bridge to the parliamentarians. Cotton spinning and weaving are carried on and there is much market gardening, but the area is mainly residential.

WALTZ, a popular round dance, introduced from Germany into France at the end of the 18th century and into England in 1812. It is written in 3/4 time and has enlisted the musical interest of many composers. Among these Chopin is supreme. As regards waltzes written expressly to be danced to, the two Johann Strausses (father and son). the famous Viennese composers, may be particularly mentioned. *(See* also DANCE.)

WALVIS BAY (formerly also WALFISH BAY), a harbour and port on the coast of South-West Africa. During German rule in South-West Africa, and technically still, an exclave (374 sq.mi.) of Cape Province; but now administered as part of the mandate. When separated politically from the hinterland, practically no development took place. South-Rest Africa, under German rule, relied on Snakopmund. Now, however, the port of Walvis Bay is beginning to develop. Vessels can lie alongside a concrete wharf, 1,500 ft. long, to which leads a channel. 30 ft. deep. The wharf is fitted with electric cranes. A cold-storage and refrigerating plant has been built, capable of dealing with 150 cattle and 200 or 300 sheep a day, and considerable quantities of chilled meat are exported. Whaling and fishing are also carried on. Walvis Bay is a regular port of call for mail steamers of British, Dutch and German lines. In consequence of its development. Swakopmund has been permanently closed as a port. In 1951 Walvis Bay had 3,329 persons (1,008 Europeans; 2,321 non-Europeans).

WALWORTH, SIR WILLIAM (d. 1385), lord mayor of London, belonged to a good Durham family. He was apprenticed to John Lovekyn, a member of the Fishmongers' guild, and succeeded his master as alderman of Bridge ward in 1368, becoming sheriff in 1370 and lord mayor in 1374. Walworth was appointed one of the tno treasurers of the parliamentary subsidy voted in Oct. 1377, and he frequently appears as partner in loans made to the king. He was one of the leaders of the opposition in London to the king's uncle. John of Gaunt, duke of Lancaster. His most famous exploit was his encounter uith Wat Tyler in 1381, during his second term of office as lord mayor. In June of that year, when Tyler and his followers entered south London, Walworth defended London bridge against them; he nas with Richard II when he met the insurgents at Smithfield, and assisted in slaying their leader *(see* TYLER. WAT), afterward raising the city bodyguard in the king's defense, for which service he was rewarded by knighthood and a pension. He subsequently served on two commissions to restore the peace in the county of Kent. He died in 1385 and was buried in St. Michael's. Crooked Lane.

WAMPUM, tubular shell beads used as a medium of exchange by some North American Indians. The beads were strung into strings, woven into belts or used as embroidered ornaments.

In what is now the northeastern United States, the English called the beads wampum or wampumpeag (derived from one of the eastern Algonkian languages; literally translated, the latter term means "strings of white [shell beads]"). The English in Virginia termed it roanoake; the French esnoguy, *matachias* or *pourceline;* the Dutch, *sewan* or *zeewan.* Wampum is found in archaeological sites east of the Mississippi river. The earliest documentary reference occurs in the Voyages of Jacques Cartier, where, under the year 1535. the following statement appears: "The most precious article they (*i.e.*, the Hurons) possess in this world is *esnoguy,* which is as white as snow. They procure it from shells in the river . . . of which they make a sort of bead. which has the same use among them as gold and silver with us; for they consider it the most valuable article in the world. It has the virtue of stopping nosebleeding; for we tried it."

According to the 16th-century documents, the eastern Indians at that time used wampum for decoration and ceremonial gift exchange. In the first decade of the 17th century, because of the inadequate supply of European-type currency, strings of wampum were used as money by whites and Indians in what is now the eastern United States.

Wampum was used as money through the 17th and first half of the 18th centuries. When machines were invented to mass-produce wampum; the resulting inflation stopped its use as money in the east. However, wampum continued to be used as money by western Indians until about the middle of the 19th century.

From the second half of the 18th century through the 19th century, the most important use of wampum in the east was in the form of belts for purposes of gift exchange. The belts usually contained woven designs which were mnemonic or pictographic devices symbolic of the ceremonial occasion being commemorated.

Anthrop.,* 51:223–236 (1949); F. G. Speck, "The Functions of Wampum Among the Eastern Algonkian," *Memoirs of the American Anthropological Association, 6, 1* (1919). (J. S. SN.; X.)

WANAMAKER, JOHN (1838–1922), U.S. merchant, who developed one of the country's first large department stores, was born in Philadelphia, Pa.. July 11, 1838, and began his career at 14 as errand boy for a bookstore. He was a clerk in a men's clothing store in 1856, and from 1857 to 1861 served as secretary of the Philadelphia Young Men's Christian association. In 1861 he established with Nathan Brown the clothing house of Brown and Wanamaker, a partnership that continued until the death of Brown in 1868. In 1869 he established John Wanamaker and Company, placing his brother Samuel in charge. In 1875 he bought the freight depot of the Pennsylvania railroad to house this store. It became his "new kind of store," *i.e.,* a collection of specialty shops under one roof, before long one of the largest department stores in the country. In 1896 he acquired the former A. T. Stewart store in New York city. Wanamaker served as postmaster general in Pres. Benjamin Harrison's administration, 1889–93. He died in Philadelphia, Dec. 12, 1922. Wanamaker was noted for his very successful use of advertising and was one of the first to employ advertising agencies.

See H. A. Gibbon, *John Wanamaker* (1926); J. H. Appel, *Business Biography of John Wanamaker* (1930). (J. R. LT.)

WANDSWORTH, a southwestern metropolitan borough (1900) of London. Eng. Pop. (1951) 330,493. Area 14.2 sq.mi. Bounded north by the Thames. it is the largest in area of the metropolitan boroughs and includes Putney. part of Clapham, Streatham, Balham and Upper and Lower Tooting. The name (Wendelesorde in Domesday Book) indicates that it was the homestead of Wendel or Wandel; the Wandle river is a small tributary of the Thames whose valley is still a feature of the main east-west thoroughfare. Huguenot place and the Huguenot burial ground are reminders of the arrival of these refugees in the 17th century and their, introduction of dyeing. calico printing and hatmaking. Improved transport enabled workers in London to live in Wandsworth and later led to an increased density of population and the introduction of industries, chiefly light engineering, brewing and paint manufacture. The borough retains many open spaces. including Tooting Bec common. Putney heath. Streatham common and Ring George's park, and parts of Wandsworth, Clapham, Putney and Wimbledon commons. The annual Oxford and Cambridge boat race starts from Putney bridge. At Wandsworth "The Election of the Mayor of Garratt" (a nearby hamlet), a political burlesque, took place between 1747 and 1796 and drew huge crowds from London. Samuel Foote wrote a comedy called *The Mayor* of *Garratt,* produced in 1763 Clapham church records the Clapham sect—who worked for the abolition of slavery in England—and in William Hewer's house Samuel Pepys died in 1703. Flats, houses, shops. etc., built on the Ackroydon estate at Tibhett's corner, Putney, in 1953–55 included the first group of point-block flats in Great Britain. The borough returns four members to parliament.

WANGANUI, a city and seaport of New Zealand, on the southwest coast of North Island. Pop. (1956) 29.671. The district is chiefly pastoral, and wool is exported, as well as meat and dairy produce, for which there are large refrigerating works. The Wanganui Collegiate school (Church of England) is one of the largest boarding schools in New Zealand. The district was the scene of conflicts with the hlaoris in 1847, 1864 and 1868, and in Moutoa gardens a monument commemorates the battle of that name (May 14, 1864). The settlement was founded in 1842.

WANG YANG-MING (1472–1529), Chinese philosopher and government official, led the revolt against the Neo-Confucianism of Chu Hsi (*q.v.*).

Wang was born in 1472 in the present Hangchow district, son of a cabinet official. Although he could not talk until the age of 5, he obtained the highest degree at 28. He traveled extensively, learned the military arts, was an athlete, practised the Taoist technique of breathing to prolong life and studied Buddhism.

However, his chief interests were public service and teaching. Beginning in 1504, he served successively as assistant in the army and justice departments, exiled official in Kweichow, high official in various provinces, a general suppressing rebellions. secretary of justice, censor and governor. He instituted local administrative systems, established academies of learning and inaugurated the celebrated "community contract." He never allowed this busy career to interrupt his teaching.

He was made an earl at 34. When hc died in 1529, his political enemies denied him the customary honours. However, in 1567 the title "duke of cultural perfection" (*Wen-ch'eng*) was conferred on him and in 1584 he was honoured in the Confucian temple. His conversations, essays, letters and official papers make up *The* Complete *Works* of *Duke Wen-ch'eng,* an indispensable classic of Chinese thought.

The Neo-Confucian idealist movement of Wang Yang-ming arose as a strong reaction against the Neo-Confucian rationalism of Chu Hsi that monopolized Chinese thought from the 12th to the 15th century. Since the beginning of the Ming period. Chu Hsi's interpretation of the Confucian classics had been accepted as the official version which scholars obediently followed in order to pass the civil service examination on their way to officialdom. The result was that the Neo-Confucianism of Chu Hsi became stereotyped, formalistic, narrow and devoid of originality or vigour. Against this empty and lifeless tradition, Wang rose in revolt. In its place he advocated sincere convictions and forthright action originating from one's own intuitive mind, which is at once pure and good. Four concepts stand out prominently in Wang's idealism: (1) love as exemplified in the great man's forming one body with the universe; (2) the identification of the mind with principle (Li); (3) the extension of native knowledge; and (4) the unity of knowledge and conduct.

In forming one body with Heaven and Earth and all things, the great man eliminates selfish desires and obscurations, manifests his clear character and fully develops his nature. This is love. With respect to the universe, love is the will to live, the process of unceasing production and reproduction. With respect to society, love is filial piety, brotherly respect and similar qualities.

In these qualities one's original nature is unfolded, goodness ensues and the principle of Heaven, the categorical imperative, operates at all times.

Following Lu Hsiang-shan (1139–93), Wang equates principle with mind, of which principle is the order and material force *(ch'i)* is the function. Instead of saying that because there is the principle of filial piety, there is the mind to be filial, as Chu Hsi said, Wang says that because there is the mind to be filial, there is the principle of filial piety. Actually, to him they are one and the same and it is the same mind whether in the individual or in the entire universe. As this original mind manifests itself, there is native knowledge. To extend this native knowledge is the supreme duty of man.

As in the case of other Neo-Confucianists *(see* CONFUCIANISM), extension of knowledge depends on investigation. Ho ever, unlike rationalists such as Chu Hsi to whom investigation *(ko)* meant intellectual investigation of things, Wang interpreted *ko* to mean rectification of the mind, for to him all principles are contained in the mind and are discoverable if the mind is clear and calm. Such a state is to be achieved through elimination of selfish desires, self-examination, quiet sitting; in short, the method of tranquillity. In these respects Wang came so close to the Meditation school of Buddhism *(see* BUDDHA AND BUDDHISM) that he was vigorously attacked as a Buddhist in Confucian disguise. However, he also emphasized having a firm purpose, courage. a will to work, rigorous training, social and political responsibility, in short, a life of activity. To him the relationship of tranquillity and activity is one of reality and function and they are therefore not to be sharply contrasted. Furthermore, he strongly attacked the Buddhists' life of emptiness and silence, their inability to assume social responsibility and selfishness in renouncing human relations for their own ends.

The equal emphasis on tranquillity and activity means that extension of native knowledge is no mere contemplation but knowledge translated into action. In Wang's theory knowledge is not complete until it becomes conduct, and conduct is not complete unless it is knowledge itself at work. Knowledge is the will, the beginning; conduct is the work, the accomplishment. At bottom they are a unity. These ideas of Wang's were not fruits of idle speculation but firm convictions attained after strenuous search and struggle. He chose Confucianism only after he had tried athletics, military craft, flowery compositions, the Taoist search for longevity *(see* TAOISM) and Buddhism as a way of life.

A man of strong conviction, he had the courage to protest the arrest of good officials and in consequence suffered the punishment of 40 strokes and was exiled to what is now Kweichow province, a barren wilderness at the time. But being a man of sharp intuition, it was there that he, at 37, lonely but vigorous in soul searching, intuited the principles of investigation of things and extension of knowledge and, a year later, the doctrine of the unity of knowledge and conduct. At 50 he found the truth of native knowledge.

Up to this time and for more than two decades he was an active official in distant parts of China and a successful general in suppressing several major rebellions. During this period his philosophy was evolving step by step just at the time when great decisions had to be made and strong actions taken. It can readily be seen that a philosophy of life arrived at in this way has a special freshness and power. His followers spread practically all over China and the school set off a strong movement that was to overshadow Chu Hsi's rationalism for about 150 years. Its influence extended to Japan, where it is called the Oyomei school; there it produced the greatest leaders of modern reform as well as Japanese Confucian thought.

Toward the end of the 16th century the movement in China began to lose its vitality and degenerated into empty talk and irresponsible conduct. and was eventually replaced by the practical and critical philosophy. However, its influence was again felt in the 20th century. especially in Sun Yat-sen *(q.v.)* and Chinese idealists who, like Wang, demanded strong convictions and decisive action. *See* also CHINESE PHILOSOPHY. (W. C.)

WAN-HSIEN, an important port on the Yangtze river in Szechwan province. western China. It is the eastern terminus of the east-west highway across central Szechwan by the shortest route to the provincial capital, Ch'eng-tu, in the west. The city is the chief commercial centre for eastern Szechwan and northern Kweichow, and its exports include goatskins and tung oil. From the down-river approach, Wan-Hsien marks the end of the worst rapids and whirlpools of the scenic but dangerous Yangtze gorges, which run for some 195 mi. down to I-ch'ang. Pop. (1953 est.) 100.000. (H. J. Ws.)

WANSTEAD AND WOODFORD, a municipal borough (1937) in the Woodford parliamentary division of Essex, Eng., about 8 mi. N.E. of London bridge. Pop. (1951) 61,623. Area 6 0 sq.mi. It is mainly residential. being a dormitory for London, but has a small amount of light industry including the manufacture of billiard balls. The borough includes 730 ac. of Epping forest, Wanstead flats being the most southerly part of the forest. In Saxon times Wanstead was owned by the monks of St. Peter's, Westminster, and afterward by the bishop of London.

WANTAGE, a market town and urban district in the Abingdon parliamentary division of Berkshire, Eng., lying in White Horse Vale, 25 mi. N.W. of Reading by road. Pop. (1951) 5,090. Area 4.4 sq.mi. It is the birthplace of Alfred the Great. The church of SS. Peter and Paul is Early English and Perpendicular. Agriculture is the main industry, though there is a large iron foundry and many people are employed at army ordnance and air force depots and the Harwell atomic energy research establishment.

WAPENTAKE, an administrative division of the counties of York, Lincoln, Leicester, Nottingham. Derby and Rutland, first clearly referred to at the end of the 10th century, and corresponding to the hundred of other English counties. In the 11th century, the same district might be described either as a wapentake or as a hundred, and the latter term sometimes ousted the former. The word wapentake. of Scandinavian origin, originally signified the clash of arms by which the folk assembled in a local court expressed assent. Danish influence was strong in the counties where wapentakes occur. (ER S.)

WAPITI, an Algonkian word, the name applied to several deer of the red deer group. The true wapiti is *Cervus canadensis* of North America, where it is often called elk. It is the second largest deer in the world, being exceeded only by the true elk (U.S. moose). It stands over five feet at the shoulder and weighs up to 1,000 lb. Its big antlers, characterized by the large fourth tine, may have a five-foot spread.

The name wapiti is also applied to several eastern Asiatic red deer characterized by large size and antlers lacking the crown of points usually developed in the typical red deer. *C. elaphus xanthopygus* and *C. e. congaricus* are such. (J. E. HL.; X.)

WAQIDI, AL- (ABU 'ABDALLAH MOHAMMED IBN 'OMAR AL-WAQIDI) (747–823), Arab historian, was the author of *Kitab al-Maghazi*, a well-known work on Mohammed's campaigns. He was born in Medina and became a corn dealer but after a time fled to Baghdad to escape his creditors. Here Yahya ibn Khalid, the vizier of Harun al-Rashid, gave him means and. some reports say, made him *qadi* of the western district of the city. In 819 he was appointed *qadi* of Rusafa on the east side by the caliph al-Ma'mun, who was his close friend and later his executor. Waqidi died in Baghdad in 823.

BIBLIOGRAPHY.—The first third of *Kitab al-Maghazi* (one leaf missing) was published by A. von Kremer from a Damascus manuscript (1856); A. Sprenger in his *Das Leben und die Lehre des Mohammad* (1861–1865) used a British museum manuscript containing the first half, all but one leaf; J. Wellhausen published an abridged German translation from another British museum manuscript under the title *Muhammed in Medina* (1882).
See also D. S. Margoliouth, *Lectures on Arabic Historians* (1930).

WAR. War in the popular sense is a conflict among political groups involving hostilities of considerable duration and magnitude. In the usage of social science certain qualifications are added. Sociologists usually apply the term to such conflicts only if they are initiated and conducted in accordance with socially recognized forms. They treat war, whether among primitive or advanced peoples. as an institution recognized in custom or in law. Military writers usually confine the term to hostilities in which the contending groups are sufficiently equal in power to render the outcome uncertain for a time. Armed conflicts of powerful states with primitive peoples are usually called pacifications, military expeditions or explorations; with small states, they are called interventions or reprisals; and with internal groups, rebellions or insurrections. Such incidents, if the resistance is sufficient, may achieve a magnitude which entitles them to the name "war." *(See* articles on wars under their names and in the *History* sections of articles on various countries.)

This article is divided into the following sections and subsections:

I. INTERNATIONAL LAW AND WAR

In international lam the concept of the equality of the belligerents was applied during the 18th and 19th centuries to their legal status rather than to their physical power. Thus, a "state of war" or war in the legal sense was distinguished from "hostilities" or war in the material sense (see *The Three Friends,* 166 U.S. 1, 1897) and was defined as the condition which equally permits two or more political groups to contend by armed force. Armed conflict within a state constituted a state of war only if the insurgents or revolutionists had been recognized by the parent state or by other states as "belligerents." Otherwise the situation was technically known as "insurgency." This legal concept of war developed with the legal concept of neutrality which required nonparticipating states to treat the belligerents impartially. In the middle ages the prevailing thought treated n-ar as necessarily just on one side and unjust on the other. "Just war" was a lawful procedure, whereby a competent authority, by proper declaration. and with proper motives. employed armed force outside his normal jurisdiction to defend rights, to rectify wrongs or to punish crimes. This concept was accepted by Grotius who said in *The* Law *of War and Peace* (1635): "It is the duty of those who keep out of a war to do nothing whereby he who supports a wicked cause may be rendered more powerful, or whereby the movements of him who wages a just war may be hampered." Grotius, however. opened the way to neutrality by adding. "In a doubtful matter. however, those at peace should show themselves impartial to either side." Cornelius van Bynkershoek. in the 18th century, developed the law of neutrality from the principle that "the question of justice and injustice does not concern the neutral." thus incorporating in international law the ideas which post-Renaissance theories of sovereignty had developed among political writers and in the practice of states. The sovereign was deemed free to initiate war for "reason of state." War was a prerogative of the sovereign as the duel was a prerogative of the gentleman. Third states must treat war as a fact and be impartial toward the belligerents unless one of them violated neutral rights. This legal concept of war was embodied in the legislation of many states after the United States neutrality law of 1794, and in the Hague conventions of 1907, but it was never accepted in Catholic theory which continued the medieval tradition, or in popular thinking and government propaganda, which often referred to the relative justice of the causes of the belligerents. Pres. Woodrow Wilson's statement on the outbreak of World War I that Americans should be "impartial in thought as well as in action" was widely criticized, although he was actually reiterating a portion of Washington's farewell address and seeking to provide moral foundations for the prevailing legal theory.

Subsequent developments tended to revert to the Grotian theory. War was "outlawed"; *i.e.,* international law ceased to recognize a state of war as a condition in which the belligerents are equally entitled to carry on their conflict by armed force. but assumed that one is the aggressor and the other the victim.

(Q. W.)

The advocates of the outlawry of war theory felt that so long as the institution of war remained respectable and enjoyed a recognized place in the field of international relations, the root of the evil remained. Their solution of the problem was, in part. to oust war from its privileged position by denying it a legal status and placing a state indulging in hostilities against another state beyond the pale.

The statesmen primarily responsible for the idea of bringing about the renunciation of war by means of an ad *hoc* treaty were Aristide Briand. French minister of foreign affairs, and Frank B. Rellogg. United States secretary of state. In 1927 Briand proposed to the Gnited States the conclusion of a bilateral treaty covering the ground suggested by the advocates of the outlawry of war. In replying to this proposal, Secretary Kellogg suggested that instead of contenting themselves with a bilateral declaration. the two governments might make a more signal contribution to world peace by joining in an effort to obtain the concurrence of a large group of powers.

The draft multilateral treaty proposed by the United States on June 23, 1928, was promptly accepted by 14 other governments, signed at Paris on Aug. 27. 1928, and subsequently ratified by 63 states. It is commonly known as the Pact of Paris or the Rellogg-Briand pact. Its terms mere, in part, as follows:

ARTICLE I

The High Contracting Parties solemnly declare in the names of their respective peoples that they condemn recourse to war for the solution of international controversies, and renounce it as an instrument of national policy in their relations with one another.

ARTICLE II

The High Contracting Parties agree that the settlement or solution of all disputes or conflicts of whatever nature or oi whatever origin they may be, which may arise among them, shall never be sought except by pacific means.

Although at the time great hopes were entertained as to the effect which these declarations would have in the preservation of peace, they had no observable deterrent effect upon the aggressions which shortly followed in Manchuria in 1931 or in China proper at a later stage; nor upon the Italian invasion of Ethiopia, the German-Italian interventions in Spain, or any of those which finally culminated in World War II.

The Kellogg pact and other agreements for the renunciation of war, however. had important legal effects. They made it expedient for states to refrain from formal declarations of war, induced states to refuse to recognize the fruits of aggression (the Stimson doctrine), justified states in refusing to observe neutral obligations for the benefit of aggressors (United States sale of destroyers to Great Britain and Lend-Lease act, 1940, 1941) and provided the legal basis for definition of the crime of aggressive war at the Nürnberg and Tokyo trials after World War II (see WAR CRIMES). Thus these agreements, now incorporated in the United Nations charter, can be said to have "outlawed war" in the legal sense of a situation in which contending states are equally entitled to use armed force to settle their dispute. (N. AL.; X.)

The **United Nations.**—As stated in the United Nations charter, "all members shall give the United Xations every assistance in any action it takes in accordance with the present Charter and shall refrain from giving assistance to any state against which the United Nations is taking preventive or enforcement action." (Art. 2, par. **5.)** It is true, opportunity was given for impartiality if the United Nations failed to determine which party mas the aggressor. This contingency, however, was not anticipated because it was assumed that the Security council would meet its "primary responsibility for the maintenance of international peace and security," (art. 24) by performing its obligation to "determine the existence of any threat to the peace, breach of the peace, or act of aggression . . . and decide what measures shall be taken . . . to maintain or restore international peace and security." (Art. 39.)

These provisions of the charter gave more positive form to the changes in international law wrought by the Covenant of the League of Nations (1920), which required discriminatory treatment against the state which resorted to hostilities in violation of its covenants, and the Kellogg pact. Since the latter instrument condemned war and obliged the parties to renounce war as an instrument of national policy, and never to seek the settlement of any dispute or conflict except by pacific means. it was difficult to see how hostilities could begin unless one or both had violated their obligations. The concept that war was outlawed was given practical application in the policies observed by most states in discriminating against Japan in its Manchurian and Chinese hostilities, against Italy in the Ethiopian invasion, against Hitler in his invasions which led to World War II and against the North Korean and Chinese Communists after their aggressions against the Korean Republic in 1950. The Stimson doctrine (1931) calling for nonrecognition of fruits of aggression, the U.S. Lend-Lease act (1941) to aid the victims of aggression, and the Niirnberg trials declining to recognize the aggressor state's declaration of war as an "act of state" shielding its agents from criminal prosecution, were logical consequences of this outlawry of war.

Hostilities occurring after the Kellogg-Briand pact were not "states of war" in the sense understood in 19th century international law. Hostilities were permitted by international law only if exercised by a state within its domestic jurisdiction, in necessary self-defense, or in pursuance of its rights or duties under the Kellogg-Briand pact, the United Nations charter or other valid treaty. Otherwise the initiation of hostilities, even if formally declared "war," had become illegal. No state could in principle initiate a state of war in which it and its enemy would be legally entitled to equal treatment by other states.

Doubtless because of the inadequacies of the procedures of the United Nations, hostilities might occur in which no authoritative decision would be given distinguishing the aggressor from the defender. In such a situation different states might reach different conclusions and some might maintain neutrality. The new international law outlawing war might, for a long time, prove ineffective in producing the practical results intended as did, for long periods of time, national legislation outlawing private dueling. Furthermore, declarations or other acts initiating hostilities, ineffective as they might be to produce a legal state of war under international law, would doubtless continue to produce that state under the domestic law of the enacting belligerent. Special war powers would become exercisable, and legislation and treaties applicable in time of war would be invoked. In international law, however, the critical problem for determining the legal consequences of hostilities for both participants and nonparticipants was not "when did war begin and end?" but "who was the aggressor?" *(See* also *The Law* of *War*, below.)

II. TYPES OF WAR

Apart from the distinction between war in the legal sense and war in the material sense, wars have been classified as limited and absolute. The latter term refers to wars the object of which is the extermination or unconditional surrender of the enemy. Limited wars are fought to gain reparation for a particular injury, to acquire a particular territory or advantage or to gain recognition of a particuiar claim. As K. von Clausewitz pointed out, there is a tendency for all wars, however limited their original aim, to become absolute if belligerents are equal in power and tenacity.

Wars have also been classified as "international" when between states in the same community of nations, "imperial" when between states in different communities of nations or of very different civilization, and "civil" when between the government and a rebelling or insurgent group in the same state. In a list of 278 wars participated in by the members of the modern community of nations from 1480 to World War II, 135 were international, 65 imperial and 78 civil. *(See* Q. Wright, *A Study* of *War*, 1942, p. 641 ff.) These wars varied greatly in magnitude, from relatively minor episodes involving only two small countries and lasting only a few months, to such events as the Thirty Years' War, the Seven Years' War, the Napoleonic Wars and World Wars I and II, involving all of the great powers, many other states, millions of casualties, and, with the exception of the first, extending all over the world. The civil wars, including the French Huguenot wars of the 16th century, the Great Rebellion and the German Thirty Years' War in the 17th century, the French Revolution in the 18th century, the American Civil War and the Chinese Taiping rebellion in the 19th century, and the Russian and Chinese revolutions in the 20th century, were extraordinarily costly in life. Imperial wars were as a rule the least costly in life because of the usual marked disparity in military power between the belligerents. Each of 15 international wars during the modern period (four in the 17th, seven in the 18th, two in the 19th and two in the 20th century) included substantially all of the great powers as belligerents. Five of these were consequences or causes of contemporaneous civil wars.

Wars during the modern period have averaged four years in length, though the range is large. Long wars such as the Thirty Years' War were usually interspersed with truces. Wars of considerable duration have usually been divided into "campaigns" conducted in one area under one command for one season. These, in turn, have been composed of "battles" in which forces come into direct contact for one or two days and "sieges" in which direct contact may be maintained for a longer time. Night and winter fighting, liowever, became more practicable and these distinctions were less significant in World Wars I and II. Fighting was practically continuous, although campaigns could be distinguished by geographical separation. Wars showed a slight tendency to decrease in length during the modern period, but in all other aspects they tended to increase in magnitude. There were more battles, more participants, larger forces, larger numbers of casualties, more extensive areas of occupation and greater mechanization resulting in much heavier economic costs. This tendency was by no means continuous. The costs of the Thirty Years' War of the 17th century were very great. World War II, however, was greater in all these respects than any other war in history.

War can be considered from a number of points of view. It is characterized by intentional violence and thus can be classed with crime, police action, executions, duels, prize fights, gladiatorial combats, mob violence, insurrections, rebellions. interventions, pacifications and reprisals. It is also a process for solving conflict and can, therefore, be classed with negotiation, mediation, conciliation, arbitration, and adjudication as well as with fights, duels, strikes, elections and legislative procedures. In modern times, war has usually been considered an abnormal social or legal situation and thus resembles states of martial law, of anarchy and of high tension. War also characterizes a type of intergroup relations and thus falls in a category which includes alliance, entente, friendship, strained relations, cold war and breach of relations. The connotation of the term war can hardly be appreciated unless these numerous aspects are borne in mind.

This wealth of connotation has resulted in wide metaphorical extensions of the term war to almost any opposition deemed important. Literature is full of references to wars between economic classes, between the sexes, between the generations. Industrial warfare is waged by strikes and lockouts. Party wars are conducted by oratory and ballots. There are wars of words, of books, of opinions; mars against disease, crime and poverty; wars among species of animals and plants resulting in the displacement of one by the other; wars of bacteria and insects against man. These metaphorical uses indicate no clear discrimination between "competition" where groups or individuals are striving for limited resources or opportunities without necessarily any consciousness of one another, and "conflict" where groups or individuals are consciously opposing one another. The concept war seems more applicable to the latter situation. Thus the "struggle for existence" which, according to Darwin, accounted for organic evolution and the "economic competition" which regulates prices and distribution in a free economy have no real analogy to war. There are, however, phenomena among animals such as the sexual combat of stags, the slave-taking activities of ants, the struggle for dominance among monkeys and the defense of the nesting site by birds which have an analogy to war.

The study of war has become a discipline with a large literature from the points of view of social science, of law, of practice and of history. War has also figured largely in literature, poetry, art and rhetoric. It has been an absorbing topic of human interest and has commanded admiration as well as detraction with the latter attitude gaining in popularity after great and destructive wars. Opposition to war reached a high point in public opinion, at least among democratic countries, after both World Wars I and II.

III. THE SOCIOLOGY OF WAR

1. Causes **of** War.—War has been a variable phenomenon in human history. Wars have been more frequent, more intense, more extensive and longer in some periods of history than in others. Some pairs of states have fought frequently, some not at all. Some states have been more at war than others. This variability suggests that the causes of war are to be found in the varying social institutions and relations rather than in any constant characteristics of human nature. Nevertheless, it is men that make war, and there must be qualities of human nature which make men capable of initiating and participating in war when the circumstances are suitable.

Among animals and primitive peoples, wars consist of brief attacks by individuals or small groups upon others with whom they recognize few social relations. Such wars, and the same is true of imperial wars by civilized states against savages. are only one step removed from the hunt. Their psychological causes are however more varied. The drives of dominance, sex, territory and revenge are more important than that of food. The occurrence of the appropriate stimulus to one of these drives and obstruction to its smooth realization causes hostility. Among primitive peoples group customs regulate the expression of these drives and determine the circumstances when hostility, whether in the form of feud or war, is appropriate. Tribal mores tend to become more warlike as culture becomes more complex, technology more efficient, government more integrated, and extragroup contacts more abundant.

As civilization advances, the belligerents increasingly recognize themselves as members of some supergroup. This supergroup may, as in civil wars, be a highly organized state or it may be a group with no organization at all, such, for example, as that which included both Islam and Christendom in the middle ages. "International wars" take place among state members of a supergroup with a very decentralized organization but with some social standards and interests recognized by all the members. The superficial cause of such wars lies in the desire of each state to continue to exist and the necessity it feels to be sufficiently prepared to win any war which might end its existence. All the states appreciate that the supergroup itself is insufficiently organized to protect them. The necessity that each feels to protect itself leads to the condition of "power politics." The stability of such a system tends to decline if the number of states diminishes, if the disparity in power between the great and the small increases, if military technology favours the offensive, if the technology of communication and transport shrinks effective distances and reduces geographical barriers, and if the growth of population outdistances the food supply and deteriorates standards of living. The progress of a civilization tends to all of these results and consequently the cultural and social solidarity and the opposition to war which civilization also develops are counterbalanced by these conditions which render the power equilibrium less stable. Efforts are usually made to strengthen the organization of the supercommunity so that it can more effectively regulate the relations of the members, settle their disputes peaceably and prevent hostilities. Such efforts may for a period increase stability, but the insistence of states upon retaining autonomy and sovereignty and their ideological differences offer obstacles to such efforts. The trend of civilizations after a certain progress toward solidarity has therefore been toward less stability and more severe wars usually ending in universal conquest.

The establishment of a "universal state" does not, however, stop wars. Civil wars occur within states, often because the government is too centralized, especially if the state is large and its culture heterogeneous. Local groups with peculiar institutions or cultural characteristics feel oppressed by the tendency of the supergroup to enforce uniformity. Wars of revolt occur which, though perhaps less frequent, are more bloody than the wars of defense or aggression in the system of power equilibrium.

When people of widely different cultures or ideals come in contact, as by discovery or the emergence of new religions and ideologies, imperial wars occur for the expansion of culture, religion, economic opportunity or political power. These are frequently waged in a peculiarly barbarous manner because the parties have so little in common. Each is a wolf to the other. But as there is usually great disparity in technological efficiency, conquest may take place aithout much bloodshed.

These illustrations suggest that after a certain stage of civilization aars are in some measure caused by either too much or too little political centralization of the supercommunity. Psychological drives of individuals and the culture and organization of the fighting groups play a part but relatively less important than in animal and primitive war. The adequacy of the degree of political centralization of a supergroup can only be determined relatively to the development of other of its aspects. Thus, with the advance of a civilization the recurrence of war may be attributed to the failure of co-ordination among the various aspects of the developing supergroup. These aspects include: contacts through communication and trade; understanding through standardization or complementarity of culture and values; co-operation manifesting mutual confidence and acceptance of common ends; and organization to maintain law, settle controversies and suppress violence. A rapid increase of contacts with no development of the other aspects stimulates imperial wars, usually initiated by the group equipped with the most advanced military techniques. A rapid centralization of organization while the other aspects of the supercommunity lag is likely to lead to civil wars initiated by the group whose institutions and ideologies are least harmonious with those of the majority. A lag in centralization of organization behind the other aspects leads to international wars initiated by the most aggressive state or by the state against which time is running in the power competition. Peace depends upon the development of the various aspects of the civilization at the same rate.

Civilizations have been organized in various ways at different stages of their history. Western civilization became organized in antiquity in the highly centralized Roman empire, in the middle ages in the Catholic Church which lacked material power but maintained common standards of value, and in the modern period in the system of sovereign territorial states, united through a weak system of international law and the practice of balance of power politics. Each of these systems maintained relative peace and stability for about a century, the *Pax Romana* of the and century, the *Pax Ecclesiae* of the 13th century, and the *Pax Britannica* of the 19th century. During these periods the various aspects of the European community were developing synchronously. Roman legions, however, had to defend the peace against barbarians on the periphery, the popes had to manifest the solidarity of Christendom by crusades against the infidels, and Great Britain had to act as balancer in Europe, utilizing its superior sea power and its overseas empire. These periods of peace ended when the regulating authorities became weak or when the emergence of new ideologies, the development of new contacts, the progress of science and invention. increases in population or exhaustion of resources produced disharmonies beyond their capacity to adjust.

A similar analysis may explain the varying probability of war between different pairs of states. The relationships between any two states may be expressed in terms of "distances." The

United States and Canada were at war in 1812 and in conditions of great tension in 1840 and 1890. They came nearer to one another technologically in the sense that their people communicated and traded more abundantly. They also came nearer ideologically in the sense that the values and culture patterns of their peoples became more similar. Social distances between the tno countries also shrank as co-operation between their governments and citizens increased. Finally there was a shrinkage in political distance as they accepted common political institutions and organizations such as the International Joint commission (1909), the Permanent Joint Board of Defense (1940), the United Nations (1945) and the North Atlantic pact (1949). These changes proceeded synchronously; relations between the tno countries became more friendly, and the probability of war diminished. On the other hand, the United States had never been at war with Russia, regarded Russia as its first friend in the Civil War period and was an ally fighting a common enemy in 1945, but by mid-century there was great tension between the two countries. The technological distance had decreased with the progress of aviation and the possibilities of atomic bombing, but ideological and social distances had increased. Common membership in the United Nations may be considered as registering some decrease in political distance. yet in view of the "iron curtain" and the failure of the Soviet Union, until 1954, to join the specialized agencies. the decrease in political distance had been slight.

Differentials in the rate of change in these various aspects of the "distances" between two states seem to be more significant in determining the probability of war than the magnitude of the distances themselves. Rapid change in any one of these aspects of distance unaccompanied by parallel changes in the others is likely to lead to tensions and war. It is to be observed, however, that in general wars. the orientation of states because of alliances may result in pairs of states being at war with each other contrary to expectations which would have been drawn from the changes in their distance from one another. As a civilization shrinks, all distances tend to be reduced and wars tend to become general. Consequently, analysis of the probability of war between pairs of states becomes a less useful guide than analysis of the supercommunity as a whole.

Analysis of its internal composition may indicate the probability that a state will initiate war. A state that seeks to co-ordinate all the activities of its citizens to comprehensive ends, admitting little local, functional or individual autonomy, usually finds it necessary to deflect latent resentments by focusing them upon an external enemy. It is doubtfui whether a highly centralized, totalitarian dictatorship can exist without such a scapegoat. Democratic states that permit much internal competition and conflict among political parties, business concerns, propaganda organizations. religious movements and individual opinions have less need of an external enemy, but their lack of unity makes them vulnerable to fifth column penetrations or attacks by aggressive neighbours. Disparities in the forms of organization and in the power of states decrease the stability of a system of power politics.

The state, though composed of lesser groups, is eventually composed of individuals and it is in the minds of individuals that, as stated by the constitution of the United Nations Educational, Scientific and Cultural organization (UNESCO), wars are made. Psychologists generally agree that there is nothing in human nature that makes war inevitable, but the circumstances of early education, social discipline and political loyalty develop latent aggressive tendencies in most people, which can be focused upon a political enemy. The child may suppress the aggressive disposition which he feels toward his parents in the process of training for social behaviour and which he feels whenever he is frustrated in achieving his objectives. He learns that co-operation pays in the "in-group" and so he displaces these latent aggressions upon an "out-group." As the area of co-operation expands, the outgroup becomes a foreign state, or in a bipolar world, the organization at the opposite pole.

This analysis suggests that modifications in early education, greater understanding of the psychological processes involved, opportunities for relieving aggression upon impersonal enemies of humanity like disease and war itself, general allegiance to some universal values such as those expressed in the Universal Declaration of Human Rights. and the cultivation of a spirit of tolerance, comprehension, and appreciation by each people of the diverse cultures of the world, might reduce or divert the acquired psychic characteristics which produce intergroup tensions and war.

If we consider the human race as a whole, it is clear that the causes of war have greatly changed in history. War was originally a function of the internal structure of each fighting unit, and, as there were very many of these units, the probability of any unit of a class being at war at a given time might have been calculated from statistical averages. The change has been in the direction of reducing the number of fighting units so that there is less statistical basis for such calculations. Change has also been in the direction of integrating this smaller number of units into a single unit so that war has tended to become a function, not of a fighting unit, but of the entire human community of which all fighting units are parts. Thus the problem of war has shifted from that of classifying fighting units to that of analyzing the organization of human society as a whole. The freedom of the individual fighting unit to escape war through intelligence has, therefore, been reduced but the freedom of the human race as a whole to escape war has been increased provided it can understand and control itself. Predictions from being based upon the analysis and measurement of numerous independent agencies insusceptible of central control has come to be based upon the analysis of a few personalities exercising central control. The moral and subjective factors have tended to become more important than the material and objective factors. War can less and less be treated from the deterministic point of view. More and more it must be treated from the moral point of view. The individual can less profitably be interested in studying the historical causes of war in order to decide a policy for himself or his group. He can more profitably be interested in the engineering of peace for the human race as a whole.

2. Consequences of War.—The political consequences of war have been of major importance in history. War has been the principal instrument for creating states and empires, and it has also destroyed states and empires through absorption by conquest and through disintegration by successful rebellion. On a larger scale, war has made major contributions toward developing and integrating the historic civilizations, but also toward their eventual disintegration and destruction. Unlike science and technology, which have tended toward the continuous civilization of man, war has produced great oscillations over periods of one or two millenniums.

In the modern period, from the age of discoveries to the 20th century, war tended to integrate historic civilizations and national states into one world whose peoples engaged in continuous communication and trade, recognized many common standards of value, acknowledged the rule of international law, and co-operated through international unions for numerous economic, social and political ends. From the 17th to the 20th century, wars became less frequent. Europe as the centre of the world prospered under the *Pax Britannica* of the 19th century and maintained a high degree of order but at the expense of many imperial and civil wars in the extra-European world.

After World War I, the consciousness of one world and the effort to organize it through the League of Nations and the United Nations became more widespread. New techniques of war had, however, encouraged aggression by governments and parties opposed to the humanitarian, liberal, democratic and tolerant standards which had become widely accepted throughout the world. The necessities imposed by the unprecedented devastations of the world wars themselves and the rise of totalitarian despotisms as their consequence had initiated a process of disintegration. Under post-World War II conditions the political effect of war may have changed. World Wars I and II had tended to disintegrate civilization though efforts to control war and develop international co-operation through the United Nations had arisen.

War has had economic consequences which have varied in importance and in direction; its destruction of life and property tended to increase during the modern period, although until World War I the major wars tended to be less frequent. The increasing economic destructiveness of war for both sides when waged between states of similar industrial development made statesmen more reluctant to resort to it. Such considerations have postponed wars, and it has been suggested that the suicidal effect of hydrogen-bomb war may permanently prevent resort to such war.

On the other hand. war, unless excessively destructive, intensifies social cohesion within the fighting group and stimulates economic activity. Among industrial states it creates full employment during the war and in the period of preparation before, and of reconstruction. after. Birth rates usually sink during the war, but rise afterward, compensating for war losses. John Stuart Mill commented on the rapidity with which populations recovered economically from war. These countereffects manifested themselves more slowly after World War I. Distortion of production and international trade resulted in extraordinary currency fluctuations, unparalleled depressions, and policies of national autarchy. The physical destruction of World War II was greater and the economic division of the world more profound, but the controls within each of the economic areas was more adequate, and reconstruction proceeded no less rapidly than after World War I. But the deteriorating influence of war upon economic progress was greater as manifested by the long delay in restoring either economic or political peace.

The effects of war on population and cultural standards are equally momentous. Losses of life directly attributable to war have varied greatly among primitive peoples, among the historic civilizations, and in different periods in the life of each of these civilizations. European wars have tended to be progressively more destructive of life from the 15th century onward, though the 17th century was exceptionally destructive and the 19th exceptionally peaceful. It has been estimated that some 10% of all deaths in modern civilization can be attributed directly or indirectly to war. Deaths from war-spread epidemics and from war-induced famines have been much greater than deaths of soldiers and civilians through direct action of belligerents. These indirect effects upon population, however, were reduced through the progress of medicine and sanitation. (See Wright, *A* Study of War, pp. 212, 246, 570.)

War losses have probably been adversely selective and have tended to deteriorate racial stocks. Great wars have been followed by crime waves, anti-intellectual movements, hordes of displaced persons, widespread persecutions, the growth of intolerance and unrest and. in general, deterioration of the standards which have usually been thought to characterize civilization. On some people, however, the moral effects have been the opposite. Great wars have been followed by strong antiwar movements.

With the progress of science and technology, augmenting the destructiveness of weapons upon civilian as well as armed forces, with increasing communications and general awareness of conditions throughout the world, and with more effective control of other periodic visitations which formerly upset human societies, such as pestilence and famine, war has had a more and more catastrophic effect on human existence whether viewed politically, economically, socially or culturally.

3. Control of War. — Efforts to control war have been made in all civilizations, especially in periods after unusually devastating wars. The Napoleonic Wars induced numerous peace societies in England and the United States. Associations for promoting arbitration and the development of international law were stimulated by the mid-19th century wars of nationalism. The League to Enforce Peace and other organizations to promote international control of war both in neutral and belligerent countries became active while World War I was still in progress. During the interwar period, discussions of the control of war were continuous and abundant both within and outside the League of Nations (*q.v.*), and this discussion was augmented by the outbreak of World War II and the establishment of the United Nations (*q.v.*).

The control of war has been urged since the earliest records through individual pacifism and nonresistance. Various Christian and Hindu sects have especially supported this method. Movements of neutrality and isolation adopted by some states as national policies have also been supported as contributions to peace. Such efforts can hardly eliminate mar unless their influence is universal. A world largely nonresisting or neutral may even stimulate aggressors to initiate war, although, as Gandhi argued, if nonresistance is carried to the limit. the conqueror may find himself frustrated. For a full account of the history of this approach, see PACIFISM.

The control of war has also been urged by the very different method of political'action to stabilize the balance of power, to create a universal empire or to establish and strengthen international organization. Following World War II, movements to develop the United Nations into a world government were prominent. In a culturally heterogeneous world, such efforts imply some group coercion which itself may result in war. Efforts designed to maintain the balance of power were relatively effective during the 19th century when Britain was in a favourable position to serve as balancer, but under less favourable conditions, activity by a state to restore the balance may be interpreted by others as manifestation of aggressive intentions and may precipitate war. In fact, preventive war has been considered a necessary instrument of balance of power politics. World empire implies war to create it. even if the object is eventual peace. International organization, if based only on consent, is ineffective against aggression, and if based on coercion implies, as does the balance of power, war as a possible instrument. World government, contemplating a voluntary federation of states rather than their initial compulsion as in the case of empire, cannot be established until sufficient solidarity exists in the world to permit universal consent. Furthermore. federations when not compelled to cohere by danger of invasion have tended to disintegrate The problem of world government differs greatly from that of territorially limited government.

Economic reforms in the direction of free trade have been urged not only to promote prosperity but also by men like Richard Cobden and Cordell Hull to prevent war Socialists from an opposite point of view have urged the social control of economic activity with the same dual purpose on the theory that capitalistic competition, and the class struggles and imperial expansions it is said to engender, had been the major cause of war in modern history. Economic liberalism has probably contributed to the stabilization of peace when. as during much of the 19th century, political relations were themselves stable, but there is no evidence that it can in itself make them stable. The Marxist analysis of the cause of war has been vigorously contested on grounds both of theory and history. Experience with socialism organized by national governments provides no evidence of its alleged peacefulness. On the contrary, the more their economies have been centrally planned the more states have become autocratic, despotic and aggressive. As a consequence, international trade has declined, economic differentials at national boundaries have been augmented, international co-operation has languished, and international tensions have increased.

Educational activity emphasizing the costs of war and attempting to create attitudes deemed appropriate to a peaceful world have been prominent in the writings of such philosophers as Erasmus and William James, and in the work of peace societies. After World War I, education at all levels, at least in the democracies, gave great emphasis to international relations, international organizations and the problem of war. UNESCO was dedicated to the promotion of peace and security through activities in the fields of education, science and culture. The findings of social psychology concerning the influence of individual frustrations, attitudes and tensions upon intergroup relations presented opportunities for education at all levels, transnational co-operation in all fields and mass communication of all kinds.

Military interest in the control of war has looked toward reduction of armaments, prohibition of particularly destructive or aggressive weapons and regulation of the conduct of war. Doubting the possibility of eliminating war altogether, moderation of its human and economic cost was urged. Legal interest in the control of war was directed, especially after the growth of modern international law in the 16th and 17th centuries, toward regulation of both the initiation and the conduct of war, and toward development of methods for settling international disputes peacefully. These efforts at times undoubtedly influenced the occurrence and conduct of war, but they never achieved the results hoped for by their advocates. Rapidly changing military technologies and sentiments of more intense nationalism weakened the influence of such regulations.

Plans to control war failed to solve the dilemmas arising from the fact that the necessary universality of acceptance requires coercion which implies war as an instrument, or time which implies the continuance of self-help in the short run, or revolution, destroying national loyalties, which implies violence at least in the short run. Many ideal systems for the control of war might work if peoples and governments would accept them sincerely, universally and simultaneously, but the problems of lack of confidence, of the nonconcurring group, and of the transitional period are not easy to deal with. The problem of controlling war may have to be considered not as action to realize a plan, but as a continuous process of adjustment to maintain stability in a complex world. Such adjustment requires continuous action on all fronts—educational, economic, political, military and legal—to maintain balance between the local and the universal, the short run and the long run, coercion and consent, the individual and the group.

IV. THE LAW OF WAR

1. Initiation **of** War.—Even primitive peoples usually observe certain formalities on the initiation of war, and the states of the historic civilizations not only required such formalities, but often recognized that war was just only if the initiating group had sufficient cause and proper motives. They sometimes explicitly forbade all war in certain places and in certain times, as did the medieval peace and truce of God.

International law in the 18th and 19th centuries abandoned these requirements of justice and treated war as a fact which began with the first hostile act by a sovereign state intended to initiate war. The practice of formal declaration of war was abandoned in most instances. Nineteenth-century international law, however, recognized certain requirements of justice in the initiation of hostilities short of war. Thus reprisals were permissible only for the purpose of remedying a legal injury after peaceful means had failed and if proportioned in severity to that injury. Hostilities in self-defense were permissible only in case of instant and overwhelming necessity to prevent irreparable injury to a state's territory, officials or nationals, and if confined to such necessity. Intervention was permissible only on the basis of a treaty with the state in whose territory the action took place, provided that treaty had not been made with one faction of a civil war.

The 20th-century movements to regulate the initiation of war involved all earlier methods. The first Hague convention of 1899 recognized the general interest of all members of the community of nations in preventing the outbreak of war and the third Hague convention of 1907 required a declaration or an ultimatum with a time limit before initiating hostilities. Treaties neutralizing certain areas or states, such as Switzerland (1815) and Belgium (1839) increased in number, and "cooling-off treaties" such as the Bryan treaties made by the United States in 1913 prohibited war during a period of time when the disputing states were obliged to attempt conciliation. The League of Nations covenant, the Kellogg-Briand pact and the United Nations charter included general prohibitions upon the initiation of war. Considering the general ratification of these treaties, any armed hostility became illegal under international law unless permitted by legally defined circumstances. These circumstances include hostilities to suppress mob violence, insurrection or rebellion within the state's domestic jurisdiction, hostilities for necessary individual or collective self-defense. hostilities in pursuance of express permissions in a treaty binding on the state in whose territory the action takes place, or hostilities under authority of the United Nations or in pursuance of obligations undertaken in the charter.

2. Conduct of War.—Rules for the conduct of war are no less characteristic of all cultures and civilizations than are the rules for the initiation of war. Usually, however, no clear distinction has been made between rules of expediency such as principles of strategy and tactics, rules of discipline such as prohibitions against unauthorized seizures or hostilities by subordinates, and rules of international law such as those relating to the treatment of prisoners of war and respect for flags of truce. These three types of prescription were confused by some of the early jurists of international law such as Balthazar Ayala. Grotius, however, confined his treatment to rules of international law, though he distinguished what is permissible to a belligerent deduced from the nature of war and what is desirable drawn from better practices giving consideration to morality. humanity and mutual interest. Grotius' distinction is recognized in modern rules of war. codified in the Geneva and Hague conventions and developed by practice, juristic commentary and judicial opinion. These rules permit a belligerent to exercise certain extraordinary powers beyond those which a state enjoys in time of peace. These include the power to invade and occupy enemy territory, to destroy enemy armed forces, to requisition and confiscate types of enemy property, to visit, search, capture and condemn certain types of neutral property at sea. These exercises of power are considered "military necessities" if the enemy is to be brought to submission. The law of war, however, restricts the exercise of these belligerent powers from considerations of humanity, mutual convenience of the belligerents and neutral interest. Wanton cruelty would not forward the strategic interests of a belligerent and is likely to impair those interests by arousing adverse neutral opinion. Perfidy, such as the misuse of flags of truce and violation of armistices, makes useless these symbols and agreements, confidence in which is in the mutual interest of the belligerents. Unnecessary injury to neutrals may make them enemies. Rules forbidding injuries to the enemy of this type are therefore sanctioned by self-interest.

Some rules of war, such as those prohibiting the destruction of enemy property, are specifically subject to nonobservance in circumstances of "military necessity." (Fourth Hague convention, 1907, reg. art. 23 g.) Other rules are stated absolutely such as that forbidding the killing of enemy persons who have surrendered (ibid., 23 c). It is, however, recognized that most rules may be overridden in circumstances justifying reprisals, that is, retaliatory measures to compel enemies to observe the law. Reprisals against prisoners of war were, however, explicitly forbidden by the Geneva convention of 1929 (art. 2).

The jural character of rules of war is indicated by their sanctions which reside not only in the mutual interests of the belligerents, but also in the protests and possible action by neutrals, in reprisals by the other belligerent, and in judicial proceedings. Such proceedings are required before condemnation of maritime captures and before punishment of alleged war criminals. While such proceedings have usually been conducted against enemy or neutral individuals in prize courts and military tribunals of one belligerent, proposals were made for international tribunals as, for instance, the proposed International Prize court suggested at the Hague conference of 1907. The Nurnberg and Tokyo tribunals after World War II were international in the sense that they were based on agreements among many of the United Nations. The Axis powers were, however, not represented and the jurisdiction of the tribunals extended only to Axis nationals. It was argued that this discrimination was justified because the United Nations, comprising a large portion of the world's population, was competent to represent the community of nations, and the Axis poners, not being lawful belligerents. had no claim to participate. The opinion rendered by the numerous international and national war crimes tribunals after World War II greatly developed the law of war, especially on such subjects as the defense of superior orders. the killing of hostages, the justifiability of reprisals, and the liabilities of judges, doctors and administrators for inhumanities.

While the rules for the conduct of war have developed especially for application during "states of war" when belligerents could be considered legally equal, they have also been applied with some modification in cases of insurrection, intervention, occupation, reprisals and other "hostilities short of war." Juridical analysis of the legal consequences of aggression has concluded that an "aggressor" acquires no new powers from his unlawful initiation of hostilities. Consequently the aggressor is liable to compensate for all losses of life and property received by his victim or by third states if such losses resulted from acts illegal under the international law of peace. On the other hand, the defender acquires all the powers of a belligerent against the aggressor and the powers which a belligerent has in relation to neutrals against nonparticipants. But in exercising these powers, even the defender is bound to observe the humanitarian restrictions imposed by the traditional law of war. (Draft Convention on Aggression, Research in International Law, American Journal of *International* Law, vol. 33, Nov. 1939, p. 823 ff.)

3. Termination of War.—Wars have usually been terminated by treaties of peace, but in some cases one belligerent has been conquered and his entire territory annexed, and in others, peace has been generally recognized after prolonged cessation of hostilities without a treaty. Hostilities usually terminate by armistice or capitulation before termination of the war. Though hostilities ended in 1945, World War II continued against Germany until declared ended by the western Allies in 1951, and against Japan until the peace treaty with that country came into force in 1952.

Under 19th-century international law, apart from special provisions in the treaty of peace, the termination of war automatically restored peaceful relations, liberated prisoners of war, revived treaties which had been suspended by war and restored property the title to which had not been transferred. Opinions differed as to whether territorial boundaries were fixed by the line of military occupation (uti possidetis) or were restored to the prewar position (status *quo* ante bellum), but opinion tended to the latter view as the distinction, insisted upon in the Hague convention, between "military occupation" and "completed conquest" became accepted. However, the issue was usually not important because the treaty of peace determined the boundaries.

The outlawry of war in international law which developed after World War I raised new issues in respect to the termination of hostilities. The aggressor is considered guilty of an international delinquency and consequently should not, in principle, participate as an equal in the making of peace. Furthermore, treaties, in principle, should be mutually beneficial to the parties and an imposed peace is not likely to have this character. This fact has always made the enforcement of treaties of peace especially difficult, and the implication of the Stimson doctrine, that treaties made under duress against the state are invalid, might, under the new international law, render such treaties legally ineffective. The theory has therefore been suggested that the defender and its allies. acting as agents of the communitv of nations to suppress aggression have, in principle, the right to demand unconditional surrender of the aggressor and to establish oeace. The situation is said to be analogous to that of a state which has suppressed insurrection or rebellion within its territory. The use of the term "unconditional surrender" by Pres. F. D. Roosevelt at Casablanca (1943) to describe the conditions for ending hostilities with the Axis powers recalled the use of this term by Gen. Ulysses S. Grant at Appomattox and suggested that the action of the United Nations against the Axis was not war but the suppression of an insurrection against the world community.

The war crimes trials against the Axis leaders accorded with this analogy, although after the American Civil War, southern leaders were granted an amnesty after being indicted. Treaties of peace were concluded by the United Nations with Italy, Finland, Hungary, Bulgaria and Rumania, but the treaties did not conform to the traditional type because they included the novel provision that, though the Axis powers were expected to ratify, the treaties would come into force when ratified by the Soviet Union, the United Kingdom, the United States and France. They were, therefore, in principle, declarations of peace by the UN. The western powers made peace with the German Federal Republic in 1951 by unilateral declarations following negotiations of "contracts" ending the occupation, and with Japan in 1952 when a peace treaty of traditional type with that country went into force.

(Q. W.)

V. WAR AND MILITARY POLICY

War in the military sense is the art of forwarding group ends by the use of armed force; in Clausewitz's famous phrase, "the continuance of politics by other means." It includes military policy, strategy and tactics. (Tactics and strategy are treated under those headings; see also ARMY; AIR FORCES and related articles.)

Military policy is a branch of foreign policy. The latter has the general objective of securing the existence and forwarding the interests of the state. Military policy co-ordinates military means to these ends in time of peace as well as of war. It requires the identification of the potential enemy; the estimate of his strength and his weakness: the development of military resources, weapons and plans; and, generally, the continuous co-ordination of these activities with diplomacy. Ordinarily, the authority responsible for defense is organized separately from the foreign office responsible for diplomacy, but it is not easy to distinguish the functions of the two sharply. The capacity to make and retain allies and to advance mutual interests by peaceful means is perhaps the most important element in defense in time of war as well as of peace. The maintenance of this capacity is in the hands of the foreign office which is sometimes called the first line of defense.

The defense department or departments frequently develop policies which conflict with those of the foreign office. Military policy, which emphasizes military preparedness and the use of military threats or action to achieve national interests, tends to create international suspicion and to induce opposing coalitions. Consequently, countries which concentrate on military policy are more likely to initiate wars, to win the first battles, but to lose the war, than are those which concentrate on foreign policy.

States have varied greatly in military policy. In some, professional military men dominate the government and the mailed fist is only slightly concealed beneath the velvet glove in the conduct of foreign policy. In such states domestic policy is subordinated to military requirements in materials, resources and population, and in the maintenance of secrecy. morale and civilian obedience. Individual freedom is thereby reduced, the government controls economy, military forces are large and on the alert, and plans for mobilization and attack are continually developed by the military staffs. Such states have been characterized as "garrison states."

The opposite type insists on subordinating the professional military men to civilians at the head of the defense departments who are, in turn, subordinated to the chief executive or the legislature responsive to popular opinion. The foreign office and diplomacy usually occupy a position superior to the defense departments and usually minimize the use of force or threats. Military preparedness lags and if, as a last resort, armed force is used, materials, weapons and plans have to be in considerable measure improvised. The high economic level and the development of science and individual initiative which are likely to characterize such a state may, however, provide a suitable basis for such improvisation. Herbert Spencer distinguished these military and industrial types of states, but most actual states occupy points halfway between, varying considerably in military policy according to the changing tensions of international relations.

Military policy generally has a close relation to geographic position, political history and social ideals. States without geographical barriers protecting them from invasion of powerful enemies and with a history of frequent invasion are likely to be more dominated by military policy than are states which have long felt secure behind the shelter of mountains, deserts or oceans. Opinion in such states is likely to accept national power and efficiency as more worthy ideals than individual liberty and democratic discussion. The existence of these ideals will reciprocally influence the character of the state.

States also differ in the particular characteristics of their military policy. Some states emphasize the army, some the navy, some the air force. Some states give primary consideration to the armed forces, some to allies. Some emphasize weapons in being, some industrial potential. During the 19th century Great Britain emphasized sea power, Germany land power and the United States minimized all the armed services except when actually engaged in war, relying for security upon the oceans and the presumably friendly relations with Great Britain, which controlled the seas.

Conditions common to all states impose some limitations upon military policy. The nature of the objectives of the two opposing groups influences the intensity of the conflict. As a man threatened with murder will resist more fiercely than one threatened only with defeat in a boxing or wrestling match, so a group facing extermination or enslavement will make more effort than one which fears only the loss of a distant colony or a frontier fortress. In either sort of war the actual fighters will of course do their utmost, for no man ever killed or risked being killed wholly in cold blood. The difference will be the extent to which the furious emotions of combat will spread throughout the nation or other fighting group and the corresponding proportion of the available resources which will be diverted to military purposes. In practice, wars of extermination are rare. Each side prefers to ease its own task by giving the other something to hope for in case of surrender. Prolonged slaughter both frightens and disgusts normal men; they begin to fear the consequences to themselves should it continue indefinitely. Another check upon war is what may be called the irreducible minimum of individualism. Wars are community affairs in which individuals willingly participate only to the extent that they can identify themselves with their community through national patriotism or any other sort of loyalty. If any community is pushed too hard, the moral forces of loyalty and consequent self-sacrifice become exhausted and are replaced by the desire for peace at any price. These three, rational fear, disgust and the irreducible minimum of individualism combine to form a moral limitation upon military policy.

Wars not intended to end in the permanent political destruction of the conquered group may be called politically limited. Politically unlimited conflicts, although not so exceptional as wars of extermination, are historically rare. Even wars which temporarily reduce the conquered to impotence are greatly outnumbered by those in which the political aim of the conqueror is only to weaken the conquered without depriving them of independence. Modern instances are the Spanish-American War, in which the U.S aim of destroying Spanish sovereignty in Cuba was accomplished without the necessity for invading Spain itself, and the Russo-Japanese War of 1904 in which the Japanese aim of driving the Russians from Manchuria was accomplished without invading Russia proper. At the opposite extreme from the policy of extermination is the policy of "cold war," or "war of nerves," in which the object is to persuade another state to modify its policy and yield some political point by the mere threat of war without any actual fighting or casualties whatsoever. Between the policies of extermination and threat, the possible gradations are almost infinite.

Economic requirements always limit military policy. Fighting men cannot get their own living but must be supported either by the noncombatant parts of their own community or by seizing wealth belonging to their enemies. In practice, however, the moral and political limitations almost invariably create an imperative desire for peace long before the economic resources of the fighting group have been exhausted to the point of famine and pestilence. Nor is the degree of limitation concerned with the wealth or poverty of the fighting group. The question is entirely one of proportion, of whether or not the social order is strained by the diversion of a dangerous percentage of the available wealth to military and therefore to economically unproductive purposes.

Technical conditions which include the nature and the destructiveness of weapons, the level of tactical and strategic knowledge and the degree of peacetime preparedness, affect military policy especially by influencing the probable duration of war. The social destructiveness of war is not, however, directly related to the physical destructiveness of weapons. Periods of strictly limited and of imperfectly limited war have followed each other alternately without the slightest change in weapons. In every period the tools of peace are the weapons of war; in other words, the scientific knowledge and manufacturing skill which is available for the design and manufacture of arms equals that which is available for construction and for the other forms of producing wealth. Gunpowder was discovered toward the beginning of the modern scientific development which extended and enriched European civilization. A society which can manufacture poison gas can also produce antigas defense. On the other hand. two unarmed groups could kill each other off to the last man if they chose.

At the same time a military policy providing better armament, or organization, or more skillful commanders may effect a rapid victory in a struggle with a power of approximately equal resources. Similarly, technical superiority may permit a small, weak group to resist for a long time, sometimes even to conquer a group stronger than itself in every other respect.

Technological inventions during the 20th century, especially the airplane, radio and the atom bomb, reduced the protective influence of geographical barriers. and induced all states with sufficient power to attempt an independent policy to pay more attention to military policy. These inventions increased the disparity of military power between great and small states and induced some of the latter to abandon military policy altogether, placing themselves under the protection of a great neighbour. The increase of the destructiveness of war had. it is true, provided a strong impulse for the subordination of military policy to international organization, giving greater assurance of security through law. International institutions had not yet created confidence in the reliability of collective security. After World War II, military policy tended to dominate in all of the great powers.

VI. HISTORY OF WAR

The study of hostilities among animals can contribute knowledge of typical psychological situations leading to war; of the influence of specialized techniques (such as the panther's striking power, the antelope's fleetness, the buffalo herd's mass charge, the tortoise's heavy armour, the co-operativeness of the social insects) upon the frequency and intensity of war; of the relative survival value of different techniques upon the individual, the group and the species; and of the relationship of conflict, competition, co-operation, territorial control, hierarchic dominance, and other social and psychological factors related to hostilities upon the course of organic and social evolution.

War properly so-called, however. is a human phenomenon and its history may be divided into primitive, historic and modern warfare roughly in accordance with major inventions in the fields of communication and weapons. Historic warfare is distinguished from primitive warfare by the fact that it occurred among groups that used writing and usually the horse. Modern warfare began among groups that used printing and the gun. These inventions were rapidly followed by the steamboat, locomotive, motorcar and airplane; the telegraph, telephone, radio and radar; the rifle, machine gun and the chemical and atomic bomb; until warfare came to be conducted by instruments of communication, transport and destruction greatly extending the biological equipment of man or animals.

Primitive war was usually highly formalized. Ostensibly it had the object of vindicating the group's mores which were offended, or thought to have been offended, by a member of another tribe. War was seldom fought for economic gain or political conquest among the hunting and collecting peoples. With the advent of herding and agriculture the latter objectives played an increasing role. Whatever its ostensible purpose, primitive war served to manifest the unity of the fighting group, its distinctiveness from its neighbours and the reality of its customs and institutions. War distinguished the co-operating "in-groups" from all opposing "out-groups," thus contributing to its social solidarity.

Historic warfare arose when agriculture. communications and political organization had developed sufficiently to permit division of labour, the accumulation of surpluses and states of large area and population. Its characteristics differed among various civilizations and at different stages in the same civilization. The civilizations of Babylonia, of classical antiquity and of Japan appear to have been much more warlike than those of Egypt, China and India (see Wright, op. *cit.*, p. 572).

An individual civilization usually began with many groups, each with a ruler conscious of the religion, the organization and the economic needs of the group, struggling to maintain the group against the pressure of others and to increase its power. The interest of the group was identified with the interest of the ruler to maintain and augment his position, wealth and glory. Such struggles tended to reduce the number of independent groups by conquest—the principle of the fish in ancient Indian philosophy because it had been observed that the great fishes smalloned the smaller. The destructiveness of warfare tended to increase with the size of belligerents and the progress of military invention. The war of dash and maneuver tended to be succeeded by the war of mass and attrition, usually ending in the unification of the civilization by universal conquest. This was followed by over-centralization, corruption and decay, permitting the external and internal barbarians eventually to destroy the civilization and to begin the development of a new one. The great wars which usually preceded universal conquest were frequently accompanied by unsuccessful efforts at conciliation, disarmament and peaceful federation. This course of change can be studied in the civilizations of Egypt, Mesopotamia, China and India; and there is some evidence of similar changes in the warfare of the civilizations of Mexico, the Andes, Gaul and central Asia. The historic record is, however, clearer for the classic civilization of ancient Greece and Rome and the Christian civilization of medieval Europe.

1. Ancient War.—The early Greeks were in touch with the older Oriental civilizations, concerning which there is considerable information. One of the earliest Sumerian sculptures from Babylonia, probably dating from about 4000 B.C., shows soldiers fighting in close order, wearing helmets and carrying spears and shields. The chief technical innovation in oriental warfare of which there is knowledge was the introduction of the horse; with the aid of this powerful and originally terrifying beast, the Hyksos, an Asiatic and probably nomadic tribe, temporarily conquered Egypt about 1750 B.C. When first known to the Greeks, the orientals had long possessed organized and disciplined armies equipped with metal weapons, and to some extent with metal armour. They had infantry, cavalry, missile-using auxiliaries, fortifications and warships, distinguished from the merchant ships of the day by sharp proms or rams and propelled like those merchantmen by oars, with sails as auxiliary power. Existing Egyptian models show companies of soldiers uniformly equipped and marching in step. One oriental people, the Assyrians, had made conquest their chief business, specializing in war waged with great energy and cruelty until they themselves had been annihilated.

The Greek civilization, which afterward became Greco-Roman, entered in 431 B.C. a period of great and destructive wars lasting until 29 B.C. The Greek political unit was the city-state, which worshiped gods who were primarily local deities. Consequently, when the increasing pressure of population in 5th-century Greece could no longer be eased by colonization, there was no moral unity either political or religious sufficient to limit strife strictly. The first of the great Greek internal struggles, the Peloponnesian War between confederacies of city-states led respectively by Athens and Sparta, continued for 27 years with two short pauses, producing such a crop of atrocities that thereafter the tone of Greek life was permanently lowered. No lasting peace resulted from Athens' defeat. The rise of the half-Greek kingdom of Macedonia to dominance in Greece and the rapid conquest of the vast Persian empire by Alexander the Great enormously extended the area of Greek culture without ending its internal conflicts. The conquest and assimilation of the Mediterranean world by Rome, of which the chief military incident was the defeat of the Semitic, north African power of Carthage in spite of the temporarily successful invasion of Italy by a Carthaginian army under Hannibal, unified Greco-Roman civilization in what was, in a sense, a confederation of city-states. The last century of Roman expansion, however, saw a series of Roman civil wars which, although they did not affect the unity of the state, were accompanied by massacres and bred an intense longing for peace.

Technically the art of war improved throughout the period, with armies gradually changing from civic militias to mercenary forces Although all free citizens seem to have been legally liable for service in these militias, the recruiting field was narrowed by the universality of slavery and because the citizens had to find their equipment. It was not worthwhile to mobilize more than a handful of those too poor to buy armour, since (except for a brief interval under Alexander and his immediate successors) heavy infantry was the chief arm. The principal weapon of the Greek heavy infantryman was a thrusting spear, the formation being a single deep line called the phalanx. During the pre-Roman period light infantry, cavalry and siege artillery improved; catapults were sometimes used in open warfare as "field artillery." The Romans returned to dependence upon a civic militia of heavy infantry, but in a new form, the legion. They replaced the thrusting spear with two heavy throwing spears, and fought at close quarters with a short thrusting sword which could be effectively used in formations more flexible than the phalanx; the latter therefore could be out-maneuvered. Also, the legion stood in three lines, permitting successive shots and keeping the reserves out of the moral strain of being close behind the immediate combatants. Distant campaigning compelled the professionalizing of the legion coincidentally with the beginning of the Roman civil wars.

In A.D. 29 Augustus became emperor and established a strict limitation of war. He reduced the numbers of the professional army, which he set at about 333,000, and this tiny constabulary long guarded and policed the Roman world from the Atlantic to the Euphrates and from the Rhine to upper Egypt. He systematically disarmed the free civilians, who became unwarlike and remained so until long after ancient times.

The internal decline of Roman society was accompanied by a lowering of the quality of the Roman troops, which could no longer be paid or disciplined as regularly as before. Consequently, increased numbers had to be raised, the support of which burdened the diminishing revenues. By about A.D. 400, numbers may have reached 750,000. The army became chiefly barbarian in personnel. partly because barbarians were cheap to maintain compared with civilized men; partly because the latter were increasingly unwarlike. Meanwhile two combined causes made armoured cavalry superior to infantry; first, the need for mobility in an army used chiefly for running down raiders; second, the lowering of military quality which made infantry unable to resist cavalry charges without massing in close formations covered by hedges of thrusting spears. In turn, these close formations lowered infantry offensive power, making cavalry the offensive arm.

Nevertheless, except for the south and east coasts of Britain and perhaps a strip along the Danubian frontier, the Roman armies everywhere prevented the permanent occupation of imperial territory by the outer barbarians. In the 5th century, as the material side of civilization continued to decline, the reality of local government in the western provinces was taken over by barbarian hereditary commanders or barbaric auxiliary units in the Roman army. This process, however, is generally recognized by historical scholarship to have differed greatly from successful invasion. The commanders in question were usually Romanized or at least half-Romanized; in every case except the mutinous Vandal chieftain in Africa they acted legally as deputies of the emperors, and none except the Vandal ever made war on an emperor.

2. Medieval War.—The middle ages, from about A.D. 500 to 1500, strictly limited warfare within Christendom by a new moral unity centring in the catholic, *i.e.*, universal, church. Early in the period the empire gradually became Christendom, as the moral authority of the church increased, while the power of the emperors declined.

Technically, armoured cavalry remained the chief arm throughout the period, but before A.D. 800 the typical soldier in the west was no longer a professional, but a feudal militiaman. Professional armies, being expensive, were always small compared with the populations supporting them. To be effective they had to be regularly paid and capable of rapid movement over long distances, which conditions the debased Roman society, too impoverished to maintain its road system, could no longer fulfill. After the loss of many provinces to the fanatical Moslems, the western part of the diminished remnant of Christendom—its peoples still disarmed as they had been since Augustus—had to meet a new trial: devastation by mobile and ferocious raiders. Scandinavian sea pirates called Vikings, Magyar horsemen and Moslems. A remedy was found by organizing western Christendom for local defense on an aristocratic militia system under hereditary leaders. most of whom were descended from the wealthy class of the earlier dark ages, although some were "self-made."

Superficially; it is hard to recognize medieval wars as limited; all rich laymen were soldiers, and medieval literature is full of tales of battles, and medieval art full of every sort of military symbol. Nevertheless, the evidence is clear that the frequent armed strife between medieval Christians was socially trivial. The Plantagenet and Valois families could squabbie over the crown of France through the Hundred Years' War without general and lasting strain to the social order in France through such prolonged hostilities. Large armies operating far from their bases were exceptional; volunteer forces were raised for special occasions, usually crusades against non-Christians. The 50,000 volunteers with whom William the Conqueror is recorded to have invaded England were numerous for such a campaign. Private wars between nobles seem to have troubled general public order less than the violence incidental to modern labour strikes.

The essence of the strict medieval limitation of war was that prolonged offensive campaigns on a large scale within Christendom were made impossible. In general, Christians felt Christendom to be one country whose differences were unimportant compared with the gulf between Christian and non-Christian. Technically, limitation was assured by the nature of the military obligation and the taxing system. All freemen except the highest were bound by oath to serve an immediate superior in arms at their own expense; but except for the defense of their own locality they had to serve for 40 days only in each year. Beyond that time their superior had to pay them, and this the law and custom of the time forbade. The ordinary expenses of government had to be met by the hereditary ruler from the rents and dues from lands which he individually owned; he could not increase these rents and dues because they were fixed by custom. Emergency taxation was a free grant to the feudal superior by his inferiors, usually to a king by his great vassals, which they could refuse at will. Consequently most medieval armies were tiny. In the Albigensian crusade the decisive battle of Muret was won by a striking force of 900 armoured cavalry, supported only by an even smaller body of ill-armed infantry; while in famous fights like Poitiers and Agincourt the victors, the Black Prince and Henry V of England, commanded numbers of fewer than 8,000 and 15,000 respectively.

Through the early and central middle ages a typical army consisted primarily of armoured cavalry. Usually, but not always, infantry were ill-armed and of secondary value. On the defensive the armoured horsemen would habitually dismount, as Harold's elite did at Hastings, and form the front rank or ranks, while the lesser men stood behind them in a deep mass. On the offensive, although archers might support mounted charges with their fire, the average value of foot soldiers was slight. City militias were usually better than peasant infantrymen. Fortification was prevalent, while siegework declined, so that sieges remained long until near the end of the period.

Warships remained rowing vessels fighting by ramming or retrograded to sailing ships fighting by the primitive method of boarding.

Although the aristocratically commanded feudal militias followed up their success in repelling the Vikings and other raiders of the dark ages by crushing the Spanish Moslems and the pagan Prussians and Lithuanians, and by long maintaining themselves against the Moslems in distant Syria, nevertheless their military shortcomings were obvious. Their character made high training and discipline impossible. Consequently, western sovereigns often chose to use their scanty revenues to hire mercenaries with some professional skill who would at least remain while paid. These mercenaries were usually of a cosmopolitan sort, frequently unemployed and generally hated as savage plunderers. Throughout most of the period. the Byzantine emperors of Constantinople kept up a professional standing army which long maintained much of the high Roman military tradition.

In the 14th and still more in the 15th century the medieval limitation of war began to weaken. The moral authority of the church diminished through the corruption of the higher clergy. Sovereigns became more cynical and cruel. and war, although remaining small in scale, became more ferocious with the increasing employment of the mercenaries just described. At the same time military technique developed. The rise of mercenaries, although socially harmful, was technically a symptom of greater wealth and a more specialized economy. The English longbowman, drawing his bow to the ear, became a valuable auxiliary to the armoured man-at-arms. The Swiss, whose poverty made armour and horses rare among them, developed a true attacking infantry for the first time since the ancient Romans. Although armed chiefly with clumsy long pikes, their great attention to drill made their deep formations both mobile and maneuverable. The appearance of disciplined infantry diminished the importance of cavalry, and by improving pioneer work would in any case have shortened sieges. (See also NAVIES, EARLY HISTORY OF.)

3. Modern War.—Modern civilization was ushered in by the discoveries of Columbus and his contemporaries, bringing most sections of the world into continuous contact with one another; by the integration of modern states under absolute monarchs who claimed temporal sovereignty above the religious claims of Christendom; by the use of the printing press to make people conscious of vernacular languages and national differences; and by the use of gunpowder by sovereigns to reduce the castles and the autonomy of the feudal nobility. The first effective use of gunpowder was in siege artillery which, against fortifications unsuited to counter battery work, made 15th-century sieges rapid affairs. In 1453 the siege by the Turks of Constantinople, the most strongly fortified of medieval cities, lasted only jj days. Toward the end of the 15th century the French and Turkish governments raised small, permanent standing armies.

War has been an important factor in spreading western civilization throughout the world and in creating the conditions for a world civilization. Four phases can be distinguished in the history of modern war, the first three lasting nearly 150 years.

The ***Religious*** Wars.—In the first phase, ending in 1648, the chief military events were the religious wars. After about 50 years, during which the diminishing limitation of war inherited from the middle ages was further weakened, the moral unity upon which that limitation had rested was destroyed by the appearance of various Protestant religious bodies determined upon the reform of the church. When added to the struggle for power of the rising princes, the fearful popular passions resulting from this theological conflict produced a series of savage and de'structive wars culminating in the Thirty Years' War, the most horrible military episode in western history prior to the 20th century.

Throughout this phase, armies remained small in proportion to population, because much of the medieval feeling against taxation continued. The Spanish army which invaded the Netherlands in 1566 and proved invincible to the Dutch in mobile warfare numbered only 11,000; the peace strength of the largest early 17th century standing armies in Christendom, the French and Swedish, was only 15,000 each; and until after the end of the religious wars, concentrations of 20,000 men were seldom seen on either side in a battle.

The destructiveness and horror of the wars of the time resulted from the nature of the troops and the absence of a regular supply system. Militias of the medieval sort still existed but continued to decline. and were seldom used for serious fighting except in the case of civic militias defending towns. The typical soldier was the temporarily hired and ruffianly cosmopolitan mercenary, socially similar to his late-medieval predecessors in evil. The irregularity of his employment seldom permitted his' higher commanders to control him firmly. Indiscipline was increased by irregularity in pay; sovereigns were tempted to enlist more men than they could long support. The high discipline in the armies of Spain, the first military power of the period, owed much to the constant stream of bullion from Mexico and Peru. Worst of all was the chronic lack of an efficient commissariat. In the French and German religious struggles even a commander desirous of controlling his men was usually compelled to let them scatter to forage in order to live. The hardened scoundrels who ordinarily composed these foraging parties became a curse to the civil population.

No such orgies of wanton destruction and violent crime as those of the Thirty Years' War had been seen in Europe since the Viking raids of the 9th century. The constant ravaging bred famine and pestilence. Cannibalism was frequent; usually it was the dead bodies of executed criminals which were eaten, but once, in Alsace, prisoners were actually, killed for food. Historians long held that three-quarters of the German-speaking peoples perished, and later estimates of a loss of one-third put the dead at 7,000,000.

Tactically the wars of the time showed a rapid development of the revolutionary influence of gunpowder. Both siege and field artillery became handier and more mobile. In the early 16th century, before fortifications suitable both for resisting shot and for mounting cannon of their own were designed, sieges were lightning affairs. In 1523 the strong but old-fashioned defenses of Landstiihl in the Rhineland were battered down in one day. Later, however, earthworks and stone towers of a new type, capable of offering a long resistance, were developed. Field artillery scored its chief successes early in the period; at Ravenna in 1512 both French and Spanish guns played a great part, the French pieces contributing greatly to the final victory; and at Marignano in 1515 the French field pieces, firing upon the deep Swiss formations, prepared the way for the last great success of armoured cavalry of the medieval type. Increasing poverty caused by the religious wars seems later to have reduced the proportionate number of guns available. Both infantry and cavalry were increasingly armed with hand firearms. Late 16th-century cavalry tended to abandon the lance for the pistol, although afterward a return to shock action took place. Infantry muskets which could kill a horse at 400 paces—if they chanced to hit him—are found early in the period, and before its end about three-fifths of the average infantry unit were musketeers, the rest being pikemen for close combat. The use of armour steadily decreased; to be strong enough to turn bullets it had to be unbearably heavy.

In naval warfare the gun became the chief weapon. Since many guns made ships too heavy to be rowed, sails became the chief propellant outside of the Mediterranean where some row galleys were still found useful in the frequent summer calms. Tactics under sail, however, developed only slowly.

During the middle phase of the agonizing Thirty Years' War, Gustavus Adolphus of Sweden, in his brief but brilliant career, showed that the efficiency of armies could be increased and the social destructiveness of war simultaneously decreased by a regular supply service which permitted the men to be kept with the colours. Toward the end of that struggle the weakness of governments permitted the appearance of peace propaganda by broadsheets and other means. The peace of Westphalia (1648) established the doctrine of territorial sovereignty. Europe was permanently divided in religion under the theory that the sovereign could decide the religion of his subjects.

The 18th-Century Limited Wars.—From the end of the Thirty Years' War in 1648 to the attempt of the revolutionary French republic to enforce universal compulsory service in 1793, a strict limitation of war prevailed.

After the Thirty Years' War Europe was sick of blood, as ancient Rome had been after the civil wars before Augustus, and as the 20th century world was to be after 1918. The medieval idea of legitimate, hereditary government remained, together with much of the medieval social order and institutions. Upon these foundations, and especially upon the classical culture then common to all educated men. a new moral unity was built by means of a humanist cult of moderation, reason and decorum. Anything, so felt the men of Louis XIV's day, was better than the destructive passions which they despised under the common name of "enthusiasm."

The late 17th- and 18th-century conduct of land warfare carried further the military reforms of Gustavus Adolphus. Although a certain "floating supply" of irregularly employed cosmopolitan mercenaries remained, armies became permanent standing forces loyal to their sovereigns, who in western Europe were also their national leaders. Uniforms seem first to have been introduced under Louis XIV. Compared with the straggling and usually criminal plunderers who had preceded them, the new standing armies were habitually and fully supplied by an elaborate system of magazines, and were at the same time strictly disciplined, both to increase their tactical efficiency and to prevent their harming either friendly or nominally hostile civilians. Gen. Thomas Gage, commanding for England in Boston in 1774–7j, hanged two of his own soldiers merely for breaking into a colonist's shop. Under such conditions service in the ranks was little better than honourable slavery, so that only the more adventurous individuals or the poor would enlist. Frequent desertions furnished another argument in favour of strict control. Outside Prussia, militia service as a citizen-soldier almost disappeared. Only in Prussia was there a real system of training reserves for the standing army by a partial and highly selective system of compulsory service which spared the middle class and all artisans, taking only such peasants as could be spared from necessary farm labour.

Until about 1700 a dwindling proportion of infantry still carried pikes, but after that date the introduction of the bayonet made the musket and bayonet the universal weapons of infantry, and infantry tactics were directed toward developing the greatest possible firepower. A highly specialized tactical system adapted to the unfenced open-field agriculture of most of central and western Europe was devised. When deployed for battle the men stood in shallow formations usually three deep, and marched slowly forward to close with the enemy, carefully keeping their alignment, because any who advanced beyond their comrades would have their ears blown in by the detonation of the coming discharge. The high point of the art was to "reserve fire" until very near, to compel the enemy to throw away his fire by firing too soon, and then to pour in one's own volley at murderously close range while the enemy was reloading. All firing was supposed to be by volleys at command, and a single "perfect volley," like Wolfe's at Quebec in 1759, might decide a general action. The point about reserving fire explains the much misunderstood incident of the English officer who, at Fontenoy in 1745, taunted the French guards to fire first. Although he may have been drunk, he was by no means merely playing the fool; behind his bravado lay a sound tactical principle. The disappearance of the pike somewhat increased the combative value of cavalry. On the other hand, the shallow infantry formations diminished that of artillery; in no important battle do guns seem to have been decisive.

Although military numbers increased, especially around 1700 toward the end of Louis XIV's reign, in accordance with the general increase in population, aggregate wealth and strictness of political organization, nevertheless those numbers remained far smaller in proportion to population as compared with conscript forces of the 20th century. France in the time of Louis XIV had a population of about 19,000,000; if fully mobilized under universal service this would have given him nearly 2,000,000 soldiers, whereas his greatest numbers may not have exceeded 300,000. Eighteenth-century governments, although stronger than their early modern and medieval predecessors, had only limited authority over the persons and purses of the governed; and economies could not sustain more than 3% of the population in the field.

The humanist reverence for moderation and reason, together with the restricted numbers of the armies, their professional character and the high standard of training and discipline necessary for the tactics of the day, resulted in an economical conduct of war. Since governments seldom desired to destroy a rival government, but only to gain concessions from it, wars were for limited political objectives. Generals could not rashly expend soldiers trained for many years and not easy to replace. Accordingly, as in most professional armies throughout history, he who won by skill and craft was more admired than he who won by mere pounding. Superficially this seems contradicted by the amazing battle losses—the Russians at Zorndorf in 1758 had 37% and the Prussians 30% casualties in a few hours—and also by the extreme boldness of commanders like Marlborough, Charles XII of Sweden and Frederick. But the contradiction is more apparent than real: Marlborough was relieved for incurring excessive losses; Charles XII was admittedly rash to folly; and Frederick through all his daring offensives was always careful to keep his army in being to fight another year. Although in weak hands such methods degenerated into slackness and formalism, the essential reasonableness of the effort to win without excessive bloodshed was recognized.

The same desire for economical warfare was reflected in the part played by fortresses and entrenched lines. The great military engineer Sebastien Vauban constantly insisted that the besieging troops should keep covered, advance by sapping and wear down the garrison by their fire instead of assaulting. His chief technical invention was that of "parallels," successive entrenched lines to shelter the besieging infantry.

Naval tactics appropriate to the sailing ship fighting by gunfire were devised. Since ships are always much longer than they are broad, they can mount more guns on the broadside than either ahead or astern. Consequently the best formation of such a fleet is in line ahead which permits all broadsides to fire. Before 1700 warships had become specialized into ships of the line and lighter craft, the former being more stoutly constructed and mounting heavier batteries. Throughout most of the period naval battles were fought in parallel lines. Toward the end, however, the frequently indecisive results of such engagements and their disadvantage to the fleet (which, being to windward, must receive hostile broadsides without effective reply while bearing down to close quarters) led to the more decisive procedure of attempting to break the hostile line by cutting it in pieces.

Revolutionary and National War.—The great and destructive wars after 1793 were characterized by the widely extended authority of governments over the governed, the expression of this authority being the universal compulsory-service mass army with its corollaries of almost unlimited taxation and the regimentation of civilian life. All these things were first attempted by the revolutionary French, and few prolonged wars of the sort ended, otherwise than in the destruction of the government of the defeated side by revolution. The vast authority necessary for such colossal efforts was later to be called total or totalitarian.

After the destruction of the 18th-century humanistic moral unity which had insufficiently appealed to the imagination and had therefore attracted no strong loyalty, no moral force able to end or moderate potential strife was found. The destructiveness of war even to the victor, the material advantages of international trade. and the stability of the European balance of power regulated by British policy supported by sea power, limited fighting in Europe during the century between the Napoleonic Wars and World War I. During that century all the wars in Europe together cost few more lives than did the American Civil War (1861–65), itself less costly in life than the Lopez War in South America (1865-jo) , and the Chinese Taiping rebellion (1850–64). The driving force of interclass struggle for political and economic equality, and of international conflict for national self-determination and imperial expansion increased tensions during the latter part oi this period and led to the two most destructive wars of history from 1914 to 1945.

The first episode of the period is that of the Revolutionary-Napoleonic wars between France on one side and on the other, England, supported by a series of temporary coalitions, the last of which finally crushed Napoleon in 181j. In Aug. 1793 the French revolutionary politicians: justly fearing for their lives because of what all Europe felt to be their crimes! and terrified by the threatened dissolution of the French regular army, passed the first universal compulsory-service law in history. Although the immediate tangible result of this law has been much debated, it was, very logically, accompanied by attempts to control and compel the labour of the civilian population. Meanwhile new tactics and strategy were developed. The raw revolutionary levies could not be sufficientlydisciplined to stand in close formations and fire volleys at command Profiting perhaps by the experience of French officerswho had served in the American Revolution, those levies discovered the effectiveness of fire at will by agile swarms of skirmishers who offered no target for the volleys of the hostile regulars. For bayonet charges the revolutionaries formed in tumultuous columns of shouting men. At the same time their very deficiencies helped them to march well; the chaos of their supply system freed them from the slow movement and distribution of food to and from magazines, and compelled them to live off the country. Their lack of tents and baggage wagons left them unencumbered. Their new formations and their mobility. together with favourable chances of war against the sluggishly led armies of the First Coalition, saved the republic.

The high talent of Napoleon systematized the new procedure. For years his rapid marches. bold attacks, and contempt for the accepted rules of war bewildered opponents. Under him the French, who had already taken the offensive before his rise to power, entered every capital in Europe from Madrid to Moscow. Preoccupied with numbers, he used the conscription law of 1798, which replaced the original law of 1793 and made men liable from their 20th to their 25th year, to give him constantly larger armies. Another innovation was the concentration of guns in great batteries, thus making artillery again a decisive arm

Nevertheless his successes only increased his difficulties. England, secure from invasion through her superior fleet, could probably have been worn down had Napoleon achieved a true peace on the continent; but this he could not do. Although the Revolutionary-Napoleonic ideas appealed to certain elements, Europe could neither be revolutionized nor permanently cowed. Napoleon's constant aggressions, his violations of neutral states and the humiliating treaties imposed upon temporarily helpless enemies bred permanent distrust and desire for revenge. Chronic looting by the French angered Europe Rivals began to learn his methods; Austria, and to some extent Prussia, copied the French mass army.

In vain Napoleon increased his numbers. Feeling himself constantly driven to advance still further while an undefeated continental power remained, in 1812 he led into Russia the largest field army yet known to history, nearly 500,000 men. When inflexible Russian national spirit and the climate brought disaster, his political position at once began to crumble, as one by one every continental power turned against him. Although exhausted France raised another almost equally large army, French military quality was now declining. and in the autumn of 1813 the victory of overwhelming allied numbers at Leipzig was the beginning of the end.

The military history of the 99 years from Napoleon's fall to 1914 was marked by the survival of the mass army and by the absence (except for the American Civil War) of prolonged mass warfare. At first, universal service survived only precariously through military theory and through the action of Prussia. In a Europe as sick of blood as after the Thirty Years' War, a moderate peace was made with France and a short-lived attempt was made to renew the 18th-century limitation. France and Austria, although both retained universal legal liability for service, drafted so few men and for such long terms that their armies became professional in spirit. When in 1830 a Dutch force besieged the citadel of Antwerp, a mutual agreement to spare the town by confining firing and active operations to the side of the citadel which faced the open country was made in 18th century fashion. For a full generation Europe saw no war between great powers.

Nevertheless, 18th-century humanistic moderation could not really be revived. The closely connected forces of democracy and nationalism, both intertwined with the rise of the commercial middle class and with the romantic movement in thought and letters. again became active. A capital instance of romanticism was the undue admiration for Napoleon. Dazzled by his victories and moved by the melodrama of his meteoric rise and fall, men insufficiently considered the proved weaknesses of his political and military system. The work of both great 19th-century theorists of war, the French-Swiss, Antoine Jomini, and still more the Prussian, Clausewitz, is touched with this error. Clausewitz, although a profounder philosopher than Jomini, too often calls Napoleon "the god of war." Meanwhile Prussia, a poor but vehemently ambitious power, carried the revolutionary French idea of universal service even further by adding universal peacetime training.

Toward the middle of the 19th century strife between the great European powers was renewed with the wars for Italian and German unification and the Crimean War to check the ambition of Russia. The stability of the balance of power prevented these wars from spreading or seriously straining the social order of Europe. The American Civil War, a four years' war of exhaustion in which the defeated South fought to the last gasp, showed that fearful struggles were still possible. Socially, 1861–65 followed the Revolutionary-Napoleonic pattern of fierce popular passions and of mass armies raised by compulsory service. Technically, however, this was the first of the industrial wars. Machine industry and ease of communication by steamship and railway specialized the economy of various regions, making them vulnerable to blockade. The South had imported manufactured goods from the North and from Europe, paying for them by exporting tobacco and especially cotton, so that the cutting of its external communications by the North damaged it. Railroads also made it possible to supply large armies more easily and permit rapid strategic movement; steamships made movement at sea independent of winds, and at the same time tied fleets more closely to their bases by necessitating regular supplies of fuel. Other effects of industrialism upon naval warfare were evident in ironclad ships, anchored mines, torpedoes and a rudimentary submarine.

The first effect of industrialism upon land. tactics was to strengthen the defensive by arming the infantry of both sides with rifles, thus suddenly increasing the effective range of hand firearms from less than 100 to more than 600 yd. Cavalry charges, close infantry formations and volleys at command became equally impossible, and toward the close of the struggle troops in the presence of an enemy formed a habit of entrenching in order to live at all. The combination of rifle fire and entrenchment helped to postpone tactical decisions, thus tending toward a strategy of exhaustion. The use of railroads, on the other hand, made it possible for commanders to move troops rapidly and contributed to offensive power and the ultimate victory of the Union.

The significance of the new strong defensive, however, was lost upon Europe. The able Prussian chief of staff, Count Helmuth Carl von Moltke, is said to have contemptuously called the American Civil War, "a struggle between two armed mobs. . . from which nothing could be learned." European soldiers continued to believe in rapid decisions obtained by dashing, Napoleonic offensives. This belief, plus the skillful use of railroads, produced the rapid Prussian victories of 1866 and 1870. In 1866 Austria was beaten in seven weeks. In 1870 the French regular army was put out of action in four weeks. The real significance of both cases was the political weakness and inferior command of the victims. Austria was a dynastic state with no general patriotism; the France of 1870 was riddled with faction, while Moltke had developed a railroad system permitting rapid mobilization and a decentralized system of command suited to large-scale operations, since it left subordinate commanders free to act according to circumstances.

The moderate peace made in 1866 eventually led to an Austro-Prussian alliance, but the immoderate terms of 1871—by which not only German-speaking Alsace, but also French-speaking Lorraine were taken from France—produced lasting political strain.

