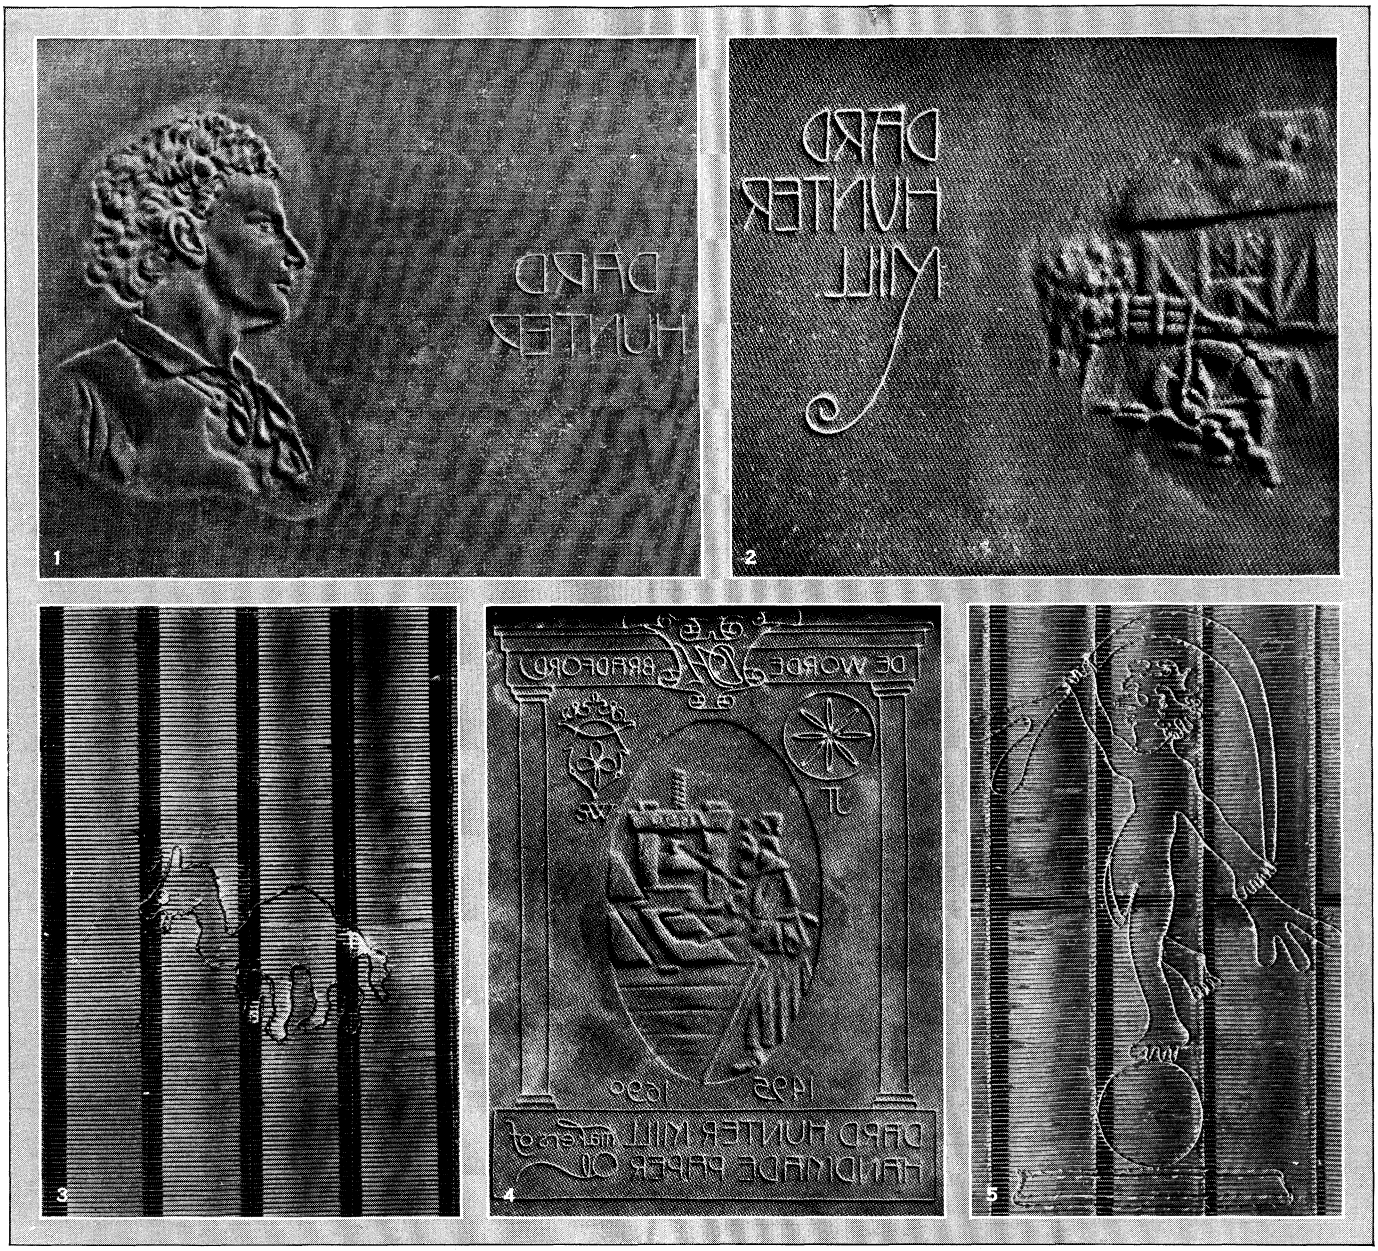
WATER POLO is played by two teams of seven players each in both outdoor and indoor pools. Although a game of "football in the water" was proposed in London as early as 1870 and aquatic handball matches were played in the mid-1870s. it was not until the 1880s that an organized game, similar to the modern one, was instituted. The London Water Polo league was founded in 1888, and the game spread in popularity to the continent and the U.S.