Meanwhile every continental European power and also Japan hastened to organize a mass army on Prussian lines and to imitate Moltke's system of command and general staff. Although no two great European powers fired a shot at each other until 1914, the expense of the colossal armies and of the increasingly large and complicated warships which made up the battle fleets resulted in heavy political and financial strain.

During the 43 years of armed peace there developed an exaggerated cult of the offensive, regardless of the defensive strength of existing weapons. In vain did the Russo-Turkish, Anglo-Boer, Russo-Japanese and Balkan Wars repeat the lesson of entrenchment and a postponed decision. Before 1866 the rifle had become a breechloader; it became a magazine rifle and was next supplemented by the machine gun. Soldiers closed their minds and continued to estimate the strength of armies chiefly in terms of infantry numbers.

World Wars.—World War I began with the Austrian invasion of Serbia on July 29, 1914, followed by the entry of Germany as ally of Austria, of Russia as protector of Serbia, and of France and England in entente with Russia, later joined by Japan, Italy and the United States. After six weeks' fighting the two largest field armies ever seen, each of nearly 2,000,000 men and both seeking a rapid decision by means of a neo-Napoleonic offensive, found themselves stalemated in trench lines which soon stretched from Switzerland to the North Sea. As the most extreme measures, including the violation of neutral Belgium by the Germans in order to turn the French left, proved indecisive throughout this first phase of movement, so the failure to break the trench barrier determined the entire course of the war. Without room to maneuvre and thus condemned to frontal attacks, for more than four years the neo-Napoleonic generals who had despised fortification failed to solve the problem in siege warfare set by modern fire power, especially by the machine gun, combined with trenches and barbed wire. Notwithstanding delusive instances in which success repeatedly seemed within reach, every assault finally failed in mud and blood. Attempts to crush the defensive by multiplying guns and shells finally resulted in bombardments so severe that assaulting troops themselves could not advance across the chaos of shell craters.

Although all nations had declared war in a mood of exaltation, the most intense official propaganda could not keep the spirit of the original belligerents from being worn down by the long, grinding struggle. The enormous authority of governments and the use made of the credit system merely hastened collapse by intensifying the various war efforts. In 1917 the comparatively primitive social order of Russia dissolved after something like 8,000,000 casualties had been inflicted upon its ill-equipped armies, and France threatened to break down as large sections of its army mutinied. In 1918 the governments of Austria and Germany were overthrown by revolution, while their armies, although on the verge of dissolution, were still in the field. Total losses were estimated at 10,000,000 soldiers and an equal number of civilians dead, and 20,000,000 wounded as a direct result of hostilities, and another 20,000,000 dead from war-spread epidemics and famines throughout the world. Economic costs were estimated at $338,000,000,000, of which $186,000,000,000 were direct costs. This estimate did not consider the gains from war-stimulated production or the losses during and after the war from war-produced distortions in currencies and trade. (See Wright, *op. cit.*, p. 219; see also WAR FINANCE: COST OF WORLD WARS I AND II.)

Statesmen, soldiers and peoples everywhere agreed that such results must not be repeated. A political attempt was made to limit war through a League of Nations, but the United States failed to join and a treaty was imposed upon Germany which followed the evil precedent of those made by the French Revolution and Napoleon in that it neither reconciled the two parties nor destroyed the defeated politically.

Simultaneously there began an active discussion of military theory. On the one hand, serious military efforts would henceforward require even further extensions of governmental regimentation of all life. All policy must concentrate on success. On the other hand, a victory won by the methods and at the ruinous cost of 1914–18 was worth winning only on the melancholy assumption that the consequences of defeat might perhaps have been even worse. Thus the war of gigantic efforts and sacrifices was to be politically intensified and at the same time militarily moderated.

In general, the French and British authorities during the interwar period hoped to avoid undue loss by relying upon naval blockade while acting on the defensive by land, to which end the French strongly fortified their frontier with Germany in the Maginot line. The Germans, on the contrary, planned to achieve a quick decision. Under a dictatorial government they rearranged their national life, both to resist blockade and to build powerful striking forces.

The means by which the Germans hoped to gain a rapid and economical decision were based upon certain technical developments of the latter part of World War I, especially the high training of a military elite and the use of new, highly mobile military instruments. Intensive training had made possible the considerable success of their new offensive method of 1917–18, which involved extraordinary secrecy in the approach march. then a sudden and short bombardment without preliminary ranging shots, and finally a dashing advance in which the protection of the flanks of the leading units was left to the reserves at the disposal of the higher command. The motive power of two new instruments. the tank and the plane, was the internal combustion engine. In Nov. 1917 several hundred British tanks, without preliminary bombardment, had suddenly broken through the German front in an attack which if adequately supported by the British higher command might have ended the war. Planes, originally used only for reconnaissance and regulating long-range artillery fire, were fitted with bombs for attacking surface targets and with machine guns useful either against such targets or against other planes. The use of tanks and planes in highly trained hands and in co-operation with the older ground arms promised abundant opportunity for the rapidity and surprise which are the soul of maneuvre.

World War II began in Sept. 1939 with a German attack on Poland followed by the entry of France and England in fulfillment of their guarantees to Poland. Germany had rapid and cheaply bought successes in Poland in Sept. 1939 and in Norway, the Netherlands and France in May and June 1940. The Germans officially estimated their losses at 200,000, of which only 40,000 were killed. These figures may be compared with the French loss of 500,000 at Verdun in 1916, the German loss of more than half that number, and the British of more than 60.000 on the first day of the Somme attack alone. The Germans claimed to have captured some 400,000 prisoners in Poland, and 2,000,000 in the west in 1939–40. Even assuming the German admissions were far too low, the contrast of this first stage of the war with 1914–18 is striking.

The German method was to make every effort to achieve surprise, closely co-ordinating the action of planes and mechanized ground forces with each other and with infantry and artillery. A prominent feature was the rapid division and envelopment of large hostile forces through the sudden creation of deep salients thrust forward by mechanized columns. Throughout, the aim was to win by speed and maneuvre, confusing the hostile command and troops, rather than pounding on the latter in the 1914–18 fashion.

After the occupation of western Europe to the Pyrenees, Germany turned to the invasion of Britain by bombing docks, airports, factories and cities, but the superior quality of British fighters and aid from the United States saved the island from invasion. Germany, and Italy which had attacked France just before that country's fall in June 1940, then turned to the invasion of the Balkans, Greece and North Africa and in June 1941 to a mass attack on Russia. Russian defense in depth turned the tide at Stalingrad in the autumn of 1942 after Leningrad and Moscow had been under long bombardment and the Ukraine occupied to the Caucasus. Japan, at war with China since 1937, attacked the U.S. fleet at Pearl Harbor in Dec. 1941 and rapidly spread its empire through southeast Asia, the Netherlands Indies and the Pacific to the borders of India, Australia and Hawaii. In the summer of 1942, German forces in the Caucasus and Egypt, and Japanese forces in the Indian ocean threatened to meet at Suez. They failed to do so, however. and in Nov. 1942 the tide turned with U.S. victory at Guadalcanal in the Solomons, British victory at El Alamein in Egypt, Russian victory at Stalingrad and Allied landings in North Africa. The Allied nations, with their industrial machine in full production and their armies. air forces and navies increasing in power, moved in from the South Pacific: North Africa and the British channel. preceded by intensive strategic bombing after air superiority had been acquired in all theatres. The Russian and western Allies joined hands on the Elbe in April 1945 and the atomic bomb gave the *coup de grace* to Japan in August of that year.

The general horror at the mass massacres by the Nazis, the general alarm at the rapid initial success of Axis aggressions, and the general acceptance, at least formally, of the Atlantic charter (Aug. 21. 1941) and the Declaration of United Nations (Jan. 1, 1942) had produced a military coalition of the non-Axis world. The productive power of the United States, the tenacity of the British, Russians and Chinese, and the co-operative planning of the chiefs of staff brought overwhelming power to bear and induced unconditional surrender of .Italy on Sept. 8. 1943, of Germany on May 4, 1945, and of Japan on Sept. 2, 1945. The losses were greater than those of World War I in men (estimated 22,000.000 military and civilian dead and 34,000,000 wounded), four times greater in wealth (estimated $1,348,000,000,000 of which $1,167,-000,000,000 were direct military costs) and greatest of all in social and political disturbance. Long after hostilities ceased the cold war between Communist and non-Cdmmunist portions of the world: which had begun soon after the Yalta conference (Jan. 1945) marking the high point of the United Nations unity, was still going on. The two halves of the world were engaged in a race in both conventional and atomic armaments, and there had been small wars in which they opposed each other—in Greece, Vietnam, and especially in Korea. The Korean war, the first instance in which an international organization had utilized military force to suppress aggression, may have marked a new departure in the history of war. In these hostilities, which lasted three years (1950–53), 1,000,000 North Korean and Chinese Communist forces were in the field and an almost equal number were under the United Nations command, mostly from the Korean Republic and the United States, but including forces from 1 j other members of the United Nations. The battle dead on both sides were estimated to have exceeded 1,000,000 (United States: 34,000), which, added to the civilian deaths in Korea; totaled about 5,000,000.

The failure of the Maginot line and the rapid advances. first of the Axis and then of the United Nations, convinced many that the offensive had permanently gained over the defensive. The combined air-tank-infantry attack on land. new devices for amphibious landing, Schnorkel-equipped submarines, and strategic bombing culminating in the atomic bomb had prevented the deadlock of 1914–18 from recurring. Science, however, had begun to produce land mines, antitank guns and rockets with proximity fuses to stop the land and amphibious attack; sonar detection and air-borne rockets to destroy submarines; homing torpedoes and air-borne bombs to destroy capital ships; radar detection, jet planes, proximity fuses with antiaircraft guns, rockets, ram jets and guided missiles to stop the air attack. The offensive, on the other hand, was developing hydrogen bombs, intercontinental ballistic missiles and earth satellites. Thus the balance of offensive and defensive power was uncertain. But the Geneva Summit conference in August 195 j suggested that there was a general conviction among the governments that both sides in the cold war had sufficient retaliatory power to make hydrogen-bomb war suicidal, thus establishing an atomic stalemate in which no rational statesman would voluntarily initiate such a war. The possibility of wars not using such weapons (as in Korea) remained, with the danger that such a war might develop into a general war. Efforts continue to promote stability and a relaxation of tensions by negotiating political settlements. disarmament agreements and collective security arrangements t~ prevent small wars.

Whatever might be the balance of offensive and defensive, however, it seemed clear that science, industrial production and propaganda had become major instruments of war, and that war had come to be too destructive &en to the victor to be a useful instrument of policy. Nevertheless, political ingenuity was unable to construct an equilibrium of power or world institutions for law enforcement to control it.

WAR, ARTICLES OF. In the United States, a code of regulations that formerly provided for the disciplinary government and administration of criminal justice in the U.S. army and air force. The comparable regulations in the U.S. navy were known as the Articles for the Government of the Navy and those for the coast guard as Disciplinary Laws of the Coast Guard. All were superseded in May 1951 by the Uniform Code of Military Justice that applied to all branches of the armed forces under the department of defense. The Articles of War trace their origin to the time of the American Revolution when the British army was regulated by the Mutiny act and the British Articles of War. These regulations were well-known to the colonists and were used as a guide in drafting the American military code.

Whatever its name, a military code consists of a system of rules specifying offenses for which a soldier may be tried. These offenses may be military in nature such as desertion, mutiny or cowardice, or they may be offenses which are regarded as crimes in civil life, such as murder, rape, larceny or arson. A military code also sets forth the procedure to be followed and frequently provides for safeguards to the soldier in the form of the right to counsel, appellate review, protection against compulsory incrimination and other rights generally provided to a person accused of crime. In the United States the military codes have always been established under art, i of the constitution which gives congress the power to make rules for the government and regulation of the land and naval forces rather than under the judiciary article of the constitution. *See* MILITARY LAW.

WAR, LAWS OF: *see* LAWS OF WAR.

WARBECK, PERKIN (*c.* 1474–1499), English pretender, was executed for conspiring with the earl of Warwick (of the house of York) to contest the right of Henry VII (Tudor) to the throne. He was the son of Jean de Werbecque, a poor burgess of Tournai in Flanders, and his wife Katherine de Faro. According to his confession made in 1497, which may be accepted as substantially true, he spent part of his boyhood with various masters at Antwerp and Middelburg; went to Portugal about 1489 with the wife of the Yorkist, Sir Edward Brampton; spent a year there in the service of a knight named Peter Vacz de Cogna; and then entered the service of a Breton merchant named Pregent Meno, who took him to Ireland in 1491. There, by his own account, the citizens of Cork, seeing him dressed in his master's silks, insisted that he must be Edward, earl of Warwick, or a bastard son of Richard III. Eventually he was persuaded to impersonate Richard, duke of York, the younger of the murdered sons of Edward IV, and received encouragement from the earls of Desmond and Kildare. He was then invited to France by Charles VIII, but had to leave that country because of the treaty of Étaples between Charles and Henry VII (Nov. 1492). He went to the Netherlands, where he was welcomed as her nephew by the dowager duchess of Burgundy, Margaret, sister of Edward IV and Henry VII's bitter enemy. In 1493 Henry, who already knew the true name and history of the pretender. protested to the Burgundian government and to the regent Maximilian against Margaret's activities. When they refused to interfere, he prohibited all trade with the Netherlands (Sept. 1493). Two months later Warbeck mas accepted as a royal prince by Maximilian at Vienna. Next summer both were back in the Netherlands, Maximilian acknowledging Warbeck as rightful king of England. James IV of Scotland and a number of prominent men in England were drawn into the conspiracy, but through the treachery of Sir Robert Clifford, Henry VII discovered its details and the executions of Sir William Stanley and a number of Warbeck's English supporters broke the back of the plot.

Nevertheless in June 1495 Warbeck sailed from Flanders with perhaps 1,400 or 1,500 troops provided by Maximilian. On July 3 he appeared off Deal, but a few of his men who landed were captured and the attempt was a fiasco. An attempt on Waterford in Ireland, with Desmond's help. was no more successful and Warbeck then sailed off to Scotland. James IV welcomed him; arranged his marriage to Katherine Gordon, daughter of the earl of Huntly; and in Sept. 1496 helped him in a brief raid into Northumberland. Next year Warbeck went off to take advantage of the Cornish rebellion which had broken out in May as a protest against the direct tax proposed by the king to meet the cost of repelling the Scottish advances. However, by the time he landed at Whitesand bay, near Land's End (Sept. 7), the rebellion was over. Some country people did join him and he advanced as far as Taunton. There, on the approach of the royal forces, he deserted his followers on Sept. 21 and fled to sanctuary at Beaulieu in Hampshire. A week later he surrendered upon promise of pardon and made. full confession to the king. He was at first kept in very easy custody, but after attempting flight in June 1498 was more rigorously imprisoned and also made to repeat his confession twice in public. On Nov. 23, 1499, he was hanged for endeavouring to escape from the Tower with the earl of Warwick. (R. B. WM.)

WARBLER, a bird name applied to certain small song birds which belong to two quite different groups: new world warblers which form the family Parulidae and old world warblers of the family Sylviidae.

New World Warblers or Wood Warblers.—These comprise about 120 species of small songbirds (up to seven inches long), which form the new world family Parulidae (formerly Compsothlypidae or Mniotiltidae). Although these birds are closely related to the new world tanagers, they take their name from their superficial resemblance in form, structure and habits to the distantly related old world warblers, from which they differ most obviously in such technical details as having nine primary flight quills instead of ten as the old world warblers have.

The wood warblers are mainly North and Central American but a few live in South America. These birds live in forest, brush or in swampy grass country. They are active insect eaters, most species gleaning for their food from leaves and twigs or grass, for which their thin bills fit them; but the black and white warbler, *Mniotilta varia,* creeps along tree trunks and some species such as the ovenbird (*q.v.*) *Seiurus aurocapillus,* and the water thrushes, *Seiurus* species, walk (not hop) on the ground. Some species also fly out and catch insects on the wing. In eastern United States the autumn migrating birds are conspicuous in wood lot and hedgerow as they go southward to their winter quarters, often traveling in loose flocks. In colour, grays, olives and yellows predominate and the brighter males are often conspicuously marked with yellow, orange, red, black or white. Some species are brown above and spotted below.

G. RONALD AUSTING FROM NATIONAL AUDUBON SOCIETY

YELLOW WARBLER (DENDROICA PETECHIA)

Many wood warblers have weak, lisping songs but a few have loud voices. The nest usually is a simple cup in a tree or bush, but it may be placed on the ground or hidden in a hole, either in a tree or in the ground; the ovenbird makes a covered nest on the forest floor. The two to five eggs are usually white, speckled with brown, and the young are hatched with little or no down. Both parents share nest duties.

Among the better-known North American species are the gaily coloured yellow warbler, *Dendroica petechia;* the black and orange redstart, *Setophaga ruticilla,* of gardens and orchards (*see* REDSTART); the black-throated green warbler, *Dendroica virens,* with bright yellow cheeks and black throat, of woodlands; the yellow-breasted chat, *Icteria virens,* with its long tail and heavy bill, that skulks in thickets and gives an unusually loud variety of calls; and the yellowthroat (*q.v.*), Geothlypis trichas, with its black mask, that lives in bulrushes and marshy thickets.

Old World Warblers.—The family Sylviidae contains about 400 species, which are intimately related to the thrushes (family Turdidae) and the old world flycatchers (family Muscicapidae). Their name refers to the well-developed songs of some species. The family occurs mainly from Europe and Asia to Australia and Africa, but a few of these birds, notably the kinglet (Regulus) and gnatcatcher (*q.v.*) (*Polioptila*), live in the Americas. Many of these warblers in Europe are familiar enough to have received special names, such as the blackcap (*q.v.*) (Sylvia *atricapilla*), the mhitethroat (*q.v.*) (Sylvia communis), the chiffchaff (*Phylloscopus* collybita) and the goldcrest (*q.v.*), which in America is called a kinglet.

These warblers are mostly small birds (up to 12 in. long) with slender bills adapted for feeding on insects which they capture by gleaning actively among the leaves and twigs of the trees and shrubs, or among the grasses of upland or marsh, wherever the different species live. In colour they are variable but mostly dull: some tree warblers are predominantly green and olive; some grass warblers are streaked brown, buff and black above; others are more boldly marked; and the wren warblers of Australia may be black and white or with bright chestnut or shining blue in bold patterns. Usually the sexes are alike in appearance.

The birds pair and their nests vary from simple cups to domed structures placed in trees, bushes or grass, or hidden in the ground. The tailorbirds of the Indian region sew leaves together into purse-shaped containers for their nests. The eggs, from 3 to 12 in number, are usually speckled and the young, which may hatch downy or naked, are cared for by both parents. (A. L. Rd.)

WARBURG, OTTO HEINRICH (1883–), German biochemist (b. Freiburg, Baden, Oct. 8, 1883), son of the physicist Emil Warburg (1846–1931), was awarded the 1931 Nobel prize in medicine and physiology "for his discovery of the nature and mode of action of the respiratory enzyme." After studying at Berlin and at Heidelberg under Emil Fischer and others, he obtained doctorates in chemistry (1906) and in medicine (1911). In 1930 he was appointed director of the Max Planck Institute for Cell Physiology in Berlin-Dahlem. He concerned himself chiefly with the investigation of vital processes by physical and chemical methods. His work threw entirely new light on the complicated mechanisms by which oxidation and reduction is brought about in living cells. He showed that every breathing cell contains a respiratory enzyme, the nature of which he established as a ferrous organic dye.

His observations and methods found important applications in the study of cancer and one of his most important publications was Stoffwechsel der *Tumoren* (English trans. The *Metabolism of Tumours,* 1930). Warburg devised instruments and techniques which are widely used by chemists and physiologists. He became a member of the Royal society in 1934. (W. J. Bp.)

WARBURTON, WILLIAM (1698–1779). English critic and bishop of Gloucester, participant in many literary quarrels and an early advocate of abolition of the slave trade, was born at Newark, Nottinghamshire, on Dec. 4, 1698, son of the town clerk. He was ordained in 1727. During 18 years in the parish of Brant Broughton, Lincolnshire, to which he was appointed in 1728, he wrote The Alliance Between Church and State (1736) and The *Divine* Legation of Moses in two volumes (1737–41). In the latter, his best-known work, he demonstrated, on deist principles, the divine authority of the Mosaic writings, which deists denied.

Warburton won Alexander Pope's friendship through a series of articles in The Works of the Learned (1738–39) defending the Essay on Man against the *Examen* of Jean Pierre de Crousaz. Through Pope he met Murray, afterward Lord Mansfield, and Ralph Allen, who, said Johnson, "gave him his niece and his estate, and, by consequence, a bishopric." Warburton's edition of Shakespeare, incorporating Pope's earlier work, appeared in 1747, Sir Thomas Hammer's unauthorized use of his earlier notes on Shakespeare led to a heated controversy. Warburton defended his Divine Legation against continuing attacks, and disputed with Bolingbroke over Pope's behaviour in regard to the Patriot King. His edition of Pope's works appeared in 1751. A series of preferments culminated in his appointment to the see of Gloucester in 1759. He defended revealed religion in his View of Lord *Boling*broke's Philosophy (1754) and Remarks (1757). His biographer Richard Hurd shared in the writing of Remarks, which was directed toward Hume's Natural History of Religion. In 1762 he attacked Methodism in The Doctrine of Grace. He died at Gloucester on June 7, 1779.

Warburton's works were edited (7 vol., 1788) by Hurd with a biographical preface, and the correspondence between the two friends—an important contribution to the literary history of the period—was edited by Parr in 1808.

See John ***Selby*** Watson, ***Life of Warburton.*** (**Pa.** H.)

WAR COLLEGES (in some countries called staff colleges), institutions for the instruction of military officers in the art of war. They form the highest level of military education. Officers are usually assigned to them between the ages of 30 and 40 for periods of 6 to 12 months. They are distinct from technical military schools, and deal only with the higher direction of war, grand strategy and staff work.

In the United States the Naval War college (founded 1884) at Newport, R.I., the Army War college (1901) at Carlisle barracks, Pa., and the Air War college (1946) at Montgomery, Ala., are maintained by the three services separately. The National War college (1946) at Washington, D.C., takes 100 to 125 officers from all the services each year, preparing them for the highest staff and command responsibilities and especially for joint commands. The Industrial College of the Armed Forces, also at Washington, trains officers in logistics and industrial mobilization.

In Great Britain the navy, army and air force each have their own staff college. In addition the ministry of defense maintains the Joint Services Staff college (for instruction in interservice staff duties) and the Imperial Defence college. At the latter, founded in 1927, courses of one year's duration are attended by service officers from all commonwealth countries and by civil servants, with the object of promoting close co-operation in military planning at the higher level. There is also a Civil Defence Staff college, maintained by the home office, where short courses are held for those responsible for organizing civil defense.

Australia, Canada, India and Pakistan have their own war and staff colleges (under various names), each of which reserves vacancies in its courses for British service officers and those of other commonwealth countries.

At the United States, British and commonwealth colleges vacancies are often allotted to officers of the armed forces of allied and friendly countries.

In France the system is similar with the three armed services operating war colleges. Higher phases of instruction are given in the Cours Supérieur Interarmées (joint services advanced course), the Centre des Hautes Etudes Militaires (centre of advanced military studies) and the Institut des Hautes Etudes de Défense Nationale (national defense college of higher studies).

Higher military education in the Soviet Union is more specialized, and great stress is laid on technical preparation. At Leningrad there is the Budyenny Military Electrotechnical academy, and also the Military Air Engineering academy. At Moscow the Zhukovski Air Engineering academy trains engineers, aerodynamicists and aircraft designers.

The Frunze Military academy, also at Moscow, is a staff and command school, training officers of all services for duties up to the level of army corps commands. The topmost level of military education in the Soviet Union is the Voroshilov Higher Military academy in Moscow. Roughly equivalent to the National War college in Washington, it prepares selected, mature officers of all the services for the highest commands.

Co-ordination and guidance of all higher military education in the Soviet Union is vested in a special organization, GUVVUZ, or Managing Department of Higher Military Teaching Establishments. The chief of GUVVUZ is on the staff of the defense ministry and also is a deputy minister of education, linking the military and educational bureaucracies.

Most countries with sizable military forces have war colleges.

At Paris, the NATO Defense college prepares selectqd officers from the North Atlantic alliance countries for NATO staff and command duties. (W. H. HR.; C. N. B.)

WAR CONTROL OF FOOD. Evolved by trial and error in World War I, food control became in World War II an indispensable part of war economy. Shortage of food arises in time of war partly because supply is reduced by enemy action and partly because demand is increased by the needs of the fighting services and by higher incomes of civilians. In countries like Great Britain, dependent for more than half its food on imports, food shortage during both wars was accentuated by loss of shipping and scarcity of foreign exchange. Food control became necessary for (1) maintenance of an adequate supply in spite of reduced imports; (2) regulation of prices, margins and profits; and (3) ensuring an even flow of distribution and a fair allocation of supplies to consumers. (See RATIONING.) (E. M. H. L.)

UNITED STATES

World War I.—The first United States experience with food control on a significant scale was obtained during World War I. On Aug. 10, 1917, legislation was enacted giving the president extensive powers to control production, distribution and prices of foods, feeds, fuel, fertilizer and items used in their production. President Wilson immediately established the United States Food administration and appointed Herbert Hoover food administrator.

In the administration of the Food Control act, particular importance was attached to the problems of cereals, sugar and fats. The act made special provision for guaranteed minimum wheat prices to encourage production. For a similar purpose with respect to lard and pork, the Food administration also announced that it would attempt to maintain hog prices. Buying and selling of critical foodstuffs was centralized to control the influence on prices and assure supplies for the government and for export. An International Sugar committee was formed to buy the Cuban crop for allocation among the allied countries, and domestic sugar supplies were purchased for resale at pooled prices.

Other activities of the Food administration covered a wide range and applied in some measure to nearly all foods. Prominent among these activities were efforts to limit price advances, with particular emphasis upon the limitation of margins and maximum rates of profit for food processors and distributors. The major reliance was placed upon so-called "voluntary controls" of various types, although extensive use was also made of the broad licensing powers conferred by the Food Control act. Administration was decentralized so far as possible, and state, county, municipal or local agencies were given a considerable degree of independence in carrying out some activities.

World War II.—In World War II food control was undertaken on a much larger scale. Little reliance was placed upon voluntary methods; compulsory controls, sometimes of great complexity, were used in a wide variety of situations.

Activities during the period of defense preparation and through most of the first year following the attack on Pearl Harbor in Dec. 1941 reflected the controlling official view that food would not become a significant element in United States mobilization for war. On the contrary, it was feared for a time that problems of farm price and income support would be made more difficult, since in 1939 the first effect of war in Europe was a further reduction in the foreign demand for United States agricultural produce. Immediately after the invasion of Poland, Secretary of Agriculture Henry A. Wallace set up an advisory council to consult on wartime problems of agriculture. This council maintained the general position that such adjustments as might subsequently be required should come through voluntary co-operation between government and the food industry rather than the imposition of regulations.

Several significant proposals for action on the food front were attempted within the National Defense Advisory commission, reestablished by the president on May 28, 1940. The staff of the co-ordinator of national defense purchases took the lead in proposing the reorganization and advance planning of food procurement by the military. Representatives of the consumer advisor co-operated on these procurement problems and initiated the commission's recommendation to the secretary of agriculture which led to his first action to secure an increase in hog production in 1941. Staff members of several divisions within the NDAC collaborated with representatives of the department of agriculture, bureau of the census and the bureau of the budget in formulating plans for gathering comprehensive information regarding the adequacy of available food storage space. This proposal was rejected by the NDAC transportation division at the insistence of its warehousing representative, with one result that in 1945 the special committee to investigate food shortages for the house of representatives reported "one of the fundamental mistakes made in the war-food program was in the failure to expand cold-storage space in keeping with the increases in production which farmers were asked to make."

During the life of the NDAC, the agricultural adviser, Chester C. Davis, called attention to some of the important food problems that might be in the offing. In testifying on the proposed lend-lease legislation, he took the lead in advocating that it be made applicable to food. In March 1941, Davis also recommended to the president that he establish a food organization headed by a strong administrator, to obtain information regarding food supplies and requirements and carry out other features of the government's food program. The president rejected this proposal and transferred the functions of the agricultural division of NDAC to the department of agriculture on the grounds that it had the facilities for co-ordinated action with regard to food and could avoid confusion and duplication. The president added that since the British were interested in obtaining only a few commodities for which quite complete information was available "it seems inadvisable just now to risk creating the alarm that might arise from a broad survey of agricultural supplies . . . . For the same reason, I do not think that we need to establish an office of food supply or food administration at this time."

This decision more or less set the limits within which food problems would be considered for the next several months. The department of agriculture would undertake such co-ordination of its established peacetime activities as seemed necessary to promise "first the guarantee of an adequate supply of food for the needs of this nation and supplemental needs of those nations whose defense is essential to this country, and, second, the provision of sufficient agricultural raw materials for expanded defense production." (Letter from the president to the secretary of agrioulture, May 1941.) It also would assume full responsibility for programming and procurement of food to be supplied on lend-lease. Co-ordination of military procurement was continued in the Office of Production Management, established in Jan. 1941. Some food responsibilities also were assumed by the Office of Price Administration and Civilian Supply, created by executive order in April 1941, although authority was vague and only minor problems of food pricing were expected to arise, chiefly in connection with imported items. In this period limited activity also was undertaken on such matters as export control, import control, foreign development, and foreign procurement, by a succession of agencies: the Office of Export Control, established in July 1940; the Economic Defense board, created in July 1941; and the Board of Economic Warfare, formed in April 1942.

Creation of the War Production board and enactment of the Emergency Price Control act in Jan. 1942 increased the complexity of agency relationships in dealing with food matters. Powers of the WPB covered allocation; planning of food and fibre requirements; control of industrial capacity, raw materials and labour used in the manufacture of food supplies and equipment; and assignments of shipping space for the importation of foods. Under the allocation authority, WPB determined when food commodities should be rationed and delegated authority for rationing to OPA through directives issued by the chairman.

The Price Control act made OPA responsible for preventing inflationary price rises, but effectively restricted this responsibility by making price control action on agricultural commodities subject to special standards and requiring prior approval by the secretary of agriculture. During the period of congressional deliberation which resulted in the inclusion of these provisions demanded by agricultural interests, there began the controversy between OPA and the department of agriculture which intermittently characterized their relations thereafter.

By the fall of 1942 the arrangements for handling food problems began to be recognized as inadequate. Shortages of meats, fats and oils, dairy products and processed foods were becoming apparent. With full employment and higher money incomes for low-income families, together with the shortages of other goods which limited alternative spending opportunities, the domestic civilian demand for food—particularly for animal products—was increasing rapidly. Military requirements were expanding. Great Britain and the U.S.S.R. were requesting large quantities of food under lend-lease arrangements, and already difficulties were arising in filling these requirements with appropriate types of foodstuffs. Finally, the Allied invasion of North Africa in Nov. 1942 brought up the problem of food for liberated people.

Important aspects of the general problem had been outlined early in the year in a report submitted by a committee established to examine the fats and oils situation. This led to an exchange of correspondence between the chairman of WPB and the secretary of agriculture over the possibility of revising the existing assignment of food responsibilities, but no action was taken at that time. Subsequently an attempt was made to reconcile conflicting proposals for the co-ordination of food activities in the establishment of a food requirements committee in June 1942. The secretary of agriculture was made chairman of this committee, which reported to the chairman of WPB and comprised representatives of agencies having significant food responsibilities. In practice this committee did not prove to be an effective administrative device.

Food price control continued to give rise to many difficulties. During the summer of 1942 friction between the OPA and the department of agriculture became acute over questions relating to the agricultural commodities to be controlled, the levels at which ceilings should be fixed, farmer liability under penalty provisions of price regulations, and relationships between ceilings and the price supports used to encourage production. In Oct. 1942, the Price Control act was amended by enactment of the Economic Stabilization act which modified somewhat the special standards applicable to agricultural commodities. In the same month the Office of Economic Stabilization was established by an executive order which gave the director authority to settle differences over food price policies. Under this arrangement, differences between agencies over food matters were to be referred to the chairman of the WPB if they involved supply or distribution, but to the director of economic stabilization if they related to pricing problems. The OES did not attempt to participate in the formulation of integrated programs, and mostly preferred to take jurisdiction after agency disagreements had become clearly defined. Hence it performed a function of arbitration and compromise, but contributed little toward the reconciliation of fundamental conflict between the price stabilization program and the system of floor prices administered by the department of agriculture.

In Dec. 1942, President Roosevelt issued an executive order directing the secretary of agriculture to "assume full responsibility for and control over the nation's food program" and transferring to him additional authority, largely from WPB. Subsequent orders were issued and organizational changes were made within the department, including the establishment of a War Food administration in March 1943 and its abolition in June 1945. But the order issued in Dec. 1942 fixed the main pattern of food administration for the remainder of the war.

Under this arrangement the department of agriculture assumed primary responsibility for the co-ordination and direction of activities relating to: (1) the planning of food requirements, both domestic and export; (2) food production and processing; (3) allocation, distribution, and priority controls; and (4) procurement of food by the military services and buying for lend-lease, foreign relief and other government programs. An extensive system of interagency committees was developed for administration of the requirements and allocations work, and for participation in the Combined Food board—an agency that had been established in June 1942 to facilitate consultation among British, Canadian and United States food authorities. These functions, together with its position as procurement agency, gave the department control over food shipments for lend-lease and foreign relief, over the control of commercial exports, and over the development of production on procurement of foods from other countries. To encourage production, goals were announced for each important commodity, and returns to farmers were supported through commodity loans, direct purchase and subsidies, as well as by allowing market prices to advance. To ensure proper distribution of supplies and aid public procurement, a variety of food distribution orders and reservation, or "set aside," orders were issued. Allocation decisions governed the supplies available for rationing. Administration of food rationing remained in the OPA, along with price control, and was affected very little by the transfer of allocation powers from WPB to the department. Development of the various detailed regulations, orders and other methods that were used for food and related items in itself represented a considerable accomplishment. There were many imperfections, administration at times was lax or unstable, and sometimes evasion or violation was extensive. Although action often was belated and frequently received much criticism, real progress was made in the development of control techniques applicable to the problems that were recognized.

After enactment of the Economic Stabilization act, the rapid advance of prices was effectively checked in 1943. Up to that time, food prices as a group had increased by approximately 40% over their level in 1940. From then on they changed relatively little until controls were suspended.

The appearance of shortages in 1942 and the prospect of other difficulties ahead focused attention upon food rationing. Controls were put into effect for sugar in April 1942, for coffee in Nov. 1942, on processed foods in March 1943, and for meats, fats and certain dairy products also in March 1943. It was estimated that these programs covered roughly one-third of the food distributed for civilian use. Although some features were obviously inadequate, rationing was remarkably effective at first. This effectiveness deteriorated, however, especially in the case of the most important meats and fats program, and effective control was lost well before rationing was abolished.

From 1941 onward, increased production of any item found to be in short supply was generally emphasized as the most important goal of wartime food policy. By 1944 food production reached a record level officially estimated at 38% above the 1935–39 average. Out of the supplies available, the country provisioned the best-fed military forces in history, maintained restricted commercial exports, and expanded lend-lease food allocations until in 1943 they amounted to slightly more than 8% of the total. But the largest part of the increase in supply was absorbed by the continuous rise in domestic civilian consumption.

The expansion in gross agricultural output that made possible these increases was mostly accomplished by the end of 1942. It was achieved with moderately expanded acreage, a curtailed labour supply, limited additions to farm equipment, and an increase in the use of fertilizer. Most important of all, it benefited from favourable weather conditions that continued throughout the war.

Involved in this expansion was a spectacular increase in the production of oil-bearing crops to a high in 1943 that was 86% above the 1940 level. This was of particular importance in partially compensating the curtailment of imports. The largest components in the total expansion, however, consisted of increases in feed production and in livestock production brought about by the rise in civilian consumer demand and official emphasis upon the alleviation of meat shortages. The upsurge in livestock production reached its peak in 1943, but remained high for the remainder of the war period.

Policies during 1944–45 reflected alternate fear of excessive food surpluses and concern over shortages. In the spring of 1944 it was believed that the war in Europe would be over by the end of the year, and government procurement was curtailed. Record marketings of hogs created temporary gluts in stockyards and processing plants. To provide outlets for the enlarged supplies of pork and lard, export controls were lifted and meat rationing was in effect suspended. As a result, civilians in 1944 consumed 2,500,000,000 lb. more meat than had been estimated as their requirement. Per capita meat consumption for the year was approximately 150 lb. compared with a prewar average of 126 lb.

By late summer. markets had been cleared but the policy of holding down government inventories mas continued. In the late fall and winter it became apparent that optimistic expectations had not materialized and that commitments for lend-lease and relief requirements could not be filled in the months ahead. Attempts were made to restore the effectiveness of rationing and other controls, but the deterioration had gone too far. The early months of 1945 saw a genuine crisis in the administration of food affairs.

After the German collapse in May and the Japanese surrender in Aug. 1945, most food controls were abolished or relaxed in response to new fears of price-depressing surpluses. This action did not anticipate the acute need for additional food that would soon arise in Europe and some other parts of the world—needs that were aggravated but not caused by disappointing yields abroad. Hence the most important food crisis of the war developed about six months after the cessation of hostilities.

In Feb. 1946 Pres. Harry S. Truman asked 12 prominent citizens to collaborate with former President Hoover in working out a voluntary program to conserve food grain for export in the pattern of the action he had directed during World War I. Although production continued to be large, and after 1943 some progress had been made in shifting the emphasis from feed and livestock to the production of food grains, the supplies simply were not available. The reserves of wheat had been fed to livestock after the so-called "surpluses" of feed grains on hand at the beginning of the war had been used up in the expansion of livestock production. GREAT BRITAIN

World War I.—During the first tno years of World War I food traders continued to operate much as in normal times. Business as urual and the free play of supply and demand were accompanied by steadily rising prices with wages lagging behind. The earliest example of state interference in Great Britain nas the creation in Aug. 1914 of a royal commission to undertake the purchase and import of sugar. when supplies from central Europe were cut off. Early in 1915 the board of trade undertook the import of meat for the army but left civilian supplies to private trade.

On April 1, 1916, the use of cereals and sugar for brewing was limited, and in Oct. 1916 a royal commission on wheat supplies was established. leading to bulk buying of imported wheat and other cereals on behalf of the Allied governments. This was followed by the appointment of Lord Devonport as the first food controller. To economize wheat by increasing the rate of flour extraction the flour mills were taken over and run on government account as from April 1917. In June 1917 Lord Devonport mas succeeded by Lord Rhondda who brought with him U. F. Wintour and E. F. Wise from the war office with far-reaching plans for controlling supplies, prices and distribution. The price of bread was reduced with the aid of a subsidy from one shilling to ninepence for a four-pound loaf. A descending scale of prices was fixed for livestock. which was partly designed to give effect to a policy of reducing the number of cattle. This was followed early in 1918 by the institution of government purchase and slaughter of livestock and centralized distribution of both home-produced and imported meat.

This ambitious scheme, conceived and organized by Sir Francis Boys as director of meat supplies in 1917 and 1918, was bequeathed by him to his successor Sir Henry Turner in 1940, who directed it during and after World War II. Under Lord Khondda not only cereals, sugar and meat but butter and cheese, bacon and ham, oils and fats, canned goods. eggs, tea and fruits were imported by the government. Home-produced food, such as milk, fish: potatoes and vegetables! proved more difficult to control; when maximum prices were fixed without control of the supply, as for rabbits, they tended to disappear from the shops.

From 1917 to 1921 the ministry's turnover was £1,200,000,000 on which its net profit after paying expenses was about £7,000,000; in addition the wheat commission's loss on the bread subsidy was £138,000,000, and the sugar commission ended with a loss of £22,000,000 in 1921.

Distribution and Ration Levels.—The first step in control of distribution mas taken in Nov. 1916 when allocations of sugar to wholesalers were cut to 60% of the amount issued in 1915. The wholesalers were responsible for passing on the cuts to retailers and manufacturers. This made no allowances for changes in trade or movements of population and since it gave no assurance of fair distribution to consumers, led to queues and growing unrest. For nearly a year the cabinet could not make up its mind to authorize rationing, partly for fear that it mould encourage the enemy, and it was not till Jan. 1918 that rationing of sugar was started. Queues for butter, margarine and meat were the next problem, and local rationing schemes were authorized. In London half a million people were standing in queues every Saturday during January and February; but after the rationing of these foods started on Feb. 25 queues practically vanished. On April 7 meat rationing was applied to the whole country. Finally on July 14, 1918. only four months before the Armistice, new ration books were issued covering sugar, meat, bacon and fats.

World War 11.—Experience gained in World War I made it clear that in the event of another war food control would be essential. At the outbreak of war in 1939, free markets for grain, sugar, meat, dairy produce and oilseeds were suspended, prices were frozen. stocks at home and afloat were requisitioned, and the ministry became the sole buyer of imported supplies. In the absence of a ministry of shipping the ministry of food made its own chartering arrangements with a committee of the Baltic exchange; all refrigerated space was voluntarily placed at the ministry's disposal by the liners' conferences. Imports of less essential foods were allowed to continue for several months without hindrance and it was not till March 1940 that control of imports and shipping was complete enough to ensure that the best use could be made of the limited tonnage available. Buying agencies were established abroad and bulk contracts were made with overseas governments or producers' organizations. In 1941 a British food mission was sent to the U.S. and in 1942 co-operated in setting up a Combined Food board charged with the duty of allocating world exports of basic foods. On arrival at British ports the task of handling, storage and distribution to wholesalers or processors was entrusted to special wartime associations of importers acting as the ministry's agents.

In World War I the wheat commission employed a few selected brokers and the device of creating *ad hoc* wartime companies to act as the ministry's agents had been applied only to oilseeds which were handled by the United Kingdom Oilseed Brokers association. In World War II this device was applied with minor variations to most food imports. Thus the first-hand distribution of meat was carried out by the Meat Importers National Defence Association Ltd. (M.I.N.D.A.L.), of bacon by B.I.N.D.A.L., of butter and cheese by a Butter and Cheese association, and of imported and home produced eggs by the National Eggs Distributors association. By means of a collective contract with the whole of a trade it was possible to override existing trade connections without giving rise to charges of discrimination or claims for compensation and to provide an agreed rate of remuneration for services rendered by the trade as a whole. The trade was given an incentive to operate economically by pooling its resources and dividing the work and remuneration equitably among its members.

Control of Home-Produced Food.—One of the chief differences between the two wars lay in the more complete control of home-produced food. In this the ministry was helped by prewar producers' marketing boards, especially for milk and potatoes, whose organizations were well adapted to centralized control. In England and Wales all milk collected from farms was bought at fixed prices by the Milk Marketing board who then sold it to the ministry for allocation to distributors and manufacturers of milk products. Potato growers received a fixed price negotiated each year and the ministry undertook to buy any surplus not disposed of through private channels. By controlling transport and prices it was able to ensure a regular flow of potato supplies and encourage the storage of long-keeping varieties. Deteriorating and surplus stocks were disposed of for processing or feeding to stock.

For the control of home-grown cereals the ministry relied on grain merchants certified under the prewar Wheat act. All millable wheat went to controlled flour mills to be milled into flour of a prescribed grist. When the extraction rate was raised to 85% or more, imported white flour and sometimes a small amount of other cereals were added as an admixture. Sugar beet was collected as in peacetime by the beet factories. Control of eggs was exercised through authorized packing stations where eggs were bought on the ministry's account and resold at a subsidized price to retailers for allocation to consumers. The most elaborate scheme was that for meat and livestock, which was based on the 1918 plan referred to. Each farmer had to sell his livestock for slaughter through specified collecting centres, or, in the case of pigs, at bacon factories, where they were graded and paid for by the ministry's agents. The ministry prohibited private slaughter, save in exceptional cases, and slaughtering was concentrated in 600–800 slaughterhouses instead of about 16,000 before the war. In this way leakages to the black market were virtually eliminated, and all meat, except rabbits, game and poultry, was obtained by the ministry for resale to retail-butchers to meet the ration requirements of their registered customers. As in 1918, wholesale distribution of both home-produced and imported meat was entrusted to eight regional Wholesale Meat Supply associations, which were wartime companies including as members all dealers and distributors of imported and home-produced meat.

Control *of* Prices *and* Profits.—In World War II prices were more effectively controlled than in World War I. Relations between the ministry and the food trades started on a basis of mutual confidence which was further developed under Lord M'oolton who became minister of food in 1940. Plans of control had been worked out beforehand and two general principles had been agreed, first that so far as possible no firm should be allowed to improve its competitive position as a result of war; and secondly, that so far as loss of trade or good will was inevitable, it should be fairly spread without discrimination. This led to willing cooperation. when the emergency arose: not only between the food trades and the government but between traders themselves, which found its expression in the formation of wartime associations and the acceptance of pooling based on prewar turnover. Execution and policing of food-control measures, once they were accepted as necessary and workable: could be delegated to representative bodies of traders; and regulations imposed by statutory order were reinforced, and sometimes rendered unnecessary, by detailed rules adopted by trade organizations themselves. On Sept. 1, 1939, two days before the declaration of war, the provision exchanges undertook to hold the existing level of wholesale prices for a wide range of foods until statutory orders could be made. The closing of the Liverpool grain futures market and the settlement and liquidation of existing contracts was carried out by voluntary arrangement with the Defence committee of the Corn Trade federation: the ministry stepping into the shoes of the first seller and last buyer in each chain and guaranteeing the settlement of intermediate positions where the outbreak of war prevented fulfilment of contract.

Up to the end of 1939 the chief cause of the rise in food prices was the increase in freight rates and the devaluation of the pound. In Dec. 1939 it was decided to stabilize food prices with the aid of subsidies. Starting with £13,000,000 in the first year of war, food subsidies grew to £168,000,000 in 1944–45. (After the war they reached £465,000,000 in 1948–49.) The food items in the cost of living index were kept stable at a level between 20% and 25% above that ruling in Aug. 1939; during World War I the food index was twice the prewar level by July 1917 and reached 230 by Oct. 1918. Including the cost of subsidies the food index would have been 250 in 1918 and 150 in 1944. This ditierence was in part due to the effect of the ministry's bulk buying in restraining inflationary tendencies in world markets. In order to fix prices at retail it was necessary to control prices and profit margins at each stage of processing and distribution based on a fair assessment of costs of handling; in general this could best be achieved where the ministry owned or effectively controlled the product at some stage. The policy of prescribing maximum prices by order without controlling supplies and distribution, as with home-grown fruit and poultry, frequently meant that the goods disappeared from the shops or went to favoured customers. From 1943 onward the ministry was compelled by pressure of public opinion to control prices of fresh vegetables; but since centralized collection and distribution were impossible, either supplies dried up or there was a tendency for price orders to be evaded by conditional sales and inferior grading.

Administration.—The administrative machinery of food control was similar in the two wars. The staff of the ministry at its maximum was 8,000 in 1918 and 10,000 in 1944. In addition 25,000 were employed in 1,800 local food offices in 1918 and 35,000 in 1,250 local food offices in 1944. Rationing, licensing of retailers and caterers and welfare food schemes were the main tasks of the local offices, supervised by 19 divisional food officers in areas corresponding to civil defense regions. These officers represented the minister in relations with regional commissioners and were responsible for emergency feeding arrangements and liaison with the local military authorities. In addition there were area commodity officers for each of the principal commodity control schemes.

Catering.—The number of catering establishments increased from 111,000 serving 11,000,000 meals daily in May 1941 to 147,000 serving 23,000,000 meals in Dec. 1944. The policy mas to provide nearly everyone with an opportunity to supplement household rations. Two thousand British restaurants were opened, and canteens were made compulsory in factories employing more than 250. Industrial canteens grew from 1,500 before the war to 30,500 in 1944. School meals served rose from 250,000 daily before the war to 1.850,000 in Feb. 194j. Special allowances of meat and other foods were provided in canteens for heavy workers, munition workers and school children. Agricultural workers, miners and other workers for whom canteen facilities could not be provided, received a special cheese ration of 12 oz. weekly and in 1944 were assisted by a scheme for providing snacks, sandwiches and pies. By the autumn of 1944 more than 1,000,000 of these packed meals were being served in 5,000 villages. Emergency feeding centres for use after severe bomb attacks, shelter feeding, cooking depots, mobile kitchens and Queen's Messenger convoys, able to move into a raided area and provide tea and snacks within an hour, played a vital part in civil defense. The total amount of food consumed outside the home represented about 9% of total civilian consumption, of which canteens received two-thirds and ordinary restaurants one-third.

Planning of Food Supplies.—Before 1939 imports provided more than half of the United Kingdom's meat, four-fifths of the sugar, nine-tenths of the cereals and nearly all the fats. Only milk, fish: potatoes and vegetables were mainly home produced. Reckoned in nutrients, two-thirds of the calories and more than half the total protein were imported. About 22,000,000 tons of food and feeding stuffs were imported, of which 4,000,000 came from countries occupied by the axis during World War II. Because of the urgent need to release ships for transport of munitions and troops, the ministry of food was able to obtain only about half the prewar tonnage for all its imports during each of the three years 1942–44. Since preference had to be given to the most essential foods, more than 5,000,000 tons of imported foods and nearly 2,000,000 tons of fruit and vegetables had to be dispensed with. The most critical situation developed during 1940–41, when more than 1,000,000 tons of food were sunk at sea and about 250,000 tons were lost or damaged by air attack. Early in 1941 food imports were threatened not only by enemy action but by shortage of dollars to pay for them. After the passing of the Lend-Lease act more than 1,000,000 tons of cheese, lard and canned meat and fish arrived from the C.S. in 1941, and the total rose to 1,700,000 tons in 1943. In 1943 and 1944 about 10% of the nations food, measured in calories, and 18% of its animal protein and fats were obtained under lend-lease. Home production of food nas increased by growing more wheat, potatoes and vegetables, and milk production expanded in spite of reduced oilcake supplies. In the five years 1940–45 total calories never fell more than 10% below prewar standards. At the worst period in 1941 animal protein was reduced by nearly 20% and fats from all sources by 13%. The biggest reductions in that year were in fruit, sugar, meat and fish, offset by increases in milk, bread, flour and potatoes. The pattern of diet became monotonous and less palatable, and rationing lowered the consumption of rationed foods in all except the poorest families; but there was some evidence of improved nutrition at the lowest income levels, mainly the result of increased milk consumption by mothers and children.

Regulation of Stocks.—Under the Essential Commodities (Reserves) act, 1938, the government had acquired before World War II about 500,000 tons of wheat, 150,000 tons of sugar, 240,000 tons of whale oil and 18,000 tons of canned meat. These reserve stocks were barely sufficient to offset the slowing down of arrivals during the early months of the war and at the end of March 1940 total stocks under the ministry's control were at their lowest point, under 3,000,000 tons, of which half were cereals. By the end of 1943, in spite of reduced imports, they had been built up to a peak of 6,668,000 tons. At the end of World War II stocks mere higher than at the beginning and it was possible to release 1,000,000 tons of food for the relief of liberated countries in Europe.

WAR CONTROL OF SHIPPING. **World War** I.—In July 1914, of 8,000 ocean-going vessels the British empire owned more than 4,000; France, Italy, Belgium and Portugal together owned about 1,000; a further 1,000 were owned by Germany and Austria and were either immobilized or captured; some 2,000 covered the rest of the world. When therefore the Allied organization was developed, in the last year of the war, it was natural that it should be built on the basis of the British system; and the countries associated in this organization, which included the United States, ultimately controlled, with the addition of the neutral tonnage which they had chartered or requisitioned, some 90% of all ocean-going tonnage.

The control was simple, dealing with few units, compared with those exercised by the ministries of munitions or of food. The total prewar value of all ocean-going ships before World War I was not more than £300,000,000. The total amount of steel sunk in the ships lost during the war was only about 5,000,000 tons! that is, not more than 12% of the steel production of the U.S. alone in a single year. On the other hand, the allocation of ships involved choosing between different supply services, giving a preference to wheat over munitions, or coal over ore or vice versa. It involved decisions of policy affecting a vastly wider range.

Before World War I two departments of the British administration were concerned with merchant shipping, the marine department of the board of trade and the transport department of the admiralty. The latter small department, with its limited but varied experience, was gradually thrust by the introduction of the submarine into the central position in prominence.

State Requisitions, **Aug.** 1914.—From the first it was recognized that the government could not act as it did in the South African war, and go into the market as an ordinary charterer. In Aug. 1914 a proclamation was issued giving powers to requisition ships with compensation to the owner.

The powers were chiefly exercised by the transport department. They were limited to the transport of troops from Canada, Australia, India and New Zealand, and to the carriage of supplies from England to France and the front. But though the tonnage requisitioned in the first six months did not exceed some 20% of the British mercantile marine! it was enough to push freights up. Other causes were tending to the same result. Sinkings were indeed in this period more than offset by new building. But a large mass of enemy tonnage was withdrawn from world tonnage and the delays inevitably caused by naval precautions reduced the average amount of transport a vessel could accomplish in a given time. In July 1914 the normal price for a six-months' charter of an ordinary tramp steamer was three shillings a month on the dead weight. By December it had reached six shillings. By the end of the first year, in the summer of 1915, it had reached 15 shillings. This increase not only made the goods carried more expensive but it also reflected the fact that there was already a shortage of shipping space, although the effect of submarine warfare had scarcely been felt.

Blue Book Rates.—These rates did not apply to ships requisitioned by the government. For these ships standard rates—the so-called blue book rates—were fixed on the advice of a committee which met in the first months and, with slight modifications, were applied throughout the war without regard to the outside freight market. They were somewhat in excess of the market when they mere introduced (the rate for an ordinary tramp was then equivalent to about seven shillings per month on the dead weight) but were moderate by comparison with the arrangements made by the government for industries and would have given profits not exceeding those of a boom year in peace. Shipowners' profits became in 1916 the subject of severe and legitimate criticism. On a capital value of some £172,000,000 in 1914 British shipping had by the autumn of 1916 made a net profit of some £262,000,000 (after deducting all payment of taxes). This resulted however not from excessive payments by the government but from competition in the ordinary freight market for the inadequate tonnage left over when the government had taken what it needed.

Shipping in the Second Year.—The strain upon shipping was constantly increasing. Losses increased? averaging 87,000 tons gross per month as compared with 55,000 in the first year. Building fell from 1,000,000 tons in the first year to 500,000 in the second. Naval and military demands increased and the proportion of British tramp tonnage requisitioned rose from 20% to 30%. Demands upon the freight market for the raw materials required for munitions were also serious, and the standard time charter rate (which had been 3 shillings in July 1914) rose to 27 shillings in Dec. 1915 and to nearly 40 shillings by the summer of 1916.

Ship Licensing Committee, Nov. 1916.—In Nov. 1916, a Ship Licensing committee was appointed by the board of trade, with the power to exercise a licence control over British tonnage. The intention was to force ships out of employment that were serving no British or Allied interest, and so make it easier for more important requirements to find their transport. The principle was a sound one as far as it could be applied. But the committee was unable to find, after some months of investigation, more than a negligible amount of tonnage engaged in work that was obviously unimportant; and they were unwilling to prohibit any other employment; therefore, they brought no substantial relief to the general situation. Honever, ineffective for its original purpose, the committee soon assumed a role for which it was much better fitted. It became the executive for putting policy into effect as regards all British tonnage not under requisition. When a "limitation" of freight rates was imposed on the French coal trade it was the Ship Licensing committee which made it effective by refusing licences to ships trying to escape from that trade to more lucrative employment. When the ministry of munitions was anxious about ore imports from Spain or South Africa because colliers found it profitable to hasten back in ballast for another coal cargo, the committee refused licences for such ballast voyages. When the cabinet fixed a limit to the tonnage to be chartered to the Allies the committee enforced the decision as regards chartered ships in conjunction with the transport department which enforced it as regards requisitioned ships.

A second committee established by the board of trade at the same time—the Requisitioning (Carriage of Foodstuffs) committee—had a shorter life. This committee had power to requisition or direct the employment of British ships so as to assist the importation of food or other accessories. In practice it confined its action to the importation of grain (mainly wheat).

The committee directed more vessels than the market by itself was capable of attracting. The effect was immediate and dramatic. North Atlantic freight rates dropped in five months from 16 shillings to 8. Weekly imports increased from 510,000 quarters to 665,000 quarters. But at the moment when the committee was achieving its objects its activities had to be first restricted and then stopped. The reasons are interesting and instructive. Wheat was getting more than its share of tonnage.

Shipping Control **Committees.**—Of these the most interesting was the appointment in Jan. 1916 of the Shipping Control committee, presided over by Lord Curzon and including two well-known shipowners and an eminent financier. A survey led them to the conclusion that a reduction of 13,000,000 tons must be made in British imports, and they therefore recommended the temporary prohibition of all imports, except specified essentials, amounting to a total rate of 13,000,000 tons per annum; the withdrawal of vessels from naval and military service; and the limitation of British tonnage allotted to the Allies to the amount in their service on April 1, 1916. Little came of their three recommendations. A scheme of import prohibitions which, even if fully enforced, would have shut out not 13,000,000 but 4,000,000 tons was approved but in actual application excluded less than 2,000,000 tons.

Imports Restriction.—In 1917 the government appointed an Imports Restriction committee, presided over by Sir Henry Babington Smith and consisting of the principal officials of the board of trade, the ministry of shipping (into which the transport department had now expanded) and the chief departments demanding tonnage: the war office, ministry of munitions, food commission, etc. The instructions given to the committee were to reduce the supply programs by about 500,000 tons a month. But just as the committee was beginning its work, the intensive submarine campaign began; shipping losses increased very seriously; and it grew clear that the monthly reduction required must be at least 1,000,000 tons. The task of selecting commodities for exclusion on this scale was beyond the capacity of the committee, and once more the hope that programs would be reduced within the limits of transport was deceived.

Shipping in the Third Year.—From the summer of 1916 to that of 1917, the shipping situation was more serious than at any previous period. Its gravity was reflected in the increasing freight rates and shipowners' profits, which now reached their maximum. British time-charter rates rose to 40 shillings a ton deadweight, a record, as compared with 3 shillings immediately before the war. In Feb. 1917, the new submarine campaign began and met with immediate success. Within a few months the submarine blockade became a greater danger to the Allies than the surface blockade was to Germany.

Throughout the year the control over commodities was developing both in range and in character. To sugar and wheat, which were already controlled by the Sugar and Wheat commissions, were added all the main articles of food, and the whole was centralized under a newly established ministry of food. The ministry of munitions extended its effective control over all the raw materials of munitions manufacture and indeed over all metals required for all purposes. The war office developed a similar control over flax, hemp, jute, leather, wool and other materials. The board of trade, under somewhat less drastic and more commercial methods, covered the bulk of the remaining imports.

These developments had important consequences on the shipping problem. In the first place, all the imports of the commodities so controlled were government cargoes, and it was natural that they should be transported in requisitioned tonnage. The war office could ask the shipping authority to arrange to carry wool or flax (for whatever purpose it might be used) just as it asked for transport of supplies destined direct for the army. But, in the second place, the incorporation within the government machine of the specialists from the business world who were needed for these intricate and detailed controls, meant that the government had, for the first time, in its service the advice of adequate experts in the activities affected.

The Ministry of Shipping.—The coalition government formed at the end of 1916 established a ministry of shipping, under a shipping controller, Sir Joseph (later Lord) Maclay who had a seat in the cabinet, with statutory powers. The transport department was absorbed in the new ministry, while the Shipping Control committee became an advisory committee to the controller. It was shortly afterward decided to extend requisition at rates based upon blue book terms over all British ships. The comparatively moderate profits on requisitioned ships only made the fantastic profits on free ships more of a public scandal.

Liner Requisition.—A new and ingenious system of liner requisitioning was therefore devised. All liners were formally requisitioned and paid at blue book rates. But the owners continued to run them, taking first any government supplies, then following any other direction they might receive, and if any space remained, offering freight on the market, the freight, however, being henceforth paid to the government. The liner cargoes thus became an integral part of the general transport and supply program, and indeed an increasingly important part of it, amounting at the end to four-fifths of the country's imports.

Tonnage Priority Committee.—Another committee, the Tonnage Priority committee, was of more importance. It was a national committee, consisting of the actual executive officers from the different departments who were handling the several supply arrangements, and its chairman was the parliamentary secretary of the ministry of shipping (Sir Leo Chiozza Money). It brought those who were making competing, and in their total effect impossible, demands upon the shipping authorities into direct contact with each other.

The new and intensive submarine campaign began in Feb. 1917. It converted the shipping difficulties from a serious inconvenience into a grave menace.

In the first 12 months 470 ocean-going ships (1,000 if we count all sizes) had been lost. The continuance of loss at this rate would have brought disaster upon all the Allied campaigns and might even have involved unconditional surrender. At this stage, after much hesitation and conflict of opinion, the convoy system was introduced, and had an immediate success. (See SHIPPING, HISTORY OF: *International* Rivalry.)

The Fourth Year.—By the autumn the situation had become less desperate but more immediately difficult. Two great events had happened. The U.S. entered the war. Finance was at once displaced as the governing consideration in the Allies' policy. Henceforward the Alliance as a whole, was practically self-sufficient. Shipping became definitely the limiting factor. Nor did the entry of the U.S. relieve the actual shortage of tonnage. Its potential building capacity gave a different perspective to the future, but it was undeveloped. And its military effort, so vital a factor in the strategical position, necessarily increased the strain on shipping. At no time during the rest of the war were there as many U.S. ships in war service as those required to carry its own men and stores. The second great event was the striking and dramatic success of the convoy system. From its first introduction it more than counteracted the effect of the new submarine method; and losses were reduced to less than the rate of 1916. In spite, however, of the much greater hope for the future given by both U.S. building capacity and the convoy system, the actual disparity between the shipping available and the demands upon it was greater in the autumn of 1917 than it had ever been. Seventeen million tons deadweight of the world's tonnage had been lost and less than half had been replaced. Great Britain alone had lost 10,000,000 tons, and, even allowing for ships it had bought, built or captured, its net loss was over 4,000,000 tons.. France and Italy had lost about 2,000,000 tons and had built practically nothing. Nor had the U.S. yet begun to build seriously. At the same time the demands upon shipping were greater than at any previous period. All the distant expeditions (except the long abandoned one to the Dardanelles) were fully maintained. The scale of the war in France was continually increasing. The navy was at its maximum strength. Serious food troubles were anticipated in Great Britain, France and Italy. The U.S. military effort, with its great demands on transport, was beginning.

By this time, however, the mechanism for securing economical compression of the British supply demands on transport, for selecting only the most essential, for making the utmost use of shipping available was being rapidly perfected. The big control departments, the food and munitions ministries and the war office, examined and pruned down the demands of their many branches, with the expert knowledge that had been obtained by the incorporation of numberless experts from the different trades now brought within the area of control. The Ship Licensing committee was (to some limited extent) pruning off the more obviously useless employment of ships. The Tonnage Priority committee was examining the demands in more detail and contributing to the same end. Special committees like the Imports Restrictions committee of Jan. 1917 and the later cabinet committees of the same year were forcing the departments to make reductions.

And in this national system the final authority now consisted in a cabinet committee (presided over by Lord Milner) consisting of the ministers in charge of the great ministries concerned, on the one hand of shipping and on the other of the great supply departments, particularly the war office and the ministries of munitions and food, attended by their chief officials.

But by this time the problem was more than national. And the national system required to be supplemented by an international organization which could incorporate the needs of France and Italy and to some extent the U.S. with those of Great Britain and devise a common shipping policy. Controls similar in general character and purpose had been established in France and Italy, but a British cabinet committee could not judge between British and French or Italian needs of sugar or of wheat. Nor could a British shipping department do so. Obviously the persons best qualified were the sugar and the wheat experts of the different countries. On this principle the Allied system was based. "Program committees" were formed of the experts in each main supply (wheat, sugar, meat and fats, oils and seeds, nitrates, hides, wool, flax, hemp and jute, paper, etc.).

These committees submitted their demands first severally to Allied councils of ministers (food and munitions), and then all together to a supreme Allied shipping authority, formed on the same principle.

SHIPPING CONTROL IN WORLD WAR II

Preparations in the Interwar Years.—In World War **I,** as has been shown, the government had to construct a system of control both of shipping and of the supplies of food, munitions and raw materials which it had to carry, without any previous experience. In the subsequent 21 years of peace, memories of the first war were reflected in defense preparations for any further war. The Committee of Imperial Defence had planned a comprehensive war organization; and a part of this had been established even during the last years of peace. In addition arrangements had been made to set up ministries of shipping, food and economic warfare immediately on the outbreak of war; and this was duly done. Before the end of 1939 this national machinery was supplemented by a number of Anglo-French committees covering the whole range of supplies. This Allied system was based upon the one that had been developed in the last year of World War I. Jean Monnet, who had been the principal French representative, at the official level, in the earlier system, was appointed chairman of the Anglo-French co-ordinating committee with a joint mandate from the two prime ministers.

Defects in the Control System on the Outbreak of War.— In reality, as distinct from merely formal structure, it was unhappily far from true to say that the second war started where the first left off. In 1918 the newly created Allied councils for shipping, food and munitions, with some scores of program committees, composed of officials, formed the climax of a system of control which had been gradually hammered into efficiency by three and a half years of war. Commodity programs had been compressed and relieved of all but absolute essentials. Under the pressure of shipping shortage the ministry of shipping had become highly efficient and was at the pivot of the whole Allied supply system; and the officials concerned, both national and Allied, had learned to work with each other. In World War II this process was reversed, the formal structure being first established and the reality of effective, co-ordinated control being gradually developed within it. Moreover there had been some grave mistakes in planning shipping war policy. The mercantile marine department of the board of trade had in 1938 estimated that British shipping alone, even without assistance from neutral tonnage (which in peacetime was bringing in nearly a quarter of British imports), would be able to bring in about 48,000,000 tons. Unhappily the estimate was seriously mistaken. Carrying rapacity proved much less; and the different departments requiring imported supplies proceeded with plans which assumed much more. The mistaken policy of relying on licences was soon corrected and a policy of general shipping requisitioning was announced and began in gradual instalments. The supply programs, however, caused great difficulties; they were pared down to essentials only under the pressure of actual necessity. Dry cargo tonnage was less by about 3,000,000 tons gross than on the outbreak of World War I. The mistake had several causes; undue optimism by the admiralty which, with the new invention of "asdic" for detecting submarines and the tried system of convoy, thought it had mastered the submarine menace; an inadequate allowance for the delays which would result from port congestion, assemblage in convoy and other conditions; and perhaps a general climate, of over-optimism in Whitehall in the "appeasement" period. The same reasons partly explain the reluctance to bring in and store, in peacetime, large quantities of iron ore, grain and timber. With some encouragement, perhaps, from the inactive character of the hostilities in the first period, unwelcome decisions—for example to impose rationing—were postponed; nevertheless, in spite of the fact that shipping losses were at this time comparatively slight, consumption exceeded imports; and there was a drain on the inadequate stocks.

Shipping Stringency in the Early Months of World War 11.—Critical shortages soon began to appear. As early as November wheat stocks fell so far that some mills had to stop work. This situation was relieved but at a considerable cost, partly by buying wheat from North America with dollars instead of Australian wheat with sterling and partly at the expense of other imports. Iron ore imports, for instance, came in at only just over half the quantity demanded, and by Feb. 1940 some works were beginning to close down. This situation was relieved by the switching of requisitioned tramps; but at the end of the first year of war the imports were 2,000,000 tons short of what had been demanded. Both wheat and iron ore moreover were brought in at the expense of timber, of which less than half the quantities demanded were secured. In the meantime the warnings given to the supply department by the ministry of shipping that the earlier estimates of importing capacity were much too optimistic, had little effect. In Jan. 1940 the ministry of supply actually raised its total demands from 23,900,000 to 30,600,000 tons, which put the total import requirements for a year up to 53,700,000 tons, about 10,000,000 tons more than could be actually achieved.

Improvements in Control System.—These difficulties had at least one compensating advantage. They accelerated an improvement in the system for determining priorities and making the most of what transporting capacity was available. The most important early measure was the decision to requisition instead of relying upon licensing. This enabled the ministry, so far as it was itself competent to decide what imports deserved priority, and from what sources of supply, to give immediate effect to its decisions. Imports rapidly increased. In the first three months, September to November (before requisition), the monthly average had been about 3,000,000 tons; in three months, March to May, after requisition, the average had risen to 4,000,000 tons and, though some of this improvement was the result of seasonal conditions, the new system of requisitioning was entitled to most of the credit.

Priorities.—Requisitioning, however, did not solve the question of priorities. So far as the total demands exceeded shipping capacity and there was no superior authority to decide between them, priorities were necessarily determined in practice by the actual allocation of tonnage by the shipping authority. The ministry of shipping, beset by competing demands which it could not satisfy, was involuntarily a master and not a servant of the supply services. As in World War I it eagerly sought a master for itself, which could only be the war cabinet, or some body endowed by it with the requisite authority, to determine priorities between the main demanding departments. The task of creating such an authority was simplified by the fact that two great departments, the ministries of supply and food, were responsible for all but a small fraction of the total demands. If the total allocations between these two ministries could be determined and adjusted suitably from time to time: they could each of them settle their own internal priorities. The ministry of supply, for example, could decide how much iron ore it would get at the expense of timber (since both were within its own control) and similarly the ministry of food how much sugar it would import at the expense of grain.

Review of the Import Program.—The first important step to this end was taken in Dec. 1939. The war cabinet appointed Sir Samuel Hoare (later Lord Templewood) to review the current import program. The proposal was made that the ministry of food should plan on the basis of 19,000,000 to 19,650,000 tons, the ministry of supply 23,640,000, with 1,150,000 for miscellaneous unallocated imports. The total proved a very close estimate and the proposed division, which was endorsed by the cabinet, set a standard for departmental scaling down which was of great value. The process of actual pruning was, however, intricate and unending. It improved gradually as the supply departments acquired more knowledge, skill and effective control of all consumption of imported goods by individuals and by industries. But in detail programs were subject to constant revision with the changing war situation; and the machinery through which the war cabinet exercised its ultimate control had to be given a permanent character.

The normal form of this machinery was that of a Cabinet Imports committee, presided over by a minister and served by a committee of departmental officials from the supply and shipping ministries. Through this machinery, decisions on competing demands which could not be settled at a lower level were taken as they were required.

Anglo-French Organization.—This national system had of course to be intermeshed with the Allied, that is the Anglo-French, organization since French supplies were partly dependent on manufacture in Great Britain and largely upon British shipping, and in some cases Britain's requirements could be aided by switches from France. There were nine separate Allied executives, for shipping, food, armaments and raw materials, oil, air production and supply, economic warfare, textiles and hides, timber and coal requirements. These were composed of officials, both British and French; and a co-ordinating committee, presided over by a permanent chairman appointed jointly by the French and British governments, was formed on a panel system from the chairmen of the executives with a few extra members. Though formally as complete in structure as the Allied system of executives in 1918 it had not in fact achieved an equal efficiency by the time that the fall of France brought it to an end. The stronger departmental organization in Great Britain, the British control of the margin of transferable shipping, the larger proportion of neutral ships on British time charter and the location of the Allied system in London were advantages to the British supply departments only partly compensated by the fact that the chairman of the co-ordinating committee was an able Frenchman. Nevertheless useful work was accomplished. British oil stocks were drawn on and British tankers diverted to give emergency help to the French; and French coal supplies, which had been gravely depleted by an unexpected shortage of coastal ships, severe winter weather, falling coal output in Great Britain and the overrunning of the coal mines of eastern France by the German armies, were replenished by a remarkable increase in shipments in May 1940 to more than 1,750,000 tons.

In the meantime another mistake in the prewar calculations, which aggravated all the difficulties of the earlier months, must be noted. It had been expected that war conditions would throw neutral tonnage on to the market and that the British government would easily acquire it. In fact freights rose and neutral owners had much more attractive opportunities than those offered them by the ministry of shipping. This situation changed after the German invasion of western Europe, when ships of countries previously neutral, especially Norwegian and Danish, came into British control and were important offsets against the increased losses. But in the first six months of the war little of this shipping was available and, as it had brought in a substantial proportion of British imports in peacetime, its sudden loss was a serious blow, the greater because it had not been expected.

Tankers and Oil Supplies.—So far shipping control has been described in the terms of dry-cargo tonnage. It was this which constituted the intricacy of the problem of organization as it was to a large extent transferable from one commodity to another over a very wide range. Tankers, carrying all forms of oil products from oil fuel to petrol, were also, of course, of the utmost importance; and though this kind of British tonnage had been increased by 1,750,000 gross tons since World War I, the increased demand for mechanized civilian and military transport, for warships, army trucks and aeroplanes was even greater; and the danger of a crippling deficiency was very serious at several stages of the war.

Passenger Shipping.—Ordinary passenger travel was almost suspended in the Atlantic and Mediterranean areas. This made enough ships available for the conveyance of troops in the early period of the war, when the struggle was mainly concentrated in western Europe and long-distance troop movements were comparatively small. But a large number of vessels of this type were converted for use as armed merchant cruisers and engaged in convoy work, a service in which many were lost. At a later stage this resulted in a shortage of troop-carrying vessels. Even in the first stage, however, the effect on ordinary imports was of some importance; for most passenger vessels carry goods as well; and vessels taken either for cruiser service or for troop-carrying were almost entirely lost to the importing services. A special liner section was established in the ministry and every effort made to reduce the inevitable loss to a minimum by skilful management.

Building and Losses.—With total tonnage about 1,250,000 gross tons less than in 1914, or 3,000,000 less in the case of dry cargo ships, the current output of merchant ships in British yards on the outbreak of World War II, was less than half of what it had been on the outbreak of World War I. Between 1911 and 1913 the average output had been more than 2,000,000 gross tons; but in every year since 1931 it had been less than 1,000,000. An attempt was made to raise it and a special department, at first attached to the ministry of shipping and later transferred to the admiralty, was formed for the purpose. But merchant ships were in direct competition with naval vessels for both skilled men and materials; and the navy was very inadequately equipped with certain types of ship, especially destroyers and other convoying vessels. That was the impelling reason for the destroyer deal with the United States in the autumn of 1940 and for the expensive use of passenger vessels as armed cruisers; it was also the reason, since a difficult question of priority was involved, for the transfer of responsibility for shipbuilding to the admiralty early in the war. In the event only about 1,000,000 gross tons were turned out in the first year of the war, and British yards never improved much upon this rate; there was regrettably little dilution of skilled by unskilled labour of the kind found possible in the later U.S. shipbuilding. But at the outset many gains were possible from other sources. Enemy shipping was captured; some neutral tonnage acquired; and in the first nine months of the war, when losses were comparatively small, the total gains approximately offset losses, nontankers showing a net gain of 57,000 gross tons (849,000 against 792,000) and tankers a net loss of 33,000 tons (174,000 against 141,000). In this period the stringency was partly caused by the failure of neutral ships trading as such to come to British ports, partly by the delays caused by war conditions, partly by the withdrawal of merchant ships into naval service and partly by increased demands for imported raw materials for the munitions industries. Even in this period, however, though losses were only at an annual rate of about 1,250,000 gross tons, they exceeded the current building output. The other acquisitions from European sources, whether of captured enemy ships or of neutrals in European waters, were in the nature of a single capital gain; no repeated acquisition of this kind could be expected. British building was inelastic. It was soon evident that, if losses increased and if demands also rose with the extension of the war, the only adequate answer must be found, if it could be found at all, across the Atlantic.

The Ministry of Shipping. — Within a few months of the outbreak of hostilities an efficient ministry of shipping had been constructed from a mixed team of shipowners and staff from the shipping offices, civil servants and others drawn from outside. Something of the same composite staff was to be found at this time in all the departments, especially the civilian ones, and in general the precedents of World War I were followed. In the ministry of shipping there was one interesting difference, not perhaps an improvement, as compared with the earlier war. In 1917 there had been a very complete welding of shipping and lay experience, every main branch including both shipowners and civil servants in positions of real responsibility. In one branch a shipowner would be at the head, with a civil servant as his deputy; and in another the positions were reversed. In World War II the association was on the whole between branches controlled by shipowners and others by civil servants. This was partly because, with a more extended Whitehall organization, the number of civil servants of the requisite quality who could be spared for a single ministry was less adequate. But each branch probably lost something from the absence of one or other of the two elements. In this new form of somewhat less intimate association co-operation was on the whole cordial and efficient, under an able director-general, Sir Cyril Hurcomb, a civil servant who had held a responsible post in the ministry of the earlier war.

The Fall of France. — The fall of France in June 1940, while transforming the military situation, also changed the shipping problem and had a considerable impact on organization. The first effect was to give a momentary, and very deceptive, relief to the shipping stringency. Much Norwegian and Danish and some Dutch, tonnage came from the recently invaded countries; no more ships had to be supplied for French imports; no more transport, after Dunkirk, was needed to take men or goods across the English channel. All the longer-term consequences, however, involved the greatest danger of a shipping shortage which would be fatal to the successful continuance of the British war effort. Italy entered the war and the Mediterranean was practically closed, so that men and supplies for the middle east had to go round the Cape of Good Hope. The manufacture of munitions and imports had to be rapidly stepped up to re-equip an army which had come back without guns or trucks. Above all losses were bound to increase. The "asdic" with which French destroyers had been fitted came into the hands of the Germans who thus were enabled to seek and find an answer to it. Hostile submarines and aircraft could operate more closely from French bases. The rate of sinkings more than doubled.

American supplies were now of crucial importance. A British purchasing mission had been established in Ottawa, Canada, at the outbreak of war, and later transferred to New York. It was headed by a Canadian, A. B. Purvis, who was also chairman of an Anglo-French Purchasing board established to co-ordinate the purchases in the United States of the British mission and a similar French mission. On the fall of France both the Anglo-French co-ordinating committee in London and the board in New York came to an end. The former was replaced by a North American Supplies committee, through which the demands of the different departments were transmitted to the British mission in New York. The latter mission was in general placing its orders direct with individual American manufacturers. But the U.S. government was preparing to enlarge its own rearmament; and the task of estimating, and to some extent controlling, competing demands on U.S. industry was entrusted to the treasury, then under Henry Morgenthau. The immediate result was a request for a comprehensive. statement of requirements from overseas. The co-ordinating machinery in London was therefore developed further and a British supply council established at Washington. Purvis was chairman of this council, the other members being representatives of the principal purchasing departments. The main executive work of placing orders was still carried out by the British organization in New York; but general policy was now determined in Washington, to which the centre of gravity passed definitely when the president stepped up the United States' own armament in the summer of 1940.

The first expression of the willingness of President Koosevelt to give greater help was the arrangement in the autumn of 1940 under which 50 old U.S. destroyers were turned over in return for the right to establish United States bases in the West Indies. A few months later, in March 1941, this was followed by the Lend-Lease bill, which ensured that U.S. supplies would not be cut off through the inability of Great Britain to find the dollars to pay for them.

Until this time either finance or shipping might have been the main limiting factor to the extent of Great Britain's overseas supplies and therefore of its war effort. Henceforth for some years the limiting factor was shipping. By the spring of 1941 the danger was imminent. Losses of British or British-controlled tonnage at this time were at the annual rate of nearly 5,000,000 tons gross, or in terms of deadweight 7,700,000 tons. Against these British new building was only at the rate of about 1,400,000 tons deadweight. The shipping at Britain's disposal, thus being reduced at the rate of more than 5,000,000 tons deadweight a year, was already seriously inadequate for the demands on it. In 1938 British dry-cargo imports had totalled 52,000,000 tons; in 1940 they had fallen to 43,500,000 tons. They now fell to a rate of only about 30,000,000, which had to cover not only all food imports but raw materials for munitions manufacture. Oil supplies (including oil fuel for the navy and all industrial purposes and petrol for motor transport and aviation) were in a no less dangerous position; oil stocks had fallen to the danger level of 4,500,000 tons and were still falling rapidly.

The British Shipping Mission to Washington. — Against the grave dangers of starvation, the closing of munitions factories for want of raw materials and the crippling of the British war effort, the only possible source of substantial relief was the United States. The prime minister therefore decided to establish a British shipping mission in Washington. It was headed by Sir Arthur Salter, parliamentary secretary of the ministry of shipping from 1939 and chairman of the North American Supplies committee in London since the fall of France. It was the task of this mission to obtain the largest possible allocation of U.S. tonnage for British services and to urge a great increase in U.S. shipbuilding.

United States Shipping.——Up to this moment no merchant ships had been supplied by the U.S. government, though a few U.S. ships (mainly old laid-up tonnage built in World War I) had been bought for cash. Moreover the United States' resources were very limited. Its overseas mercantile marine consisted of only about 7,000,000 tons (deadweight) of dry-cargo and passenger vessels and about 5,000,000 tons of tankers; and all were fully employed, for the most part in work that seemed essential. American shipbuilding had almost ceased between 1921 and 1937 and, though there had been some revival, the output in 1941 was only 1,000,000 tons deadweight. Besides this, the Neutrality act prevented U.S. ships from entering a war zone; and congress was opposed not only to participation in the war but to all action which might lead to it. On the other hand the president, supported by his principal cabinet members and officials, was determined to do all that was possible in these circuinstances. In a few weeks he had declared Suez to be outside the "war zone" (since Egypt was a neutral) and U.S. ships were allowed to carry British supplies to the near east; and he had ordered the maritime commission to allocate 2,000,000 tons to the war effort. Under this impulse the transport of U.S. goods between the west and the east coast was transferred from shipping through the Panama canal to the railways; oil transport up the east coast was similarly transferred from sea to land. Before the year was over 1,500,000 tons of U.S. dry-cargo tonnage was in British service, and more than 750,000 tons of tankers. The fall in British imports was arrested and oil stocks raised to the full capacity of British storage. Even more important for the future was the decision to raise the building program for 1942 from the current rate of 1,000,000 tons to the astonishing rate of 8,000,000 tons—a decision which was in fact fully implemented.

By Dec. 1941 the problem set in April was solved. On the basis of the war as it then was, that is without Japan as a belligerent or American troops and supplies to transport, shipping resources were adequate. Against total Allied and neutral losses of 6,500,000 tons deadweight, the U.S. building program alone promised 8,000,000 tons, and British and Canadian building a further 2,500,000 tons. (Canada, it should be noted, which had built no overseas vessels before the war, was now by a remarkable effort building almost as much as the United Kingdom.) British imports in 1941 exceeded consumption, dry-cargo stocks and oil stocks each rising by 2,600,000 tons.

After Pearl Harbor.—This situation was completely transformed by the entry into the war of Japan and the United States after Pearl Harbor. Losses greatly increased, being about as high in the first six months of 1942 as in the whole of 1941. In the meantime the shipping demands of the U.S. army and navy were of course very great—exceeding combined building by 2,700,000 tons. It was only in May 1942 that U.S. building, in spite of its immense extension, matched current U.S. losses; and only in August that combined building overtook combined losses. In the meantime greatly increased demands were made on a seriously reduced total tonnage. British dry-cargo imports fell to 23,000,000 tons, and stocks were again depleted. Oil stocks fell similarly. The shipping situation was as serious as it had been in the spring of 1941.

The Combined Board System.—Meanwhile now that the United States was an Allied belligerent, the whole organization in Washington was transformed. No longer did the British missions make contracts with individual industrialists with the assistance of the U.S. administration. All supplies were allotted through U.S. departments under the control of combined Anglo-U.S. boards. The competition was no longer between British war needs and American peace needs but between different war needs.

It is interesting to compare the combined system of supply as it developed in 1942 and 1943 with the Allied system in World War I in 1917 and 1918. In the first war. although there was an elaborate Allied machinery, its working was simplified by the fact that London was the indisputable centre of the whole system. In that war British shipping was throughout supplying assistance to all the Allies, including the United States; and the general American war effort had not been fully extended when hostilities ceased. In World War II the position was reversed. The United States was fully extended. It was its shipping, and its supplies in general, upon which other Allies drew. Increasingly, therefore, Washington became the centre of main supply policy. Nevertheless Washington never became the sole centre in the sense in which London had been in the earlier war; and the combined boards were constituted in both capitals. In 1942 British military effort was equal to that of the U.S. and the British machinery of planning had been more fully developed. Though, therefore, the centre of gravity increasingly moved toward Washington the contribution of each country to supply policy was not unequal. For shipping, a Combined Shipping Adjustment board in Washington was formed, with the chairman of the war shipping administration (Vice-Admiral E. S. Land) as the U.S. member (represented frequently by the deputy administrator, Lewis Douglas) and the head of the British Shipping mission as British member. The major principles to guide transfers of tonnage were discussed at this board; but the bulk of the work continued in the form of constant detailed negotiations between the WSA and the mission (located in the same building). Nothing like a "pool of shipping" in the fullest sense of the term was attempted. Each country managed its own transport, except for occasional interchanges, and the British used the shipping under their own control so far as it would suffice. The real task of the combined system was to determine how much, on what principles and to what services U.S. tonnage should be allotted for British assistance. The president had laid down the main principle that the output of the great U.S. building program should be regarded as available for the combined war effort and allotted according to need; and in applying this principle major importance was attached to the losses sustained by each country. In practice monthly allocations were planned, especially though not exclusively for certain defined services (*e.g.*, transport to the near east, across the Atlantic to the United Kingdom and so on), Great Britain with this assistance supplying its own shipping for the rest. The allocations once made, all subsequent arrangements for British services were made either by the ministry of war transport in London or, as regards shipping from U.S. ports, by the British shipping organization at New York.

United States Shipbuilding.—In the meantime the United States building program for 1943 was raised in March 1942 from 8,000,000 to 14,000,000 tons, and in October to 18,800,000 tons. From Aug. 1942 current combined output exceeded current losses. There was still, however, throughout the year and the following winter, a severe shipping stringency as the military and naval demands were greatly increasing with the extension of the war in the far east and in Europe, for which the previously depleted tonnage was inadequate. By the spring of 1943, however, the new building had transformed the situation. Each month showed a net gain of about 1,000,000 tons. By the summer there were about 6,000,000 tons of U.S. shipping in British service. There was enough cargo tonnage for all the military projects, and every prospect that the continuing net gains would meet any extra demands of the future. There were still difficulties as to passenger ships, escorting vessels and landing craft; but the improvement in the general position enabled some building capacity to be diverted to these special classes of construction. Thus the shipping problem, as a main factor in the Allied war effort, had been solved. As in World War I, success had been the reward of naval protection, increased building, efficient national and Allied systems of organizing and economizing supplies. In 1943 combined building exceeded losses by over 16,000,000 deadweight tons; and it was then evident that, in the last crucial stages of the war, shipping would return to its proper role as the servant of the services which demanded transport, able to supply all that was required of it.

In 1944, therefore, and the remaining months of the war in 1945, the problem of shipping control was of a different character. Total tonnage was adequate for the demands on it and it was increasing every month. In June 1943 the nontanker shipping under British control totalled 14,250,000 gross tons; in December of that year it had risen to more than 15,250,000, and in Sept.

1944 to more than 16,250,000. While gains had increased losses had fallen. In 1944 the gains were 2,287,000 gross tons, the losses 1,017,000, the net gain being thus 1,270,000. In the same year the gains in tanker tonnage were 470,000 dead weight, the losses 226,000, net gain 244,000. In the meantime dry-cargo imports into Great Britain, which had fallen to 22,900,000 tons in 1942 averaged 25,700,000 tons in 1943 and 1944, and stocks of imported food and ram materials were higher by 2,500,000 tons at the end of 1944 than they had been at the end of 1942.

The difficulties that confronted the shipping authorities in supplying the tonnage required for the invasion of Europe in June 1944 and the subsequent operations, though different, were, however, serious. Both ports and the inland transport system were strained to the utmost. Moreover the task of organizing shipping secretly for the vast enterprise of D-day was one of the greatest intricacy. The ships had to be assembled to an exact timetable, and a delay of even a few days would have entailed dispersal for the replenishment of stores and water and incalculable confusion. One day's delay was in fact enforced by rough seas, but no more. The intricate and interlocked arrangements for troop-carrying vessels, cargo ships, naval protecting forces and landing craft worked smoothly both on D-day and after.

WAR CRIMES. The term war crimes has never been successfully defined. After the end of World War II three categories of this offense against the law of nations came to be recognized: (1) crimes against peace—the planning. preparation, initiation or waging of a war of aggression, or a war in violation of international treaties, agreements or assurances; or participating in a common plan or conspiracy for the accomplishment of any of the foregoing; (2) war crimes (also called conventional war crimes)—violations of the laws or customs of war such as murder, ill-treatment or deportation to slave labour, or for any other purpose, of the civilian population of occupied territory; murder or ill-treatment of prisoners of war or persons on the seas; killing of hostages; plunder of public or private property; wanton destruction of cities, towns or villages or devastation not justified by military necessity; and (3) crimes against humanity—murder, extermination. enslavement, deportation and other inhumane acts committed against any civilian population, before or during a mar, or persecutions on political, racial or religious grounds in execution of or in connection with any other war crime.

Trials of individuals for specific violations of the laws or customs of war (the so-called conventional war crimes) have a long historical basis. Thus, the Scottish national hero Sir William Wallace (*q.v.*) was tried in England in 1305 for the wartime murder of numerous members of the civilian population, during the course of which he allegedly spared "neither age nor sex, monk nor nun." When the American Civil War ended in 186j Henry Wirz, a former Confederate officer, was tried and convicted by a federal military tribunal, and was executed, for the murder of, and for conspiracy to ill-treat, federal prisoners of war confined at the Andersonville prisoner-of-war camp which Wirz had commanded. And the treaty of peace which ended the South African War in 1902 specifically provided that certain acts contrary to the usages of war which had been committed by Boers would be tried by British courts-martial.

World War I.—At the conclusion of World War I a commission on responsibilities was created by the preliminary peace conference, its mission being that of "inquiring into the responsibilities relating to the war." In its report the commission recommended trials before national courts of the victors and, where appropriate, before a high tribunal which would be inter-Allied in composition. The report contemplated war crimes trials for violations of the laws or customs of war (of which it listed 32 categories) and for crimes against humanity. Failure to take the necessary action to prevent or end violations of the laws or customs of war would itself constitute a war crime. The commission recommended that some "special measures" be taken with respect to those responsible for instigating the war and for violating the neutrality of Belgium and Luxembourg. The United States representatives on the commission dissented from those portions of the report that referred to crimes against humanity; to the conclusion that heads of state should be liable to criminal prosecution; and to the conclusion that special measures should be adopted to deal with those responsible for the war. The Japanese representatives made a reservation to the conclusion under which heads of states would be held criminally responsible for political acts and they did not concur in the provision making failure to act to prevent or end violations of the laws or customs of war an affirmative offense.

The Versailles peace treaty in 1919 called for the trial of the former German kaiser, Wilhelm II, by a specially constituted international tribunal (art. 227). The treaty also contained German recognition of the right of the Allies to bring to trial before national or international military tribunals persons accused of having committed acts in violation of the laws or customs of war and an undertaking by the German government to hand such persons over to the Allies for trial (art. 228–230). The treaty contained no provision for trials for the offense of crimes against humanity and only indirectly, as to the former kaiser, was there provision for a trial for the offense of crimes against peace. Inasmuch as the Netherlands. where the kaiser had taken refuge, refused the Allied request for extradition, he was never tried. And because of German resistance to the surrender of those individuals accused of war crimes, the Allies ultimately agreed to permit the cases to be tried by the supreme court of Leipzig (Germany). The results of the trials that followed clearly indicated the ineffectiveness of this method of attempting to punish persons accused of war crimes. The great majority of those tried were acquitted, despite strong evidence of guilt; those convicted received grossly inadequate sentences (and, in several instances, were quickly permitted to escape from prison); and all were treated as heroes by the German press and public.

World War 11.—Beginning early in World War II various announcements were made concerning the intention of the Allies to mete out punishment to those guilty of war crimes. On Oct. 25, 1941, while the United States was still neutral. Pres. Franklin D. Roosevelt called attention to the atrocities being committed by the Nazis in occupied countries. On that same day Prime Minister Winston Churchill associated the British government with the Roosevelt statement and made retribution for these crimes one of the major purposes of the war. On Jan. 13. 1942, the declaration of St. James was signed by the governments in exile of nine countries of Europe that were then occupied by the Nazis. These nations, too, made punishment of war crimes a principal war aim. During the course of the war there were a number of other pronouncements on this subject, the most important of which were (1) the Moscow declaration (Nov. 1, 1943) wherein Roosevelt, Churchill and Marshal Joseph Stalin of the U.S.S.R. stated that at the time of the granting of any armistice to Germany those German officers and men and members of the Nazi party responsible for atrocities, massacres and executions in occupied areas would be sent back to the countries in which their acts had been committed in order that they might be tried and punished "according to the laws of these liberated countries and of the Free Governments which will be erected therein"; and that those "major criminals" whose offenses had no particular geographical location would be punished by a joint decision of the Allied governments; and (2) the Potsdam declaration (July 26, 1945) with respect to Japan, made by Truman, Churchill and Pres. Chiang Kai-shek of China, and later adhered to by the U S S R., which stated that "stern justice shall be meted out to all war criminals including those who have visited cruelties upon our prisoners."

Trial of Nazi Leaders.—During Oct. 1943 representatives of 17 of the Allied nations met in London and established the United Nations War Crimes commission, the functions of which included the investigation of war crimes and the formulation of general measures necessary to ensure the detection, apprehension. trial and punishment of accused war criminals. On Aug. 8, 1945, representatives of the United Kingdom, the United States and the

U.S.S.R. and of the provisional government of France signed the London agreement, which included a charter for an international military tribunal for the trial of the major Axis war criminals whose offenses had no particular geographical location. Nineteen other governments later adhered to this agreement. The first session of the tribunal, which consisted of a member and an alternate appointed by each of the four signatory countries, took place in Berlin on Oct. 18, 1945, under the presidency of the Soviet member, Gen. I. T. Nikitchenko. At that time an indictment uas lodged against 24 of the former Nazi leaders charging them with numerous crimes against peace, conventional war crimes, crimes against humanity and conspiracy, and charging a number of organizations (such as the Gestapo, the Nazi secret police) with being criminal in nature. All subsequent sessions of the tribunal were held in Nurnberg, Ger.. under the presidency of the British member. Lord Justice Sir Geoffrey Lawrence. The other members of the tribunal were Francis Biddle of the United States and Henri Donnedieu de Vabres of France. The judgment of the tribunal was reached on Oct. 1, 1946. 12 of the accused (including Martin Bormann, who was tried *in absentia)* being sentenced to death by hanging and three to life imprisonment. General Nikitchenko dissented from the acquittal of the accused Hjalmar Schacht, Franz von Papen and Hans Fritsche; from the refusal of the tribunal to sentence the accused Rudolf Hess to death; and from the decision not to declare the *Reich* cabinet, the German general staff and the high command of the German armed forces to be criminal organizations.

Trial of Japanese War Leaders.—On Jan. 19, 1946, Gen. Douglas MacArthur, supreme commander for the Allied powers in Japan, issued a charter for an international military tribunal for the far east for the trial of major war criminals in that area. The tribunal which was thereafter appointed ultimately consisted of the representatives of 11 governments (Australia, Canada, China, France, India. the Netherlands, New Zealand, the Philippines, the U.S.S.R., the United Kingdom and the United States). The trial began in Tokyo in May 1946, under the presidency of Sir William Webb of Australia, and concluded with the reading of the judgment on Nov. 12. 1948. The accused were charged with various crimes against peace, murder, other conventional war crimes and crimes against humanity. Of the 25 accused against whom sentences were adjudged, 7 received sentences to death by hanging and 16 to life imprisonment. Dissents were filed by three members of the tribunal, R. Pal of India, Henri Reimburger of France and B. V. A. Roling of the Netherlands.

Subsequent **Proceedings.**—Twelve other trials of major war criminals were held at Nurnberg under international authority. These trials, called the "Subsequent Proceedings," had as their legal basis Control council law no. 10. a law promulgated on Dec. 20. 1945, by the zone commanders of the four powers which were occupying Germany. In addition, there were thousands of Germans and Japanese tried by various national courts, either military or civilian, for conventional war crimes. It has been estimated that over 2,000 separate trials took place (including approximately 950 conducted by the United States, 550 by Great Britain and 275 by Australia) involving many times that number of accused. Included in this category were the trials by United States military commissions of Gen. Tomoyuko Yamashita and Gen. Masaharu Homma in Manila in 1945. Both of these accused unsuccessfully attempted to secure the intervention of the United States supreme court to prevent the imposition of the death sentences which they had received.

Criticism of the Trials.——From the very outset the post-World War II program for the punishment of war criminals was vigorously attacked and vigorously defended, both on political and on legal grounds. One of the legal arguments most frequently advanced against the program was that war crimes trials were ex post facto in that they allegedly punished for acts that had not been criminal when committed. This argument was directed primarily at the offenses of crimes against peace and some of the crimes against humanity.

The Nurnberg tribunal, however, held that long before the Nazi or other aggressions of World War II, a series of international declarations, acts and treaties, culminating in the pact of Paris of 1928, ratified by Germany and nearly all other states, had established a rule of customary international law making aggressive war illegal and the initiation or waging of such a war, with knowledge of its character and freedom of choice, an individual crime. *(See* WAR.) Many of the crimes against humanity and the majority, if not all, of the conventional war crimes (murder, rape, pillage, etc.) are offenses under the criminal law of every civilized nation. As to these offenses the attack was directed at the fact that the vanquished were being tried in the courts of the victors where, it was claimed, they could not receive fair and objective treatment. This particular criticism was heard less and less frequently as time went on and, in the great majority of cases, war crimes courts demonstrated their objectivity and fairness. Much criticism was also directed at the refusal of the courts which tried these cases to entertain such defenses as that the act charged as a war crime had been committed as a matter of military necessity or as a result of the receipt of orders from a superior.

Despite these criticisms, it would appear that trials for war crimes are so well embedded in the laws of war that they may be expected as a sequence to any conflict that ends with one side victorious and the other defeated (Indeed, since the end of World War II conventional war crimes have been the subject of specific international legislation in the Geneva conventions of Aug. 12, 1949, for the protection of war victims.) The passage of time has, however, resulted in a lessening of the antagonism felt toward those individuals who were convicted of war crimes after World War II and who were sentenced to imprisonment. Both the peace treaty with Japan and the Bonn agreements which terminated the occupation of west Germany contained provisions which resulted in advancing the dates of release of all but a few.

WARD, AARON MONTGOMERY (1843–1913), **U.S.** merchant, who introduced the mail-order method of selling general merchandise, was born in Chatham. N.J., on Feb. 17, 1843. The oldest of seven children, he went to work at an early age in a cooperage to help support his family. In 1859, at the age of 16, he became a salesman in a general store in St. Joseph, Mich., for $6 a month and board; later he was made manager at $100 a month and board. During that period he conceived the idea of a business that would buy goods at wholesale for cash and sell to the consumer by mail for cash with middlemen's costs eliminated. In 1866 he moved to Chicago and worked for various firms as a traveling salesman. In Aug. 1872, with a capital of $1,600. Ward issued his first catalogue, a single sheet listing 30 items. The following year his brother-in-law, George R. Thorne, bought a half interest in the business for $800. The firm prospered.

In 1886 Ward, while retaining the presidency. turned the management over to Thorne and his five sons. During the next 20 years Ward devoted much of his time to the preservation of the natural assets of Chicago's lake front and vigorously opposed attempts to build public or other structures in Grant park. Ward died Dec. 7, 1913, in Highland Park, Ill. (F. W. JN.)

WARD, ARTEMUS (pen name of CHARLES FARRAR BROWNE) (1834–1867), was one of the best and most popular 19th-century U.S. humorists. Born in Waterford. Me., on April 26, 1834. he served as a printer's apprentice in nearby towns and later went to Boston, Mass., to work as a compositor for *The Carpet* Bag, a humour magazine. After spending seven years in Ohio as a journeyman printer, and as "local" editor of the *Toledo Commercial* and the *Cleveland Plain Dealer,* he went to

New York in 1860 to work on *Vanity Fair.* Later he turned to humorous lecturing with considerable success in both the Cnited States and England. His British tour was interrupted by his death in Southampton on March 6, 1867.

Browne's humorous writing was commonplace until 1858, when as local editor of the *Plain Dealer* he created the character Artemus Ward. Adopting the language and viewpoint of Artemus Ward, whom Browne characterized as an itinerant showman, he wrote a series of letters for the *Plain Dealer, Vanity Fuir* and *Punch* in which he commented upon many subjects. His principal books are *Artemus Ward: His Book* (1862); *Artemus Ward: His Travels* (1865); and *Artemus Ward in London* (1867). Of the humorous devices in his writing, misspelling was the most outstanding; the most prominent feature of his lectures was his "dead-pan" delivery. His techniques had considerable influence upon other humorists, including, especially in his role as a lecturer, Mark Twain.

See Don C. Seitz, *Artemus Ward, a Biography and Bibliography* (1919); A. J. Nock (ed.), *Selected Works of Artemus Ward* (1924), an excellent edition of his writings. (J. Q. R.)

WARD, DAME GENEVIÈVE (1838–1922), English actress, was born in New York city on March 27, 1838, and at the age of 18 married Count Constantine de Guerbel. She studied singing in Italy and in Paris, and made her first appearance under the stage name of Ginevra Guerrabella at Bergamo in the opera *Stella di Napoli* (1855). After the loss of her singing voice in 1862 she taught singing in New York, but in 1873 she went to London and began a long dramatic career. In 1918 she published, with Richard Whiting, a volume of reminiscences, *Before and Behind the curtain.* In 1921 she was made a Dame of the British empire. She died on Aug. 18, 1922.

WARD, JAMES (1843–1925), English psychologist and metaphysician, was born at Hull on Jan. 27, 1843. He was educated at the Liverpool institute, at Berlin and Gottingen and at Trinity college, Cambridge; he also worked in the physiological laboratory at Leipzig. Subsequently he devoted himself to psychological research, became fellow of his college in 1875 and university professor of mental philosophy in 1897. His work shows the influence of Leibniz and R. H. Lotze, as well as of evolution. His views are further worked out, through criticism of pluralism and as a theistic interpretation of the world, in his Gifford lectures (*The Realm of Ends,* 1911; 3rd ed., 1920). Ward died on March 4, 1925.

Ward published *Naturalism and Agnosticism* (1899; 3rd ed., 1907); *Heredity and Memory* (1913); *Psychological Principles* (1918; 2nd ed., 1920); *A Study in Kant* (1922); and *Essays in Philosophy,* ed. by W. R. Sorley and G. F. Stout, with memoir by O. W. Campbell (1927); numerous articles in the *Journal of Physiology,* in *Mind* and in *The British Journal of Psychology.*

WARD, JOHN QUINCY ADAMS (1830–1910), U.S. sculptor, was born near Urbana, O., on June 29, 1830. He studied under Henry K. Brown of New York, and by 1861, when he opened a studio there, he had executed busts of the U.S. public officials Josua R. Giddings, Alexander H. Stephens and Hannibal Hamlin, prepared the first sketch for the "Indian Hunter" (Central Park, New York) and made studies among the Indians themselves for the work. In 1863 he became a member of the National Academy of Design in New York, and he was later its president. He died in New York city on May 1, 1910.

WARD, SIR JOSEPH GEORGE, 1ST BART., cr. 1911 (1856–1930), New Zealand politician, was born at Emerald Hill, Melbourne, on April 26. 1856, son of a merchant. At 13 he entered the post and telegraph department. In 1887 he entered parliament as Liberal member for Awarua. Appointed treasurer in the Seddon cabinet of 1893, he was the prime minister's chief lieutenant until Seddon died in 1906, and he then succeeded to the premiership and the leadership of the Liberal party.

His ministry was defeated in Feb. 1912, but Ward returned to office as minister of finance in the national (war) cabinet of 1915–19. In Dec. 1928 he again took office as prime minister. He resigned in May 1930 and died on July 7, 1930.

WARD, LESTER FRANK (1841–1913), U.S. sociologist, the earliest and most prolific of the "founders" of systematic American sociology, was born in Joliet, Ill., June 18, 1841. Privations of his youth are thought to have had a considerable influence on his later social philosophy of amelioration and progress. After serving in the Union army during the Civil War, he graduated from Columbian college (later George Washington university), Washington, D.C., in 1869, and from the law school in 1871. He did not practise law but turned to government service, mainly in geology, botany and paleobotany. He was called to a professorship in sociology at Brown university in 1906 by his admirer and collaborator, James Q. Dealey, and taught there until his death on April 18, 1913. He made some significant contributions to botany, notably his theory of sympodial development.

In the formulation of his sociological system, Ward was greatly influenced by Auguste Comte (*q.v.*), especially in his conception of sociology as the fundamental social science and the guide to sound and effective planning for a better social future. Ward's sociological conceptions were mainly a synthesis of: (1) his own views on the relations between cosmic and social energy; (2) the principles of organic development derived in part from his paleobotany; (3) Hegelian dialectic; (4) Wilhelm Wundt's notion of "creative synthesis"; (5) hedonistic psychology; (6) social Darwinism; and (7) Comte's dictum that the primary responsibility of sociology is to plan a better future based on sociological teachings.

Ward adopted a dynamic and telic attitude toward sociology, decrying a static and descriptive approach and holding that sociology should be primarily concerned with social function rather than social structure. He divided sociology into two main fields, pure and applied. The former deals mainly with the origins and organization of social life, the latter with "the artificial means of accelerating the spontaneous processes of nature" through the application of sociological principles, as embodied in realistic education. Ward's main interest and contribution was in applied sociology and social betterment.

Ward renounced the doctrine that mankind must depend upon the slow, wasteful and bloody processes of cosmic and biological evolution to assure the development of society and contended that the development of sociology and of the social sciences in general had by then presented mankind with a sound and reliable body of information and adequate social techniques whereby the social future could be scientifically planned and a better era assured and hastened. Such a planned or "telic" society Ward called a "Sociocracy," and its dynamic agent was to be realistic education. He suggested the institution of a great academy of the social sciences in Washington which would inform! advise and guide legislators in the needed social planning. Social scientists would occupy much the same role as did the sociologist-priests in Comte's plan for a social utopia. Ward's emphasis on studying function rather than structure and on social planning later exerted considerable influence on Thorstein Veblen (*q.v.*) and the institutional economists.

Ward's most impressive book was his pioneer *Dynamic Sociology,* 2 vol. (1883), which embodied his earlier synthesis of the field and principles of sociology; it was brought down to date and condensed in his *Outlines of Sociology* (1898). *Pure Sociology* (1903) is the final summation of his theory; it is presented in more clear and elementary form in Dealey and Ward's *Textbook of Sociology* (1905). *Applied Sociology* (1904) is the authoritative exposition of Ward's notions of "social telesis." a sociocracy and social planning. Ward's intellectual autobiography is *Glimpses oj the Cosmos* (6 vol., 1913–18).

(H. E. BAR.)

WARD, MARY AUGUSTA (MRS. HUMPHRY WARD) (1851–1920), British novelist, was born on June 11, 1851, at Hobart, Tasmania, where her father, Thomas Arnold (1824–1900), was then an inspector of schools. She was brought up mainly at Oxford, and her early associations with a life of scholarship and religious conflict are deeply marked in her own later literary career. She was brought into close connection during this period with Edward Hartopp Cradock, who was principal of Brasenose college from 1853 till his death in 1886, some of whose characteristics went into the portrait of the "Squire" in *Robert Elsmere.* In 1872 she married Thomas Humphry Ward.

In 1881 she published her first book, *Milly and Olly,* a child's story illustrated by Lady (then Mrs.) Alma-Tadema. This was followed in 1884 by a more ambitious, though slight, study of modern life. *Miss Bretherton,* the story of an actress. In 1885 Mrs. Ward published an admirable translation of the *Journal Intime* of the Swiss philosopher Henri Amiel, with a critical introduction. In Feb. 1888 appeared *Robert Elsmere,* a powerful novel tracing the mental evolution of an English clergyman. The character of Elsmere owed much to reminiscences both of T. H. Green, the philosopher, and of J. R. Green, the historian. The book was reviewed by W. E. Gladstone in the *Nineteenth Century* (May 1888, "Robert Elsmere and the Battle of Belief"), and made its author famous.

Mrs. Ward's next novel, *David Grieve,* was published in 1892. In 1895 appeared the short tragedy, the *Story of Bessie Costrell.* Mrs. Ward's next long novel, *Helbeck of Bannisdale* (1898), treated of the clash between the ascetic ideal of Roman Catholicism and modern life. The element of Catholic and humanistic ideals entered also into *Eleanor* (1900), in which, however, the author relied more on the ordinary arts of the novelist. In *Lady Rose's Daughter* (1903)—dramatized as *Agatha* in 1905—and *The Marriage of William Ashe* (1905), modern tales founded on the stories respectively of Mlle. de Lespinasse and Lady Caroline Lamb, she relied entirely and with success upon social portraiture. Later novels were *Fenwick's Career* (1906), *Diana Mallory* (1908), *Daphne* (1909), *Canadian Born* (1910), *The Case of Richard Meynell* (1911), *Delia Blanchflower* (1913), *The War and Elizabeth* (1918), etc. Mrs. Ward died in London on March 24, 1920.

BIBLIOGRAPHY.—Stephen L. Gwynn, *Mrs. Humphry Ward* (1917); J. Stuart Walters, *Mrs. Humphry Ward: Her Work and Influence* (1922); Janet P. Trevelyan, *The Life of Mrs. Humphry Ward* (1923).

WARD, WILFRID PHILIP (1856–1916), British man of letters, was born at Ware, Hertfordshire, on Jan. 2, 1856, the second son of William George Ward. In 1906 he became editor of the *Dublin Review.* He died in London on April 8, 1916. His works include: *W. G. Ward and the Oxford Movement* (1889); *W. G. Ward and the Catholic Revival* (1893); *Life and Times of Cardinal Wiseman* (1897); *Life of John Henry Cardinal Newman* (1912) and several volumes of essays.

WARD, WILLIAM GEORGE (1812–1882), English Roman Catholic theologian, was born on March 21, 1812. He was educated at Christ Church and Lincoln college, Oxford, and became a fellow of Balliol in 1834. He regarded Newman as a mere antiquary. When he was persuaded to hear Newman preach, he at once became a disciple. He took deacon's orders in 1838 and priest's orders in 1840. From that period Ward and his associates worked for union with the Church of Rome; in 1844 he published *Ideal of a Christian Church,* in which he openly contended that the only hope for the Church of England lay in submission to the Church of Rome. The University of Oxford was invited, on Feb. 13, 1845, to condemn "Tract XC," to censure the *Ideal* and to degrade Ward from his degrees. The two latter propositions were carried and "Tract XC" only escaped censure by the *non placet* of the proctors, Guillemard and Church. The condemnation precipitated an exodus to Rome. Ward left the Church of England in Sept. 1845, and was followed by many others, including Newman himself. In 1868 he became editor of the *Dublin Review.* He died July 6, 1882.

See *William George Ward and the Oxford Movement* (1889) and *William George Ward and the Catholic Revival* (1893), both by his son Wilfrid Philip Ward.

WARD, that which guards or watches, and that which is guarded or watched. In architecture the inner courts of a fortified place are called wards; *e.g.,* the upper and lower wards of Windsor castle *(see* CASTLE). The "ward" in a lock is the ridge of metal which fits exactly into the corresponding "ward" or slot of the key *(see* LOCK). Boroughs, cities and parishes may be divided into wards, for the conducting of local elections, etc. In the same way, large establishments, such as hospitals, asylums, etc., are divided into wards. In law, "ward" is a term for minors or persons under guardianship *(see* INFANT; MARRIAGE; ROMAN LAW).

An electoral division in U.S. municipalities is called a ward. Except where the commission and city-manager forms of government are used, the municipal legislative branch is a city council made up of representatives from the various wards of the city. The wards are supposed to be of about equal population, each ward having either one or two aldermen, chosen by the qualified voters of the ward, in the city council. Each ward is divided into one or more voting precincts or divisions. *See* C. C. Maxey, *An Outline of Municipal Government* (1923).

WAR DEBTS: *see* INTER-ALLIED DEBTS.

WARDEN, a word frequently employed in the ordinary sense of a watchman or guardian, but more usually in England in the sense of a chief or head official. The lords wardens of the marches, for example, were powerful nobles appointed to guard the borders of Scotland and of Wales; they held their lands *per baroniam,* the king's writ not running against them, and they had extensive rights of administrating justice. The chief officer of the ancient stannaries of Cornwall has the title of lord warden *(see* STANNARIES) as has also the governor of Dover castle *(see* CINQUE PORTS).

WAR DEPARTMENT: *see* GOVERNMENT DEPARTMENTS.

WARDHA, a town and district in Bombay state, India. They take their name from the Wardha river. The town of Wardha, well known as the last headquarters of Mahatma Gandhi, was established on a treeless black soil plain at the old village of Palakwari in 1866 at the spot where the branch line to Warora was expected to take off. Pop. (1951) 39,827

WARDHA DISTRICT was carved out of Nagpur in 1862. Area 2,429 sq.mi.; pop. (1951) 538,903. There are cotton mills at Hinganghat and Pulgaon. The language is Marathi.

WARDLAW, HENRY (d. 1440), son of Sir Andrew Wardlaw, was educated at Oxford and Paris and nominated by the papal court at Avignon bishop of St. Andrews (consecrated 1403). He was tutor to James I, restored the cathedral, and, on the return of James from England, became one of his principal advisers. He persecuted the Wycliffites. Wardlaw issued the charter of foundation of St. Andrews university, in 1411.

WARDROBE, a portable upright cupboard for storing clothes. The earliest wardrobe was a chest, and it was not until some degree of luxury was attained in regal palaces and the castles of powerful nobles that separate accommodation was provided for the sumptuous apparel of the great. The name of wardrobe was then given to a room in which the wall-space was filled with cupboards and lockers. As a "hanging cupboard" it dates back to the early 17th century. For probably 100 years such pieces, massive, but often with well-carved fronts, were made in fair numbers. During the 18th century the tallboy or highboy was much used for clothes. Toward its end, however, the wardrobe began to develop into its modern form, with a hanging cupboard at each side, a press in the upper part of the central portion and drawers below. As a rule it was of mahogany, but as soon as satinwood and other finely-grained foreign oods began to be obtainable in considerable quantities, many elaborately and even magnificently inlaid wardrobes were made.

WARDROBES, THE. Although originally *garderoba* (wardrobe) and *camera* (bedroom) were synonymous, *garderoba* was early distinguished as the small room attached to the bedchamber, where clothes were kept and articles of value stored. Mediaeval kings and emperors, magnates of church and state, all had a wardrobe as well as a bedroom. But no continental *vestiarium* (wardrobe) experienced such development as that through which the *garderoba* of the kings of England passed. From a place of deposit, a mere adjunct of the king's chamber (*q.v.*), the king's wardrobe in England grew into a third treasury, and, in the 13th century, dispossessing the chamber as the financial and directive agent of the royal household (*q.v.*), became a full administrative department. Not even the wardrobe of the popes, which enjoyed some measure of authority between the 6th and the 11th centuries, can compare with it, while the wardrobe of the kings of France was always a subordinate branch of the chamber.

The increasing administrative burden of the chamber, relieved only partially by the growth and independent establishment of the exchequer (*q.v.*), imposed further duties upon the *garderoba regis* (king's wardrobe). So ably did it discharge them that, by the end of John's reign, it had developed into a rudimentary office, and before long took over from the chamber the routine work of the household. A clerical keeper or treasurer, and a lay steward, were responsible for its management, their revenue mainly coming from the exchequer, to which the keeper accounted. His statements were attested by the controller, his immediate subordinate, also a clerk, who kept a counter-roll of receipts and expenses. Under Edward I the controller became the recognized keeper of the privy seal (*see* SEALS), and the cofferer who was the third clerical officer, obtained definite title and position. Beginning as the personal clerk of the keeper, he rose to be chief bookkeeper and cashier, and the usual *locum tenens* of the keeper. By the close of the 13th century, because public matters claimed more and more of the attention of the chancery, the wardrobe had become the household secretariat; the domestic 'chancery as well as the domestic exchequer. Nor did it fulfil only domestic and peaceful functions. As the household was the nucleus of the army when the king waged war in person, the wardrobe then undertook the financial administration of the campaigns. The finances of most of Edward I's expeditions. of the Scottish offensives of Edward II and Edward III, and of a number of the campaigns of the Hundred Years' War, were administered in this way.

Thus the king's wardrobe, or wardrobe of the household, came to have a wider military and a political importance. The reason lay in its all-round usefulness. Its machinery was adaptable, and its officers, appointed by word of mouth. were directly answerable to the king. Its funds could be augmented or diminished at need, and. although its accounts had to be submitted to the exchequer for audit, it actually spent the money. It also had the use of a seal which, though in the first instance personal to the sovereign, could be and was increasingly employed in state business. These and similar considerations commended the wardrobe to king, aristocracy and ministers alike. Yet the jealous and vigilant barons did not hesitate to attack the wardrobe whenever they felt it was being used as an instrument of prerogative. It mas, for example, a result of the baronial ordinances of 1311, that in 1312 the privy seal was taken away from the controller and given a keeper all to itself.

The Great Wardrobe.—Differentiation and centralization were as ceaselessly at work within the mardrobe as without. Since both chamber and wardrobe accompained the household wherever it went, they needed places in which to store their heavier and bulkier commodities. Rooms in the king's manors were set apart for this purpose, the wardrobe being held responsible for the custody and replenishment of the stocks kept in them. A subdepartment, the great wardrobe, *magna garderoba regis*, a term in use by 1253, constituted itself to direct the necessary labour. The description "great" referred to the size and quantity of the goods stored, not to the status of the office, which was inferior to the king's wardrobe. The clerk of the great wardrobe was its head, and to begin with, all its officials, excluding the two or three stationed with the more important stores, followed the court. Up to 1324 the clerk was financed by the wardrobe, but from that year he received his revenue from, and accounted to, the exchequer, except for a brief return to former usage between 1351 and 1360. Owing to the nature and variety of the work, it was practically impossible for the clerk or his assistants to reside continually in the household. The great wardrobe was not simply a depository. Besides collecting, safeguarding and distributing goods, it also manufactured and repaired them.

The Tower of London was its first centre, but from the beginning of the 14th century, houses in the city of London were also used. Among them was a house in Bassishaw (Basinghall) ward, near the weekly cloth markets of Weavers' Hall and Bakewell Hall, and the house in Lombard street which had once belonged to the Bardi merchants. Larger and better quarters were bought in 1361, in the parish of St. Andrew's by Baynard's Castle. Here the office and its staff lived until the great fire of 1666. They then found accommodation in Buckingham street in the Savoy, but later removed to Great Queen street.

Hardly had the great wardrobe taken shape before the privy wardrobe, *priuata garderoba regis,* made its appearance as a travelling store for chamber, wardrobe and great wardrobe. There had early been in the household a small wardrobe of robes arid arms for current use, but only toward the end of the 13th century did it develop even a modest organization. Its officers were as much chamber as mardrobe servants, and such money as they needed was supplied by the wardrobe or the great wardrobe. Although their work was the care and transport of articles wanted from day to day, they soon found it advisable to have a central depository. Between 1323 and 1344 they set up a store in the Tower of London, chiefly of arms and armour. This, used by chamber and great wardrobe as well as by the household, came to be known as the privy wardrobe in the Tower. The keepers of this wardrobe, also clerks of the chamber until 1356, took their revenue from the exchequer, which also audited their accounts. Before 1360 it had separated itself from the household though it left behind a small privy wardorbe, which survived well into the 16th century, to carry on its original work. By 1399 it was as independent of great wardrobe arid chamber as it was of the household. It was looted by the peasants in revolt in 1381.

In consequence of both internal and external differentiation, and with the adoption of special means for financing war, under parliamentary control the king's wardrobe, from the latter part of the 14th century generally described as "the household," slowly degenerated into a simple office of household accounts. The process was not materially hindered even when the treasurer of war was the treasurer of the household. The privy wardrobe in the Tower lost both name and identity in the 15th century with its transformation into the king's armouries in the Tower. But the great wardrobe. still the storehouse for the household, came to be known as "the wardrobe." The cofferer of the household and the officers of the great wardrobe were suppressed in 1782 by Burke's act for economical reform. Such of their duties as were retained were divided among the lord chamberlain (*q.v.*), the lord steward (*q.v.*), and the surveyor of the buildings.

WARE, the name of a father and two sons, all ordained ministers, leaders of the Unitarian movement at the time of its development as a distinct religious denomination in the United States.

HENRY WARE (1764–1845) was born in Sherborn, Mass., on April 1, 1764 and graduated from Harvard in 1785. He came into prominence in 1805 when he was named Hollis professor of divinity at Harvard. His election precipitated the Unitarian controversy, since it indicated that control of the college was no longer in the hands of the Calvinists. In 1820 Ware defended his theological liberalism in a pamphlet debate with Leonard Woods of Andover Theological seminary which attracted wide attention. He died at Cambridge, Mass., on July 12, 1845. Henry Ware was married three times and was the father of 19 children; a number of his children and grandchildren achieved distinction.

HENRY WARE (1794–1843), son of the elder Henry by his first wife, was born in Hingham, Mass.: on April 21, 1794, and graduated from Harvard in 1812. After serving as minister of the Second church in Boston, where Emerson became his colleague and successor, he was called in 1830 to a professorship at the Harvard Divinity school. His talents were pastoral and practical rather than theological, but he was a gifted preacher and his influence on his students was profound. He died at Framingham, Mass., on Sept. 22,1843.

WILLIAM WARE (1797–1852), also son of Henry Sr. and his first wife, was born in Hingham, on Aug. 3. 1797, graduated from Harvard in 1816. In 1821 he became minister of the newly organized Unitarian church in New York city, where he stayed 15 years. The remainder of his career was devoted to literature. He wrote three historical romances dealing with the early growth of Christianity, the best known being *Zenobia* (1837). His work is a reminder of the close relationship between Unitarianism and literary culture in the flowering of New England. He died at Cambridge, Mass., on Feb. 19, 1852.

See George *H.* Williams (ed.), *The Harvard Divinity School* (1954); John Ware, *Memoir of the Life of Henry Ware, Jr.* (1846). (C. *WT.*)

WARE, WILLIAM ROBERT (1832–1915), U.S. architect and educator, established the first school of architecture in the United States. He was born in Cambridge, Mass., on May 27, 1832. After graduation from Harvard he worked in the New York atelier of Richard Morris Hunt (*q.v.*) and later formed a partnership with Henry Van Brunt in Boston, where he gave instruction to their assistants. Among the many buildings executed by the firm were several for Harvard including Memorial hall and alterations to the library, adapting for the first time in America Henri Labrouste's system of stack construction.

In 1865 Ware was appointed to establish a school of architecture at the Massachusetts Institute of Technology, Cambridge. To supplement his training with Hunt, Ware made a year's survey of schools and apprenticeship in Europe and England. His theories of teaching stated in his *Outline of a Course of Architectural Instruction* (1866; reprinted 1942) emphasized architectural design within a liberal arts background, leaving technical training in construction for postgraduate office practice. Ware went to Columbia university in 1881 to organize courses in architecture and he remained there until his retirement in 1903. He died in Milton, Mass., June 9, 1915. His writings include *Modern Perspective* (1883) and *The American Vignola* (1902–06). (CE. S.)

WARE, an urban district in the East Hertfordshire parliamentary division of Hertfordshire, Eng., on the Lea, 3 mi. N E. of Hertford. Pop. (1951) 8,253. Area 2.1 sq.mi. It is an ancient malting town with some factories making pharmaceutical and surgical goods, furniture, plastics, rail cars and coaches. The huge 16th-century "Great Bed of Ware," preserved in the Victoria and Albert museum, London, was formerly in various local inns. The Priory, founded in the 14th century, is now the administrative headquarters; Ware park, in the 16th century owned by the Fanshawes, is now a hospital.

WAREHAM, a municipal borough in the parliamentary division of South Dorset, Eng., 17 mi. S.E. of Dorchester by road, between the Frome and Piddle rivers. Pop. (1951) 2,745. Area 1.1 sq.mi. The site as the gateway to the Isle of Purbeck has been occupied from very early times, and earthworks round the town are probably Saxon. St. Martin's church, said to have been founded by St. Aldhelm about 701, was rebuilt in the 11th century, neglected for centuries and rededicated in 1936. Edward the Martyr (d. 978) was buried in Lady St. Mary's church but was later removed to Shaftesbury abbey, the marble coffin remaining at the church, however.

Wareham priory existed in 876 and was destroyed by Canute in 1015. The castle existed before 1086 and was the scene of much fighting during the civil wars.

In the 10th century there was a mint at Wareham, then a thriving port. Purbeck was at that time more of an island than it is now, with marshes high up the Frome valley. It is a peninsula about 15 mi. long and 8 mi. wide, whose low sandy shores on the north skirt Poole harbour and Studland bay, and whose rising coast on the south culminates in the limestone cliffs of St. Alban's or St. Aldhelm's head, 400 ft. above the sea. A range of chalk downs runs west-east across the peninsula, ending in vertical cliffs north of Swanage; in the south are limestone quarries which produce the so-called Purbeck marble.

WARENNE, EARLS. The Warennes derived their surname from the river of Guarenne or Varenne and the little town of the same name near Arques in Normandy. William de Warenne, who crossed with William I in 1066, was a distant cousin of the Conqueror, his grandmother having been the sister of Gunnora, wife of Richard I of Normandy. De Warenne received as his share of English spoil some 300 manors in Yorkshire, Norfolk, Surrey and Sussex, including Lewes castle. He was wounded at the siege of Pevensey and died in 1089, a year after he had received the title of earl of Surrey. Both he and his successors were more commonly styled Earl Warenne than earl of Surrey.

His son William, 2nd earl (c. 1071–1138), was a suitor for the hand of Matilda of Scotland, afterward queen of Henry I. He was temporarily deprived of his earldom in 1101 for his support of Robert, duke of Normandy, but he commanded at the battle of Tenchebrai (1106) and was governor of Rouen in 1135.

William de Warenne, 3rd earl (d. 1148), was, with his half-brother Robert de Beaumont, earl of Leicester, present at the battle of Lincoln, where his flight early in the day contributed to Stephen's defeat.

He remained faithful to the queen during Stephen's imprisonment, and in 1146 he took the cross, and was killed near Laodicea in Jan. 1148.

His daughter and heiress, Isabel, married in 1153 William de Blois, second son of King Stephen and Matilda of Boulogne, and in 1163 Hamelin Plantagenet, natural son of Geoffrey, count of Anjou. Both Isabel's husbands appear to have borne the title of Earl Warenne.

Earl Hamelin was one of those who at the council of Northampton denounced Becket as a traitor; he remained faithful to his half-brother Henry II during the trouble with the king's sons, and in Richard I's absence on the crusade he supported the government against the intrigues of Prince John.

William de Warenne (d. 1240), son of Isabel and Hamelin, who succeeded to the earldom in 1202, enjoyed the special confidence of King John. In 1216, however, as the king's situation became desperate. the earl repented of his loyalty and, shortly before the death of John, made terms with Prince Louis. He returned to his lawful allegiance immediately upon the accession of Henry III and was, during his minority, a loyal supporter of the crown. He disliked, however, the royal favourites who came into power after 1227 and used his influence to protect Hubert de Burgh when the latter had been removed from office by their efforts (1232). Warenne's relations with the king became strained in course of time. In 1238 he was evidently regarded as a leader of the baronial opposition, for the great council appointed him as one of the treasurers who were to prevent the king from squandering the subsidy voted in that year.

His son John de Warenne (*c.* 1231–1304) succeeded in 1240 and at a later date bore the style of earl of Surrey and Sussex. In the battle of Lewes (1264) he fought under Prince Edward and on the defeat of the royal army fled with the queen to France. His estates were confiscated but were subsequently restored. He served in Edward I's Welsh campaigns and took a still more prominent part in Scottish affairs, being the king's lieutenant in Scotland in 1296–97.

In Sept. 1297 he advanced to Stirling and, giving way to the clamour of his soldiers, was defeated by William Wallace on the 11th. He invaded Scotland early the next year with a fresh army and, joining Edward in the second expedition of that year, commanded the rear at Falkirk.

John de Warenne (1286–1347) succeeded his grandfather in 1304 and was knighted along with the prince of Wales in 1306 two days after his marriage with the prince's niece Joanna, daughter of Eleanor of England, countess of Bar. From that time onward he was much engaged in the Scottish wars, in which he had a personal interest, since John Baliol was his cousin and at one time his ward.

As there were no children of his marriage, his nephew Richard Fitzalan II, earl of Arundel (*c.* 1307–1376), became heir to his estates and the earldom of Surrey. His northern estates reverted to the crown, and the southern estates held by Joanna of Bar during her lifetime passed to Fitzalan. The Warrens of Poynton, barons of Stockport, descended from one of Earl Warenne's illegitimate sons by Isabella de Holland.

See G. E. C(*okayne*), *Complete Peerage,* vol. vii (1896); and John Watson, *Memoirs of the Ancient Earls of Warren or Surrey* (2 vol., *1782).*

WARFIELD, DAVID (1866–1951), U.S. actor, was born in San Francisco. Calif., on Nov. 28, 1866. His first contact with the theatre was as an usher at the Bush Street theatre in San Francisco, and his first speaking role was in *The Ticket of Leave Man,* performed in Napa, Calif., in 1888. In 1890 he arrived in New York city and began performing monologues and light comedy sketches. It was David Belasco who, seeing him perform in the slapstick Jewish comedy of the Weber and Fields company, gave him his first serious acting opportunity. Beginning in 1901 with *The Auctioneer,* Warfield was starred in one Belasco success after another. His portrayal of Anton von Barwig in Charles Klein's *The Music Master* was so successful that he performed the role more than 1,000 times between 1904 and 1907. Other successes were *A Grand Army Man* (1907), *The Return* of *Peter Grimm* (1911) and *The Merchant of Venice* (1922). Warfield died in New York city on June 27, 1951. (S. W. H.)

WAR FINANCE: COST OF WORLD WARS I AND II. This article discusses the nature of the costs of war and then presents an estimate of the costs of World Wars I and II. In later sections the methods used to finance these wars are outlined and evaluated, and some of the common fallacies regarding war finance are analyzed.

NATURE AND ESTIMATE OF AMOUNT

The most important costs of war are not measurable by the yardstick of money. The noneconomic and psychic costs of wars are not reducible to simple monetary terms. They include such costs as "blood. sweat and tears," terror, anxiety, bereavement, hatred. moral degradation, physical and mental disease and impairment and loss of life. To these must be added such real private and social costs as depletion of natural resources, lost productioq, shifts of working populations to war pursuits in which they are untrained and unproductive, housing shortages, lowering of living standards due to shortages of food. clothing and living conveniences, lowered birth rates, unrequited depreciation and obsolescence of capital equipment.

Thus the national income of Germany was impaired in both World Wars I and II by loss of territory and population. France suffered the loss of such natural resources as coal mines and forests. Britain suffered from reduction of labour power. The Balkan countries were tortured by starvation. All or nearly all warring countries lost economic efficiency, although these real costs of war differed in both kind and degree for the various belligerents.

For practical purposes, however, war finance is restricted to the direct money costs of public expenditures, revenues, debts and administration brought about by wars. The study of war finance also includes consideration of the impact of public policies dealing with war finance (taxation, borrowing, inflation, etc.) upon the national economies, primarily but not exclusively, of belligerent countries. Thus, for example, the war finance problems of the United States in World War I began before actual belligerence in 1917, and in World War II before actual belligerence in 1941.

Even with this restricted definition, there is wide variance between estimates of the money costs of both World Wars I and II. One of the primary causes of this variance is disagreement as to the proper duration of the war period itself. The period prior to the commencement of actual hostilities, covering defense and preparedness costs assignable specifically to a war, is not unambiguous. Neither is the period after the close of the war, covering postwar reconstruction costs or foreign aid. Determinations were made, but they contain elements of arbitrary judgment and are not always in agreement with each other. For World War I, some computations were founded on the assumption that the war ended with the Armistice of Nov. 1918. Others placed the end at the signing of the various peace treaties of 1919–20. Others included the cost of policing occupied areas, such as the Rhineland. Still others included payments for demobilization of men and reconversion of war industries. Some, finally, extended the postwar period so as to offset war costs by compensation for war damages, but added costs of reconstruction, of mar pensions and allowances, and foreign exchange lost as a result of depreciated domestic currencies.

The analysis given in Table I of the money costs of World War I is based upon studies by Edwin R. A. Seligman of Columbia university, and covers national budgets for the war years. Without detailed allowance for exchange variations, the costs of the belligerent nations were converted into U.S. dollars to afford a rough basis of comparison. These estimates were designed to allow for normal growth in peace expenditures, including peacetime military expenditures. The estimates made no allowance for price-level changes.

Table I.—Total War Expenditures: World War I
(in 000,000s)

Great Britain	Aug. 4, 1914—March 31, 1919	£8,601	$41,887	
Australia	Aug. 4, 1914—March 31, 1919	291	1,461	
New Zealand	Aug. 4, 1914—March 31, 1919	76	365	
Canada	Aug. 4, 1914—Aug. 31, 1919		1,545	
South Africa	Aug. 4, 1914—March 31, 1919	33	243	
India	Aug. 4, 1914—March 31, 1919	119	584	
British empire				$46,085
France	Aug. 3, 1914—March 31, 1919	169,000 fr.	$32,617	
Russia	Aug. 1, 1914—Oct. 31, 1917	51,500 Rb.	26,522	
Italy	May 23, 1915—May 31, 1919	L. 81,016	15,636	
Belgium	Aug. 2, 1914—Oct. 31, 1918	5,900 fr.	1,387	
Rumania	Aug 27, 1916—Oct. 31, 1918		907	
Serbia	July 28, 1914—Oct. 31, 1918		635	
United States	April 5, 1917—June 30, 1919		32,261	
Entente powers				$109,965
Germany	Aug. 1, 1914—Oct. 31, 1919	204,268 M.	$48,616	
Austria-Hungary	July 28, 1914—July 31, 1919	119,504 kr.	24,858	
Turkey	Nov. 3, 1914—Oct. 31, 1918		1,802	
Bulgaria	Oct. 4, 1915—Oct. 31, 1918		732	
Central powers				$76,008
Total				$232,058
Loans to Allies				
Great Britain		£1,739	$8,467	
France		6,700 fr.	1,293	
Germany		9,500 M.	2,261	
United States			9,102	
Total				$21,123
Total net war expenditures*				$210,935

*"The figures cover the cost of the war up to a period from six to twelve months after the conclusion of hostilities. In many countries however, large expenses directly connected with the winding up of the war continued, and in any final statement the prodigious figures of the cost of reconstruction and reparation would have to be added. These will without much doubt ultimately well-nigh double the above estimate." Edwin R. A. Seligman, *Essays in Taxation,* 10th ed., rev., p. 7.57, Macmillan Company (New York, 1925).

According to Seligman, the total gross cost of World War I during the fiscal years of combat alone amounted to $232,058,000,000, while the net cost reached $210,935,000,000. Computing average daily expenditures for the various countries. Seligman found that for Great Britain the figures ranged from $9,500,000 (1915) to $32,500,000 (1918). Corresponding figures are: for Germany $13,000,000 (1914) to $34,500,000 (1918); for Italy, $4,500,000 (1914) to $10,500,000 (1918); for Russia, $5,800,000 to $47,000,000. For the U.S. the second month of the war showed a cost of $15,000,000 per day. which increased to nearly $50,000,000 in Oct. 1918. The daily war expenditures for all belligerents averaged $164,500,000.

The interwar period was characterized by an overlapping of national payments of principal and interest on national debts, veterans' pensions and relief costs of World War I with the rising military expenditures preparatory to World War II. The additional costs stemming from the world-wide depression of the 1930s also reduced the possibility of repayment of earlier mar obligations. Many times in history the total costs of an earlier war had not been met when a later war began. Great Britain, for example, may be said never to have finished paying for the Napoleonic Wars. The extent of the overlap in the case of World Wars I and II, however. was unprecedented.

As of the latter 1950s the total costs of World War II had not yet been estimated with either the precision or the reliability of the Seligman estimates of the total costs of World War I. In the case of one major belligerent, China, no estimates worth reproducing appeared to be available. If we ignore costs incurred after June 1948 (interest on war debts, pensions and care of veterans, grants-in-aid and credits for rehabilitation and reconstruction, etc.) the highly tentative results of Table II may be presented. As will be noted from this table itself, the beginning and ending dates differ for the several belligerents, and the omission of data for China leads to a serious underestimate. The total in U.S. dollars (at 1956 value) comes nevertheless to nearly $1,167,000,000,000, or nearly three times the 1956 gross national product of the U.S. World War II was a "million million dollar war," even in the restrictive meaning of war finance and with the restrictive choice of beginning and of ending dates used in this article. The National Industrial Conference board predicted that by 1972 the total costs of World War II to the U.S. alone may rise to $700,000,000,000 as the volume of continuing costs increases steadily.

TABLE 11.—*Estimated Minimum Costs of World War 11*

Country	Cost
U.S. (July 1, 1940–June 30, 1946)	$387,000,000,000
Germany	272,000,000,000
U.S.S.R.	192,000,000,000
United Kingdom	120,000,000,000
Italy	94,000,000,000
Japan	56,000,000,000
Canada	15,680,000,000
France (1935 to the capitulation)	9,000,000,000
(after Normandy landings)	6,000,000,000
South American countries	8,000,000,000
Belgium	3,250,000,000
Poland (to fall of Warsaw)	1,550,000,000
Netherlands (to invasion)	925,000,000
Czechoslovakia (1935 to invasion)	800,000,000
Greece (1935–42)	220,000,000
Yugoslavia (1935–42)	200,000,000
Mexico	200,000,000
China (estimates unreliable)	...
Estimated minimum costs of World War II	$1,166,825,000,000

METHODS OF FINANCING

War costs are met by a number of fiscal methods in various combinations, of which the following are the most important: (1) Taxes; these may be either direct—on the income and wealth of individuals and corporate bodies—or indirect—mainly sales and excise levies on goods and services. (2) Compulsory loans; these include compulsory purchases of public securities and taxes made more acceptable by promises of future partial refunds, with or without interest. (3) Voluntary domestic loans; these involve the purchase of public securities either from voluntary savings or from credit created by banking systems. (4) Foreign loans; these loans may be of two types: in cash or credits in the foreign country, or in goods or in kind (lend-lease). (5) Creation of money (the printing of new paper money) either by the public treasury or by a central bank or other semipublic institution.

None of these methods of financing is limited to war costs, but many are used almost exclusively for this purpose. Many novel, interesting and far-reaching expedients which sometimes proved of permanent value have been devised under each head, to meet the added demands of war periods.

Taxes.——For example, in the U.S. the expansion of the importance of the personal income tax came as a result of World Wars I and II. In each conflict, the rates for the higher brackets were increased drastically, although never to the 100% level proposed by Pres. Franklin D. Roosevelt in 1942 for incomes over $25,000. At the same time, exemptions were lowered to such a point that the income tax became for the first time a "mass base tax" during World War II. A further change in income tax administration which appeared to be permanent was a shift in 1943 to a "pay-as-you-go" or deduction-at-source system, which enabled high wartime rates to produce tax yields a year sooner than they would have done otherwise. (This shift was accompanied by partial forgiveness of 1942 taxes due on the prior lagged basis.) (See INCOME TAX.)

Wartime corporate income-tax rates were raised and supplemented by excess-profits levies on all corporate income substantially above a prewar base and affecting a relatively high percentage of capital income. These excess-profits taxes, at rates up to 85%, were deemed unfair to growing companies and were also accused of encouraging wasteful expenditures. They were replaced after the close of hostilities. (See EXCESS-PROFITS TAX.) Proposals to apply the same principle to taxation of differential incomes of individuals were made many times but were not enacted.

A number of European and Asian countries experimented with capital levies and special taxes upon the property of persons not suffering war losses. A similar proposal was made but not enacted in Great Britain after World War I. (See CAPITAL LEVY.) Capital levies had not as of the latter 1950s found much backing in the U.S., perhaps because the distinctions between war sufferers and others were less marked than in countries with relatively larger losses in manpower or capital through bombing or invasion.

Before World War I the U.S. federal government's excise taxes were largely limited to levies on tobacco products and liquors. The exigencies of war finance produced a multitude of "nuisance taxes," mainly on semiluxuries. It is conceivable that these might have been combined into a federal sales tax in World War II, had not state sales taxes previously pre-empted much of the field. At any rate, proposals for federal sales taxes were voted down, as were proposals for spending taxes to be added to the income tax. (A spendings tax is essentially an income tax with a savings deduction.) In Great Britain and many other belligerent countries. general sales levies did result. and at high rates. The British purchase tax was $16\frac{2}{3}\%$ on most items and $33\frac{1}{3}\%$ on luxuries.

Compulsory Loans.—Compulsory loans have been generally frowned upon by specialists in public finance, although a certain amount of public pressure has often accompanied subscription to voluntary ones. With the publication of John Maynard Keynes's How *to* Pay for *the War* (1939) there came a substantial revision of this appraisal. particularly in Great Britain and the dominions. Part of the increased income tax of the smaller taxpayers in the United Kingdom was made refundable after the war at a time chosen by the state. This form of taxation was not particularly successful. Payments seem to have been looked upon as taxes by the payers, and refunds were never made in purchasing power equivalent to what was promised.

Voluntary Domestic Loans.—In considering voluntary loans, one must distinguish between purchases by nonbankers from voluntary savings and purchases by bankers and others from credit created by bank expansion. The first type of loan is generally not inflationary in its effects. although occasionally purchasers of government securities may require credit expansion for other investment projects. The second type of loan is approximately as inflationary as would be the printing of the same amount of new paper currency.

In both World Wars I and II, the second more than the first, attempts were made to place loans primarily with voluntary savers who would, it was hoped. reduce private consumption and private investment in order to buy and hold government securities. (The holding throughout the war and postwar emergency is of course as important for financial stability as the initial purchase.) These attempts were not entirely successful in the case of any major belligerent power. In World War I the main inducement was high interest rates, which became higher as the combat progressed. In World War II receipt of high interest by the public creditor was frowned upon generally as a maldistribution of income akin to profiteering. Rates were held down, giving rise to the phrase "two per cent war." but purchasers were effectively guaranteed against capital losses by express or implied promises of governments and central bankers to repurchase the securities at or above par. This process of guaranteeing bond prices led to monetization of much of the public debt, since the promises concerned could not be fulfilled except by credit expansion to repurchase the debt offered for resale. In both wars a wide variety of securities of varying rates and maturities was offered, designed to fit the desires of different classes of lenders. In general, the longer the issue, the higher the rate was. In the U.S., in World War II, banks and corporations were not permitted to hold some of the most attractive (highest yield) long-term issues, the so-called Series E bonds, and private individuals' holdings were also restricted in amount. An important difference between British and U.S. practice was the widespread use by the British of perpetual annuities (consols) with no due date whatever. The longest U.S. issues were 25-year bonds, paid at maturity with the proceeds of refunding issues.

Even with the inducements of high interest rates in World War I, and price fixing in World War II, much of the voluntary domestic lending was done by the commercial banks, who either held the securities themselves or advanced credit for others to buy them. Either procedure produces an increase in "checkbook money" and, therefore, inflationary pressure. Over the five fiscal years 1941–46 inclusive, the U.S. banking system absorbed $89,300,000,000 of federal securities, as against $131,400,000,000 for all other investors. (See Table VI.)

Foreign Loans.—Foreign lending shifts part of the cost of a war from the borrowing to the lending country. If the loan is repaid subsequently, lending permits the war cost of the war generation in the borrowing country to be shifted to the subsequent generation which repays the loan. This special case is interesting, because it is the only one which permits politicians to do what they usually advertise they intend to do, namely, to share the cost of a war with future generations. If the lending country is also a belligerent, the loan increases the cost of war as far as it (the lending country) is concerned, the increase being reimbursed to a subsequent generation if the loan is repaid. Even here, if we view the world as a unit, the cost of the war is borne by the war generation, but from the point of view of the borrowing country alone. there has been a partial escape.

In both World Wars I and II the United States was the major lending country. In World War I and shortly thereafter, U.S. loans took the conventional form of dollar credits in the Cnited States. The face amount of the loans was scaled down substantially in subsequent negotiations, but it proved impossible for the European debtors to repay them except indirectly—out of the proceeds of private U.S. loans to Germany and German reparations payments to the Allies. A major reason for the difficulty in payment was the high U.S. tariff, which hampered the sale of European goods in the United States. After U.S. loans to Germany ceased (1928–29), dollars for reparations payments were no longer available to the German government for reparations and the triangular repayment process on the U.S. war debts broke down.

TABLE III.—*World War I Debts Owed to the United States as of June 30, 1948*
(in $000,000. Figures are rounded and will not necessarily add to totals)

In World War II a larger volume of U.S. lending was carried on in kind, through the medium of lend-lease (see INTER-ALLIED DEBTS). Repayment (sometimes in the form of the specific goods lent. *i.e.*, warships, and sometimes in the form of "reverse lend-lease") was only fractional, as of the latter 1950s, but the

Total	$7,819,322,000

*Revised as of Sept. 30, 1946.

acrimony of the "war debt" controversy of the 1920s and early 1930s had been avoided. thanks to the lend-lease expedient. Table IV gives a commodity and country breakdown of the $46,500,000,000 of lend-lease aid expended by the United States between March 1941 and Dec. 1945. The country breakdown, which is perhaps the more revealing, indicates that two-thirds of the total went to the British Commonwealth countries and nearly one-fourth to the U.S.S.R. Table V gives only a commodity breakdown of the $7,800,000,000 of reverse lend-lease received by the U.S., almost entirely from commonwealth countries.

Creation of Money.—The most forthright form of inflationary financing is resort to the printing of new paper money. It is also normally the last resort, to which governments turn when they cannot collect taxes and when their credit breaks down. Usually the printing is not done by the government directly, but by the central bank which then lends the newly printed money to the government. The most extreme examples of this sort of financing have occurred in the wake of wars which have been lost, or have been highly destructive, or both. Austria, Germany. Hungary, Poland, Rumania and Russia suffered major "hyperinflations" after World War I. China, France, Greece, Hungary, Italy, Japan and Poland were among the major victims after World War II. (See Table VII.) In the U.S. and Great Britain, monetary expansion was confined initially to credit or checkbook money, the result of the creation of deposit credits by the commercial banking system. Expansion of currency was limited to amounts needed as a consequence of general monetary expansion and the results thereof.

Of all these alternative forms of war finance, only the foreign loans enable cost to be shifted from the generation which fights the war—in the borrowing country—to the generation which repays the loan. Of all these alternatives, none avoid inflation from the supply side (reduction of real output) unless they produce actual treasury surpluses (or unless real output is not in fact reduced). Taxation and domestic lending by nonbankers, if sufficient in amount, can, however, prevent inflation from the demand side, by reducing private demand for goods and services in the same proportion as government demand is increased. Prices of specific goods and services will, however, rise and fall sharply even in this case, for the wartime composition of demand is different from the peacetime one. There is no system of war finance which can prevent upward pressure on the price of steel, but some systems of war finance can balance such a rise by forcing down the prices (net of tax) of peacetime goods like candy, cigarettes and so on.

Good resolutions to avoid borrowing and inflation are common

at the outbreak of every major war. They are, however. forgotten as soon as the tax burden which would be necessary for such a purpose becomes apparent A major belligerent is considered highly fortunate if it can meet half its war costs by taxation The U.S was perhaps the wealthiest participant in both World Wars I and II. At the start of U.S. participation in World War II, Henry Morgenthau. Jr.. secretary of the treasury. affirmed his intention to finance the war at least two-thirds by taxation. (The World War I proportion had been approximately one-third.) But over the six fiscal years 1941–46 inclusive. the record (Table VI) shows that of $387,000,000,000 of federal expenditures. $220,700,000.000 (57.3%) was in fact met by borrowing.

EVALUATION OF FINANCING METHODS

Problems of Taxation.— Single-minded reliance on taxation in war finance would not be an unmixed blessing. High taxation reduces the popularity of war and perhaps reduces morale. meaning the will to attack or to resist. It may therefore lose the mar in the name of sound finance. There are also fears of adverse reactions on productive effort and efficiency, supported by much evidence in individual examples but nothing definitive for an economy as a whole. The Australian statistical economist Colin Clark has propounded the thesis. leaning most heavily upon French experience, that taxes aggregating more than 25% or 30% of the national income of a democratic country may themselves be inflationary (even if they can be enacted and enforced for a long period, which Clark doubts) in that they reduce total supply to an even greater extent than they reduce total demand. Clark's statistical estimate is tentative and may be too low, but it is plausible that some such limit to taxation must exist well short of 100%, particularly in countries which try to maintain most of their civil liberties in wartime.

Perhaps even more important than the aggregate tax burden is the question of its distribution among social and income classes. Spokesmen for each group in war situations proclaim their patriotism and willingness to shoulder increased burdens — provided only that other groups bear their fair shares as well. (Concepts of fairness, in this matter as in many others, differ widely from group to group.) Representatives of labour, for example, have been in the Anglo-Saxon countries the main advocates of increased rates in the higher brackets, together nith higher corporate and excess-profit levies, as bases of war finance. Business spokesmen, on the other hand, prefer to concentrate income-tax increases in the lower brackets and to broaden the income-tax base by lowering exemptions. while expanding the scope of indirect (excise) taxation.

Inflationary Finance.— Maior reliance on voluntarv loans. whether from domestic or foreign sources. made out of genuine saving, is hardly possible for important powers in prolonged wars, although tsarist Russia made a valiant attempt to finance World War I by this means. Sooner or later. in the case of a destructive modern war the prospects for repayment deteriorate As a result, the borrowing country must create the money or credit which is ostensibly being lent to it. and the economy passes to some form of inflationary finance.

An almost infallible sign that passage to inflationary finance is contemplated, or has already occurred. is the suspension of the convertibility of the national currency into gold (World War I) or into the more stable currencies of the world, such as the Swiss franc and the U S. dollar (World War II).

Inflationary finance does not necessarily lead to immediate inflation. In the earlier stages of hostilities, as in 1939–40 in Britain and 1941–42 in the U.S.. there may exist substantial reserves of labour and other resources nhich are unemployed involuntarily. These can be put to work at existing nages and prices as a result of increased demand. which can itself be created by inflationary war finance. Even in these cases. "bottlenecks" of fully employed resources appear early in the expansion process. trade unions and trade associations take advantage of the situation to raise wages and prices which they consider "substandard" or "unfairly low" before full employment or production is reached, and inflation gets under way in appreciable measure before any point identifiable as "full employment" is attained. In the discussion which follows, inflationary war finance will be treated as meaning actual inflation, despite the possibility of an interval in which it does not.

There are two major objections to wartime inflation, whether financed by the printing press or by credit expansion. The first standard objection is that inflation distributes the burden of war costs in an arbitrary and capricious manner. The distribution among the citizens depends on the fixity of their incomes rather than the amounts. Creditors, *renfiers* and pensioners, rich and poor alike, are ordinarily the hardest hit, followed by landlords, civil servants and other salaried employees. At the other extreme, positive gains accrue to heavy debtors, rich and poor alike: including speculators who, foreseeing inflation, deliberately put themselves in a debtor position in order to buy real assets. The second standard objection to wartime inflation is that after the process reaches a certain point not easily identified, it is at least as effective in lowering production as high wartime taxes mould have been. Inflation, generally speaking, puts a greater premium on hoarding of raw materials and durable goods; on holding of real estate, jewelry, foreign exchange and a wide variety of other assets, relative to most types of productive activity, than exists in normal times. Therefore, resources shift from productive to nonproductive uses, so that the production and employment effects of inflation eventually prove disappointing, particularly if the economy passes to a situation of "hyperinflation" in which the price level rises faster than the money supply. This is not to deny the major claim made for inflation. namely that its earlier and milder stages usually encourage both production and employment. This is generally true so long as the inflating country's money illusion persists in considerable degree, which may be quite long in countries without recent inflationary history. Money illusion is a term applied to people's tendencies to regard a dollar as a dollar, or a franc as a franc, whatever may be happening to its purchasing power. Money illusion has been important in inducing people to hold larger money balances during the earlier stages of an inflation than they otherwise would have done, and likewise in inducing them to work more effectively and increase production in response to higher money returns. It therefore serves to increase output and employment, and simultaneously to retard inflation.

*Rough estimate. †Year 1948, as per cent of Jan.–June 1939. ‡Not available. Source: A. J. Brown, *The Great Inflation, 1939–1951*, Tables III and IV, pp. 302–305, published for the Royal Institute of International Affairs by the Oxford University Press (1955).

Despite the strictures of economists and financiers against war inflation and inflationary war finance, it is almost impossible in practice for an important democratic power to wage a major war without a considerable rise in its general price level. This is particularly true if the country starts from a situation at or near full employment. The democratic political process apparently requires considerable time before any adequate program of noninflationary finance can be prepared. and before its burden distribution (as well as the total burden) can be made palatable to the representatives of the electorate. The more realistic question is whether war inflation can be reversed after hostilities end. Again there is no mechanical reason nhy it cannot be reversed; the problem is the political one of resistance by business. labour, agricultural and debtor economic interests. After World War I a reversal was attempted in Britain, the U S , Japan and a few other countries, in the name of commercial morality and sound finance. The method used was the accumulation of gold reserves and eventual return to the pre-1914 gold standard at the pre-1914 price of gold This reversal was successful only temporarily. and then in the depths of a severe economic depression intensified by these deflationary policies. After World War II the fear of reneued depression outweighed considerations of financial morality. Deflationary measures were limited to "currency reforms," featuring partial confiscation of wartime savings which had been held in currency or public securities. They had varying degrees of success and equity—those in west Germany and the U.S.S.R. being apparently the most effective. In no country had the general price level by 1956 returned to its pre-1939 level, and price index numbers have been reconstructed on a postwar base (usually 1947–49). (*See* Table VII.)

Suppressed Inflation.—This discussion of inflation has dealt up to this point with the ordinary or "open" variety. In open inflation any increases in the supply of money, or decreases in the supply of goods, are permitted to exercise their full influence on all prices. Open inflation, however, is seldom if ever tolerated in wartime without some restraints. In World Wars I and II particularly, and in the second more effectively than in the first, inflation was to a considerable extent suppressed or repressed by direct controls over individual prices, wages, rents and so on. At the controlled prices of goods and services, demand generally exceeded supply, and the more so since part of the supply was usually diverted to free. illegal or "black" markets. (In defeated or badly weakened countries, especially, this diversion eventually caused the breakdown of much or all of the control system.)

Because it involves continuous maintenance of imbalance betueen demand and supply, suppressed inflation has been called a "disequilibrium system" by a leading U.S. exponent, J. K. Galbraith For many of the more important groups of commodities, price controls were supplemented by quantitative restrictions on demand, such as rationing of consumption goods and allocation of labour and production goods. Proposals for generalized "expenditure rationing" of all goods were made by a group at the Oxford Institute of Statistics during World War II and again by a group at Stanford university, Stanford, Calif., in the early 1950s when the Korean conflict threatened to expand. They were not adopted, however. and for most goods and services rationing was quite informal during both wars. Pure chance: favouritism and "tie-in sales" by dealers, time available for shopping and waiting in line and barter arrangements were perhaps the four most important factors in determining who got what among the scarcer items.

The disequilibrium system of suppressed inflation was probably less damaging to public morale in Great Britain and the U.S. in both World Wars I and II than rival systems which might have led to heavier taxation or more inflation. There were complaints about controls and shortages, and substantial evasion, but until shortages became really acute citizens did not resent the savings forced on them by the disequilibrium system as much as they would probably have resented taxation so drastic as to make savings impossible at wartime levels of consumption, or open inflation in which the value of their savings would have evaporated visibly. It was further anticipated, both in Great Britain and the U.S., that World War II in particular would be followed after a short boom by return to the depressed conditions of the 1930s. In the case of such a depression, the accumulated wartime savings could have been released to support economic activity without risk of inflation. Anticipated depression and possible unemployment in the postwar period also encouraged accumulation of savings during wartime, and aided the maintenance of the disequilibrium system itself. As is well known, however, the predictions of postwar depression proved entirely erroneous, at least in the "cold war" atmosphere of the decade 1946–55.

In no country was it practicable after World War II to retain wartime savings immobile in cash or government securities, awaiting the long-postponed postwar depression. In the U.S. the controls of the disequilibrium system were repealed piecemeal within 18 months of the close of World War II. (They might have broken down in a wave of violations had they remained on the books.) The subsequent rush to spend drove U.S. prices to levels approximately predictable from the wartime accumulation of liquid assets—money, credit and government securities convertible into cash without risk of loss. This is not to say that the inflation mould have proceeded no further in the absence of controls than it did after their repeal. On the contrary, greater over-all monetary expansion might have been required if massive inflation had begun earlier. At any rate: the wartime savers were expropriated by the postwar price rise quite as they would have been by open inflation during the war—but the postwar price raise came too late to affect wartime morale and war production.

In Britain. the Netherlands and the Scandinavian countries, controls mere retained for several years longer and removed only gradually. None of these economies had by 1956 returned completely to its pre-1939 pattern of freedom. The difficulties which developed were different from the U.S. ones. In a regime of controls, it was not always easy to provide incentives to work, to invest, to move from place to place or from one activity to another, for people who could live off their past savings or present earnings as comfortably as the rationing system permitted. Another problem was that of obtaining sufficient exports to pay for these countries' necessary imports, since at the low controlled prices the home market stood willing and eager to buy all that was produced. A third problem was the relative unprofitability of controlled (essential) production as compared with uncontrolled (nonessential) lines. and the constant threat of drawing productive resources precisely where they were least wanted.

It is highly probable that suppressed inflation, or the disequilibrium system. will underlie the war finance of participants in any future major war, at least in its early stages (before adequate and equitable tax revisions can be made). It seems doubtful, on the other hand. whether the unique morale benefits of suppressed inflation, as compared either with taxation or open inflation, can be expected to recur until their history in World War II and its aftermath is largely forgotten.

SOME FALLACIES OF WAR FINANCE

A number of the more pervasive fallacies of war finance have been touched upon in the foregoing discussion, but it may be worth while to consider them explicitly in view of their popularity as wish fulfillment among both voters and politicians.

Transfer of Costs to Future Generations.—Perhaps the most important and widespread of such fallacies is the fixed idea that a country can, by borrowing or by other forms of financial legerdemain, transfer its war costs to future generations (without borrowing abroad during wartime) and thus evade them so far as concerns the wartime generation itself. Unfortunately for this hardy perennial, there are real costs underlying the monetary ones, the real costs being goods and services. When the government uses these real goods and services for war, it bids them away from other spenders once and for all. These other spenders pay these real costs in goods and services at the time they are bid away. No manipulation of borrowing and lending can conceal this. On the other hand, if the resources used by the government in wartime are not bid away from others but from involuntary unemployment, they do not cost the government anything whatever in real terms—at least in the limited sense in which "cost" is being discussed here. If the government finances itself by taxes, the taxpayers pay the cost, although in some cases they may shift it to others by the intricate processes of tax shifting. If the government finances itself by loans, it is the savers and lenders who are deprived of real goods and services. If the government raises funds in mays which lead to open inflation. the cost is borne by the fixed income groups. If there is suppressed inflation. the cost is borne by consumers and others aho, unable to buy what they want at controlled prices, are forced to save instead.

When a war loan is subsequently repaid, there is no assumption of the cost of the war by the postwar generation as a whole. but only a transfer from the taxpaying to the bond-holding members of this generation. Similarly when the network of controls of a disequilibrium system are removed after a war, there is a transfer between groups in the postwar generation. The gain is to the nartime savers who can now buy all they want, and the loss is to the fixed-income members of the postwar generation whose purchasing power is cut. If the controls are lifted in conditions of depression and unemployment, the gain to the wartime savers or their heirs will involve no balancing loss. The involuntary savers of wartime, or their successors, will recover postwar approximately what they lost in wartime. On the theory of shifting war costs to postwar generations, however, their fate should have been precisely the reverse.

"The Boche Will **Pay"** Theory.—If the costs of war cannot be shifted to future generations in one's own country (except, again, by foreign loans floated during wartime), it follows that they cannot be shifted to future generations of one's allies or enemies, even if one's country emerges completely victorious. The opposite view, embodied in the slogan, "The Boche will pay," dominated French war finance in World War I, and the attempt somehow to "make the Boche pay" in later decades explains French intransigence on the issue of reparations.

To the extent mar indemnities can be collected, victorious countries are repaid after the war for part or all of their mar costs and defeated countries must pay the corresponding postwar increment to their war costs. The war costs themselves, however, meaning the real goods and services, will have been paid in the first instance by each country on its own, and by the generation which fought the war. A country may be fortunate enough to have its war costs repaid in part or in full by defeated enemies after the close of hostilities, but it cannot avoid paying those costs at the outset.

The receipt of reparations, or the repayment of war loans, is not an unmixed blessing to all econoinic interest groups in the receiving countries. Payment is ordinarily made in part by increasing the paying country's exports of goods and services to the rest of the world, including the receiving country, and in part by reducing the paying country's imports of goods and services from the rest of the world, again including the receiving country. These processes are not normally looked on with favour by either the export industries or the import-competing industries of the receiving country, who sometimes attempt to check them by export subsidies, high tariffsor import restrictions. It goes without saying that if the receiving country is an important trading partner of the paying country, such restrictions reduce greatly the likelihood of the reparations ever being collected or the war loans ever being repaid.

TABLE VIII.—*National Debt and Annual Interest Charge, U.S., Selected Years, 1916–50, Showing Effects of World Wars I and II*

Year ending (June 30)	Total gross debt in ($000,000,000)	Annual interest charge (in $000,000)	Per cent of gross national product	
			Principal	Interest
1916	1.2	23	2	Less than 0.05
1919	25.5	1,054	35	1.4
1930	16.2	606	18	0.7
1939	45.9	1,149	50	1.3
1950	257.4	5,613	100	2.2

Effectiveness of the Disequilibrium System.—It is generally fallacious to believe that direct controls. or the disequilibrium system. can permit a war to be financed with neither heavy taxation nor price inflation. This belief is correct only to the extent that the controls concerned are retained indefinitely after the close of hostilities, or at least until the onset of a postwar depression or stagnation, and are then repealed gradually so as to maintain purchasing power. However, such a postwar depression or stagnation may never come, and in most actual situations the controls are repealed or nullified early enough to generate postwar inflation, or else the abnormal savings they have induced are expropriated by a capital levy or a currency reform.

Effectiveness **of** a Balanced Budget.—Even when a war begins in a situation of full employment of resources, it is widely believed that a balanced government budget will suffice to prevent inflation, and the aim of war finance on the taxation side is limited to achieving such a balance. This belief, too, is usually false, and a surplus budget will usually be required to prevent inflation. There are two reasons for this result, which K. E. Boulding called "the principle of overfinance." (1) The supply of goods and services may fall, by reason of war damage and diversion of resources to military uses. If so, maintenance of the peacetime volume of money demand will produce inflationary results. (2) A balanced budget taxes marginal dollars from those who would otherwise have saved some portion, and transfers them to a government which spends the entire amount. There is then a net expansionary effect. To compensate for it. a budget surplus mould be desirable, but this is highly difficult to achieve under wartime conditions.

Effectiveness **of** Sales **of Securities.**—When it comes to loan finance, popular thinking does not distinguish adequately between the effects of sales of securities to the banking system and sales to genuine (nonbank) savers. To put the matter differently, the public draws too sharp a distinction between financing a war by printing new money and by bank credit expansion. Sales of securities, particularly long-term securities, to nonbankers is a real alternative to taxation and inflation, unless there is an express or implied guarantee to repurchase these securities whenever their market price declines. This is equally true of sales to bankers, if they increase their holdings of government securities by reducing their holdings of commercial paper or other assets. On the other hand, loans financed by the lender (or his banker) either by the printing of new paper money or by the creation of checkbook money on the books of a commercial bank are just as inflationary as any other means of currency or credit expansion.

Bankruptcy.—Whether war loans are domestic or foreign, from savers or from banks, inflationary or noninflationary, they increase the borrowing country's national debt. Table VIII illustrates the effects of World Wars I and II on the national debt of the U.S. and its annual interest charge.

A discussion of war finance need not involve full treatment of the related subjects of debt burden and debt management. One important fallacy, however. should be mentioned, namely. that a domestically held debt may bankrupt the borrowing government. This is not correct. In the first place, the principal may never come due if, as in the British case, it takes the form of perpetual annuities or consols. In the second place, when portions of the principal come due, they can be repaid by new borrowings, known as refunding issues, if they cannot be paid out of current surpluses. Finally, even if a refunding issue cannot be floated on terms satisfactory to the government, payment can always be made in money printed for the purpose of debt retirement. Governments possess monetary sovereignty or, as A. P. Lerner has put it, "Money is a creature of the State." A government may choose to repudiate a debt, or to meet it by inflationary means, but however large its outstanding obligations and however meagre the resources available to meet them. it cannot be forced into bankruptcy against its will save by another government. See also **Inflation and Deflation; Debt, Public.**

WAR GRAVES. The United States maintains a national cemetery system in which any member of the armed forces who dies during or after honourable service in war or in peace may, upon application being made to the quartermaster general. receive a grave site marked with a durable headstone and be buried with military honours. This award includes burial space for spouses and minor dependent children. Provision is also made for supplying a government headstone to mark the graves of the far greater number of military dead—about 80% of the whole—for whom burial in private cemeteries may have been provided. The American Battle Monuments commission. an independent authority established in 1923 and reporting directly to the president, administers two groups of military cemeteries in foreign lands, one serving as a memorial to those dead of World War I whose relatives requested burial abroad, the other similarly associated with World War 1 With interments restricted to war fatalities, only these cemeteries may be regarded as war graves in the strictest sense of the term.

Without precedent in history, excepting possibly the example of the ancient Greek city-states which paid signal honours to their citizen soldiers slain in battle, American burial practices may, in part, be attributed to extraordinary conditions formerly encountered by the regular military establishment in the Indian borderlands. In those days post commanders were compelled to bury all the dead of their garrison communities. Also important has been the traditional policy of reliance on citizen levies in time of war.

During the Civil War the federal government recognized the obligation of affording a decent burial to all who fell in defense of the republic. Army regulations required individual burial in registered graves. and an act of congress. approved April 16, **1862,** authorized the president "to purchase cemetery grounds . . . to be used as a national Cemetery." This led to the establishment in 1864 of Arlington National cemetery (*q.v.*) near Washington, D.C.. the best-known national cemetery. Between 1862 and 1870 a total of 299,696 Union dead mere laid to rest in 73 national cemeteries. Recovery of many of these remains from scattered battlefields and reinterment in a national cemetery served to commit the national government to an obligation to return war dead to their native soil. The graves of soldiers who served in the Confederate states army were subsequently marked at public cost by a distinctive marble slab. The precedent of the 1860s was applied without question to the Spanish-American War, the Philippine insurrection and the north China expedition. Furthermore, the nation assumed another obligation of far-reaching consequence in according to next of kin of the dead brought back from these distant theatres the privilege of selecting a national cemetery or some private burial ground as the final resting place. Another major tenet of policy emerged from World War I when in deference to wishes expressed by many relatives of the dead, the government made provision for permanent burial overseas.

World War I.—When the United States took up arms against Germany in 1917, the secretary of war established a specialized organization consisting principally of quartermaster graves registration companies for care of the dead. Identification tags became a required item of equipment for every soldier. Trained in the techniques of body identification, the theatre graves registration service performed an unprecedented feat by identifying over 95% of all fatalities.

Return of World War I remains came to a culmination with the entombment of the Unknown Soldier at Arlington National cemetery on Nov. 11, 1921. Of approximately 79,000 World War I fatalities, 46,520 were shipped to the United States, with 5,800 going to national cemeteries and 31,591, including the unknown dead, being interred in eight national military cemeteries—one in England, one in Belgium and six in France. Established and developed over a period of 11 years, these cemeteries remained under administration of the war department until 1934, when they were transferred to the American Battle Monuments commission.

World War II.—Despite the destructiveness of World War II, there were no basic changes in U.S. policy or organizational arrangements for care of the dead and final disposition of remains. Yet the mechanization of tactical units, together with the increased power and range of air fleets, transformed warfare from prolonged battles of attrition between sluggish infantry masses to violent conflicts between mobile formations, endowed with firepower never before delivered in action. Ocean tides claimed the bodies of many slain in amphibious assault landings; air routes to distant targets behind enemy lines were strewn with the remains of fallen airmen. The fragmentation of bodies, particularly those recovered from plane wrecks and incinerated tanks, imposed difficult problems of identification. In brief, a new situation demanded refinements in the application of techniques and improvements in details of organization.

Following World War II, the secretary of war established the American Graves Registration service, with separate overseas commands under direction of the quartermaster general. The memorial division of the office of the quartermaster general served much as a special staff in the planning and general supervision of operations. The postwar graves registration organization was charged with final disposition of the dead of all armed services—the army, navy, marine corps and coast guard services—as well as several civilian agencies, such as the maritime commission and the American Red Cross.

After consultation with leading experts, the quartermaster general established central identification laboratories in which unidentified remains were subjected to X-ray and fluoroscopic examination. Anthropologists then applied their techniques to skeletal remains for determination of race, sex, approximate height and age and probable cause of death. Many such examinations led to individual identification of airplane and tank crew members, while others disclosed evidence for consideration of the War Crimes commission. Out of 360.812 World War II fatalities, 281,857 were recovered, leaving 78,955 "nonrecoverable" dead. Of those recovered 273,366 (96.98%) were identified. These unknown dead numbered 8,491.

The American Graves Registration service completed its task on Dec. 31, 1951, having shipped 171,264 casketed remains to the United States and 3,803 to next of kin in foreign countries for burial in private cemeteries. Of those returned to the United States, 38,472 were interred in national cemeteries. The National Memorial Cemetery of the Pacific, at Honolulu, T.H., and the Puerto Rico National cemetery, both of which were established subsequent to hostilities, received 13,652 war remains. In addition, the American Graves Registration service completed approximately 93,130 interments in 14 newly established military cemeteries. Including 8 cemeteries of World War I, the American Battle Monuments commission administers 22 cemeteries—2 in England, 3 in Belgium, 1 in the Netherlands, 1 in Luxembourg, 11 in France, 2 in Italy, 1 near the site of ancient Carthage in north Africa and 1 at Manila in the Philippine Islands. Aside from war graves proper, the commission administers the American cemetery at Mexico City (established 1850) which harbours 750 unknown American dead of the Mexican War.

Korean Conflict.—The United Nations reaction to communist aggression in Korea called forth all the refinements of mortuary methods developed during World War II. Graves registration forces assigned to the U.S. 8th army evacuated the dead of all UN contingents to several temporary cemeteries established in southern Korea. Flags of the various nations marked national plots, all flying with the standard of the UN. With the assistance of U.S. officers, the Korean army organized its own graves registration service for the care of Korean dead.

Upon decision to adopt the unprecedented expedient of returning American remains before the conclusion of a major military operation, all American fatalities were evacuated directly from the place of death to the central identification laboratory at Kokura, Jap., for identification and casketing prior to shipment to the San Francisco port of embarkation. Remains previously buried were exhumed and sent through Kokura to San Francisco. The Graves Registration service then established a single cemetery at Tanggok, near Pusan, to serve as the final resting place for other United Nations war dead.

As a result of communist tactics of evasion, many of the remains of UN servicemen who fell between the Yalu river and the armistice line of 1952 were never recovered. Of 36,922 American fatalities, 29,730 were recovered. Of this number 28.730 were identified and returned to the United States. Numbering 853, the unknown dead were interred in the National Memorial Cemetery of the Pacific. Approximately 20% of the remains returned to the United States went to national cemeteries.

By the mid-1950s the national cemetery system included 87 "installations" under the department of the army and 12 assigned to the department of the interior for administration. Altogether these cemeteries contained 719,873 interments (1956), of which 151,789, mostly Civil War remains, were unknown. With about 125,000 burials in the overseas military cemeteries, the U.S. government afforded perpetual care for approximately 850,000 graves of its military dead. As defined in an act of congress (62 Stat. 234; 24 U.S. Supp. iv, 281) the following were eligible for burial in the national cemetery system: (1) those who died while serving in the armed forces of the United States, namely male and female members of the army, navy. marine corps, air force and coast guard service; (2) those who died subsequent to service in the armed forces; (3) U.S. citizens who served during war in the armed forces of an allied nation; (4) spouses and minor dependents of persons named in the three preceding categories.

Any individual falling within the first three categories, either male or female, might, upon application, at the death of his or her spouse, receive a grave site together with the reservation of an adjoining site. In event of remarriage, the surviving veteran, if desirous of burial beside the second spouse, had the option of disinterring the first one at personal expense. The award of two grave sites also applies when the veteran dies first. Dependents may be buried in either of the two allotted sites. (E. SE.)

GREAT BRITAIN

The Imperial War Graves commission (renamed the Commonwealth War Graves commission in April 1960) assumed responsibility for the permanent marking and care of the graves of those members of the British fighting services who fell in World Wars I and II, which were deemed to have ended, for the commission's purposes, on Aug. 31, 1921, and Dec. 31, 1947, respectively.

The origins of the commission may be traced to the imagination of Sir Fabian Ware who directed a mobile unit which the British Red Cross society and the Order of St. John of Jerusalem sent out to the western front in Sept. 1914 to search for missing soldiers.

A branch of the army, at first financed by the Red Cross. was formed in 1915 to register, mark and care for the graves of the fallen and in 1916 a directorate of graves registration and inquiries at the war office was created. The year 1916 also saw the formation, under the presidency of the prince of Wales, of a national committee for the care of soldiers' graves. to which dominion representatives were appointed. In March 1917 the prince of Wales sent to the prime minister a memorandum proposing that a permanent organization representing all parts of the empire should be formed to care for the graves. The proposal was endorsed by the Imperial War conference of that year. and the Imperial War Graves commission was thereupon constituted under royal charter on May 21, 1917. The commission guided by Sir Fabian Ware recommended; and in June 1918, the Imperial War conference decided that the cost of carrying out the commission's decisions should be borne by the respective governments in proportion to the numbers of the graves of their dead. Furthermore, when the commission obtained, in 1940, a supplemental charter extending its powers to cover the permanent marking and care of the graves of World War II, the participating governments agreed that the work should continue to be financed on this principle.

The commission decided to base its work on the principle of equality of treatment and thus to mark every known grave with a headstone of the same simple design. This headstone stood 2 ft. 8 in. above the ground and was 1 ft. 3 in. broad and 3 in. thick. At the top was engraved the badge of the regiment or unit; then followed the rank, name, unit, date of death and age; below these was incised the appropriate religious emblem; and at the foot a personal inscription chosen by the relatives. In Dec. 1939 the commission decided to adopt the same design for the graves of World War II. In every cemetery containing more than 40 graves was placed a tall Cross of Sacrifice, to which was fixed a crusader's sword of bronze. In the largest cemeteries was placed another central memorial—the great altarlike Stone of Remembrance, bearing the .inscription "Their Name Liveth For Evermore." The effect aimed at was that of an English garden, with the headstones standing in long flower borders in a setting of mown lawn, there being no grave mounds. In France, Belgium, the Netherlands and Germany the caretakers appointed were for the most part British ex-servicemen.

The marking of graves was only a part of the commission's task of commemoration, for large numbers of the dead of both wars had no known burial place. Accordingly, memorials recording the names in stone or bronze were built or planned in all the countries where the major campaigns were fought. Such were the Menin gate at Ypres, Belgium, the Somme memorial at Thiepval, France, the Gallipoli memorial at Cape Helles, Turkey. and the Salonika memorial at Lake Doiran, Greece. Such, too. were the R'orld War II memorials at Bayeux, Groesbeek near Nijmegen, Cassino, El Alamein, Singapore, Rangoon and Dunkirk. The main naval memorials were erected at Chatham, Portsmouth and Plymouth, and extensions to these bore the names of those lost in World War II. The largest memorial to the air forces of the commonwealth was built on Cooper's hill, above Runnymede, Surrey. The memorial to the merchant navy and fishing fleets was built on Tower hill, London, the missing dead of World War II being commemorated on an extension erected in Tower Hill gardens.

The cemeteries, graves and memorials of World War I were protected by a series of international agreements, which were revised to apply to World War II. In each country the commission's authority under the agreement is exercised by a joint committee of distinguished foreign and commonwealth members. In 191j France undertook to buy the sites of all mar cemeteries and granted to the Allied nations the perpetual "enjoyment" of such lands. Other governments followed this example.

The commission published for World War I a series of printed registers, containing lists of the dead, with brief details. A similar series was begun after World War II. The work of the commission is illustrated in a series of books of fine photographs of cemeteries and memorials entitled "Their Name Liveth." A supplemental charter of 1941 empowered the commission to compile a record of civilian subjects of the crown dying by enemy action.

To provide income for the permanent maintenance of the graves, cemeteries and memorials of World War I, it was agreed in 1926 that an endowment fund be established by the United Kingdom and dominion governments. The fund when completed in 1940 amounted to £6.000.000. but the income from this sum became insufficient to meet costs, and the additional income required was provided by annual grants by the Cnited Kingdom and other commonwealth governments. The commission commemorated 1,104,-890 dead of the commonwealth who fell in World War I. The total for World War II was 571,000. (F. C. SI.)

WARHAM, WILLIAM (*c.* 1450–1532), archbishop of Canterbury during the period of Henry VIII's divorce from Catherine of Aragon. He belonged to a Hampshire family and was educated at Winchester and New college. Oxford. Later he took holy orders and became master of the rolls in 1494. He helped to arrange the marriage between Prince Arthur and Catherine of Aragon (1496); and was partly responsible for negotiating treaties with Scotland, Burgundy and Maximilian I. In 1502 Warham was consecrated bishop of London and became keeper of the great seal; in 1504 he became lord chancellor and archbishop of Canterbury. In 1509 he married and then crowned Henry VIII and Catherine of Aragon but. gradually withdrawing into the background, he resigned the office of lord chancellor in 1515 and was succeeded by Cardinal Wolsey. This resignation was possibly a result of his dislike of Henry's foreign policy.

Warham was present at the Field of Cloth of Gold in 1520, and he assisted Wolsey as assessor during the secret inquiry into the validity of Henry's marriage with Catherine in 1527. Throughout the divorce proceedings Warham's position was essentially that of an old and weary man. He was named as one of the counselors to assist the queen but, fearing to incur the king's displeasure and using his favourite phrase, *ira principis mors est* ("the wrath of the ruler means death"). he gave her very little help; and he signed the letter to Clement VII which urged the pope to assent to Henry's wish. Afterward it was proposed that the archbishop himself should try the case but this suggestion came to nothing.

He presided over the convocation of 1531, when the clergy of the province of Canterbury voted £100,000 to the king in order to avoid the penalties of praemunire and accepted Henry as supreme head of the church with the saving clause "so far as the law of Christ allows." In his concluding years, however, the archbishop showed rather more independence. In Feb. 1532 he protested against all acts concerning the church passed by the parliament which had met in 1529, but. it should be noted. this did not prevent the important proceedings which secured the complete submission of the church to the state later in the same year. Against this further compliance with Henry's wishes Warham drew up a protest; he likened the action of Henry VIII to that of Henry II and urged Magna Carta in defense of the liberties of the church.

He died on Aug. 22, 1532, and was buried in Canterbury cathedral. Warham was chancellor of Oxford university from 1506 until his death. Although opposed to reform, he was connected with the English humanists, and there is a sympathetic account of his. personal characteristics in Erasmus' *Ecclesiastes.*

See W. F. Hook, *Lives of the Archbishops of Canterbury,* vol. vi (London, 1860–76); J. Gairdner in *Dictionary of National Biography,* vol. lix (1899); J. D. Mackie, *The Earlier Tudors, 1485–1558* (Oxford, Toronto, 1952).

WARKWORTH, a town of Northumberland, Eng., 40 mi. N. of Newcastle by road, contained almost entirely within a loop of the river Coquet. $1\frac{1}{2}$ mi. above its entry into the North sea. Pop. (1951) 922. Area 1.8. sq.mi. Warkworth lies on the coastal road connecting Amble with Alnwick which crosses the Coquet by a narrow stone bridge of two round arches dating from the 14th century. The southern end is guarded by a gatehouse now in ruins. The nearby church of weathered sandstone has a Norman nave and chancel and a tower built about 1200 and a 14th-century spire. The ruins of the castle dominating the town include masonry dating back to about 1200, the magnificent Lion tower forming an imposing entrance to the Great hall and a 15th-century keep. Upstream lie 14th-century remains of the famous Hermitage, the outer portion built in stone and the inner chapel and chamber hewn from the sandstone cliff. (E. M. Hw.)

WARMING, JOHANNES EUGENIUS (EUGEN) **BÜLOW** (1841–1924), Danish botanist, best known for his pioneering nork in plant ecology. was born at Manø on Nov 3, 1841. and received the Ph D degree (Copenhagen) in 1871 He was professor of botany at the Royal Institute of Technology, Stockholm (1882–85), and professor of botany and director of the botanical garden at Copenhagen (1885–1911). Warming traveled to Brazil (1863–66), to Greenland (1884), to Finnmark in Nornay (1885) and to the West Indies and Venezuela (1890–92). He died at Copenhagen on April 2, 1924.

Warming's nearly 300 publications covered several aspects of botany He contributed significantly to knonledge of the nature of ovules (1878) and published a monograph on the Podostemaceae (1881–1901) His first attempt to classify life forms of flowering plants nas in *Om skudbygning, overvintrmg og foryngelse* (1884; "On Shoot Structure. Wintering and Rejuvenation"). his life-form system appearing in final version in *økologiens grundformer* (1923; "Fundamental Ecology"). *Om Grønlands vegetation* (1888, "On Greenland's Vegetation") and *Lagoa Santa* (1892: a study of Brazilian flora) are classic accounts of arctic and tropical vegetation. respectively. In 1895 Warming published his *Plantesamfund* (Eng. trans. *Oecology of Plants,* 1925), a work that laid the foundation of modern plant ecology and gave great impetus to the study of this science. The far-reaching influence of this work was due in large part to the ingenious manner in which the author elucidated the relation between plants and external environment. Warming's *Dansk plantevaekst* (1906–19; "Danish Vegetation ") described vegetation of Danish beaches, marshes and forests His textbooks. *Haandbog* i *den systematiske botanik* (1879; Eng. ed., *Handbook of Systematic Botany,* 1895) and *Den almindelige botanik* (1880; "General Botany") were translated into several languages.

See C. Christensen, *Den Danske botaniks historie* (1924–26), which includes a listing of Warming's publications; V. Meisen (ed), *Prominent Danish Scientists Through the Ages* (1932). (J. W. TT.)

WARM SPRINGS, a centre for aftertreatment of poliomyelitis, located in Meriwether county, Ga., U.S., about 70 mi. S.W. of Atlanta. The celebrated springs return to the surface 800 gal. of water per minute at a temperature of about 88° F. Indians are said to have believed in their miraculous healing qualities and in the 19th century Georgians popularized the springs as a holiday resort. The national prominence of Warm Springs dates from Franklin D. Roosevelt's visit following an attack of polio in 1921. Convinced that the warm aaters would aid in the aftercare of polio victims who needed supported exercise, Roosevelt organized the Warm Springs foundation in 1927. This nonprofit corporation has since developed a complete medical community there. Roosevelt died at Warm Springs on April 12, 1945; the "Little White House," his residence there, is now open to the public. The village of Warm Springs, 1 mi. S.W. of the springs, developed as a railroad junction for the resort and was incorporated under its present name in 1924. (J. N. A)

WARNER, CHARLES DUDLEY (1829–1900), U.S. essayist and novelist, was born in Plainfield, Mass., on Sept. 12, 1829. In 1851 Warner graduated from Hamilton college, Clinton, N.Y. In 1858 he received a bachelor of laws from the University of Pennsylvania, and later practised law in Chicago (1858–60). In 1861 he began to edit the *Hartford* (Conn.) *Courant* and the series of sketches which he wrote for that paper gained him a national reputation; they were collected in *My Summer* in *a Garden* (1870). He wrote ten travel books. With Mark Twain he collaborated on *The Gilded Age* (1873), a novel of unscrupulous politics in post-Civil War Washington. Warner was the first editor of the "American Men of Letters Series." In 1889 he published *A Little Journey in the World,* the first part of his trilogy concerning the making, misuse and final loss of a great fortune; *The Golden House* (1895) and *That Fortune* (1899) completed the work. He died in Hartford on Oct. 20. 1900.

WARNER ROBINS, a city of Houston county, in central Georgia, U.S., is 16 mi. S. of Macon. In 1940 it was known as Wellston and was a small village of about 50 inhabitants beside the Georgia Southern and Florida railroad. When the federal government later built an army air base there, the city sprang into being like a boom town of gold rush days. It was incorporated in 1933 under its new name, honouring Brig. Gen. Augustine Warner Robins. one of the founders of the modern U.S. air force. The depot that was to occupy the base was activated one month before the Japanese attack on Pearl Harbor. In July 1946 the depot was designated Warner Robins air matériel area, as part of the air matériel command. The base later became the home of the 14th air force ("Flying Tigers"). In 1952 the air force base was declared permanent. By mid-20th century the population had increased to about 8,000 and it more than doubled in the decade 1950–60. (For comparative population figures *see* table in GEORGIA: *Population.*) A modern school system has been developed and the city has many civic and fraternal organizations and several health, nelfare and recreational agencies. (S. B. K)

WAR OF 1812. A conflict that began June 18, 1812, with a declaration of war on Great Britain by the United States. It was terminated by a treaty of peace signed at Ghent, Belg., Dec. 24, 1814, and approved by the U.S. senate on Feb. 16, 1815.

Causes.—The long struggle between Great Britain and Napoleonic France, covering most of the period between 1793 and 1815, led both belligerents to infringe on the rights and impair the interests of neutrals. Great Britain incurred additional American resentment by its actions along the frontier between Canada and northwestern United States. The early years of the Anglo-French war were beneficial to American shippers, who, as neutrals, were able to trade with both belligerents. In particular. American shippers were able to supplant French and Spanish ships in the carrying trade between France and Spain and their West Indian colonies. But this form of trade was ended. or rendered hazardous, by the decision of the British courts in the case of the American ship "Essex" in 1805. The courts in this case held that U.S. ships could not carry goods from French colonies to France even when the voyage was broken by stopping at a U.S. port. In the same year the British naval victory at Trafalgar (Oct. 21) ended Napoleon's hope of invading England and led him to attempt to ruin England by excluding its trade and products from the continent of Europe. Napoleon's "continental system" was embodied in his Berlin and Milan decrees (Nov. 21, 1806, and Dec. 17. 1807), which not only barred British ships from all ports under French control, but declared the British Isles under blockade. They threatened with confiscation any neutral vessel that visited a British port. paid British duties or even allowed itself to be searched by a British cruiser. Meanwhile the British. in two orders in council (Jan. 7 and Nov. 11, 1807), announced. in effect, a blockade of the ports of France. its possessions and its allies. and forbade neutral vessels to enter such ports unless they first called at British ports and paid British duties on their cargoes. Thus Napoleon, whose object was to ruin British commerce, announced: "No trade with or through England." Great Britain, whose object was to keep that commerce alive, countered with: "No trade except through England." An American merchant vessel seeking to trade with Europe could not conform to both enactments. If it obeyed one party, it courted confiscation by the other. To the United States, both British orders and French decrees instituted mere "paper blockades," contrary to the principles of international law.

There was little to choose between the impositions of the belligerents on neutral trade, but British naval policy added another grievance in the form of impressment (*q.v.*). The impressing of British subjects for enforced service in the Royal Navy was a practice to which the United States could not object so long as it was applied to British subjects on British soil or on British merchant vessels. But controversy arose when the British asserted a right to stop American ships on the high seas and remove seamen whom the captors alleged to be British subjects and, in some cases, deserters from the Royal Navy. The U.S. merchant marine did, in fact, harbour many fugitives from British naval service who attempted to conceal their identity with false certificates of American citizenship. Another difficulty arose from the fact that the

British rule of indelible allegiance conflicted with the U.S. policy of naturalization. The same man might be a British subject under British lam and a U.S. citizen under U.S. law. The United States not only complained of the rough-and-ready methods by which British naval officers determined, without appeal, the allegiance of sailors on Americah ships; it condemned the invasion of American ships for the purpose of impressment as a violation of U.S. sovereignty. Offers to exclude British deserters from American ships in return for abandonment of impressment were rejected by the British government. A climax in the controversy occurred in June 1807, when the British frigate "Leopard" fired upon the U.S. frigate "Chesapeake" and removed four sailors alleged to be British deserters. In this attack on a public vessel, the British realized that they had gone too far and eventually made amends.

Pres. Thomas Jefferson (*q.v.*) was unwilling either to submit meekly to infringement of American rights or to defend them by force of arms. Under his leadership congress adopted a policy of "peaceable coercion," designed to exact respect for American rights by economic pressure. The Embargo act (Dec. 22, 1807) closed all U.S. ports to foreign commerce and permitted only coastwise trade. When the embargo proved more injurious to the United States than to the great belligerents, it was repealed (March 1, 1809) in favour of the milder Non-Intercourse act, which opened American trade to all countries except France and England. This was, in turn, replaced by a third measure (May 1, 1810), which removed restrictions on trade but provided for revival of nonintercourse against whichever belligerent should fail to revoke its orders in council or decrees in the event of such revocation by the other. Napoleon thereupon pretended to revoke the Berlin and Milan decrees insofar as they affected the United States, and Pres. James Madison (*q.v.*), accepting fiction as fact, revived nonintercourse against Great Britain in Feb. 1811. When England still refused to revoke the orders in council, Madison, in Nov. 1811, urged congress to prepare the nation for war, and on June 1, 1812, in a special message, urged a declaration of war against Great Britain. Congress, in spite of strong opposition, especially from New England and New York, responded with a declaration of war that Madison signed on June 18. Two days before, peaceable coercion had won a tardy victory in a British announcement that the orders in council were to be revoked, but, because of the slowness of transatlantic communication, news of this action did not reach the U.S. government for several weeks.

Early in his administration, Madison had warned the British government that failure to modify its commercial restrictions might mean war with the United States. The most urgent demand for war, however, had come not from the president but from a group of congressmen, most of them young men newly elected in 1810 to the 12th congress. These men, the "war hawks," coming mainly from western and southern states, included Peter B. Porter of western New York, Henry Clay (*q.v.*) of Kentucky (chosen speaker of the house of representatives), Felix Grundy of Tennessee and John C. Calhoun (*q.v.*) of South Carolina. Fiery and aggressive, they bitterly resented the economic injuries and the national humiliation to which the United States had been subjected. The westerners had an additional grievance in the supposed British connection with a new outbreak of Indian hostility in the northwest. British authorities in Canada were sympathetic with the efforts of the Shawnee leader, Tecumseh, to check the advance of white settlement into the Indian country. Without actually inciting the Indians to hostilities against the Americans, British agents supplied them with arms and ammunition as means of retaining their friendship. When more than 60 American soldiers were killed and 100 wounded in a surprise attack on Gov. William Henry Harrison's frontier army by the Indians at Tippecanoe (Nov. 7, 1811), westerners blamed the British and raised the cry that only by expelling the British from Canada could the frontier enjoy security. In the south, especially in Georgia and Tennessee, the "war hawks" expected to utilize war with England to wrest Florida from England's ally, Spain. The importance of this frontier expansionist urge as a motive for war is problematical. At most, it was secondary to the maritime grievances. The western desire for Canada, however, must be coupled with the rankling of the impressment issue to explain why the mar went on after news of the repeal of the orders in council reached America.

Military and Naval Events. — The congress that declared war after a seven-month debate had done little to strengthen the army or navy or to supply the treasury with funds, and the United States entered the war inexcusably ill prepared. The chief feàture of the war was expected to be the invasion of Canada, yet the U.S. government had failed to ensure control of Lakes Erie, Ontario and Champlain. Because of the British command of Lake Erie, the frontier post of Detroit (with an army of 2,000 men) was surrendered by Brig. Gen. William Hull to the British under Maj. Gen. Isaac Brock in the second month of the war. A few weeks later, attempts to invade Canada on the Niagara frontier and via Lake Champlain were complete fiascoes. Meanwhile, Commodore Isaac Hull (*q.v.*) put to sea in command of the "Constitution" (*q.v.*) and on Aug. 19 captured the British frigate "Guerrière." The year 1813, though marked by many failures, brought two notable successes to American arms in the northern theatre: the destruction of the British squadron on Lake Erie by Master Commandant Oliver Hazard Perry's fleet (Sept. 10, 1813) and the ensuing victory of Maj. Gen. William Henry Harrison's army over Brig. Gen. Henry A. Procter's British and Indians at the battle of the Thames on Oct. 5, 1813 (see THAMES, BATTLE OF THE).

By the summer of 1814 the United States at last had a well-trained army in the Niagara region, commanded by competent officers (Maj. Gen. Jacob Brown and Brig. Gen. Winfield Scott), but this advantage was counterbalanced by the arrival in Canada of veteran British regiments, released from service in Europe by the defeat and first exile of Napoleon. The hard-fought battles of Chippawa (July 5, 1814) and Lundy's Lane (July 25, 1814) restored American military prestige but accomplished little else. Another American naval victory, this time on Lake Champlain (Sept. 11, 1814), saved New York from a projected invasion via the Hudson valley. Elsewhere the British took the offensive. Despite the American recapture of Detroit, British forces held Michilimackinac, controlled access to Lake Michigan and occupied the Mississippi river as far south as northern Illinois. An amphibious British force ravaged the shores of Chesapeake bay and burned the public buildings in Washington, D.C. (in retaliation for similar American acts at Toronto), but was repulsed at Baltimore. It was during the attack on Raltimore that Francis Scott Key (*q.v.*) composed "The Star-Spangled Banner," now the U.S. national anthem. Another British army under Lieut. Gen. Sir Edward Pakenham landed near the mouth of the Mississippi river, but on Jan. 8, 1815, was defeated with heavy losses in the battle of New Orleans by the defenders under Maj. Gen. Andrew Jackson.

Meanwhile, U.S. frigates, sloops of war and privateers had inflicted heavy damage on British commerce and had won great acclaim by their victories in a large majority of duels with British naval vessels of similar ratings. Their victories, salutary to American morale. failed to disturb Britain's control of the sea through its vastly superior navy. Before the war ended, most U.S. naval vessels were captured or shut up in port, and the commercial blockade of the American coasts was complete.

Peace Negotiations. — On Dec. 24, 1814, two weeks before the battle of New Orleans, a treaty of peace had been signed at Ghent, Belg., where British and American commissioners had met in August as an indirect consequence of an offer of mediation by Tsar Alexander of Russia. The United States had fared so badly in the war that it was in no position to ask cessions of territory and finally dropped even its demand for the abandonment of impressment. It proposed merely a return to the situation before the war (status quo *ante bellum*). The British, on the other hand, came to Ghent with formidable demands — a permanent Indian reservation in the northwest, retention of several forts on U.S. soil and cessions of territory in Maine, in New York and between Lake Superior and the upper Mississippi. The Americans refused all these demands, and their position was strengthened by news of British defeats at Baltimore and on Lake Champlain, and by the advice given to the British government by the duke of Wellington, who argued that territorial exactions were not warranted by the military situation. The British, consequently, accepted the U.S. proposal for restoration of the prewar situation, with certain provisions in behalf of Indian tribes who had helped the British.

Though the treaty fulfilled not one of the U.S. objectives in the war, it received unanimous approval of the senate on Feb. 16, 1815, and was joyously hailed by the public. It headed off a potentially separatist movement in New England, where both the war and the commercial restrictions which preceded it had been extremely unpopular. New England opposition culminated in the Hartford convention (Dec. 1814–Jan. 1815). This gathering, in spite of some secessionist talk, went no further than to propose certain amendments to the constitution, and, with the coming of the news of peace, the convention and its proposals were quickly forgotten. Though the United States gained none of its avowed aims in the war, popular mythology soon converted defeat into victory. This process was facilitated by several circumstances: the series of military successes in the war's closing months left a taste of victory; the end of the war in Europe brought an end also to the issues of impressment and paper blockades; finally, the war did actually subdue Indian resistance, since Tecumseh died in the battle of the Thames and the Creek confederacy in the south was crushed by Andrew Jackson in 1814. Indirectly, this Creek war paved the way for the acquisition of Florida in 1819. The war marked the end of a period of American dependence on Europe and gave a stimulus to the sense of nationality in the United States. *See* also UNITED STATES (OF AMERICA): *History;* and Index references under "War of 1512" in the Index volume.

WAR OFFICE, BRITISH.[1] The term applies to (1) the building which houses the controlling staff of the army, and (2) the controlling staff itself. As regards the local habitation of the staff, in Cromwellian days this was often in the field and was the tent of the secretary to the commander in chief whose official title was secretary at war.

After the Restoration (1660), George Monk, as lord general, took up his residence at a house in Whitehall called the Cockpit and this became the headquarters of the army. About 1684 the headquarters were moved to the "horse guards," *i.e.,* the barracks of the king's guards at Whitehall, and there it remained until 1856 when it moved to Buckingham house, Pall Mall. In 1907 it moved to its quarters in Whitehall.

From the Earliest Times to the Crimean War (1854–56).— The details of the early administrative history of the army are very obscure. William the Conqueror created the offices of high constable and marshal and their duties appear to have been somewhat analogous to those of the contemporary adjutant general and quartermaster general.

Although the origin of the board of ordnance is obscure it was certainly in existence in the early part of the 14th century, and it is the oldest military office with a continuous history. Charles II created the title master general of ordnance in 1664. The headquarters of the board were for centuries at the Tower of London. In 1855 the letters patent for the board were revoked and its duties vested in the secretary of state for war. In the 18th century, the office of master general of the ordnance was held by the chief military leaders and generally carried with it cabinet rank. Marlborough was twice master general of ordnance.

The office of secretary of state for war appears to have had its origin in a council of war of Charles I. The clerk to Charles' council was the secretary at war and he had a counterpart in the New Model army. After the Restoration he became secretary at war to all the forces in England and Wales, and was in fact nothing more than the private secretary of the commander in chief. When Monk (who had become duke of Albemarle) died in 1670 the office of secretary at war grew in importance, because of the fact that Charles II did not appoint a commander in chief. Gradually the office became separated from that of the commander in chief, arriving at complete divorcement in 1704, when the office became a political post. In 1794 was created a new post, the secretary of state for war, and in 1801, because the armies were largely employed in the West Indies, the direction of colonial affairs was transferred from the home office to the secretary of state for war who became secretary of state for war and the colonies. In 1855 the office of secretary at war was merged into that of the secretary of state, but it was not finally abolished until 1863.

The office of the deputy secretary at war appears to have been created at least before the 18th century. The holder of the appointment was the senior permanent official in the department of the secretary at mar. When the departments of the secretary of state and secretary at war were amalgamated the post was abolished and in its place that of permanent undersecretary of state created. The office of the commander in chief dates back to the Restoration. At various times the title has been captain general, generalissimo: general on the staff and lord general. The first holder of the appointment was the duke of Albemarle, whose special charge was the care of men while the board of ordnance looked after the matériel. In the 17th century when the commander in chief was on foreign service, many of his duties were usurped by the secretary at war.

The office of adjutant general to the forces originated in the parliamentary army. After the Restoration the first appointment was made in 1673. From 1685 there was a continuous line of adjutants general. The quartermaster general first appeared in 1686. Previous to this his duties had been carried out by the provost marshal, scout master general and the harbinger.

The office of commissary general of musters was established just after the Restoration and abolished in 1818. The chief duty of the commissary general of musters was to keep up the establishment and to issue a certificate to the paymaster general for the actual number of men serving. At the outset of the standing army the medical service was entirely regimental, but in 1663 was initiated central control which developed into a directorate in the early part of the 19th century.

From the Crimean War (1854–56) **to** 1904.—Military administration underwent great changes during the period following the outbreak of the Crimean War. The duties of the secretary of state for war were divorced from those of the colonies; the commissariat office was transferred to the war department; the office of secretary at war was merged into that of the secretary of state; the board of general officers and the medical department were absorbed by the war department, and the war department became known as the war office. The military control remained in the hands of the commander in chief, while the secretary of state was responsible to parliament. However, under the War Office act (1870) the final welding was effected and the secretary of state became responsible for all military administration.

After the Esher Report: 1904 Onward.—The next great change took place when, following the publication of the Esher report (Feb. 1904), the issue of letters patent abolished the office of commander in chief and established an army council on the same lines as the board of admiralty, with the characteristic feature of a civilian minister—the secretary of state for war—presiding over a body composed jointly of junior ministers, the permanent undersecretary of state and military members of council with a civilian secretary. The main constitutional feature of the changes in organization was that an imperial general staff was established whose chief was, as first military member of the army council, subject to the presidency of the secretary of state, though it has always been well understood that, as prescribed by the Esher report, there should be no civilian interference in purely military matters except on the broadest questions of policy.

The pattern set in 1904 was in general adhered to thereafter, and may be said to have stood the test of two world wars. In the

[1]The permission of the controller of H.M. stationery office has been obtained for the inclusion of this article.

intervening years there were important developments arising from general changes in the defense structure, and from increasing specialization, besides numerous changes of nomenclature. World War I was marked by the creation of the ministry of munitions, the ministry of pensions, the air ministry and the ministry of national service. All these relieved the war office of important functions. (See also GOVERNMENT DEPARTMENTS.)

In the years between World Wars I and II the main changes were that, by order in council, commanders in chief in the field were taken outside the control of the war office except for certain restricted and somewhat technical purposes, and that, inside the office, a number of duties were transferred to the master general of the ordnance from the quartermaster general, who remained responsible for supply and quartering. The first important change in war office organization brought about by World War II was that the duty of providing the army with armaments and vehicles was taken outside the office altogether and transferred to the ministry of supply, with the consequent abolition of the historic post of master general of the ordnance. Coupled with this change was a strengthening of the organization for fulfilling the duties of the general staff in connection with research and development in the fields of weapons and vehicles. Under the general supervision of the chief of the imperial general staff, an officer with the style of deputy chief of the imperial general staff and the rank of lieutenant general, and himself a member of the army council, became responsible for this work and for organization. He was given the help of a civilian scientific adviser, and the relationship of the general staff to the ministry of supply was that the former prescribed what the army needed and the latter, so far as financial and technical conditions allowed, provided it.

The second change of outstanding importance was that, with the formation of the chief of staffs committee, under the minister of defense, the general staff, always in fact responsible for strategy to the cabinet as a whole rather than to the secretary of state, became in principle as well as in fact responsible to the minister of defense. After the ministry of defense had become, in 1947, a permanent part of British constitutional arrangements, the secretary of state for war, in common with the other heads of service departments, ceased to sit in the cabinet. The appointment in 1956 of a full-time chairman of the chiefs of staff committee, replacing the system whereby either the first sea lord, the chief of imperial general staff or the chief of air staff took the chair at meetings, was a further step in making the imperial general staff part of an interdepartmental team responsible to the cabinet through the minister of defense rather than part of the war office staff, which in name it still was. This process was carried one stage further by the arrangements set out in the white paper *Central Organisation for Defence* (Cond. 476 of 1958) whereby "The Chiefs of Staff are responsible through the Chief of the Defence Staff to the Minister of Defence for the conduct of military operations."

For the equivalent government department in the U.S., *see* GOVERNMENT DEPARTMENTS: *United States*. (T. *J. E.*; W. T. Ws.)

WARP AND WEFT. Warp threads are those that run lengthwise of the fabric; weft threads run transversely. In the manufacturing of practically all kinds of woven textures, there are many differences: (1) the raw material from which uarp is made is almost invariably of a higher grade than that used for weft; (2) the number of turns per inch or "twist" in warp threads usually exceeds that in the weft threads or picks; (3) multiple-fold or multiple-ply yarns are more often used for warp than for weft; (4) coloured threads appear in both, but much more frequently in the warp; (5) the fibrous material from which warp threads are made may be the same as that used for the weft threads, or the two may be entirely different; (6) warp threads are often starched or sized, but ueft threads are seldom so treated.

Except for knitted fabrics or other similar structures in which one series of yarns only is used, the warp and weft threads interweave together to form the structure of the fabric and to give it complex designs. *See* WEAVING.

WAR PENSIONS. The first pension law in the United States was passed by congress on Sept. 29, 1789. It provided that "The military pensions which have been granted and paid by the States respectively . . . shall be continued and paid by the United States." A treasury surplus motivated Pres. James Monroe to urge congress to establish a service pension for all Revolutionary soldiers in need. This law, enacted on March 18, 1818, the first to pay pensions on the basis of honourable military service and not on disability, resulted in so many veterans applying for pensions that the surplus quickly was wiped out. On May 1 of that year congress authorized a "scythe of retrenchment" in the form of an act that took one-third of the pensioners off the rolls.

The pendulum soon swung the other way. Laws passed in 1828, 1832 and 1833 granted full pay for life to certain surviving Revolutionary War soldiers. On March 18, 1836, a law was passed extending benefits to volunteers or militiamen called into United States service to suppress Indian depredations in Florida.

Service pensions for veterans of the War of 1812 were not authorized until Feb. 14, 1871. This law was liberalized on March 9, 1878, by reducing the minimum service requirement from 60 days to 14 days, and by authorizing pensions to widows of War of 1812 veterans, irrespective of the date of marriage.

The United States broadened its pension system by an act of July 14, 1862, the "general law pension system," which granted pensions to veterans and their dependents because of disability or death due to service. In 1887 congress passed a service pension bill for Mexican War soldiers. At least 60 days' service or participation in a battle was required for a service pension.

One of the most controversial service pensions for U.S. veterans was that finally granted to those aho served in the Civil War. Pres. Benjamin Harrison signed it on June 27, 1890.

Service pensions for Indian war veterans followed, in an act of July 27, 1892. For Spanish-American War veterans. the pensions were authorized in an act of June 5, 1920. The latter law also provided service pensions for survivors of the China relief expedition and the Philippine insurrection. Pensions for widows and minor children of Spanish-American War, Philippine insurrection and Chinese Boxer rebellion veterans were granted by a law passed July 16, 1918. Six years after the Armistice ended World War I, congress provided an adjusted compensation or "bonus" for the servicemen who fought in that war.

Several amendments to the bonus law mainly extended the deadline for filing applications. But in Jan. 1936, congress passed a law allowing veterans to exchange adjusted compensation certificates for government bonds carrying 3% interest. The bonds matured in 1946, but were redeemable at any time before that date. A law passed July 3, 1930, provided a disability allowance for World War I veterans, depending on the degree of permanent incapacitation.

This act, together with all other pension and compensation acts for service from and including the Spanish-American War, was repealed by an act of March 20, 1933, which overhauled the entire U.S. system of relief for veterans and dependents of deceased veterans. The new act of 1933, as amended, provided for the payment of compensation at wartime rates for death or disability incurred in Sine of duty during the Spanish-American War, the Philippine insurrection, Boxer rebellion, World War I and any future wars. Peacetime rates—80% of wartime rates—were payable for service-connected death or disability incurred on or after April 21, 1898, during other than wartime periods. For those with disability exceeding 50%, the law also provided additional allowances for wife, child and dependent parents.

From 1944 to 1957 a number of laws were passed increasing rates of compensation and pension. As of Jan. 1, 1958, veterans were entitled to compensation for disabilities incurred due to service, assuming a discharge other than dishonourable. Additional amounts were payable for dependents if the veteran was 50% or more disabled. Disability pensions were payable to veterans uhose total and permanent disability was not due to service, assuming eligibility based on a discharge other than dishonourable and assuming his income was not over $1,400 a year without dependents, or $2,700 a year if he was married or had a minor child. Death pension benefits might be paid to an eligible widow and to children where the veteran died of causes not due to service.

The Servicemen's and Veteran's Survivor Benefits act became effective Jan. 1, 1957. Eligible surviving widows, children and dependent parents of all servicemen and veterans who died on or after Jan. 1, 1957, as a result of service were not eligible for benefits under any previous law. If the serviceman or veteran died prior to Jan. 1, 1957, benefits were determined under the previous law, but a surviving dependent who received such benefit might elect benefits under the Survivor Benefits act if such an election nould be financially advantageous. Under the Survivor Benefits act. payments were monthly and the rate of payment was partially related to military pay.

For service-connected deaths occurring prior to Jan. 1, 1957, examples of monthly payment rates to eligible survivors were: widow. no child. $87; widow. one child, $121 (each additional child, $29); no widow, one child, $67; no widow. two children. $94; no nidow, three children, $122 (each additional child, $23); one parent. $75; two parents each $40.

For service-connected deaths occurring on or after Jan. 1. 1957, examples of monthly payment rates to eligible survivors were: widow, one child $112 plus 12% of the current basic pay of the rank held by the veteran at the time of his death; no additional allonance, in general, for children of an eligible widow; no widow, one child. $70; two children, $100; three children, $130; and $25 for each additional child Parents might receive benefits subject to income limitations For example. a single parent with an income under $1,7jo per year might receive benefits at a rate ranging from $15 to $7j monthly.

Death compensation for surviving disabled children of such serviceman or veteran also varied depending upon the date of death, and with such factors as the length of time the child was unable to support himself, whether his eligible widowed mother was still living and whether the child received benefits under the War Orphans Educational Assistance act.

The Survivor Benefits act was also designed to revise the six months death gratuity which ranged from $800 to a maximum of $3,000 and it also extended social security coverage to armed forces personnel on a contributory basis

In the early days of the nation. pensions were granted only by acts of congress. Later, the executive branch of the government was given authority to grant pensions under limits set by law.

The administration of pension and compensation laws has historically fallen upon the secretary of war or the department of the interior, but after July 21, 1930, the pension bureau became part of the Veterans administration (*q.v.*). These compensation and pension benefits, so administered, are generally exempt from creditor's claims and from legal process, except for claims of the United States arising under laws relating to veterans.

(C. R GY. J. W. CE.)

Great Britain.—War pensions in Great Britain are the responsibility of the ministry of pensions and national insurance. This department was formed in 1953 by the amalgamation of the ministry of pensions—set up in 1916 to deal with the great number of claims then arising from World War I and to take over existing war pensions from the service departments, including pensions from the South African War and some earlier wars—with the ministry of national insurance. At the time of this amalgamation certain functions relating to medical and surgical treatment for war pensioners. previously performed by the ministry of pensions, were transferred to the ministry of health and the department of health for Scotland. The ministry of pensions and national insurance is also responsible for pensions for death or disablement resulting from service in the armed forces after Sept. 2, 1939, and for war pensions to former members of the mercantile marine, etc., civil defense forces and to war-injured civilians. Pensions for death or disablement resulting from service in the armed forces between Oct. 1, 1921, and Sept. 2, 1939, remained the responsibility of the respective service department as do all purely service pensions.

War disablement pensions are granted when the disablement can be certified as either attributable to or aggravated by service. Entitlement to pension is not necessarily established because the person concerned has been invalided from the armed forces. But nhere a person leaves the forces by invaliding or otherwise there is no onus on him to prove that his disablement was the result of service if the claim is made not later than seven years after service terminated, and the benefit of any reasonable doubt is always given to him; if he has been invalided on account of disability nhich nas not noted when his service began there is a presumption that the condition was the result of service unless the evidence establishes otherwise. The determination of entitlement to pension is vested in the minister, but appeals against unfavourable decisions may be made to an independent statutory body, the Pensions Appeal tribunal. Appeals against a decision of a Pensions Appeal tribunal may be made to the high court on a point of law.

When entitlement is admitted pension is granted in accordance nith a medical assessment of the war disablement without reference to earning capacity or employment factors. This assessment is based on a comparison of the pensioner with a normal healthy person, the extent of the nar d~sablementbeing expressed as a percentage. 100% representing total incapacity. (Pension is payable while war disablement to the extent of 20% or more exists. If the d~sablementfalls to less than 20% a settlement is made by means of a gratuity or weekly payments for a limited period or both.) If the disability is not attributable to but only aggravated by service, pension may be discontinued on the ground that such aggravation has passed away.

A war disablement pension comprises a basic amount related to the medical assessment, with certain additions according to the individual circumstances. The basic amount in 1958 was 85*s.* a week for 100% disablement for a pensioner whose rank was private soldier or equivalent with higher rates according to rank; *e.g.*, 91*s.* 8*d* for a sergeant. £346 a year for a captain. To these amounts may be added an allowance for a wife, 10*s.* a week (£36 a year for officers) and allowances for children, 7*s.* 6*d.* a week for each child (officers, £30 a year). Both the basic amount and the additions for family are proportionate to the degree of disablement (thus a sergeant whose disablement was assessed at 50% and who had a nife and one child would receive 54*s* 7*d*). But if a partially disabled pensioner has to undergo treatment for his war disablement and is thereby prevented from working he receives allowances which bring his pension up to the 100% level.

Although the medical assessment on which the basic amount of pension is decided is made independent of the earning capacity of the disabled person, employment factors are recognized in connection nith two supplementary allowances. An unemployability supplement of 55*s.* meekly can be awarded when war disablement is the main cause of a pensioner's being unable to work over a long period. Secondly. where a partially disabled pensioner is able to work but is prevented by his nar disablement from following work of his former standard he may be granted an allonance of up to 34*s.* a week, or such smaller sum as will bring his pension up to the 100% rate. Other supplementary grants include an allomance for attendance payable to a pensioner receiving 100% pension and living at home who requires the help of another person. The maximum grant is 70*s.* a week. For a pensioner who wears an artificial limb, or whose disability otherwise causes extra wear and tear of clothing, there is an allowance of £6 or £10 a year. There is an allowance of either 20*s.* or 10*s.* a week for the provision of comforts for certain very severely disabled pensioners. There is also an age allowance at rates ranging from 5*s.* to 15*s.* a week for pensioners who are aged 6; years or more and whose pensioned disablement is 40% or over.

About 1,900 of the most severely handicapped pensioners are provided with motorcars. Tax and insurance are borne by the health departments and an annual allowance is paid to the pensioner toward upkeep. Less severely disabled pensioners are provided with weather-protected motor tricycles and are paid a small petrol (gasoline) duty allowance. The health departments are responsible for the supply of the cars and tricycles and for the payment of the annual allowances referred tb in this paragraph.

The ministry of pensions and national insurance is responsible for arranging for medical and surgical treatment where the need for it arises from the disablement resulting from service but the health departments are responsible for the actual provision of the treatment, including the supply of all kinds of surgical and medical aids and appliances.

War pensions are granted to widows and, under certain conditions, to parents and other dependents of members of the armed forces whose death is certified to be caused by or hastened by service, the general rules as to determination of entitlement applying as in disablement claims. For the widow who is over 40 years of age or has a child in her care or is incapable of self-support, the basic rate of pension is 66s. a week, with higher rates according to her husband's rank; for the widow with none of these qualifications the rate is 20*s*. a week with addition according to rank. Additional allowances are paid to widows for their children, the rate being 25s. a week for each child (£73 a year in the case of an officer's widow). The widow of a member of the armed forces below commissioned rank who has a child in her care may receive a supplement in respect to her rent of the amount by which the rent exceeds 6s. a week, subject to a maximum payment of 25s. weekly. For a child who has lost both father and mother the rate of pension is 30*s*. weekly up to 15 years of age and then 40*s*. (£112 10*s*. a year for an officer's child). These pensions can be supplemented according to the circumstances. A pension may be granted to a parent (or other dependent) who is in pecuniary need. In determining need consideration is given to the support which the deceased person gave or could be expected to have given had he survived. The maximum pension is 27*s*. 6d. weekly to one parent and 40*s*. to two parents (£95 and £120 a year respectively in the case of an officer). Parents' pensions can be claimed at any time even though the parents were not in pecuniary need at the time the son died. The allowances for children of disabled men or of widows are payable until the age of 16 (18 in the case of officers) and they may be continued beyond this where the child is a student, an apprentice or is incapable of self-support by reason of infirmity. Education allowances for children may also be paid in addition to the normal allowances. These education allowances are designed to help parents with school fees and incidental expenses. The maximum rate for each child is £80 a year. War pension allowances for children are payable in addition to the national family allowances.

At Dec. 31, 1957, over 580,000 war disablement pensions were being paid. About 238,000 of these related to World War I and earlier wars and nearly 343,000 to World War II and later service in the armed forces. The latter total included 3,800 pensions to former members of the mercantile marine and 13,800 pensions to former members of the civil defense forces and civilians injured by enemy action. Of the 580,000 disablement pensioners about 446,000 were married and were receiving allowances for their wives and for 386,000 children. Nearly 17,400 pensioners were receiving unemployability supplements, about 15,800 the allowance for lowered standard of occupation, 9,300 the allowance for attendance, 20,700 the comforts allowance and 55,600 the age allowance. About 14,500 women were receiving war disablement pensions. The total number of war widows' pensions being paid was 154,200 — 82,400 relating to the World War I. About 75,100 parents, orphans and other dependents were receiving pensions, 24,200 from World War I. About 29,300 war pensioners are resident overseas (including 7,900 in Canada and 3,900 in the United States). Expenditure in respect of actual war pensions and allowances was approximately £88,700,000 in the financial year 1956–57—£36,700,000 in respect to World War I. Cumulative expenditure on war pensions after Aug. 4, 1914, was nearly £2,630,000,000 by March 1957. (T. W. C.)

WARQLA (OUARGLA), a town of the Algerian Sahara. Pop. (1954) 6,456, the majority of mixed Berber and Negro blood. It is walled and is entered by six gateways, which are fortified. The French fort, barracks, hospital and other buildings are south of the native town. The oasis in which Warqla is situated contains two or three other small fortified *ksurs* or villages, the largest and most picturesque being Ruissat. The population of the oasis is (1954) 27,034.

WARRANT, in law, indicates an authority in writing empowering a person to do an act or to execute an office. The term is applied to a great variety of documents of very different kinds.

Executive and Administrative. — While the royal prerogative was insufficiently defined and limited, a great many executive acts were authorized by royal warrant (per speciale *mandatum regis*) which now either depend on statute or are dealt with by departments of State without the need of recourse to the personal authority of the sovereign. There is hardly any exercise of the royal will which does not depend on the issue of a warrant attended with the strictest formalities designed to secure the responsibility of some minister for it, in illustration of the great constitutional principle that "the King cannot act alone." (See PREROGATIVE; PRIVY COUNCIL.) Under present constitutional practice royal warrants are as a general rule countersigned by a member of the cabinet or other responsible officer of State. By an act of 1435 (18 Hen. VI. c. 1) letters patent under the great seal must bear the date of the royal warrant delivered to the chancellor for their issue. This act still applies to all patents, except for inventions. The form and countersignature of warrants for affixing the great seal is regulated by the Great Seal Act 1884. Pardon, which was granted for centuries only by letters patent under the great seal, has since 1827 in England and 1828 in Ireland been granted in case of felony by warrant under the royal sign manual countersigned by a secretary of State (7 and 8 Geo. IV. c. 28, s. 13; 9 Geo. IV. c. 54, s. 33). The prerogative of the crown with reference to the control of the navy and army is largely exercised by the issue of warrants. In 1871 the purchase of commissions in the army was abolished by royal warrant. The convocation of naval courts-martial and the appointment of judge-advocate and provost-marshal at such court is by warrant of the Admiralty or of the officer on foreign or detached service who by his commission is entitled to convene such a court. (See Naval Discipline Act 1866, s. 58; Army Act 1881, s. 179.) A general court-martial for the army is constituted by royal warrant or convened by an officer authorized to convene such court, or his lawful delegate (Army Act 1881, s. 48). Appointments to certain offices under the crown are made by warrant of the king or of the appropriate department of State. In the navy and army the officers called warrant officers are so styled because they are appointed by warrant and do not hold commissions. Certain tradesmen to the court are described as "warrant holders," because of the mode of their appointment. Abuses of claims to this distinction are punishable (Merchandise Marks Act 1887, s. 20; Patents Act 1883, s. 107). The issue of warrants under the hand of a secretary of State, so far as they affect personal liberty, depends in every case on statute, *e.g.*, as to the surrender of fugitive criminals (EXTRADITION), or the deportation of undesirable aliens (see ALIEN), or the bringing of prisoners as witnesses in courts of justice. The right of a secretary of State by express warrant in writing to detain or open letters in the post office was recognized by orders in council and proclamations in the 17th century and by various acts, and is retained in the Post Office Act 1836 (s. 25).

Judicial and Quasi-Judicial Warrants. — Unless a statute otherwise provides a judicial warrant must be in writing under the seal, if any, of the court, or under the hand and (or) seal of the functionary who grants it. Committal for breach of privilege of the House of Commons is by warrant of the Speaker. During the Tudor and Stuart reigns frequent attempts were made by the crown and great officers of State to interfere with personal liberty, especially as to offences of State. The legality of these proceedings was challenged by the judges in Elizabeth's reign. On the abolition of the Star Chamber it was enacted (16 Car. I. c. 10) that if any person be imprisoned by warrant of the king in person, of the council board, or any of the privy council, he is entitled to a writ of habeas corpus, and the courts may examine into the legality of the cause of detention. This enactment, and the Habeas Corpus Act 1679, put an end to the interference of the executive with matters belonging to the judicature; but until 1763 there survived a practice by which a secretary of State issued warrants to arrest individuals for State offences, and to search or seize the books and papers of the accused. The latter practice was examined and declared illegal in the famous case of *Entick* v. Carrington (19 How. St. Tr. 1030) where it was held that a secretary of State is the king's private secretary and has not, as such, the authority of a magistrate to issue a warrant. Still more important were the cases of *Leach* v. *Money* (19 St. Tr. 1001) and *Willus* v. *Wood* which declared the illegality of "general" or "uncertain" warranty, *i.e.,* warrants which do not testify the name of the person to be arrested. All privy councillors are included in the commission of the peace for every county. The council itself is said to have power to issue warrants of arrest for high treason, but the power, if it exists, is in abeyance in England. As a result of the gradual restriction of the royal prerogative, the term warrant has come in modern times oftenest to be used of documents issuing from courts of justice. Few documents issuing from the superior courts are called warrants. In these courts writs and orders are more generally used. In courts of record which try indictments a "bench warrant" is sometimes used for the arrest of an absent defendant, but the word warrant has for judicial purposes become most closely associated with the jurisdiction of justices of the peace. As a general rule no one can be arrested for a misdemeanour. But to this rule there are many statutory exceptions, as in the case of street offences, gambling, cruelty to animals, offences against the person, profanity and other misdemeanours, also of a breach of the peace actually committed in the presence of a constable. In the case of felonies, no warrant is necessary. At common law a justice of the peace, a sheriff, a coroner, a constable and even a private person, may arrest any one without warrant for a treason, felony or breach of the peace committed, or attempted to be committed, in his presence. A constable (whether a constable at common law or a police constable appointed under the Police Acts) may arrest a person indicted for felony; a constable or a private person may arrest on reasonable suspicion that he who is arrested has committed a felony. But in the latter case he does so at his peril, for he must prove (what the constable need not) that there has been an actual commission of the crime by some one, as well as a reasonable ground for suspecting the particular person. What is a reasonable ground it is of course impossible to define, but, in the case of a constable, a charge by a person not manifestly unworthy of credit is generally regarded as sufficient. An accused person who has been bailed may be arrested by his bail, and the police may assist in the arrest. In neither case is a warrant necessary. Nor is it necessary for the apprehension of one against whom the hue and cry is raised. The king cannot arrest in person or by verbal command, as no action would lie against him for wrongful arrest. In those cases in which arrest without warrant is illegal or is found inexpedient, information in writing or on oath is laid before a justice of the peace setting forth the nature of the offence charged and to some extent the nature of the evidence implicating the accused; and upon this information, if sufficient in the opinion of the justice applied to, he issues his warrant for the arrest of the person incriminated. The warrant, if issued by a competent court as to a matter over which it has jurisdiction, becomes a judicial authority to the person who executes it, and resistance to such a warrant is a criminal offence. The issue of a warrant by a justice of the peace is a judicial act, and provided he is acting within his jurisdiction, he cannot be sued for a "false imprisonment" by the person arrested, even though he has acted unreasonably in issuing it and the prisoner is acquitted. Speaking generally, a constable to whom a warrant is issued is protected from any action at law for executing it if it was apparently legal on the face of it, because he is bound to obey it. But if he arrested the wrong person or arrested without having the warrant in his possession, he is liable in an action for "false imprisonment." Entry upon the land or seizure of property cannot as a rule be justified except under judicial warrant. The only common law warrant of this kind is the search warrant, which may be granted for the purpose of searching for stolen goods. Special powers for issuing such warrants are given by the Army, Merchant Shipping, Customs, Pawnbrokers and Stamp Acts, and for the discovery of explosives or appliances for coining and forgery. The Official Secrets Acts of 1911 to 1920 are remarkable in that they disperse with the necessity of the intervention of a justice of the peace in the case of a search for official documents and enable the constable to make such a search on the order of a superintendent of police if it appears that "immediate action is necessary." The Criminal Law Amendment Act 1885 allows the issue of search warrants where it is suspected that a female is unlawfully detained for immoral purposes. Execution of the decisions of a court of summary jurisdiction is secured by warrants, part of the process of the court, such as warrants of distress or commitment. A warrant may also issue for the apprehension of a witness whose attendance cannot be otherwise assured. The forms of warrants used by justices in indictable cases are scheduled to the Indictable Offences Act 1848. Those used for summary jurisdiction are contained in the Summary Jurisdiction Rules of 1886.

As a general rule, warrants must be executed within the local jurisdiction of the officer who issued them. Warrants, etc., issued by a judge of the High Court run through England, in criminal as well as in civil cases: and the same rule applies as to courts having bankruptcy jurisdiction. The warrants of justices of the peace can be executed on fresh pursuit within 7 m. of the boundary of the jurisdiction, and if properly backed by a local justice or officer in any other part of the British Isles. *(See* SUMMARY JURISDICTION.) There is also a special provision as to executing warrants in the border counties of England and Scotland. Under the Extradition Acts and Fugitive Offenders Act 1881 provision is made for the issue of warrants in aid of foreign and colonial justice; but the foreign and colonial warrants have no force in the United Kingdom. The word is used as to a few judicial or quasi-judicial matters of civil concern, *e.g.,* warrant to arrest a ship in an admiralty action *in rem;* and in the county courts warrants to the bailiffs of the court are used where in the High Court a writ to the sheriff would be issued, *e.g.,* for attachment, execution, possession and delivery.

Financial and Commercial. — Payment out of the Treasury is generally made upon warrant. Treasury warrants are regulated by many of the acts dealing with the national debt.

Payment of dividends by trading corporations and companies is generally made by means of dividend warrants. Mercantile warrants are instruments giving a right to the delivery of goods, generally those deposited at a dock or warehouse, and by mercantile custom regarded as documents of title to goods.

Scotland. — By art. xxiv. of the Articles of Union royal warrants were to continue to be kept as before the union. The Secretary for Scotland Act 1885 enabled the crown by royal warrant to appoint the secretary to be vice-president of the Scotch Education Department. The lord advocate's warrant runs throughout the whole of Scotland. Warrants issued by courts of summary jurisdiction agree in the main with those in use in England, though their names are not the same. *(See* SUMMARY JURISDICTION.) There are many statutory provisions as to other warrants.

(W. F. C.)

UNITED STATES

Judicial warrants can be divided into the two classes of warrants of arrest and warrants of search and seizure. The use of general or John Doe warrants, which did not specify the name of the person to be arrested nor the place to be searched nor the character of the goods to be seized, and the use of writs of assistance having a like effect, a practice condemned in 1763 by Lord Camden in *Entick* v. *Carrington* (19 How. St. Tr. 1030) and one of the abuses complained of by the colonists in the Revolutionary War, led to the prohibition of the issuance of such warrants by constitutional provisions. The 4th amendment to the U.S. Constitution thus provides against unreasonable searches and seizures and prohibits the issuance of any warrant "but upon probable cause, supported by Oath or affirmation, and particularly describing the place to be searched, and the person or things to be seized." Though this amendment is only a limitation upon the powers of the Federal Government, similar restrictions upon the States are to be found in the State Constitutions.

Warrants of arrest, which are necessary where under the common law or under statutory provision no power to arrest without warrant may be exercised, may be issued by those officers designated by the State or Federal statutes. These ordinarily include judges, U.S. commissioners, justices of the peace and judicial or quasi-judicial officers of municipal corporations. A similar power is conferred upon certain administrative officers in the exercise of their functions, the commonest example being that of warrants issued by the Department of Labor in the deportation of aliens. Under the traditional laws of parliamentary privilege a power to issue warrants of arrest for breach of privilege resides in the speaker of a legislative assembly or the president of a senate. The warrant issues at the behest of the complainant upon a complaint setting forth the facts or information upon which the guilt of the offender is based. Probable cause must be shown in the sense that the complainant must make out a *prima facie* case for concluding that the person accused was guilty of the crime. The complaint must be accompanied by the affidavit of the complainant. The forms and requisites governing the issuance of the warrant must be strictly complied with. The legality of the warrant and the arrest thereunder can be contested by a *habeas corpus* (*q.v.*) proceeding or by an action for false imprisonment. Analogous to the ordinary warrant of arrest is the bench warrant which is issued by the court itself for arrest for contempt or after indictment found or against a recalcitrant witness.

The issuance of search warrants is governed generally by the same limitations surrounding warrants of arrest. The description of the property to be seized must be so particular that the officer charged with the execution of the warrant will be left with no discretion respecting the property to be taken. It may issue for the recovery of stolen property, for the seizure of property used for the commission of a crime or in the possession of a person intending to use it for such a purpose. The warrant should be executed only during the day-time but the officers when resisted may forcibly enter the premises. In its execution its limitations must be strictly observed, and the search confined to the character of goods enumerated in the warrant. Resistance to its execution is punishable. The legality of its issuance is in some instances reviewable by writ of certiorari to a superior tribunal. In all cases the legality of its issuahce and execution can be contested by an action of trespass against the officer. In order to make more effective the constitutional prohibition against unreasonable searches and seizures the Federal courts refuse to admit any evidence obtained as a result of a search without a warrant or under an illegal warrant. The majority of the State courts, however, admit such evidence and leave the complainant to his civil action against the offending officer. The enforcement of the constitutional protection against unreasonable searches and seizures has become a matter of intense moment in the prosecution of offenses against the 18th amendment and legislation under it seeking to make effective the constitutional prohibition against the sale, manufacture and transportation of intoxicating liquor. The assertion of these new and penetrating powers of government has, in communities where their assertion is regarded as an infringement upon the liberty of the citizens, precipitated issues akin to those that agitated the citizenry during the controversy over general warrants and writs of assistance.

Other judicial warrants may be briefly adverted to. The escape warrant is issued for the recapture of prisoners who have escaped from custody. The warrant of commitment is the process by which a court directs a ministerial officer to take a person to prison either before or after trial. Orders directing the execution of an offender are known as death warrants, commonly issued by the governor of the State. In some States their issuance is by statute a prerequisite to the execution of the death sentence; in others the pronouncement of the sentence in open court is sufficient authority for its execution. The landlord's warrant is directed by a landlord to a constable to levy upon the goods of his tenant and sell them in order to constrain the latter to pay the rent. Under the Federal Bankruptcy Act of 1898, Section 69, a judge may issue a warrant to a marshal authorizing him to seize the property of a bankrupt upon proof that the latter is neglecting his property or allowing it to deteriorate. A tax warrant is the authority under which a collector is authorized to collect taxes.

Numerous other warrants of a financial or commercial nature are also known to the American law. The term warrant is used to apply to an order or draft for the payment of an indebtedness. School warrants thus issue for the payment of an indebtedness incurred by a school board or district. Like a check or draft it is a conditional payment of the debt. Similarly there are municipal warrants, treasury warrants, State warrants, reclamation warrants, dividend or interest warrants of private corporations. Land warrants are transferable certificates issued by the Government entitling the holder to a specific tract of public land. A warrant of attorney is a writing addressed to one or more attorneys authorizing them to appear in court in behalf of the person who gives the warrant and confess judgment in favour of some particular person named in the warrant. They are commonly used to facilitate the collection of negotiable instruments and such a provision authorizing the confession of judgment on the note is commonly appended to the negotiable instrument. Some States by statute prohibit judgments by such confession. (J. M. LA.)

WARRANT OF ATTORNEY. A warrant of attorney to confess judgment is a security for money (now practically obsolete) in the form of an authority to a solicitor named by a creditor, empowering him to sign judgment in an action against the debtor for the sum due, with a clause that the warrant shall not be put into force in case of due payment.

WARRANTY, etymologically, another form of guarantee (*q.v.*). It is used, however, in a rather different sense. The sense common to both words is that of the collateral contract. A warranty expresses the collateral responsibility of the principal actor, while guarantee expresses that of his surety. It differs from a condition in that a condition forms the basis of the contract and a breach of it discharges from the contract, and from a representation in that the latter does not affect the contract unless made a part of it expressly, or by implication as in contracts of insurance and other contracts *uberrimae fidei,* or unless it be fraudulent. These distinctions are not always maintained. Thus in the Real Property act 1845, s. 4, condition seems to be used for warranty.

Warranty as it affected the law of real property was, before the passing of the Real Property Limitation act, 1833, and the Fines and Recoveries act, 1833, a matter of the highest importance. A warranty in a conveyance was a covenant real annexed to an estate of freehold, and either expressed in a clause of warranty or implied in cases where a feudal relation might exist between feoffor and feoffee. The warranty, as described by Littleton, s. 364b, 697, was an outgrowth of feudalism, and something very like it is to be found in the *Liber Feudorum.* At the time of Glanvill the heir was bound to warrant the reasonable donations of his ancestor. Warranty was one of the elements in Bracton's definition of homage, 78*b*, *"juris vinculum quo quis astringitur ad warrantizandum defendendurn et acquietandum tenentem suum in seisina versus omnes."* For an express warranty the word *warrantizo* or warrant was necessary. The word give implied a warranty, as did an exchange and certain kinds of partition. In order to bind heirs a clause of warranty was required. This was either lineal, collateral or commencing by disseisin. The feoffor or his heirs were bound by voucher to warranty or judgment in a writ of *warrantia chartae* to yield other lands to the feoffee in case of the eviction of the latter. Vouching to warranty was a part of the old fictitious proceedings in a common recovery in use for the purpose of barring an entail before the Fines and Recoveries act. Warranty is now superseded by covenants for title. The more usual of these are now by the Conveyancing act, 1881, deemed to be implied in conveyances. For the implied warranties of title and quality *see* SALE OF GOODS. Vouching to warranty was at one time important in the law of personalty as well as of realty. Warranty, as it exists at present in the law of personalty, is either express or implied. The principal cases of implied warranty occur in the contracts of sale and insurance. There is also an implied warranty in other kinds of contract; *e.g.,* of seaworthiness by the shipowner in a contract between him and a charterer for the hire of a ship. In all cases of implied warranty the warranty may be excluded by the special terms of the contract. For breach of warranty an action may be brought directly, or the breach may be used as ground for a counterclaim or for reduction of damages, but the breach will not in the case of a warranty proper entitle the person suffering by it to a rescission of the contract. Thus in a sale the property passes although the warranty be broken. In some cases warranties on sale are the subject of statutory enactments, as the merchandise marks acts and the sale of food and drugs acts.

Scotland. — Warranty is a term imported into Scots law in connection with mercantile law. Differing from the English interpretation it signifies a material condition of the contract, breach of which discharges from the contract in the option of the other party (see Sale of Goods act, 1893, ss. 53 [5] and 62 [1]). The term native to Scots law is warrandice. It occurs in connection with deeds transferring land or discharging obligations, and is in the form of a warranty by the grantor that his title is good. Warrandice is either real or personal. Real warrandice is that whereby warrandice lands are made over, as indemnity for those conveyed, to assure the person to whom they were conveyed from loss by the appearance of a superior title. Real warrandice is implied in excambion or exchange of lands. Its effect is that the excamber, in case of eviction, may recover possession of his original lands. Personal warrandice is either express or implied. There is an implied warrandice in every onerous deed. Express warrandice may be either simple, against the future acts of the grantor; from fact and deed, against the grantor's own acts whether past or future; or absolute, *i.e.*, against acts and deeds whether (1) of the grantor or (2) of a third prior to the date of the deed. A clause of warrandice is the Scottish equivalent of the English covenants for title. By the Titles to Land Consolidation (Scotland) Amendment act, 1869, a clause of warrandice in the form given in the schedule to the act imports absolute warrandice as regards the lands and the title deeds thereof, and warrandice from fact and deed as regards the rents.

United States. — In the United States the common law warranty accompanying the conveyances of real property seems never to have been known. Personal covenants of title were developed in its place and with greater vigour than in England inasmuch as purchasers were unaccustomed to examine titles with the particularity that is common in England. These covenants of title generally embrace the covenant of seisin or right to convey, the covenant against incumbrances, the covenant for quiet enjoyment and of warranty. This modern covenant of warranty, which is not recognized in England, is quite different from the common law covenant of warranty. Under this covenant the grantor warrants that he will defend the grantee against all lawful claims by third persons. In some states by statute these covenants are implied from the simple terms granting the estate; in other states by statute no such covenants are implied but must be express. The quitclaim conveyance ordinarily imports no covenants, but as altered by statute in some states it carries with it a covenant of title. In sales of personal property, warranties are governed by sec. 12–16 of the Uniform Sales act. Any affirmation of fact or promise by the seller relating to the goods and inducing the buyer to purchase them is regarded as an express warranty. In the absence of express warranties the buyer is protected by the implication of warranties of title and quality. In contradistinction to the English law of sale, rescission for breach of warranty is permitted. The buyer may tender back the goods and recover the purchase price. (See SALE OF GOODS.) Sec. 65 and 66 of the Uniform Negotiable Instruments law govern the character of warranties that accompany the transfer of negotiable instruments with or without indorsement. Warranty in insurance law operates to relieve the insurer of liability for breach thereof. Legislation commonly provides that no statements of fact made by the insured shall be regarded as warranties relieving the insurer of liability unless made with the intention to deceive or material to the risk.

WARRAU (WARRAUNAN or GUARAUNAN), an independent linguistic stock of South American Indians, mostly concentrated in the delta of the Orinoco river but also scattered through the coastal portions of British and Dutch Guiana (Surinam) as far east as the Coppename river. At one time they may have occupied part of Trinidad. The Warrau probably originally represented an early, simple cultural stratum whose culture was enriched before the European discovery by contact with neighbouring Arawak and Carib. Typical of the delta Warrau are rectangular pile huts raised above the water or swamp. Entire villages, with streets and plazas, were formerly constructed on a common platform of logs, resting on poles sunk into the mud or on the trunks of trees. Fishing is more important than hunting, and the Warrau are famous canoemen. Manioc is the staple cultivated food plant, with maize given a secondary place. Men go naked except for a penis sheath or string. Women wear aprons of palm fibre strings or of bark cloth. Both sexes remove all hair from face and body. Baskets are usually woven by men, as are also hammocks and cotton bands. Pottery is scarce and crude and reportedly is dried in the sun rather than fired. Plural wives are the rule. Both bride and groom are whipped as part of the marriage ceremony. The people are fond of music and dancing. and each settlement has its community music master. The important supernatural beings are: Abore, who invented all things; Korroremana, the creator of males; and the spirits of the forest, water and sky. Each village has a headman and also a shaman or medicine man. The latter is believed to control spirits whom he contacts while in a trance induced by drinking green tobacco juice.

WARREN, SIR CHARLES (1840–1927), English soldier and archaeologist, was born at Bangor, Wales, on Feb. 7, 1840. In 1857 he entered the royal engineers. From 1861 to 1865 he was engaged in a survey of Gibraltar, but then went to Palestine where he became interested in archaeology. He conducted excavations at Jerusalem until 1870. and made for the Palestine Exploration fund the first systematic archaeological survey of the Holy Land. He published The Recovery of Jerusalem (1871), and, with C. R. Conder. The Survey of Western Palestine (1884). In 1876, on the outbreak of the Kaffir War, he commanded the Diamond Fields horse. He quelled an uprising in Bechuanaland, and in 1879. as administrator of Griqualand West he organized a force to defend the Transvaal. In 1884 he explored in Arabia Petraea, but before the year was over was again sent to South Africa to restore order in Bechuanaland. He proclaimed the territory south of the Malopo river a crown colony under the name of British Bechuanaland. He served in the Boer War as lieutenant general in command of the 5th division but after the British disaster at the Tugela river was transferred to an administrative post. He died at Weston-supermare, Eng., on Jan. 21, 1927. Among the more notable of his later books was *On* the Veldt in the Seventies (1902).

WARREN, EARL (1891–), 14th chief justice of the United States, is best known in the field of jurisprudence for his 1954 opinion declaring racial segregation in the public schools unconstitutional. Born on March 19, 1891, in Los Angeles, Calif., and raised in Bakersfield, he was educated in the Kern county public schools and at the University of California, Berkeley (B.L., 1912; J.D., 1914). He served successively as clerk for a state legislative committee (1919), deputy city attorney for Oakland (1919–20), deputy district attorney (1920–25) and district attorney (1925–39) for Alameda county and attorney general of California (1939–43). Elected governor of his native state for three terms (1943–53), Warren received wide popular support from both parties. Only once—in 1948 when he was the Republican candidate for vice-president — did he ever lose an election. He was named chief justice by Pres. Dwight D. Eisenhower in 1953.

In 1954 Warren spoke for a unanimous court in the school-segregation cases (Brown v. Board of Education, 347 U.S. 483), which are among the most important decisions in the court's history. "In the field of public education," Warren stated, "the doctrine of 'separate but equal' has no place. Separate educational facilities are inherently unequal." Other notable opinions by Warren included: Cooper v. Aaron (358 U.S. 1, 1958), reaffirming and explaining the school-segregation decisions; *U.S.* v. *Harriss* (347 U.S. 612, 1954), sustaining the constitutionality of the Federal Lobbying act; Quinn v. U.S. (349 U.S. 155, 1955) and *Watkins* v. *U.S.* (354 U.S. 178, 1957), protecting the rights of witnesses before congressional investigating committees; Pennsylvania v. *Nelson* (350 U.S. 497. 1956) barring enforcement of state sedition laws that duplicate federal legislation on the same subject; and Trop v. *Dulles* (356 U.S. 86, 1958), invalidating a federal statute revoking the citizenship of deserters from the armed forces. Although voting often in support of government (*e.g.*, antitrust) regulation in the economic area, Warren also showed a marked sensitivity to claims of governmental infringement of civil liberties. Accused by some of a disregard for precedent and a proneness to sweeping liberal judgments, he was hailed by others as a courageous leader seeking to adapt legal rules to rnodern conditions in the light of moral considerations. (E. E. P.)

WARREN, GOUVERNEUR KEMBLE (1830–1882), U.S. army officer in American Civil War, was born at Cold Spring, N.Y., on Jan. 8, 1830. After graduating from West Point in 1850, he became an engineer officer, served on mapping and lndian expeditions, and was appointed assistant professor of mathematics at West Point in 1859. When the Civil War broke out, he joined the 5th New York volunteers, with whom he fought at Big Bethel. Promoted to brigadier general in 1862 for distinguished service on the peninsula, he took part in the second battle of Bull Run, Antietam and Chancellorsville. In 1863 he was named chief engineer of the army of the Potomac. His greatest moment came at the battle of Gettysburg, where he commandeered Vincent's brigade just in time to occupy the vital summit of Little Round Top, an exploit which probably saved the day for the Union. In 1864 and 1865, he ably commanded the 5th corps at the Wilderness and Spotsylvania, Cold Harbor and Petersburg, but, after the battle of Five Forks, was relieved by Gen. Philip H. Sheridan for alleged dilatoriness. A court of inquiry completely exonerated him in 1881–82. Warren was an efficient officer who displayed initiative at crucial moments. He died at Newport, R.I., Aug. 8, 1882.

See Emerson Gifford Taylor, *Gouverneur* Kemble *Warren (1932).* (H. L. T.)

WARREN, JOSEPH (1741–1775), U.S. soldier and patriot, born at Roxbury, Mass., June 11, 1741. He graduated at Harvard college in 1759, studied medicine at Boston, and soon acquired a high reputation in his profession. The passage of the Stamp act aroused his patriotic sympathies and brought him in close connection with Samuel Adams. John Adams and Josiah Quincy, Jr., as a leader of the popular party. He drafted the "Suffolk Resolves," which urged forcible opposition to Great Britain, if such should be necessary, pledged submission to such measures as the Continental Congress might recommend, and favoured the calling of a provincial congress. These resolves were unanimously adopted by a convention at Milton (*q.v.*) on Sept. 9, 1774. Warren was a member of the first three provincial congresses (1774–75), president of the third, and an active member of the committee of public safety. On June 14, 1775, he was commissioned a major general, but three days later, and before his commission was made out, he took part as a volunteer, under the orders of Putnam and Prescott, in the battle of Bunker Hill (Breed's Hill), where he was killed.

WARREN, ROBERT PENN (1905–), U.S. writer best known for his novels, was born in Guthrie, Ky., on April 24, 1905. In 1921 he entered Vanderbilt university in Nashville, Tenn., intending to study science, but after meeting Donald Davidson and John Crowe Ransom he turned to literary studies, joining the group of poets called the "Fugitives." Later he was associated with the "Agrarians," being one of the contributors to their I'll *Take* My *Stand* (1930).

Warren graduated from Vanderbilt in 1925, took an M.A. at the University of California, Berkeley, in 1927, did further graduate study at Yale, 1927–28, and took a bachelor of literature in 1930 at Oxford, where he was a Rhodes scholar. From 1930 to 1957 he taught at Southwestern college at Memphis, Tenn., Vanderbilt university, Louisiana State university, Baton Rouge, the University of Minnesota. Minneapolis, and Yale university. With Cleanth Brooks he edited the influential *Southern Review* (1935–42) and several widely used textbooks (including *Understanding Poetry).*

Warren's poetry includes *Selected Poems, 1923–1943* (1944), *Brother to Dragons* (1953) and *Promises* (1957; Pulitzer prize for poetry, 1958). *The Circus in the Attic* (1948) is a collection of short stories. His novels include *Night Rider* (1939), *At Heaven's Gate* (1943), *All the King's Men* (1946; Pulitzer prize for fiction, 1947), *World Enough and Time* (1950), *Band of Angels* (1955) and *The Cave* (1959). He collected some of his critical pieces in *Selected Essays* (1958). In most of Warren's work, whether in verse or prose, there are vigorous handling of southern subject matter, technical virtuosity, symbolical intensity and a religious attitude that might be called neo-Calvinistic. (R. St.)

WARREN, a city of Ohio, U.S., on the Mahoning river 15 mi. N.W. of Youngstown; the seat of Trumbull county. The population in 1960 was 59.648. (For comparative population figures see table in OHIO: *Population*) Warren is a central city of the Youngstown-Warren standard metropolitan statistical area (*see* YOUNGSTOWN). It was founded in 1799 by Ephraim Quinby of Washington, Pa., a stockholder in the Connecticut Land company, mhich in 1795 had purchased from the state of Connecticut, for $1,200,000, about 3,000,000 ac. of land in that portion of the present state of Ohio retained by Connecticut when it ceded its western lands to the federal government in 1786—an area known historically as the Western Reserve. For $1,625 Quinby purchased 441 ac. from the company and founded the settlement which he named for Moses Warren, a surveyor for the company. In 1800, upon the organization of Ohio territory, the entire Western Reserve was attached to it, as Trumbull county, and in 1803 Warren became the county seat. (The modern Trumbull county is greatly reduced in area, several other counties having been formed subsequently.) Warren was incorporated as a village in 1334 and as a city in 1869. It became a port in 1840 upon completion of the Pennsylvania and Ohio canal from Pittsburgh to Akron (nhere it connected with the Ohio and Erie canal); the canal mas used until the mid-1850s, by which time it was replaced by railroads. Modern transportation facilities also include the Ohio turnpike and the Youngstown municipal airport, both of which are within 9 mi.

Iron, steel and electrical products are leading industries. W. D. and J. W. Packard produced early electric lamps and the Packard automobile there. Packard Music hall in the city is a centre of culture and entertainment. Dana's Musical institute, founded in Warren in 1869, was moved to Youngstown and became a part of Youngstomn university in 1941. (N. W. AD.)

WARRINGTON, a market town, municipal (1847), county and parliamentary borough of Lancashire, Eng., 18 mi. W.S.W. of Manchester on the north bank of the Mersey and the Manchester Ship canal. Pop. (1951) 80,694. Wilderspool, south of Warrington was a walled town of the Romans. In the Domesday survey the Warrington hundred consisted of nearly ten hides of land and covered several parishes. The manor and hundred were granted to Paganus de Vilars, the first lord of Warrington. William le Boteler obtained the first royal charter to hold a fair in 1255. For nearly 700 years the town has had two weekly markets, and two annual fairs held in July and November. Hermit friars of the order of St. Augustine established a friary there toward the end of the 13th century. Warrington declared for the king during the Civil War but surrendered in 1643. In 1648 the Scots under the duke of Hamilton surrendered to Cromwell in the town. In 1651 the Scottish army, commanded by King Charles II, was defeated at Warrington bridge. A grammar school, established by Sir Thomas Boteler in 1526, was controlled by the local education authority after 1933 and new premises were opened in 1940. A bluecoat school mas founded in 1665. The Warrington academy was established in 1757 to provide education for dissenters who were debarred from entry to established universities. Its tutors included Joseph Priestley (*q.v.*) and John Aiken, Warrington circulating library, founded in 1760, formed the nucleus of the Warrington municipal library founded in 1848; it was the first English library supported by local rates. Bank park, purchased by the corporation in 1872, surrounds Bank hall, an 16th-century building now the tonn hall. St. Elphin's church (Decorated style) has a lofty central tower and spire and the crypt of a much earlier church beneath the chancel. Warrington manufactures iron, steel, metal and nire products, leather and cotton goods, paper products. chemicals, soap, gas stoves and fork trucks. It has large engineering works and breweries.

WARKISTON, ARCHIBALD JOHNSTON, LORD (1611–1663), Scottish judge and statesman, son of James Johnston. was baptized on March 28, 1611, educated at Glasgow and passed advocate at the Scottish bar in 1633. In 1637 he drew up the remonstrances of the Covenanting leaders against Charles I's attempt to force the English liturgy upon Scotland and. with Alexander Henderson, was a principal author of the National covenant of 1638. In June 1639 he took part in the negotiations leading to the treaty of Berwick. when his firm attitude displeased the king. He was appointed in 1640 to attend the general of the army and the committee and on June 23 wrote to Lord Savile asking for definite support and the acceptance of the National covenant by the leading opposition peers in England. In October he was a commissioner for negotiating the treaty of Ripon. In 1641 he led the opposition on the point of control of state appointments during the king's visit to Scotland.

In accordance with the king's short-lived policy of conciliation Johnston was appointed a lord of session. Nov. 13, 1641, with the title of Lord Warriston. and was knighted and given a pension. In the same month the parliament appointed him a commissioner at Westminster for settling the affairs of Scotland, and he was later (1643) made a member of the committee of both kingdoms, which directed the military operations. Early in 1644 he took his seat in the Assembly of Divines, where he was strongly opposed to independency and to lay control in ecclesiastical affairs. He was also member for Edinburgh in the Scottish parliament (1643–47) and speaker of the barons. In Oct. 1646, Johnston was made king's advocate after Charles had surrendered himself to the Scots. In 1648 he became the leader of the Remonstrants, the party opposed to the "engagement" concluded by the predominant party with Charles at Carisbrooke. (See ENGLISH HISTORY.) In October, after the defeat of the "engagers" at Preston he met Cromwell at Edinburgh and helped to promote the Act of Classes (Jan. 23, 1649), disqualifying royalists; but after the king's execution good 'relations with Crornwell were broken off, and Johnston was officially present at the proclamation of Charles II as king in 1649 at Edinburgh. On March so, he was appointed lord clerk register; in May 1650 he pronounced sentence on the earl of Montrose. After the defeat of Dunbar (Sept. 3, 1650) at which Johnston was present, he urged the removal of David Leslie from the command, and on Sept. 21 delivered a violent speech in Charles's presence attributing all the troubles to the opposition of the Stuarts to the Reformation.

Johnston now committed himself to the faction of the Remonstrants who desired to exclude the king and whom he represented in London in 1656. On July 9, 1657, he was restored by Cromwell to his office of lord clerk register, and on Nov. 3 was made a commissioner for the administration of justice in Scotland. He sat in the upper chamber of Cromwell's parliament (Jan. 1658) and of Richard Cromwell's parliament; and on the latter's abdication and the restoration of the Rump, he was chosen a member of the council of state and continued in the administration as a member of the committee of public safety.

At the Restoration he escaped abroad and was condemned to death in his absence (May 13, 1661). In 1663 he was discovered at Rouen and with the consent of Louis XIV was brought over and imprisoned in the Tower. Taken to Edinburgh in June and confined in the Tolbooth, he was hanged at the Market Cross on July 22. His head was exposed on the Netherbow and afterward buried with his body in Greyfriars churchyard.

Johnston was a man of energy. His devotion to the Scottish Church amounted to fanaticism. He had by nature no republican leanings. When, however, Presbyterianism was attacked, he desired, like Pym, to restrict the royal prerogative. His acceptance of office under Cromwell hardly deserves the censure it has received. But in his dying speech he condemned the act as a fault which he had committed in order to provide for his numerous family. Johnston was wanting in consideration for his opponents. He was hated by Charles I, whose statecraft was vanquished by his inflexible purpose, and by Charles II, whom he rebuked for his dissolute conduct.

See W. Morison, *Johnston of Warriston* (1901); *Diary of Sir A. J. Warriston, 1650–54, ed. by D.* H. Fleming (Scottish Hist. Soc., 1919).

WARRNAMBOOL, seaside and tourist resort in Villiers shire, Victoria, Austr., 165 mi. S.W. by rail from Melbourne. Pop. (1961) 15,697. The town first became important as a port for exporting the products, mainly agricultural, of the closely settled hinterland. Later its wide streets, fine buildings and parks and commanding position on the coast made it popular as a resort. The surrounding district produces wool, wheat, potatoes and dairy products.

WARSAW (Polish WARSZAWA), *wojewodztwa* (province) of Poland. Area 11,353 sq.mi. Pop. (1960) without the city of Warsaw, 2,314.800. The province of Warsaw. formerly the principality of Mazovia, is situated in the great central plain and drained by the Vistula and its affluents. In the north the Baltic uplands begin; in the south the province includes part of the southern plateau. The plain is sandy and not very fertile and suffers much from the periodic inundations of the Vistula, particularly near the confluence of the Bug and Narew. Thrifty Mazovian peasants, however, prosecuted the cultivation of the soil with considerable success. The principal crops are rye, oats, barley, wheat and potatoes, while beetroot is cultivated for sugar in some areas. Gardening and beekeeping are also practised. There are large forests, particularly in the north where there are also wide marshes, especially on the Wkra near Mlawa. The shipping of the Vistula is an important occupation, as are the agricultural industries: flour milling, distilleries, breweries and sugar factories. Saw mills and match factories and especially tanneries also became important. There is an important industrial area including the metal industries, the manufacture of machinery, locomotives and other goods at Warsaw and the textile manufactures of Zyrardów, forming a link between Warsaw and Lodz.

The chief towns are Warsaw (*q.v.*), Plock (pop. [1960], 42,000), Wloclawek (pop. [1960] 63,000), Zyrardów, Gostynin, Grojec, Plonsk, Radzymin, Sochaczew, Ciechanow, Wlochy, Mlawa, Pultusk and Przasnysz.

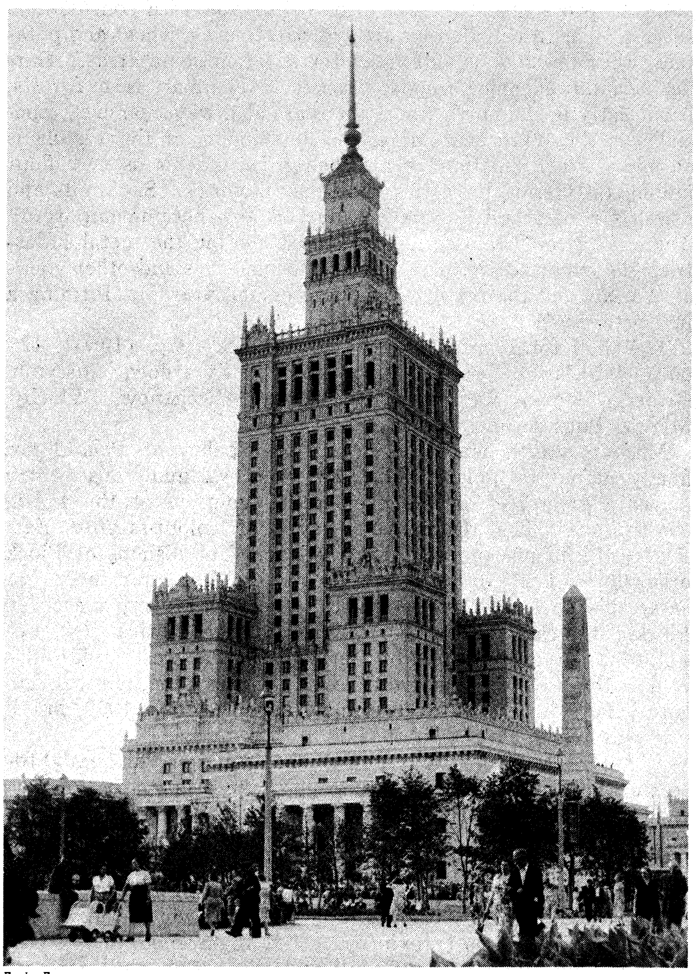
Mazovia was a semi-independent principality of Poland not finally united to Poland till 1529, when its numerous gentry played a great part in the democratic evolution of the Polish constitution. The region sent waves of colonists into East Prussia, Lithuania and even the Ukraine. The bishops of Plock originally had all Mazovia as their diocese, but later there was an archbishopric at Warsaw, which in the 16th century succeeded Plock as the capital city. Warsaw became the political centre of Poland when the advance of Germany in the west and Polish colonization of Lithuania and the Ukraine threw the political centre of the state eastward. Germany occupied it in 1939, but it was returned to Poland in 1945.

WARSAW (Polish WARSZAWA), the capital of Poland and the seat of the Roman Catholic archbishop (the primate of Poland), is situated on the Vistula. The capital's greater part lies on the left bank, on the terrace rising about 360 ft. above sea level and 105 ft. above the river which there has a breadth of 450 to 650 yd. The two parts of the town are connected by three road and two railway bridges. The area of the city, which ranks as a separate *wojewodztwo* (province), rose from 46 sq.mi. to 54 sq.mi. between 1920 and 1939; after World War II it was increased to 172 sq.mi. Pop. (1939 est.) 1,289,000; (1945 est.) 153,000; (1950) 803,888; (1960) 1,136,000.

Although a great part of the Warsaw that existed before 1939 was destroyed in World War II, it was rebuilt by the 1950s on the skeleton of its old streets and avenues. The medieval Stare Miasto (old town), with its picturesque market place and narrow streets. and the 14th-century Gothic cathedral of St. John, was faithfully reconstructed as it had been and so mas the main thoroughfare running southward. The central point of old Warsaw was the royal castle (Zamek) situated between the old town and the Vistula. Built by the dukes of Mazovia, enlarged by Sigismund II Augustus and Sigismund III Vasa. embellished by Stanislaw II Poniatowski. it was destroyed by the Germans in 1944. In Castle square stands Warsaw's finest monument, the column of King Sigismund III Vasa. erected in 1043 and re-erected in 1949.

At this point begins Krakowskie Przedmiescie (Cracom boulevard). the most imposing thoroughfare of the city, dating back to the 15th century and lined by palaces and churches. The oldest is

St. Anne's (1454), where the Gothic style is harmoniously blended with the baroque. Three other notable churches of Cracow boulevard are the Carmelites' (1672). which is baroque with a stone façade; the church of the Order of Visitation (1728–61), with the most beautiful rococo interior in Warsaw; and the Holy Cross church (1682–1757), containing the heart of Frédéric Chopin. Among the palaces of Krakowskie Przedmiescie the largest is that of the council of ministers. built in 1643 and rebuilt in neoclassic style in 1818. Further on is the University of Warsaw (1818) in the former Casimir palace. At the southern end of the boulevard stands the neoclassic Staszic palace) built by Antonio Corazzi (1822), housing scientific institutions. In the front of Staszic palace stands the monument of Nicolaus Copernicus, the famous Polish astronomer, by B. Thordwaldsen (1830). In the same boulevard is the monument of Adam Mickiewicz, Poland's greatest poet, by Cyprian Godebski (1898).



P. I. P.

PALACE OF SCIENCE AND CULTURE (1951–55), WARSAW

Nowy Swiat (New World) street (18th- and early 19th-century with houses in neoclassic style), is the continuation of Krakowskie Przedmiescie. Further south it becomes Ujazdow avenue, Warsaw's Champs-Elysées, laid out in 1731, with 19th-century residences now housing many embassies. At the end of the avenue stands Belweder (Belvedere) palace, built in the 17th century and reconstructed in 1822 in classic style. This palace's garden is contiguous with Lazienki park—the pride of Warsaw—formerly a royal hunting grounds. In the middle of the park stands Lazienki palace (1784–93), built by Stanislaw II Poniatowski, a masterpiece of Polish classicism. with an open-air theatre. It contains the monuments of John III Sobieski (1788) and Prince Joseph Poniatowski. by Thordwaldsen. The last-named is a replica in bronze of the original which stood in the Saxon square but was destroyed by the Germans in World War II. The replica was a gift of the citizens of Copenhagen. A monument to Chopin (by Waclaw Szymanowski) in the Ujazdow avenue, destroyed by the Germans in 1940, was recast and unveiled in May 1958.

Parallel to Ujazdow avenue is Marszalkowska street, a central business thoroughfare with a new residential district: Constitution square (1952) and the Palace of Science and Culture (1951–55). This palace, with a congress hall for 3.000, museums, exhibition galleries, two theatres and a motion-picture theatre, is also the seat of the Polish academy of sciences. A gift of the U.S.S.R., it has 30 stories and is 757 ft. high. While the first thoroughfare, with its three successive names, looks almost exactly as it was before World War II, Marszalkowska street is modern in appearance.

There are two main west–east thoroughfares. One is Jerusalem avenue connecting the former suburb of Praga, on the right bank of the Vistula across the Poniatowski bridge (1913), with the main railway station. The other, more to the north, is General Swierczewski street (1949) connecting the centre of the city, by way of a 200-yd. tunnel and the Slasko-Dabrowski (formerly Kierbedz) bridge, with Praga. In Jerusalem avenue stands the National museum. with galleries of Polish and other European paintings and collections of decorative art. ,It is the most important of Warsaw's 1j museums. At the point where Jerusalem avenue crosses Nowy Swiat stands the big building of the central committee of the Polish United Workers' party (1948–51).

Among other palaces worth noting are: the Primate's palace, built in 1605 and rebuilt in classic style; Krasinski palace (1676–95), Warsaw's finest baroque building; Ostrogski palace (159j and 1690), now housing the Chopin institute; and the former treasury buildings (1825), by Corazzi, now the,town hall. There are 17 theatres including the opera house, the Polish theatre (1913) and the National theatre, the tradition of which dates back to 1765. Grand theatre (1825–32), another work of Corazzi, with imposing classic porticoes, was destroyed by the Germans in 1939, but was reconstructed in the 1950s. Saxon gardens (1725) in the city's centre, is Warsaw's oldest public gardens, adorned with sculptures. Contiguous to it is Saxon (now Victory) square with the tomb of the Unknown Soldier (1923). In the middle of the former Jewish quarter of Muranow stands the monument of the Heroes of the Ghetto (1947), commemorating the Jewish rising against the Nazis in 1943. Besides the university, Warsaw has a school of engineering or Politechnika (1902), schools of commerce (1906), a school of agriculture (1906) and academies of medicine, arts and sciences.

In the southern outskirts is the baroque rural seat of John III Sobieski, Wilanow (1674–92), built in a fine baroque style by Augusto Locci. After World War II a monument of Sobieski was moved there from Lwow, now in the U.S.S.R. The Zoological gardens (1928) are on the right bank of the Vistula. The city also has seven sports stadiums, with a huge Decennium stadium (1955) for 80,000 spectators, built on the right bank, near Poniatowski bridge. There are seven railway stations in the town which is connected by six trunk lines with Vienna, Berlin, Danzig, Leningrad. Moscow and Kiev. Two long-distance lines (to Lodz and to Gliwice in Silesia) were electrified in 1957. The airport of Okecie, $4\frac{1}{4}$ mi. south from the city's centre, has direct permanent communications with ten European capitals and the seven biggest Polish cities. There is also a river port at Zeran.

Warsaw's industrial establishments suffered enormous destruction in 1939–44, but postwar reconstruction and development changed the city into one of the important industrial centres of the country. There are foundries and steelworks. automobile, motorcycle and tractor factories, electrical. pharmaceutical 'and chemical industries, printing works and factories for ready-made clothes and food products. The tailors and the famous Warsaw shoemakers that, before World War II, were the most numerous of the several thousand small shops where articles were made by hand, regained their importance after 1957.

History.—Warsaw became a city at the turn of the 13th and 14th centuries. It was protected by walls with two gates and a number of towers. There was also a small castle, the seat of the local castellany. As early as 1339 Warsaw was an important town, a papal tribunal being held there during a dispute between the

Polish cronn and the Teutonic order. In the middle of the 14th century it became the capital of the duchy of Mazovia (Mazowsze). In 1526 Warsaw together with Mazovia was incorporated into the Polish crown. In 1568 the first permanent bridge was built across the Vistula and the town became an important trade centre between Poland and Lithuania. On March 16, 1596, by decision of King Sigismund III, it became the capital of Poland and the royal seat. It had then 15,000 inhabitants. Numerous palaces and residences were built and new fortifications erected. In 1655–56 the town was destroyed and burned by the Swedish army of Charles X Gustavus but rapid reconstruction followed during the reign of John III Sobieski. At the beginning of the 18th century it suffered great economic losses, increased by pestilence during the War of the Polish Succession. Under the Saxon (Wettin) kings reconstruction was planned along the main wide thoroughfares running south of the old town. The greatest development in many fields followed during the reign of Stanislaw II Poniatowski, the last king of Poland. when planned quarters were laid out, such as Zoliborz in the north, Ujazdow in the south and the splendid park of Lazienki.

The citizens of Warsaw took an active part in the political life of the country, especially during the great reforms of the "four years' *sejm*" which on May 3, 1791, voted the parliamentary constitution. In April 1794 the people of Warsaw led by Jan Kilinski, a master shoemaker, helped the Polish troops liberate the town from Russian occupation and subsequently heroically defended it against the joint siege of Russians and Prussians. On Nov. 2, the suburb of Praga was burned and its population massacred by Russian troops under Gen. A. V. Suvorov. During 1796–1806 Warsaw fell under Prussian occupation and the number of inhabitants sank from 116,000 to 65,000. .Liberated by Napoleon it became in 1807 the capital of the duchy of Warsaw and in 1815 the capital of the "Congress" kingdom of central Poland under the emperor of Russia as king of Poland.

The period 1815–30 was one of growth and also of a notable industrial development. Protesting against political oppression, Warsaw gave, on Nov. 29, 1830. the signal for an insurrection against the Russians and became the centre of the movement until its suppression by Field Marshal I. F. Paskevich, after the heroic defense of the city by Gen. Jozef Sowinski in the suburb of Wola (Sept. 6. 1831). The Russians built a fortress (1832–33) on the left bank of the Vistula directed against the city and serving also as the state prison. The ruinous cost of its construction fell upon the inhabitants. The last remains of political self-government were destroyed during this time: the university and the Warsaw Scientific society were closed. Economic improvement began during the mid-19th century when railway connections with Cracow, Vienna, Berlin and St. Petersburg were established. There was also an increase in trade with Russia. During 1860–62, however, Warsaw was again the scene of mass demonstrations against Russia, which were followed on Jan. 22, 1863, by another insurrection. In spite of the intense russification following the crushing of this insurrection, the city's economic and cultural life developed rapidly. In 1872 it had 276,000 inhabitants. It became an important railway junction and intermediary for the trade between Russia and the west. After 1875 the town was encircled by a belt of fortifications, blocks of flats were built and a water supply and drainage system were planned and executed by an Englishman, William Lindley. Its population rose in 1903 to 756,400. In 1905 Warsaw again witnessed a powerful revolutionary movement. Ten years later, on Aug. 5, 1915, during World War I, the Russians left the town taking with them the machinery from the factories. The German occupation that followed was a period of unemployment and misery.

On Nov. 11, 1918, Warsaw became the capital of the restored Polish state and government offices, scientific and cultural institutions were reinstated. In Aug. 1920 Warsaw played an important part in holding back Soviet troops and winning a decisive battle at Radzymin, 10 mi. northeast of the city. According to the 1931 census, 66 8% of Warsaw's 1,158,914 inhabitants were Roman Catholics, and 30.2% of the Jewish faith; 70.5% used Polish as their mother tongue while 28.4% were Yiddish-speaking.

From the very first day of World War II Warsaw was subject to air bombing by the Germans. The damage of the first week increased to an appalling extent during the siege which began on Sept. 8, 1939. A week later Gen. Julian Rommel, the military commander of Warsaw, rejected the demand for capitulation. Stefan Starzynski, the mayor of Warsaw, who had done a great deal for the city in restoring old buildings and erecting new ones, became the soul of the resistance. Warsaw was faithful to the motto of its coat of arms:. *Contemnit procellas* ("Defying the storms"). On Sept. 27, Warsaw—without ammunition, food, water and light—capitulated, The Germans entered the city with Hitler on Oct. 1. During the Nazi occupation of 1939–44 German authorities persecuted the inhabitants and carried tens of thousands of them (mostly the intelligentsia) to their camps of death. mainly to that of Oswiecim (Auschwitz). Thousands of patriots were tortured to death in prisons. A closed ghetto was established (1940) and about 450,000 Jews were crowded there and then carried away to be murdered in extermination camps. On April 19, 1943, an uprising broke out in the ghetto; it was suppressed by the Germans after three weeks' struggle and the ghetto was erased from the earth. In 1940–44 Warsaw was the main centre of the Polish movement of resistance and a great number of clandestine newspapers appeared. In their campaign against Polish culture the Nazis destroyed monuments, closed the theatres, libraries and scientific institutions.

On Aug. 1, 1944, when the Soviet armies were approaching Warsaw, an uprising broke out in the town and street fighting, carried on mostly by young boys and girls. lasted more than two months. About 100,000 persons were killed or murdered by S.S. troops and on Oct. 2 Gen. Tadeusz Bor-Komorowski. the Polish commander, was forced to lay down his arms. A great part of the inhabitants were transported to camps in Germany, the remainder being expelled from the town. The Germans then started the methodical destruction of the city. They blew up the ancient Royal castle, burned the palaces, churches, museums, libraries and blocks of flats. Praga, on the right bank of the river, was saved from complete destruction by being taken on Sept. 14 by Soviet troops. On Jan. 17, 1945, the empty ruins of Warsaw were liberated by the Soviet army under Marshal K. K. Rokossovsky, including some Polish units. The population rapidly flocked back to the ruins to start a new life in primitive conditions, and large-scale reconstruction was begun with the help of the whole country.

From Oct. 19 to 21, 1956, Warsaw was the theatre of yet another, and this time bloodless historic upheaval, namely the return to power of Wladyslaw Gomulka, a Communist and national leader.

WARSAW TREATY ORGANIZATION, the name usually given to the unified military command established by the U.S.S.R. and its satellite states in eastern Europe through the signing of the Warsaw treaty on May 14, 1955. The treaty was a 20-year mutual-defense pact between the U.S.S.R., Albania, Bulgaria. Czechoslovakia, east Germany, Hungary, Poland and Rumania. Marshal Ivan S. Koniev, deputy defense minister of the U.S.S.R., who had led the 2nd Ukrainian army against Germany in 1943–45, became the commander of the unified forces. The agreement provided not only for a unified military command but also for the maintenance of Soviet army units on the territory of the other participating states. The United States government estimated that the Warsaw pact nations' armies included about 6,000,000 men, made up of between 175 and 225 Soviet divisions and 80 satellite divisions.

The Warsaw treaty was one of the first steps taken by Nikita S. Khrushchev and Nikolai A. Bulganin, after their assumption of power early in 1955, to strengthen the Soviet hold over the satellite area following the limited concessions of the preceding regime of Georgi M. Malenkov. The immediate occasion was the Paris agreement between the western powers to admit west Germany to the North Atlantic Treaty organization (*q.v.*), the formal induction of west Germany as a NATO member having occurred on May 9.

As usual in Soviet propaganda moves, the Warsaw treaty began with a declaration of peaceful motives. The signatory parties agreed, in accordance with the principles of the UN charter, to abstain from violence or the threat of violence in international relations. But the remilitarization of west Germany authorized by the Paris agreements, according to Soviet pronouncements. posed a threat to the national security of peace-loving states and required a defensive counteraction. A further indication of the fact that the Warsaw treaty was also a lever to enhance the bargaining position of the U.S.S.R. in European diplomacy was the concluding article of the treaty, which stipulated that the agreement would lapse when a general east-west collective-security pact should come into force. In July 1955, the U.S.S.R. proposed the dissolution of both NATO and the Warsaw Treaty organization in favour of an all-European security system to include the United States. See GENEVA SUMMIT CONFERENCE (1955).

The rebellions in Poland and Hungary in 1956 both involved nationalist hostility to the terms of the Warsaw treaty. Unrest and popular resentment against extensive Soviet interference in Polish local affairs. together with the presence of many Russian advisers in Polish political and economic administration, came to a head under the leadership of the Polish Communist Wladyslaw Gomulka. As premier he secured the uithdrawal of Soviet troops to the frontier and halted Polish uprisings as well. In Hungary a similar widespread opposition to the presence of Russians flared into open revolt after the successful Polish example. The Hungarian Communist Imre Nagy became premier, and also denounced the Warsaw treaty. Soviet leaders appeared willing to revise the Warsaw treaty with respect to the provision for Soviet garrisons in satellite countries. But Nagy failed to halt continued violent Hungarian attacks on the retiring Soviet troops, which were then reinforced and turned to crush the rebellion, thereafter remaining in Hungary

In Dec. 1957 rumours circulated that the Warsaw pact nations had agreed on increased armaments if west Germany accepted nuclear weapons or bases as a NATO member. The Warsaw Treaty organization, in short. served a double purpose: it became an instrument of Soviet efforts to check the expansion of NATO and to justify the maintenance of garrisons and bases close to NATO territories; at the same time Soviet garrisons were designed to inhibit new outbreaks of "counterrevolutionary" action in the satellites, as Khrushchev intimated in an April 1958 speech in Czechoslovakia. (G. B. C.)

WART is the name for different kinds of benign growths of the skin and adjacent mucous membranes, all having an uneven, rough, cornified "warty" surface. The common warts average the size of a split pea, and usually occur on fingers, backs of hands, palms and soles. They are caused by a filterable virus which after invading the skin may stay latent for several months before the wart develops. The contagion spreads and often. a few months after its onset, dozens of warts are present in the infected area. Common warts spread from person to person by direct contact, possibly also from contact with contaminated objects (*e.g.*, gymnasium floors). Interestingly, in some cases this infectious gron th can be cured by suggestive psychotherapy; hence the success of charms and other superstitious procedures in curing warts. The flat juvenile warts are smaller, flatter, less uneven on the surface and spread more rapidly than common warts. The face and extremities of children are often densely covered with hundreds of these unsightly tiny lesions. This condition, too, is a contagious disease of viral origin. So-called venereal warts develop in the male or female genital region when this region is kept moist by some discharge. Venereal warts are conical pointed elevations shooting up close to each other. By confluence they may form profuse cauliflowerlike vegetations. They are contagious but not necessarily acquired by sexual intercourse. They are caused by the same virus as common warts.

Seborrheic warts occur on the trunk of adults. They are flatly elevated, have a friable greasy top and darken to brown or even black as they grow to the average size of a nickel Their cause is unknown. Neither of these mart varieties is likely to degenerate into cancer, but expert knowledge. and in some cases microscopic examination, is required to differentiate them from the much more serious premalignant lesions. Treatment of warts is different according to type, size and localization, and should never be undertaken by a layman. Many popular methods of treatment cause ugly and unnecessary scarring. (S. RON.)

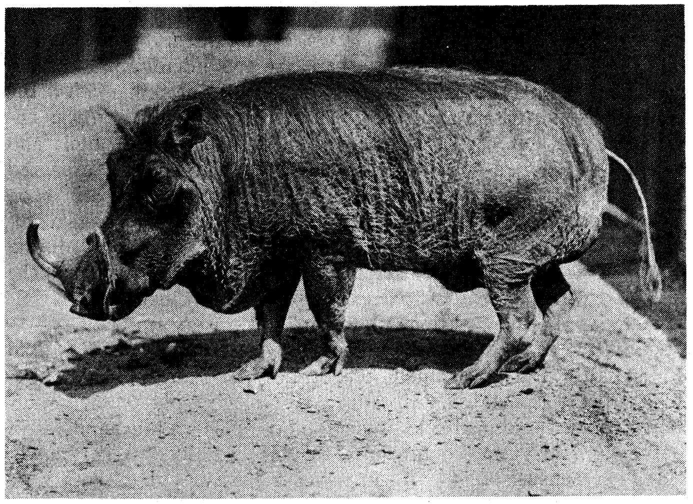
WARTA or WARTHE, a river of Poland and Germany, and the chief affluent of the river Oder. It rises in the Carpathian mountains. Its total length is 473 mi, and it is navigable up to Konin in western Poland, a distance of 265 mi. Its banks are mostly low and flat. its lower course especially running through drained and cultivated marshes. It is connected with the Vistula through its tributary the Notec and the Bydgoszcz canal. The area of its drainage basin is 20,737 sq.mi.

WARTBURG, THE, a castle near Eisenach in the former grand-duchy of Saxe-Weimar. It is magnificently situated on the top of a precipitous hill, and is remarkable not only for its historical associations but as containing one of the few well-preserved Romanesque palaces in existence. The original castle. of which some parts—including a portion of the above-mentioned palace—still exist, mas built by the Landgrave Louis "the Springer" (d. 1123), and from his time until 1440 it remained the seat of the Thuringian landgraves. Under the Landgrave Hermann I, the Wartburg was the home of a boisterous court to which minstrels and "wandering folk" of all descriptions streamed; Walther von der Vogelweide and Wolfram von Eschenbach both refer to the noise and constant crush of crowds passing in and out at the Wartburg "night and day"; and it was there that in 1207 took place the minstrels' contest (Sangerbrieg) immortalized in Wagner's *Tannhäuser.* Some years later it became the home of the saintly Elizabeth of Hungary (see **ELIZABETH.** SAINT) on her marriage to Louis the Saint (d. 1227), to whom she was betrothed in 1211 at the age of four.

Wagner, with a poet's licence, has placed the Sangerkrieg during Elizabeth's residence at the Wartburg. It was to the Wartburg, too, that on May 4, 1521, Luther was brought for safety at the instance of Frederick the Wise, elector of Saxony. and it was during his ten months' residence there that he completed his translation of the New Testament. From this time the castle was allowed gradually to decay. It was restored in the 18th century in the questionable taste of the period; but its subsequent magnificence it owed to the Grand-Duke Charles Alexander of Saxe-Weimar. with whom it was a favourite residence.

WARTHE: see WARTA

WART HOG, the designation of certain hideous African wild swine (see SWINE), characterized by the presence of large warty protuberances on the face and the large size of the tusks in



BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

WART HOG (PHACOCHOERUS AETHIOPICUS)

both sexes. Frequently the adults have no incisors, and nearly bare skins except for a mane along the back which may be long. Two forms are recognized, the southern *Phacochoerus ae aethiopicus,* which formerly ranged as far south as the Cape, and the northern *P. ae africanus,* which extends to the mountains of Abyssinia. In south and east Africa wart hogs frequent open country near water and dwell in holes. In Abyssinia, they spend the day among bushes or in ravines, feeding at night. They are active and wary.

WARTON, JOSEPH (1722–1800), English critic and poet and forerunner of the Romantic poets, was born at Dunsfold, Surrey, in April 1722, the eldest son of Thomas Warton, the elder (*c.* 1688–1745). Educated at Winchester, where he became a friend of William Collins, and Oriel college, Oxford, he took orders and was subsequently rector of Winslade and Tunworth and prebendary of St. Pauls and Westminster. In 17jj he returned to Winchester as a master, becoming headmaster in 1766. In 1793 he retired to Wickham, Hampshire, where he held a living until his death there on Feb. 23. 1800.

Though lacking Collins' genius, Warton shared his impatience with the didactic temper of the poetry of the time, as is shown by *The Enthusiast, or the Lover of Nature* (1744). In the preface to *Odes on Various Subjects* (1746) he declares that "the fashion of moralizing in verse has been carried too far" and that invention and imagination are the chief faculties of the poet. His *Essay on the Genius and Writings of Pope* (vol. 1, 1756 and vol. 2, 1782) which claimed that Pope's poetry is of second rank because moral and ethical verse is essentially inferior, was regarded as revolutionary, especially by Samuel Johnson, a fellow member of the Literary club. whom Warton had the temerity to contradict publicly. In 1797 Warton published Pope's works in nine volumes.

WARTON, THOMAS (1728–1790), English poet laureate, was a son of Thomas Warton, vicar of Basingstoke and professor of poetry at Oxford. He was born on Jan. 9, 1728. In a poem written in 1745 he shows the delight in Gothic churches and ruined castles which inspired so much of his subsequent work in romantic revival. Most of Warton's poetry, humorous and serious—and the humorous mock-heroic was better within his powers than serious verse—mas written before the age of 23, when he took his MA. degree and became a fellow of his college (Trinity, Oxford). He did not altogether abandon verse; his sonnets. especially, which are the best of his poems, were written later. But his main energies were given to omnivorous poetical reading and criticism. He was the first to turn to literary account the mediaeval treasures of the Bodleian library. It was through him, in fact, that the mediaeval spirit which always lingered in Oxford first began to stir after its long inaction and to claim an influence in the modern world.

Warton, like his brother. entered the church, and held, one after another, various livings, but he did not marry. He gave little attention to his clerical duties, and Oxford always remained his home. In 1749 he published a heroic poem in praise of Oxford, *The Triumph of Isis.* He mas a very easy and convivial as well as a very learned don, with a taste for pothouses and crowds as well as dim aisles and romances in manuscript and black letter. The first proof that he gave of his extraordinarily wide scholarship was in his *Observations on the Faerie Queene* (1754). Three years later he was appointed professor of poetry and held the office for ten years, sending round, according to the story, at the beginning of term to inquire whether anybody wished him to lecture. The first volume of his monumental work, *The History of English Poetry* (3 vol., 1774–81), is still indispensable to every student of English literature. A work of such labour could proceed but slonly, and it was no wonder that Warton flagged in the execution of it and stopped to refresh himself with annotating (1785) the minor poems of Milton, pouring out in this delightful work the accumulated suggestions of 40 years.

In 1785 he became Camden professor of history and was made poet laureate in the same year. His busy and convivial life was ended by a paralytic stroke in May 1790.

Warton's poems were collected in 1777, and he was engaged at the time of his death on a corrected edition which appeared in 1791, with a memoir by his friend and admirer, Richard Mant. They were edited in 1822 for the *British Poets* by S. W. Singer. Among his minor works were an edition of Theocritus (1770); a selection of Latin and Greek inscriptions; the humorous Oxford *Companion to the Guide* and *Guide to the Companion* (1762); *The Oxford Sausage* (1764); lives of Sir Thomas Pope and Ralph Bathurst, college benefactors; a *History of the Antiquities of Kiddington Parish,* of which he held the living (1781); and an *Inquiry into the Authenticity of the Poems attributed to Thonzas Rowley* (1782)

The History of English Poetry from the close of the 11th to the Commencement of the 18th Century, to which are prefixed two Dissertations: I. On the Origin of Romantic Fiction in Europe; II. On the Introduction of Learning into England (1774–81) was only brought down to the close of the 16th century. There are later editions, with annotations and corrections, by Richard Price (1824) and again by W. C. Hazlitt (1871). In both these editions other scholars collaborated.

Rinaker, *Thomas Warton* (Urbana, Ill., 1916); Eric Partridge (ed.), *The Three Wartons; a Choice of Their Verse* (New York, 1928); J. Densin. *The Wartons; Studies in English Literature* (1876).

WARWICK, EARLS OF. The earldom of Warwick was created by William II in 1088 for Henry de Beaumont, who had held Warwick castle since its building by William the Conqueror 20 years before.

The **Beaumonts.**—Henry, younger brother of Robert, count of Meulan. was lord of Neubourg, near Beaumont-le-Roger in Normandy, and Rufus gave him the great midland estate of the English noble, Thurkill of Arden. The new earl was an intimate friend of Henry I, whose succession he did much to promote. He died in 1123, and was buried at Preaux (Normandy). Roger, his eldest son, held the earldom until his death in 1153. As a member of the powerful Beaumont group, headed by Waleran of Meulan and the earl of Salisbury, Roger was deeply involved in the struggle between Stephen and the empress Matilda (Maud). The next earls were two of his sons. William died childless on crusade in Palestine (Nov. 1184). Waleran, his brother, survived until Dec. 1204, and left a son, Henry, still a minor. Henry was first styled earl in June 1213, and died in Oct. 1229. His son, Thomas, had only a brief career, for he was recognized as earl in 1233 and died in June 1242, leaving his sister Margaret (d. 1263) as his heiress. Her two husbands, John Marshall (d. Oct. 1242), and John du Plessis (d. Feb. 1263). a trusted servant of Henry III. were both styled earls of Warwick. Margaret was followed by her cousin, William Mauduit. grandson of earl Waleran, an undistinguished man, who held to the king in the Barons' Wars and died in 1268.

The **Beauchamps.**—The succession to the Beaumont lands and title then passed to Mauduit's sister's son, William de Beauchamp, lord of Elmley and head of the Worcestershire branch of a great Norman family. He was a close friend of Edward I, one of his principal captains in Wales and Scotland, and prominent in politics until his death in June 1298. Guy, his son and successor, fought at Falkirk (1298) and at the siege of Stirling (1303–04). Before Edward I died, Guy was a bitter enemy of Piers Gaveston (*q.v.*), and, in the new reign, he was largely instrumental in compassing the favourite's murder. As an ordainer, Guy, described by a contemporary as a "discreet and well-informed man," was a principal leader of the baronial opposition to Edward II (*q.v.*). He died suddenly (of poison, it was said) in 1315. Thomas I, Guy's son, was married to the daughter of his guardian, Roger Mortimer, earl of March. By inclination a soldier, he made a great name for himself in the early campaigns of the Hundred Years' War. He fought at Crecy and Poitiers, was one of the original knights of the Garter, spent three years with the Teutonic order in the Baltic lands, and died of plague while fighting near Calais in Nov. 1370. His son. Thomas II, grasping, ambitious yet cowardly, spent himself in factious opposition to Richard II. With Thomas of Gloucester and the Arundels, he led the lords appellant, who sponsored the excesses of the Merciless Parliament (1388) against the king's friends (*see* ENGLISH HISTORY: *Richard II*). When Richard's vengeance overtook him in 1397, Thomas cringed abjectly, and escaped with imprisonment and forfeiture. He was restored by Henry IV (1399), and died in April 1401. Richard de Beauchamp, his son and successor, spent most of his career as a soldier and administrator in Lancastrian France, dying there as the king's lieutenant in 1439. His son, Henry (b. March 1425), received extraordinary marks of favour from Henry VI. In virtue of his descent, through his mother, from Edward III, he was made premier earl in April 1444, and created duke of Wanvick three days later. When Henry died (June 1445) the male line of the Warwick Beauchamps became extinct. and the dukedom lapsed, as did the earldom itself on the death of his infant daughter, Anne, in 1449.

The great Beauchamp estates in the midlands and the Welsh marches passed to Anne Neville, daughter of Richard de Beauchamp, earl of Warwick, and wife to Richard Neville. known to posterity as Warwick the Kingmaker. Her marriage, together with that of her brother, Henry de Beauchamp, duke of Wanvick. to her sister-in-law, Cicely Neville. had been planned to unite the power of the Nevilles and the Beauchamps. A few months after the Beauchamp lands came to Anne, the Warwick title was revived for her husband and herself (1450), and he acquired the Neville earldom of Salisbury when his father was beheaded after the defeat of the Yorkists at the battle of Wakefield in 1460. After her husband was killed at Barnet in 1471, Anne's rights in the Beauchamp inheritance were abrogated by statute in favour of her daughter, Isabel, wife of George, duke of Clarence, the brother of Edward IV. He took the Warwick title and held it until his attainder in 1478. It was allowed to pass to his son, Edward Plantagenet, in 1483, but when he was executed in Nov. 1499, for alleged plotting with Perkin Warbeck, the earldom became extinct.

The title was revived in Feb. 1547 for John Dudley, afterward duke of Northumberland (*q.v.*), on the ground of his descent from Richard de Beauchamp, earl of Warwick. Although Dudley was attainted and executed (Aug. 1 j j3) for his attempt to enthrone Lady Jane Grey. the Warwick title was still used by his son John until he died childless in Oct 1 554. Ambrose Dudley, his brother and heir, was confirmed in the title of earl of Warwick by Elizabeth I (Dec. 1561), and held it until his death in Feb. 1590. It then lapsed again, for Ambrose's only male heir, his brother, Robert Dudley, earl of Leicester, had predeceased him.

In 1618 James I revived the earldom once again, this time in favour of Robert, 3rd Baron Rich, whose wife, Lady Penelope Rich (*q.v*), was the Stella of Sir Philip Sidney's *Astrophel* and Stella. He was not descended from the old family of Warwick, nor did he pcssess Warwick castle, let alone any part of the ancestral lands. The earldom continued in this family until the death of Edward Rich (Sept. 1759), when it lapsed again. Two months later it was revived for the fifth time when Francis Greville, who had been created Earl Brooke of Warwick Castle in 1746, became earl of Warwick. The Grevilles were a cadet branch of the Beauchamp family, and the earldom still remains with them.

See Sir William Dugdale, *History and Antiquitzes of Warwickshire* (London, 1656); Joseph Edmondson, *An Historical Account of the Noble Family of Greville* (London, 1766); The Countess of Warwick, *Warwick Castle and its Earls,* 2 vol (London, 1903). (GY. T.)

WARWICK, RICHARD BEAUCHAMP, EARL OF (1382–1439), son of Thomas Beauchamp, was born at Salwarp in Worcestershire on Jan. 28, 1382, and succeeded his father in 1401. He had some service in the Welsh War. fought on the king's side at the battle of Shrewsbury (1403) and at the siege of Xberystn yth (1407).

In 1408 he started on a pilgrimage to the Holy Land, visiting on his way Paris and Rome, and fighting victoriously in a tournament with Pandolfo Malatesta at Verona. From Venice he took ship to Jaffa, whence he went to Jerusalem. and set up his arms in the temple. On his return he travelled through Lithuania, Prussia and Germany, and reached England in 1410. Two years later he was fighting in command at Calais.

Up to this time Warwick's career had been that of the typical knight errant. During the reign of Henry V his chief employment was as a trusted counsellor and diplomatist. He nas an ambassador to France in Sept. 1413, and the chief English envoy to the coronation of Sigismund at Aix-la-Chapelle and to the Council of Constance in the autumn of 1414. During the campaign of Agincourt he was captain of Calais. where in April 1416 he received Sigismund with such courtly magnificence as to earn from him the title of the "father of courtesy."

Warwick's sage experience made it natural that Henry V should on his deathbed appoint him to be his son's governor. For several years thereafter he was engaged chiefly as a member of the council in England. In 1428 he received formal charge of the little king's education. He took Henry to France in 1430, and while at Rouen had the superintendence of the trial of Joan of Arc. In 1431 he defeated Pothon de Xaintrailles at Savignies. Next year he returned to England. The king's minority came nominally to an end in 1437. Warwick was then chosen to succeed Richard of York in the government of Normandy. He died at his post there on April 30, 1439. His body was brought home and buried at Wanvick. His tomb in St. Mary's church is one of the most splendid specimens of English art in the 15th century. (See also WARWICK, EARLS OF.)

Stevenson, *Letters, etc., illustrative of the English Wars in France,* "Rolls" series (1861–64). For modern accounts consult J. H. Wylie, *Henry IV*, 4 vol. (1884–98); C. L. Kingsford, *Henry V* (New York, 1901); and Sir James Ramsay, *Lancaster and York* (1892); *see* also *The Pageants of R. B., Earl of Warwick,* reproduced in facsimile from the Cottonian manuscript (1908).

WARWICK, RICHARD NEVILLE, EARL OF (1428–1471), called (since the 16th century) "the Kingmaker." was born Nov. 22, 1428, the eldest son of Richard Neville. earl of Salisbury by Alice, daughter and heiress of Thomas Montacute, earl of Salisbury. He was created earl of Warwick in March 1450, since his wife Anne, to whom he was betrothed by 1436, was sister and coheir of Henry Beauchamp, duke and earl of Warwick. Entering political life in 1452, he and his father became from 1453 supporters of Richard, duke of York, with whom they took up arms in 1455 against Henry VI and the duke of Somerset. At the battle of St. Albans (May 22, 1455) Warwick contributed to the Yorkist victory by penetrating the Lancastrian's defenses. He was appointed captain of Calais in Aug. 1455 and maintained himself in office despite rivals (notably Henry, duke of Somerset, 1459–60) until his death. Much of his influence he owed to his use of the garrison and naval forces there. To pay for the upkeep of Calais he was privateering at the expense of Hansard and Castilian fleets in 1458. He invaded England (Aug. 1459) to help York seize the king; but the desertion of their men at Ludlow on Oct 12, 1459, compelled them to flee, York to Ireland, Warwick with York's son Edward (the future Edward IV) to Calais. In May 1460 he sailed to Ireland to consult York and having returned by sea to Calais, he and Edward invaded Kent and entered London on July 2. Eight days later they defeated and captured Henry VI at Northampton. Warwick's ambition to be the arbiter of the realm under a neak king appeared in the autumn when his influence almost certainly prevented York from assuming the crown and brought about instead a succession award in parliament (Oct. 31) which kept Henry on the throne but made York the heir. While Warwick was guarding Henry in London the earl of Salisbury, his father, and Richard of York were defeated and slain at Wakefield (Dec. 30. 1460). Attempting to bar the Lancastrian advance on London he took out Henry VI with an army but was routed at St. Albans (Feb. 17, 1461) when the Lancastrians recaptured Henry. Warwick was compelled to flee westward to join Edward. son of Richard, duke of York. Together they re-entered London and York's son was proclaimed king as Edward IV on March 4, 1461. Although after the death of Salisbury the earl had become the greatest landlord in England, military events forced him to acquiesce in Edward's occupation of the throne. The battle of Towton (March 29, 1461). in which Edward commanded and Wanvick fought, ended in the destruction of the Lancastrian army and made the Yorkist cause safe in the south. But Henry VI and his mettlesome queen, Margaret of Anjou, had escaped to Scotland and, aided by the French and Scots, kept the north in turmoil until 1464. While exercising a general supervision of Edward IV, Warwick now strove to extend his own immediate authority in the north, where his family interests mainly lay, based on the castles of Middleham and Sheriff Hutton. The victory of the Yorkist cause in the north was really the triumph of the house of Neville at the expense of the Percies. Wanvick's brother George (chancellor since 1460) became archbishop of York in 1465, while another brother, John, Lord Montagu, who was responsible for the final Lancastrian defeat in 1464, became earl of Northumberland, ousting the Percies from their hereditary title. While his relations with Edward IV were nominally amicable Warwick had begun. at least from 1463, to advocate an alliance with France against the king's preference for Burgundy. Edward's marriage (May 1464) to Elizabeth Woodville and the favour accorded to her relatives sowed enmity between the king and Warwick, whose brother was deprived of the chancellorship in 1467. In July 1469 the king's brother. George, duke of Clarence, whom Warwick had been decoying for at least a year, married at Calais the earl's eldest daughter Isabel. Instigated by him, revolts broke out in which many of the king's friends perished, including the earl of Pembroke and Sir Richard Woodville, treasurer and father of the queen. For a short time Edward was held at Middleham; but he was not the man to be used as a puppet and in Oct. 1469 he returned to London. In Feb. 1470 a fresh revolt engineered by Warwick started in Lincolnshire, and on its suppression the king turned against him and Clarence, who both fled to France (April 1470). At Angers (July 1470) under the aegis of Louis XI. king of France. Warwick was reconciled to Margaret of Anjou, queen of Henry VI. and he returned to England at Michaelmas with Clarence, driving Edward IV to escape overseas to Charles duke of Burgundy. Henry VI, confined in the Tower since 1465, was restored to the throne and Warwick was undisputed master; but the situation was highly unstable. Edward IV landed in Yorkshire (March 1471) and, outwitting Warwick, who stood on the defensive at Coventry, reached London. The earl followed him, but was slain at Barnet (April 14, 1471). His younger daughter. Anne, married Richard. duke of Gloucester, the future Richard III, in 1472 and in 1483 his vast estates were merged in the crown.

Most contemporary references are highly favourable to him and he left a deep impression in the country and abroad. As a politician and diplomat he excelled Edward IV; but he was an indifferent soldier, who allowed himself to be surprised at St. Albans (1461) and by the Scots at Alnwick (Jan. 1463). He was outmanoeuvred by Edward IV in 1471. He was more at home on sea and himself took the helm during the voyage to Calais in 1459. He was far from blind to economic factors, witness his interest in mining in the north during the 1460s and the trade pact with France, 1470–71. No other Englishman of the century pursued conciliation with France successfully and without loss of popularity.

WARWICK, SIR ROBERT RICH, 2ND EARL OF (1587–1658), colonial administrator and admiral, was the eldest son of Robert Rich. earl of Warwick, and his wife, Penelope Rich (*q.v.*), and succeeded to the title in 1619. His interest in colonial ventures involved him in disputes with the East India company (1617) and with the Virginia company, which in 1624 was suppressed through his action. In 1627 he commanded an unsuccessful privateering expedition against the Spaniards. His Puritan connections and sympathies, while estranging him from the court, promoted his association with the New England colonies. In 1628 he indirectly procured the patent for the Massachusetts colony, and in. 1631 he granted the "Saybrook" patent in Connecticut. Compelled the same year to resign the presidency of the New England company, he centinued to manage the Bermudas company and Providence company which. founded in 1630. administered Old Providence on the Mosquito coast. Meanwhile in England Warwick opposed the forced loan of 1626, the payment of ship money and Laud's church policy, and with his brother the first Lord Holland (see HOLLAND, HENRY RICH) was recognized as one of the heads of the Puritans. In March 1642 the commons, in spite of the king's veto, appointed him admiral of the fleet, and in July he gained the whole navy for the parliament. He raised forces in Norfolk and Essex on the outbreak of the war, and as lord high admiral (1643–45) he intercepted the king's ships and relieved threatened ports. In 1643 he was appointed head of a commission for the government of the colonies, which the next year incorporated Providence Plantations, afterward Rhode Island, and in this capacity he exerted himself to secure religious liberty. He died on April 19, 1658.

WARWICK, a municipal borough and the county town of Warwickshire, Eng., on the Avon, 21 mi. S.E. of Birmingham by road. Pop. (1951) 15,349. Area 7.9 sq.mi.

Warwick (*Waerincgwican* in 737, *Warwic* in Domesday) occupies rising ground commanding a crossing of the Avon river. An early settlement was fortified by Aethelflaed against the Danes in 914. At Domesday, Warwick was a royal borough containing 225 houses, 19 of which belonged to burgesses enjoying the privileges they had had in the time of Edward the Confessor. William the Conqueror ordered the castle to be enlarged, and, together with the borough. Henry I granted it to Henry de Newburgh (or Beaumont), who was created earl of Warwick. The motte of this castle ("Ethelfleda's Mount") is at the southwest end of the present castle which was begun about 1330 by Thomas Beauchamp, earl of Warwick. In 1449 the estates and the earldom passed to Richard Neville. the Kingmaker. The Clarence tower was added in the reign of Edward IV and the Bear tower by Richard III. There are only traces of the old town walls. but the east and west gates remain, with chapels above them. Although the borough owed its early importance to the castle and to its position, and received a grant of a fair in 1261, it developed independently. It received no charter until it was incorporated in 154j after it had come into the king's hands in 1499. Other charters were granted in 1554, 1613. 1664, 1683 and 1693, of which that of 1554 allowed the appointment of assistant burgesses (discontinued in 1698). The charter of 1693 conferred the title of "Mayor, Aldermen and Burgesses" on the corporation.

The castle stands on a rock rising sheer out of the river. The battlemented walls and towers are 14th and 15th century but the interior is largely the work of Fulke Greville who was granted the castle in 1604 by James I and who finally converted it from fortress to mansion. The residential part contains famous collections of pictures and armoury. The beautiful park and gardens are open to the public; in a greenhouse is the "Warwick vase" of the 4th century B.C. ($5\frac{1}{2}$ ft. high and 7 ft. in diameter), that came from Hadrian's villa at Tivoli. In spite of a great fire, which did much damage in 1694, Warwick has many mediaeval and Tudor timber-framed buildings as well as 17th-century and Georgian houses. St. Mary's church was largely rebuilt after the fire in a mixture of Perpendicular and Renaissance styles, the Beauchamp chapel (1443–64) remaining untouched. A church had existed on this site before the Conquest and was made collegiate by Roger de Newburgh. the second Norman earl, in 1123. At the dissolution Henry VIII granted the foundation to the burgesses of the town. The Leycester hospital (or Maison Dieu) is a fine half-timbered building with a galleried courtyard (c. 1415). It was originally used as the hall of the united guilds of the Holy Trinity and the Blessed Virgin Mary and St. George the Martyr. The earl of Leicester founded the hospital in 1571 for the reception of 12 disabled men. The market hall (1670) is now used as a museum. There are numerous charities in the town, the principal being those of Henry VIII. Sir Thomas White and Thomas Oken. St. Nicholas park was opened to the public in 1933. The King's school existed in the reign of Edward the Confessor and may have been as early as 914. It was refounded by Henry VIII in 1545. Warwick returned two members to parliament from 1295. but in 188j the number was reduced to one. It has now no independent representation and is in the Warwick and Learnington division of the county. Warwick's industries include the manufacture of gelatin, concrete mixers, bodies for heavy trucks and motorcars and fairground equipment.

WARWICK, a city in Kent county, R.I., U.S., is situated on the western shore of Narragansett bay, 10 mi. S. of Providence. A part of the Providence-Pawtucket standard metropolitan statistical area, its population has grown rapidly from 23,196 in 1930 to 68.504 in 1960. (For comparative population figures see table in RHODE ISLAND: Population.)

The first settlement was at Shawomet in 1643 by Samuel Gorton (*q.v.*) and later was named for Robert, earl of Warwick, who supported Gorton in his quest to gain protection of a royal charter against the Massachusetts Bay colony. Town government was organized in 1647. After the widespread destruction caused by King Philip's War (1675–76), the township was rebuilt and grist-mills and fulling mills were established on the Pawtuxet river. The town was unaffected by the American Revolution, although several of its inhabitants including Gen. Nathanael Greene (*q.v.*) acquired military fame. In the 19th century Warwick became active in textile manufacturing.

Warwick was incorporated as a city in 1931 with a mayor and council, but is basically a group of more than 20 scattered villages, united administratively.

In the early 1960s Warwick had about 70 manufacturing plants, principally textiles, metals and machinery. There are some dairy farms, market gardens, and apple orchards within the city's area but farm land has been increasingly lost with urbanization. The city is predominantly residential and has a wide variety of housing including summer cottages. Many workers commute to Providence. (V. H. WH.)

WARWICKSHIRE, a midland county of England bounded by Leicestershire, Northamptonshire, Oxfordshire, Gloucestershire and Staffordshire. Lillington (on the outskirts of Leamington Spa) and Meriden, northwest of Coventry, each claims to stand in the exact centre of the land. The geographical area is 983 sq.mi. Northwest of the Avon river, watering a rich valley on a line from northeast to southwest, the county drains principally to the Trent through the Tame and its tributaries, the Blythe. Rea, Anker and minor streams. Between these valleys, and dividing the system from that of the Avon, the land rises in gentle undulations. Many canals intersect the county. The land is formed for the most part of Keuper marls and sandstones, the sandstones forming picturesque scarps. The Bunter rocks are represented only between Birmingham and Sutton Coldfield. From this side the Avon receives the Swift, the Sowe and the Alne. An important fault crosses the area from Kenilworth northward to Tamworth, and brings up the coal measures on the eastern side. The Upper coal measures, with the so-called Permian beds, occupy the larger part of the Warwickshire coal field, while the productive Middle coal measures crop out in a narrow fringe along the north and east. The eastern margin of the field is marked by an inlier of Cambrian and Pre-Cambrian rocks, the Hartshill quartzite (Cambrian) being quarried. The district north of the Avon was distinguished by Camden as the Woodland, as opposed to the southern or Feldon, "a plain champain." The Woodland embraced the ancient forest of Arden and the Feldon included the end of the Vale of Evesham and the Vale of the Red Horse, which lies beneath a spur of the Cotswolds and is crossed by the Fosse way. It is not difficult to trace the influence of the scenic characteristics of the county in the writings of its most famous son, William Shakespeare.

History. — Warwickshire, the area once largely occupied by the forest of Arden, is poor in prehistoric antiquities. One Roman road, the Fosse way, cuts across the southeast of the county and another, Watling street, bounds it on the northeast. The earliest English settlers were a tribe of Hwicce who, pushing up the Severn valley early in the 6th century, made their way by the Avon valley and the Fosse way until the vast forest of Arden, from the Avon to modem Birmingham. barred progress northward. The extent of their settlement is indicated by the ancient limits of the diocese of Worcester. In the 7th century the Hwiccan territory became part of the kingdom of Mercia. In 675 Cosford was included in the endowment of Peterborough, and in 757 Aethelbald was slain at Seckington.

The shire of Warwick originated in the 10th century about Aethelflaed's new borough at Wanvick (*q.v.*) and appears in the Saxon Chronicle of 1016. Warwickshire offered little resistance to William the Conqueror, who was at Warwick in 1068 and had the castle enlarged by Turehil, a sheriff. Henry I granted the borough with Aethelflaed's fortress to Henry de Newburgh, son of Roger de Beaumont, whom he created earl of Wanvick. The earldom and castle subsequently passed to William de Beauchamp whose grandson, Thomas, began building the present castle about 1330. Through his wife, Anne Beauchamp, Richard Neville, the Kingmaker, obtained the earldom and estates in 1449. In 1547 they were given to John Dudley in whose family they remained until 1589.

In the wars of the reign of Henry III, Simon de Montfort placed Kenilworth castle in charge of Sir John Giffard, who in 1264 attacked Warwick castle and took prisoner the earl and countess of Wanvick, who had supported the king. During the Wars of the Roses the Nevilles, represented by the earl of Warwick, supported the Yorkist cause, while Coventry was a Lancastrian stronghold. On the outbreak of the Civil War of the 17th century Warwickshire and Staffordshire were associated for the parliament under Lord Brooke. The Battle of Edge Hill was fought in 1642, and in 1643 Birmingham was partly burned by Prince Rupert's forces. Coventry was attacked in 1642, and skirmishes took place at Southam and Warwick. The greatest disaster of all was the bombing of Coventry during World War II, Birmingham also enduring its share.

Warwickshire returned 2 members to the parliament of 1290, and in 1295 Coventry and Warwick were each represented by 2 members. Tamworth returned 2 members in 1584. Under the Reform act of 1832 the county returned 4 members in 2 divisions; Birmingham was represented by 2 members and Tamworth lost its members. Under the act of 1868 the representation of Birmingham was increased to 3 members, and under the act of 1948 the county returns 6 members in 6 divisions (Nuneaton, Rugby, Solihull, Stratford-on-Avon, Sutton Coldfield, Warwick and Leamington), Birmingham 13 members and Coventry 3.

Architecture. — Some traces of pre-Norman architecture appear in the fine church of Wootton Wawen in the Arden (western) district. For ecclesiastical architecture Coventry with its three spires is famous, and among village churches there are many fine examples. Of those retaining Norman portions may be mentioned Wolston, Berkswell, Polesworth, Curdworth, Burton Dassett, a very noteworthy building, and Warmington, where there is a chapel with a priest's chamber above it. There are also fine examples of Decorated work, such as Knowle, Solihull, Temple Balsall and Brailes. Among the numerous religious houses in the county several have left remains, for example the Cistercian foundations of Combe abbey, Merevale and Stoneleigh. The abbey at Stoneleigh (its remains overshadowed by an 18th-century mansion) was a 12th-century foundation, but a majestic gatehouse of the 14th century also stands. Maxstoke priory was a foundation for Augustinian canons of the 14th century; Wroxall abbey was a Benedictine nunnery of the 12th century. Warwick castle and Kenilworth castle, the one still a splendid residence, the other a no less splendid ruin, are described under those towns. Among fortified mansions Maxstoke castle is of the 14th century; Baddesley Clinton hall is of the 15th; Astley castle is a good specimen of various periods. Compton Wynyates is an outstandingly beautiful Elizabethan house. Charlecote park is a modernized Elizabethan hall in an exquisite situation on the Avon above Stratford-on-Avon, the birthplace of William Shakespeare. Many smaller buildings are beautiful examples of half-timbered work. Among larger examples are Coughton court (16th century), near Alcester, and Packwood house (partly 15th century), 11 mi. S.E. of Birmingham.

Agriculture and Industries. — The climate is mild and healthy. The soil is on the whole good and consists of various loams, marls, gravels and clays, well suited for most of the usual crops. The county is rich in pastureland, and dairy farming is extensive. The principal crops are wheat and oats, followed by mangels, and there are excellent orchards and market gardens and also some of the finest woodlands in England. The National trust owned 589 ac. in the county in 1953 and protected 115 ac.

The industrial part of the county is the north. Warwickshire includes Birmingham, the greatest manufacturing centre of the Midlands, though the suburbs of that city extend into Staffordshire and Worcestershire. Metalworking in all branches is prosecuted there, besides numerous other industries. Coventry is noted for aircraft, motorcars and cycles, and, with Bedworth and Nuneaton and the intervening villages, is a seat of the ribbon and tape makers. Rugby is a centre of the electrical industry, with an important radio station. At Sutton Coldfield the then most powerful television transmitter was inaugurated by the British Broadcasting corporation in 1949. A rich coal field occurs in the northeast, extending outside the county northward from Coventry. Clay, limestone and other stone are quarried at various points, and a small amount of iron ore is raised. Coal, lime and cement are the chief mineral products.

Population and Administration.—The area of the administrative county is 873 sq.mi. with a population in 1951 of 490,740. The geographical county (983 sq.mi.) had a population in 1901 of 897.835 and in 1951 of 1,861,670, the chief centres of increase lying naturally in the parts about Birmingham and Coventry. Warwickshire has one court of quarter sessions and is divided into 17 petty sessional divisions and 2 boroughs with their onn commissions of the peace (Leamington Spa and Sutton Coldfield). There are 2 county boroughs (Birmingham and Coventry), 6 municipal boroughs, 3 urban districts, 9 rural districts and 240 civil parishes. Birmingham and Coventry have separate courts of quarter sessions and Warwick is an assize town. The county is mainly in the Birmingham and Coventry dioceses, carved largely out of that of Worcester.

WASH, THE, a shallow bay of the North sea, 12 by 15 mi., between Lincolnshire and Norfolk. Eng. It formerly extended as far inland as Peterborough and Cambridge but was infilled by silt, mainly brought down by the Witham, Welland, Nene and Great Ouse rivers but partly washed in by coastal currents. Reclamation was inaugurated at several points and sea walls were built to protect the low coastal lands. At low tide the river waters reach the sea through shallow creeks between banks of sand and mud. The two main channels, Boston deep and Lynn deep. provide anchorage for small vessels trading to Boston and King's Lynn respectively. (T. HER.)

WASHBURNE, ELIHU BENJAMIN (1816–1887), **U.S.** congressman. cabinet member and diplomat, was born at Livermore, Me.. Sept. 23, 1816. He graduated from the Harvard law school in 1839 and the next year moved to Galena, Ill. Success in his profession led to politics and election to congress in 1852. There. as a Whig and then as a Republican, he gained a reputation as an advocate of economy by opposing extravagant grants of land to railroads, excessive pensions and other raids on the treasury. He bitterly opposed Stephen Douglas' Kansas-Nebraska act and as ardently supported Lincoln for the senate in 1858 and for the presidency in 1860. When the Civil War broke out he pressed the interests of his fellow townsman, U. S. Grant, for military appointment, and at its close joined the radicals in Reconstruction and in support of Grant for the presidency. His reward was a complimentary place in Grant's cabinet of 12 days' duration and then appointment as minister to France. He died in Chicago, Oct. 23, 1887.

WASHING MACHINES. Although household washing machines, mechanical devices for washing clothes, have been used for many years, they did not come into general popularity until World War I.

An electric motor (occasionally a gasoline engine) combined with a drive shaft, gears. a belt or some combination of these, activates the mashing action by means of an agitator, a revolving cylinder or an agitating basket which moves the clothes through the water or the water through the clothes. This also creates currents in the water which assist the cleansing action.

Agitator Washer.—In this type fins or blades on a cone designed to fit over a central shaft comprise the agitator, which turns back and forth or pulsates up and down. Agitators may be solid or perforated and are made either of metal or plastic. They differ in size. shape, number and arrangement of blades or fins according to the make of washer. Some operate at one speed only and some at more than one. Most agitators operate in an inside tub of rigid metal, usually perforated or in a metal-impregnated rubber tub which is sturdy, flexible and not perforated.

Cylinder Washer.—In this type a perforated cylinder usually made of porcelain enamelled steel holds the load to be washed as it revolves in a tub of water. Projections or baffles within the cylinder cause the clothes to drop back into the water as the cylinder turns. In some washers of this type the cylinder turns in one direction whereas in others it reverses at intervals.

Agitating Basket Washer.—In this type a combination of tub design and movement produce washing action. The inside tub with a partially swirled or corrugated surface and a base that looks like an inverted bowl tips as it moves rapidly up and down to swirl the clothes about through the water.

These washing mechanisms are enclosed in a housing or shell of characteristic design, usually made of synthetic enamel on sheet metal or porcelain enamelled steel. Less frequently it is of aluminum, stainless steel or nickel copper. It also encloses gears, belt, other moving parts and the motor and protects them from water, dust and lint. The motor (usually $\frac{1}{4}$ or $\frac{1}{3}$ h.p.) is grounded and insulated from other metal parts of the washer. Usually it is permanently lubricated with a sealed-in lubricant.

Automatic Washers.—Mechanical washers are automatic, semiautomatic or nonautomatic in their operation. The automatic, which first appeared in 1937, washes, rinses and extracts water with no attention from the operator after the load is placed in the washer. the power turned on and the timing device set. A later development of fully automatic washers went one step further, drying the clothes so they are ready to put away or to iron. The automatics save the most time and labour, but they are also the most expensive.

Semiautomatic Washers.—This type also is power driven and, while the clothes require no handling through the entire wash-rinse-extraction cycle, one or more of the steps are controlled by hand.

Nonautomatic Washers.—This washer, sometimes called the conventional type, is power driven and has a power-driven spinner or wringer which extracts the water. Although they save less of the operator's time, nonautomatic washers are great labour savers and can be used any place power is available. They require some handling of the clothes throughout the process. Clothes must be directed through the wringer or lifted into the spinner basket for water extraction after each step of the process. Often nonautomatic washers are filled through a hose and emptied either by gravity or by a pump. They also may be filled by hand, an advantage in homes without running water.

Water Extraction.—There are three general types of water extractors used with clothes washers. Some are equipped with an electrically driven wringer, two parallel rubber-covered rolls which revolve in opposite directions to squeeze the water from the clothes. Some have two hard rubber rolls. whereas others have one hard and one soft roll or two soft rolls. The soft rubber is used to minimize the danger of damage to buttons, hooks, snaps, zippers or other fastenings and trimmings. Wringers are designed to swing about and lock in convenient positions.

Another type of water extractor is a spinner that removes water by centrifugal action. With this type a perforated cylinder or basket either within the tub or attached to it is driven at a high speed to force out the water by centrifugal action. The third type removes water by squeezing action. In mashers which have a sturdy inside metal-impregnated rubber tub this flexible tub collapses on a vacuum principle to squeeze water from the clothes.

Water Requirements.—The total amount of water required varies widely with the washing machine used. From 6 to 20 gal. of water are required each time the tub is filled. Spray rinses that sometimes are interspersed between deep agitated rinses frequently take less. Automatic washers' requirements range from 25 to 65 gal. for a complete cycle but most automatic machines use only from 35 to 45 gal.; of this the amount of hot water (ideally 135°–160° F.) varies from 15 to 25 gal. per complete cycle. For white linens and cottons the hotter the water used the better the results.

Many washing machines are so constructed that the operator may predetermine both the washing time and the water temperature. With the automatic machines this is done by adjusting the automatic control before the washer starts. This became important as the synthetic fibres and finishes appeared in steadily increasing numbers in the laundry hamper.

Many man-made products give up soil quickly and easily and can be thoroughly washed by machine in a very short time. This is important also with wool fabrics such as blankets, snow suits, etc., which often are sensitive both to high temperatures and agitation.

Soft or softened water is a great asset. If the water is hard the use of a mechanical water softener or the addition of a water softening agent is highly desirable when soap is used. For best results, all the water, including the rinse water, should be softened when soap is used. A practical alternative when water is hard is the use of synthetic detergents made especially for use with hard water.

There are low-sudsing and high-sudsing synthetic detergents. Recommendations for the type that works best in an individual washer are usually made by the manufacturer. The amount of synthetic detergent used varies with the hardness of the water, quantity and degree of soil, the type of washer and the type of detergent. When soap is used, a substantial amount of standing suds on top of the wash water should be maintained. Because of the hard-water problem in the United States, a trend toward an increased use of synthetic detergents developed.

Washers range in size, rated in capacity for pounds of clothes, from 8 to 10 lb. Most are rated at 9 lb. There are, however, some small-capacity washers, usually called portables, designed to wash a maximum of 2, 4 or 6 lb. Some of these extract water with a spinning action, others with hand operated wringers. and some have no provision for water extraction. While they are a convenience under certain conditions, they cannot be considered a substitute for a standard-size washer. They use a small amount of water, occupy little space and often do an acceptable small job.

Washers load from the top or from the front. Some are permanently installed in one spot whereas others are movable and may be rolled into position near the water supply and a drain and later rolled away for storage.

Washing Procedure. — New developments in washing machines greatly altered washing habits. In many homes in the U.S.. for example, there no longer is one general washday each week, washing being done instead one load at a time whenever a load accumulates that suitably may be washed together.

According to accepted procedure each load is sorted according to colour, amount of soil, washing time and water temperature. Extremely soiled or stained articles are pretreated. Heavily soiled clothes may be soaked in the machine for from 10 to 20 minutes only either in cold or lukewarm water; sometimes a small amount of soap or synthetic detergent is added. This usually is an agitated soak.

In some automatic washers this presoak is part of the regular cycle. Often this is a matter of setting the dial that controls the cycling to include the soak or not as the operator chooses. This is followed by a hot (or warm) soapy wash and two or more rinses. Water is extracted from the clothes and fresh water added after each step of this process.

Later developments include improvement in safety devices, more reliable cycling, better bearings and more durable and attractive finishes.

Modern designing of washing machines coupled with the trend in the U.S. toward smaller houses made washing machines acceptable for installation in kitchens, first-floor service rooms, bathrooms, bedrooms, halls and sometimes even in a sewing room that doubles as a guest room.

Experimental models of ultrasonic washers, which rely on high-frequency wave action for cleansing, appeared in the early 1950s, but none was in general use. (E. DA.)

WASHING SODA, the common name for the decahydrate of sodium carbonate ($Na_2CO_3.10H_2O$), also called sal soda and used in household and laundry work.

See ALKALI MANUFACTURE.

WASHINGTON, BOOKER TALIAFERRO (1856–1915), U.S. Negro educator and reformer, for many years a leader of American Negroes, first president of Tuskegee institute, was born on April 5, 1856, in a slave hut on a plantation in Franklin county, Va. At Malden, W.Va., where the family (his mother, himself and two other children) moved after emancipation, dire poverty precluded regular schooling for the boy, and at the age of nine he began working with his foster father in a salt furnace and later in a coal mine.

In 1872 his determination to secure an education carried him to Hampton (Va.) Normal and Agricultural institute, where he worked as a janitor to help defray his school expenses. Upon graduation from Hampton in 1875, Washington returned to Malden to teach children in a day school and adults at night. After two years of teaching and eight months (1878–79) of study at Wayland seminary in Washington, D.C., he joined the staff at Hampton to participate in a successful experiment inaugurating a new educational program for American Indians.

Two years later, in 1881, he was selected to head a newly established Negro normal school at Tuskegee, Ala., an institution with two small, converted buildings, no equipment and very little money. Tuskegee Normal and Industrial institute became the singular achievement of his life's work. At his death, 34 years after its founding, Tuskegee had over 100 well-equipped buildings. more than 1,500 students, a faculty of nearly 200 teaching 38 trades and professions and an endowment of approximately $2,000,000. His success at Tuskegee gained him national acclaim, and he emerged as the most influential spokesman for the American Negro.

Washington believed that the best interests of the Negro were to be realized through education rather than by political agitation for civil rights, and he was opposed by many Negro intellectuals who deplored particularly his emphasis on industrial education. During his lifetime he delivered numerous speeches and established organizations to promote the advancement and welfare of the Negro, among them being the National Negro Business league.

Among the dozen books he wrote are two autobiographies, Up *From Slavery* (1901), translated into at least 18 languages, and My *Larger Life* (1911), which completed the exposition of his philosophy of education and of life. In recognition of his achievement, Harvard university conferred upon him the honorary degree of master of arts (1896), and Dartmouth college, Hanover, N.H., that of doctor of laws (1901).

His death at Tuskegee on Nov. 14, 1915, was attributed to overwork.

See Samuel R. Spencer, Jr., *Booker T. Washington and the Negro's Place in American Life* (1955); Anson Phelps Stokes, *A Brief Biography of Booker Washington (1936).* (J. M. BK.)

WASHINGTON, BUSHROD (1762–1829), **U.S.** jurist, nephew of George Washington, was born in Westmoreland county, Va., on June 5, 1762. His father was John Augustine Washington, brother of George Washington. He graduated in 1778 from the College of William and Mary, Williamsburg, Va., where he was an original member of Phi Beta Kappa. After graduation he served in the colonial army until the end of the American Revolution. He studied law in the office of the noted Philadelphia lawyer, James Wilson, and then took up the practice of law in Alexandria, Va., moving to Richmond in 1790. He served in the Virginia house of delegates in 1787 and in the following year sat in the convention which ratified the federal constitution for Virginia. In 1798 he was appointed associate justice of the U.S. supreme court by Pres. John Adams. He was George Washington's literary executor and supervised the preparation of John Marshall's *Life of Washington* (5 vol., 1804–07); and on Mrs. Washington's death in 1802 he inherited Mount Vernon and a part of the estate. He died in Philadelphia on Nov. 26, 1829, and was buried at Mount Vernon.

WASHINGTON, GEORGE (1732–1799), general, statesman and first president of the United States, was born in Westmoreland county, Va., on Feb. 22 (new style; Feb. 11, old style),

1732. *(See* WAKEFIELD ESTATE.) His father was Augustine Washington, who had gone to school in England, had tasted seafaring life and was then managing his growing Virginia estates. His mother was Mary Ball, whom Augustine, a widower, had married early the previous year. The paternal lineage had some distinction. an early forebear was described as "gentleman"; Henry VIII later gave the family lands; and its members held various offices. But family fortunes fell with the Puritan revolution, and John Washington. grandfather of Augustine, migrated in 1657 to Virginia. The ancestral home at Sulgrave, Northamptonshire *(see* SULGRAVE MANOR), is maintained as a Washington memorial. Little definite information exists on any of the line until Augustine. He was an energetic, ambitious man who acquired much land. built mills, took an interest in opening iron mines and sent his two oldest sons to England for schooling. By his first wife, Jane Butler, he had four children; by his second, six. He died April 12, 1743.

Childhood and **Youth.**—Very little is known of George Washington's early childhood, spent largely on the Ferry Farm on the Rappahannock river opposite Fredericksburg, Va. Mason L. Weems's stories of the hatchet and cherry tree and of young Washington's repugnance to fighting are apocryphal efforts to fill a manifest gap. He attended school irregularly from his 7th to his 15th year, first with the local church sexton and later with a schoolmaster named Williams. Some of his schoolboy papers survive. He was fairly well trained in practical mathematics—gauging, several types of mensuration and such trigonometry as was useful in surveying. He studied geography, possibly had a little Latin and certainly read some of The *Spectator* and other English classics. The copybook in which he transcribed at 14 a set of moral precepts or *Rules* of *Civility* was carefully preserved. His best training. however, was given him by practical men and outdoor occupations, not by books. He rode over the half-dozen family farms or plantations, watched the slaves at work and mastered tobacco growing and stock raising. Early in his teens he was sufficiently familiar with surveying to plot the fields about him.

At his father's death the 11-year-old boy fell under the guardianship of the eldest son. Lawrence, a man of fine character who gave him wise and affectionate care. Lawrence inherited the beautiful estate of Little Hunting Creek that had been granted to the original settler, John Washington, and on which Augustine had done much since 1738 to develop. Lawrence married Anne (Nancy) Fairfax, daughter of Col. William Fairfax, cousin and agent of Lord Fairfax, one of the chief proprietors of the region. He also built a house and named the 2,500-ac. holding Mount Vernon, in honour of the admiral under whom he had served in the siege of Cartagena. Living there chiefly with Lawrence, though he spent spme time with his other half brother. Augustine (called Austin), near Fredericksburg, George entered a more spacious and polite world. Anne Fairfax Washington was a woman of charm, grace and culture; Lawrence had brought from his English school, Appleby, and his naval service much knowledge and experience. A valued neighbour and relative, George William Fairfax. whose large estate, Belvoir, was about 4 mi. distant, and other relatives by marriage, the Carlyles of Alexandria, helped form George's mind and manners. After 1748 Fairfax was husband of the attractive Sally Cary, whose vivacity, good humour and ease made her congenial.

The youth turned first to surveying as a profession. Lord Fairfax. a middle-aged bachelor who owned more than 5.000.000 ac. in northern Virginia and the Shenandoah valley, came to America in 1746 to live with his cousin, George William, at Belvoir, and to look after his properties. Two years later he sent to the Shenandoah valley a party to survey and plat his lands to enable him to make regular tenants of the squatters moving in from Pennsylvania. With the official surveyor of Prince William county in charge, Washington went along as assistant. The 16-year-old lad kept a disjointed diary of the trip which shows skill in observation. He describes the discomfort of sleeping under "one thread Bear blanket with double its Weight of Vermin such as Lice Fleas &c"; an encounter with an Indian war party bearing a scalp; the Pennsylvania-German emigrants, "as ignorant a set of people as the Indians they would never speak English but when spoken to they speak all Dutch"; and the serving of roast wild turkey on "a Large Chip," for "as for dishes we had none." As part of his compensation for the work of the survey, Washington received a patent for 550 ac. in Frederick county which he always referred to as "my Bullskin plantation."

The following year (1749), aided by Lord Fairfax, Washington received an appointment as official surveyor of Culpeper county, and for more than two years he was kept almost constantly busy. Surveying not only in Culpeper but also in Frederick and Augusta counties, he made journeys far beyond the tidewater region into the western wilderness. The experience taught him resourcefulness and endurance and toughened both body and mind. Coupled with his half brother Lawrence's ventures in land it also gave him an interest in western tracts and an appreciation of the importance of western development that endured throughout his life. He was always disposed to speculate in western holdings and to view favourably projects for colonizing the west; and he greatly resented the limitations which the crown in time laid on the westward movement. Lord Fairfax in 1752 determined to take up his final residence in the Shenandoah valley and settled there in a log hunting lodge which he called Greenway Court, after a Kentish manor of his family. There Washington was sometimes entertained and had access to a small library which Fairfax had begun accumulating at Oxford.

Plantation Life.—The years 1751–52 marked a turning point in Washington's life, for they placed him in control of Mount Vernon. His half brother Lawrence, stricken by tuberculosis, went to Barbados in 1751 for his health, taking George along. From this sole journey beyond the present borders of the United States Washington returned with the light scars of an attack of smallpox. In July of the next year Lawrence died, making George executor and residuary heir of his estate in the event of the decease of his daughter, Sarah, without issue. As she died within two months, Washington at the age of 20 became head of one of the best Virginia estates. He always thought farming the "most delectable" of pursuits. "It is honorable." he wrote, "it is amusing, and, with superior judgment, it is profitable." And of all the spots for farming, he thought Mount Vernon the best. "No estate in United America," he assured an English correspondent, "is more pleasantly situated than this." His greatest pride in later days was to be regarded as the first farmer of the land. He gradually increased the estate until it exceeded 8.000 ac. He twice enlarged the house (1760, 1785) and he improved the grounds with greenhouses, a deer paddock. a bowling green, and a "shrubbery." He tried to keep abreast of the latest scientific advances.

For the next 20 years the main background of Washington's life was the work and society of Mount Vernon. He had to manage the 18 slaves that came with the estate and others he bought later; by 1760 he paid tithes on 49 slaves—though he strongly disapproved of the institution and hoped for some mode of abolishing it. He gave assiduous attention to crop rotation, fertilizing and stock management. For diversion he was fond of riding, foxhunting and dancing; of such theatrical performances as he could reach; and of duck-hunting and sturgeon-fishing. He liked billiards and 'cards and not only subscribed to racing associations but ran his own horses in races. In all outdoor pursuits, from wrestling to colt-breaking, he excelled. A friend of the 1750s describes him as "straight as an Indian, measuring six feet two inches in his stockings"; as very muscular and broad-shouldered, but though large-boned, weighing only 175 pounds; and as having long arms and legs. His penetrating blue-gray eyes were overhung by heavy brows; his nose was large and straight; and his mouth was large and firmly closed. "His movements and gestures are graceful, his walk majestic, and he is a splendid horseman." He soon became prominent in community affairs. was an active member and later vestryman of the Episcopal Church and as early as 1755 expressed a desire to stand for the Virginia house of burgesses.

Early Military Career.—Traditions of John Washington's feats as Indian fighter and Lawrence Washington's talk of service days helped imbue George with military ambition. Just after Lawrence's death, Lieut. Gov. Robert Dinwiddie appointed him adjutant for the southern district of Virginia at £100 a year (Nov.

1752). The next year he became adjutant of the Northern Neck and Eastern Shore. Then in 1753 Dinwiddie found it necessary to warn the French to desist from their encroachments on Ohio valley lands claimed by the crown, and after sending one messenger who failed to reach the goal he determined to dispatch Washington. On the day he received his orders, Oct. 31, 1753, Washington set out for the French posts. His party consisted of a Dutchman to serve as interpreter; the expert scout Christopher Gist, for guide; and four others, two of them experienced traders with the Indians. Theoretically, Great Britain and France were at peace, but actually war impended, and Dinwiddie's message was an ultimatum: the French must get out or they would be put out.

The journey proved rough, perilous and futile. Washington's party left what is now Cumberland, Md., the middle of November, and despite wintry weather and wilderness impediments reached Ft. Le Boeuf, at what is now Waterford, Pa., 20 mi. south of Lake Erie, without delay. The French commander was courteous but adamant. As Washington reported, his officers "told me, That it was their absolute Design to take possession of the Ohio, and by God they would do it." Eager to carry this alarming news back, Washington pushed off hurriedly with Gist. He was lucky to get back alive. An Indian fired at them at 15 paces, but missed; when they crossed the Allegheny river on a raft Washington was jerked into the ice-filled stream but saved himself by catching one of the timbers. That night he almost froze in his wet clothing. He reached Williamsburg on Jan. 16, 1754, where he hastily penned a record of the journey. Dinwiddie, who was labouring to convince the crown of the seriousness of the French threat, had it printed, and when he sent it to London it was reprinted in three different forms.

The enterprising governor forthwith planned an expedition to hold the Ohio country. He made Joshua Fry colonel of a provincial regiment, appointed Washington lieutenant colonel and set them to recruiting troops. Two agents of the Ohio company, which Lawrence Washington and others had formed to develop lands on the upper Potomac and Ohio rivers, had begun building a fort at what later became Pittsburgh, Pa. Dinwiddie, ready to launch into his own war, sent Washington with two companies to reinforce this post. In April 1754, the lieutenant colonel set out from Alexandria with about 160 men at his back. He marched to Cumberland only to learn that the French had anticipated the British blow; they had taken possession of the fort of the Ohio company, and had renamed it Ft. Duquesne. Happily, the Indians of the area offered support. Washington therefore struggled cautiously forward to within about 40 mi. of the French position and erected his own post at Great Meadows, near what is now Confluence, Pa. With this as base, he made a surprise attack, May 28, 1754, upon an advance detachment of 30 French, killing the commander, Coulon de Jumonville, and nine others and making the rest prisoners. The French and Indian War (*q.v.*) had begun.

Washington at once received promotion to a full colonelcy and was reinforced, commanding a considerable body of Virginia and North Carolina troops, with Indian auxiliaries. But his attack soon brought the whole French force down upon him. They drove his 350 men into the Great Meadows fort (Ft. Necessity) on July 3, besieged it with 700 men and after an all-day fight compelled him to surrender. The construction of the fort had been a blunder, for it lay in a water-logged creek bottom, was commanded on three sides by forested elevations approaching it closely and was too far from Washington's supports. The French agreed to let the disarmed colonials march back to Virginia with the honours of war, but they compelled Washington to promise that Virginia would not build another fort on the Ohio for a year and to sign a paper acknowledging responsibility for *"l'assassinat"* of M. de Jumonville; a word which Washington later explained he did not rightly understand. He returned to Virginia, chagrined but proud, to receive the thanks of the house of burgesses, to be made a colonel by Dinwiddie and to find his name mentioned in the London gazettes. His remark in a letter to his brother that "I have heard the bullets whistle; and believe me, there is something charming in the sound" was commented on humorously by Horace Walpole and sarcastically by George II.

An Aide to Braddock.— The arrival of Gen. Edward Braddock and his army in Virginia in Feb. 1755, as part of the triple plan of campaign which called for his advance on Ft. Duquesne, Gov. William Shirley's capture of Niagara and William Johnson's capture of Crown Point, brought Washington new opportunities and responsibilities. He had resigned his commission in Oct. 1754 in resentment of the slighting treatment and underpayment of colonial officers and particularly because of an untactful order of the British war office that provincial officers of whatever rank should be subordinate to any officer holding the king's commission. But he ardently desired a part in the war; "my inclinations," he wrote a friend, "are strongly bent to arms." When Braddock showed appreciation of his merits and invited him to join the expedition as personal aide-de-camp, with the courtesy title of colonel, he therefore accepted. His self-reliance, decision and masterful traits soon became apparent.

At table he had frequent disputes with Braddock, who when contractors failed to deliver their supplies attacked the colonials as supine and dishonest, while Washington defended them with warmth. His freedom of utterance is proof of Braddock's esteem. Braddock also accepted from him the unwise advice that he divide his army, leaving half of it to come up with the slow wagons and cattle train and taking the other half forward against Ft. Duquesne at a rapid pace. Washington was ill with fever during June, but joined the advance guard in a covered wagon on July 8, begged to lead the march on Ft. Duquesne with his Virginians and the Indian allies and was by Braddock's side when on July 9 the army was ambushed and bloodily defeated.

In this defeat Washington displayed the combination of coolness and determination, the alliance of unconquerable energy with complete poise, which was the secret of so many of his successes. So ill that he had to use a pillow instead of a saddle and that Braddock ordered his body servant to keep special watch over him, he was everywhere at once. At first he followed Braddock as the general bravely tried to rally his men to push either forward or backward, the wisest course the circumstances permitted. Then he rode back to bring up the Virginians from the rear and rallied them with effect on the flank. To him was largely due the escape of the force. His exposure of his person was as reckless as Braddock's, who was fatally wounded on his fifth horse; Washington had two horses shot under him and his clothes cut by four bullets without being hurt. He was at Braddock's deathbed, helped bring the troops back and was repaid by being appointed, in Aug. 1755, while still only 23 years old, commander of all the Virginia troops. But no part of his later service was conspicuous. Finding that a Maryland captain who held a royal commission would not obey him, he rode north in Feb. 1756 to Boston to have the question settled by the commander in chief in America, Governor Shirley; and bearing a letter from Dinwiddie, had no difficulty in carrying his point. On his return he plunged into a multitude of vexations. He had to protect a weak, thinly settled frontier nearly 400 mi. in length with only some 700 ill-disciplined colonial troops; to cope with a legislature unwilling to support him; to meet attacks on the drunkenness and inefficiency of the soldiers; and to endure constant wilderness hardships. It is not strange that in 1757 his health failed and in the closing weeks of that year he was so ill of a "bloody flux" that his physician ordered him home to Mount Vernon.

Victory Without Promotion.— In the spring of 1758 he recovered sufficiently to return to duty as colonel in command of all Virginia troops. As part of the grand sweep of several British armies organized by Pitt, Gen. John Forbes led a new advance upon Ft. Duquesne. This time Forbes resolved not to use Braddock's road but to cut a new one west from Raystown, Pa. Washington disapproved of the route, but played an important part in the movement. Late in the autumn the French evacuated and burned Ft. Duquesne, and Forbes reared Ft. Pitt on the site. Washington, who had just been elected to the house of burgesses, was able to resign with the honorary rank of brigadier general.

But though his officers expressed regret at the "loss of such an excellent Commander, such a sincere Friend, and so affable a Companion," he quit the service with'a sense of frustration. He had thought the war excessively slow. The Virginia legislature had been niggardly in voting money; the Virginia recruits had come forward reluctantly and had proved of poor quality—he had hanged a few deserters and flogged others heavily. Virginia gave him less pay than other colonies offered their troops. Desiring a regular commission such as his half brother Lawrence had held, he applied in vain to the British commander in North America, Lord Loudoun. to make good a promise that Braddock had given him. Ambitious for both rank and honour, he showed a somewhat strident vigour in asserting his desires and in complaining when they were denied. He returned to Mount Vernon somewhat disillusioned.

Marriage and Stepchildren.—Immediately on resigning his commission he was married, Jan. 6, 1759, to Martha Dandridge, the widow of Daniel Parke Custis. She was a few months older than he, was the mother of two children living and two dead and possessed one of the considerable fortunes of Virginia. Washington had met her the previous March and had asked for her hand before his campaign with Forbes. Though it does not seem to have been a romantic love match, the marriage united two harmonious temperaments and proved happy. Martha was a good housewife, an amiable companion and a dignified hostess.

Some estimates of the property brought him by this marriage have been exaggerated, but it did include a number of slaves and about 15,000 ac., much of it valuable for its proximity to Williamsburg. More important to Washington were the two stepchildren, John Parke ("Jacky") and Martha Parke ("Patsy") Custis, who at the time of the marriage were six and four, respectively. He lavished great affection and care upon them, worried greatly over Jacky's waywardness and was overcome with grief when Patsy died just before the Revolution. Jacky died during the war, leaving four children. Washington adopted two of them, a boy and a girl, and even signed his letters to the boy as "your papa." Himself childless, he thus had a real family.

A Virginia Planter.—From the time of his marriage Washington added to the care of Mount Vernon the supervision of the Custis estate at the White House on the York river. As his holdings expanded they were divided into farms, each under its own overseer; but he minutely inspected operations every day and according to one visitor often pulled off his coat and performed ordinary labour. As he once wrote, "middling land under a man's own eyes, is more profitable than rich land at a distance." To the eve of the Revolution he devoted himself to the duties and pleasures of a great landholder, varied by several weeks' attendance every year in the house of burgesses in Williamsburg. For the years 1760–74 he was also a justice of the peace for Fairfax county, sitting in court in Alexandria.

In no light does Washington appear more characteristically than as one of the richest, largest and most industrious of Virginia planters. For six days a week he rose early and worked hard; on Sundays he irregularly attended Pohick church (16 times in 1760), entertained company, wrote letters, made purchases and sales and sometimes went fox-hunting. In these years he took snuff and smoked a pipe; throughout life he liked Madeira wine and punch. Though wheat and tobacco were his staples, he practised crop rotation on a three-year or five-year plan. He had his own waterpower flour mill, blacksmith shop, brick and charcoal kilns, carpenters and masons. His fishery supplied shad, bass, herring and other catches, salted as food for the Negroes. Coopers, weavers and his own shoemaker turned out barrels; cotton, linen and woolen goods; and brogans for all needs. In short, his estates, in accordance with his orders to overseers to "buy nothing you can make yourselves," were largely self-sufficient communities. But he did send large orders to England for farm implements, tools, paint, fine textiles, hardware and agricultural books, and hence was painfully aware of British commercial restrictions.

He experimented in breeding cattle; acquired at least one buffalo, with the hope of proving its utility as a meat animal; and kept stallions at stud. He also took pride in a peach and apple orchard. His care of slaves was exemplary. He carefully clothed and fed them, engaged a doctor for them by the year, refused to sell them—"I am principled against this kind of traffic in the human species"—and administered correction mildly. They showed so much attachment that few ran away.

In the social life of the tidewater region he meanwhile played a prominent role. The members of the council and house of burgesses, a roster of influential Virginians, were all friends. He visited the Byrds of Westover, the Lees of Stratford, the Carters of Shirley and Sabine Hall and the Lewises of Warner Hall; Mount Vernon often was busy with guests in return. He liked house parties and afternoon tea on the Mount Vernon porch; he was fond of picnics, barbecues and clambakes; and throughout life he enjoyed dancing, frequently going to Alexandria for balls. Cards were a steady diversion, and his accounts record sums lost at them, the largest reaching nearly £10. In bad weather his diary sometimes states, "at home all day, over cards." Billiards was a rival amusement. Not only the theatre, when available, but concerts, cockfights, the circus, puppet shows and exhibitions of animals received his patronage.

He insisted on the best clothes—coats, laced waistcoats, hats, coloured silk hose—bought in London. The Virginia of the Randolph~Corbins, Harrisons, Tylers, Nicholases and other prominent families had an aristocratic quality, and Washington liked to do things in a large way. It has been computed that in the seven years prior to 1775 Mount Vernon had 2,000 guests, most of whom stayed to dinner if not overnight.

Prerevolutionary Politics.—Washington's contented life was interrupted by the rising storm in imperial affairs. The British ministry, facing a heavy postwar debt, high home taxes and continued military costs in America, decided in 1764 to obtain revenue from the colonies. Up to that time Washington, though regarded by associates, in Col. John L. Peyton's words, as "a young man of an extraordinary and exalted character," had shown no signs of personal greatness and few signs of interest in state affairs. The Proclamation of 1763 interdicting settlement beyond the Alleghenies irked him, for he was interested in the Ohio company, the Mississippi company and other speculative western ventures. He nevertheless played a silent part in the house of burgesses and was a thoroughly loyal subject. (See also UNITED STATES: History.)

But he was present when Patrick Henry introduced his resolutions against the Stamp act in May 1765 and shortly thereafter gave token of his adherence to the cause of the colonial Whigs against the Tory ministries of England. In 1768 he told George Mason at Mount Vernon that he would take his musket on his shoulder whenever his country called him. The next spring, April 4, 1769, he sent Mason the Philadelphia nonimportation resolutions with a letter declaring that it was necessary to resist the strokes of "our lordly masters" in England; that courteous remonstrances to parliament having failed, he wholly endorsed the resort to commercial warfare; and that as a last resort no man should scruple to use arms in defense of liberty. When, the following May, the royal governor dissolved the house of burgesses, he shared in the gathering at the Raleigh tavern which drew up nonimportation resolutions, and he went further than most of his neighbours in adhering to them. At that time and later he believed with most Americans that peace need not be broken.

Late in 1770 he paid a land-hunting visit to Ft. Pitt, where George Croghan was maturing his plans for the proposed 14th colony of Vandalia. Washington directed his agent to locate and survey 10,000 ac. adjoining the Vandalia tract, and at one time he wished to share in certain of Croghan's schemes. But the Boston Tea Party of Dec. 1773 and the bursting at about the same time of the Vandalia bubble turned his eyes back to the east and the threatening state of Anglo-American relations. He was not a member of the Virginia committee of correspondence formed in 1773 to communicate with other colonies, but when the Virginia legislators, meeting irregularly again at the Raleigh tavern in May 1774, called for a continental congress, he was present and signed the resolutions. Moreover, he was a leading member of the first provincial convention or revolutionary legislature late that summer, and to that body he made a speech which was much praised for its pithy eloquence, declaring that "I will raise one thousand men, subsist them at my own expense, and march myself at their head for the relief of Boston."

The Virginia provincial convention promptly elected Washington one of the seven delegates to the first continental congress. He was by this time known as a radical rather than a moderate, and in several letters of the time he opposed a continuance of petitions to the British crown, declaring that they would inevitably meet with a humiliating rejection. "Shall we after this whine and cry for relief when we have already tried it in vain?" he wrote. When the congress met in Philadelphia on Sept. 5, 1774, he was in his seat in full uniform, and his participation in its councils marks the beginning of his national career. Later Patrick Henry, being asked who was the greatest man in congress, replied: "If you speak of eloquence, Mr. Rutledge of South Carolina is by far the greatest orator; but if you speak of solid information and sound judgment, Colonel Washington is unquestionably the greatest man on that floor."

His letters of the period show that while still utterly opposed to the idea of independence, he was determined never to submit "to the loss of those valuable rights and privileges, which are essential to the happiness of every free State, and without which life, liberty, and property are rendered totally insecure." If the ministry pushed matters to an extremity, he wrote, "more blood will be spilled on this occasion than ever before in American history." Though he served on none of the committees, he was a useful member, his advice being sought on military matters and weight being attached to his advocacy of a nonexportation as well as nonimportation agreement. He also helped to secure congressional approval of the "Suffolk Resolves," which looked toward armed resistance as a last resort and which did much to harden the king's heart against America.

Returning to Virginia in November, he took command of the volunteer companies drilling there and served as chairman of the committee of safety in Fairfax county. The unanimity with which the Virginia troops turned to him, though the province contained many experienced officers and Col. William Byrd of Westover had succeeded Washington as commander in chief, was a tribute to his reputation and personality; it was understood that Virginia expected him to be its general. At the March 1775 session of the legislature he was elected to the second continental congress and again set out for Philadelphia.

Head of the Colonial Forces. — Washington's choice as commander in chief of the military forces of all the colonies followed immediately upon the first fighting, though it was by no means inevitable and was the product of partly artificial forces. The Virginia delegates differed upon his appointment. Washington himself recommended Gen. Andrew Lewis for the post, and Edmund Pendleton was, according to John Adams, "very full and clear against it." It was chiefly the fruit of a political bargain by which New England offered Virginia the chief command as its price for the adoption and support of the New England army. This army had gathered hastily and in force about Boston immediately after the clash of British troops and American minutemen at Lexington and Concord on April 19, 1775. When the second continental congress met in Philadelphia on May 10, one of its first tasks was to find a permanent leadership for this force. On June 15 Washington, whose military counsel had already proved invaluable on two committees, was nominated and chosen by unanimous vote. Beyond the considerations noted, he owed his choice to the fact that Virginia stood with Massachusetts as one of the most powerful colonies; that his appointment would augment the zeal of the southern people; that he had made an enduring reputation in the Braddock campaign; and that his poise, sense and resolution had impressed all the delegates. The scene of his election, with Washington darting modestly into an adjoining room and John Hancock flushing with jealous mortification, will always impress the historical imagination; so also will the scene of July 3, 1775, when wheeling his horse under an elm in front of the troops paraded on Cambridge common he drew his sword and took command of the army investing Boston. News of Bunker Hill had reached him before he was a day's journey from Philadelphia, and he had expressed confidence of victory when told how the militia had fought. In accepting the command he refused any payment beyond his expenses and called upon "every gentleman in the room" to bear witness that he disclaimed fitness for it. At once he showed characteristic decision and energy in organizing the raw volunteers, collecting provisions and munitions and rallying congress and the colonies to his support.

The first phase of Washington's command covered the period from July 1775 to the British evacuation of Boston in March 1776. In those eight months he imparted discipline to the army, which at maximum strength slightly exceeded 20,000; he dealt with subordinates who, as John Adams said, quarreled "like cats and dogs"; and he kept the siege vigorously alive. Having himself planned an invasion of Canada by Lake Champlain, to be entrusted to Gen. Philip Schuyler, he heartily approved of Benedict Arnold's proposal to march north along the Kennebec river and take Montreal and Quebec. Giving Arnold 1,100 men, he instructed him to do everything possible to conciliate the Canadians. He was equally active in encouraging privateers to attack British commerce. As fast as means offered, he strengthened his army with ammunition and siege guns, bringing heavy artillery from Ticonderoga over the frozen roads early in 1776. His position was at first precarious, for the Charles river pierced the centre of his lines investing the town, and if Howe had moved his 20 veteran regiments boldly up the stream he might have pierced Washington's army and rolled either wing back to destruction. But all the generalship was on Washington's side. Seeing that Dorchester heights, just south of Boston, commanded the city and harbour, and that Howe had unaccountably failed to occupy it, he seized it on the night of March 4, 1776, placing his Ticonderoga guns in position. The British naval commander declared that he could not remain if the Americans were not dislodged, and Howe, after a storm disrupted his plans for an assault, evacuated the city on March 17. He left 200 cannon and invaluable stores of small arms and munitions. After stamping out the smallpox in Boston and collecting his booty, Washington hurried south by land to take up the defense of New York.

Sources of Military Strength. — Washington had won the first round, but there remained five years of war, during which the American cause was repeatedly near complete disaster. It is unquestionable that Washington's strength of character, his ability to hold the confidence of army and people and to diffuse his own courage among them, his unremitting activity and his strong common sense constituted the chief factors in achieving American victory. He was not a great tactician: as Jefferson said later, he often "failed in the field"; he was sometimes guilty of grave military blunders, the chief being his assumption of a position on Long Island in 1776 which exposed his entire army to capture the moment it was defeated. At the outset he was painfully inexperienced, the wilderness fighting of the French war having done nothing to teach him the strategy of maneuvering whole armies. One of his chief faults was his tendency to subordinate his own judgment to that of the generals surrounding him; at every critical juncture, before Boston, before New York, before Philadelphia, in New Jersey, he called a council of war, and in almost every instance accepted its decision. Naturally bold and dashing, as he proved at Trenton, Princeton and Germantown, he repeatedly adopted evasive and delaying tactics on the advice of his associates; however, he did succeed in keeping a strong army in existence and maintaining the flame of national spirit, and when the auspicious moment arrived, he planned the rapid movements which ended the war.

One element of Washington's strength was his sternness as a disciplinarian. The army was continually dwindling and refilling; politics largely governed the selection of officers by congress and the states; and the ill-fed, ill-clothed, ill-paid forces were often half prostrated by sickness and ripe for mutiny. Troops from each of the three sections, New England, the middle states and the south, showed a deplorable jealousy of the others. Washington was rigorous in breaking cowardly, inefficient and dishonest men and boasted in front of Boston that he had "made a pretty good sort of slam among such kind of officers." Deserters and plunderers were flogged; and Washington once erected a gallows 40 ft. high, writing that "I am determined if I can be justified in

the proceeding, to hang two or three on it, as an example to others." At the same time the commander in chief won the devotion of many of his men by his earnestness in demanding better treatment for them from congress. He complained of their short rations, declaring once that they were forced to "eat every kind of horse food but hay."

Campaigns in Middle Colonies.—The darkest chapter in Washington's military leadership was opened when, reaching New York in April 1776, he placed half his army, about 9,000 men, under Israel Putnam, on the perilous position of Brooklyn heights, Long Island, where a British fleet in the East river might cut off their retreat. He spent a fortnight in May with the continental congress in Philadelphia, then discussing the question of independence; and though no record of his utterances exists, there can be no doubt that he advocated complete separation His return to New York preceded but slightly the arrival of the British army under Gen. Sir William Howe, which made its main encampment on Staten Island till its whole strength of nearly 30,000 could be mobilized. On Aug. 22, 1776, Howe moved about 20,000 men across to Gravesend bay on Long Island. Four days later, sending the fleet under command of his brother Adm. Richard Howe to make a feint against New York city, he thrust a crushing force along feebly protected roads against the American flank. The patriots were outmaneuvered, defeated and suffered a total loss of 5,000 men, of whom 2,000 were captured. Their whole position might have been carried by storm, but fortunately for Washington, General Howe delayed. While the enemy lingered, Washington succeeded under cover of a dense fog in ferrying the remaining force across the East river to Manhattan, where he took up a fortified position. The British, suddenly landing on the lower part of the island, drove back the Americans in a clash marked by disgraceful cowardice on the part of Connecticut and other troops. In a series of actions Washington was forced northward, more than once in danger of capture, till the loss of his two Hudson river forts, one of them with 2,600 men, compelled him to retreat from White Plains across the river into New Jersey. There he slowly retired toward the Delaware, and as he went his army melted away, till it seemed that armed resistance to the British was about to expire.

It was at this darkest hour of the Revolution that Washington struck his brilliant blows at Trenton and Princeton, reviving the hopes and energies of the nation, Howe, believing the American army soon would dissolve totally, retired to New York, leaving strong forces in Trenton and Burlington. Washington at his camp west of the Delaware planned a simultaneous attack on both posts, using his whole command of 6,000 men. But his subordinates in charge of both wings failed him, and he was left on the night of Dec. 25, 1776, to march on Trenton with about 2,400 men. He completely surprised the unprepared Hessians and after confused street fighting killed the commander, Rall, and captured 1,000 prisoners, with arms and ammunition. The immediate result was that General Cornwallis hastened with 8,000 men to Trenton, where he found Washington strongly posted behind the Assunpink river, skirmished with him and decided to wait overnight "to bag the old fox."

During the night the wind shifted, the roads froze hard, and Washington was able to steal away from camp, leaving his fires deceptively burning, march around Cornwallis' rear and fall at daybreak upon the three British regiments at Princeton. These were put to flight with a loss of 500 men, and Washington escaped with more captured munitions to a strong position at Morristown, N.J. The effect of these victories was threefold; they heartened all Americans, brought recruits flocking to camp in the spring and encouraged foreign sympathizers with the American cause. (See also TRENTON AND PRINCETON, BATTLES OF.)

Valley Forge.—Thus far the important successes had been won by Washington; then they fell to others, while he was left to face popular apathy, military cabals and the disaffection of congress. The year 1777 was marked by the British capture of Philadelphia and the surrender of Burgoyne's invading army to Gates at Saratoga (*see* SARATOGA, BATTLES OF) followed by intrigues to displace Washington from his command. Howe's main British army of 18,000 left New York by sea on July 23, 1777, and landed on Aug. 25 in Delaware not far below Philadelphia. Washington, despite his inferiority of force, for he had only 11,000 men, mostly militia and in La Fayette's words "badly armed and worse clothed," risked a pitched battle on Sept. 11 at the fords of Brandywine creek, about 13 mi. north of Wilmington. While part of the British force held the Americans engaged, Cornwallis with the rest made a secret 17-mi. detour and fell with crushing effect on the American right and rear, the result being a complete defeat, from which Washington was fortunate to extricate his army in fairly good order. For a time he hoped to hold the Schuylkill fords, but the British passed them and on Sept. 26 triumphantly marched into Philadelphia. Congress fled to the interior of Pennsylvania, and Washington, after an unsuccessful effort to repeat his stroke at Trenton against the British troops posted at Germantown, had to take up winter quarters at Valley Forge. His army, twice-beaten, ill-housed, and ill-fed, with thousands of men "barefoot and otherwise naked," was at the point of exhaustion; it could not keep the field, for inside of a month it would have disappeared. Under these circumstances, there is nothing which better prcves the true fibre of Washington's character and the courage of his soul than the unyielding persistence with which he held his strong position at Valley Forge through a winter of semistarvation, of justified grumbling by his men, of harsh public criticism and of captious meddling by a congress too weak to help him.

Intrigues.—Washington's enemies seized the moment of his greatest weakness to give vent to an antagonism which had been nourished by sectional jealousies of north against south, by the ambition of small rivals and by baseless accusations that he showed favouritism to such foreigners as La Fayette. The intrigues of Thomas Conway, an Irish adventurer who had served in the French army and had become American inspector general, enlisted Thomas Mifflin, Charles Lee, Benjamin Rush and others in an attempt to displace Washington. Gen. Horatio Gates appears to have been a tool of rather than a party to the plot, expecting that the chief command would devolve upon himself. A faction of congress sympathized with the movement and attempted to paralyze Washington by reorganizing the board of war, a body vested with the general superintendence of operations, of which Gates became president; his chief of staff, James Wilkinson, the secretary; and Mifflin and Timothy Pickering, members. Washington was well aware of the hostility in congress, of the slanders spread by Dr. Rush and James Lovell of Massachusetts and of the effect of forgeries published in the American press by adroit British agents. He realized the intense jealousy of many New Englanders, which made even John Adams write his wife that he was thankful Burgoyne had not been captured by Washington, who would then "have been deified. It is bad enough as it is." But Washington decisively crushed the cabal when, the loose tongue of Wilkinson having disclosed Conway's treachery, he sent the latter officer on Nov. 9, 1777, proof of his knowledge of the whole affair.

With the conclusion of the French alliance in the spring of 1778 the aspect of the war was radically altered; and the British army in Philadelphia, fearing that a French fleet would blockade the Delaware while the militia of New Jersey and Pennsylvania invested the city, hastily retreated upon New York city. Washington hoped to cut off part of the enemy, and by a hurried march with six brigades interposed himself at the end of June between Sir Henry Clinton (who had succeeded Howe) and the Jersey coast. The result was the battle of Monmouth on June 28, where a shrewd strategic plan and vigorous assault were brought to naught by the treachery of Charles Lee (*see* MONMOUTH COURT HOUSE, BATTLE OF). When Lee ruined the attack by a sudden order to retreat, Washington hurried forward, fiercely denounced him and restored the line, but the golden opportunity had been lost. The British made good their march to Sandy Hook and Washington took up his quarters at New Brunswick. Lee was arrested, court-martialed and convicted on all three of the charges made against him; but instead of being shot, as he deserved, he was sentenced to a suspension from command for one year. The arrival of the French fleet under D'Estaing in July 1778 completed the isolation of the British and Clinton was thenceforth held to

New York city and the surrounding area. Washington made his headquarters in the highlands of the Hudson, and distributed his troops in cantonments around the city and in New Jersey.

Yorktown.—The final decisive stroke of the war, the capture of Cornwallis at Yorktown, is to be credited chiefly to Washington's vision. With the domestic situation intensely gloomy early in 1781, he was hampered by the feebleness of congress, the popular discouragement and the lack of prompt and strong support by the French fleet. A French army under Rochambeau having arrived to reinforce him in 1780, he pressed Admiral De Grasse to assist in an attack upon either Cornwallis in the south or Clinton in New York. In August the French admiral sent definite word that he preferred the Chesapeake, with its large area and deep water, as the scene of his operations; and within a week, on Aug. 19, 1781, Washington marched south with his army, leaving Heath with 4,000 men to hold West Point. He hurried his troops through New Jersey, embarked them on transports in Delaware bay and landed them at Williamsburg, Va., where he had arrived on Sept. 14. Cornwallis had retreated to Yorktown and entrenched his army of 7,000 British regulars. Their works were completely invested before the end of the month; the siege was pressed with vigour by the allied armies under Washington, consisting of 5,500 Continentals, 3,500 Virginia militia and 5,000 French regulars; and on Oct. 19 Cornwallis surrendered. By this campaign, probably the finest single display of Washington's generalship, the war was brought to a virtual close.

Washington remained during the winter of 1781–82 with the continental congress in Philadelphia, exhorting it to maintain its exertions for liberty and to settle the army's claims for pay. He continued these exhortations after he joined his command at Newburgh on the Hudson in April 1782. He was astounded and angered when some loose camp suggestions found expression in a letter from Col. Lewis Nicola offering a plan by which he should use the army to make himself king. He blasted the proposal with fierce condemnation. When the discontent of his unpaid men came to a head in the circulation of the "Newburgh address" early in 1783, he issued a general order censuring the paper, and at a meeting of officers on March 15 read a speech admonishing the army to obey congress and promising his best efforts for a redress of grievances. He was present at the entrance of the American army into New York on the day of Clinton's evacuation, Nov. 25, 1783, and on Dec. 4 took leave of his closest officers in an affecting scene at Fraunces' tavern. Traveling south, on Dec. 23, in a solemn ceremonial immortalized by the pen of Thackeray, he resigned his commission to the continental congress in the state senate chamber of Maryland in Annapolis and received the thanks of the nation. His accounts of personal expenditures during his service, kept with minute exactness in his own handwriting and totaling £24,700, without charge for salary, had been given the controller of the treasury to be discharged. Washington left Annapolis at sunrise of Dec. 24 and before nightfall was at home in Mount Vernon. (See also AMERICAN REVOLUTION, THE.)

In the next four years Washington found sufficient occupation in his estates, wishing to close his days as a gentleman-farmer and giving to agriculture as much energy and thought as to the army. He enlarged the Mount Vernon house in 1786; he laid out the grounds anew, with sunken walls or ha-has; and he embarked on experiments with mahogany, palmetto, pepper and other foreign trees, English grasses and grains. His farm manager during the Revolution, a distant relative named Lund Washington, retired in 1785 and was succeeded by a nephew, Maj. George Augustine Washington, who resided at Mount Vernon till his death in 1792. Washington's losses during the war had been heavy, caused by neglect of his lands, stoppage of exportation and a depreciation of paper money, which cost him hardly less than $30,000. He then attempted successfully to repair his fortunes, his annual receipts from all his estates being from $10,000 to $15,000 a year. In 1784 he made a tour of nearly 700 miles to view the wild lands he owned to the westward, congress having made him a generous grant. As a national figure, he was constrained to offer hospitality to old army friends, visitors from other states and nations, diplomats and Indian delegations, and he and his household seldom sat down to dinner alone.

A More Perfect Union.—Viewing the chaotic political condition of the United States after 1783 with frank pessimism and declaring (May 18, 1786) that "something must be done, or the fabric must fall, for it is certainly tottering," Washington repeatedly wrote his friends urging steps toward "an indissoluble union." At first he believed that the Articles of Confederation might be amended. Later, especially after the shock of Shays's rebellion, he took the view that a more radical reform was necessary but doubted as late as the end of 1786 that the time was ripe. His progress toward adoption of the idea of a federal convention was, in fact, puzzlingly slow. Though John Jay assured him in March 1786 that breakup of the nation seemed near and opinion for the convention was crystallizing, Washington remained noncommittal. But despite long hesitations, he earnestly supported the proposal for a federal impost, warning the states that their policy must decide "whether the Revolution must ultimately be considered a blessing or a curse." And his numerous letters to the leading men of the country assisted greatly to form a sentiment favourable to a more perfect union. Some understanding being necessary between Virginia and Maryland regarding the navigation of the Potomac, commissioners from the two states met at Mount Vernon in the spring of 1785; from this seed sprang the federal convention. Washington approved in advance the call for a gathering of all the states to meet in Philadelphia in May 1787 to "render the Constitution of the Federal Government adequate to the exigencies of the Union." But he was again hesitant about attending, partly because he felt tired and infirm, partly because of doubts about the outcome. Although he hoped to the last to be excused, he was chosen one of Virginia's five delegates.

Washington arrived in Philadelphia on May 13, the day before the opening of the convention, and as soon as a quorum was obtained was unanimously chosen its president. For four months he presided over the constitutional convention, breaking his silence only once upon a minor question of congressional apportionment. Though he said little in debate no one did more outside the hall to insist on stern measures. "My wish is," he wrote, "that the convention may adopt no temporizing expedients, but probe the defects of the Constitution to the bottom, and provide a radical cure." His weight of character did more than any other single force to bring the convention to an agreement and obtain ratification of the instrument afterward. He did not believe it perfect, though his precise criticisms of it are unknown. But his support gave it victory in Virginia, where he sent copies to Patrick Henry and other leaders with a hint that the alternative to adoption was anarchy; while a letter of his published in a Boston newspaper, declaring that "it or dis-union is before us to chuse from," told powerfully in Massachusetts. He received and personally circulated copies of the Federalist. When once ratification was obtained, he wrote leaders in the various states urging that men stanchly favourable to it be elected to congress. For a time he sincerely believed that, the new framework completed, he would be alloued to retire again to privacy. But all eyes immediately turned to him for the first president. He alone commanded the respect of both the parties engendered by the struggle over ratification, and he alone would be able to give prestige to the republic throughout Europe. In no state was any other name considered. The electors chosen in the first days of 1789 cast a unanimous vote for him, and reluctantly—for his love of peace, his distrust of his own abilities and his fear that his motives in advocating the new government might be misconstrued all made him unwilling—he accepted.

On April 16, after receiving congressional notification of the honour, he set out from Mount Vernon, reaching New York in time to be inaugurated on April 30. The ceremony was performed in Wall street, near the spot now marked by Ward's statue of Washington, and a great crowd broke into cheers as, standing on the balcony of Federal hall, he took the oath administered by Chancellor Livingston and retired indoors to read congress his inaugural address.

President of the United States.—Washington's administration of the government in the next eight years was marked by the caution, the methodical precision and the sober judgment which had always characterized him. He regarded himself as standing aloof from party divisions and emphasized his position as president of the whole country by a tour first through the northern states and later through the southern. A painstaking inquiry into all the problems confronting the new nation laid the basis for a series of judicious recommendations to congress in his first message. In selecting the four members of his first cabinet, Thomas Jefferson as secretary of state, Alexander Hamilton as secretary of treasury, Henry Knox as secretary of war and Edmund Randolph as attorney general, Washington balanced the two parties evenly. But he leaned with especial weight upon Hamilton, supporting his scheme for the assumption of state debts, taking his view that the bill establishing the Bank of the United States was constitutional and in general strengthening the authority of the federal government. Distressed when the inevitable clash between Jefferson and Hamilton arose, he tried to keep harmony, writing frankly to each and refusing to accept their resignations.

But when war was declared between France and England in 1793, he again took Hamilton's view that the United States should completely disregard the treaty of alliance with France and pursue a course of strict neutrality, while he acted decisively to stop the improper operations of the French minister, Genet. He had a firm belief that the United States must insist on its national identity, strength and dignity. His object, he wrote, was to keep the country "free from political connections with *every* other country, to see them independent of all, and under the influence of none. In a word, I want an *American* character that the powers of Europe may be convinced that we act for *ourselves,* and not for others." The sequel was the resignation of Jefferson at the close of 1793, the two men parting on good terms and Washington praising Jefferson's "integrity and talents." The suppression of the Whisky insurrection (*q.v.*) in 1794 by federal troops whom Hamilton led in person and the dispatch of John Jay to conclude a treaty of commerce with Great Britain tended further to align Washington with the Federalist party. Though the general voice of the people compelled him to acquiesce reluctantly to a second term in 1792 and his election that year was again unanimous, during his last four years in office he suffered from a fierce personal and partisan animosity. This culminated when the publication of the terms of the Jay treaty, which Washington signed on June 25, 1795, provoked a bitter discussion, and the house of representatives called upon the president for the instructions and correspondence relating to the treaty. These Washington, who had already clashed with the senate on foreign affairs, refused to deliver, and in the face of an acrimonious debate firmly maintained his position.

Early in his first term Washington, who by education and natural inclination was minutely careful of the proprieties of life, established the rules of a virtual republican court. In both New York and Philadelphia he rented the best houses procurable, refusing to accept the hospitality of George Clinton, for he believed the head of the nation should be no man's guest. He returned no calls and shook hands with no one, acknowledging salutations by a formal bow. He drove in a coach drawn by four or six smart horses and with outriders and lackeys in rich livery. He attended receptions dressed in a black velvet suit with gold buckles, with yellow gloves, powdered hair, a cocked hat with an ostrich plume in one hand and a sword in a white leather scabbard. After being overwhelmed by callers, he announced that except for a weekly levee open to all, persons desiring to see him must make previous engagements. On Friday afternoons Mrs. Washington held more informal receptions, at which the president appeared and chatted gravely with both ladies and gentlemen. Though the presidents of the continental congress had made their tables partly public, Washington, who entertained largely, inviting members of congress in rotation, insisted that his hospitality be entirely private. He served good wines and the menus were elaborate, but such visitors as Senator Maclay complained that the atmosphere was too "solemn." Indeed, his simple ceremony offended many of the more radical antifederalists, who did not share his sense of its fitness and accused the president of conducting himself as a king. But his cold and reserved manner was caused by native diffidence rather than any excessive sense of dignity.

Retirement. — Earnestly desiring leisure, feeling a decline of his physical powers and wincing under opposition abuse, Washington refused to yield to the general pressure for a third term. This refusal was blended with a testament of sagacious advice to his country in the *Farewell Address* of Sept. 19, 1796, written largely by Hamilton but remolded by Washington and expressing his ideas. Retiring in March 1797 to Mount Vernon, he devoted himself for the last two and a half years of his life to his family, farm operations and care of his slaves. In 1798 his seclusion was briefly threatened when the prospect of war with France caused his appointment as commander in chief of the provisional army, and he was much worried by the political quarrels over high commissions; but the war cloud passed away. On Dec. 12, 1799, he exposed himself on horseback for several hours to cold and snow and, returning home exhausted, was attacked late next day with quinsy or acute laryngitis. He was bled heavily four times and given gargles of "molasses, vinegar and butter," and a blister of cantharides (a preparation of dried beetles) was placed on his throat, his strength meanwhile rapidly sinking. He faced the end with characteristic serenity, saying, "I die hard, but I am not afraid to go," and later: "I feel myself going. I thank you for your attentions; but I pray you to take no more trouble about me. Let me go off quietly. I cannot last long." After giving instructions to his secretary, Tobias Lear, about his burial, he died at 10 P.M. on Dec. 14 without pain or struggle. The news of his death placed the entire United States in mourning, and the sentiment of the country permanently endorsed the famous words of Henry Lee, embodied in resolutions which John Marshall introduced in the house of representatives, that he was "first in war, first in peace, and first in the hearts of his countrymen." When the news reached Europe the British channel fleet and the armies of Napoleon paid tribute to his memory; and many of the political and intellectual leaders of the time joined in according him a pre-eminent place among the heroes of history.

BIBLIOGRAPHY.—The earliest known portrait of Washington is that by Charles Willson Peale, painted in 1772. A long line of painters and sculptors followed, and their work may be found criticized in Justin Winsor's *Narrative and Critical History of America,* vol. vii. Washington himself thought highly of the likeness by Joseph Wright, painted in 1782. According to Winsor, the favourite profile is Houdon's, while Gilbert Stuart's canvas had been popularly preferred for the full face and John Trumbull's florid paintings for the whole figure. Stuart's pictures are somewhat idealized, while all the later portraits suffer from the fact that the artificial teeth worn by Washington in later years altered the expression of his face. Houdon's statue hardly does justice to Washington's imposing stature; he was 6 ft. 3 in. tall in his prime and weighed 220 lb., carrying himself with great dignity and poise. But the Houdon bust, modeled from life at Mount Vernon, is excellent. For the iconography see Gustav Eisen, *Portraits of Washington,* in 3 vol. (1932).

The fullest compilation of Washington's *Writings* is the United States bicentennial commission edition, edited by John C. Fitzpatrick in 39 vol. (1931–44). This displaces the older works, Worthington C. Ford, *The Writings of George Washington* in 14 vol (1889–93), and Jared Sparks's edition in 12 vol. (1834–37). John C. Fitzpatrick has separately edited Washington's *Diaries* in 4 vol. (1925). Much the fullest and best biography is that by Douglas Southall Freeman in 6 vol. (1948–54), which is supplemented by a seventh volume written by his associates John A. Carroll and Mary A. Ashworth (1957). Among good earlier biographies now corrected by Freeman are those by John Marshall (including plagiarized material) in 5 vol. (1804–07); Washington Irving, also in 5 vol. (1855–59); Edward Everett Hale (1888); Henry Cabot Lodge (1889); Woodrow Wilson (1897); Worthington C. Ford (1899); and Norman Hapgood (1901). Rupert Hughes published an incomplete 3-vol. biography in 1926–29. The best recent 1-vol works are John C. Fitzpatrick, *George Washington Himself* (1933); Shelby Little, *George Washington* (1931); and Marcus Cunliffe, *George Washington: Man and Monument* (1958).

Valuable studies on special aspects of Washington's career include Charles H. Ambler, *George Washington and the West* (1936); Hugh Cleland, *George Washington in the Ohio Valley* (1956); John Corbin, *The Unknown Washington,* largely on his constitutional ideas (1930); Paul Leland Haworth, *George Washington, Country Gentleman* (1925); Eugene E. Prussing, *The Estate of George Washington, Deceased* (1927); Thomas G. Frothingham, *Washington, Commander in Chief* (1930); H. L. Ritter, *Washington As a Business Man* (1931); and Charles W Stetson, *Washington and his Neighbors* (1956). Paul Leicester Ford's *The True George Washington* (1896) is a classic examination of all sides of Washington's career and personality, while

Charles Moore has examined *The Family Life of George Washington* (1926). For a treatment of the military and political background of the times *see* the large histories by W. E. H. Lecky, George Otto Trevelyan, George Bancroft, Justin Winsor, John Bach McMaster, Edward Channing and L. H. Gipson. The best work on Martha Washington is by Anne Hollingsworth Wharton (1897), supplemented by Paul Wilstach, *Mount Vernon, Washington's Home and the Nation's Shrine* (1916). (*A.* N.)

WASHINGTON, HENRY STEPHENS (1867–1934), U.S. petrologist whose *Manual of the Chemical Analysis of Rocks* (4 ed., 1904 to 1930) became standard for students throughout the world, was born on Jan. 15, 1867, in Newark, N.J. Washington and three associates devised a "Quantitative Classification of Igneous Rocks" published in the *Journal of Geology* in 1902. He used this framework in tabulating 8,600 rock analyses which he collected from world-wide literature for the years 1884 to 1913 inclusive, resulting in his *Chemical Analyses of Igneous Rocks* published in 1917 by the United States geological survey, which continued the work for the years 1914 to 1953. Washington was an organizer, in 1919, of the International Union of Geodesy and Geophysics. He was co-author of a chapter on the constitution of the earth (a National Research council publication in 1951). He died on Jan. 7, 1934, in Washington, D.C. (H. E. ME.)

WASHINGTON, nicknamed the "Evergreen state" for its extensive forests of fir and pine and "Chinook state" for its salmon industry, is a state of the Pacific northwest of the United States. It is bounded on the north by the Canadian province of British Columbia (at the 49th parallel); on the east by Idaho; on the south by Oregon and the Columbia river; and on the west by the Pacific ocean, the Strait of Juan de Fuca and Puget sound. Its extreme length east and west is 341 mi., its extreme width north and south is 238 mi.; and its total area is 68,192 sq.mi., of which 66,709 is land area, including 1,483 sq.mi. of inland water surface, and 530 sq.mi. is boundary water (Puget sound). It is 20th in size among the states, being, with the exception of Hawaii, the smallest state west of Iowa. Washington was proclaimed a state Nov. 11, 1889, becoming the 42nd state in the union; the capital is Olympia. The state bird is the willow goldfinch, the state flower is the coastal rhododendron and the state tree is the western hemlock (*Tsuga heterophylla*). The state flag is dark green bearing in its centre a reproduction of the state seal, a circle bearing the legend "The Seal of the State of Washington 1889" around a bust of George Washington. In 1853 Columbia was suggested as the name of the prospective territory, but because it resembled that of the federal district, Washington was substituted.

PHYSICAL GEOGRAPHY

Physical Features and Soils.—Washington, in fact the entire Pacific northwest, lies within the realm of the western cordillera of the western hemisphere. The state lies between the extremes of approximately latitude 45° 34' and 49" N. and longitude 116° 57' and 124° 48' W. Volcanism and glaciation have been responsible for most of the landscape and soil cover. The region lies within the "Pacific ring of fire," and the highest peaks in the Cascade range are extinct volcanoes. Mt. Rainier (14,410 ft.), Mt. Adams (12,307 ft.), Mt. Baker (10,778 ft.), Glacier peak (10,528 ft.) and Mt. St. Helens (9,677 ft.) were built upon an older mountain system during the Pleistocene period of geologic history.

The Olympic mountains and the Willapa hills come so near to the Pacific shore line that there is only a very narrow coastal lowland. Mt. Olympus (7,954 ft.) is the highest point in the rugged Olympic peninsula. Immediately to the east is the Cowlitz-Puget trough, the northern end of which, Puget sound, is submerged and provides one of two of the largest natural harbours on the Pacific coast of the western hemisphere. Rivers flowing into the sound have silted up their estuaries to form rich farm lands.

The Cascade range, which divides the state into two distinct geographic sections, extends from British Columbia to the Columbia river: Its width at the international boundary is about 100 mi., and it narrows to 50 mi. at the river where its gorge provides the only good break through the Cascade-Sierra Nevada mountain chain in a distance of over 1,000 mi.

East of the Cascades lies a large interior region known as the Inland empire. A merging of the Okanogan highlands and the frontal ranges of the Rockies forms a northern enclosure. To the south and east lies the Columbia plateau, which is one of the largest and deepest lava beds in the world. Parts of it are covered with thick layers of glacial material, other portions have had their topsoil washed away by glacial melt water, so that bedrock protrudes through thin but rich soil. Rivers fed by glacial waters also carved deep trenches called coulees, of which the Grand coulee is the most formidable. It is a depression from 500 to 1,000 ft. in depth and about 50 mi. in length. The upper half of the coulee is used as an equalizing reservoir to store water for the Columbia river basin project. Farther to the south and the east is the Palouse country, a hilly area where winds and snow have deposited thick layers of sediments of volcanic and glacial origin. A unique soil of exceptional depth and fertility has developed from these sediments. In the central part of the state, the Big Bend country and the Columbia basin are semiarid but, by the use of dry-farming methods and irrigation, good crops are produced with consistency. (*See* also COLUMBIA RIVER.)

Climate.—Because of the north-south direction of the mountain ranges which lie athwart the prevailing westerly winds, the climatic zones of the state assume an essentially north-south orientation. Air, thick with moisture, reaching the state from the west has a cooling effect in summer and a warming influence in winter. Whereas this moderating factor extends to the interior, the weather, nevertheless, varies pronouncedly in different parts of the state. Along the coast line, precipitation is excessive—at one point in the south foothills of the Olympic mountains it exceeds 140 in. West of the Cascades the mean annual temperature is very moderate, and the annual range is but 15°–30° F. The interior, on the other hand, is semiarid and desert conditions prevail along the Columbia river at Hanford, which has but 6 in. of precipitation a year. Some places have an extreme annual temperature range of over 120° F. There are areas in western Washington that have 280 days free of killing frost; Walla Walla has 200 such days. Other parts of the interior, however, have only 100.

The Rocky mountains generally shield the state from easterly and northeasterly winds generated on the northern Great Plains. However, when the winds become sufficiently intense, they occasionally surmount or break through the barrier and cause cold spells, called "cow killers" in olden days. A mild fohn wind, known as a chinook (*q.v.*), sometimes brings relief and removes snow.

Due to peculiar circumstances, the weather of the state tends to be dry and stable in late spring and summer and wet and capricious in winter. This is in reverse of the situation in most parts of the United States.

Vegetation and Animal Life.—The Douglas fir, Washington's most important lumber tree, grows on both the east and west slopes of the Cascades, but reaches its greatest dimensions in the west, growing on hills and benches at elevations from near sea level to more than 5,000 ft. Some Douglas firs reach a height of 300 ft., with diameters of 12 to 15 ft. Western red cedar, also important, attains a height of up to 200 ft. and a diameter of up to 10 ft. Ponderosa pine (some of which reach a height of 175 ft. with a diameter of 6 ft.), with an average height of about 100 ft. and diameter of 3 ft., is the most valuable tree of the eastern part of the state. Other important trees include the western hemlock, which grows in all parts of the state, and the Sitka spruce, growing in the coastal fog belt. Grand, silver, noble and alpine firs are common, as is the western larch. More than 3,000 species of wild flowers, shrubs, vines, ferns and mosses are found in the state from the ocean shore and the humid western slopes of the Cascades to the mountain ranges, the Columbia basin and the semiarid plateaus. Among the most spectacular is the state flower, the rhododendron.

The abundant animal life attracted the pioneer hunters and fur traders. Elk, deer and bear may be found in the forests and mountains. Mountain goats have increased in numbers under the protection of conservation laws. Fur-bearing animals include large numbers of beavers, martens, muskrats, skunks, weasels, otter, mink, raccoons, opossums and foxes. Important carnivorous animals are the coyote, bobcat and mountain lion. Because of the extensive forests and wide differences in climate and topography, the state supports a large and varied bird population, including ducks, geese and other migratory waterfowl, pheasants, grouse, sage hens and other upland game birds and numerous species of songbirds. Native fish include the rainbow, steelhead, cutthroat, silver and Dolly Varden trouts; eastern brook, Mackinaw and Loch Leven trouts and bass, perch, crappie, catfish and sunfish have been introduced. Many of the lakes were barren until successfully stocked by the state, which operates 25 hatcheries. Five species of salmon, including the Chinook, or king, salmon, are found there and the rivers, sounds and coastal and offshore waters teem with many varieties of fish, shellfish and other marine life.

State and National Parks.—The state park system includes more than 60 parks, historical, geological and other areas. Deception Pass State park has had the largest total number of visitors, and Twin Harbors State park the largest number of night campers. The Dry falls of the Grand coulee, 400 ft. high and about 3 mi. wide, on the prehistoric Columbia river, are a part of Sun Lakes State park. State game and recreation areas include Banks lake and Potholes and Long lake reservoirs.

National parks in the state include Olympic National park, almost 1,400 sq.mi. of wilderness area on the Olympic peninsula, and Mt. Rainier National park, containing 378 sq.mi., with 26 glaciers on the 14,410-ft, mountain. The national park service also administers the Coulee dam national recreation area, which includes the Franklin D. Roosevelt lake, formed by Grand Coulee dam across the Columbia river. Fort Vancouver National monument, western headquarters of the Hudson's Bay company, 1825–49, and U.S. military reservation for 100 years thereafter, was established in 1954. Whitman National monument, site of the mission set up by Marcus Whitman (see *History: Joint Occupation,* below) and scene of the Whitman massacre in 1847, was established in 1940.

HISTORY

Exploration and Early Settlement.—For most of its history, the Pacific northwest has had the misfortune of being appraised from the standpoint of its geographic position rather than its economic potentialities or its inherent attractiveness for living. Early European mariners sought the region with a view of discovering a passage to the far east, but the first men on record to have seen the region were Juan Pérez, in 1774, and Bruno Heceta, the following year. Sent to determine the status of Russians in Alaska, they described the shore line, and Heceta's men were the first white persons known to have set foot on Washington soil.

Of more enduring significance were the exploits of Capt. James Cook. In 1778, on his third voyage to the Pacific, he discovered the Hawaiian Islands, which he named Sandwich Islands; visited the coast of the Pacific northwest; and put in at Nootka sound for repairs. His crew gathered a lucrative cargo of furs, the sale of which at Canton gave impetus to the maritime fur trade. Notable were the achievements of those who followed. Capt. Charles Barkley, whose wife was the first white woman known to have visited the northwest coast, discovered the Strait of Juan de Fuca in 1787. Capt. John Meares sailed into this passage the following year and bestowed upon it the name of the apocryphal explorer. Capt. George Vancouver, whose mission was both diplomatic and exploratory, surveyed Puget sound and the waters behind Vancouver Island in most expert fashion in 1792. The same year, Robert Gray, a Boston mariner, discovered the Columbia river and thereby gave the United States its first claim to the "Oregon country," as the land drained by the river was called. Later in the year, Vancouver's second in command, William Broughton, also entered the river and made an even more extensive reconnaissance. The maritime fur trade, ruthlessly exploitative, declined rapidly thereafter.

Overland explorations to the Pacific, which previously had proved abortive, succeeded at the turn of the century. Alexander Mackenzie, a Scotsman and partner in the North West company, made the first crossing of North America by a northern route in 1792–93. He did not, however, find "the river of the West." This honour fell to Meriwether Lewis and William Clark, who in 1805–06 reached the main course of that stream. They entered Washington from Idaho by the Snake river which they followed to the Columbia which in turn took them to the sea. They returned by substantially the same route.

David Thompson, a dauntless explorer and superb geographer for the North West company, built posts, called "houses," in the upper courses of the Columbia. One, Spokane house, built in 1810 near the juncture of the Little Spokane and Spokane rivers, became the first building constructed by white men in Washington. John Jacob Astor's Pacific Fur company, a subsidiary of the American Fur company, used Astoria as its regional base of operations. Ft. Okanogan and Ft. Spokane, opposite Spokane house, were interior posts. Misfortunes, chiefly at sea, and the War of 1812 prompted authorities at Astoria in Oct. 1813 to sell out to the North West company, which then had the trade of the region to itself until it was absorbed by the Hudson's Bay company in 1821. Under John McLoughlin, "Father of Oregon" and chief factor of the department of the Columbia, this giant corporation maintained a successful monopoly and warded off the onslaughts of what the company regarded as American interlopers.

Joint Occupation.—The Oregon country did not become the subject of serious diplomatic discussion until after the War of 1812. Spain, in 1819, and Russia, in 1824–25, accepted boundary adjustments on the Pacific slope which eliminated them from the Columbia drainage area. Britain and the United States, the remaining claimants, recognized the ultimate significance of the region but felt themselves too ill-informed to make a final disposition. In 1818 they made a ten-year agreement, erroneously called "joint occupation." The subjects of either government could settle without impairing the claims of the other. In 1827 the arrangement was renewed indefinitely subject to termination by either power upon 12 months' notice. This approach proved workable until the flood of Americans poured over the Oregon trail in the 1840's. It soon became obvious to the Hudson's Bay company that settlement spelled doom to a declining fur trade on the Columbia. Both American and British statesmen also realized that delay in achieving a final boundary solution endangered the peace. Because this and other factors were propitious to the United States position, the treaty of 1846 favoured the U.S. by extending the 49° parallel boundary westward from the Rockies to the Strait of Georgia. The privileges and properties of the Hudson's Bay company were guaranteed but later relinquished for $650,000.

The Indians of the Pacific northwest, on the whole peaceably inclined, had been curious about the white man's religion to which they attributed his extraordinary powers. In 1831 a delegation of Flathead and Nez Perce Indians visited St. Louis to request the "black robes" and the "Book." Methodists and American board missionaries responded. Marcus Whitman, representing the latter, located a station at Wailatpu, near the present city of Walla Walla. Two Catholic secular priests, Fathers Francois Norbert Blanchet and Modeste Demers, went in 1838 to serve the Canadian elements among the fur traders and retired employees. To familiarize the Indians with the history of the church, they devised a chart on a long board called the "Catholic ladder." Jesuits established missions on the upper Columbia. The presence of several denominations, each claiming to represent the only true faith, the influx of immigrants, often carrying disease, and a knowledge of what had happened to Indians in the east produced a confused situation culminating in the Whitman massacre of Nov. 29, 1847. It set back missionary activity in the interior for over a decade.

During the 1830s there were sprinklings of white persons along the Willamette and lower Columbia rivers. In 1842 American pioneers went over the Oregon trail. Congress, probably out of deference to the joint occupation agreement, had done nothing to provide law or civil government for the Oregon country. When the settlers were confronted with this void, they impaneled their own grand and petit juries, designated persons to act as guardians and as executors of estates, instituted bounties on predatory animals and finally, in 1843, established a provisional government which lasted five years. It brought the Oregon country through the crisis of the Whitman massacre and the resulting Cayuse War. In the act of Aug. 14, 1848, creating Oregon territory, Congress gave this extralegal regime retroactive recognition.

Achievement of Statehood. — Under Oregon territory, which embraced all of the present Pacific northwest, the people residing north of the Columbia constituted an ineffective minority. Protests against the effects of distance from the seat of government at Salem and neglect of local needs induced congress to create the new territory of Washington, March 2, 1853. Its boundary ran along the Columbia river to the 46th parallel and thence eastward to the crest of the Rocky mountains. Washington did not assume its present shape until Idaho territory was cut away in 1863.

Isaac I. Stevens, the first territorial governor, had also been designated superintendent of Indian affairs. In 1854–55 he negotiated a series of treaties in nhich the Indians agreed to surrender much of their land. Incongruities in the treaties themselves. delay in ratification, nonfulfillment of some of the government's obligations and trespasses by white men resulted in disturbances and bloodshed during the years 1855 to 1859.

Puget sound, much less disturbed during the years of tension and hostilities in the interior, developed at a rapid rate. Tumwater, the first permanent settlement (1845), was followed by Smithfield, later Olympia (1850); Steilacoom (1851); Port Townsend (1852); and Seattle (1852). Commerce, agriculture and lumbering provided the stimulus to this growth. Soon, attention was again directed to the interior, since gold discoveries in the Selkirk ranges in the middle 1850s caused prospectors to flood the Inland empire, as the area east of the Cascades then became known. Walla Walla, the key outfitting point, was the wholesaling metropolis of the region until the middle 1880s. Miners provided an excellent market for local cattle which found the native bunch grass practically a complete food. When the early mining boom, which had been confined largely to placer operations, subsided, new outlets for livestock appeared. It had, furthermore, been discovered that the rich pastures, particularly in the Palouse country, could be converted to grain fields yielding phenomenal crops. New mineral strikes were made during these years and since the new diggings were largely in the nature of lode mines a more stable industry was assured. The growth in wealth and population led to agitation for statehood, and a constitution was drafted in 1878, but congress declined to pass an enabling act. Stock raising and farming rivaled mining as the basis of prosperity. The Northern Pacific railroad projected in the 1860s was completed in 1883 and brought new hordes of settlers to expand the economy. The resulting population increase from 75,116 in 1880 to 357,222 in 1890 (375%) was the territory's best claim to statehood, which was attained Nov. 11, 1889. Growth continued, with rich strikes of gold in the Klondike in 1897, and later in Alaska, stimulating the trade of cities on Puget sound, and the new prosperity was celebrated at the Alaska-Yukon exposition in 1909.

Perhaps the major development in the state through the first half of the 20th century was the Columbia basin and related projects designed for purposes of hydroelectric power generation, irrigation, flood control, navigation improvement and stream flow regulation, and recreation. The first navigation improvement project on the river was authorized in 1911. Construction of Bonneville and Grand Coulee dams in the Columbia basin project began in 1933; Bonneville was completed in 1937 and the main structure of the Grand Coulee in 1941. Irrigation on the project began in 1948 and irrigation with water from behind Grand Coulee dam began in 1952. The power plant at Grand Coulee was completed in 1951. (For details see COLUMBIA RIVER.)

Washington Politics. — Washington state politics have not observed strict party lines. For more than 40 years, the state leaned toward the G.O.P., except for the elections of 1896 when a fusion of Democrats and Populists had been effected; 1912, when Theodore Roosevelt's Progressives captured the state; and 1916, when Woodrow Wilson triumphed. In 1932 the trend was reversed. Democratic candidates for president carried the state from then on to 1938. Except for holdovers, the Democrats monopolized the state's congressional delegation until 1942 and from 1934 to 1960 there has been but one Republican U.S. senator from the state. Democrats have held most of the state's elective offices from 1932 through 1960 and except for the sessions of 1947 and 1949, have had majorities in both houses of the legislature. Dwight D. Eisenhower. Republican, was favoured for president by Washington voters in 1952 and 1956 and Richard M. Nixon, Republican, in 1960.

GOVERNMENT

Washington is governed under its original constitution, adopted on Oct. 1, 1889, and later frequently amended. Except for the powers of initiative and referendum which the people possess by virtue of a constitutional amendment in 1912, the legislative authority of the state is vested in the legislature, consisting of a senate and a house of representatives. Its regular meetings occur in January of odd-numbered years at Olympia, the capital, and are limited by the constitution to 60 days. Special meetings may be called by the governor at his discretion. Senators are elected for four years (half of the senatorial body retires every two years) and representatives for two years each. In 1935 the state legislature enacted a blanket primary law which provided that at primary elections voters may vote for candidates irrespective of party designation.

The state legislature is limited in three ways: (1) by the constitution, by which it is forbidden to enact special laws with respect to 18 subjects; (2) by the governor, whose veto of any bill or item therein must be overridden by a two-thirds vote of both houses, or the bill dies; and (3) by the people, who have the powers of initiative, referendum and recall. Amendment seven to the state constitution, as approved by the electorate in 1912, required that an initiative petition contain the signatures of 10%, but in no case more than 50,000, of legal voters and that referendum petitions have signatures of "six per centum of legal voters, but in no case more than 30,000 of legal voters." In 1956 a new amendment (30) changed the number of signatures required for initiative petitions to "eight per centum of the number of voters registered and voting for governor at the last preceding regular gubernatorial election" and referendum petitions to 4% of such signatures. Measures enacted by the people became susceptible to legislative alteration when amendment 26, adopted in 1952, permitted the legislature by a two-thirds vote to amend laws enacted through popular vote and made such amended acts immune to referendum. The state supreme court on Dec. 24, 1957, held that the legislature could, therefore, "change the law completely within the realm of the subject matter of the law." The legislature may still, if it wishes, refer any bill it has passed to the people for approval. Any elective officer, with the exception of judges of courts of record, is subject to recall.

The executive department consists of governor, lieutenant governor. secretary of state, treasurer, auditor, attorney general, superintendent of public instruction, commissioner of public lands and insurance commissioner, each chosen for a term of four years. In 1921 the legislature passed an act known as the Administrative code. which abolished about 70 boards and commissions that had come into existence from time to time and distributed their duties among ten ne departments. In view of new functions and reallocations of duties. these were increased in the second half of the 20th century to 16 departments, three commissions and a veterans' council, each having a full-time director and permanent staff.

The judicial department is composed of the supreme court of the state, the superior courts for the counties and courts of justices of the peace for cities, towns or precincts. The last named deal with civil cases involving less than $300 and criminal cases below the rank of felony. Justices of the superior courts are elected for four years. The jurisdiction of the supreme court is almost entirely appellate.

Finance. — Property values, total personal income and taxes increased from 300% to 500% during the three decades prior to 1960. The assessed valuation of property subject to tax was approximately $4,500,000,000 (one-half of actual value).

Most important in the history of the state's finances was the tax revolution which during the years 1932 to 1937 effected a change from a property tax base to one of sales and excise taxes.

Bottom right: Port of Tacoma, a well-protected harbour in the western part of Puget sound

In 1927 property taxes amounted to $16,109,673 or 57.22% of the total, whereas in 1937 these amounted to but $3,303,166 or 6.43% of the total. All sales taxes which in 1927 constituted but 16.95% of the total represented 76.76% in 1937. Washington's per capita sales tax collections in the second half of the 20th century were the highest among the states in both amount (more than $75) and proportion to the total (55%) in 1958. Other major revenues in that year were the business and occupation tax, gasoline tax, licenses, motor vehicle excise taxes and liquor board net profits. General property taxes still are the basis for local levies.

Efforts to establish an income tax have been nullified by two adverse decisions of the state supreme court in 1930 and 1933 and the defeat by the electorate of income tax amendments to the state constitution in 1934, 1936, 1938 and 1942. Another obstacle to alteration of the tax base is the 1944 amendment to the state constitution which limits aggregate tax levies upon real and personal properties in excess of "forty mills on a dollar of assessed valuation."

POPULATION

The population of Washington in 1860 was 11,594; in 1890 it was 357,232; in 1910, 1,141,990. By 1950 it had reached 2,378,963, and in 1960 it was 2,853,214.

The 1960 figure represents an increase of 19.9% over the population in 1950. The population per square mile in 1960 was 41.8, as compared with 34.9 in 1950 and with 49.6 for the U.S. in 1960.

Of the 1960 population 1,534,309, or 54.8%, lived in incorporated places of 2,500 or more, as compared with 54.7% in 1950, when these places constituted the urban area. The entire urban population, which included also the thickly settled suburban area, or "urban fringe," adjacent to Seattle, Spokane and Tacoma, and ten unincorporated places of 2,500 or more outside this fringe, in 1960 amounted to 1,948,664 or 68.3% of the state total.

*Populations are reported as constituted at date of each census. †Includes Fairhaven and New Whatcom cities consolidated and incorporated as Bellingham City in 1903.

Note: A dash indicates place did not exist during reported census, or data not available.

The number of households in 1950 was 736,988. The average population per household was 3 in 1950.

The population of the state was distributed by colour and nativity in 1950 as follows: 89.3% native white; 8% foreign-born white; and 2.7% nonwhite. Of the foreign-born white population, 24.9% was born in Canada, 10.9% in Sweden and 12.2% in Norway.

Of the population 8.9% was 65 years old or over; and 53.7% of the population 14 years old and over was in the labour force.

Of the total number of employed males, 12.4% was engaged in agriculture; 10.8% in construction; 25.3% in manufacturing; 10.4% in transportation; and 18.1% in wholesale and retail trade.

EDUCATION

During the territorial period, public schools of Washington were sustained by a levy of two mills of territorial tax matched by local levies of like amount. Substantial state support began with the "Barefoot School Boy" law of 1895 which provided each school district with $6 of state funds for each child of school age, subventions which were increased from time to time. In 1933 the basis of support was changed to a grant of 25 cents per day for each pupil in attendance. This stipend likewise later was enlarged.

To enable the public schools to pay salaries of a minimum set by the legislature, state subsidies were voted in 1945. The policy of state aid for school construction was initiated in 1947 when a $20,000,000 bond issue was voted. The electorate approved of a $40,000,000 issue in 1950. Education has become primarily a state responsibility.

The total public school enrollment was 590,000 (including 13th and 14th grades) in the late 1950s as contrasted with 390,000 ten years previously; costs per pupil in attendance were approximately $350 and $230 for the same period. The trend toward the consolidation of school districts continued, the number being reduced to fewer than 500 in 1960 from more than 1,400 in a period of 20 years.

Higher Education. — The state-supported University of Washington, Seattle, was established in 1861 as the Territorial University of Washington; the name was changed to the present when the territory became a state in 1889. Divisions include colleges of architecture and urban planning, arts and sciences, business administration, education, engineering, fisheries. forestry and pharmacy; graduate school; schools of law, medicine, dentistry, nursing and social work; and division of adult education. Some of the university's facilities include Charles Lathrop Pack Demonstration forest, 2,300 ac., at La Grande; Lee Memorial forest, 160 ac., near Maltby; biological laboratories at Friday Harbor on the San Juan (Haro) Islands; West Seattle research laboratory for electronic research, in West Seattle; and a center for graduate study at Hanford, located at Richland, administered under contract with the Atomic Energy commission.

Washington State university, Pullman, university and land-grant college, was chartered in 1890 as Washington State Agricultural College and School of Science; the name was changed to Agricultural College, Experiment Station and School of Science of the State of Washington in 1891, to State College of Washington in 1905 and to Washington State university in 1959. The three state colleges of education are Central Washington College of Education, at Ellensburg, established as Washington State Normal school in 1890, name changed to present in 1937; Eastern Washington College of Education, at Cheney, established as Washington State Normal in 1890, and name changed to present in 1937; and Western Washington College of Education, at Bellingham, chartered as Washington State Normal School at Bellingham in 1893 and name changed to present in 1937. Ten publicly accredited community junior colleges are merged with an extended secondary school program.

Privately endowed universities and colleges include, in Spokane, Gonzaga university (Roman Catholic; 1887) and Whitworth college (affiliated with the United Presbyterian Church in the U.S.A.; 1890); in Tacoma, Pacific Lutheran university (1894), name changed from Pacific Lutheran college in 1960, and College of Puget Sound (related to Methodist Church; 1888); in Seattle, Seattle Pacific college (affiliated with the Free Methodist Church;

1891) and Seattle university (Roman Catholic; 1891); in Walla Walla, Whitman college (nonsectarian; 1859); and in College Place, Walla Walla college (Seventh-day Adventist; 1892).

HEALTH, WELFARE AND CORRECTIONS

Public Health. — The department of public health deals with vital statistics and preventive medicine services and provides supervision of sanitation and local health services. Although no longer in charge of direct medical care to children, the work of the section of maternal and child health and crippled children has been substantially enlarged. In 1959 this department was assigned the establishment of "a state-wide program for the study, treatment and rehabilitation of persons suffering from alcoholism."

Assistance. — The department of assistance determines eligibility and degrees of need of claimants for assistance in the categories of old age, dependent children and foster care, blindness, disability, medical care, general need and burials. Reductions in the state's direct assistance payments, caused by the operation of the Old Age and Survivors insurance and unemployment insurance, have, to a considerable degree, been offset by accentuated health problems of old persons and by prolonged economic recessions which have resulted in unemployed persons' losing eligibility for further benefits.

Special Training for Young Persons. — Notable among several reallocations of functions of state welfare agencies was the law of 1951 which placed a new emphasis upon the needs of young persons. Subordinated to the department of institutions, the division of children and youth services became responsible for mentally, physically, emotionally and socially handicapped children. Although institutional care is provided at special schools, homes, hospitals and youth camps, the policy of the division is to retain, insofar as possible. parental ties and to establish young persons in normal homes and sound social environments.

Rehabilitation and Correction. — The program of the department of institutions has changed pronouncedly from one of custody and correction to one of rehabilitation and treatment. Besides operating three hospitals for mental health, the penitentiary at Walla Walla, the reformatory at Monroe and a system of honour camps, the department administers a bureau of criminal identification, two veterans' homes and a veterans' colony.

THE ECONOMY

Agriculture. — The acreage of farm land increased from approximately 15,200,000 ac. before World War II to more than 17,500,000 ac. in the second half of the 20th century, but the number of farms decreased from more than 80,000 to about 65,000. Crop land harvested amounted to about 4,300,000 ac., the remainder being classified largely as pasture and woodland. The total value of farm land and buildings increased from $593,000,000 before World War II to $2,324,000,000 by 1960. Tenancy has become negligible since many large and prosperous operators rent land, and the small unit farmers generally are full owners. The degree to which motor power has been substituted for animal power in the operation of farm equipment is no better revealed than in the reduction of the number of horses, which in 1915 numbered 311,000 and by the 1960s only 37,000. Also, there were fewer sheep, which in 1920 numbered 725,000 but in 1960 fewer than 250,000. Because the feeding of high-quality stock from grain surpluses has become profitable, the number of cattle has increased from fewer than 500.000 in 1910 to more than 1,000,000 by the second half of the 20th century.

Dry field peas constituted a bonanza crop during the years 1935 to 1949 and reached a peak production of 5,259,000 bags valued at $25,500,000 in 1943. Acreage reductions cut this figure to about 1,000,000 bags in the 1950s, and, whereas there was some recovery by 1960, green peas for processing supplanted the other variety in production and value. With the Columbia basin project lands going under cultivation, sugar beets, tried but virtually abandoned at the turn of the 20th century, went into conspicuous production, as did another comparatively new crop, dry edible beans.

The ten leading farm products by value in the second half of the 20th century were wheat, milk, apples, cattle and calves, eggs, hay, barley, hops, chickens and broilers, and pears. Washington enjoyed first place among states in the production of apples, hops, potatoes (late summer), spearmint and peppermint; and ranked high in the production of dry peas. green peas for processing, Bartlett and other pears, apricots, filberts and sweet cherries.

Mining. — Washington mines had during the century ending in 1960 yielded mineral and mineral aggregates to a total value of more than $1,000,000,000. Production pronouncedly stimulated by World War II expanded with even greater rapidity thereafter, metal production doubling during the ten-year period beginning 1944. All minerals increased in yield from $36,483,000 in 1944 to more than $60,000,000 annually by 1960. Coal, which attained a production of 4,000,000 tons valued at $14.000.000 in 1918, declined because of competition and other factors but large reserves remained if demand should revive. Sand and gravel constituted the largest nonmetal products, and zinc, lead, gold and silver were the leading metals.

Several factors were responsible for the boom in metals production during the period from 1933 to 1955: United States government policies of pegging the price of gold; purchasing silver; the discoveries of remarkably rich veins in Stevens and Ferry counties; and the development in the northeastern part of the state of the largest known body of low-grade lead and zinc ore in the United States. Research in electrometallurgy gave new significance to the magnesite (magnesium carbonate) ores of Stevens county, and the availability of cheap electric power from the Bonneville and Grand Coulee projects prompted the establishment of aluminum reduction plants at Vancouver, Longview, Spokane, Tacoma, Mead and Wenatchee, and an aluminum rolling mill at Trentwood.

The need for fissionable materials and the resulting reconnaissances brought to light in northeastern Washington deposits of uranium and a processing plant was established in 1957. The year 1957 also witnessed the beginning of flow from the first commercially producing oil well in the state near Ocean City, Grays Harbor county. The Holden copper mine of the Howe Sound company, located on Lake Chelan in Chelan county, once the largest single metallic mine operation in the entire Pacific northwest, including Alaska, ceased operation in 1957.

Forests and Lumbering. — Except for 1914, when Louisiana reported the largest production of lumber, Washington led the states from 1905 to 1938, but in that year it yielded first place to Oregon and by 1954 had also fallen to third place behind California. The state retained paramountcy in the production of wood pulp, but lost it in the production of plywood. Of the total land area of the state, over half (23,868,000 ac.) was in forest, of which 19,490,000 ac. were of commercial quality and 1,279,000 ac. productive but reserved. Annual tree growth in commercial stands of the state was about 650,000,000 cu.ft. in the 1950s, less than the cut of almost 800,000,000 cu.ft.

There are seven national forests entirely within the state and parts of two others within its boundaries, and the total area of these lands is 5,674,000 ac. These and Olympic National park with area of 888,558 ac., Mt. Rainier National park of 241.571 ac., as well as 116 state recreation areas with a total area of more than 65,000 ac. are available to the public for recreation.

Fisheries. — Washington relinquished its leadership in Pacific coast fisheries to California in 1922 and suffered further decline in the depression years of the early 1930s. Whereas by 1960 the amount of the annual catch had declined to about 136,000,000 lb., processed value had increased to more than $35,000,000.

The construction of irrigation and power dams placed the entire salmon industry in jeopardy. To offset these injuries, fishways were constructed around some dams. The state expanded its program of operating hatcheries for commercial and game fish and has taken steps to clear streams of obstructions and polluting elements. The Pacific International Salmon Fisheries commission administrated a program to preserve the salmon fisheries of Puget sound and adjacent waters.

Manufacturing and Transportation. — The pattern of growth of the state's manufacturing industry since 1899 has in the main followed that of the nation, although the rate of growth, particularly between 1899 and 1909, has been somewhat greater. Lumbering and lumber products, paper and paper products have been resource-oriented industries, whereas transportation equipment, particularly aircraft since 1916, has been labour-oriented. Most pronounced has been the progress in the processing of primary metals, which depends upon abundant and cheap energy, and of atomic chemicals, which depends upon the substantial water supply from the Columbia river. (For hydroelectric development *see* COLUMBIA RIVER.) These diverse factors redound to the stability and prosperity of the state's industry.

The ten leading industries deal with transportation equipment; lumber and wood products; pulp, paper and paper products; food and kindred products; primary metals; chemicals and chemical products; printing and publishing; machinery (except electrical); fabricated metals; and stone, clay and glass products. Only the first two of these industries and agriculture outranked tourism.

By the middle of the 20th century, the state highway system had recovered from the exceptionally heavy use to which it was put during the World War II period. To meet the demands of postwar tourist traffic, the state legislature in 1947 enacted the Limited Access Highway act, which placed 2,388 mi. of the state's highways under a master plan for conversion to limited access. Two important bridges, the first a concrete pontoon bridge across Lake Washington, the other a suspension bridge across Puget sound at Tacoma, facilitated motor traffic across these waterways. In 1960 there were approximately 56,000 mi. of highways in the state. The state was served by ten airlines, and there was a total of more than 100 airports and a dozen seaplane bases, in addition to privately owned restricted-use airports. There were almost 6,000 mi. of railroad track.

WASHINGTON, **D.C.,** the capital city of the United States, conterminous with the District of Columbia. centre of a metropolitan area extending over adjacent territory in Maryland and Virginia. By the middle of the 20th century Washington had become an important world capital and a news centre equal to or of greater importance than such European capitals as London, Paris and Berlin.

The city lies on the northeast bank of the Potoinac river at the head of tide and navigation, 40 mi. S.W. of Baltimore, 135 mi. S.W. of Philadelphia and 226 mi. S.W. of New York city. Its area is 69 sq.mi. The population in 1960 was 763,956, a decrease of 4.8% from 1950. The standard metropolitan statistical area, as defined by the census bureau, comprises, in addition to the city of Washington, Arlington and Fairfax counties and the independent cities of Alexandria (*q.v.*) and Falls Church in Virginia and Montgomery and Prince Georges counties in Maryland; its 1960 population was 2,001,897, an increase of 36.7% over 1950. Silver Spring, Md., is a large residential suburb.

Washington'has sometimes been called "Uncle Sam's company town." Its first business is service to the federal government and to its 241,000 civilian employees who work and live in the metropolitan area. Military personnel are stationed at Ft. Lesley J. McNair and the navy yard in Washington; at nearby Andrews air force base in Maryland; and in Virginia at Ft. Myer, Ft. Belvoir and the marine corps base in Quantico.

The climate of Washington is characterized by frequent periods of high humidity, occasional periods of oppressive heat in summer and moderately mild winters. The mean winter temperature (December, January and February) is 35° F. and the mean summer temperature (June, July and August) 75°. Extremes range, however, from a maximum of 106° to a minimum of −15°. There is an average annual precipitation of 42.2 in., evenly distributed throughout the year.

HISTORY

Origins of the Capital.—The United States was the first nation in the world to plan a capital exclusively for its seat of government, although in the 20th century Australia, Pakistan and Brazil followed that example. Before 1800 the congress of the young republic sat in eight cities—Philadelphia, Baltimore, Lancaster, York, Princeton, Annapolis, Trenton and New York. In 1783, while convened in Philadelphia, congress was unable to raise money to pay the soldiers who had served to the end of the Revolution. Pennsylvania troops stationed nearby, upon finding themselves furloughed without pay, defied their officers and marched to the statehouse to demand justice from congress and the executive council. Neither the Pennsylvania state government nor the city offered protection. James Madison commented that if the city would not support congress, it was high time to remove to another place. Congress did, in fact, adjourn to meet three days later in Princeton, N.J.

Competition was very keen to secure the seat of government, for it seemed to ensure a bright commercial future for any small town and would increase the prestige and wealth of established centres. Kingston, N.Y., made the first offer and in rapid succession invitations followed from New York; Boston; Philadelphia; Newport, R.I.; Wilmington, Del.; Trenton, N.J.; Reading and Lancaster, Pa.; Annapolis, Md.; Williamsburg, Va.; and Yorktown, Pa. During the debate in congress a question was raised as to the jurisdiction proper for congress to exercise over the place of the permanent government. The constitution of the United States settled the question as far as it touched the relationship of federal to state authority. By that document congress is given power "To exercise exclusive Legislation in all Cases whatsoever, over such District (not exceeding ten Miles square) as may, by Cession of particular States, and the Acceptance of Congress, become the Seat of the Government of the United States . . ." Unfortunately neither the constitution nor the later "residence act" spelled out the relationship of congress to citizens living within the ten-mile square, although James Madison in The *Federalist,* which sought to win converts to ratification of the constitution, declared that local citizens would as a matter of course enjoy the rights of self-government.

The debate on the "residence act" early recognized the wisdom of placing the national capital on a navigable waterway and in a geographically central location between Georgia and New Hampshire. The advantages of relatively easy access to the trans-Allegheny west were also obvious. But sectional conflict ran strong. Madison, Jefferson and Washington all urged a site on the Potomac river, for they believed a southern capital essential to the economic recovery of the war-scarred south; northerners, apart from their aspirations for a locality uithin their region, were opposed to any place within slaveholding territory. According to Jefferson, the deadlock in congress was finally broken by a "deal" between himself and Alexander Hamilton: Jefferson aligned enough votes to ensure federal assumption of state war debts in return for Hamilton's support of a southern site for the capital. The act passed in 1790 specified a district not exceeding ten miles square to be located on the Potomac river "at some place between the mouths of the Eastern Branch and the Connogocheague." The president was authorized to appoint three commissioners who, under the direction of the president, were to survey and define the district, to purchase or accept the necessary lands and to provide suitable buildings for the public offices. To give time to complete these arrangements, the seat of government was to remain in Philadelphia until 1800.

George Washington's first reference to this decision occurs in his diary under date of July 12, 1790: "and about noon had two bills presented to me by the joint committee of Congress. The one, an act for establishing the temporary and permanent seat of the Government of the United States." On Jan. 24, 1791, Washington sent a message to congress stating that he had selected a site and directed commissioners "to survey and limit a part of the territory of the ten miles square on both sides of the river Potomac so as to comprehend Georgetown in Maryland and extend to the Eastern Branch." He suggested that congress choose whether the area should extend lower in Maryland and include the town of Alexandria in Virginia or reach farther north. Without any discussion congress accepted the president's first proposal, placing the southern extremity of the federal district at the mouth of Hunting creek just below Alexandria. Public opinion endorsed the choice.

As commissioners, Washington appointed Thomas Johnson of Frederick, Md.; Daniel Carroll of Rock Creek, Md.; and David Stuart of Hope Park near Fairfax Court House, Va. While Andrew Ellicott of Maryland surveyed the bounds of the ten-mile square, laid obliquely with the compass ($69\frac{1}{4}$ sq.mi. within Maryland, the remainder to the south in Virginia), the president faced two problems: exactly where within the federal district the city should rise and how to induce the planters and farmers who owned the land to sell it at a reasonable price. Washington entrusted the first task to Maj. Pierre Charles L'Enfant (*q.v.*), a young French engineer who had served in the Revolutionary War. As soon as L'Enfant had chosen the site bordering the Eastern branch and the Potomac and encompassing Jenkins hill to the east and most of the valley of Tiber creek, the president began negotiations with the 19 principal proprietors of the land needed. With some difficulty he persuaded them to convey it to him in trust, "in consideration of the great benefit we expect to derive from having the federal city laid off upon our lands," upon condition that "the president shall have the sole power of directing the federal city to be laid off in what manner he pleases." Half the lots were to go to the public and half to the original owners. For the streets the proprietors were to receive no compensation, but for the land taken for public use, they were to be paid at the rate of £25 per acre. On March 31, 1791, Jefferson wrote to Washington, "The acquisition of ground is really noble. . . . I think very liberal reserves should be made for the public."

Plan of the City.—At the president's request, Major L'Enfant undertook to prepare a plan of the city. "After much menutial search for an eligible situation," he wrote, "I could discover no one so advantageously to greet the congressional building as that on the west end of Jenkin's Heights, which stands as a pedestal waiting for a monument." For the "presidential palace" he selected a ridge west of Tiber creek near the' Potomac. The plan placed the executive mansion on a north-south axis intersecting an east-west axis from the congress house to the river. Near the intersection at which L'Enfant proposed to place an equestrian statue, the shaft of the Washington monument rose in the 19th century. A broad thoroughfare, Pennsylvania avenue, was to run from the congress house to the president's palace, about which the executive department office buildings should be grouped. Waterfalls cascading from the terrace of the congress house should descend into a pool at the foot of what came to be called Capitol Hill and thence flow into the Potomac through a mile-long grand canal bordered by gardens. The shore of the Eastern branch with its deep water should serve as the city's commercial centre, while an arcade stretching due east from the congress house should accommodate shops. Upon a gridiron of irregular rectangular blocks L'Enfant's plan superimposed diagonal avenues devised to converge at the capitol and the executive mansion and to form scores of squares, circles and triangles at street intersections, where monuments and fountains should be placed. The Frenchman designated a square on a small hilltop overlooking the Potomac beyond the executive mansion as the site for a national university.

Unhappily, L'Enfant delayed the completion of his map, which had to be engraved in order to have copies to show potential buyers the location of lots available for private purchase. Time became important, since the commissioners in charge of building the public edifices in the city they named Washington had to supplement the $190,000 advanced by Maryland and Virginia and public auction of lots in the city appeared to be the only feasible way of raising the money. Since L'Enfant refused to co-operate with the commissioners, the president reluctantly dismissed him and requested Andrew Ellicott to prepare from L'Enfant's sketch the map for the engraver.

The public auctions brought in disappointingly small sums, but while land for the principal streets was surveyed and cleared and a few private dwellings went up, the commissioners advertised for plans for the halls of congress and the president's house. The plan accepted for the capitol was that of William Thornton, a versatile West Indian doctor who had lived for a time in Philadelphia but had had no previous architectural experience. George Washington laid the cornerstone on Sept. 18, 1793, amid solemn Masonic ceremonies. The most suitable design for the executive mansion was submitted by James Hoban, an Irishman. Built of Virginia freestone so white that as early as 1811 people occasionally spoke of the "White House," the exterior of the dignified two-story house was ornamented with an Ionic portico and balustrade. In spite of shortage of funds, labour troubles and quarrels among the men superintending the work, the commissioners had all three buildings near enough completion to permit the executive departments of the government to move to Washington in the early summer of 1800. In mid-November congress convened in the new capital, by then a community of 2,464 free inhabitants and 623 slaves.

19th Century.—George Washington envisaged a national capital eventually as large as most European cities, while Jefferson thought a century would produce a city of 100,000 and later years possibly a metropolis of 200,000. But until the Civil War, growth was slow. During the first decade in the new capital, members of congress, irked by the discomforts of the raw little city, repeatedly talked of abandoning it and returning to Philadelphia. In 1801 congress created a court system for the district and established two counties, Washington county above the Potomac, where Maryland laws should continue to prevail, and Alexandria county to the south, where Virginia law should operate, unless specific acts of congress superseded the laws of the two states. After granting city charters to Washington, Georgetown and Alexandria, congress left the municipalities largely to fend for themselves. Lack of money left Washington without proper streets or other conveniences beyond those a handful of local taxpayers could provide. In 1814, after British troops had entered the city and burned the Capitol and the president's house, a narrow majority in congress voted to rebuild the capital on the Potomac. Niggardly federal appropriations continued to make difficulties for the city. Visitors, whether from home or abroad, ridiculed the grandiose layout of the "City of Magnificent Distances" which Charles Dickens in the 1840s derisively labeled the "City of Magnificent Intentions." And yet little by little the capital developed. When fire destroyed the treasury in 1833, congress decreed that the new building must stand on the old site, but as treasury officials demanded 114 rooms, the architect, Robert Mills, lengthened the building so that it spread across the approach of Pennsylvania avenue to the White House. The Patent office and a new Post Office building, both in the classical style of architecture, went up on F street. Because congress had never approved the plan of founding a national university, the square L'Enfant had reserved for it stood empty until 1843 when the navy department built a small observatory there as a depot of charts and instruments. Three years later the red brick "Norman castle" designed by James Renwick to house the newly created Smithsonian institution began to rise on the Mall.

In the 1850s construction of two wings and a new 287-ft.-high dome for the Capitol began under the direction of Thomas U. Walter, who drew the plans. At President Lincoln's insistence, work on the dome, symbol of national solidarity, continued during the American Civil War until in Dec. 1863, to the accompanying boom of cannon fired from the Union forts ringing the district, Thomas Crawford's "Statue of Freedom" was lifted to the top of

the dome's crowning cupola. The building of the Washington monument, however, started by a private society in 1848, halted in 1855 when the society ran out of money.

Upon the outbreak of the Civil War, Washington's population suddenly doubled, for the city became the principal supply depot for the army of the Potomac, a great hospital centre and the source of government contracts. Moreover, about 40,000 former slaves from Maryland, Virginia and farther south, freed by President Lincoln's Emancipation Proclamation, poured into Washington, bringing with them difficult social and economic problems for the federal government and the federal city. At the end of the war most of the floating white population disappeared but the former slaves generally remained. Few of them had any education or knew how to adjust to city life. Repair of the streets, cut to ribbons during the war by heavy army wagons and the trampling of cattle driven to abattoirs in the city, offered some jobs for the unskilled. but unemployment was widespread. In the meantime, proposals in congress to move the capital to the midwest alarmed the local community.

In 1871, however, congress authorized construction of a $2,000,000 building west of the White House for the state, war and navy departments; established a board of public works under the new territorial government; and hinted, so Washingtonians believed, that federal appropriations would be forthcoming to ease the tax burden of laying sewers, grading and paving the streets and generally modernizing the city. Alexander Shepherd, who took charge of the board of public works, acted quickly to carry out his "comprehensive plan of improvements." It proved enormously expensive, creating a debt of over $18,000,000, partly because much of the work mas ill-planned and faulty in execution. Yet the results, though bankrupting the district and ending all local self-government, were magnificent stretches of paved, well-lighted streets, lined with carefully tended shade trees and an underground sewage system for most of the city. By 1875 Washington had become a show place of the nation. Monuments to national heroes began to multiply, supplementing Clark Mills' equestrian bronze of Andrew Jackson emplaced in Lafayette square in 1853 and his statue of George Washington unveiled in Washington circle on Feb. 22, 1860. Statues of Generals James McPherson, George Thomas, Winfield Scott, John Logan, Philip Sheridan and of Adm. David Farragut rose in the circles and squares bearing their names, while the figure of the "Great Emancipator," paid for by subscriptions raised among freedmen, was placed in Lincoln park east of the Capitol. The completion of the unadorned 555-ft. shaft of the Washington monument in 1884 seemed to contemporaries to give the city its crowning touch.

But L'Enfant's plan had been largely forgotten. In 1887, after many years of oblivion, the original manuscript of the 1791 "Plan of the City of Washington" was rediscovered and traced in the offices of the geodetic survey. The State, War and Navy building, meanwhile, had broken the stretch of New York avenue beyond the White House, just as the treasury blocked Pennsylvania avenue and the Smithsonian institution and a Gothic stone railroad depot obtruded on the Mall. Later a stone post office, set at an angle to Pennsylvania avenue at 12th street, and in 1897 the ornate Italian Renaissance Library of Congress across Pennsylvania avenue on Capitol Hill did further violence to L'Enfant's design.

L'Enfant's plan had never included the area beyond Boundary street, the Florida avenue of today. There, by the 1890s, suburban sprawl had begun to make orderly development all but impossible, although the district commissioners obtained authority from congress to engage Frederick Law Olmsted, Jr., son of the man who had landscaped the Capitol grounds in the 1870s, to map out a harmonious street and park system to govern the city's future expansion. Less obvious to the casual observer but nonetheless obstructive to wholesome civic growth were the shanties and overcrowded tenements that had sprung up in the alleys in the heart of the city. Scarcely a stone's throw from the Capitol and the White House, hidden alley slums contained thousands of Negroes and impoverished whites living in utmost squalor. In Georgetown also, officially made part of Washington in 1895, deterioration had set in, leaving islands of beautiful 18th-century houses surrounded by a sea of ramshackle dwellings without running water and sanitary facilities. The banks of Rock creek were a rubbish dump. But Chicago's "White City," created in two years' time by a team of distinguished architects, landscape gardeners and sculptors for the World's Columbian exposition, 1893, had made a deep impression throughout the United States and inspired Washingtonians to emulation. The opening in 1898 of a handsome new building on 17th street for the Corcoran Gallery of Art lent encouragement. Yet at the turn of the century the chief triumph of local leaders of the "city beautiful" and "social betterment" movements was the redemption of the tidal swamps of the Potomac flats beyond the Washington monument and the opening of the National Zoological park and Rock Creek park beyond.

20th Century. — Parks, Buildings and Monuments. — Celebration of Washington's centennial in 1900 afforded an opportunity to local members of the American Institute of Architects and other citizens interested in beautification of the capital to promote their tentative plans. Sen. James McMillan, chairman of the senate committee on the District of Columbia, enlisted the services of four experts, Daniel H. Burnham and Charles F. McKim, architects; Augustus Saint-Gaudens, sculptor; and Frederick Law Olmsted, Jr., landscape architect, whose recommendations were embodied in a report presented by Senator McMillan to the senate in Jan. 1902. As a direct result of the McMillan report and of the personal negotiations carried on by Senator McMillan and the commission, the railroad tracks and stone depot were removed from the Mall and, opening out on a wide landscaped plaza, the Union station was erected as a fitting entrance to the capital of the nation. The commission adapted and developed plans for the Mall, recommended sites for new government buildings and designed a complete park system, only part of which congress accepted. In keeping with the commission's proposals, senate and house office buildings, placed to the north and south respectively of the Capitol grounds, were finished by 1910; a building for the district government stood at 14th street below Pennsylvania avenue; a new public library occupied Mount Vernon square; a building for the recently organized National War college rose on the old arsenal grounds at the mouth of the Eastern branch; and a new Department of Agriculture building near the Smithsonian institution and, across the Mall, the United States National museum were opened.

In addition to new monuments in the triangles formed at the intersections of streets and diagonal avenues, the Grant memorial and a statue of Gen. George Meade were placed at the foot of the "Hill" and at the head of the Mall, while at the four corners of Lafayette square statues commemorated heroes of the American Revolution — Lafayette, Rochambeau, Von Steuben and Kosciuszko. Under the direction of the National Cathedral foundation, organized in the 1890s by a group of Episcopalians, the great Cathedral of SS. Peter and Paul began to rise on a commanding site in northwest Washington.

In 1910 Pres. William Howard Taft appointed the first Commission of Fine Arts, including on it three who had been identified with the park commission of 1901: Daniel H. Burnham; Frederick Law Olmsted, Jr.; and Charles Moore. The commission chose the Mall site for the Lincoln memorial beyond the Washington monument but was unable to prevent the location of the Department of Interior building on 18th street near a cluster of non-governmental edifices, the Constitution hall of the Daughters of the American Revolution, the building of the Union of American Republics and the American National Red Cross headquarters. Thanks to Mrs. William Hoaard Taft, however, the Tidal basin, constructed when the Potomac flats were drained, was planted with the Japanese cherry trees presented to her by the mayor of Tokyo in 1912. Disease in some of the trees forced the superintendent of public grounds to replace a number of them, but before the end of the 1920s the circle of healthy blossoming trees every spring drew admiring crowds and launched Washington's annual cherry blossom festival.

Although hampered by the erection of temporary government office buildings during World War I, many of which remained on the Mall for the next 35 years, the Commission of Fine Arts exerted a steady influence to effect the ultimate realization of the Mall plan. Dedication in 1922 of the Lincoln memorial heightened public confidence in the judgment of the commission. It had selected Henry Bacon as architect of the building and Daniel Chester French as the sculptor to design the impressive bronze figure of Lincoln. The commission's advice thereafter was generally accepted on the design and location of public buildings, monuments and fountains. Zoning laws administered by a zoning commission established in 1920, the banning of billboards in residential and other specific areas and the Shipstead act of 1930, which empowered the Commission of Fine Arts to pass upon the character of structures to be built on private property, provided further safeguards for the aesthetic development of the capital. Thus the lines of the Folger Shakespeare library, for which Paul Cret was architect and which faces on East Capitol street, harmonizes with the adjacent Library of Congress annex.

The commission selected the site and design for the Arlington Memorial bridge spanning the Potomac at the end of the Mall and leading to Arlington National cemetery. There, near a beautiful amphitheatre, is the Tomb of the Unknowns (formerly Tomb of the Unknown Soldier). On the brow of the hill looking out over the river toward the Washington monument and the Capitol stands the early 19th-century pillared mansion which, built by George Washington Parke Custis, Martha Washington's grandson, was once the home of Robert E. Lee. In 1909, in belated acknowledgment of the services of Pierre Charles L'Enfant, his remains were placed in a grave marked with a fitting stone on the terrace of the Lee mansion.

The Commission of Fine Arts, intent upon encouraging the development of a monumental city, successfully fought for a generally uniform height and classical style of architecture for public buildings. Commission taste accounted for the façade of the series of departmental buildings that gradually filied most of the "federal triangle" bounded by Pennsylvania avenue, 15th street and north B street, renamed Constitution avenue. The individual buildings were designed by about six different firms of architects but the over-all effect is that of a unit, although an inner plaza invisible from the street gives variety to the group placed about the Post Office building. Across Constitution avenue on the Mall where the Pennsylvania railroad depot once stood, the National Gallery of Art, made possible by the gift of Andrew W. Mellon, was built in the late 1930s. John Russell Pope, the architect for the gallery, also designed the National Archives and the Public Health Service buildings located at the far end of Constitution avenue where another group of handsome public and semipublic edifices was built—the National Academy of Sciences and National Research Council building in Alexandrian Greek architectural style, and nearby the Pan American annex, Constitution hall and an administration building for the Daughters of the American Revolution, and a second building for the American National Red Cross. As the department of state outgrew the building it had shared with the war and navy departments. that structure turned into an overflow for the White House offices and a new State Department building began to rise in "Foggy Bottom" off Constitution avenue near the river. On the hill the imposing Corinthian-columned Supreme Court building built by Cass Gilbert faced the Capitol grounds and a second house office building adjoining the first went up on south B street, renamed Independence avenue. In the square to the rear of the Library of Congress the Library annex was placed. Only the Pentagon, in 1941 the still unfinished headquarters for the war department, located across the Potomac, displayed any architectural deviations from the classical form the Commission of Fine Arts prescribed. Thomas Jefferson indirectly determined the architecture for the Jefferson memorial near the Tidal basin, for the domed rotunda was an adaptation of his design for the University of Virginia library.

Expansion of the city's parks, which the McMillan commission had originally urged, moved forward more slowly than did the federal building program. For years the acquisition of land for nen parks and playgrounds was limited to purchase of two or three small plots in Georgetown and northeast Washington and a narrow strip of parkway connecting Potomac park and the Mall with the "Zoo." In 1924, however, congress set up a park-purchase commission and by an amendment to that act in 1926 established a National Capital Park and Planning commission charged with formulating and directing on a regional basis plans for thoroughfares, city parks, playgrounds and recreation centres, improved transport facilities and the eradication of slums. The result in the course of the next 15 years was a park system that embraced about 6,900 of the 11,287 ac. in the District of Columbia and, through collaboration with a Maryland National Capital Park and Planning commission and later a Northern Virginia Regional commission, many thousands of acres in the emerging metropolitan area. Rock Creek park was extended into Maryland; reclamation of the swampland along the Eastern branch made possible the Anacostia parkway; while the Mount Vernon Memorial highway along the Potomac in Virginia linked George Washington's home with the city named in his honour. Magnificent beeches, elms, magnolias, dogwoods, oaks, sycamores and maples cover much of the parkland, just as shade trees line many of the city's streets and avenues. The district's parks were administered by the national park service in the department of the interior, the playgrounds by a unit of the district government and the school grounds and recreation facilities by the board of education. In 1935 a recreation board took charge of the recreation facilities of all three agencies.

Housing.—Meanwhile, attempts to wipe out alley slums in Washington and Georgetown proved abortive. Congressional acts passed as early as 1892 and enlarged in scope in 1906 authorized the demolition of unsanitary dwellings, but the strong recommendations of a housing commission appointed by Pres. Theodore Roosevelt were unable to resolve legal complications which arose over private property rights. Before 1914 the one successful public project was the razing of the shanties in the notorious Willow Tree alley and the making of a playground in the block where the building of the department of health, education and welfare would later stand. An act of 1914 forbidding all alley dwelling after Oct. 1, 1918. was in turn rendered inoperative by the housing shortage that developed during and lasted long after World War I. Neither private philanthropy, which through organizations such as the Sanitary Housing company undertook to get families out of the alley dwellings into decent low-rental houses, nor the district public welfare department, nor the National Capital Park and Planning commission was able to handle the problem. Not until 1934 did a new Alley Dwelling authority secure the necessary powers to launch an effective slum-clearance program, beginning with the alleys in "Foggy Bottom." But further projects were soon crippled by insufficient funds and then by World War II.

The decade of the 1930s nevertheless saw Washington become a centre of social and economic reform directed by new federal agencies. The New Deal brought to the capital men and women to staff the Works Progress administration, the Securities and Exchange commission, the Social Security board, the functioning of the National Labor Relations board and a dozen other new planning and administrative units. Washington thus assumed a position of importance in national affairs far exceeding that of earlier years. Before World War I an English writer described the city as the principal "foundry" of government and the headquarters of scientific research but observed in cultural areas a pronounced provincialism. By 1940 Washington had launched a National Symphony orchestra and acquired by gift a National Gallery of Art containing the Mellon, Kress and Widener collections.

Effects of World War *II*.—When the United States entered World War II, Washington became the headquarters of planning operations for supply of all the Allied forces, as well as the administrative centre for a long array of new agencies aimed at regulating the wartime economy. The newly organized Office of Scientific Research and Development directed the programs that produced new types of military weapons and paved the way for government sponsorship in the postwar era of applied and basic research on a hitherto unheard-of scale. As leadership in diplomatic negotiations to hasten the end of the war fell to the United States, Washington became the political capital of the free world. Every added responsibility of the government increased the number of people crowding into the city. The district's swelling population spilled over into nearby Maryland and Virginia, in spite of gasoline restrictions which made commuting difficult.

Building postponed during the war was resumed in 1947. The White House, remodeled in Theodore Roosevelt's day to provide offices outside but adjacent to the residence, in 1949–51 underwent complete rebuilding, although careful architectural planning preserved the exterior of the original Hoban design A second senate office building to the east of the first was finished in 1959, while work began on a third house office building southwest of the Capitol grounds. At the same time an extension of the east front of the Capitol got under way, an operation involving removal of the huge pillars of the east portico. A second National museum under construction on Constitution avenue adjacent to the 1910 building resulted in demolition of several of the temporary structures erected in World War I. An additional Department of State building in "Foggy Bottom" began to alter the looks of the shabby section of the city adjoining the Rock Creek parkway. Nearby, George Washington university acquired several blocks of land and embarked upon a large expansion of its campus and buildings. Private enterprise built dozens of new office and apartment buildings, and labour unions grown powerful during the war chose to erect headquarters in Washington. Of these the most conspicuous were the International Brotherhood of Teamsters building near Union station and the American Federation of Labor headquarters on 16th street next to St. John's Episcopal church. Farther north on 16th street the National Education association erected its headquarters, a large glass and marble structure, while on the hill at Maryland avenue the Veterans of Foreign Wars opened a new building of similarly modern design. A bell tower commemorating Sen. Robert Taft was completed in 1959 on a square below the old senate office building. Renovations in Georgetown (*q.v.*) brought about a reversal of the usual American norm whereby white families move out of a neighbourhood when Negroes move in, for the lingering charm of the little 18th-century city and its convenience to government offices in "Foggy Bottom" hastened a movement begun during the war which transformed Georgetown within a decade from a run-down village heavily populated with impoverished Negroes into a fashionable residential section occupied almost exclusively by white people. In order to preserve the town's historic character, congress then forbade architectural changes unless approved by the Commission of Fine Arts.

In the interim, urban blight in the United States led congress to pass the Housing act of 1949, granting federal aid to states and cities for urban renewal. In Washington, while criticisms sounded at the slavishness with which two generations of architects had adhered to the McMillan scheme of 1901, said to have been "obsolete" when it was adopted, the National Capital Planning commission, the Redevelopment Land agency, the National Capital Housing authority and several departments of the district government collaborated in determining which sections of the city should be completely razed, which partially cleared and where the residents of the blighted areas should be relocated. Most of southwest Washington was entirely cleared, new multiple-family dwellings were erected there and an elaborate plan for a civic centre and an inner loop of a new circumferential highway system was accepted. Work began also on redeeming sections in northeast and the central area in north est Washington.

POPULATION CHARACTERISTICS

The centrifugal trend of Washington's white population to the suburbs increased after World War II. Government policies of decentralization abetted the movement, reducing the former concentration of research facilities in Washington and heightening the importance of locations in the outlying areas. Thus the Naval Medical Research institute and the National Institutes of Health at Bethesda; the U.S. Naval Ordnance laboratory at White Oak; the Army's Office of Operations Research and the Army Chemical Corps research centre at Ft. George Meade were all established in the Maryland suburbs, and agencies such as the Johns Hopkins university applied physics laboratory under contract with the government rarely remained in Washington. The decision to move the central intelligence agency to new quarters in McLean, Va., underscored the government's policy. In 1950 the District of Columbia, which 30 years before had contained 76.5% of the persons living in the metropolitan area, had only 61.6%.

Negroes drawn to the capital during World War II and after by the government's nondiscriminatory employment policies generally remained in Washington. A decision of the supreme court in 1953 which upheld the validity of laws passed in the district between 1869 and 1873 forbade racial discrimination in restaurants and places of public entertainment and, together with the court decree of 1954 declaring segregated schools unconstitutional, further encouraged an influx of Negro citizens. Difficulty in obtaining desirable housing in the Maryland and Virginia suburbs kept well-to-do Negro families in the district.

GOVERNMENT

Administration and Finance. — Throughout most of its history, Washington has not enjoyed self-rule but has been governed by the federal congress. The city was chartered in 1802, with a mayor appointed annually by the president and an elective council of two chambers. At about the same time, congress renewed the municipal charters of Georgetown and Alexandria, the two cities that existed within the federal district before Washington came into being. Modifications of Washington's charter in 1812 vested in the city council the right to elect the mayor; in 1820 a new charter permitted white resident property-owners to elect him, and a third charter in 1848 removed the property qualification for municipal voting. Three years later a similarly broadened elective franchise went into effect in Georgetown. Meanwhile. in 1846, retrocession to Virginia of the trans-Potomac part of the original ten-mile federal square took Alexandria out of direct congressional control. In 1867 congress, adhering to the principle later accepted by the states upon ratification of the 14th amendment to the constitution, enfranchised male Negroes in Washington and Georgetown. By 1869 one Negro sat on Washington's 14-man board of aldermen and out of 21 councilmen 7 were Negroes, a proportion in keeping with the racial distribution of the city's population. But white opposition to Negro voting and confusion arising from the overlapping jurisdictions of the two city governments, county officials and a metropolitan police force led congress in 1871 to repeal the municipal charters and create the Territory of the District of Columbia with a new unified government for the entire district. The president, with the concurrence of the senate, appointed a governor, secretary, board of public works, board of health and a governor's council, while 22 members of a lower house and a delegate to the national house of representatives were elected by adult males irrespective of their colour. During the three years of the territory's existence, never more than three Negroes sat on the governor's council nor more than five in the house of delegates. Extravagant spending by the board of public works in its efforts to modernize the city brought the District of Columbia to bankruptcy in 1874 and, coupled with continuing white hostility to Negro suffrage, caused congress to abrogate the territorial government and substitute a commission of three presidential appointees.

Four years later the Organic act of 1878 established a permanent commission form of government. By the terms of that act the executives of the district government consist of two civilian residents of the district and an officer of the corps of engineers of the U.S. army appointed by the president with senate concurrence. The president, the three commissioners and the judges of the district courts appoint most of the administrative officers and boards, although in 1952 authority to make some appointments was vested in the commissioners alone. Lesser posts are filled by civil service examination.

The president appoints the judges of the district courts. The municipal court includes a civil and a criminal division, a juvenile court and a domestic relations court. One judge sits on local tax cases in the tax court. At a higher level are the municipal court of appeals; the U.S district court for the District of Columbia, until 1938 known as the supreme court of the District of Columbia; the U.S. circuit court of appeals for the District of Columbia circuit; and the supreme court of the United States. A District of Columbia code of laws was first completed in 1929.

Congress, acting usually upon the recommendations of the house and senate committees on the District of Columbia and of the subcommittees on district appropriations, legislates for the district, sets its tax rate and fixes its annual budget. All local revenue—derived from real estate and income taxes, a 2% sales tax and license fees—is paid into the U.S. treasury and all accounts are audited by treasury officials. Between 1878 and 1922 the United States matched local tax revenues with annual appropriations and thereafter reduced the federal contribution to a figure that for 40 years thereafter averaged about 10% of the total budget.

Adoption of the 23rd amendment to the federal constitution in 1961 gave Washington residents the right to vote in elections for president and vice-president of the United States. The amendment, supported by advocates of "home rule" for Washington, allotted three electoral votes to the District of Columbia but did not othernise change the area's governmental status.

Metropolitan Area.—The results of a population of increasing density spreading over a constantly expanding geographical area introduced serious and unfamiliar problems, for political control is divided between two state governments and congress, and yet decisions on many matters must affect all parts of the whole. Problems concerning intelligently planned land use; the location of highways, factories, residential subdivisions, shopping centres and parks; how to halt pollution of the Potomac and tributary streams and yet develop adequate sewage systems; and, above all, how best to conserve for the future the region's water supply were to be met only by prompt unified action. As the co-ordinating role of a new National Capital Regional Planning council proved too limited to resolve these difficulties, in 1957 a joint congressional committee on Washington metropolitan problems undertook a thorough study. Its recommendations included the establishment of a regional development agency, a regional sanitary board, a co-ordinator for national capital affairs in the executive office of the president and a metropolitan fiscal agency. For, as the committee's final report noted: "Washington's ideal, which 50 years ago was thought presumptuous in aspiring to become 'a capital worthy of the Nation,' is now obliged to aim still higher and become a great world city, an epitome of urban ideals of the Western World and a model for growing cities throughout the free world." (Senate Report No. 38, 86th Congress, first session, *Meeting the Problems of Metropolitan Growth in the National Capital Region*, p. 12, 1959.)

THE ECONOMY

Commerce and Industry.—Real estate transactions rank after government in the city's economy, with the tourist and convention trade a close third. Approximately 6,500,000 tourists visit the city every year, making Washington second only to New York as an American sight-seeing centre. Headquarters for a large number of national organizations, the capital also serves as host to about 350 conventions each year.

For 145 years the city's industry was of little importance The bulk of manufactures consisted of goods for local consumption and items made for the federal government at the navy yard and later at the naval gun factory and other government installations. Only about 21,000 people are employed in the fewer than 500 privately owned manufacturing concerns The character of some of these concerns, however, placed the city in a special category, for after World War II companies engaged in scientific research services and production of scientific equipment began to multiply rapidly. From 7 in 1940. the number of these firms, popularly called research and development companies, grew to about 50 by the 1960s. Proximity to government contracting offices and the number of scientists and highly trained technicians that war brought to Washington explain this growth. In the suburban area. where space for industrial plants was more readily available, the expansion was still greater, from 8 research and development establishments in 1940 to more than 75 in the 1960s. exclusive of nonprofit organizations. Employment does not run large compared with that of heavy industry; according to the economic development committee of the Washington board of trade, in the late 1950s four companies nith fewer than 9.000 employees accounted for over half the total employed in "r & d" industries in the entire metropolitan region Nevertheless, after 1950 greater Washington ranked first among U.S. metropolitan areas in the number of scientific persons employed per 1.000 of the population: these included scientists in the government service. Much of the work of the private companies is directed toward problems of national defense and deals with data processing, electronic devices, applications of nuclear energy and the like.

Transportation and Communications.—Five railways enter the city and the several airlines yearly fly nearly 500,000 passengers into and out of the Washington National airport. Construction of a second national airport 30 mi. to the south at Chantilly, Va., was begun in 1959. Interstate buses offer alternate means of travel. Potomac river steamboats, once popular, no longer offer passenger service except for summer excursions to Mount Vernon and an amusement park downstream. Within the city the D.C. Transit company operates buses, electric street railways and special sightseeing buses; a number of local and interstate companies conduct bus tours to points of interest in and about the capital. Washington has several radio and television stations.

EDUCATION, SCIENCE AND CULTURE

Public and Private Schools.—Washington is an educational centre of considerable importance. The public-school system, under the control of a board of education appointed by the district court judges of the District of Columbia, embraces kindergartens; elementary and secondary schools; a business high school; and manual training, normal and night schools. From 1862 to 1954 racial segregation obtained in the public schools, although in the 20th century a white superintendent was the administrative head of both white and Negro school systems. In 1954, after the supreme court decreed that racially segregated schools were unconstitutional the board of education and school officials moved quickly to establish an integrated system, the first to go into effect in any large city nhere a dual system had formerly operated. In addition to the public schools there were established several Roman Catholic schools, tno Episcopal preparatory schools attached to the Cathedral of SS. Peter and Paul, the nonsectarian Friends school started by Quakers, and other private schools, as well as seminaries, small colleges and the Episcopal College of Preachers, providing refresher courses for Episcopal ministers.

Higher Education.—At mid-20th century, of all the metropolitan areas in the United States, Washington had the highest educational level of adults 25 years of age and over Whereas in the San Francisco-Oakland area, ranking second, about 10% of the adult population had four years or more of college training, in the Washington area the proportion was more than 15%. Five universities in Washington offer graduate work. a great deal of it in evening classes to enable students who earn their living at daytime jobs to win advanced degrees. Georgetown university, located on the heights above the Potomac in Georgetown, is the oldest of these institutions. Founded by Bishop John Carroll in 1789 as Georgetown seminary to train young men for the Roman Catholic priesthood and later chartered by congress as a university, it comprises a liberal arts college, school of medicine, graduate school, law school, dental school and a school of foreign service.

In 1821 Baptists in Washington obtained from congress a charter for a nonsectarian institution, the Columbian College in the District of Columbia, from which grew Columbian university in 1873 and, by a change of name in 1904. George Washington university. Benefiting from a small congressional endowment in 1831, a gift of $1,000,000 from W. W. Corcoran in 1872 and later gifts from other men. the university acquired a campus to the west of the White House in the vicinity of the department of state buildings. Besides a junior college and the Columbian college of arts and sciences, primarily for undergraduates, the university includes a graduate council which gives the Ph.D. degree, a school of medicine, a law school. school of pharmacy, school of engineering. school of education. school of government, a division of special students and several research units under contract with the federal government The Catholic University of America was incorporated in 1887 to serve as the head of Roman Catholic schools in the United States. It opened in 1889 in a building near the Soldiers' home. Although designed especially for advanced theological studies, the university later comprised schools of the sacred sciences, philosophy, letters, physical sciences, biological sciences, social sciences, jurisprudence, law and technological sciences. Affiliated are a Franciscan convent; Dominican, Paulist and Marist houses; and Trinity college for girls.

The American university under Methodist auspices was chartered in 1893 and acquired a 90-ac. wooded campus in the northwest section of the city but did not enroll students until shortly before World War I. A downtown centre, purchased much later, accommodates a graduate school, the Washington college of law, a school of business administration and a school of government and public administration; the college of arts and sciences, mainly undergraduate, and a newer school of international service occupy the uptown campus. Adjacent, on land donated by the university, stands Wesley seminary, which opened in 1958.

Howard university, chartered in 1867 for the higher education of Negroes, is situated southwest of the Soldiers' home. It was named in honour of Gen. Oliver O. Howard, one of its founders and its president from 1869 to 1873. Howard, one-time head of the Bureau of Freedmen, and his associates had intended to make the new university biracial; their own sons were enrolled in the first classes, and most of the faculty members also were white men. But by the mid-1880s the student body had become virtually all Negro and remained so until after World War II, when a few white students again sought admission, particularly to the graduate school of social work. The faculty, predominantly Negro after 1890, often included some white scholars. The university comprises a college of liberal arts, a law school, school of medicine, school of dentistry, school of pharmacy, school of engineering and architecture, school of music, school of religion and a school of social work. The university has a small endowment but is supported chiefly by annual congressional appropriations administered through the federal department of health, education and welfare.

Gallaudet college at Kendall Green in northeast Washington is an outgrowth of a school for deaf mutes founded in 1857 on the farm given for the purpose by Amos Kendall, postmaster general in President Jackson's cabinet. The school was incorporated as the Columbia Institution for the Instruction of the Deaf and the Dumb and the Blind and, though a private foundation, from its beginning received congressional appropriations. Its first head was the son of Thomas H. Gallaudet (*q.v.*) who introduced into America the use of sign language for teaching deaf mutes and for whom the college was later named. Sign language instead of lip reading is still the standard method of teaching employed at both Kendall school (the secondary school) and Gallaudet college. For a few years in the 1860s the Columbia institution also accepted blind students but later, as special schools for the blind developed elsewhere, limited enrollment to the deaf. Its name was changed to Gallaudet college in 1954 and it was the first in the United States to provide higher education for the deaf.

At Ft. McNair, on the grounds of the former Washington arsenal, the National War college and the Industrial College of the Armed Forces occupy an imposing building designed by Stanford White. At the National War college officers selected from the armed services and civilians chosen from the department of state spend a year in intensive study of international problems. The work of the Industrial college is directed at problems of military procurement and supply. A large specialized library serves both colleges. The U.S. army medical department maintains a research and graduate school in Washington.

Scientific and Cultural Institutions and Activities.— Among the institutions, both public and private, which have increased Washington's stature as a centre of learning and scientific research, the national archives and the Library of Congress are outstandingly important. When in 1936 the national archives opened in a new building near the apex of the "federal triangle" between Pennsylvania and Constitution avenues, the government's manuscript records and official correspondence, formerly scattered in scores of federal installations in and out of Washington, were brought together in carefully indexed, well-ordered collections covering virtually every phase of national development. The Library of Congress is much older. It contains more than 36,900,000 books, pamphlets, bound newspaper volumes, manuscripts, maps, prints, photographs, recordings and movie films, as well as a collection of microfilmed copies of doctoral dissertations and studies located in other libraries. Founded in 1800, the congressional library was wiped out in 1814 when British troops burned the Capitol; it was re-established by purchase of Thomas Jefferson's library and again largely destroyed by fire in 1853. Rebuilt by purchase and by gift, the collections occupied part of the Capitol itself until a separate building on the square to the east was completed in 1897. An annex, to the rear of the main building, was finished in 1939. The reading rooms are open to the general public and special facilities for study are available to scholars. A legislative reference service supplies congress with information, while a copyright office and a card catalogue division, which sells catalogue cards to other libraries and maintains a national union catalogue, are more than self-supporting. Another unit of the library loans books in braille and Moon type and recordings, called talking books, to the blind. The law library is the largest of its kind in the world. Ever since 1866 when the Smithsonian institution's collections of publications of learned societies and of scientific periodicals were transferred to the Library of Congress, it has formed, together with the library of the department of agriculture and after 1956 the National Library of Medicine in Cleveland, a vast national repository of scientific materials.

The Smithsonian institution (*q.v.*), founded in 1846 with money bequeathed to the United States by the Englishman James Smithson for the express purpose of enlarging and disseminating "knowledge among men," was the first organization to give the capital a unique position in the world of science. Joseph Henry, the Smithsonian's first secretary, and John Quincy Adams, who as a member of the house of representatives in 1846 helped determine the policy, believed that the increase of human knowledge was as important as its dissemination; Henry laid the groundwork for fundamental scientific research under government sponsorship. After the Library of Congress took charge of the earlier collection, the institution continued to publish scientific articles and, through the studies prepared by the Bureau of American Ethnology and the materials assembled and put on exhibit at the U.S. National museum, became a leading source of data on cultural anthropology, primarily of the American Indian. The original National museum building, located east of the Smithsonian, opened in 1881 in time to be the scene of President Garfield's inaugural ball. But when in 1910 the squat-towered red brick edifice proved too small, a much larger building was erected across the Mall where not only the scientific exhibits but the national collection of paintings were housed. Shortly after World War I, the Freer Gallery of Art was opened as part of the Smithsonian institution. The gallery stands to the west, near the department of agriculture buildings, and contains the collection of oriental art and American paintings presented to the United States between 1906 and 1916 by Charles L. Freer of Detroit, Mich.

Besides the Smithsonian institution, the geological survey, organized in 1879, and the Naval observatory, which in 1893 moved from its one-time location beyond the White House to Observatory hill of Massachusetts avenue, carried on some fundamental research under government auspices in the late 19th century, but after 1901 the federal government gradually relegated basic research to universities and private foundations. Applied research, aimed at the solution of specific problems, expanded in Washington, however, before World War I, chiefly under the aegis of the national bureau of standards, organized in 1901; the National Advisory Committee for Aeronautics, formed in 1915; and the National Research council, established in 1916, itself an offshoot of the then 53-year-old advisory National Academy of Sciences. During the 1920s and 1930s additional installations appeared, notably the Naval Research laboratory (1923); the National Institutes of Health (1930) under the public health service, which in 1938 established its research center in Bethesda, Md.; the National Cancer institute (1937); and, at Beltsville, Md., an agricultural research station (1934). After World War II renewed attention to basic research brought into being the National Science foundation (1950) with its headquarters in the capital.

In the field of basic research in the physical sciences the Carnegie Institution of Washington is of major importance. It was endowed by Andrew Carnegie in 1902 "to encourage in the broadest and most liberal manner, investigation, research and discovery, and the application of knowledge to the improvement of mankind; and in particular to conduct, endow and assist investigation in any department of science, literature or art." Archaeological research, mostly in the Mayan region of Mexico, after replacing the historical research the institution once supported, in turn largely yielded to the programs carried on by the departments of terrestrial magnetism, astronomy and geophysics. The geophysical laboratory and the laboratory of terrestrial magnetism in Washington are world-renowned.

In the realm of the social sciences, the Brookings institution, founded and endowed in 1928 by Robert Brookings, a St. Louis merchant and industrialist, sponsors studies in government, public administration and economics, including labour relations. After 30 years on Jackson place facing Lafayette square, its headquarters were moved to a new building on Massachusetts avenue.

The American Association for the Advancement of Science and a long list of other national scientific and scholarly organizations maintain headquarters in Washington. The Washington Academy of Sciences, formed in 1898 as a federation of local societies with and without national affiliations, originally included the Philosophical Society of Washington which dated from 1871 and was dedicated to mathematical and physical sciences; the Anthropological Society of Washington, founded in 1879, which published *Transactions* (1879 *et seq.*, with the co-operation of the Smithsonian institution) and *The American Anthropologist* (1888–98; from 1898 published by the American Anthropological association); the Biological Society of Washington (1880); the Chemical Society of Washington (1884); the Entomological Society of Washington (1884); the National Geographic society (1888), which has sponsored scientific explorations in Alaska and South America and publishes the *National Geographic Magazine* (1888, *et seq.*), special maps and in 1895 issued *National Geographic Monographs;* and the Geological Society of Washington (1893). Several newer societies later became members of the academy and published reports and articles in the Academy's *Proceedings* and *Journal.* Most of the other local scientific societies formed in the late 19th and early 20th centuries gradually disappeared. Among the best-known nonscientific learned societies which have national headquarters in Washington are the American Historical association (1884), which publishes the *American Historical Review* (1886, *et seq.*); the American Planning and Civic association, which publishes an annual (1929, *et seq.);* the American Political Science association (1903), which publishes the *American Political Science Review;* and the American Institute of Architects. The last-named was founded in 1857 and through its publications early became a national clearinghouse of architectural ideas. In 1902 it saved from demolition the century-old Octagon house and turned that fine example of William Thornton's architectural skill into the institute's headquarters.

Members of all these societies are eligible for election to the Cosmos club. Founded in 1878 to provide a common meeting ground for scientists, scholars and men of letters, the club long occupied the house looking out over Lafayette square in which Dolly Madison spent the last years of her life. The wish of the federal government to use the space flanking the square for federal buildings led the club in the 1950s to move to larger quarters on Massachusetts avenue. There the club maintains a considerable library for its members.

Exclusive of such private collections, libraries in Washington number about 250, ranging in character from that of the Franciscan monastery to that of the Washington public library with its branches and its main building, the gift of Andrew Carnegie, on Mount Vernon square, Virtually every embassy, every school and university and every labour union with national headquarters in Washington maintains a library. The Daughters of the American Revolution have a large genealogical collection housed in Constitution hall at D and 18th streets; at Dumbarton Oaks in Georgetown, Harvard university has its volumes and manuscripts dealing with Byzantine art and church history; the Folger Shakespeare library, which stands next to the Library of Congress annex on Capitol Hill, contains the largest collection of Shakespearean materials in the world and also has valuable data on 17th and 18th century British America. Only the New York metropolitan area makes available to the U.S. public more extensive collections of books and manuscripts than are to be found in Washington.

WASHINGTON, a city in southwestern Pennsylvania, U.S., the seat of Washington county, is approximately 22 mi. S.W. of Pittsburgh's golden triangle. Formed in 1910 by a consolidation of the boroughs of Washington, South Washington and North Washington, it was chartered as a city in 1924 and is the centre of an agricultural, industrial and coal-mining territory which extends into several neighbouring townships and hamlets. In general, the eastern part of the city's sphere of influence has been coal mining in nature, while the western and southern parts have been agricultural. The principal industries of the region have been steel and glass making. The city is included by the census bureau in the Pittsburgh standard metropolitan statistical area (*see* PITTSBURGH); the area between Pittsburgh and Washington tended to develop into various suburban residential communities.

In the period before the American Revolution, Washington and its region was more properly an extension of Virginia rather than of Pennsylvania. In Aug. 1776 the first court west of the Monongahela river was held under Virginia jurisdiction about three miles from the city's present site. At the same time, the region was included in Virginia's district of West Augusta and was the cause of much dissension between the Virginians and the Penns. The latter group's claim was finally validated by the Virginia constitution of June 1776.

Laid out by David Hoge in 1781, Washington was first known as Catfish's Camp after a Delaware chief who had a camp there about 1750. Known also as Dandridge Town and Bassett-town for short periods, it received its present name about 1781. It was a centre of rebel activity during the Whisky insurrection (*q.v.*) of 1794; the home of David Bradford, one of the rebel leaders, still stands on South Main street. The National road was completed to the town in 1817.

Washington and Jefferson college, a private college for men and the oldest institution of higher learning west of the Alleghenies, was formed by the consolidation of two colleges in 1865. Both had resulted from academies developed by Presbyterian ministers in the last 15 years of the 18th century. The first crematory in the United States was built in Washington in 1876 by Francis Julius LeMoyne (1798–1879), who had to contend with an aroused public opinion, which forced the construction of the building at night. He was also an ardent abolitionist of the pre-Civil War period.

For comparative population figures see table in PENNSYLVASIA: Population. (P. R. J.)

WASHINGTON, MOUNT, highest (6,288 ft.) peak of the White mountains in New Hampshire, U.S., noted for its extreme weather conditions at all seasons. The treeless summit is accessible by an eight-mile road from the Glen house in Pinkham notch, by the three-mile cog railway from the Base station near Crawford notch and by marked trails maintained by the U.S. forest service and the Appalachian Mountain club. Summit buildings, which must be anchored against high winds, include Tip-Top house and Summit house. open to the public in summer, Mt. Washington observatory and the Mt. Washington television transmitter. Weather at the summit has often been called the worst in the world and the highest free air movement ever recorded—231 m.p.h.—was measured at the observatory in 1934. The summit tract and the cog railway, owned by Dartmouth college, are surrounded by the far-flung White Mountain National forest. From this ridgepole of New England flow three of the region's major rivers, the Connecticut, the Androscoggin and the Saco. (R. S. Mo.)

WASHINGTON, TREATIES OF. Among various important international agreements signed at Washington, D.C., were the Webster-Ashburton treaty of Aug. 9, 1842, which settled the northeastern boundary of the United States and provided for Anglo-U.S. naval co-operation in the suppression of the international slave trade; and the North Atlantic treaty of April 4, 1949, a mutual security pact signed by Belgium, Canada, Denmark, France, Iceland, Italy, Luxembourg, the Netherlands, Norway, Portugal, the United Kingdom and the United States and later signed by various other powers (see NORTH ATLANTIC TREATY ORGANIZATION). More properly known by the designation treaties of Washington, however, were certain treaties of 1871 and 1921–22.

Treaty of 1871.—The treaty of Washington, May 8, 1871, was the achievement of an eminent Anglo-American joint high commission which was convened to settle a number of disputed issues. Chief among these were the "Alabama" claims of the United States against Great Britain, arising out of the U.S. Civil War. But Canada had certain important questions bearing on its relations with the U.S., viz., the settlement of the perennial Northeast Atlantic fisheries dispute, the renewal of commercial reciprocity with the U.S., which had lapsed in 1866, and the payment of an indemnity for damages inflicted on Canada by Irish Fenian raiders from the U.S. (see FENIANS). To cope with these Canadian questions Sir John A. MacDonald, the Canadian prime minister, was made a member of the British commission, but he served nevertheless under the authority of the British government rather than as a Canadian. The joint high commission wrote into the treaty three rules of due diligence pertaining to the duty of a neutral and made them retroactive so as to form the explicit basis for the "Alabama" claims arbitration that ensued at Geneva (see "ALABAMA" ARBITRATION). The Canadian desire for reciprocity was refused as were the Fenian claims, and the inshore fisheries were reopened to U.S. fishermen, subject to payment of an indemnity by the U.S., the amount to be decided subsequently by a mixed commission. Over and above its actual provisions, the treaty proved to be of decisive and permanent value in harmonizing the relations of Britain, Canada and the U.S.

TREATIES OF 1921–22

The Washington conference (*q.v.*) of 1921–22 resulted in seven treaties and agreements. These were, in the order in which they were signed: (1) the treaty (four-power pact) relating to insular possessions and insular dominions in the Pacific ocean signed Dec. 13, 1921, by the U.S., the British empire, France and Japan; (2) a declaration accompanying the four-power pact stating that it was the understanding of the signatory powers that the pact applied to the mandated islands of the Pacific; (3) the treaty for the limitation of naval armament signed Feb. 6, 1922, by the above four powers and Italy; (4) the treaty relating to the use of submarines and noxious gases between the same five powers; (5) an agreement supplementary to the four-power pact, defining the application of the terms "insular possessions" and "insular dominions" as relating to Japan, signed Feb. 6; (6) the treaty (nine-power treaty) relating to principles and policies to be followed in matters concerning China, signed Feb. 6 by the above five powers and Belgium. the Netherlands, Portugal and China; (7) the treaty between the nine powers relating to the Chinese customs tariff.

Four-Power Pact.—The four-power pact was an ambiguously worded agreement by the signatories "as between themselves to respect their rights in relation to their insular possessions and insular dominions in the region of the Pacific Ocean." The treaty went on to provide that, should a controversy arise between any of the parties over "any Pacific question" which they could not settle between themselves, they were to summon the other parties to a joint conference "for consideration and adjustment." Furthermore, "if the said rights are threatened by the aggressive action of any other power," the parties "shall communicate with one another fully and frankly in order to arrive at an understanding as to the most efficient measures to be taken, jointly or separately, to meet the exigencies of the particular situation." The treaty was to remain in force for 10 years and thereafter was subject to the right of any one of the parties to terminate upon 12 months' notice.

On its face this treaty was a consultative agreement on the part of the four powers, but especially on the part of the three, the U.S., Great Britain and Japan, whose interests in the Pacific were most in danger of a clash. This was especially true of the U.S. and Japan, which, upon at least three previous occasions (the Taft-Katsura memorandum of 1905, Root-Takahira agreement of 1908 and the Lansing-Ishii agreement of 1917), had endeavoured to arrive at an understanding. Anglo-Japanese relations were concurrently regulated by the alliance of 1902, which had been renewed and strengthened in 1911. This alliance was up for renewal again in 1921 at the time of the Washington conference. British diplomacy preferred to continue the alliance and have the U.S. join it, a viewpoint shared by Sen. Henry Cabot Lodge of the U.S. delegation. But for political reasons this course was not practicable, and the four-power pact became the alternative. The pact declared the Anglo-Japanese alliance terminated, but as an instrument itself for consultation among the powers the pact was never invoked thereafter. The U.S. senate, as a condition for its acceptance of the pact. wrote in a reservation to the effect that "under the terms of this treaty there is no commitment to armed force, no alliance, no obligation to join in any defense."

The declaration concerning the mandates was designed merely to cover a legal technicality arising out of the failure of the U.S. to join the League of Nations. The supplementary agreement, noted under (5) above. specified the "insular possessions and dominions" of Japan as the southern portion of Sakhalin Island, Formosa and the Pescadores, and the islands under mandate to Japan.

Naval Limitation Treaty.—The five-power naval limitation treaty was a detailed agreement respecting capital ships and aircraft carriers. The treaty designated by name the capital ships (defined as vessels of war exceeding 10,000 tons standard displacement or carrying guns with a calibre exceeding 8 in.) which each nation might retain. The aggregate tonnage thus to be retained was 525,850 for the U.S.; 558,950 for the British empire; 221,170 for France; 182.800 for Italy; 301,320 for Japan. All other capital ships, built or building, not so named, were to be scrapped, except that France and Italy were authorized to replace existing tonnage to be retired in 1927, 1929 and 1931. The U.S. was to scrap 15 pre-Jutland ships (ships built prior to the battle of Jutland in 1916) and 11 uncompleted ships; the British empire was to scrap 20 pre-Jutland ships and 4 uncompleted ships; and Japan was to scrap 10 pre-Jutland ships and 6 uncompleted ships and to abandon its program for 8 ships not yet being built. The number of capital ships of the U.S. and British empire was to be stabilized in 1936 at 15 each, and the number of Japanese ships was to be stabilized in 1935 at 9. In the case of France and Italy the number of vessels was not fixed, but no vessel was to exceed 35,000 tons displacement. Subject to certain specified exceptions and replacement provisions, the contracting powers agreed to abandon their capital-ship building programs. The total capital-ship replacement tonnage was not to exceed 525,000 each for the U.S. and the British empire, 315,000 for Japan and 175,000 each for France and Italy, resulting in a final ratio of 5–5–3–1.67–1.67. No capital ship was to exceed 35,000 tons or to carry a gun with a calibre in excess of 16 in.

Restrictions were likewise placed upon aircraft carriers as follows: total tonnage was not to exceed 135,000 for the U.S. and the British empire respectively, 60,000 for France and Italy respectively and 81,000 for Japan. No aircraft carrier was to exceed 27,000 tons displacement or to carry a gun with a calibre in excess of 8 in.

An essential corollary to these ship limitations was art. xix of the treaty, under which the U.S., the British empire and Japan agreed to the *status quo* with regard to fortifications and naval bases in their respective territories and possessions located inside an area bounded on the east by the 180th meridian, on the north by the 30th degree of latitude, on the west by the 110th meridian and on the south by the equator. In addition, Japan agreed to maintain the *status quo* in the Kurile Islands. The significance of this nonmilitarization agreement meant that no two of the powers could launch an offensive attack on each other, and thus the naval ratio of 5–5–3 was made palatable to Japan.

The treaty also laid down precise rules for scrapping and replacement and stipulated the periods in which scrapping was to be effected. Finally it contained certain miscellaneous provisions, viz., (1) Should any contracting power consider the requirements of its national security materially affected by any change of circumstances, it might request a conference with the other contracting powers with a view to reconsidering and amending the treaty. (2) After eight years from the coming into force of the treaty, the U.S. was to arrange a conference to consider changes rendered necessary by possible technical and scientific developments. (3) Should any contracting power become engaged in a war affecting its naval defense, upon due notice it might suspend for the period of hostilities its treaty obligations. (4) The treaty was to remain in force until Dec. 31, 1936, subject to the right of any contracting power to give notice two years before that date of its intention to terminate the treaty. Upon such notice taking effect, the treaty was to terminate as regards all the contracting powers. Restive under the limitations of the treaty. Japan subsequently demanded parity with Britain and the U.S.; its demand being rejected, Japan gave notice of termination and the treaty expired at the end of 1936.

At the Washington conference the British, who had suffered grievously from German submarines, strongly advanced the argument for the abolition of this type of vessel, but they encountered opposition from all the other participants, especially the French. The U.S. delegation was prepared to advocate limitation, though not abolition, of the submarine and the extension of the ratio principle to this and other types of auxiliary war craft. But even this proved impossible, and in lieu thereof the five powers signed an innocuous treaty reiterating the traditional rules of visit and search (*q.v.*) at sea and pledging themselves not to use the submarine as the Germans had used it in 1914–18. They also agreed to outlaw the use of poisonous gases in warfare. When it came to placing restrictions on military aviation, including the use of bombing planes against surface craft. none of the powers was prepared to enter into treaty engagements on the subject.

Nine-Power Treaty.— The nine-power treaty was a kind of international bill of rights for China. The other eight powers convenanted together (1) to respect China's sovereignty, independence and territorial and administrative integrity; (2) to aid China in developing and maintaining an effective and stable government; (3) to use their influence in promoting the principle of equal opportunity for the commerce and industry of all nations throughout China; and (4) to refrain from taking advantage of conditions in China to seek special rights or privileges in that country. Among the many unsatisfied demands put forward by the Chinese at the conference was the demand for tariff autonomy. By the customs tariff treaty the powers promised to establish an international commission to study the question.

See WASHINGTON CONFERENCE; DISARMAMENT; FAR EAST: RELATIONS WITH THE WEST.

See Goldwin Smith, *The Treaty of Washington, 1871: a Study in Imperial History* (1941). For the Washington treaties *see* WASHINGTON CONFERENCE. (R. W. V. A.)

WASHINGTON CONFERENCE. The genesis of this unusual international conference, held in Washington, D.C., from Nov. 12, 1921, to Feb. 6, 1922, lay in the widespread fear of an arms race between the powers victorious in World War I. Particularly acute was the fear of unrestrained competition in naval armaments between Great Britain, the United States and Japan, a prospect that arose out of the expanding naval power of these three nations during the war. Britain was alarmed lest the United States seize control of the seas; Japan feared that overwhelming U.S. sea power would threaten its independence in the far east; the U.S. government's naval building programs (under both Pres. Woodrow Wilson and Pres. Warren G. Harding) lent support to these fears, but a strong revulsion of feeling on the part of the U.S. public, given direction especially by Sen. William E. Borah, forced the abandonment of these plans in favour of a conference. In addition, information supplied confidentially by the British government that it would accept parity with the U.S. persuaded the Harding administration to take the initiative and call a conference.

Organization of Conference.— It is important to note the countries participating. The navies of France and Italy being a primary consideration in British strategic thinking, the presence of those countries was required. Furthermore, ill feeling between France and Britain and also between France and Italy raised political questions which were important factors in relation to any disarmament arrangement.

Issues concerned with the political situation of the far east and bearing on the new power position won by Japan and on the status of China called for the presence of a Chinese delegation. Finally, three other powers with interests in the far east, viz., Belgium, the Netherlands, Portugal, were invited, apparently for the sake of appearances. This made a total membership of nine powers. Conspicuous by its absence was the U.S.S.R., historically a far eastern power but brusquely excluded despite its protests and expressed desire to be present.

Among the leading personalities at the conference were Charles Evans Hughes, the U.S. secretary of state and chairman of the conference, Elihu Root and Sen. Henry Cabot Lodge; Arthur James Balfour, prime minister of Great Britain and head of the British delegation, and Lord Lee of Fareham, first lord of the admiralty, who had been instrumental in smoothing the way for the conference; Aristide Briand, the French premier; Baron Taka-Akira Kato, most influential among the Japanese delegation; and V. K. Wellington Koo, who had previously made his voice heard at the Paris peace conference in behalf of China.

Problems Considered.— At the outset Hughes created a public sensation by proposing that the U.S. scrap 15 capital ships then under construction and 15 older predreadnought battleships, that Great Britain scrap 4 new capital ships and 19 older ones and that Japan abandon its program of building 8 capital ships and scrap 7 under construction and 10 predreadnoughts. The effect of carrying out the plan would be approximate parity between the U.S. and Britain, with Japanese tonnage constituting three-fifths of either of the other two. This was the famous 5–5–3 ratio (500,000 tons for the U.S.; 600,000 for Britain, the discrepancy being accounted for in the greater age of the British vessels; 300,000 for Japan). France and Italy were requested to reduce their capital ship tonnage to the ratio of 1.75 each, a proposition that met with objections, but which was eventually accepted, with minor changes in the U.S., British and Japanese tonnages and consequently in the French and Italian ratios. (*See* also WASHINGTON, TREATIES OF: *Naval Limitation Treaty.*) Thus the conference resulted in limiting the number of capital ships and, to that extent, in restricting naval rivalries among the five powers. But that was all that it accomplished in this respect. Submarines, which had proved so effective during World War I and which the French now especially wanted, other auxiliary vessels and aircraft were omitted from the naval limitation treaty.

Related to the problem of naval limitation were the political problems of the far east. These can be classified under two main headings: (1) the ominous rivalry between the U.S. and Japan, which can be traced back to 1905, but which was accelerated by the ambitions which Japan revealed and the gains which it made during World War I; (2) the pressure from the Chinese to rid themselves of the "unequal treaties" and gain a position of strength *vis-à-vis* the western powers and Japan. American-Japanese ill will had broken out into the open at the Paris peace conference (see PARIS, CONFERENCE OF), exacerbated in dehates over Japan's right to dominate the Chinese province of Shantung. In 1920 a quarrel arose over the island of Yap, the issue being the question of control over the international cables. Other issues, by no means minor, also existed.

From the conference emerged the four-power pact, an agreement of the British empire, France, Japan and the United States, each to respect the insular possessions and dominions of the others in the Pacific and to consult together in the event of a controversy arising over "any Pacific question." This, coupled with an agreement in the naval limitation treaty to maintain the military status quo in the respective territories and possessions of the powers in the North Pacific between Singapore and Pearl Harbor satisfied their mutual security requirements. As a result of this treaty Japanese-American relations entered a ten-year period of comparative friendship. China's position was theoretically improved by a treaty signed by all nine powers recognizing its administrative independence and reaffirming the open door.

WASHINGTONIA, a genus of the palm family (Palmae), named in honour of George Washington. comprising two handsome species, natives of southern California, Arizona and adjacent Mexico.

WASHINGTON UNIVERSITY, a privately endowed, coeducational, nonsectarian institution of higher learning, chartered in 1853 at St. Louis, Mo. See ST. LOUIS.

WASHITA RIVER, a Great Plains stream rising in the Texas Panhandle in Hemphill county, near the Oklahoma border. The river. 500 mi. long, flows southeast in Oklahoma past Cheyenne, Clinton, Mountain View, Anadarko, Chickasha, Pauls Valley and Davis and empties into Lake Texoma, formed by Denison dam in the Red river downstream from the former mouth of the Washita at Woodville.

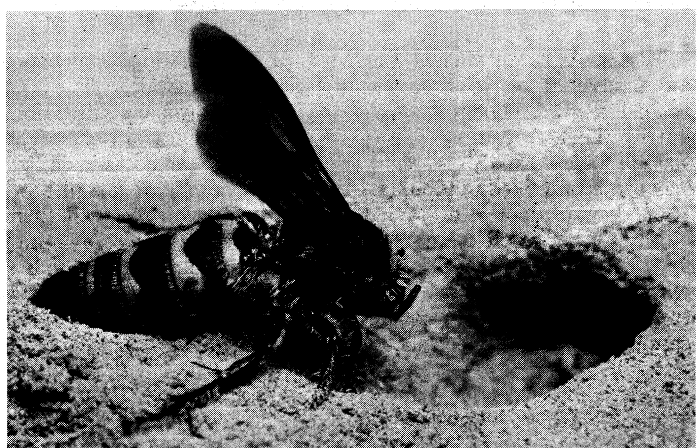
A broad, shallow valley cut into a vast expanse of flat land marks the upper course of the river. Most of the year, save for the periods of maximum rainfall in spring and early summer, the stream bed is dry and sand-choked. From Anadarko to Lake Texoma, increased rainfall has created a permanent winding stream that is sluggish and subject to severe floods. In Murray county, southeast of Davis, the Washita has cut a gorge into the Arbuckle upland 350 ft. deep in which it flows for 20 mi. emerging at the southern boundary of the county.

On Nov. 23. 1868, in the battle of Washita, General Custer's men killed Cheyenne Indian Chief Black Kettle and many of his warriors; the result was severely weakened Indian resistance to the white man (see CUSTER, GEORGE ARMSTRONG). (M. J. L.)

WASP, a general name applied to any of those insects of the order Hymenoptera that have biting mouth parts and 12- or 13-segmented antennae, are normally winged, have the abdomen attached to the thorax by a slender petiole and. in the female and worker, are provided with a formidable sting. In habits they differ from the bees in being carnivorous or parasitic. There are more than 20.000 known species, the vast majority of which are solitary wasps. The comparatively few social species comprise certain subfamilies of the family Vespidae, which differ from other wasp families in having the wings folded longitudinally when at rest. Included are the hornets, builders of the familiar large paper nests in trees or shrubs, on buildings or elsewhere above ground. and the yellow-jackets, which also build large paper nests but out of sight in the ground. For a discussion of the social wasps see SOCIAL INSECTS.

The majority of the solitary wasps construct nests or cells, which they provision with permanently paralyzed insects or spiders. An egg is deposited in each cell and the wasp larva hatching from that egg feeds to maturity upon the food with which its cell has been provisioned. The nest builders belong to several different families. Certain sections of the Vespidae, including the large subfamily Eumeninae, have varied nesting habits: some nest in wood or pithy plant stems; others dig tunnels in the soil; and still others, known as mason or potter wasps, construct nests of mud, which are sometimes vaselike or juglike and may be found attached to twigs or other objects. All of these wasps provision their nests with caterpillars, which they have paralyzed by stinging.

The Pompilidae or spider wasps usually construct single cells in the ground, in rotten wood or in rock crevices and provision them with spiders. The Sphecidae or thread-waisted wasps con-



ROSS E. HUTCHINS

FIG. 1.—DIGGER WASP (SPHECIDAE) AT ITS BURROW IN THE GROUND

tain forms of diverse habits. Most of them nest in the ground and use leafhoppers, treehoppers, cicadas. stink bugs, bees, winged ants, beetles or caterpillars as food for their young, each species or group confining itself to one type of prey. Some build series of cells in rose canes or other pithy stems or twigs and provision with aphids or leafhoppers; and still others, known as mud daubers, construct small nests of mud. often in attics or outbuildings and store them with paralyzed spiders.

Three major groups of solitary wasps do not construct nests but are parasitic. These wasps are the superfamilies Chrysidoidea. Scolioidea and Bethyloidea. The Chrysidoidea are the cuckoo wasps. They are mostly brilliant metallic green or blue in colour and have the abdomen strongly convex with only three or four exposed segments. Most of them lay their eggs in the nests of solitary bees or wasps and the larvae hatching from those eggs feed on the bee or wasp larvae or on the food with which the parent bee or wasp has provisioned the nest. The Scolioidea include the families Mutillidae, Tiphiidae and Scoliidae. The Mutillidae are the so-called velvet ants. Their bodies are clothed with long thick hair of contrasting colours, often black and red, and the females are wingless and antlike in appearance. Most Mutillidae are parasitic on the larvae and pupae of solitary bees and wasps, but a European species develops parasitically in the nests of bumblebees and certain African species are parasites of tsetse flies. The Mutillidae occur principally in the warmer areas. The species of Tiphiidae and Scoliidae are mostly parasites of beetle grubs that live in the soil. The female wasp digs into the soil to locate the grub, paralyzes it by stinging and deposits an egg on it; the wasp larva feeds externally on the beetle grub. One Asiatic species of Tiphiidae (*Tiphia* polilliavora) was introduced into the United States as a natural enemy of the destructive Japanese beetle (Po-*pillia* japonica) and became well established there. The Bethyloidea comprise small to very small wasps (some of them less than 2 mm. in length) that develop as external parasites of other insects, especially the larvae of various beetles and moths.

WASSAIL, an ancient English form of "toasting" and hence any convivial occasion, especially at Christmastide. The Old English wes *hál* ("be in good health") was an ordinary salutation, but by the 12th century it was used as a drinking formula. The wassail bowl usually contained spiced ale or wine. Wassailing was often practiced outdoors by villagers who took a wassail bowl from door to door and drank health to those who received them kindly. Even apple trees were wassailed; a toast was thrown into a tree to propitiate the spirits; cider was drunk from the bowl, with the song: "Old apple tree, We've come to wassail thee, Every twig, apples big, Every bough, apples enow!" The large wassail candle at feasts is mentioned by Shakespeare. See also TOASTS.

WASSERMANN, AUGUST VON (1866–1925), German bacteriologist and discoverer of serodiagnosis in syphilis (the Wassermann reaction) was born on Feb. 21, 1866, at Bamberg in Bavaria. He studied in Erlangen, Munich, Strassburg (Aus.) and Vienna, and in 1888 began to practise as a physician in Strassburg. He was then engaged as an assistant at the Robert Koch Institute for Infectious Diseases, Berlin, where, from 1906, he directed the department of experimental therapy and serum research. In 1913 he became director of the Kaiser Wilhelm institute in Berlin-Dahlem. Wassermann died in Berlin on March 15, 1925.

He was a prolific contributor to medical literature. His best-known works are contained in the Handbook of Pathological *Microorganisms* (1902–09), which he published in collaboration with Wilhelm Kolle. The blood serologic test for syphilis that Wassermann announced in 1906 is highly specific and sensitive, though technical error in its interpretation is not uncommon and factors other than syphilis can cause a false positive reaction.

WAST, HUGO (pseudonym of GUSTAVO MARTÍNEZ ZUVIRÍA) (1883–), Argentinean novelist, the most prolific and popular novelist of his country, was born in Córdoba on Oct. 23, 1883. A lawyer by profession, he was active in public life as a national deputy (1916–20), newspaper editor, publisher, university professor and, after 1931, director of the National library in Buenos Aires.

Wast's most characteristic novels, Flor de *Durazno* (1911), *Valle* negro (1918) and Desierto de *piedra* (1925), treat of rural customs. In them he depicts the people of the countryside, emphasizing their struggle against nature and adversity and their ability to endure hardships. Some—La *casa* de *los cuervos* (1916), El *jinete* de fuego (1926) and *Tierra* de *jaguares* (1927)--deal with historical subjects, while others—Los ojos vendados (1921) and Ciudad turbulenta, *ciudad alegre* (1919)—treat of socioeconomic urban problems. Many of. his novels have been translated into foreign languages.

Wast is also an adept short-story writer, *Sangre* en el *umbral* (1927) being his most important collection.

See Ruth Sedgwick, "Hugo Wast, Argentina's Most Popular Novelist." *Hispanic* American Historical Review, 9:116–126 (1929); H. H. Hespelt,' "Hugo Wast—Argentine Novelist," *Hispania,* 7:360–367 (1924).

(L. LL.)

WASTE, a term used in English law in several senses, of which four are the most important: (1) "Waste of a manor" is that part of a manor subject to rights of common, as distinguished from the lord's demesne (see COMMONS; MANOR). (2) "Year, day and waste" was a part of the royal prerogative. acknowledged by a statute of Edward II, De Praerogativa Regis. The king had the profits of freehold lands of those attainted of felony and petit treason, and of fugitives for a year and a day with a right of committing waste in sense (3) thereon. After the expiration of a year and a day the lands returned to the lord of the fee. This species of waste was abolished by the Corruption of Blood act, 1814 (see FELONY). (3) The most usual signification of the word is "any unauthorized act of a tenant. for a freehold estate not of inheritance, or for any lesser interest, which substantially alters the permanent character of the thing demised (a) by diminishing its value, (b) by increasing the burden on it, (c) by impairing the evidence of title and thereby injuring the 'inheritance' " (West Ham Charity Board v. *East* London *W.W.*, 1900. 1 Ch. 624, 637; cf. Pollock on Torts, 357).

Waste in sense (3) is either voluntary or permissive. Voluntary waste is by act of commission, as by pulling down a house, wrongfully removing fixtures (*q.v.*), cutting down timber trees, *i.e.*, oak, ash, elm, 20 years old, and such other trees, *e.g.*, beech, as by special custom are counted timber in the district, opening new quarries or mines (but not continuing the working of existing ones) or doing anything which may—for this is the modern test—alter the nature of the thing demised, such as conversion of arable into meadow land.

Although an act may technically be waste, it will not as a rule constitute actionable waste or be restrained by injunction in the absence of some prohibitive stipulation if it is "ameliorating"; *i.e.*, if it improves the value of the land demised. In the case of timber estates upon which trees of various kinds are cultivated solely for their produce and the profit gained from their periodical felling and cutting, the timber is not considered as part of the inheritance but as the annual fruits of the estate, and an exception arises in favour of the tenant for life. Under the Settled Land act, 1925, a tenant for life may grant building, mining, forestry and other leases for the prescribed terms "for any purpose whatever, whether involving waste or not" and is also protected as regards waste in the execution and repair of improvements. Permissive waste is by act of omission, such as allowing buildings to fall out of repair. A "fermor"—a term which here includes "all who held by lease for life or lives, or for years by deed or uithout deed" by the statute of Marlborough, (1267)—may not commit waste without licence in writing from the reversioner.

Acts of equitable waste were, before 1875, not cognizable in courts of common law. However, by the provisions of the Law of Property act, 1925 (s. 135), an equitable interest for life without impeachment of waste does not confer upon the tenant for life any right to commit equitable waste, unless an intention to confer such right expressly appears in the instrument creating the equitable interest.

A copyholder may not commit waste unless allowed to do so by the custom of the manor. The penalty for waste is forfeiture of the copyhold (see COPYHOLD). The Agricultural Holdings act, 1923, by provisions giving compensation for improvement as regards the holdings to uhich it applies, overrides some of the old common law doctrines as to waste.

(4) "Waste of assets" or "devastavit" is a squandering and

misapplication of the estate and effects of a deceased person by his executors or administrators (see ESTATES, ADMINISTRATION OF and Administration of Estates act, 1925, s. 29). Executors and administrators may now be sued in the county court for waste of assets (County Courts act, 1888, s. 95).

Remedies for Waste.—The landlord is entitled to compensation for deterioration in the value of a holding by the failure of the tenant to cultivate according to the rules of good husbandry or the contract of tenancy.

Proceedings may be taken either by action for damages or by application for an injunction or by both combined. and either in the king's bench or in the chancery divisions.

The law of waste as it affects ecclesiastical benefices will be found under DILAPIDATION.

Scotland.—In Scots law "waste" is not used as a technical term, but the respective rights of fiar and liferenter are much the same as in England. As a general rule. a liferenter has no right to cut timber, even though planted by himself. An exception is admitted in the case of coppice wood, which is cut at regular intervals and allowed to grow again from the roots. Grown timber is also available to the liferenter for the purpose of keeping up the estate or repairing buildings.

Before making use of mature timber for estate purposes, the liferenter should give notice to the fiar. He is also entitled to the benefit of ordinary windfalls. Extraordinary windfalls are treated as grown timber. Liferenters by constitution (*i.e.*, by grant from the proprietor) as opposed to liferenters by reservation (where the proprietor has reserved the liferent to himself in conveying the fee to another) have, as a rule, no right to coals or minerals underground if they are not expressed in the grant or appear to have been intended by a testator to pass by his settlement. Where coals or minerals are expressed in the grant, and also in cases of liferent by reservation, the liferenter may work any mine which had been opened before the beginning of his right, provided he does not employ a greater number of miners or bring up a greater quantity of minerals than the unburdened proprietor did. All liferenters are entitled to such minerals as are required for domestic consumption and estate purposes.

United **States.**—U.S courts adapted the common law doctrine of waste to the requirements of a continuously expanding country. The application of the English law of waste was thus restricted to stimulate the development of the land by the tenant in possession. Good husbandry upon his part was the criterion by which the character of his acts as waste was determined. The conversion of meadow and wood land into arable land mas thus permissible.

With the disappearance of pioneer conditions, a tendency toward greater stringency in the application of the doctrine of waste became apparent, particularly in such highly industrialized states as those of the northern Atlantic seaboard. The difference, however. lies largely in a change in the character of what good husbandry demands rather than a change in the legal principle. The remedy for waste lies either by an action at lam for damages caused by waste or by an injunction to restrain further waste and to compel an accounting for the waste done. (A W R ; X)

WATCH, a portable mechanical timepiece. When matches were first made is uncertain, but there can be little doubt that the first appeared shortly after the invention of the mainspring by Peter Henlein of Niirnberg. Clocks had originally been weight driven. but after the invention of the mainspring they could be made portable. The escapement used in the early watches was the same as that used in the early clocks, the verge or vertical escapement. Early watches were made in Germany and at Blois in France. By the middle of the 20th century it was being contended that they originated in Italy.

MECHANISM

The rate of going of a watch (*i.e.,* its timekeeping) is governed by a controlling element in the form of an oscillating system. Since the latter part of the 17th century, this has taken the form of the balance and spring. The energy required to maintain the balance in oscillation is stored in the mainspring and replenished when the watch is wound.

The energy stored in the mainspring is transmitted to the balance by the wheel train and escapement, the motion of the balance itself controlling the release of the escapement and consequently the phase of the maintaining impulse. A friction drive to the hands is provided from a wheel rotating at a convenient rate, usually once per hour. The hands may thus be set to time without deranging the remainder of the watch.

The Mainspring.—The mainspring consists of a fiat steel band stressed in bending; when the watch is wound, its curvature is increased and energy thus stored.

In the first spring-driven timekeepers the mainspring was open, as in the modern alarm clock. It was hooked to an arbor at its centre or "eye," while its outer end was attached to the frame. A ratchet and click allowed the arbor to be rotated during winding without disturbing the first wheel or "great wheel" of the train, which was loose on the arbor. During going, the spring drove the great wheel via the ratchet and click.

One of the main defects of these early portable timepieces was the variation in the torque output of the mainspring. An attempt to remedy this was the stackfreed. which acted against the pull of the mainspring when fully wound, exerting less restraint as the mainspring ran down. It was, in effect, little more than a crude auxiliary spring. Solution of the problem was advanced between 1515 and 1540 by the invention of the fusee. In this arrangement the mainspring is made to rotate a barrel, in which it is housed; a length of catgut, later replaced by a chain, was wound on it, the other end being coiled around the fusee. This is a drum cut in the form of a curved-sided volute or a hollow-sided threaded cone. When the mainspring is fully wound, the gut or chain pulls on the smallest radius of the fusee; as the mainspring runs down. the leverage is progressively increased as the gut or chain pulls on a larger radius. With correct proportioning of mainspring and fusee radii. an almost constant torque may be obtained throughout the run. The going barrel, fitted to all modern watches. has superseded the fusee and obviated the need for maintaining work to keep the watch going during winding. By careful proportioning of barrel arbor and barrel diameters to mainspring thickness, torque variations have been reduced to a minimum. The use of Geneva stopwork in high-class precision watches eliminates the most serious variation in torque, which occurs when the spring is fully wound.

The Controlling System.—In the earliest timekeepers, a weighted crossbar or foliot or a wheel with a heavy rim known as the balance was used to control the rate of going of the mechanism. It was subjected to no systematic constraint, and it would not be possible to define its period of oscillation mathematically. Consequently, its period of oscillation and hence the rate of the timekeeper were dependent on the driving force; this explains the great importance of the fusee.

Robert Hooke claimed to be the first to control the oscillations of a balance by a hairspring or balance spring, c. 1660; it was applied to watches for him by Thomas Tompion. Early illustrations show a balance with two pins on either side of a straight biade spring; this, when deflected by the balance, provided the restoring couple. The amplitude of the balance must. in this case, have only been small. Christiaan Huygens (*q.v.*) devised the spiral balance spring in 1675 and had watches made by Thuret to prove his theories. Besides Hooke, another who claimed priority was the *abbe'* Jean de Hautefeuille.

The balance spring is a delicate ribbon of steel or other suitable material, generally wound into a spiral form. The inner end is pinned into a collet, which fits friction-tight on the balance staff, while the outer end is held in a stud fixed to the movement. This spring acts on the balance as gravity does on the pendulum—it provides the restoring couple. If the balance is displaced to one side the spring is wound and energy stored in it; this energy is then restored to the balance, causing it to swing nearly the same distance to the other side if the balance is released. If there were no frictional losses (caused by air friction, internal friction in the spring material and friction at the pivots), the balance would swing precisely the same distance to the other side and continue

FIG. 1.—WATCH MOVEMENT

to oscillate indefinitely; because of these losses, however, the oscillations would, in practice, die away. It is the energy stored in the mainspring and fed to the balance through the wheel train and escapement which maintains the oscillations. The frequency is generally $2\frac{1}{2}$ c.p.s. or 18,000 half cycles per hour.

Invention, as applied to timekeepers, was greatly stimulated during the 18th century by the need for a good timekeeper for determining longitude at sea. The problem was finally solved by John Harrison (*q.v.*), originally a Yorkshire carpenter, with his no. 4 marine timekeeper. This timekeeper, however, was difficult to construct, and of all the devices embodied in it only his maintaining power (which drives the balance during winding in fusee timepieces) was later adopted by others. The marine chronometer as developed by John Arnold and improved by Thomas Earnshaw is closely akin to the modern form of this instrument. Perhaps the only improvements on the Earnshaw form (c. 1790) are in the balance and spring.

Errors in the Balance and Spring.—A watch's performance depends on the uniformity of the period of oscillation of the balance and spring. The balance takes the form of a wheel with a heavy rim, while the spring coupled to it provides the restoring torque. The balance possesses moment of inertia, and this is dependent on its mass and configuration. The spring should. ideally. provide a restoring couple directly proportional to the displacement from its unstressed or zero position. A system of this kind will have a periodic time $T = 2\pi\sqrt{\frac{I}{G}}$ where **I** is the moment of inertia of the balance and G the restoring couple of the spring per unit displacement. If these factors do not change. or remain in constant ratio, the periodic time will evidently remain constant and the watch will have a uniform rate. Any departure from uniformity of rate should be examined in relation to variations in the above expression. The balance is mounted on pivots and, in watches of good quality, these run in jewels. Two jewels are used at each end of the balance staff, one pierced to provide a bearing, the other a flat end stone providing axial location by bearing against the domed end of the pivot. Frictional effects at the pivots influence the performance of the watch in various positions; for example, lying and hanging.

The balance and spring can be brought to time or "regulated" by varying either the restoring couple provided by the spring or the moment of inertia of the balance. In the first case (by far the more common) this is generally effected by providing a pair of curb pins mounted on a movable regulator index. The spring constant G is given by the expression $G = \frac{Eht^3}{12l}$ where E is

Young's modulus of elasticity (see ELASTICITY) and h, t and l represent the height, thickness and length of the spring. Evidently the only factor that may be changed in use is l, and the spring therefore passes between a pair of curb pins mounted on the index; movement of the curb pins will effectively lengthen or shorten the spring, thus making the requisite change in the spring constant. In the second instance, screws are provided at one or two pairs of opposite points on the rim of the balance; these screws are friction-tight in their holes and thus can be moved in or out so as to adjust the moment of inertia of the balance. In "free-sprung" watches no regulator index is provided, and the only adjustment available is the screws on the balance rim.

Errors of *Isochronism.*—Errors of isochronism are recognized when the periodic time of the balance varies with the amplitude of oscillation. The following occur with the watch in the lying position (*i.e.*, with the balance staff vertical): (1) curb pin errors; (2) centrifugal error (with cut compensation balance only); (3) departures from Hooke's law in the spring material; (4) "point of attachment" effect; (5) escapement error.

Curb pin errors occur when the regulator curb pins do not positively clamp the spring, which will thus be out of contact with them during part of the oscillation. its effective length being then measured from the stud instead, so that any change in the amplitude of oscillation will change the length of time for which the spring is in contact with the pins and cause an error of isochronism.

Centrifugal error is of decreasing importance (except in the older types of marine chronometer), as the cut compensation balance is seldom used today. However, with a cut balance the moment of inertia mill vary with angular velocity, since the rim will be sprung outward because of centrifugal loading. This will cause the effective value of the moment of inertia to vary with the amplitude of oscillation, tending to cause the timekeeper to lose at high amplitudes.

Departures from Hooke's law (see ELASTICITY; MATERIALS, STRENGTH OF) depend on the particular spring material involved and can cause errors of isochronism of the order of 20 seconds per day.

"Point of attachment" effect occurs because the balance spring cannot in practice be anchored at zero radius (ie., on the true axis of the balance) but has to be pinned to the collet, which anchorage is at an appreciable radius. Hence, particularly if a flat spiral spring is used. elastic side-thrust couples will be set up through the eccentric development of the spring as it coils and uncoils. These couples will give rise to disturbances to the periodic time, and these will vary with amplitude.

A theoretical analysis of escapement error was developed by Sir George Airy. The function of the escapement is to supply the balance and spring with energy obtained from the mainspring. via the wheel train. to maintain the balance in oscillation. If an oscillating system receives a forward impulse when approaching the zero position it will be caused to gain. while under the same condition a backward impulse would cause a loss; after the zero position, the effects are reversed. With the lever watch escapement, the net effect of the action of the escapement is to cause a loss. This amounts to approximately two to five seconds per day over the normal working range of amplitudes, that is, between 180 and 270 degrees.

Positional Errors.—Because of the type of pivot on which the balance and spring is mounted. a change of position from lying to hanging will cause an increase in the frictional losses; in the hanging position the amplitude will be reduced by about 40°–60° as compared with the amplitude in the lying position. All the five types of isochronal error will therefore take effect when the watch is moved from the lying to the hanging position.

A general idea of effects caused by eccentric movement of the centre of gravity may be formed if one considers the centre of gravity of the balance to lie below the axis in the zero position. At all amplitudes up to 180° the restoring couple caused by the spring will be augmented by a restoring couple caused by gravity, so that the watch would tend to gain. If the amplitude is increased, the spring couple will be opposed by the gravity couple at the extremes of displacement, and in fact the effect on periodic time becomes zero at an amplitude of about 220°. Beyond this amplitude the effect reverses, and the gravity couple would cause a loss.

In practice, it is most difficultto make a balance spring in which the centre of gravity remains on the axis for all displacements of the balance. In general, the centre of gravity will move in a complex manner depending on the exact configuration of the spring and its inner and outer terminations. This movement can be greatly reduced by raising an overcoil at the outer end of the spring and terminating this at the stud in a plane above that of the body of the spring. This invention was made by Abraham Louis Breguet (c. 1800), and overcoil springs are named after him. The theoretical conditions governing the form of overcoil to ensure a stationary centre of gravity and to eliminate lateral pressure at the balance spring collet were established by E. Philips, an Englishman working in France (c. 1860).

Temperature Errors.—The full expression for the periodic time of the balance and spring is $T = 2\pi\sqrt{\frac{12mk^2l}{Eht^3}}$, where m is the mass of the balance; k, its radius of gyration; E, Young's modulus of elasticity; and h, t and 1, the height, thickness and length of the spring respectively. A change of temperature may evidently affect all these factors except m. If the temperature rises, the moment of inertia of the balance will increase, because of an increase in k caused by the expansion of the balance. As regards the spring, variations in h and 1 will cancel one another, while with a rise of temperature the increase in t will tend to make the spring stiffer. Changes in E are of the greatest importance: with steel springs, E decreases by 240 parts in 10^6 per degree centigrade of temperature rise.

The net change in timekeeping, in seconds per day, is given by the expression $At = -86400\,\alpha_1 + 129600\,\alpha_2 + 43200\,C$, where α_1 is the coefficient of expansion of the balance, α_2 the coefficient of expansion of the spring material and C the temperature coefficient of Young's modulus or thermoelastic coefficient.

The first of these effects causes a loss, the second a gain, and the third either a gain or a loss with rise of temperature, according to the particular spring material. For a steel spring and brass balance, the first effect causes a loss of 1.6sec. per day per degree centigrade, the second a gain of 1.4sec. per day per degree centigrade, and the third a loss of 10.5 sec. per day per degree centigrade. Thus the timekeeper would lose nearly 11 sec. per day for every degree centigrade of temperature rise.

For marine timekeepers, which have to encounter a wide range of temperatures, the problem was solved by John Harrison, who used a pair of curb pins mounted on a brass and steel bimetallic strip; with changes of temperature, the curb pins moved along the spring, thus changing its effective length and compensating for the errors of the system as a whole, largely for changes in Young's modulus.

This arrangement was superseded by a balance which changed its moment of inertia with the temperature. Pierre Leroy's balance was of the fluid compensation type, with alcohol thermometers causing the displacement of mercury threads in glass tubes. Later, the bimetallic compensation balance was developed by Arnold and Earnshaw.

Earnshaw's form, in which brass was fused onto the outside of the steel balance rim, is identical in principle with the bimetallic balances still used in some very high-grade watches. The unequal expansion of the brass and steel caused the rim, which was attached to the balance arm at one end and free at the other, to curl inward or outward with changed temperature. This effected changes in the moment of inertia of the balance. The rate of change of moment of inertia with temperature could be adjusted by moving compensation weights or screws toward or away from the free ends of the rim. In this way the rates of the timekeeper could be made exactly equal at two temperatures.

However. if these temperatures differed by about 30° C., an error of approximately $2\frac{1}{2}$ sec. per day would remain at a temperature midway between the extremes. If the metals of the rim have constant coefficients of expansion this "middle temperature error" is bound to occur, and many ingenious "auxiliary compensations" were developed during the 19th century, principally in marine chronometers.

About 1900 certain nickel-iron alloys were developed by C. E. Guillaume. In these, the coefficient of expansion is not constant: it varies nith temperature. One of the series, containing about 40% nickel. when used with a brass outer rim gives virtually

FIG. 2.— LEVER ESCAPEMENT

continuous temperature compensation for a steel balance spring, over the range from 0° to 30° C. Temperature errors of less than $\frac{1}{20}$ sec. per day per degree centigrade can readily be achieved with a carefully adjusted Guillaume balance.

Guillaume also developed an alloy known as Elinvar (c. 1912). This has a low value of temperature coefficient of Young's modulus. Further development of this alloy enabled the compensation balance to be dispensed with, except for the very highest grade of timekeeper intended for observatory trials. Moreover, it is rustless and much less affected by magnetism than steel.

Subsequently improved alloys of low temperature coefficient were developed. In these, the mechanical properties are greatly superior to the original Elinvar, elastic limits as high as 50 tons per square inch being achieved. Temperature errors with these springs when used with a monometallic balance are often less than 1 sec. per day per degree centigrade. The alloy developed by the Hamilton Watch company in the Cnited States is also highly stable in its elastic properties.

Effect of Adjustment.—After adjustment against all these types of error, a man's wrist watch of moderate quality will perform to within about 70 sec. per day between the lying position and two edgewise positions differing by 90° in orientation. High-grade commercial watches can be adjusted to within approximately 20 sec. per day in five positions. while watches intended for observatory competition work, if of pocket size, may have differences of rate in positions amounting to 3 sec. per day. or even far less.

Escapements. — Of the great number of escapements invented. only five came into general use: the verge or vertical; the cylinder or horizontal; the duplex; the lever (either jeweled or pin palletj; and the chronometer or detent.

The verge escapement consisted of two pallets projecting from the balance staff, working with an escape wheel of contrate form, sometimes known as the crown wheel. The teeth of this wheel impelled the two pallets alternately. The balance was coupled to the escape wheel during its entire vibration and not only while receiving impulse; because of the geometry of the wheel and pallets, the balance caused the escape wheel to turn backward against the driving torque of the wheel train during its supplementary arc. Consequently, the balance was subject to constraint during its entire swing. and the timekeeping was much affected by the torque available at the escape wheel, the condition of the oil and the state of the working surfaces in the escapement.

The cylinder escapement was introduced by George Graham in 1726. It was a considerable improvement over the verge. in that the escape wheel did not turn backward during the supplementary arc of the balance. Thus, the constraint on the balance was caused only by the frictional couple set up by the locking pressure of the escape-wheel teeth on the circular surfaces of the cylinder, either inside or out. Originally, cylinder watches had a steel cylinder and brass escape wheel, which cut the steel cylinder when the oil began to dry up; then ruby cylinders were used in some fine watches (Thomas Mudge's cylinder watches, *c.* 1750, were the first really satisfactory pocket watches).

Eventually it was found that a hardened steel wheel working with a hardened steel cylinder caused far less wear. The escapement was long used in this form for the majority of cheap watches, but it is now relatively uncommon.

The duplex escapement came into use toward' the end of the 18th century; it aimed at further reducing constraint on the balance by separating the functions of locking and impulse. The escape wheel had two sets of teeth (whence "duplex"); the long teeth served for locking in conjunction with the ruby roller on the balance staff, while the raised triangular teeth delivered impulse to the impulse finger or "hook," also mounted on the staff. It was a single-beat escapement, delivering impulse in alternate swings only (*i.e.*, once per cycle), and so, if the balance received an adverse shock in wear, reducing its amplitude below a critical value, it would "set" and the watch stop. A well-made duplex watch was an accurate timekeeper, and this escapement was used in fine English matches as late as 1880. The American Waterbury "dollar" watch used a simplified form of duplex escapement.

The lever escapement was invented by Thomas Mudge in 1765. In this escapement, the balance is free to execute its supplementary arc, being coupled to the escapement only while effecting unlocking and receiving impulse. This resulted in a marked improvement in timekeeping. The escapement was developed into its modern form, with a club-tooth escape wheel and double-roller safety action, by Josiah Emery and A. L. Breguet. Although this form (fig. 2) had been reached by the beginning of the 19th century it was not universally adopted until c. 1915.

The club-toothed wheel is, in good-quality watches, made of hardened steel. with the acting surfaces ground and polished. It is much less subject to wear than the ratchet-tooth variety. and its geometry reduces loss of motion between wheel and pallets. In the double-roller safety action the intersection between guard pin and roller is much deeper than in the single-roller. and any friction caused by jolts encountered in wear takes place at a smaller radius and causes less constraint on the balance. The safety action should only operate on relatively severe jolts, since the locking faces of the pallet stones are so inclined as to "draw" the lever over to the appropriate banking pen when locking occurs. This escapement, by far the most important watch escapement today. is used in its jeweled form in watches of moderate to excellent quality and with steel pallet pins and a simplified fork and roller action in cheap watches.

The chronometer escapement was originated by Pierre Leroy, but much development was required. Arnold and Earnshaw, working in rivalry, brought it into its modern form, Earnsham's version of the escapement being unaltered in principle even today. It is a single-beat escapement, and the balance is free to execute its supplementary arc unconstrained. Unlike the lever escapement, the escape wheel delivers impulse directly to the balance, locking being effected on a separate unit, the detent. Perhaps the most important feature favouring long-term stability of rate is that the escapement functions without oil (in the lever escapement oil on the pallet stones is bound eventually to dry up or thicken and so reduce the balance amplitude). The chronometer escapement is not very suitable for a watch. being liable to "set"; but for marine chronometers its supremacy has not yet been seriously challenged.

The Wheel Train. — In a watch it is necessary to achieve a step-up ratio of approximately 4.000 : 1 between barrel and escape pinion. This involves four pairs of gears, the ratio per pair commonly being between 6 : 1 and 10 : 1. Because of considerations of space, the pinions must have a low number'of leaves — commonly from 6 to 12. This entails a number of special gearing problems. aggravated by the fineness of their pitch. Any error in centre distance, form or concentricity is therefore proportionately more important than in larger types of gearing.

A special form of cycloidal gearing is used, in which the pinion has hypocycloidal dedenda, and the wheel epicycloidal addenda.

The generating circle, which is common to both wheel and pinion, has a diameter equal to the pitch circle radius of the pinion. This special case of hypocycloid is a straight radial line, and watch pinion leaves are of this form below the pitch circle. The range of modules encountered is from about 0.25 mm. in a large pocket watch to 0.07 mm. in a lady's very small wrist watch. A six-leaf pinion of 0.07-mm. module has an over-all diameter of about 0.5 mm. only. In practice, the cycloidal form is approximated.

Jewels.—A patent was taken out by Nicholas Facio in 1704. which covered the use of jewels in watches. Diamonds and sapphires were used. The sapphires were pierced with diamond splints and steel wires charged with diamond ponder; this was practised only in England until about 1790. Synthetic jewels made from powdered alumina fused in the oxyhydrogen blowpipe later came into use. Colourless unless certain materials are added, they are usually coloured to a ruby red, although the clear stones are considered slightly harder.

R'atch jewels are worked up from the raw material to exceedingly close limits and with a very high polish. A uniform outside diameter is highly important, since jewels are fitted by the friction jeweling method, being pressed into accurately sized holes smaller than the jewels themselves and held there by the interference and consequent elasticity of the surrounding metal. The hole diameter of a typical balance jewel is about 0.1 mm , with a unilateral tolerance of 2.5 microns. The holes are drilled undersize nith diamond charged wires, and opened to their final dimensions with a stepped lapping mire. Finally, they are "olived" with a bowed lapping wire to reduce friction.

TYPES OF WATCH

Wrist Watches.––Until the beginning of the 20th century. watches were almost invariably made to be carried in the pocket However, the wrist watch rapidly gained popularity and after 30 years more than 50 wrist watches were made to 1 pocket watch. The diameters of the movements of men's wrist watches range from roughly 23 to 30 mm., while ladies' round movements are commonly betneen 14 and 20 mm. in diameter. Shaped movements are made both in men's and in ladies' sizes. Second hands are commonly fitted on movements down to about 18-mm. diameter, and the centre seconds ("sweep" second hand) arrangement is frequently preferred. The modern watch runs for about 40 hours.

Chronographs.—The chronograph was developed by E D. Johnson in 1855 to measure time intervals (in sporting events. for example). In these watches, an additional second hand is engaged with the wheel train by pressing the pendant, disengaged by a second pressure and returned to zero by a third. Split-second chronographs have two chronograph second hands; these begin to move together and one can be stopped to take a reading and then made to catch up with the other. It is thus possible to take the times of more than one competitor in a race.

The stop watch is made for purposes that do not warrant the more expensive chronograph. In a stop watch, the balance is actually started and stopped, whereas in the chronograph it oscillates continually. Minute and sometimes hour recorders are added to chronographs and to stop watches. All the hands are returned to zero when required by the action of strikers pressing against heart cams. In certain cases the balance vibrates more rapidly than the usual 18,000 half-cycles per hour; it is thus possible to record tenths or hundredths of a second.

Self-Winding Watches.—The first patent on the self-winding pocket watch was taken out by Louis Recordon in London in 1780. The early self-winding watches operated on the pedometer principle. The development of the self-winding wrist watch dates from the invention of an Englishman, John Harmood, who secured a patent in 1924. His system consisted of a swinging weight pivoted at the centre of the movement, coupled to the barrel arbour through reduction wheels and clicks; the weight swung between buffer stops; no winding stem was fitted and the hands were set from the bezel. Between 1930 and 1945 much development work was carried out in Switzerland, and a wide range of self-winding watches was being made there and elsewhere by the 1960s. As their mainspring is kept more uniformly wound, these watches are generally better timekeepers. (R. M. J. L.; R. A FL.)

Electric Powered Watches.—Electric powered watches use either of tuo drive systems. (1) the galvanometer drive, consisting of the conventional balance-hairspring oscillator kept in motion by the magnetic interaction of a coil and a permanent magnet; or (2) the induction drive, in which an electromagnet attracts a balance containing soft magnetic material. Both types use a mechanical contact. actuated by the balance motion, to provide properly timed electric drive pulses. Each oscillation of the balance operates a time-indicating gear train by advancing a toothed wheel one tooth. Miniature high-energy-density batteries are used as power sources (C. N. CH)

Accessory Mechanisms.—Additional mechanisms are often fitted to watches The repeating watch will strike the time on pulling a slide or pressing the pendant—sometimes to the nearest minute. The clock watch strikes the time in passing like a clock and can generally also be made to repeat The alarm watch can be set to operate a small bell or case-clapper at a predetermined time Calendar mechanisms have been added; the perpetual calendar automatically corrects for the varying lengths of month including leap year; the simple calendar gives the date and often the day of the week, the month and even the phases of the moon.

WATER. This chemical compound. having the formula H_2O, is one of the most abundant, aidely distributed and essential substances on the surface of the earth. It occurs in nature in the solid, liquid and gaseous states as ice or snow. water, and steam or water vapour, respectively. Water is a necessary constituent in the cells of all animal and vegetable tissues and in the crystals of many minerals.

Sea water contains on the average about 3.5% by weight of dissolved substances, principally sodium chloride ($NaCl$) 2.7%, magnesium chloride ($MgCl_2$) 0 4%, magnesium sulfate ($MgSO_4$) 0.2%, calcium sulfate ($CaSO_4$) 0.15% and potassium chloride (KCl) 0.05%; but traces, at least. of all the naturally occurring chemical elements are present.

Snow is probably the purest natural source of water and rain the next purest, although the latter contains dissolved gases of the air as well as traces of carbon dioxide, chlorides, sulfates, nitrates and ammonia, with organic and inorganic dust held in suspension.

Water from streams and lakes in mountainous districts is relatively free from organic impurities but may contain dissolved inorganic salts, ahile that from lowland rivers and lakes may 'be highly polluted. Water from springs and wells has filtered through the ground and has been more or less purified of organic contamination but may contain inorganic salts.

Water is essential in all animal and plant nutrition. It finds extensive use in science and industry as a solvent, a catalyst, a standard for the concrete representation of certain physical units (*e.g.,* litre, calorie), a standard of comparison for certain physical properties (*e.g.,* specific gravity, relative viscosity), a conveying medium for the transport of materials and disposal of wastes, a diluent or dispersive medium, a cooling agent, a cleansing medium and in the production and distribution of heat and power. Industrial hydrogen is obtained from water by electrolysis or hy passing steam through a bed of hot coal.

Inorganic salts in small amounts are not objectionable in potable waters but harmful bacteria thrive on the organic content. Drinking water is subjected to microscopic, bacteriological and chemical examination. In the interpretation of the chemical analysis the source and history of the water must be taken into account. Abnormally high chloride content usually means sex-age pollution. The amount and condition of nitrogenous solutes is an indication of the extent and present state of the contamination.

Certain bacteria in water convert albuminoid ammonia to free ammonia, which is then oxidized to nitrites and later to nitrates.

A high albuminoid or free ammonia content indicates recent contamination while a high nitrate content is evidence of past contamination from which the water may have been purified.

For purification of potable water see WATER SUPPLY AND PURIFICATION.

Hard Water.— Hard waters contain soluble salts of calcium and magnesium, principally as bicarbonates, chlorides and sulfates. Ferrous iron may also be present. Hardness caused by calcium bicarbonate is known as temporary since boiling converts the bicarbonate to the insoluble carbonate; hardness from the other salts is called permanent. Calcium and magnesium ions react with the higher fatty acids of soap (*q.v.*) to form an insoluble gelatinous curd difficult to remove from the material being washed and thereby cause a waste of soap, since a lather will not form until these ions have been removed from solution. This does not happen with the newer detergents, which are sulfonates of long-chain molecules; *e.g.*, alcohols. The iron is oxidized to the ferric form and appears as a reddish-brown stain on the material. The hardness of water is determined by the amount of a standard soap solution (made by dissolving castile soap in an alcohol solution) required to produce a lather that remains unbroken for five minutes in a definite volume of the water.

Water is softened on a small scale by the addition of ammonia, borax or trisodium phosphate together with sodium carbonate (washing soda). The latter precipitates the calcium as carbonate and the magnesium as hydroxide. Water is softened on a large scale by the addition of just sufficient lime to precipitate the calcium bicarbonate as carbonate and the magnesium as hydroxide followed by the addition of sufficient sodium carbonate to remove the remaining calcium salts. In the "permutite" process the water is filtered through a natural or artificial zeolite (*q.v.*), which replaces the calcium, magnesium and ferrous ions by sodium ions. The zeolite is regenerated by treatment with a strong brine solution.

In the boilers of power plants, the calcium and magnesium salts in hard waters form a hard, adherent scale on the plates. As a result of the poor heat conductivity of the scale, fuel consumption is increased and the boiler deteriorates rapidly through overheating of the plates. Sodium carbonate if present in the water hydrolyzes to give free alkali that causes caustic embrittlement and failure of the boiler plates. In some localities sulfuric acid is added to boiler feed water after softening to increase the ratio of sulfate to carbonate.

Ion-free water comparable in saline content with ordinary laboratory distilled water is produced by percolating the water through a granular bed of a polyhydric phenol formaldehyde resin, then through an amine formaldehyde resin. The phenol groups of the former replace the positive ions in solution by hydrogen ions and the amino groups of the latter absorb the acids so formed.

Water as a Standard.— Water exhibits the anomaly of having a greater density at 3.98° C. than at any temperature above or below. The litre is the volume of 1 kg. of air-free water at this temperature and 1 atm. pressure. The prototype kilogram was designed to have the mass of 1,000 c.c. of water under these conditions but because of a slight error one litre actually contains 1,000.028 c.c. The specific gravity of a substance at a temperature t is the ratio of the mass of a certain volume to the mass of an equal volume of water at the same temperature (S_t^t) or at the temperature of maximum density (S_4^t). Zero degrees centigrade (32° F.) is defined as the temperature of equilibrium between ice and air-saturated water under a pressure of 1 normal atmosphere; 100° C. (212° F.) is the temperature of equilibrium between water and steam at the same pressure. The 15° calorie is the quantity of heat required to raise the temperature of 1 g. of liquid water from 14.5° to 15.5° C. under an air pressure of 1 atm.; the 20° calorie, from 19.5° to 20.5° C.; and the main calorie is $\frac{1}{100}$ of the quantity of heat required to increase the temperature from 0° to 100° C. These calories are equivalent to 4.185, 4.181 and 4.188 joules, respectively. Water is used as a standard in the calibration of viscosimeters (see VISCOSITY).

Physical Properties of Water.—The water molecule is in the form of an isosceles triangle with an apex angle of 105° and a

dipole moment of 1.83×10^{-18} c.g.s.e. (centimetre-gram-second electrostatic units) (in the gas), the oxygen atom being negatively and the hydrogen atoms positively charged. Other properties are given in the tables. Abnormalities in the properties of water are the high dielectric constant which accounts for its solvent action and ionizing power, high melting and boiling points for its low molecular weight, high critical temperature and pressure, large heat capacity, expansion below 3.98° C. and expansion (rather than contraction) on freezing. Since ordinary ice (ice I) is less dense than water, increasing pressure decreases the temperature of melting; the other crystalline forms of ice given in table II are all denser than water so that pressure increases their melting points. P. W. Bridgman followed the melting curve of ice VII to 192° C. and 39,000 atm. The normal freezing point of water (0° C.) is 273.15° on the Kelvin or thermodynamic scale (by international agreement).

TABLE II.—Triple Points Along the Melting Curve

Phases at equilibrium	Temperature (° C.)	Pressure (atm.)
Steam, ice I, water	+0.0100	0.00603
Ice I, ice III, water	−22.0	2,000
Ice III, ice V, water	−17.0	3,400
Ice V, ice VI, water	+ 0.2	6,200
Ice VI, ice VII, water	+81.6	21,700

When water freezes near 0° C. it forms α-ice, which is hexagonal; when supercooled at least a few degrees before freezing it produces β-ice, which is rhombohedral. (See also ICE.)

Chemical Properties of Water.— Water is a relatively stable compound dissociating into hydrogen and oxygen only to the extent of 2% at 2,000° C. and 1 atm. Metals and some nonmetals are oxidized by water or steam to the oxides with the liberation of hydrogen ($3Fe + 4H_2O = Fe_3O_4 + 4H_2$, $C + 2H_2O = CO_2 + 2H_2$). Steam reduces the halogens with the liberation of oxygen ($2Cl_2 + 2H_2O = 4HCl + O_2$). With some elements disproportionation takes place ($3S + 2H_2O = SO_2 + 2H_2S$). Oxides or hydrated oxides react with water to form hydroxides which are basic, acidic or amphoteric depending on the position of the positive element in the periodic table (see PERIODIC LAW) ($CaO + H_2O = Ca^{++} + 2OH^-$; $P_2O_5 + 3H_2O = 2H_3PO_4$, $H_3PO_4 = H^+ + H_2PO_4^-$; $Al_2O_3.H_2O + 2H_2O = 2Al[OH]_3.Al[OH]_3 = Al[OH]_2^+ + OH^-$ and $Al[OH]_3 = H^+ + H_2AlO_3^-$). Neutralization is the reaction of base with an acid to form a salt and water ($Na^+OH^- + H^+Cl^- = Na^+Cl^- + H_2O$). Since water itself ionizes to a small extent into H^+ (or H_3O^+) and OH^-, hydrolysis takes place when the salt of a weak base or a weak acid or both is dissolved in water. The chlorides and sulfides of many of the elements that are not strongly metallic are often completely hydrolyzed ($PCl_3 + 3H_2O = H_3PO_3 + 3HCl$, $Al_2S_3 + 6H_2O = 2Al[OH]_3 + 3H_2S$). Metallic nitrides and hydrides are decomposed by water to give NH_3 and H_2 respectively and the hydroxide of the metal. Metallic carbides yield hydrocarbons ($CaC_2 + 2H_2O = Ca[OH]_2 +$

C_2H_2). Organic esters, *e.g.* fats, are hydrolyzed by water to yield the alcohol and the acid. Because of its small size the water molecule can fit into many ionic crystal lattices, yielding hydrates ($Na_2HPO_4.2H_2O$, $Na_2HPO_4.7H_2O$, $Na_2HPO_4.12H_2O$).

Heavy Water.—Ordinary water as obtained from fresh-water lakes contains isotopes of hydrogen in the ratio of 1 atom deuterium, D or H^2 to 6,900 of hydrogen H^1. The oxygen isotope ratio is $O^{16}:O^{18} = 506:1$ with perhaps one-fifth as much O^{17} as O^{18}. When water is electrolyzed the gas produced at the cathode is poorer in deuterium than the water, which is thus enriched in deuterium content. Practically pure heavy water (D_2O) has been obtained by the electrical decomposition of hundreds of gallons of water until only a few millilitres remain. The oxygen isotope ratio in the water seems to remain substantially unchanged during the electrolysis. Heavy water has a density at 25° C. of 1.1079 times that of ordinary water It freezes at 3.82° C, boils at 101.42° C. and has a maximum density at 11.9° C. D_2O solid phases corresponding to ices I, III, V and VI have been found; all triple points are at higher temperatures and pressures than for ordinary water. The dielectric constant of the liquid is 80 7, viscosity 10 99 and surface tension same as that of ordinary water. The ion product is about $0\ 2 \times 10^{-14}$. In general, salts are less soluble in D_2O than in H_2O and the rates of chemical reactions in solution are less. Heavy water is used to slow the speed of neutrons in nuclear investigations. When deuterium is used as a tracer in physiological studies, the amount present in tissue is usually determined by oxidation to water and measurement of the density. Snow, rain and surface waters of lakes and oceans contain tritium, H^3, in the ratio of about 1 atom of tritium to 10^{18} atoms of hydrogen. Glacial waters contain smaller quantities of tritium (see DEUTERIUM AND TRITIUM).

See N E Dorsey, Properties of Ordinary *Water-Substance* (1948); H. C. Urey and G. K. Teal, "Hydrogen Isotope of Weight Two," Reviews of Modern Physics, vol. 7, pp. 56–58 (1935). (J. A B)

WATER BOATMAN, an aquatic hemipterous insect belonging either to the family Notonectidae or to the family Corixidae. In England it is a notonectid of which the best-known species (Notonecta *glauca*) is common in the ponds. This insect feeds upon other aquatic insects and can inflict a severe sting with its beak. In the United States the Notonectidae are called hack swimmers because they suim on their backs, while water boatman refers to the Corixidae which often occur in large numbers and include more species than any other family of aquatic Hemiptera. They live on the pool bottom where they feed on organic ooze containing both plants and minute animals or consume quantities of filamentous algae or the chlorophyll therefrom. (H B. HD.)

WATERBUCK, a large south African antelope (*Kobus ellipsiprymnus*) of the tribe Reduncini. characterized by the white elliptical ring on the buttocks and the general reddish-gray colour of the long coarse hair. They have heavily fringed necks and tufted tails; long sublyrate, ringed horns are carried by the bucks. The name is extended to include the sing-sing (K. defassa), a species without the white ring. See ANTELOPE.

WATERBURY, a city of western Connecticut, U.S., on the Naugatuck river. The chief centre of the U.S. brass industry, Waterbury is the core of a metropolitan area in the Naugatuck valley which is distinguished for its diversified industrial output that also includes rubber goods, clocks and watches, chemicals, electronic parts, textiles, plastics, machine tools and Clothing. It is the financial and commercial hub of the western part of the state

The population of Waterbury was 107,130 in 1960, an increase of 2.5% since 1950; the Waterbury standard metropolitan statistical area, comprising parts of New Haven and Litchfield counties, had a population of 181,638, an increase of 17 4%. The greatest expansion occurred in 1870–1920, when the population grew from 13,106 to 91,175. Foreign-born whites compose roughly 20% of the population; the largest groups, in order, are Italian, Lithuanian, French Canadian, Polish and Irish. About 65% are Roman Catholic, 25% Protestant and 5% Jewish Only 4% are Negro The principal suburbs are: Naugatuck, a rubber manufacturing centre; Watertown, a residential and textile centre, site of Taft school; and Cheshire, site of Cheshire academy and Connecticut State reformatory.

Thirty-one families established Mattatuck plantation in 1677 which was incorporated as a town in 1686 and named Waterbury because of the abundant drainage of the steep granite hills and slopes by the Naugatuck river and its tributaries. The unsuitability of the soil for agriculture, the "great flood" of 1691, the "great sickness" of 1712, and the lure of western lands retarded the town's growth. Tall handmade wooden clocks were a notable product of late 18th-century Waterbury craftsmen. The history of Waterbury thereafter was industrialization, based mainly on brass, and population growth. Brass buttons were first made in 1802, and by the 1830s the city was the largest U.S producer of brass kettles, pins, buttons and clocks. Manufacture of dollar watches, frequently called Waterbury watches, was begun in 1879, and from 1892 they were manufactured and marketed with great success by Robert H. Ingersoll (1859–1928). A fire in 1902 and a flood in 1955 were costly natural disasters.

Waterbury was incorporated as a borough in 1825 and chartered as a city in 1853. The town and city were consolidated in 1902. From 1895 until the abolishment in 1960 of county government in Connecticut, Waterbury was co-seat (with New Haven) of New Haven county. The Democrats achieved large pluralities in most state and national elections; however, the Republicans have had frequent success at the local level since World War II.

Waterbury's educational facilities include an extension centre of the state university, a business college and two nursing schools. There are 50 public parks with an aggregate of 760 ac. The largest, Hamilton park, contains the city zoo. Numerous outdoor recreational facilities and three state parks and forests are in the area. (M. J. TE.)

WATER CHINQUAPIN (*Nelumbuim pentapetalum*), a beautiful North American aquatic plant of the water lily family (Nymphaeaceae), called also American nelumbo or lotus (*q.v.*), rare and local in ponds and slow streams from Connecticut to Michigan and southward to Florida and Louisiana. It is a stout plant, rising from a horizontal tuber-bearing rootstock, with large shield-shaped leaves, one to two feet across, some floating but mostly rising high out of the water, and solitary pale-yellow flowers, four to ten inches broad, borne on long stalks usually higher than the leaves The edible tubers and farinaceous seeds were used for food by the Indians, who probably introduced it into the eastern states It is sometimes grown in water gardens for its ornate foliage. See WATER LILY.

WATER-COLOUR PAINTING. Water colour is a pigment ground in gum, usually gum arabic, and applied with brush and water to a painting surface, usually paper. The pigment is generally spread thinly and transparently, but it can be made opaque by being mixed with a white of some covering power, and in this form is known as body colour or gouache (*q.v*). Works of art, whether executed wholly in water colour, wholly in gouache, or in a combination, are known as water-colour paintings, water-colour drawings or simply water colours.

HISTORY

EUROPE

The forms of painting which preceded the introduction of oil painting—that is, fresco painting and tempera (*qq.v.*)—are akin to water colour in the preparation of the pigment and in the absence of plastic brush texture from the completed work. Drawing with the brush with inks in varying dilutions or with coloured washes upon paper or silk is the basis of oriental painting (see CHINESE PAINTING; JAPANESE PAINTING AND PRINTS). Illuminated manuscripts (*q.v.*) and portrait miniatures have commonly been executed in water colour and body colour, though normally with a hatching, point-of-the-brush technique different from that of water colour in its modern development; yet these arts contributed to water-colour technique as it is more narrowly defined (see DRAWING (TECHNIQUES OF); MINIATURE PAINTING). What is given here is the history of European water-colour painting from the beginning of the 16th century.

Water colour has bng been an adjunct of drawing. Once the brush had been added to the pen and chalk as a standard instrument it was natural to add washes of ink or bistre to an outline drawing; and but a further short step to use coloured washes over, or in place of, the monochrome ones. The history of water-colour painting therefore overlaps on one side the history of drawing, just as on the other it overlaps the history of painting.

Indeed to make a selection, in the case of the continental schools of art, between water colourists and other draftsmen is generally to impose an arbitrary distinction between contemporaries of quite similar aims, some of whom may sporadically have tinted their drawings while the others only used a monochrome wash. But in England in the 18th and 19th centuries the name does stand for a quite recognizable distinction of craft, dividing artists such as J. R. Cozens, J. S. Cotman, David Cox and Peter de Wint who, if they worked at all in oil, did so purely as a side line, from those who were preponderantly painters in oil. This article, then, while it does not ignore the continental schools, must be devoted in most detail to the English water colourists.

16th **and** 17th Centuries.—Albrecht Dürer (1471–1528) learned to paint landscapes in water colour and gouache while still an apprentice, and the use to which he put this accomplishment in his maturity marks the beginning of the modern water colour. His landscapes and natural history drawings combine, in a way entirely characteristic of the Renaissance, his reverence for observed fact with his wonder at the works of nature. Accordingly many of them have become classics of the visual arts—the "Young Hare," the view of Innsbruck and the "Great Piece of Turf" in the Albertina at Vienna; the "Alpine Landscape" in the Ashmolean museum, Oxford. His natural history drawings are almost incredibly detailed, but their literalness does not submerge the artist's delight in the complexity of the animal or the blade of grass. The landscape drawings are equally factual, but express a feeling for the arrangement and construction of mountains and for the subtleties of aerial perspective which anticipates the painting of the 17th and 18th centuries.

Lucas Cranach the younger (1515–86) and Hans Holbein the younger (1497–1543) tinted some of their designs and water-colour portraits, but the next main outcropping of water-colour drawing occurred in the Netherlands. There, echoing an established convention in landscape painting, drawings of landscapes were made in contrasting hues of brown and blue washes by such artists as Paul Bril (1554–1626) and Tobias Verhaegt (1561–1631). It was but a short step to introduce a greater variety of colour and to aim at truth of local tone, and we find this extension undertaken by, among others, Roelandt Savery (1576–1639), Hendrik van Avercamp (1585–1663), Adriaen van Ostade (1610–85) and Cornelis Dusart (1660–1704). These drawings were produced for sale as completed water-colour drawings rather than as steps toward the construction of other works of art.

The 18th Century: England. — Whereas the water colours of Diirer and Ostade form only a section of their drawings and a comparatively small portion of their whole artistic output, the chief figures in water-colour painting in England in the 18th and 19th centuries were specialists in this medium. From the first the English landscape water colourists were differentiated into two groups according as their interests were predominantly in the scenery of their own country or that of Italy. The former. led by Paul Sandby, were generally more matter-of-fact in their approach; the latter often infused with their topography a greater imaginative intensity and a composition more closely derived from the ideal landscape of the 17th century. But both groups were versed in the methods of oil painting of Claude Lorrain, Nicolas and Gaspard Poussin and Salvator Rosa, from whom they derived the ideas of picturesque scenery which flavoured their English or Italian views. Already in the 17th century Sir Anthony Van Dyck (1599–1641) had painted water-colour landscapes in England which anticipated the later school in their treatment of atmospheric effect. The predominant characteristics of the forthcoming *floraison* were to be seen in the work of William Taverner (1703–72), an amateur whose landscapes reflect clearly enough the study of Poussin in their balance and their classical *staffage*.

After other early workers in water colour, such as Samuel Scott (*c.* 1710–72), George Lambert (1700?–6j) and John Skelton (d. 1758), came Paul Sandby (1725–1809). Through the length of his career and by the extent to which he concentrated on water-colour painting he was the first English artist in the medium to attain real prominence. His training was a strictly professional one, since he was engaged by the military authorities as a draftsman on the survey of the Highlands which followed upon the suppression of the Jacobite rebellion of 1745. But he soon settled in London and began a busy career as draftsman and as teacher. One of his favourite sketching grounds was the countryside round Windsor castle, and he drew these scenes of unspectacular pastoral charm with a style so natural that it seems more like the pictorial equivalent of conversation than like art. In his travels in Wales he struck upon more conventional picturesque scenery, and he wove motifs drawn from the mountains into more elaborate, Italianate compositions which owe a clear debt to Claude and Poussin. Like his brother Thomas Sandby (1721–98), an architect and a water colourist of less accomplishment, Paul Sandby was one of the original members of the Royal Academy, which was founded in 1768.

The artists who fall into a natural grouping with Sandby are those who were mainly concerned with the landscape and townscape of Great Britain. Michael Angelo Rooker (1743–1801) invested his meticulous study of brick and stone buildings and leafy lanes with a pleasant sympathy for antiquity. Thomas Malton, Jr. (1748–1804), instructed J. M. W. Turner in perspective drawing, and his water colours of London and Bath display elegant groups of fashionable people against a background of Georgian architecture. Edward Dayes (1763–1804) carried on the same urbane treatment of city life against its architectural background, and is notable also because Thomas Girtin, who followed a very different course, was his pupil. Also in this group were Thomas Hearne (1744–1817), who paid a visit to the Leeward Islands as draftsman to the governor; Samuel Hieronymus Grimm (1733–94), a Swiss artist who settled in England; and James Miller, who exhibited views of London from 1773 to 1791.

The artists who traveled to Italy were open to wider experiences: the grandeur of the Alpine scenery through which they passed, the paintings they saw and the cosmopolitan group of artists they met in Rome. They are preluded by Alexander Cozens (1717?–86), who, though he rarely coloured his drawings, evolved the system which his son John Robert Cozens was to infuse with such haunting appeal. John Robert Cozens (c. 1752–97) made two visits to Switzerland and Italy, the second in the train of William Beckford (*q.v.*), the author of *Vathek*. He was perfectly endowed to fulfill the requirements in landscape painting of this romantically minded patron. His technical means were of the simplest; his palette rarely went beyond tones of blue-gray, but was fully adequate to express his feelings of melancholy awe in the presence of the mountains and their mist-filled valleys. Mountains, sublime in their magnitude and unapproachableness, picturesque in their ruggedness, made a powerful assault on the enhanced sensibilities of the age. By entering into these feelings Cozens universalized the sensations of the romantic traveler of the late 18th century. His career was cut short by mental disease and he died insane in 1797; but his influence lived on, for Girtin and Turner were given his sketches to copy and took the key of their sentiments from his.

Francis Towne (1740–1816) was also spurred to his best achievements by his visits to the mountains—to the Welsh hills in 1777, to Italy and Switzerland in 1780 and 1781 and to the English lake district in 1786. His response to the scenic grandeur of these districts found expression in a uniquely personal style. Where Cozens was all evanescence, Towne was all precision of outline; he used a firm pen line to isolate areas of contrasting colour and presented the view in a subtly calculated and carefully balanced pattern. William Pars (1742–82) visited Greece as as draftsman for the Society of Dilettanti and was later sent by that body to study at Rome. His works give an individual interpretation of the Italian scene which is in somewhat the same key of romanticism as those of Cozens and Towne; but William Marlow (1740–1813), and John "Warwick" Smith (1749–1831) are more prosaic interpreters of the same subjects.

A link between the greatest achievements by the 18th-century water colourists and the new generation was provided by Thomas Monro, who displayed a remarkable flair for choosing young men of talent to copy drawings by J. R. Cozens and other water colourists. Among those who attended his house were Thomas Girtin, J. M. W. Turner, John Sell Cotman, John Varley and Peter de Wint. Of these the career of Thomas Girtin (1775–1802) alone falls almost entirely within the 18th century; the others are considered later as part of the 19th-century development of the English school of water colour. Girtin died young, but not before he had achieved maturity in his art. Apart from subjects, largely architectural ones, suggested by his visit to Paris, his material was derived from the landscapes of England and Scotland, notably the Yorkshire dales. There he had none of the usual romantic symbols—mountain peaks and chasms—to assist his effect; but he communicated serenity and a sense of the unlimited through his extraordinary command of space and ability to draw wide rolling vistas. Like Cozens he aimed at variegation of tone rather than truth of local colour; but his prevailing colour key of brownish-gray reflects his more sanguine temperament.

Of the draftsmen who inherited the tradition of English humour exemplified by William Hogarth and James Gillray, Thomas Rowlandson (1757–1827) was the most prolific. He compromised his reputation by producing a mass of inferior drawings in his later years, but the works of his prime are outstanding in the vitality of their outline and the gusto of their comment on human foibles.

William Blake (1757–1827) is a remote and lonely figure amid the landscape painters and figure draftsmen of his time. Painting was his most articulate means of expressing his mystic intuitions of the grandeur of the universe, the strength of rebellion, the innocence of childhood. He bounded his figures with long flowing lines and adjusted the colours to the peacefulness or terror of the action. The opportunity given him late in life to illustrate Dante's Inferno resulted in one of the few completely satisfying transmutations of literary into pictorial art.

The 18th Century: the Continent. — The monochrome drawings of Claude have a range of warm tone which almost places them in the same category as the drawings of Cozens and Girtin; they had a far-reaching effect on the development of the English school. But though the rococo artists of France were far from feeling any aversion to colour, they satisfied this taste in their drawings largely by the use of sanguine and coloured chalks.

The French vignettists often tinted their exquisite illustrations of contemporary fashionable life; for example, Jean Michel Moreau (Moreau le Jeune) (1741–1814), Charles Eisen (1720–78) and Charles Nicolas Cochin (1715–90). Gabriel de St. Aubin (1724–80) had an especial ability in rendering crowds and fashionable interiors by the simplest means; and the Swedish-born Nils Lafrensen or Nicolas Lavreince (1737–1807) used gouache for his minute paintings of *galant* scenes. An impetus toward landscape drawing was given by the growth of neoclassical feeling in France in the second half of the 18th century and the consequent encouragement to artists to visit Rome. Charles Joseph Natoire (1700–77), who became director of the French academy at Rome, made both figure drawings and landscapes with water-colour embellishments. Among the artists who studied in Italy were Hubert Robert (1733–1808), who was fascinated by the crumbling architecture of antiquity. and Jean Louis Desprez (1743–1804). Desprez prepared many drawings for the abbé de St. Non's works on his Italian travels. These drawings have a delicacy of outline and liveliness of colour which made them admirable models for rendering in hand-coloured etchings; they show the lighter touch of the French admiration for the picturesque.

In obedience to a widespread movement of taste the Swiss were awakening to the romantic beauties of their scenery. Johann Ludwig Aberli (1723–86) made tastefully composed drawings with delicate atmospheric effect and had as pupils Johann Biedermann (1763–1830) and Heinrich Rieter (1751–1818). Sigmund Freudenberger (1745–1801) won great popularity with his idyllic scenes from peasant life. Louis Ducros (1748–1810) took his place in Rome among the cosmopolitan group of landscape artists, including the German Philipp Hackert (1737–1807), who were well patronized by the international visitors to Italy; not least by English travelers. However, the Germans practised a more minute and detailed approach to landscape painting than was favoured by the English artists in Rome.

Meanwhile the Dutch were pursuing their own course in a direct line from their great days in the 17th century. Cornelis Troost (1697–1750) has been compared with Hogarth, and his humorous genre is carried out in a variety of methods. including water colour. The topographical draftsmen, such as Jacob Cats (1741–99) and Johannes Huibert Prins (1758–1805), took Dutch town life as their subject and treated it with a quiet meticulousness which brings it close to the work of Michael Angelo Rooker and Thomas Hearne.

The 19th Century: England. — Patronage for water colours increased greatly in the 19th century. This development was not entirely beneficial to the art, since the wealthy new class of patrons required highly finished pictures which could hold their own with oil paintings and which represented places of obvious picturesque appeal. A symptom of the changing field of patronage was the foundation of the Old Water-Colour society in 1804 by a group of artists who were dissatisfied with their treatment at the hands of the Royal Academy.

John Varley (1778–1842), a foundation member of the society, is a characteristic figure. He was a deliberate exponent of a formula for picturesque composition abstracted from the practice of Claude and Poussin. He was an extremely fast worker, and though his drawings are neat and individual in style they are somewhat arid and lacking in fire. Other successful men of his generation are Joshua Cristall (c. 1767–1847), George Barret, Jr. (*c.* 1767–1842), and John Glover (1767–1849).

Soon after its foundation the Old Water-Colour society received its most important recruits in David Cox and Peter de Wint. David Cox (1783–1859) matured into an artist with a preference for passing atmospheric effects — the wind across the heath or storm clouds above the sea — which he treated with an energetic breadth of brushwork and a rich palette of transparent colour. Peter de Wint (1784–1849) had a temperament which felt more kinship with the underlying structure of the landscape and its enduring substratum. He chose for his subject matter what would have seemed the most unpromising material — the flats of the English midlands, seldom varied except by a prominent building or clump of trees. Yet to these pastoral scenes he brought a sense of construction and space akin to Girtin's (whose work he had studied in Monro's house) and a fondness for rich deep colour, predominantly a strawberry roan; and with these simple materials he gives a tranquil and satisfying transcription of the workaday agricultural English countryside.

The reputations of John Sell Cotman and Samuel Palmer did not stand so high in their lifetimes, but have increased ever since, with better knowledge of the independence and originality of their early work. John Sell Cotman (1782–1842), a Norwich artist, saw in nature the classic and monumental effect of precise, austere pattern. He expressed this effect in perfectly controlled flat washes of cool colour, eliminating inessentials and leaving only what is balanced and universal in the scene. His halcyon days followed early visits to Yorkshire; but he had an unstable temperament and was not able to recapture indefinitely, in the face of lack of encouragement, the masterly control of his early years.

Samuel Palmer (1805–81) was one of a group of young men who met Blake in his old age and were influenced by his dedicated character. The moment of vision came to Palmer with his early visits to the Kentish village of Shoreham. Out of the experiences he had in that valley he constructed a world of his own, echoed by rich inventiveness in technique and variety of colour.

Richard Parkes Bonington (1802–28) succeeded in summing up all the tendencies of his time in his short working life span, most of which was passed in France. His water colours are marked by facility and a certain fragile brilliance. Particularly deft in the rendering of architecture, he had many followers in France and England, the most notable of the latter being Thomas Shotter Boys (1803–74), James Holland (1799–1870) and William Callow (1812–1908). A heavier but even more popular exponent of picturesque views of foreign cities — artistic souvenirs for the widening circle of travelers abroad — was Samuel Prout (1783–1852).

Meanwhile Joseph Mallord William Turner (1775–1851) was pursuing his brilliant, chameleonlike career through manifold phases and experimental advances. His drawings up to about 1800, with their harmonious tones of green, blue and gray and their skillfully exact drawing of architecture, are in the 18th-century style, the style of Rooker and Dayes, carried to its quintessence. In the most characteristic drawings of his middle period he aimed to give a generalized impression of the city or the scene he was rendering, rather than adhere to topographical exactitude. The immense range of his subjects reflects his aim for complete comprehensiveness in the types of picturesque scenery. These drawings glow with brilliant colour, their brightness being achieved by minute stipplings in which the white paper peers through the dots of colour. No doubt this discarding of broad washes for a closely modulated surface was suggested to Turner by the greater ductility of oil paint. This development was not all gain in the hands of Turner's successors, for it led to finicky neatness and lack of amplitude in Anthony Vandyke Copley Fielding (1787–1855) and Myles Birket Foster (1825–99); but Turner's virtuosity enabled him to wrest some of his most striking achievements from this method. In his last phase of water colour, as in his oil painting. he passed beyond details into an abstraction of colour and light. "Turner," said Constable—himself an accomplished water colourist—"seems to paint with tinted steam, so evanescent and so airy."

Water-colour painting does not play so large a part in the full history of English painting in the second half of the 19th century. James Duffield Harding (1797–1863) and his pupils produced drawings of foreign beauty spots with some liveliness of handling; but generally speaking the most popular specialists in the medium were unadventurous and given to overelaboration. The more interesting work was produced by men who were primarily oil painters. For instance the Pre-Raphaelites brought their medievalism of approach to drawing with the result that the water colours of Dante Gabriel Rossetti (1828–82) and Sir Edward Burne-Jones (1833–98) glow with the colour of stained glass and owe their poetry to their conscious archaism. Again, James Whistler (1834–1903) opposed the literary element and reverted to simplicity in place of overstatement; his water colours are broad in treatment, reticent in detail and delicate in colour.

The 19th Century: the Continent.—The leaders of the romantic movement in France were filled with the resolve to seek material in the most unlikely places; and this intention no doubt accounts for the unwonted popularity of English art and a corresponding curiosity about water colour, a medium the English had made peculiarly their own. Eugkne Delacroix (1798–1863) had as friends in Paris both Bonington and Thales Fielding (1793–1837), a brother of A. V. Copley Fielding; the interest he felt in their methods is reflected in his sketchbooks of north African scenes, some of the pages of which are carried out in water-colour washes of the freest kind. The influence of Bonington was not confined here. Camille Corot was so attracted by seeing one of his water colours in a Parisian dealer's window when running an errand that he decided to become a painter himself. Camille Roqueplan (1800–55) painted shore scenes and romantic groups in historical costume in just Bonington's manner and the seascapes of Eugkne Isabey (1803–86) are equally of Bonington's circle. In his turn Isabey influenced Louis Eugène Boudin's lively water-colour groups. so something of English art entered directly into the stream of French Impressionism.

Among the figure draftsmen, Louis Eugkne Lami (1800–90) enjoyed success both in Paris and in London with his pictures of fashionable life, which give an accomplished and tasteful picture of the glittering externals of society. A more mordant observer, Honoré Daumier (1808–79) turned from his lithographs to treat in coloured draaings, as in oil paintings, the sombre scenes which possessed his mind. Paul Gavarni (1804–66) and Constantin Guys (1802–92) produced poignant renderings in wash of Parisian life.

Toward the end of the century Gustave Moreau (1826–98) found water colours an adaptable medium for the expression of the jeweled decadence with which he interpreted such subjects as "Sappho" and "Salome." In complete contrast to the enameled colour and ingrown morbidity of these works are the contemporary landscapes of Henri Harpignies (1819–1916), in which the broad controlled washes and selective sense of colour are the final working out of the manner taken over by Isabey and Boudin.

Meanwhile in the Netherlands Josef Israels (1824–1911) was an exponent of social realism in his sombre studies of peasant life. Other well-known Dutch painters of the second half of the 19th century to practise in water colours were Johannes Bosboom (1817–91), Johan Jongkind (1819–91), Jacob Maris (1837–99) and Anton Mauve (1838–88). In Germany Adolph von Menzel (1815–1905) applied his immense graphic gifts to water colour as well as to lithography and pencil drawing; and Eduard Hildebrandt (1818–67) traveled round the world for exotic landscapes. In Austria Rudolf von Alt (1812–1905) used the medium with effortless accomplishment.

The 20th Century.—The artistic history of the first half of the 20th century was enlivened by the battle between traditionalists and revolutionaries. New ideas of form derived from an increased knowledge of primitive art prompted a re-examination of the fundamental principles behind painting. But into this revolution water colour only entered incidentally. Already in the 19th century Paul Cézanne (1839–1906) had worked out his extremist abstraction from landscape in his late water colours. Paul Signac (1863–1935) applied Pontillist theories in his water colours. Raoul Dufy (1877–1953) painted scenes with bright bold expanses of local colour. The German Expressionists, such as Christian Rohlfs and Emil Nolde, found the fluidity of the medium well adapted to their emphatic methods. Water colour was an essential element in the world of whimsical fantasy invented by Paul Klee (1879–1940). In England Paul Nash (1889–1946) combined romantic feeling for landscape with an austere analysis of form, and in so doing showed himself to be in the main tradition of English water colour.

THE UNITED STATES

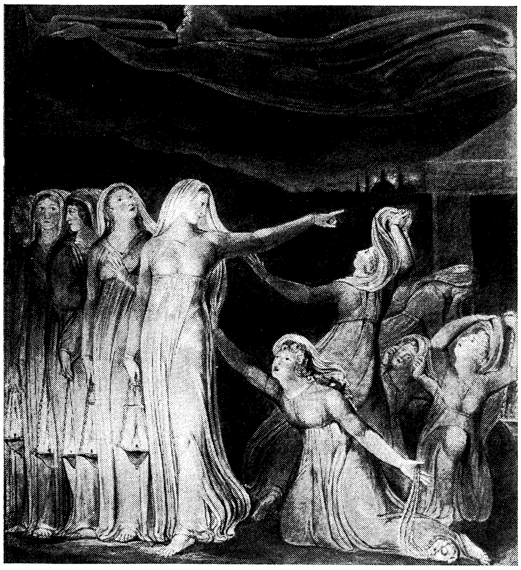
Early History.—In the new world water colour was used by those of the 16th-century explorers who could draw and wished to add colour to their observations of the aborigines, their dwellings, and the landscape; but a continuous tradition can hardly be traced to anything earlier than the heraldic painters who traveled up and down the American colonies in the 18th century, drawing and tinting achievements of arms to hang in the entrance halls of houses whose owners claimed gentility. The likeliest stimulus to real artistic activity in the medium was the military engineer or the chart maker who delineated coast lines; these men and the surveyor had some training in a journalistic sort of drawing, and they commonly used colour, if only as a local tone within pen outlines. Pierre Charles l'Enfant (1754–1825), designer of the Washington, D.C., city plan, was one such competent performer, though a late one.

By the time when there began to be a small leisure class, British drawing books were available which told young ladies how to sketch, giving neat formulas for foliage and clouds. Carington Bowles' *The Artists Assistant,* which had run to five editions in London by 1788, had a sixth in Philadelphia in 1794. David Cox's book of 1813 and Samuel Prout's of 1819 had a ready market. An early example of original U.S. publication is Fielding Lucas' *Progressive Drawing Book*, published in Baltimore in 1827, which has some explanatory colour plates; it was followed in 1835 by Rembrandt Peale's *Graphics.*

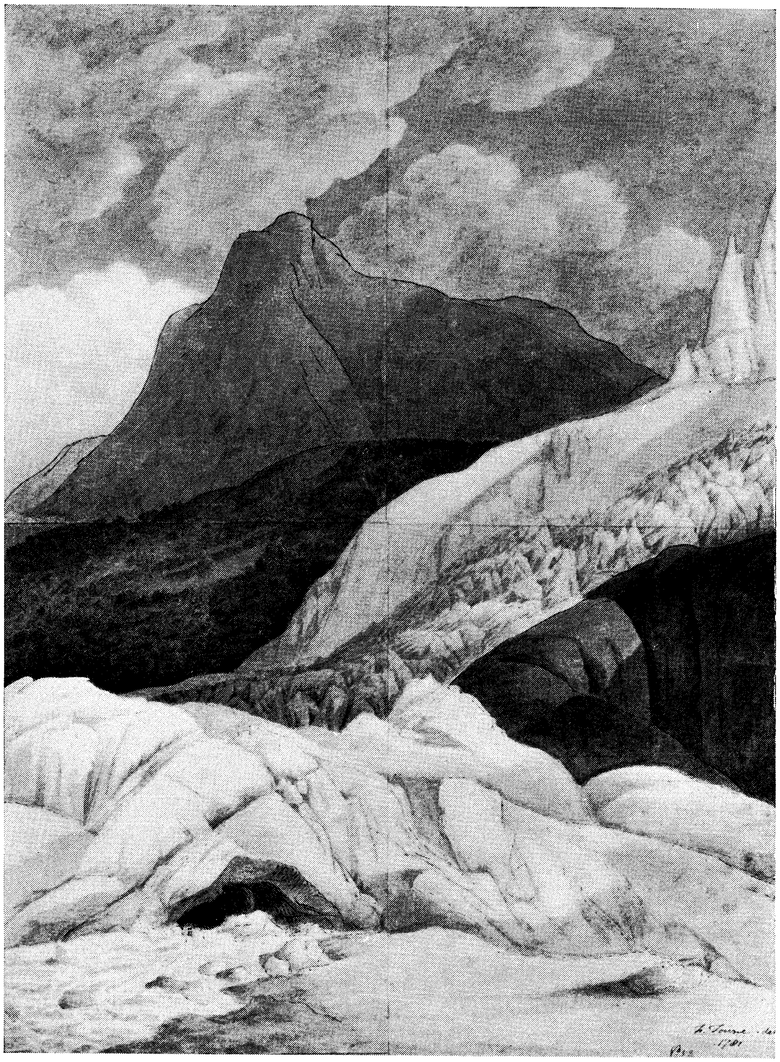
Further, the itinerants of the 18th and the early 19th centuries who painted the American, his family, his ox and his ass, his house and his barn, often used water colours for their less ambitious portraits. These were likely to be outline drawings filled in with tints, but many exist into which some inkling of the floodings and shadings of the professional technique crept, so that tones are often saturated toward the edges of their areas, and diluted within.

John Trumbull (1756–1843) and William Dunlap (1766–1839), early biographer of U.S. art and artists, were among the first native professionals. Both used water colour on a small scale. but largely as a pastime on their portrait-painting travels; yet, unlike the engineers, they drew with the brush. The Wiirttemberg immigrant, John Lewis Krimmel (1787–1821), made many records of U.S. city life, notably in Philadelphia; his work, often on a line-drawing base, did however exploit the wetness and translucency of water colour. The Russian diplomat Pavel Svinin made many large documentary water colours of similar subjects from 1811 to 1813. Around Charleston, the miniaturist Charles Fraser (1782–1860) made charming, small colour sketches of the houses he visited between 1796 and 1806. Henry Inman (1801–46) occasionally painted small portraits in water colour.

It is hard to tell how much immediate influence upon U.S. practice came from the superb records of western Indians and landscape made by such a man as the Swiss painter Karl Bodmer (1809–93) whose hundreds of dra ings were taken by his patron to Germany where a small part of the bulk was published as illustrations.



"The Wise and Foolish Virgins" by William Blake (1757–1827). Water-colour with pen and ink. In the Metropolitan Museum of Art, New York city



"The Source of the Arveiron" by Francis Towne (1740–1816). In the Victoria and Albert museum, London

George Catlin (1796–1872) and Alfred J. Miller (1810–74), Americans, did much the same sort of work; Catlin at least saw to his own publication. The great man of the time was. however, John James Audubon (1785–1851), born in Haiti and brought up in France and Pennsylvania, whose grand work *The Birds* of *America* (Lohdon, 1827–38) results from a combination of French style (in the tradition of Louis Gabriel Moreau (l'aine), Jean Pillement, Louis Debucourt and Louis Boilly) with American frontier aggressiveness and British capital and aquatinting skill The original water colours (mostly at the New-York Historical society) possess the necessary ornithological precision and an enchanting fertility in composition, along with a succession of backgrounds which portray the American landscape in many regions and moods.

Thus, up to the middle of the 19th century, most United States water colours were by-products, or amateurs' work, or were intended for reproduction. Certain of the best painters of the mid-century used water colour occasionally: William S. Mount (1807–68) sometimes recorded landscapes or invented compositions, and George Caleb Bingham (1811–79) made many figure studies with the brush and diluted ink, but seldom in colour.

Late 19th Century and After. — In the second half of the 19th century, there was a vast activity in emulation of Girtin, Cotman, Turner, Cox and de Wint. In half a dozen eastern cities there were water-colour societies; one, founded in 1866, was attracting by 1873 many British as well as U.S. painters to its annual exhibition. It is against this routine background that the truly distinguished men should be seen.

The uncompromising naturalist Thomas Eakins (1844–1916), though he restricted himself almost wholly to oil painting after about 1890, was a master of the water-colour medium, in which he presented sport and urban genre. His technique was one of rather small strokes which seldom overlapped very much, so that the tone is blond and the surface rather uniform. Winslow Homer (1836–1910) might be called a counterblast to Turner, who often used oil as if it were water colour; Homer was such a virtuoso of water colour as to raise it to the stature of oil painting. His early lithographic training and his practise in drawing as a Civil War correspondent gave him, when he turned to water colour in the 1870s, the base for an extraordinary graphic language. His eye for nature and for the outdoor life of man combined with his manual skill and sense of scale and drama in a long series of "essences," seized from children's games, sailing and hunting, the Caribbean shore and mountain picnics, in which he created almost the whole later conduct of representational U.S. water colour. Though his work. in contrast to that of the societies' neat practitioners, was labeled "unfinished" or "of mistaken eccentricity," his muscular grace, feeling of articulation and monumentality, his soaking wets and dragged drys, his eloquent blank areas and his accents of *gouache,* all triumphed over the tasteful dappling of his contemporaries.

Among the more conservative, George Inness did a good many *gouaches.* J. F. Cropsey. Alexander Wyant, Thomas Moran and the Barbizonlike Homer Martin (1836–97) sometimes painted in water colours, but their chief work was to acquaint Americans with their landscape. Their expatriate contemporary Whistler (1834–1903), already mentioned above, was far from "professional" in handling: he used water colour in flecks and patches, sometimes with pastel in combination, or on toned paper, and these works were not so wet looking or translucent as some of his Japanesque oil paintings in close harmonies. John La Farge (1835–1910), best of eclectics, was brought up in the arts; he made hundreds of water colours in Japan and the south seas as well as at home and in Europe before his great success in decorative undertakings (from 1876) plunged him into other work. His method was thorough without being stuffily academic.

French Impressionism made an entry into the United States not only by the importation of Monets but also through Theodore Robinson, John Twachtman and Childe Hassam (1859–1935). Of these only Hassam was a prolific water colourist, and he was so deep in good taste as to have more charm than power. The man who gave Impressionism real stature and a different accent was Maurice B. Prendergast (1859–1924). He developed a personal language of figures in landscape, in which half-floating ovals and squarish areas of colour. hats and trees, balloons, carriage wheels, and clouds. became elements of both a decorative pattern and a lighthearted picture. Prendergast kept a feeling of youth and romance all his life. Arthur B. Davies (1862–1928) was a poetic eclectic who derived from Whistler. Puvis de Chavannes, and the orient a dancelike. trancelike style often executed in blond (*gouache* lightened) areas on toned papers. Both these men were temporarily associated with the Ashcan school of New York, 1908, but the central men of that group used a fairly dark palette and thus tended away from water colour. Everett Shinn (1876–1953) and John Sloan (1871–1951) did come to it, the latter for some of his humorous scenes from stylish and unstylish life, the former for luminous: often nocturnal, cityscapes in mixed techniques with *gouache* and pastel. George ("Pop") Hart (1868–1933), self-taught and a great traveler, exercised the genre tradition upon Mexican villages, U.S. small towns, cockfights and a thousand things, using water colour almost exclusively.

As a relaxation from his labours at fashionable portraits and. later, monumental murals. John Singer Sargent (1856–1925) carried water-colour materials with him and painted impromptu when he had spare time; on paper his virtuosity is almost free of the pretentiousness which troubled his canvases. With stenographic brilliance he pursued transparency and fluidity beyond Turner and Homer, sometimes becoming prophetically or accidentally expressionistic, as in his rapid notes of forest fires. An interesting Boston group rose in the following of Homer and Sargent: the seascapist Charles Woodbury (1864–1940), Dodge MacKnight (1860–1950), influenced by Chinese brush drawing to create an open, not quite calligraphic but rather bristly economical landscape style; and Charles Hopkinson (1869–1935), like Sargent a portrait painter, who pursued the blinding sun-struck appearance of rocks and sea in abrupt close-ups not so emphatically structural as Marin's work. Marsden Hartley's (1877–1943) emotional response to landscape produced massive simplifications, a tilting up of the ground plane. and sometimes glutted colour; Arthur Dove (1880–1946) moved to almost fully abstract geometrical forms having something of the passion of Frans Marc. Through them the way from Impressionism of the Hassam-Sarpent-Hopkinson manner led to Expressionism, and was recapitulated in Max Weber (1881–1961), who worked his way in water colour and oil through Cubism to abstraction and Expressionism, all of which he adorned with emotional gesture and a racial reference different from the sometimes coy whimsicality of Marc Chagall (1887–).

The giant Expressionist in water colour was John Marin (1872–1953), whose early architectural training and technical labour at etching provided strength and sensitivity. His work was a rugged, concentrated structure of strong paper (seldom large), flatness of detail which managed to allow depth in composition; economical broad blunt strokes. often isolated; somewhat neutralized colour with one or two sharp accents. The compositions are often "self-framed" with jagged strokes using the same language as the subjects, which are the essence of sea, rock, sky, sun, sailing ship and pine tree. Marin's personality, akin to Winslow Homer's and to Frank Lloyd Wright's, kept the romantic part of traditional American romantic realism without the realism.

Lyonel Feininger (1871–1956) was a sort of sharp-edged diminuendo of Marin; his areas of colour seldom coincided with his criss-crossing structural pen lines. A technically similar combination with very different effect was the delicate pencil outlines and deeply suffused washes of Charles Demuth (1883–1935), whose delicious still lifes and half-Cubist half-Futurist interpretations of U.S. buildings brought him the nickname of "immaculate." Personal views of the U.S. scene were also the country of Edward Hopper (1882–) and Charles Burchfield (1893–). Hopper's gaunt buildings, somehow nobler if ugly than if meretriciously pretty, seem at first as if painted in their denotation. but then people or atmospheres about them begin to be noticed: it is Eakins with a psychological undertone. Burchfield's more patently subjective animated buildings. railway cars and trees have musical and even ideographic suggestions. Giving background to these inventive men is a body of highly skillful landscapists. Ogden Pleissner, Eliot O'Hara, Millard Sheets, John Whorf, Paul Sample, all born near the turn of the century, all incomparable craftsmen who sometimes rose above journalism. Dong Kingman (1911–), usually working in *gouache,* is a witty variant. Adolf Dehn (1895–), a sound nater colourist, fell foul of the public's pleasure in some limited fields of satire. Reginald Marsh (1898–1954) used a water-colour technique, but largely in tempera on panel, for his monumentally made but half-satirical half-sympathetic urban pictures.

An explosive group of showmen, using large paper, strong colour dropped on already wet areas and sometimes casein, *gouache* and negative techniques, includes the German-born social commentator George Grosz (1893–1959), William Gropper (1897–), who has known some oriental influence, the decorative Expressionist Lanrence Kupferman (1909–) and the German-born Hans Hoffmann (1880–), who as a teacher has influenced many abstract painters. A calmer, rather mystic group in the northwest includes Mark Tobey (1890–) of the white-line calligraphy and anxious detail. Morris Graves (1910–) of the secretly sorrowing birds and Kenneth Callahan (1907–) of the whirling or floating Blakelike figures. Reuben Tam from Hawaii (1916–) paints ideographlike trees and rocks.

Georgia O'Keeffe (1887–) stood alone with her semiabstract and often greatly enlarged details of natural objects (flowers or desert jetsam), poignant and feminine but not womanish, and sliced from life and enclosed as if in the range finder. Ben Shahn (1898–) is more likely to use tempera or casein, as Marsh did, but with the humanist's eye rather than the decorator's bravura.

TECHNIQUE

Water-colour paint, which includes not only transparent water colour but the opaque methods commonly known as *gouache* and casein, has a range and variety comparable with any other painting method.

Transparent water colour allows for a freshness and luminosity in its washes and for a deft calligraphic brushwork which makes it a most alluring medium. Too often artists, dazzled by the ease of attaining atmospheric effects, degenerated into creating slight and pretty transcriptions of nature. Consequently water colour mas condescendingly thought of as the anemic and gaudy little sister of oil painting.

During the 20th century, especially after 1940, a revitalization in water-colour painting came about. The painters liberated themselves of tight purists' notions and started adding ink, pencil, pastel, crayon and opaque white to gain new effects. Henry Moore was one of the leading innovators. The biggest change came in the general use of *gouache* and casein colours. As a result the average water-colour exhibition probably contained more opaque than transparent water colours and acquired the same serious respect which oil painting had always had.

There is one basic difference between transparent water colour and all other heavy painting mediums—its transparency. The oil painter can paint one opaque colour over another until he has achieved his desired result. The whites are created with opaque white.

The water colourists' approach is the opposite. Instead of building up he leaves out. The white paper creates the whites. The darkest accents may be placed on the paper with the pigment as it comes out of the tube or with very little water mixed with it. Otherwise the colours are diluted with water. The more water in the wash, the more the paper affects the colour; for example, vermilion, a warm red will gradually turn into a cool pink as it is thinned with more water.

The knowledge which comes through much experience, of how all colours change through dilution and the awareness that the wet wash is fresher and brighter than the dried-in wash, is necessary to successful painting. Timing—knowing when to place a wash of one colour next to a wash of another colour or over it—requires experience. If the original wash is very wet a complete merging of the two will occur: if it is still damp the edges will become fuzzy; if it is dry the newly laid wash or line will be sharp and clear.

Laying an even wash over a large area, as in a sky, should be done rapidly with a big flat brush so that one stroke is placed against the preceding one before it will have dried into the paper. If the whole area is dampened with water beforehand it can be covered with greater ease. If a graduated wash from light to dark is desired, the wash can be spread upward by starting with the lighter colour and gradually intensifying it to the darkest tone. Then by tilting the drawing board at a 45° angle, an even merging of colour will occur.

Although the most unique and beautiful attribute of water colour is the luminosity of the washes and the skillful calligraphy of the brush strokes, some painters deliberately glaze over certain colour areas with thin washes, thereby destroying some of the luminosity of such areas. The resulting heavier and more mat surface in the ground area of a landscape sets off the luminosity of the sky.

Scrubbing out colours partially or completely with a dampened sponge creates fuzzy atmospheric effects which may be desirable. The hard surface of the paper is lost, however, and transparency is lessened.

The dry-brush technique—the use of the brush containing pigment but little water, dragged over the rough surface of the paper—creates various granular effects similar to a crayon drawing. Whole compositions can be made in this way. This technique also may be used over dull washes to enliven them.

A razor blade is a valuable tool. The blade dug into a wet wash will create different textures as in foliage. Absorbent tissues can be used effectively to create shapes, as in clouds, by pressing the tissue onto the wet wash and lifting the colour.

It is often said that transparent water-colour painting is the most difficult medium of painting. Great knowledge and experience plus a nimbleness of hand and brain are required for success. The water-colourist may start with a well-conceived plan of action but should always be ready to shift his approach if, and most probably when, the washes run away from him. He must then be able to use the new possibilities which the unforeseen makes possible, thus remaining master of a situation which might otherwise cause failure.

Gouache Painting.—In contrast to transparent water colour, *gouache* (*q.v.*) painting is considered an easier medium to manipulate; though the painting can be developed with the same directness and speed. However, the use of opaque colour will allow for several layers of paint until the results are satisfactory. The *gouache* pigment has a soft pastel quality which makes for ingratiating colour relations. The painting of diluted washes over existing colours merges the two layers into unexpected passages of colour. *Gouache* and transparent colour can be used successfully in the same composition.

Casein painting came into general use about 1940. Casein is an opaque medium; when it is thoroughly dry it is not soluble in water and the chroma is at full intensity (no white loading as in *gouache).* Casein may be used with less water than *gouache,* creating a heavy impasto if one thick layer is laid over another. A palette knife or bristle brushes may be used to attain effects similar to those of oil painting. Such casein pictures, if varnished or waxed, are difficult to distinguish from oils. The quick drying of casein is sometimes considered a disadvantage, in that it is difficult to attain details and nuances of shading. Many painters develop their pictures in casein and then, after varnishing, finish the picture with oil. *(See* also TEMPERA: *Casein Painting.)*

Paper.—Water colour can be applied to almost any paper, but for most purposes the rag papers made especially for water colour give the best results. These papers are of different weights. generally running from 70 to 300 lb. to the ream. All papers of 140 lb. and less should be stretched, otherwise they will buckle, which makes for uncontrollable washes.

A good quality illustration board faced with heavy water-colour paper is generally used for gouache. Casein can be used on heavy illustration board as well as gesso panels.

Brushes. — The best sable brushes are expensive but durable and should always be used if possible. A large no. 10 or 12 round brush and two or three smaller ones are sufficient. A large flat one-inch brush for laying large washes and getting straight edges is important. The same brushes are used in *gouache* painting. Bristle brushes also can be used and in casein painting they are used almost entirely.

Water-Colour Paints. — The paints come in tubes and cakes. Cake colours in a box are handy and can be used for small outdoor sketches; otherwise the tube colours are quicker and easier to handle and are recommended.

The colours are generally listed as permanent, durable and fugitive. The fugitive colours may fade quickly and should be avoided as much as possible.

Limiting the palette to the fewest colours is wise. A surprising range can be obtained with five or six. Such a palette might consist of cadmium yellow, Hooker's green, prussian blue, burnt sienna, alizarin crimson and ivory black.

A comprehensive palette for all purposes might contain a dozen colours. The following make up one possible list: yellow ochre, cadmium yellow, Hooker's green dark, chromium oxide dull, vermilion, alizarin crimson, cobalt blue, prussian blue, burnt sienna, warm sepia, Payne's gray and black.

(A A D.; W. A.)

WATER CRESS (Nasturtium *officinale*), an aquatic plant of the mustard family (Cruciferae; *q.v.*), native to Europe and Asia, common in Great Britain, widely naturalized in the Cnited States and Canada and introduced also into the West Indies and South America. It is a creeping or floating perennial, rooting in clear. cold running water. with leaves composed of a few to several small rounded leaflets and elongated clusters of small white flowers. Its slightly pungent flavour is caused by an oil containing sulfur. Water cress is cultivated for the market in shallow streams or in prepared shallow pools of running water. These pools, called beds, have carefully graded bottoms and provision for controlling the depth of water up to about two feet. Water cress is propagated by both seeds and stem cuttings. It is widely used as a garnish and green salad, but relatively small quantities are grown for sale. (V. R. B.)

WATER DEER, Hydropotes *inermis*, a small, harsh-haired deer from eastern China and Korea. differing from all other Cervidae except the musk deer (with which it has no special affinity) by the absence of antlers in both sexes. Instead the males are armed with long, daggerlike upper tusks (see DEER). Four to seven young are born at a time, a unique condition for the hoofed, herbivorous order Ungulata.

Water deer frequent the neighbourhood of the large Chinese 'rivers, where they crouch amid the reeds and grass. When running, they arch their backs and scurry away in a series of short leaps. The water deer is one of the few deer in which there are glands neither on the hock nor on the skin covering the cannon bone. These glands probably enable deer to ascertain the whereabouts of their fellows by the scent they leave; but the subaquatic habits of the water deer render such a function impossible. The tail is a mere stump. (J. E. HL.; X.)

WATERFALL, the precipitous descent of a stream over a very marked steepening of its bed. The declivity may be so steep that the stream leaps from the waterfall brink and drops freely in air, making contact with a rock bottom again only after passing the site. If the descent is less steep and the stream maintains contact with rock bottom, the term cascade is commonly applied, even if the stream at that place is largely a series of little falls. Rapids are produced where still less marked declivities interrupt the stream's gentler gradient. They are characterized by increased velocity, great turbulence and a broken surface of the stream. The term cataract is generally limited to waterfalls of large volume. Scenic value of a waterfall lies more largely in its height, however. than in voluine of water descending over the declivity.

The energy of a waterfall causes vigorous erosion in whatever kind of rock may constitute the stream bed. At the foot of a free fall there may develop a plunge pool type of pothole unless, perchance, the fall is so high and the volume so small that the water becomes largely dissipated as spray or mist. Niagara, discharging from four of the five Great Lakes of North America, has a plunge pool reported to be deeper than the cataract is high. Bridalveil falls in Yosemite, Calif., is typical of many small mountain stream falls in losing most of the ability to erode by scattering of the water in the 620 ft. of air it traverses on the way down.

Any cataract, cascade or rapid interrupting the even slope of a river's gradient is the consequence of special conditions at its site. The most common condition is that of a resistant rock stratum

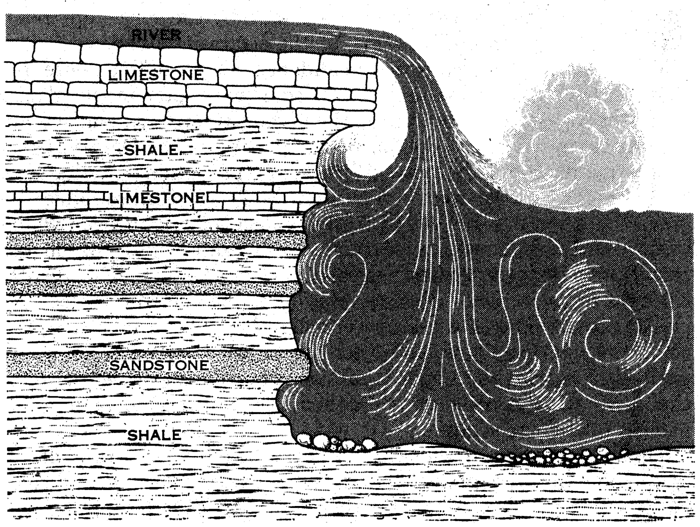

DIAGRAM ILLUSTRATING GEOLOGIC CONDITIONS AT NIAGARA FALLS

overlying a weak stratum, the edges of both being exposed in the declivity over which the stream descends. More rapid wastage of the subjacent weak rock. both by direct erosion by the tumbling water and by enlargement of the plunge pool, causes a constant undermining of the resistant stratum above until such recession of the exposed edge of the weak rock removes it far enough back under an overhang to bring the erosion on both rocks to a common rate.

Niagara Falls. — Destructive attack on the underlying weaker rock of such a cliff, over which a vertical fall plunges, may be severe even though the water so overleaps it that visitors may clamber back of the fall as in Niagara's Cave of the Winds. Spray constantly wets the cliff face and wintertime freezing in crevices disrupts the rock into loose pieces that are swept away. This causes a constant enlargement of the space behind the fall, particularly in the exposed face of the weaker rock. The more resistant lip of the waterfall, thus undermined, breaks off from time to time and the site of the waterfall actually recedes upstream. The American falls, the smaller of the two into which Goat Island divides Niagara falls, lost a mass of lip rock 150 ft. long in one fall. Horseshoe (Canadian) falls carries a greater voluine of water and thus its greater average rate of recession is responsible for its shape. Its continued rate of recession should sometime leave the American falls dry. They are now on the side, not at the end, of the lengthening gorge.

The Horseshoe falls recede in this fashion at an average rate of about four feet a year and therefore annually lengthen the gorge downstream from the great cataract by that amount. The gorge is about 73 mi. long. This length would afford a rough measure of the age of the falls if the rate of recession had been the same since the Niagara river, on the retreat of the great Canadian ice sheet, first spilled over the escarpment at Lewiston and Queenston. Volume of water, however, has been much less at times because the upper three Great Lakes have discharged by other routes to the St. Lawrence, only Lake Erie water then going over the falls.

Details of the complicated history of Niagara falls have been the subject of many studies made by both Canadian and United States geologists, and that history is not yet completely known. The falls took origin when the retreating front of the ice sheet exposed the pre-existing cliff (the Niagara escarpment) and also provided a lower discharge route for melt water dammed back of the ice front in the Michigan, Huron and Erie basins. In earlier retreatal stages, the discharge of these glacial Great Lakes had been to the Mississippi, by way of the Wabash river (Erie basin), the Illinois river (Michigan and Huron basins) and the St. Croix river (Superior basin).

Furthermore, the height of the initial Niagara, at Lewiston and Queenston, was perhaps twice that of the modern falls. The lowering of Niagara's height which took place during its recession and the production of the gorge was caused by the gentle upstream dip or decline from horizontality of the strata involved.

But the early Niagara was abandoned as an outlet route for Michigan and Huron basin overflow somewhat later in the glacial retreat because a lower route, the Trent river, was uncovered, leading eastward out of the Huron basin to enter the Ontario basin downstream from the falls. With only the volume of the Erie basin discharge, the rate of recession at Niagara must have decreased. Then began a widespread uplift in the region from which the great ice sheet was retreating, a differential uplift which became progressively greater toward the northeast. This gentle tilting is universally ascribed to relief of the ice load on the earth's elastic crust. The lake basins were slightly tilted or canted to the southwest, and the new outlet across Ontario rose with the uplift until discharge of the upper lakes again flowed into Erie and over the falls. Rate of recession must then have returned to an approximation of the early rate.

Detailed studies of the warped shore lines of the early glacial lakes show that this procedure was later repeated, the Ottawa river then becoming the outlet. By this time, the Lake Superior basin had become ice-free; indeed, the three upper lakes were high enough to flood across the low land where they now are connected by a strait and a river, making one huge water body, Lake Nipissing. Niagara, during this episode, had its second low-volume discharge. Only the continued glacial retreat, and consequent rise of the unloaded land of Ontario and Quebec, can account for the second return of the upper lakes' overflow to Erie and Niagara, a return that has persisted to the present time.

For a problem like this, full of quantities that cannot be precisely measured, only a rather tentative estimate of the time involved can be made. A Canadian geologist, E. M. Kindle, and a U.S. geologist, F. B. Taylor, collaborated in an elaborate study of the problem and their conclusion was widely accepted. Taking all variables into account, they estimated Niagara falls to be between 25,000 and 30,000 years old. Nobody conversant with the problem, however, was confident that later studies would not change that estimate. (See also NIAGARA RIVER AND FALLS.)

Falls of the Yellowstone. — In the national park of that name, these falls are caused by a structure of the underlying rock quite different from that at Niagara. The park is largely a plateau of extrusive igneous rock, up through earlier accumulations of which volcanic energy has repeatedly forced later discharges of lava, volcanic gases, steam and hot water. Some conduits or fissures thus used are today nearly vertical masses of harder rock embedded in the plateau deposits. Yellowstone river crosses two such wall-like masses. each marked by a fall. The upper fall is about 109 ft. high, the lower one about 319 ft. Waterfalls of this character cannot migrate upstream as Niagara does. They can only become lower by reason of stream notching on the brink and down the face, and presumably are fated to degenerate eventually into cascades.

Victoria Falls. — A third type of waterfall is exemplified by Victoria falls on the Zambezi river in Rhodesia. The underlying rock is a series of basalt lava flows. Like the Niagara and Yellowstone rivers, the Zambezi has made almost no valley above the cataract but plunges abruptly from a plain into this gorge. Unlike Niagara and Yellowstone, however, this gorge is exceedingly narrow and its course below the cataract is strikingly zigzag. Furthermore, the river does not enter at the head of the gorge but spills down over the side. Geologists believe that the river is only using and enlarging great fracture and fault planes that were made in the basalt plateau by earth movements. Victoria is 355 ft. high, more than twice the height of Niagara (Horseshoe falls, 158 ft.) but the full spectacle is impossible to see because of the narrowness of the gorge and the perpetual cloud of mist in its depths.

Hanging Tributaries. — Many tributary streams of larger mountain valleys of the world are hanging upon the valley walls at the point of confluence and descend to the major stream by falls or cascades. Erosive deepening of their valleys has not kept pace with that of the trunk valley. Commonly, this hanging relationship, with resulting waterfalls, has been caused by glacial deepening of the main valley, later disappearance of the glacier allowing the major stream to use a valley it did not excavate. Yosemite has five tributary creeks making this spectacular entrance, at Bridalveil, Illilouette, Ribbon and Upper and Lower Yosemite falls.

Another cause for hanging tributaries and consequently a sheer or cascading plunge of the creeks on entering the master valley is simply more rapid deepening of that valley by its river. The gorge of the Columbia across the Cascade range in Oregon and Washington has several such waterfalls. Multnomah falls has a 620-ft. drop.

U.S. Atlantic Fall Line.--The fall line of the Atlantic seaboard of the U.S. extends from New Jersey to Georgia along the boundary between the coastal plain and the Piedmont plateau, roughly parallel to the continental shore line. Every stream of the higher Piedmont that flows to the Atlantic has falls, cascades, rapids or at least quickened current where it enters the coastal plain. The Great falls of the Potomac, near Washington, D.C. (40-ft. drop in three miles), are probably the best-known example, but the Delaware, Susquehanna, Rappahannock, James, Appomattox, Roanoke, Yadkin, Broad, Savannah and other rivers are also marked by steep interruptions of the streams' gradients as they cross the fall line.

The Piedmont plateau is underlaid by relatively resistant crystalline rocks, such as granite and gneiss, while the coastal plain consists of much weaker sedimentary rocks. The streams thus pass from a more resistant to a less resistant substratum as they cross the boundary. Yet the weaker rock of the plain does not underlie the Piedmont rock, so these falls, cascades and rapids are not of the receding or Niagara type. It appears that there is a zone of consistent steepening of the surface of the Piedmont hard rocks where they go under the softer rocks of the coastal plain, the existence of which almost entirely accounts for the fall line.

Trick Falls. — The creek supplying Trick falls, in Glacier National park, Montana, has found partial passage for its water down a fissure in its channel bottom a little upstream from the falls' brink and a horizontal escape route back to the channel at the foot of the falls. In low-water stages, the falls go dry, the stream being entirely swallowed by the underground bypass and appearing like a huge spring at the base of the waterfall cliff. Enlargement of this subterranean route will sometime take even floodtime discharge. Eventually, only a natural bridge spanning the creek will remain to record the original Trick.

Celilo Falls. — Formerly on the Columbia river near The Dalles, Ore., Celilo falls was a waterfall about 20 ft. high at low water. Because the Columbia in flood rose nearly 90 ft. in the vicinity of The Dalles, Celilo falls would disappear. Rivers, however, do most erosional work in their channels during floodtime and Celilo falls, therefore, must have had its maximum alteration at times when it had no surface expression but was more than 60 ft. beneath the surface when the Columbia was carrying its floodtime discharge of 700,000 to more than 1,000,000 cu.ft. per second.

The concept of G. H. Matthes seemed to explain this anomalous subfluvial cataract. It dealt with an intense quasi-vertical vortex suction in the lee of submerged downstream-facing, vertical rock faces. It was essentially a subfluvial tornado in structure and velocity and, quoting Matthes, was "the most powerful form of concentrated energy at work on stream beds." Vertical jointing of the rock at the Celilo falls favoured this plucking action and lifting mechanism under the floodtime Columbia for the making and maintenance of the falls.

With the building of The Dalles dam below Celilo falls in the mid-1950s and the filling of its storage area the falls were permanently inundated.

Dry Falls.—Dry falls in Grand coulee, east-central Washington, is a compound abandoned cataract, totaling three miles across and 400 ft. in maximum height of the waterfall cliff. It is a product of the last occupation of Grand coulee by a greatly swollen Columbia river which, detoured by glacial ice. was forced to cross the basalt plateau of eastern Washington. Many other coulees of this region are likewise products of such detouring of large glacial rivers, and they similarly contain abandoned cataract cliffs with plunge pool basins at the foot. The U.S. bureau of reclamation. test drilling for an accessory dam in the Columbia Basin Irrigation project, found such a pothole basin excavated 300 ft. deep in the basalt and later filled with gravel. The favouring structure for most of these dry falls was the close-set, vertical. columnar jointing of the basalt. Plucking of columns in these glacial stream beds where the gradient was adequate made several such falls and accompanying downstream gorges as large as at Niagara today.

Grand Canyon.—When Maj. J. W. Powell, the first man to take a party by boat down the Grand canyon of the Colorado, was developing his plan, he was cautioned that he might encounter many receding-type waterfalls because the canyon was known to be eroded in nearly flat-lying beds of varying resistance to erosion. His reply was that the Colorado river is one of the dirtiest rivers in the world, that its load of sand, gravel and boulders had been a great longitudinal saw which must have long since cut through the hard rock lips of any such falls. He did encounter many dangerous rapids but no cataracts, despite the favouring structure of the rock. In contrast with the turbid Colorado are the Niagara, Yellowstone and Zambezi rivers. clear-water streams which consequently have done little cutting down into their bedrock floors upstream from their cataracts.

Leading Falls in Height and Volume.—The highest perennial fall known is Angel in Venezuela. It makes little contact with the sheer mountainside as it drops more than 3.280 ft. Other very high falls are Tugela, Natal. Republic of South Africa. 3.000 ft.; Kukenaam. Venezuela. 2,000 ft.; Sutherland. South Island, N.Z., 1,904 ft.; Ribbon. Yosemite, Calif., 1,612 ft ; Upper Yosemite. 1.430 ft.; Gavarnie, France, 1.384 ft.; Takkakaw, B.C., 1,248 ft.; Silverstrand Falls. Uosemite. 1.170 ft.

Niagara is doubtless the world's best-known cataract. It also has the steadiest flow of all large-volume waterfalls, discharging around 200.000 cu.ft. per second throughout the year.

Perhaps the largest mean discharge of any waterfall in the world is that of Guaíra or Sete Quedas on the Paraná river between Brazil and Paraguay. It is estimated at 470,000 cu.ft. per second and the falls' height is only 30 ft. less than that of Niagara. Another cataract of very large volume is Khon on the Mekong river, Indochina. Its estimated mean annual flow is between 400.000 and 420.000 cu.ft. per second. In descending order of volume are Paulo Affonso. on the São Francisco river. Braz.. 100.000 cu ft. per second; Urubu-Pungá, on the Paraná river, Braz., 97.000 cu.ft. per second; Iguaqu, on the Iguaqu river, on the boundary between Brazil and Argentina. 61,660 cu.ft. per second; Victoria. on the Zambezi river. Rhodesia. 38,430 cu ft. per second; Grand, on the Hamilton river. Labrador, 30.000 to 40 000 cu ft per second: and Kaieteur on the Potaro river, British Guiana, 23.400 cu.ft. per second.

Economic **Aspects.**—Waterfalls are an important economic asset if they are not too remote from industrial areas. Some falls have had their entire low-water flow detoured through hydroelectric power installations and now are spectacles only in floodtime.

Offsetting this asset, as at Niagara, has been the need for constructing navigation canals to by-pass the falls. To save Niagara's unexcelled natural scenic value: treaty regulations between the U.S. and Canada allow only 56,000 cu.ft. per second to be taken into canals and penstocks above the falls for power purposes. In the lowest stages of the river, it still discharges about 100.000 cu.ft. per second over the falls. But a strong east wind for a day or two will so lower the eastern end of Lake Erie that the smaller American falls will temporarily go dry.

The fall line has been an important controlling factor in the development of the Atlantic seaboard region since early colonial days. The individual falls were the upstream limit of early navigation. also a source of water power. The locations of Trenton. S. J. Philadelphia. Pa.. Wilmington, Del., Baltimore. Md.. Washington. D.C.. Fredericksburg and Richmond, Va., Columbia, S.C.. Augusta, Ga., and other cities mere determined, in part, by the fall line interruptions in the larger rivers entering the coastal plain:

Rivers which have not encountered fall-making conditions in the rock of their channel beds but which have adequate gradient for water-power development have been "harnessed" by construction of dams (*q.v.*), essentially artificial waterfalls with the added advantage in some cases of affording storage basins above the "falls." Man has constructed concrete and earthen barriers across some of the earth's great rivers (Mississippi, Missouri, Ohio, Columbia, Nile. Dnieper, etc.) to serve as navigation correctives, flood-control works, irrigation reservoirs, etc. The Tennessee Valley authority built 27 such "falls" on one river alone. Needless to say, the engineers have balked the falling water's tendency to dig plunge basins at the foot of the dams. The overflow is not allowed to fall freely; it slides down the sloping dam face and encounters a properly curved concrete apron at the foot which shoots the water horizontally downstream away from the structure. But these dams invariably upset the river's normal regimen both above and below the dam. In the slackened current of the reservoir, the stream unavoidably deposits its load of silt sand and gravel, gradually decreasing storage capacity. Downstream, the river has added erosional ability simply because it has been relieved of that load on its energy and can devote more attention to deepening its channel. Keither result is economically desirable. (J. H. Bz)

WATER FLEA, a popular term for certain minute Crustacea (q v.) which make flea-like jumps through the nater. Modern usage restricts the term to the Cladocera, a suborder of the Branchiopoda (q *v*). Cladocera are abundant in fresh water and a few species are marine. They are rarely over 4 mm long. The characteristic jumps result from oarlike strokes of large, biramous antennae. In some species, however, these appendages beat so rapidly that swimming is continuous. Up to six pairs of trunk limbs are present. usually enclosed within a bivalve shell. The well-known genus Daphnia is transparent. Thus. in it one can see with a microscope such activities as the beating of the heart, intestinal movements circulation of the nhite blood cells (in which phagocytosis of bacteria was first discovered), movements of the fused compound eye and the rapid beating of the trunk limbs. This last action produces a current for filter-feeding and respiration. Usually one finds only females, which reproduce parthenogenetically. the unfertilized eggs entering a dorsal brood chamber where they develop rapidly into fully formed young released at the next molt. At certain times small males appear, and fertilized resting eggs are then produced, able to withstand freezing and drying.

Cladocera are closely related to the suborder Conchostraca, from which they apparently arose by neoteny, becoming sexually mature at what was formerly a juvenile stage. By adaptive radiation Cladocera have evolved into a variety of forms, living in the mud. on aquatic plants, under the surface film, as a parasite of Hydra, as filter-feeders in the plankton and as active predators. (J. H Lo.)

WATERFORD, a county of Ireland in the province of Munster. The land area of Waterford is 454,128 ac., or 709.5 sq.mi. Pop. (1961), exclusive of Waterford city, 43,205 (total 71,343). The coast line is in some parts rocky and is indented by many bays and inlets, the principal being Waterford harbour; Tramore bay, with picturesque cliffs and extensive caves. and noted for its shipwrecks on account of the rocky character of its bed; Dungarvan harbour, much frequented for refuge in stormy weather; and Youghal harbour, partly separating County Waterford from County Cork. The surface of the county is to a large extent mountainous, providing beautiful inland scenery, especially toward the west and northwest. The Knockmealdown mountains, which attain a height of 2,609 ft., form the northern boundary with Tipperary. A wide extent of country between Clonmel and Dungarvan is occupied by the two ranges of the Comeragh and Monavallagh mountains. reaching a height of 2,504 ft.

To the south of Dungarvan there is a lower but very rugged range, called the Drum hills. The southeastern division of the county is for the most part level. Though Waterford benefits in its communications by the important rivers in its vicinity, the only large river it can properly claim as belonging to it is the Blackwater. This river is famous for salmon fishing and, particularly in the stretch between Cappoquin and Lismore, flows between high, well-wooded banks, contrasting beautifully with the background of the mountains. It enters the county east of Fermoy, and flows eastward to Cappoquin, the head of navigation, where it turns abruptly southward to enter the sea at Youghal harbour.

Waterford harbour may be called the estuary of three important rivers, the Suir. the Nore and the Barrow. but neither of the last two touches the county. The Suir reaches it about 8 mi. from Clonmel and thence forms its northern boundary with Tipperary and Kilkenny. It is navigable to Clonmel, but the traffic lies mainly on the left bank, outside the county.

Geology. — The Knockmealdown mountains are an anticline of Old Red Sandstone, cut away at the eastern end to expose Silurian strata, which are associated with an extensive series of volcanic and intrusive rocks, often crushed by earth movement. The impressive scarp formed by the Old Red Sandstone conglomerate above this lower ground is called the Comeragh mountains. The moraine-dammed cirque of Lough Coumshingaun lies in these, with a precipice 1,000 ft. in height. The unconformity of the Old Red Sandstone on the greenish and yellowish Silurian shales is excellently seen on the north bank of the Suir at Waterford. Carboniferous limestone is found in the floor of the synclinals on either side of the great anticline, that is, in the Suir valley on the north and in the green and richly wooded hollow of the Blackwater on the south. Rapidly repeated anticlinal and synclinal folds continue this structure across the country between Dungarvan and Youghal.

Rich copper mines were worked, mainly in the 19th century, in the Silurian area near Bunmahon, and the region remains full of mineral promise.

History. — In the 9th century the Danes landed. and afterward made a permanent settlement. W'aterford was one of the 12 counties into uhich King John is stated to have divided that part of Ireland uhich he nominally annexed to the English crown. On account of the convenience of the city as a landing place, many subsequent expeditions passed through the county. It suffered severely during the Desmond rebellion in the reign of Elizabeth I, as well as in the rebellion of 1641 and during the Cromnellian period.

At Ardmore, overlooking the sea from Ram head. there is a round tower 95 ft. in height, and near it a huge rath and a large number of circular entrenchments. Lismore castle, originally erected in 1185, is in great part comparatively modern. The chief ecclesiastical remains are those of the chancel and nave of the cathedral of Ardmore, where a monastery and oratory mere founded by St. Declan in the 7th century. The see of Ardmore was abolished in the 12th century. The existing monastery of Mount Melleray, a convent of Cistercians, was founded near Cappoquin in 1830, on the expulsion of the foreign members of this order from France. A large expanse of barren and rocky mountainside has been reclaimed by the monks, who have converted it into an extensive model farm, conducted on scientific lines. They maintain schools and guest houses for visitors. and have built with their own labour the large abbey church which was. dedicated in 1952. The stone used for building the church was bought from the modern ruin of Mitchelstown castle. Three other Cistercian abbeys, at Roscrea (Tipperary), Mellifont (Louth) and Portglenone (Antrim), have been founded directly from Mount Melleray and are known as its daughter houses. The abbeys of Mount St. Bernard (Leicestershire) and New Melleray (Dubuque, Ia.) are also its offshoots.

Agriculture and Industries. — The land is generally better for pasturage than for tillage. although there are considerable tracts of rich soil in the southeastern districts. In 1951 there were 52,656 ac. in crops, 27,676 ac. in hay and 222.046 ac. in pasture. Of the crop acreage more than half was planted to corn crops, mostly oats (19,763 ac.) and less than half to root and green crops. Of the latter, potatoes, turnips and mangels were the most important.

The size of farmholdings in the county averages larger than for Ireland in general. In the number of its cattle Waterford's position has fallen considerably. The woollen manufacture, except for home use, is practically extinct, but the cotton manufacture is still of some importance. There are a number of breweries and distilleries and also a large number of flour mills. The deep sea and coastal fisheries have their headquarters at Waterford, and the salmon fisheries of the Suir and Blackwater have theirs at Waterford and Lismore respectively. Waterford returns four members to *dáil eireann.*

BIBLIOGRAPHY.—C. Smith, *The Ancient and Present State of the County and City of Waterford* (Dublin, 1746); R. H. Ryland, *The History, Topography and Antiquities of the County and City of Waterford* (London, 1824); E Downey, *The Story of Waterford to the Middle of the Eighteenth Century* (Waterford, 1914); P. Power, *Waterjord and Lismore* (New York and London, 1938).

WATERFORD, a city and port and the chief town of County Waterford, Ireland. Pop. (1961) 28,138. It is situated on the south bank of the River Suir 4 mi. above its junction with the Barrow at the head of the tidal estuary called Waterford harbour. The Suir is crossed by a concrete bridge with a lifting centre bay. It was built in 1913 to replace a wooden one and connects Waterford with the suburb of Ferrybank. Waterford is governed by an elected council and a manager who is appointed by the national government. The manager's extensive powers were limited by the council's authority over rates, bylaws and loans.

Anciently Waterford was called Cuan-na-groith, the haven of the sun. By early writers it mas named Menapia. It first acquired importance under the Danes, of whom it remained one of the principal strongholds until its capture by Strongbow (Richard le Clare, 2nd earl of Pembroke) in 1171. In 1172 Henry II landed near Waterford. and received there the hostages of the people of Munster. It became a cathedral city in 1096. The Protestant dioceses of Cashel, Emly, Waterford and Lismore were united in 1833 The Roman Catholic diocese of Waterford and Lismore includes County Waterford and parts of Tipperary and Cork. John landed at Waterford in 1185 and after ascending the English throne he granted it a charter of incorporation in 1206. He landed at R'aterford in 1210 in order to establish within his nominal territories in Ireland a more distinct form of government. Richard II landed at Waterford in Oct. 1394 and again in 1399. In 1447 it was granted by Henry VI to John Talbot, earl of Shrewsbury. who was created earl of Waterford.

In 1603, after the accession of James I to the English crown, the city, along with Cork, took a prominent part in opposition to the government and to the Protestant religion, but on the aproach of Mountjoy it formally submitted. In 1619 an unsuccessful attempt was made to induce Bristol merchants to settle in the city and undertake its government. It resisted Cromwell in 1649 but surrendered to Henry Ireton in 1650. After the battle of the Boyne James II embarked at Waterford for France (July 1690). Shortly afterward it surrendered to William, who sailed from there to England. The city sent two members to parliament from 1374 to 1885, when the number was reduced to one. In 1898 it was constituted one of the six county boroughs having separate county councils.

The city is built chiefly along the banks of the river, occupying for the most part low and level ground except at its western extremity. The modern Protestant cathedral of the Holy Trinity (begun 1773, altered 1891) occupies the site of the church built by the Danes in 1096 in the Mall. There is a Roman Catholic cathedral, and St. John's college, a seminary for priests. The principal secular buildings are the town hall, the county and city courts and prisons, the customhouse and the barracks. At the extremity of the quay is a large circular tower, called Reginald's tower, forming at one time a portion of the city walls and occupying the site of the tower built by Reginald the Dane in 1003. Other remains of the fortifications, consisting of towers and bastions, are to be seen as in the Tramore railway sidings and in Castle street. The town possesses breweries, salthouses, foundries and flour and paper mills; there is a large export trade in cattle, sheep and pigs, and in agricultural produce; the traditional manufacture of Waterford glass has been recently revived. It is the headquarters of extensive salmon and sea fisheries. Waterford is second in importance to Cork among the ports of the south coast of Ireland. There is regular communication by motor and steam ships with Cork, with Dublin and Belfast, with Fishguard and with many English ports.

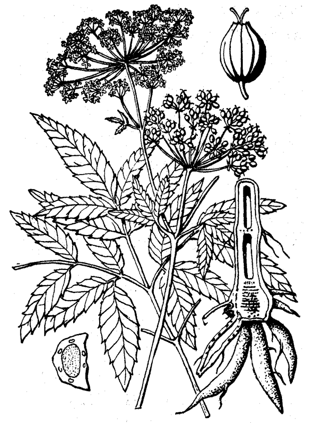
Waterford harbour is a winding and well-sheltered bay formed by the estuary of the Suir river, and afterward by the joint estuary of the Nore and Barrow. Its length to the sea is about 1 j mi. Its entrance is 3 mi. wide and is lighted by a fixed light on the ancient donjon of Hook tower (139 ft. in height) and three others. The Suir is navigable to Waterford for vessels drawing 22 ft. The shores of the harbour are studded with country residences and waterside villages. A large housing estate was built on the southern outskirts of the city toward Tramore, a seaside holiday resort 8 mi. S.

WATER GAS. When steam is passed over red-hot anthracite or coke it is decomposed, and the resultant gas. consisting of a mixture of hydrogen and carbon monoxide, is termed water gas. Enriched with gas from cracked oil. it is termed carbureted nater gas and is largely employed in industrial operations. It is also used mixed with coal gas for town purposes; when so employed it increases the poisonous character of the gas supply because of the peculiarly dangerous qualities of carbon monoxide. See GAS INDUSTRY and FUELS.

WATER GLASS. A common name for sodium silicate, made by fusing together soda ash and clean sand in a furnace. The name water glass (or soluble glass) is derived from the fact that while the substance resembles glass it can be dissolved in water by prolonged exposure. The proportions of soda and silica in water glass may be considerably varied, according to the purpose for which it is required. See ALKALI MANUFACTURE.

WATER HEMLOCK, also known as cowbane, is botanically Cicuta *virosa,* of the parsley family, Umbelliferae, a poisonous weed growing at the edges of ponds, ditches and rivers in Great Britain. It is a perennial with clusters of fleshy roots, and has large compound leaves and small white flowers appearing from July to August. It has been mistaken by human beings for celery, with fatal results. and is responsible for the death of cattle. In North America there are several native species of *Cicuta* common in marshes and wet meadows, all similarly poisonous. especially the spotted cowbane or musquashroot (C. *maculata*) of the eastern states and Canada, and the western water hemlock (C. *douglasi*) of the Pacific coast. Before its virulence became known to cattle raisers the western species caused serious losses of livestock in the Pacific northwest. Humans are sometimes fatally poisoned by mistaking the roots for other plants.

The closely allied poison hemlock (Conium *maculatum*) is a biennial plant of the family Umbelliferae, found wild in many parts of Europe, where it occurs in waste places on hedge banks, and by the borders of fields. It is also widely spread over temperate Asia and is naturalized in the cultivated districts of North and South America. It is an erect branching plant, growing from three to six feet high, from a large taproot. The stems are hollow, smooth, somewhat glaucous green, spotted with dull dark purple. The root leaves have long furrowed footstalks, sheathing the stem at the base, and are large, triangular in outline, and repeatedly divided or compound, the ultimate and very numerous segments being small, ovate and deeply incised at the edge. These leaves generally perish after the growth of the flowering stem, which takes place in the second year, while the leaves produced on the stem become gradually smaller upward. The branches are all terminated by compound, many rayed umbels of small white flowers. which are succeeded by broadly ovate fruit. Humans have been poisoned by mistaking the roots for parsnips or the seeds for caraway. See also POISON HEMLOCK; POISONOUS PLANTS. (W. C. M.)



THE WATER HEMLOCK (CICUTA MACULATA), A HERB FOUND IN SWAMPS AND LOWLANDS

WATERHOUSE, ALFRED (1830–1905), English architect of many educational and civic buildings, was born at Liverpool on July 19, 1830, and died on Aug. 22, 1905. He was a pupil of Richard Lane in Manchester. His position as a designer of public buildings was assured as early as 1859 when he won the open competition for the Manchester assize courts. This work marked him as a champion of the Gothic style. In 1868 he won the competition for the Manchester town hall, where he showed a firmer and perhaps more original handling of the Gothic manner. The same year brought him the rebuilding of part of Caius college, Cambridge, not his first university work, for Balliol, Oxford, had been put into his hands in 1867. At Caius the Gothic element was intentionally mingled with classic detail, while Balliol and Pembroke, Cambridge, which followed in (1871), were of the style of his mid-career—European Gothic tradition tempered by individual taste and by adaptation to modern needs.

Among his other educational buildings were Girton college, Cambridge; Owens college. Manchester; and Liverpool university college. He designed the Jenner Institute of Preventive Medicine, Chelsea, and the Liverpool infirmary, his largest hospital. His Natural History museum. South Kensington, marked a new epoch in the use of terra cotta. Waterhouse was a member of the Royal Institute of British architects and many other professional societies.

WATERHOUSE, GEORGE ROBERT (1810–1888), English zoologist, an expert on the classification of beetles and mammals, was born at Somers Town. London, on March 6, 1810. Educated at Koekelberg, near Brussels, he returned to England to be trained as an architect, and practised this profession from 1831 to 1835. His real taste, however, was for entomology, and in 1833 he was appointed curator of books, memoirs and insects to the Entomological society, London. In 1836 he became curator of the Zoological society of London. His catalogue of the mammals in the society's museum was not published until 1838, because of strong opposition to his adopting a more modern arrangement. Waterhouse proposed a new scheme for the classification of Heteromera Coleoptera, but this was never published, as he lost the paper that he was to have read before the new Entomological society and had not the heart to rewrite it. The dissections made for this study were eventually placed in the Natural History department of the British museum. In 1843 Waterhouse was appointed assistant in the mineralogical and geological branch of the museum, becoming keeper in 1851. When in 1857 this branch was split into the two departments of mineralogy and geology. Waterhouse continued as keeper of the department of geology. He never published anything in geology. but did a good deal of administrative work, particularly in preparation for the transfer of the department to South Kensington While there, Waterhouse spent all available spare time in aorking on beetles and mammals and in writing about them. He retired in 1880 and died at Putney on Jan. 21, 1888.

During his earlier years, Waterhouse wrote many articles on mammals. fishes and insects for Charles Knight's *Penny Cyclopaedza.* He began a *Natural Hzstory of the Mammals* in 1844, but only two volumes, on the Marsupialia and Rodentia, had been brought out (1846–48) when the work was discontinued. Waterhouse published also a *Catalogue of British Coleoptera* (1858).

(J. Rm.)

WATERHOUSE, JOHN WILLIAM (1847–1917) English painter, was the son of an artist, by uhom he nas mainly trained. As a figure painter he shows in his uork much imaginative power and a very personal style. and his pictures are mostly illustrations of classic myths treated with attractive fantasy; *e g*, "Consulting the Oracle" He was an able draftsman and a fine colourist. He was elected an associate of the Royal Academy in 1885 and academician in 189j.

He died in London on Feb 10. 1917.

WATER HYACINTH (*Eichhornia crassipes),* an aquatic herb of the pickerel weed family (Pontederiaceae), native to tropical America and widely naturalized in warm regions. It is an

JOHN H. GERARD
WATER HYACINTH (EICHHORNIA CRASSIPES) IN BLOOM. THE BLADDER-LIKE FLOATS ARE VISIBLE AT THE BASE OF THE LEAF STALKS

emersed or floating, somewhat fleshy plant. bearing smooth, nearly round. erect leaves, one-half inch to six inches broad, and loose clusters of pale-violet, orchidlike flowers, marked with blue and yellow. The bladderlike bases of the leafstalks serve as floats which keep the plant high in the water. Escaping from cultivation, it has become a troublesome weed, impeding navigation in the inland waters of the Gulf states of the U.S. and in other tropical and subtropical areas. Large expenditures of labour and money on mechanical and chemical control result in only temporary relief. On the subcontinent of India water hyacinth plants have been utilized for making paper and pressed boards.

See M. A. Azam, "Utilization of Water Hyacinth in the Manufacture of Paper and Pressed Boards, *Sci & Cult.*, vol. 6, pp 656–661 (1941).

WATERLAND, DANIEL (1683–1740), English theologian, was born at Walesby on Feb. 14. 1683. He was educated at Magdalene college. Cambridge. On Nov. 14, 1715, he became vice-chancellor of the university and in the following year mas appointed chaplain in ordinary to the king. In 1720 he published *Eight Sermons in Defence of the Dzvinity of our Lord Jesus Christ,* preached by him in St. Paul's cathedral. In 1722 he was appointed chancellor of the diocese of York. and in 1723 appeared his *Critical History of the Athanasian Creed* In 1730 he became archdeacon of Middlesex and vicar of Twickenham.

His other major works were *Scripture Vindicated* (1730–32); *The Importance of the Doctrine of the Holy Trinity Asserted* (1734); and *Review of the Doctrine of the Eucharist* (1737). His nork did much to check the increase of latitudinarian ideas within the Church of England at the time.

Waterland died on Dec. 23, 1740.

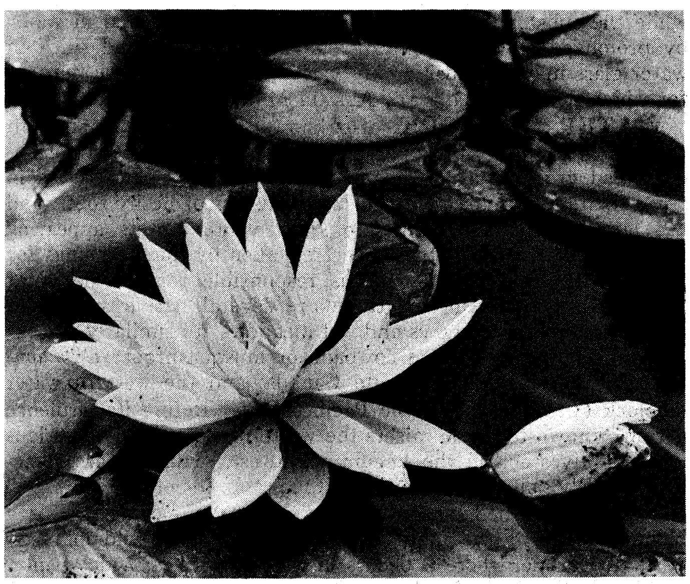
WATER LETTUCE *(Pistia stratiotes),* an aquatic plant of the arum family (Araceae. *q.v.*), very widely distributed in tropical and subtropical regions; in the United States it is native to slow streams from Florida to Texas. It is a tender, floating perennial, rarely becoming anchored by its long feathery roots. The wedge-shaped, light-green leaves form a rosette. about six inches broad. which is somewhat similar to a half-grown lettuce plant before the head is formed. In the cuplike centre of the rosette are borne the small white flowers. Water lettuce is often groun in water gardens and as an aquarium plant.

WATER LILY, a name loosely given to almost any floating plant with conspicuous flowers. but applying especially to the species of *Nymphaea*, *Nuphar* and other members of the water lily family (Nymphaeaceae). These are aquatic plants with thick fleshy rootstocks or tubers embedded in the mud and sending up to the surface circular shieldlike leaves and leafless flower stalks, each terminated by a single flower, often of great beauty, and consisting of four or five sepals and numerous stamens without any definite line of demarcation between them.

The ovary consists of many carpels united together and free, or more or less embedded in the top of the flower stalk. The ovary has many cavities and is surmounted by a flat stigma of many radiating rows as in a poppy. The fruit is berrylike, and the seeds are remarkable for having their embryo surrounded by an endosperm as well as by a perisperm. The leaf stalks and flower stalks are traversed by longitudinal air passages, whose arrangement varies in different species.

The species of *Nymphaea* are world-wide in distribution. Their flowers range from white to rose coloured, yellow and blue. Some expand in the evening only, others close soon after noon.

Nymphaea odorata, fragrant water lily, and N. *tuberosa,* tuberous water lily, are the conspicuous white water lilies of eastern North America. *Nuphar advenum* is the common yellow water lily or spatter dock of the eastern United States and Canada, and *Nuphar polysepalum,* Indian pond lily, is its counterpart on the Pacific coast. *Brasenia schreberi,* the water shield, with small yellow flowers occurs across the continent. *Nelumbium sentapetalum,* of the eastern United States, is the American lotus or water chinquapin (*q.v.*). The gigantic *Victoria regia* (*q.v.*), with leaves 4 to 7 ft. in diameter and flowers 6 to 18 in. across. also belongs to this group. It grows in the backwaters of the Amazon. often covering the surface for miles; the seeds are eaten under the name water maize. *Nymphaea alba* is common in some parts of Great Britain, as is also the yellow *Nuphar luteum* (*Nymphaea luteus*).



WILLIS PETERSON
HYBRID WATER LILY (NYMPHAEA MARLIACEA CHROMATELLA)

The seeds and the rhizomes contain an abundance of starch and are used in some places for food.

Under the general head of water lily are included the lotus of Egypt, *Nymphaea lotus*, and the sacred lotus of India and China, *Nelumbium nelumbo*, formerly a native of the Nile, as shown by Egyptian sculptures and other evidence, but no longer found in that river. *See* also LOTUS.

WATERLOO, a city of northeastern Iowa, U.S., about 50 mi. N.W. of Cedar Rapids, on the Cedar river, is the seat of Black Hawk county. Population of the city was 71,755 in 1960, an increase of 10.1% since 1950; the Waterloo standard metropolitan statistical area, comprising Black Hawk county, had a population of 122,482, an increase of 21.9%. (For comparative population figures *see* table in IOWA: *Population*.)

Settlers arriving in 1845 recognized that the river provided excellent mill sites; they called the place Prairie Rapids. The name Waterloo, adopted in 1851, is said to have been taken from a postal directory by Charles Mullan and inserted into a petition to the Cedar Falls postmaster for a post office at the settlement. After Waterloo became the county seat in 1855, it grew slowly as a railroad division point and as a centre of regional trade. It was chartered in 1868. Efforts to found local industries generally failed until the 1890s, when the practice adopted by local businessmen of making donations to attract industry met success. Subsequent industrial growth was extremely rapid. Early settlers in the county came mainly from New York, Pennsylvania, Ohio and Illinois. Many Germans, Danes and British immigrants also arrived; foreign-born and their children comprised about 42% of the population in 1900. The population in the second half of the 20th century was mainly derived from those stocks.

Major industries include meat products, farm tractors, construction machinery, metal products, textile and leather goods, corrugated boxes and soy products. Four major railroads serve Waterloo, and there is a municipal airfield.

Lying within the northeastern dairy area of Iowa, Waterloo sponsors the annual National Dairy Cattle congress, an internationally famous cattle exhibition. The city has a historical museum, and a municipal band and a symphony orchestra. The State College of Iowa (1876) lies 3 mi. W., at Cedar Falls.

(A. G. Bo.)

WATERLOO CAMPAIGN, 1815. On Feb. 27, 1815, Napoleon set sail from Elba with a force of 1,000 men and 4 guns, determined to reconquer the throne of France. On March 1 he landed near Cannes, and proceeded at once to march on Paris. He deliberately chose the difficult route over the French Alps because he recognized that his opponents would neither expect him by this route nor be able to exert combined operations in time to thwart him. Events proved the wisdom of his choice. His advance was a series of triumphs, his power waxing with every league he covered, and when he reached Paris the Bourbons had fled. But he had soon to turn his attention to war. His sudden return far from widening the breaches between the allies had fused them indissolubly together, and the four powers bound themselves to put 150,000 men apiece under arms and to maintain them in the field until Napoleon had been utterly crushed. To oppose their vast armies, Napoleon only had in March the 150,000 men he had taken over when Louis XVIII. hurriedly quitted the throne. Within ten days the emperor could have concentrated 50,000 men and struck straight at the small allied forces then in Belgium. But he wisely refrained from taking the immediate offensive. Such action could lead to no decisive result; and Napoleon therefore hastened forward the organization of an army with which to confront the Seventh Coalition. Meanwhile he sought by various means to detach Great Britain and Austria from the alliance.

Napoleon's Preparations and Plans.—By June 1 Napoleon had got together an army of 360,000 for the defence of France, one half of which was available for field service. In this army was comprised his whole means of defence; for he had no allies. On his return from Elba it is true Murat, the king of Naples, took his side; but recklessly opening an offensive campaign, Murat was beaten at Tolentino (May 2–3), and he found himself compelled to fly in disguise to France, where the emperor refused to give him an audience or employment. Napoleon thus deprived himself of the most brilliant cavalry soldier of the period. Murat's disaster had left the whole eastern frontier of France open to invasion. The country, too, was weakened by internal dissensions at the very moment when it was necessary to put every man in line to meet the rising tide of invasion.

In Belgium lay an ever-increasing force of Anglo-Dutch and Prussian trbops under Wellington and Blucher. The eastern frontier was threatened by Austrian armies, and the Russians were slowly coming up. The allies determined to avoid any risk of defeat in detail. It was arranged that Wellington and Blücher should await in Belgium the arrival of the Austrians and Russians on the Rhine. Then about July 1 the general invasion of France would be begun. Affording each other mutual support, the allies would press forward on Paris, and, after defeating Napoleon, drive him within its works. This menacing danger forced Napoleon to strike prematurely, for he determined to crush Wellington and Bliicher, whose forces lay dispersed in Belgium, before the Austrians and Russians poured across the eastern frontier.

In the early days of June Wellington and Blucher were disposed as follows. (*See* map.) The Anglo-Dutch Army, 93,000, headquarters at Brussels, were cantoned: I. Corps (Prince of Orange), 30,200, in the area Enghien-Genappe-Mons; II. Corps (Lord Hill), 27,300, in the area Ath-Audenarde-Ghent; reserve cavalry (Lord Uxbridge), 9,900, in the Dendre valley; whilst the reserve (Wellington), 25,500, lay around Brussels. The front was watched by Dutch-Belgian light cavalry.

Blücher's Prussian Army, 116,000, headquarters at Namur, were quartered: I. Corps (Zieten), 30,800, along the Sambre covering Fontaine l'Evêque-Fleurus-Moustier; II. Corps (Pirch), 31,800, in the area Namur-Hannut-Huy; III. Corps (Thielemann), 23,900, in the bend of the Meuse from Dinant to Huy; IV. Corps (Bulow), 30,300, around Liége. The front was watched by the Prussian outposts.

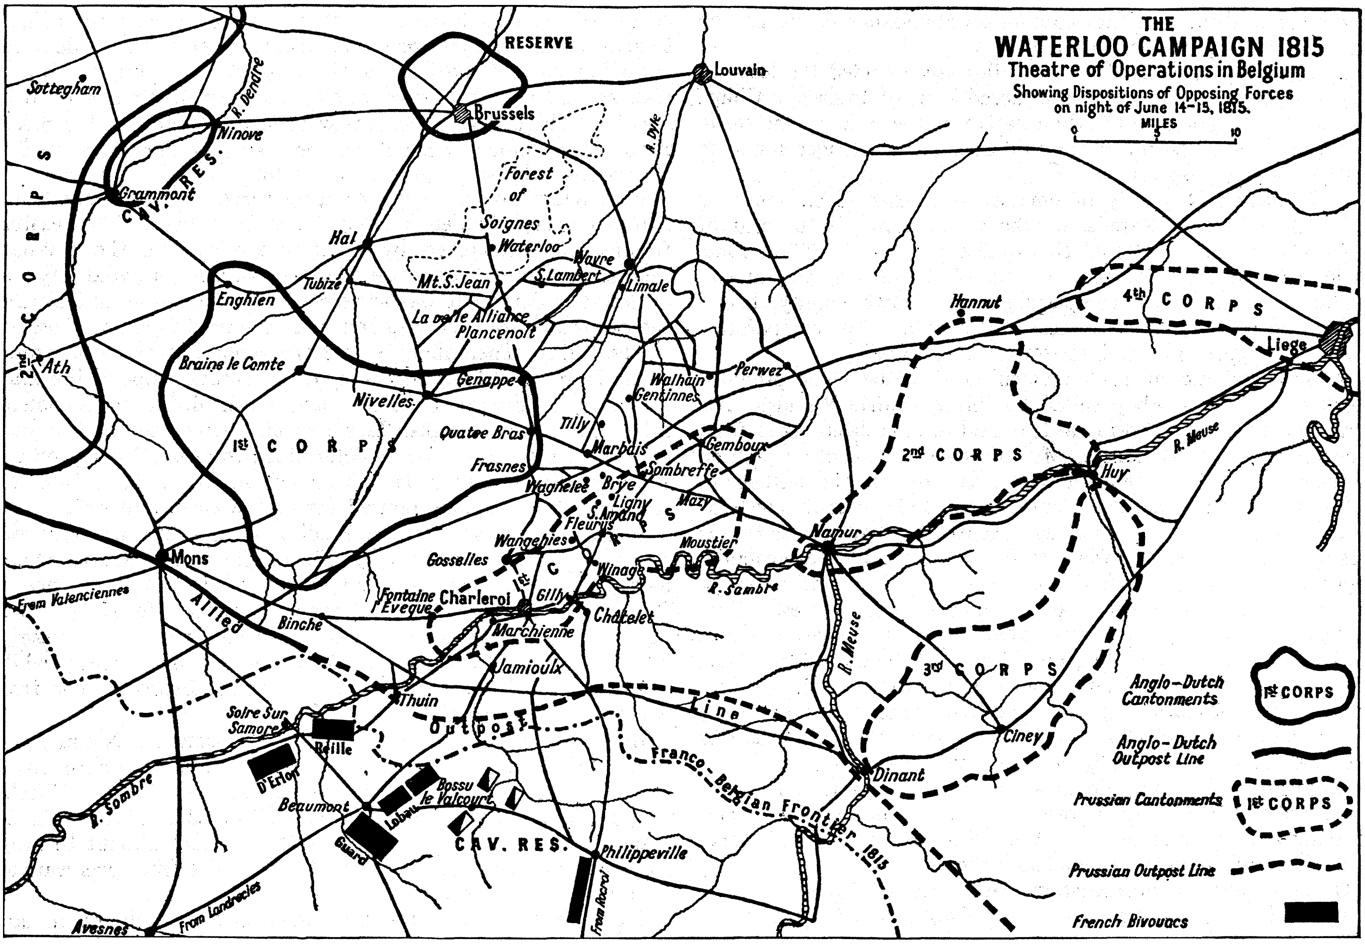
Thus the allied cantonments extended for nearly 90 m. and their mean depth was 30 m. To concentrate on either flank would take six days, and on the common centre, Charleroi, three days.

The allies had foreseen the very manoeuvre that Napoleon decided to adopt, and if an attempt was made to break their centre they intended to concentrate forwards and on their inner flanks, the Anglo-Dutch at Gosselies and the Prussians at Fleurus. They could then act united against Napoleon with a numerical superiority of two to one. They felt certain they would obtain the necessary three days' warning of the French concentration, as Napoleon's troops were then distributed between Lille, Metz and Paris (175 m. by 100 m.). To concentrate the French army, within striking distance of Charleroi, before the allies had moved a man to meet it was unthinkable. But it was the unthinkable that happened.

Whereas Bliicher had covered Fleurus by Zieten's Corps, which by a yielding fight would secure the time for the Prussian concentration, yet Wellington had only covered Gosselies by a cavalry screen which was too weak to gain the time requisite for the Duke to mass there. Hence to enable him to concentrate as arranged Wellington relied on obtaining timely information of Napoleon's plans, which in fact he failed to obtain.

The French Concentration.—The emperor made his final preparations with the utmost secrecy. The "Armée du Nord" was to concentrate in three columns—around Solre, Beaumont and Philippeville—as close to Charleroi as was practicable. On June 6 the IV. Corps (Gérard) started and soon the whole army was in motion, every effort being made to hide the movements of the troops, for there was no great natural screen to cover the strategical concentration. On June 11 Napoleon left Paris for the front, and by June 14 he had achieved almost the impossible itself. There around Solre, Beaumont, and Philippeville lay his mass of men, 124,000, concentrated under his hand and ready to march across the frontier at dawn against the unsuspicious enemy. The allies still lay in widely distant cantonments and they had not moved a man to meet the foe.

The opposing armies were of very different quality. Welling-



ton's was a collection of many nationalities, and the kernel of British and King's German Legion troops numbered only 42,000. Blucher's army was undoubtedly more homogeneous and included no specially weak elements. Napoleon led out a veteran army of Frenchmen who worshipped their leader. But there were lines of weakness in his force. For various reasons, neither Davout, Murat, Suchet, nor Clausel were employed in the "Armée du Nord." Marshal Soult, appointed chief of the staff, possessed few qualifications for this post; and neither Ney nor Grouchy who, when the campaign began were given command of the left and right wings, possessed the ability or strategic skill necessary for such positions. Again the army was morally weakened by a haunting dread of treason; and, finally, it was too small for its purpose. Locked up in secondary theatres Napoleon had left 56,500 men, of whom he might have collected over 30,000 for the decisive campaign in Belgium. Had he concentrated 155,000 of his available force opposite to Charleroi on June 14, then the issue would hardly have been in doubt. As it was he left too much to Fortune.

For his advance into Belgium in 1815 Napoleon divided his army into two wings and a reserve. As the foe would lie away to his right and left front after he had passed the Sambre, one wing would be pushed up towards Wellington and another towards Blucher; whilst the mass of the reserve would be centrally placed so as to strike on either side, as soon as a force of the enemy worth destroying was encountered and gripped. To this end he had, on the 14th, massed his left wing (Reille and D'Erlon) around Solre, and his right wing (Gerard) at Philippeville; whilst the central mass (Vandamme, Lobau, the Guard and the Cavalry Reserve) lay around Beaumont. The orders for the French advance next day, among the finest ever issued, directed that the army should march at dawn and move to the Sambre at Marchienne and Charleroi. By evening it was expected that the whole would have crossed the Sambre, and would bivouac between the sundered allies.

The Passage of the **Sambre.**—At the very outset delays occurred. Vandamme, who was to lead the advance on Charleroi, was delayed by an accident that befell the single orderly who carried the orders to the III. Corps. Gerard, too, was late as his concentration had not been completed on the 14th. Zieten's outposts fought stubbornly to delay the French advance for 24 hours and give time for Blucher's concentration. As soon as the emperor reached the front he took vigorous action, nevertheless it was after noon before the Charleroi bridge was stormed. At the same time Reille crossed at Marchienne. The emperor at once began the advance up both the Fleurus and Quatre Bras roads. It was 3 P.M. when Marshal Ney joined the army and was at once given command of the left wing. Napoleon then proceeded with Grouchy to reconnoitre the Prussian position at Gilly, and, handing over the command of the right wing to the marshal, the emperor immediately returned to Charleroi and ordered Vandamme to go to the assistance of Grouchy.

The allies had been caught unprepared. But as soon as Blücher got the first real warning of imminent danger he ordered the immediate concentration of his army at Sombreffe. Unfortunately, the orders sent to Bülow were so hazy that Bülow did not realize the need for any special haste. Thus the IV. Corps was neutralized until after the 16th. But Pirch I. and Thielemann acted with satisfactory promptness and their corps reached Mazy and Namur by nightfall. Blücher in pursuance with his plan moved to Sombreffe.

Wellington's position at night was hardly safe or even satisfactory. It was not until 3 P.M. that definite news of the French advance reached Brussels, and even then the duke was not certain of the direction of Napoleon's main stroke. Consequently he ordered his divisions to concentrate at their alarm-posts and await further orders. The danger of Blucher's position was thus enormously increased. The allies do not appear to have decided upon the course to be taken in case they were surprised, and their system of inter-communication was most imperfect. Luckily

Wellington's subordinates at the critical point acted with admirable boldness. Prince Bernard, commanding the brigade at Quatre Bras, retained his position there to check the French advance instead of drawing off to mass with his division at Nivelles. His immediate superiors approved his action. Owing to these officers Wellington retained possession of the important strategical point of Quatre Bras. Consequently Ney's advance struck into Prince Bernard's advanced troops who were forced back. But Prince Bernard firmly held his main position at the cross-roads; and, as the day was drawing on, Ney wisely decided not to push on any farther and so risk isolating the left wing. He halted and reported to the emperor.

Meanwhile Grouchy and Vandamme wasted two hours deliberating in front of the Prussian brigade at Gilly. Then at j:30 P.M. Napoleon again reached the front and vigour replaced indecision. After a brief cannonade Vandamme advanced with the bayonet and the Prussians gave way. Grouchy then moved on Fleurus and halted for the night.

Owing to Zieten's skill Blucher had secured his concentration area, one corps was in position, and two others were at hand. Thanks to his subordinates Wellington still retained a grip on Quatre Bras. His corps were assembling: I, Nivelles, Braine le Comte, Enghien; II., Ath, Grammont, Sotteghem; Cavalry, Ninove; Reserve, at Brussels. During the night the divisions were ordered to move to Nivelles, and at dawn the Reserve marched for Mt. St. Jean.

The duke had relied on information that did not come to hand. His intelligence officer, Colonel Colquhoun Grant, who was in France, was ordered to send back his reports to the duke through General Dornberg at Mons. On June I j Grant reported that the French Army was advancing, but Dornberg refused to believe the report and returned it. Owing to this officer's presumptuous folly Grant's report only reached Wellington on June 18.

On the night of the I jth the "Armée du Nord" was disposed as follows: — Left Wing, Frasnes to Marchienne; Right Wing, in front of Fleurus and astride the Sambre at Chdtelet; Centre (or Reserve), Guard, between Gilly and Charleroi; but Milhaud's Cuirassiers and Lobau's (VI.) Corps were still south of the Sambre. Thus, despite the delays, Napoleon had secured a dominant strategical position. The allies were still encouraged to attempt a risky forward concentration, whilst Napoleon's covering forces were sufficiently far forward to be able to grip whichever ally adventured his army first. The "Armée du Nord" lay concentrated "in a square whose sides measured 12 m. each; and it could with equal facility swing against the Prussians or the Anglo-Dutch, and was already placed between them."

16th June. — Early in the morning Prince Bernard was reinforced at Quatre Bras by the rest of his division (Perponcher's); and Wellington's other troops were now all on the march eastward except the reserve, who were heading southwards and halted at the cross-roads of Mt. S. Jean until the duke had resolved that their objective should be Quatre Bras. They then marched in that direction. Blucher meanwhile was making his arrangements to hold a position to the south of the Namur-Nivelles road and thus maintain uninterrupted communication with Wellington at Quatre Bras.

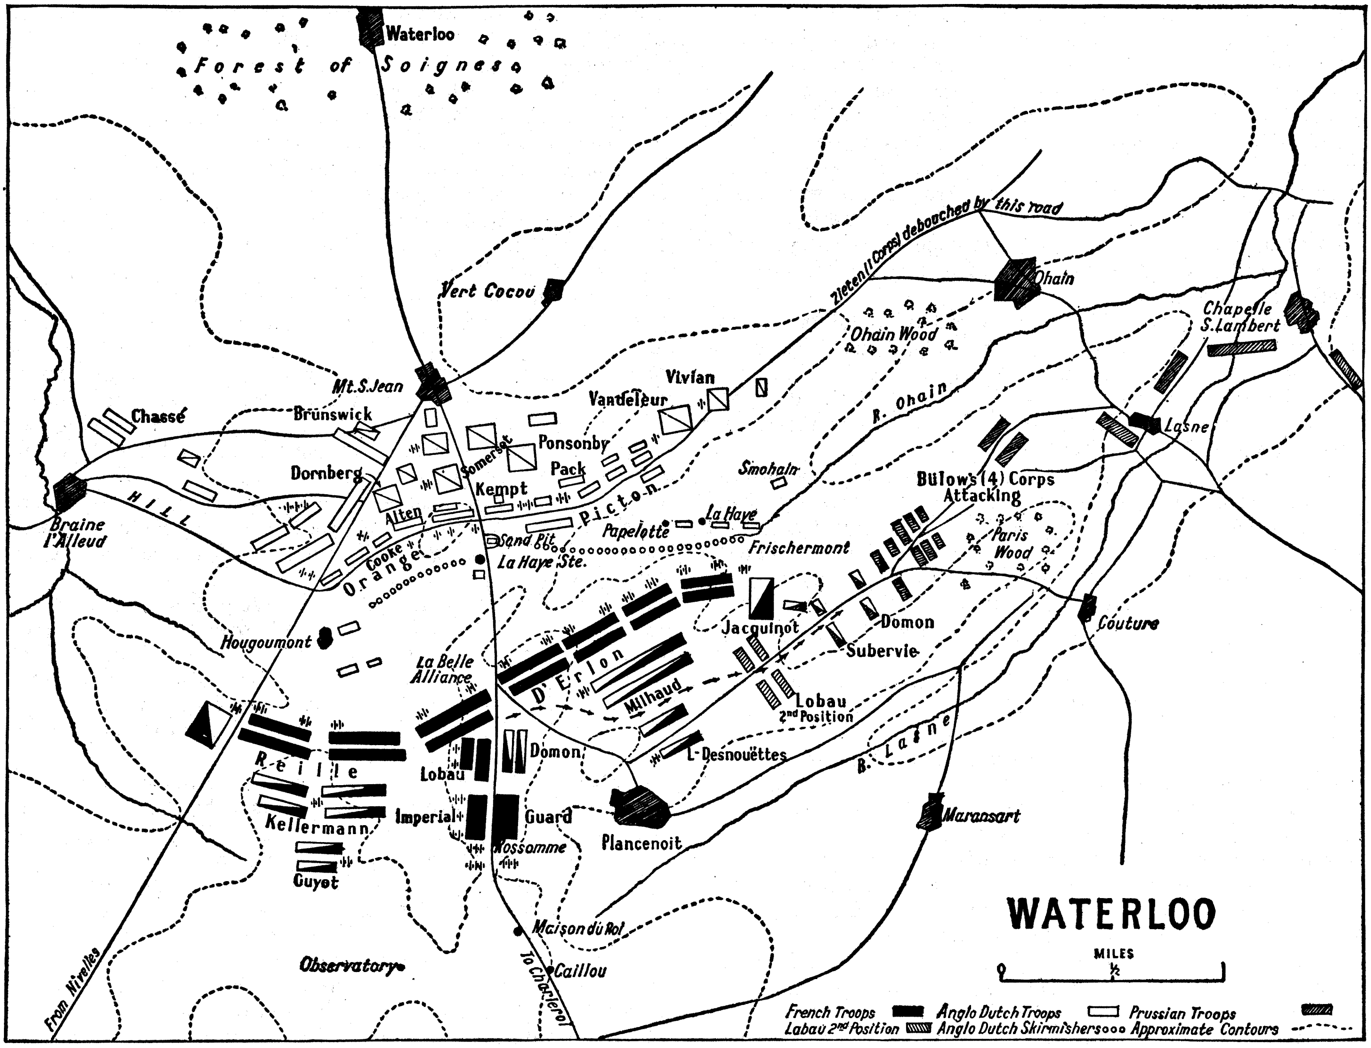
Napoleon spent the early morning in closing up his army, and writing what proved to be the most important letter of the campaign to Ney (Charleroi, about 8 A.M.): "I have adopted as the general principle for this campaign to divide my army into two wings and a reserve. . . . The Guard will form the reserve, and I shall bring it into action on either wing just as circumstances dictate. . . . According to circumstances I shall weaken one wing to strengthen my reserve. . . ." Here, in its simplest form, is the principle that underlies Napoleon's strategy in 1815. Only on the wing on which the reserve is brought into action will a decisive result be aimed at. The other is to be used exclusively to neutralize the other enemy, by holding him at bay.

Napoleon's plan for this day assumed that the surprised allies would not risk a forward concentration. The emperor intended to push an advanced guard to Gembloux to ward off Blucher, and move up the Guard to Fleurus. But once in possession of Sombreffe, the emperor would swing the reserve westward to join Key, who should then have mastered Quatre Bras and have pushed out a force to link with Grouchy, as well as another body 6 m. to the northward. The centre and left wing would then march by night to Brussels. The allies would thus be irremediably sundered. Meanwhile Napoleon and the VI. Corps waited at Charleroi for further information. Up till noon Ney took no serious step to capture Quatre Bras, which still lay at his mercy. Grouchy reported that Prussian masses were coming up from Namur, but Napoleon ignored this. Before 10 A.M. Ney reported considerable hostile forces at Quatre Bras. The marshal was ordered to crush what was in front of him and report to Fleurus. Here Napoleon arrived at 11 A M., still leaving Lobau at Charleroi. Napoleon at once reconnoitred the situation. Only one Prussian corps was showing, but it was disposed parallel to the Namur road, as if to cover a forward concentration. Had the decisive day arrived? If so, by 2 P.M. Vandamme, Gérard, Pajol and Exelmans would be available for the assault, and the Guard and Milhaud would act as a reserve. At 2 P M. Napoleon ordered Ney to secure Quatre Bras, as the emperor was attacking the Prussian corps. Whichever wing succeeded first would then wheel inwards and help the other. The decisive flank had not yet become clear.

Blucher had determined to fight. Wellington, on arrival at Quatre Bras, finding all was quiet, rode over to meet Blucher at Brye. Considering no serious force was in front of Quatre Bras, Wellington ended the interview with the conditional promise that he would bring his army to Blucher's assistance at Ligny, if he was not attacked himself. But on his return to Quatre Bras he found the situation already critical.

Quatre **Bras.**—Ney had let slip the chance when he could have mastered Quatre Bras with ease, and thereby ensured co-operation with Napoleon. He waited to mass Reille's Corps before he advanced, though the Prince of Orange had only 7,500 troops at Quatre Bras. The Prince had boldly scattered his force, made wise use of cover and showed a firm front to Key. It was 2 P M. when the French attacked. East of the road the Dutch-Belgians were forced back and the line wavered. But at 3 P.M. Merlen's cavalry rode in from Nivelles, Picton and the jth division marched up from Brussels, and Wellington himself returned. Pictonstopped the French advance, but Reille's last division was thrown in on the French left, and a hot fight broke out. The Brunswick contingent now reached Wellington and at once attacked. It was 4:1j P.M. Ney had just received Kapoleon's 2 P M. order, and he promptly pressed his attack and almost cleared the Bossu wood. However, at 5 P.M. Alten's division arrived from Nivelles, and Ney realized that he needed D'Erlon's corps to gain the cross-roads.

About 5:15 P.M. Key learned that D'Erlon, without his knowledge, had moved eastwards to co-operate at Ligny. Then at 5:30 P.M. he received Napoleon's order to seize Quatre Bras and swing in against Blucher nho was pinned at Ligny. Napoleon added, "the fate of France is in your hands." Ney's duty was clear. He must hold Wellington at Quatre Bras and allow D'Erlon to ensure that a decisive success was gained that day at Ligny. In no case could D'Erlon return in time to be of any use at Quatre Bras. Ney, beside himself with rage, sent imperative orders to D'Erlon to return and ordered Kellermann's cuirassier brigade to break through Wellington's line. The charge was admirably executed. A British regiment, caught in line, was overthrown and lost a colour. But unsupported, the horsemen were then beaten back. At that moment Ney received a verbal message from Napoleon ordering him, whatever happened at Quatre Bras, to allow D'Erlon to carry out the move to Ligny. Despite remonstrance, Ney refused to reconsider D'Erlon's recall and plunged into the fight. Then about 7 P.M. the British Guards reached Wellington and at last gave him the numerical superiority. Promptly the duke attacked all along the line, and by nightfall the French had been driven back to Frasnes. The losses were, Anglo-Dutch 4,700, French 4,300. At 9 P.M., when the battle was over, D'Erlon arrived. The corps had reached the edge of the Ligny battlefield when it received the counter-order. Thinking he was still under



Ney, D'Erlon decided to leave one division at Wagnelée and to return to the left wing. The incident was immeasurably unfortunate for the French. Had D'Erlon been used betimes at Quatre Bras, Wellington would have been crushed; had he only engaged at Ligny, D'Erlon would have ensured Blucher's annihilation. But oscillating between the two fields the Corps took part in neither. At 10 P.M. Ney wrote a short and somewhat one-sided report to Soult.

Ligny.—On the other flank there had meanwhile been waged the very bitterly fought battle of Ligny. As Blucher's dispositions gradually became clearer the emperor realized that the first decisive day of the campaign had actually come and promptly made arrangements for defeating the Prussian army in his front. Blucher, to cover the Namur road, held with the I. Corps the villages of Brye, St. Amand, and Ligny, whilst behind his centre was massed the II. Corps, and on his left was placed the III. Corps. Wellington and Bulow on arrival would act as general reserve. Blücher's army was quite visible to Napoleon on the bare open slopes, the II. Corps being especially exposed. The emperor decided to bear down Blücher's centre and right with the corps of Vandamme and Gérard and with Girard's division which he had drawn into his operations, containing the Prussian left meanwhile with the squadrons of Pajol and Exelmans, assisted by a few infantry. The Guard and Milhaud were in hand at Fleurus. Further, he could order up Lobau, and direct Ney to move his rearward corps across and form it up behind Blucher's right. When the battle was ripe, he would crush the Prussian centre and right between the Guard and D'Erlon's corps. It was a somewhat complicated manoeuvre; for he was attempting to outflank his enemy with a corps that he had subordinated to Marshal Ney. Much depended on whether Ney would grasp the full purport of his orders. The usual Napoleonic simplicity was wanting at Ligny, and he paid in full for the want.

The Prussians numbered about 83,000 to Napoleon's 71,000 (including Lobau). About 2:30 P.M. the sound of Ney's guns to the westward proved that Wellington was attacked and Napoleon then opened the battle. A fierce fight soon raged for the villages of Ligny and St. Amand. By 3:15 P.M. the battle was in full swing and Napoleon wrote to Ney, saying, "The fate of France is in your hands," and ordering the marshal to master Quatre Bras and move eastwards to assist at Ligny. Directly afterwards, hearing that Ney had 20,000 men in front of him, he sent the "pencil-note" by General La Bédoyère, directing Ney to detach D'Erlon's corps to Ligny. This the A.D.C., in a fit of mistaken zeal, took upon himself to do. Hence the corps appeared too soon and in the wrong direction. It is clear that Ney's essential duty was to co-operate at Ligny, provided that Wellington was held fast at Quatre Bras. Unfortunately, in the heat of action, Ney misread his instructions. Meanwhile the emperor had ordered Lobau to move up to Fleurus. The fight for the villages raged fiercely and incessantly, and the places were captured and recaptured. Generally the French had the better of the fighting, and Blucher was compelled to use up more and more of his reserves. The fighting grew so furious that the troops literally melted away. Even the emperor had to call on his reserves. Just as the Young and Middle Guard moved to reinforce Gérard and Vandamme, the latter reported that a hostile column, 30,000 strong, was threatening his left (in reality it was D'Erlon). This sight unnerved Vandamme's exhausted troops, and guns had to be turned on them to quell a panic. It was nearing 6 P.M. Napoleon concluded that this could not be D'Erlon, as he had arrived too soon and was marching in the wrong direction.

Napoleon sent an officer to reconnoitre. As the French attacks slackened the Prussians rallied and counter-attacked, but they were beaten back by the Young Guard. By 6:30 P.M. Napoleon learned that the force was D'Erlon's, and that it had withdrawn westwards. Thus there was no direct co-operation from the Left Wing on this decisive day. The emperor had perforce to finish the battle single-handed.

Blucher now launched a general counter-stroke against Vandamme, but the chasseurs of the Guard drove back the Prussians in disorder and Napoleon's chance had come at last. As Lobau formed up near Fleurus, the guns of the Guard opened on Ligny to prepare Bliicher's centre for assault. At 7:45 P.M. a crashing salvo from 60 guns heralded a combined onslaught by Gérard, the Guard, and Milhaud. This tremendous impact of picked troops pierced and broke the Prussian centre. Blucher promptly launched his cavalry reserve to stem the French advance. Leading a charge in person he was dismounted and ridden over, before he was rescued and borne from the field. Blucher had taken an unjustifiable personal risk, for at this crisis it was essential for the Prussians to be commanded by a chief who would keep loyally in touch and act in concert with his colleague. By 9 P.M. the battle was over and the French pressed resistlessly onwards. The beaten Prussians retired to the north of the Namur road. But in the failing light and in the uncertainty as to events on the left wing, immediate pursuit was out of the question.

The execution had again fallen short of the conception; Blucher though beaten was not destroyed, nor was his line with Wellington cut. If the Prussians now retired northwards, parallel to the direction which Wellington would follow perforce on the morrow, the chance of co-operating in a decisive battle would still remain to the allies; and Gneisenau's order issued by moonlight, directing the retreat on Tilly and Wavre, went far to ensuring the possibility of such combined action. However, Gneisenau was very remiss in not immediately reporting this vital move and the necessity for it to the duke, as it left the Anglo-Dutch inner flank quite exposed. Gneisenau apparently selected Wavre, not with the intention of assisting his ally, but rather to re-establish his own line of communication, and the presence of the Prussians on the field of battle of Waterloo must be put down to the immortal credit of Blucher and Grolmann, his quartermaster-general.

Gneisenau allowed the re-establishment of his communications to overweigh the paramount necessity of arranging concerted action with his ally. Probably Wellington's failure to co-operate at Ligny had heightened the Prussian chief-of-staff's unworthy suspicions of the duke's good faith. It was well for the allies that Blucher was able to resume command before Napoleon had time to profit from the dissensions that would probably have arisen had Gneisenau remained in control. The casualties at Ligny were very heavy. The Prussians lost 12,000 men and 21 guns, and the French 8,500 men. So close was the fighting that most of the 20,000 casualties lay on 2 sq. m. of ground.

Napoleon's plan of campaign had succeeded. Despite D'Erlon's misadventure, Key's failure had placed the Anglo-Dutch army in a precarious position. Napoleon having beaten Blucher, the latter must fall back to rally and re-form. On the other flank Key lay in front of Wellington, and the marshal could fasten upon the Anglo-Dutch army and hold it fast on June 17, sufficiently long to allow the emperor to close round its open left flank and deal it a death-blow. It was essential to deal with Wellington before Blucher could re-appear on the scene. Wellington was but imperfectly informed of the details of the result of Ligny. Certainly Blucher had despatched an aide-de-camp to warn Wellington that he was forced to retire. But the officer was shot and the message remained undelivered. Nor did Gneisenau repeat this important message directly he assumed temporary command. Gneisenau's neglect involved the allies in an unnecessary and very grave risk.

June 17.—Napoleon was unwell, and was not in the saddle as early as he would otherwise have been; and neither Soult nor Ney made any serious arrangements for an advance when every minute was golden. By early morning the duke had most of his army about Quatre Bras. But Blucher's defeat had rendered Wellington's position untenable. Still ignorant of Blücher's exact position, Wellington sent out a well-escorted officer to establish touch with the Prussians. He reported that the Prussians were drawing off to rally at Wavre. Then, about g A.M., a Prussian officer arrived to explain the situation and learn Wellington's plans. The duke replied that he should fall back and accept battle near Mt. S. Jean, provided he was assured of the support of one of Blucher's corps. He now subordinated everything to remaining in communication with Blucher. It was 2 A.M., June 18, before Wellington received an answer.

Covered by Thielemann the Prussians had drawn off towards Gembloux to join Bulow. Meanwhile, soon after dawn, the French cavalry rounded up some stragglers on the Namur road, and for a time confirmed the idea that Blucher was retiring on his base. The situation was still obscure, details about what had happened to Ney were wanting, and the direction of the Prussian retreat was uncertain. At 8 A.M. Key was ordered to take up his position at Quatre Bras, or if he reported that it was impossible the emperor would co-operate. Napoleon meant that if only a rear-guard opposed Key it was to be driven off and Quatre Bras occupied. But if Wellington was still there, the marshal was to hold him fast, and Napoleon would hasten up with the reserve and crush his enemy. Wellington in fact was there; but Ney did nothing to retain him, and at 10 A.M. the duke began to retire northwards. The last chance of bringing about a decisive French success was thus allowed to slip away.

Grouchy's Operations.—About 11 A.M. Napoleon came to a decision. He determined to send two cavalry corps, and Vandamme's and Gérard's corps, and Teste's division (33,000 and 110 guns) to follow the Prussians and discover if they intended uniting with Wellington in front of Brussels. As touch had been gained with Thielemann at Gembloux, Marshal Grouchy, who had been given command of the force, was ordered by the emperor to "proceed to Gembloux." This order the marshal obeyed literally. After an inconceivably slow march, in one badly arranged column moving on one road, Grouchy only reached Gembloux on June 17, and halted there for the night. Grouchy's cavalry who had been in touch with Thielemann's corps, at Gembloux, allowed it to slip away, and contact was lost for want of a serious effort to keep it. Grouchy did not proceed to the front and entirely failed to appreciate the situation. Pressing danger could only exist if Blucher had gone northwards, and northwards in the Dyle valley Grouchy should have sought for the Prussians. But on June 17 the marshal pushed no reconnaissances to the northward and westward of Gentinnes. (Actually Milhaud, when marching with Napoleon towards Quatre Bras, did see some Prussian infantry retiring northwards and reported this about 9 P.M. to Napoleon, but he attached little importance to it.) Had Blucher gone eastwards, then no danger threatened, for Grouchy could easily have held back any future Prussian advance on the line of the Dyle. Grouchy merely obeyed his orders literally and went to Gembloux. At nightfall the situation was in favour of the allies. The four Prussian corps were concentrated astride the Dyle at Wavre and Grouchy was actually outside them. After an unmolested retreat the Prussians were ready to take the field once more, and 24 hours before Napoleon had deemed it possible after their defeat at Ligny.

Napoleon's Pursuit of Wellington.—On the other flank, too, things had gone all in favour of Wellington. At noon Napoleon wrote to Ney that troops had been placed at Marbais to second the marshal's attack on Quatre Bras, yet Ney remained quiescent, and Wellington began his retreat unmolested. Thus on Napoleon's arrival only the duke's cavalry screen and some horse artillery remained on the position. As the emperor justly said, Ney had ruined France. This was the fatal mistake of the campaign. Although Napoleon opened a rapid pursuit as the cavalry screen crumpled up and decamped, yet he failed to entangle the rear guard so deeply as to force the duke to return to its assistance. Also a tropical thunderstorm considerably retarded the French pursuit. Only as the light failed did Napoleon arrive opposite to Wellington's position, and then by a masterly reconnaissance in force he compelled the duke to disclose the presence of virtually the whole army. The French halted between Rossomme and Genappe, bivouacking in the sodden fields.

June 18.—During the night Wellington heard that Blucher would bring two corps certainly, and possibly four, to Waterloo, and the duke determined to accept battle. Yet so far was Wellington from divining Napoleon's plan that he stationed 17,000 men (including Colville's British division) about Hal, 8 m. to his right, to repel a turning movement that he groundlessly anticipated and to form a rallying point for his right in case his centre was broken. By making this detachment the duke ran a very grave risk. But with the 67,600 men and 1j6 guns which he had in hand, he took up a truly admirable "Wellingtonian position" in front of Mt. S. Jean. He used a low ridge to screen his main position, exposing comparatively few troops in front of the crest. He occupied Hougoumont with detachments of the British Guards and placed a King's German Legion garrison in La Haye Sainte, the key of his position. The duke also took care to distribute the troops so that the indifferent and immature were closely supported by those who were "better disciplined and more accustomed to war." Full arrangements for Blucher's co-operation were made through General Muffling, the Prussian attaché on the duke's staff. The duke was to stand fast and receive the attack, whilst Blucher closed round Napoleon's exposed right. Thus the Prussians were the real general reserve on this day.

Blücher kept his promise loyally, but the execution was faulty. The Prussians did not start marching at dawn, and the rear corps (Bulow) was selected to lead the column. A fire that broke out in Wavre further delayed the march. But, despite his hurts, the old marshal was in the saddle.

Luckily the wet state of the ground (largely cornfields) and the scattered bivouacs of the French caused Napoleon's attack to be put off until 11.30 A.M. Grouchy had reported at 10 P.M., 17th, from Gembloux that the Prussians were retiring towards Wavre and Perwez. He stated that he meant to follow the Wavre column, if it was the stronger, and separate it from Wellington. But this was impossible. Grouchy was outside the Prussian left and, by following it, he must inevitably drive the allies together. The emperor answered the letter at 10 A.M., and directed the marshal to march for Wavre. Napoleon's original plan must be kept in mind when considering this letter. It will then be seen to mean that Grouchy was to place his force on Blucher's inner flank and hold him back from Waterloo. But this is just what the letter does not state precisely; accordingly Grouchy (as Ney had done previously) misread it.

Meanwhile the French army formed up some 1,300 yards from Wellington's position. Although some misgivings filled the minds of such Peninsular veterans as Soult, Reille, and Foy, none assailed Napoleon. But the late hour at which the battle opened, and Napoleon's determination to break Wellington's centre instead of outflanking his left and farther separating the allies, deprived him of any chance of beating Wellington before Blücher could intervene. Napoleon drew up his army of 74,000 and 246 guns in three lines in full view of the Anglo-Dutch army. It was an imposing array of veteran troops backed by the dark masses of the Imperial Guard. As their emperor rode along the lines the troops acclaimed him with extraordinary enthusiasm.

WATERLOO

First Phase.—About 11.30 A.M. the battle was opened with an attack by one of Reille's divisions on Hougoumont. This was merely to draw Wellington's attention to his right, and in this it failed. Half-an-hour later a battery of 80 guns unlimbered on the long spur to the S.E. of La Haye Sainte to prepare the duke's centre for the main attack. But the crest of the "Wellingtonian position" sheltered the defence from the tempest of iron. After 1 P.M., and just before he gave orders for Ney to lead the main attack, the emperor scanned the battlefield, and on his right front he saw a dense dark cloud emerging from the woods at Chapelle Saint Lambert. It was soon discovered that this was Bulow's corps marching to Wellington's assistance. A letter was now awaiting despatch to Grouchy, and to it was added a postscript that the battle was raging with Wellington, that Bülow's corps had been sighted by the emperor, and that the marshal was to hasten to the field and crush Bülow. This order at least was clear, but it was sent 12 hours too late, and when Grouchy received it he was unable to carry it out. To neutralize Bulow when necessity arose, the emperor now detached Lobau together with the squadrons of Domon and Subervie. The general, however, hardly drew out far enough from the French right; otherwise the magnificent resolution he displayed and the admirable obstinacy with which his troops fought against ever-increasing odds are worthy of all praise. Thus as early as 1.30 P.M. the Prussian intervention deranged the symmetry of Napoleon's battle-array. The emperor never considered breaking off the fight and seeking a more favourable opportunity of beating the allies in detail. He was still determined to involve both Wellington and Bulow in a common ruin.

Second Phase.—Ney was therefore ordered to attack Wellington's centre with D'Erlon's corps. Owing to a misconception the columns used for advance were over-heavy and unwieldy, and the corps failed to achieve anything of importance. As D'Erlon's troops advanced the Dutch-Belgian brigade in front of the ridge, which had been subjected to an overwhelming fire from the 80 French guns at close range, turned about and retired in disorder through the main position. This, however, was the solitary success secured by the I. corps; for the left division failed to storm La Haye Sainte and Picton's division met the remainder of D'Erlon's corps face to face, engaging them in a murderous infantry duel in which Picton fell. During this struggle Lord Uxbridge launched two of his cavalry brigades on the enemy; and the "Union brigade" catching the French infantry unawares rode over them, broke them up, and drove them to the bottom of the slope with the loss of two eagles, but the British cavalry were driven back with great loss by fresh French horsemen hurled on them by the emperor. So far no success against Wellington had been achieved, and Bulow was still an onlooker.

Third Phase.—Ney was now ordered to attack La Haye Sainte again, but the attack failed. A furious cannonade raged, and the Anglo-Dutch line withdrew slightly to gain more cover from the ridge. Ney misinterpreted this manoeuvre and led out, about 4 P.M., Milhaud's and Lefebvre-Desnouettes' horsemen (43 squadrons) to charge the allied centre between the two farms. For several reasons, the cavalry could only advance at a trot. As the horsemen closed they were received with volleys of case from the guns, and the infantry formed into squares. Against the squares the horsemen were powerless, and failing to break a single square, they were finally swept off the plateau by fresh allied horsemen. Kellermann's cuirassiers and the heavy horse of the Guard (37 fresh squadrons) now advanced to support the baffled cavalry, the latter falling in as supports. The whole 80 squadrons resumed the attack, but with no better result The cavalry gradually became hopelessly entangled among the squares they were unable to break, and at last they were driven down the face of the ridge and the most dramatic part of the battle came to an end. Had these great cavalry attacks been closely supported by infantry, there can be little doubt that they must have achieved their object. But they were not. In his handling of the three arms together, Napoleon on this day failed to do justice to his reputation.

About 4.30 P.M. Bulow at last engaged. Lobru's men were gradually overpowered and forced back into Plancenoit, the village was stormed, and the Prussian round shot reached the main road. To set his right flank free the emperor called further on his reserve, and sent Duhesme with the Young Guard to Lobau's support. Together, these troops drove Bulow out of Plancenoit, and forced him back towards the Paris wood. But the Prussians had not yet changed the fate of the day.

Fourth Phase.—Napoleon now ordered Ney to carry La Haye Sainte at whatever cost, and this the marshal accomplished with the wrecks of D'Erlon's corps soon after 6 P.M. The garrison (King's German Legion) had run out of rifle ammunition and the French bursting in seized the post. This was the first decided advantage that Napoleon had gained during the day. The key of the duke's position was now in Napoleon's hands, Wellington's centre was dangerously shaken, the troops were exhausted, and the reserves inadequate. But the Iron Duke faced the situation unmoved. Calmly he readjusted his line and strengthened the torn centre. Happily for him, Pirch I. and Zieten's corps were now at hand. Pirch I. moved to support Bulow; together they regained possession of Plancenoit, and once more the Charleroi road was swept by Prussian round shot. Napoleon, therefore, had to free his right flank before he could make use of Key's capture. To this end he sent two battalions of the Old Guard to storm Plancenoit. The veterans did the work magnificently with the bayonet, ousted the Prussians from the place, and drove them back 600 yards beyond it. But Napoleon could not turn now on Wellington. Zieten was fast coming up on the duke's left, and the crisis was past. Zieten's advent permitted the two fresh cavalry brigades of Vivian and Vandeleur on the duke's extreme left to be moved and posted behind the depleted centre. The value of this reinforcement at this particular moment can hardly be overestimated.

Fifth Phase.—The French now fiercely attacked Wellington all along the line; and the culminating point of this was reached when Napoleon sent forward the Guard, less 5 battalions, to attack Wellington's centre. Delivered in three échelons, these final attacks were repulsed, the first échelon by Colin Halkett's British Brigade, a Dutch-Belgian battery, and a brigade of Chassé's Dutch-Belgian division; the second and third échelons by the Guards, the 52nd, and the Royal Artillery. Thus ended the fifth phase.

Rout of the French.—As the Guard recoiled (about 8 P.M.) Zieten pierced the north-east corner of the French front. and their whole line gave way as the allies rushed forward on their now defenceless prey. Three battalions of the Guard indeed stood their ground for some time, but they were finally overwhelmed. Afterwards, amidst the ruins of their army, two battalions of the 1st Grenadiers of the Guard defied all efforts to break them. But, with the exception of these two battalions, the French army was quickly transformed into a flying rabble. Bdlow and Pirch I. now finally overpowered Lobau, once more recaptured Plancenoit, and sealed the doom of the French army. But Lobau's heroic efforts had not been in vain; they had given his master time to make his last effort against Wellington; and when the Guard was beaten back the French troops holding Plancenoit kept free the Charleroi road, and prevented the Prussians from seizing Napoleon's line of retreat.

When Wellington and Blucher met about 9.15 P.M. at "La Belle Alliance," the victorious chiefs arranged that the Prussians should take up the pursuit, and they faithfully carried out the agreement. Pushing on through the night, they drove the French out of seven successive bivouacs and at length drove them over the Sambre. The campaign was virtually at an end, and the price paid was great. The French had lost over 40.000 men and almost all their artillery on June 18: the Prussians lost 7,000, and Wellington over 15,000 men. So desperate was the fighting that some 45,000 killed and wounded lay on an area of roughly 3 sq m. At one point on the plateau "the 27th (Inniskillings) were lying literally dead in square"; and the position that the British infantry held was plainly marked by the red line of dead and wounded they left behind them.

Grouchy's Operations **June** 18–19.—A few words may now be bestowed on Marshal Grouchy, commanding the right wing. The marshal wrongly determined on the 18th to continue his march to Wavre in a single column, and he determined, still more wrongly, to move by the right bank of the Dyle. Breaking up from bivouac long after dawn, he marched forward, via Walhain. Here he stopped to report to the emperor some intelligence which turned out to be false, and he remained for breakfast. Hardly had he finished when the opening roar of the cannonade at Waterloo was heard. Grouchy was now urged by his generals, especially by Gérard, to march to the sound of the firing, but he refused to take their advice, and pushed on to Wavre, where he found the Prussians (Thielemann's corps of 16,000 men) holding the passages across the Dyle. A fierce fight (called the Action of Wavre) began about 4 P.M., in which the Prussians were for long victorious. Instead of concentrating his force upon one bridge over the swampy and unfordable Dyle, Grouchy scattered it in attacks upon several; and when the emperor's despatch arrived, saying Bulow was in sight, the marshal was powerless to move westward. Towards the end of the day Colonel Vallin's Hussars stormed the Limale bridge, and a large part of Grouchy's force then promptly gained the left bank. The action continued till about 11 P.M., when it died out, to recommence shortly after dawn. Thielemann was at length overborne by sheer weight of numbers, and towards 11 A.M. he was forced to retire towards Louvain. The losses were considerable, about 2,400 men on each side.

Grouchy's victory was barren. In the far higher duty of co-operation he had failed miserably. His tactical achievement could avail the emperor nothing, and it exposed his own force to considerable danger. Whilst pondering on the course he should follow, the marshal received the news of the awful disaster that had overtaken the emperor at Waterloo. In a flash he realized his danger and made prompt arrangements to begin his retreat on Namur, the only line to France that was then available. This retreat he carded out resolutely, skilfully and rapidly, slipping past Blucher and finally bringing his force to Paris But the rapid advance of the allies gave France no time to rally. Napoleon was forced to abdicate, and finding escape was impossible, he surrendered (on July 14) to the British—"the most powerful, the most unwavering and the most generous of his foes."

The causes of Napoleon's failure in the Waterloo campaign were as follows:—The French army was numerically too weak for the gigantic task it undertook. Napoleon himself was no longer the Napoleon of Marengo or Austerlitz, and though he was not broken down, his physical strength was certainly impaired. Ney failed to grasp and hold Wellington on the critical 17th of June; and on the 17th and 18th Grouchy's feeble manoeuvres enabled Bldcher to march and join Wellington at Waterloo. Napoleon's chance of success was dangerously diminished, if not utterly destroyed, by the incompetence of the two marshals whom in an evil hour he selected for high commands.

Another dominant influence in shaping the course of events was the loyalty of Blucher to his ally, and the consequent appearance of the Prussian army at Waterloo. Nor must we overlook Wellington's unswerving determination to co-operate with Blucher at all costs, and his firmness on June 18; or the invincible steadiness shown by the British troops and those of the King's German Legion.

Reviewing this campaign at St. Helena, Napoleon laid the responsibility for the disaster of Waterloo on the inaction of Marshal Grouchy who, after he had lost touch with the Prussian army (which had crossed the Dyle at Wavre in order to work round to the north in the direction of Soignes), ignored the urgent representations of his officers, and in particular of General Gérard, and refused to unite his forces with the bulk of Napoleon's army, although he could hear the sound of the guns. However grave may have been Grouchy's error, it would be unjust to characterize his failure as treason. In any case, Marshal Grouchy, in spite of the miscarriage of his first mission, fearing to depart from the orders of the emperor, showed himself deficient not only in military insight but also in character.

In this article the writer has been greatly assisted by the advice and suggestions of Lt.Col. H. W. L. Hime, R.A. (A. F. Be.)

WATERLOW, SIR ERNEST ALBERT (1850–1919), English landscape painter, was born in London on May 24, 1850. He studied at the Royal Academy schools, where, in 1873, he was awarded the Turner gold medal for landscape painting.

Elected associate of the Royal Society of Painters in Water Colours in 1880, he became a member in 1894 and was president of the society, 1897–1914. He was named an associate of the Royal academy in 1890 and academician in 1903. Waterlow was knighted in 1902.

From the early 1870s he produced a number of landscapes, with and without figures, in oil and water colour. One of his pictures, "Galway Gossips," was hung in the Tate gallery in London.

Waterlow died at Hampstead, London, on Oct. 25, 1919.

WATERMARKS, the emblems or designs in paper used originally in Italy in the latter part of the 13th century. The orientals, who were the first to make paper, did not employ watermarks, although their method of fabricating sheets of paper was almost identical with that introduced into Europe during the middle 12th century.

The original Italian watermarks consisted of devices such as crosses, circles, triangles and forms of the simplest kind that could readily be twisted in wire. Until the middle of the 19th century all watermarks were formed in outline and were produced by the use of metal wires bent to the shape of the required design. These wire objects were then sewed to the mould on which the paper was to be formed, the wire leaving its impression in the wet sheet of paper by causing the fibres to lie thinner along its course. The ordinary watermarks in hand-made paper of the present day are made in the same manner as those from the inception of the art, the only difference being in the employment of finer wire and greater skill in their formation. Plate, fig. 3, shows the wire device on the covering of a laid paper mould from the 16th century; fig. 5 gives a section of an 18th century Dutch mould with the watermarking wires in place.

About the middle of the 19th century a more complicated and artistic form of watermarking was devised and instead of being limited to simple outline forms, it was possible to cause the paper to be made in any degree of thickness or tone desired. Fig. 1 shows a mould for the watermarking of a portrait. This mould has been made by first modelling the profile in a sheet of wax so that the various degrees of light and shade may be had and then making intaglio and cameo dies from the wax model by electrotyping. Closely-woven brass wire gauze is then subjected to great pressure between the two electrotype plates, the wire cloth or gauze taking the same contour as the original wax relief.

In forming sheets of paper on a hand mould the water drains through the woven wire, leaving the moist pulp in precisely the same thicknesses as those sculptured in the wax original. The watermarking of paper in colour was invented by Sir William Congreve in 1818 (English patent, Dec. 4, 1819, No. 4419) and consisted in placing coloured paper stock (pulp) in various layers to form a homogeneous sheet of paper.

The foregoing treats only of watermarks that are produced in hand-made paper where the moist pulp lies on the wire lettering or pressed wire design during the whole process of forming the sheet.

This naturally gives a brilliant and clear-cut watermark. In machine-made paper a wire cylinder known as a "dandy-roll" or a circular rubber form is used to impart the lettering or symbol to the moist paper by rolling over its surface after the web of paper has been formed. It is therefore not possible to produce as clear or distinct a watermark on a machine as it is by the use of a finely constructed mould in the hands of a skilled craftsman.

(D. Hu.)

WATERMELON (Citrullus vulgaris), a succulent fruit of the gourd family, native to tropical Africa, under cultivation on every continent with suitable climate and soil. The word for watermelon is included in Sanskrit, and fruits are depicted by early Egyptian artists, indicating an antiquity in agriculture along with other old-world species under cultivation for more than 4,000 years. Its vines grow prostrate, with branched tendrils, deeply cut leaves and flowers borne singly in the axil of a leaf. Each flower produces either pollen or fruit. The flesh may be red, white or yellow. Weight varies from 3 or 4 lb. to 50 lb. or more. The number of fruits per vine varies from 2 or 3 to 15.

Citron melon (Citrullus vulgaris), not to be confused with true citron of the citrus family, is prized for preserves and jellies. Another species (C. colocynthis) contains a bitter constituent to which some individuals show "taste blindness." The bitter and sweet melons are found in the same habitats. Scientific discoveries applied to watermelon breeding make possible another commercial variety, a seedless hybrid that is chromosomally unbalanced and sterile but vegetatively vigorous and productive. Its immature fruit flowers can be artificially pollinated in such a way that the hybrid fruit sets and becomes a seedless fruit preferred by consumers. For the next season's production, seed must be obtained by hybridizing parental strains.

Common diseases afflicting watermelon are Fusarium wilt, anthracnose, downy mildew, stem-end rot and root knot. Cucumber beetles, cutworms, wireworms, melon aphids and mites are the important insects reducing melon production.

See also CUCURBITACEAE ; VEGETABLE. (O. J. Ei.)

WATER OPOSSUM or YAPOCK (Chironectes minimus), distinguished from other opossums by its aquatic habits. webbed hind feet, and peculiar colouration. Its ground colour is light gray. nith four or five sharply contrasted blackish bands passing across its head and back giving it a very peculiar mottled appearance; the head and body together are about 14 in. long, and the tail a little more. It feeds on small fish, crustaceans and other water animals; its range extends from Guatemala to southern Brazil.