Until the late 1920s two types of games were played throughout the world under distinctly different sets of rules. To that time in the United States the rugged body-contact style of play, involving the use of a semi-inflated rubber ball with the premium placed on retaining possession of it, was the favoured game. In other countries the water-soccer type of play, involving a fully inflated leather-covered ball with the emphasis placed on the skillful passing and tossing of it, was exclusively favoured. The tacit recognition of both of these contrasting types of play by international sports-governing bodies resulted in a unique situation whenever the Olympic games were held. If the games were held in the United States the soft-ball water polo was played, with only teams from the United States participating, because of the unfamiliarity of the aquatic squads of other nations with the soft-ball play. Whenever the Olympic games were held outside of the Cnited States, the hard-ball game was given exclusive recognition. However, colleges in the United States, which furnished most of the American water polo players, began to abandon the rugged soft-ball type of game and to substitute the hard-ball soccer type of play. Accordingly soft-ball water polo disappeared from the sports scene and after 1937 soccer water polo, played with the hard ball, was the only style of water polo played anywhere, as well as the only style officially recognized by the Olympic games committees as an international championship water sports event. There are top ranking water polo teams and leagues in most European and some British commonwealth countries, and international competition in water polo is staged on a grand scale annually in Europe and, to a slightly lesser extent, in the Americas.

In the early days of international water polo, Great Britain took the lead, but before long the pupils began to surpass the master, and France, Germany and the Netherlands produced outstanding teams. After World War II Hungary became almost supreme in the Olympic games and European championships, followed by Yugoslavia and the U.S.S.R.

The rules and laws governing the playing of water polo are pre-

WATERMARKS



WATERMARKS AND WATERMARKING DEVICES

1. A complete mould (with deckle) for the watermarking of a portrait. The profile is first worked in wax so that various degrees of light and shade may be gained, and then intaglio and cameo dies are made from wax mcdel by electrotyping
2. Hand made paper mould, combining lettering, and light and shade device for forming sheets of paper in one colour. Wires of lettering and pressed woven wire of design cause wet paper pulp to lie in many thicknesses, thus forming watermark in the sheet of paper
3. Wire device for watermarking figure of a camel in sheets of paper. Old papermakers favoured animals for watermarks
4. Mould for making hand-made paper, which combines the ordinary wire lettering and designs with the complicated light and shade device. With this mould the oval centre is produced in separate colour from balance of sheet. The wheel or star watermark (upper right-hand side) is that of John Tate who established the first paper mill in England in 1495. Watermarking device (upper left-hand side) is that of William Rittenhouse who founded the first paper mill in the Colonies in 1690
5. Wire device for a watermark showing a child swinging a rope

scribed, and amended from time to time, by the F.I.N.A. (Federation Internationale de Natation Amateur or International Water Polo board), founded in London in 1908. In the U.S., under rules adopted by the Amateur Athletic union, the playing pool or "bath" is rectangular in shape, must not be more than 30 yd. nor less than 20 yd. from end to end, the uniform width must not exceed 20 yd. nor be less than 8 yd. Measurements of a pool for female team play are 25 yd. by 17 yd. The goal nets or cages are at both ends and must be 10 ft. wide and 3 ft. above the surface of the water when the water is 15 ft. or more in depth and 10 ft. wide and 8 ft. from the bottom of the bath when the depth of the water is less than j ft.. and extend not less than 1 ft. from the end of the pool. Markers denoting the location of imaginary lines 2 yd. and 4 yd. respectively from the goal lines and parallel to them must be posted on both sides of the pool.

The required minimum depth of the water in the playing pool is 3 ft. but for international matches a minimum depth of 6 ft. is strongly recommended in the rules. Teams consist of seven players comprising the goalkeeper, three backs and three forwards. The required officials are a referee (in complete charge). a timekeeper and two goal judges The scoring of goals is signaled by the goal judges. using white and red flags to indicate their decisions.

Time for official games is 20 minutes of play consisting of two 10-minute halves with a j-minute intermission. One team wears dark blue caps and the other white, but both goalkeepers must wear red. Each player's cap is numbered to show his position—the goalkeeper is no. 1, halfback no. 4. etc.

At the beginning of the game and after half time, all the players must be in position at their own goal lines spaced at least one yard apart. The referee blows his whistle, tosses the ball into the centre of the pool and play is on. A goal is scored by the bail passing fully over the goal line, which is one foot from the end of the pool. and between the goal posts into the goal net or cage. Whenever the ball passes over the goal line but not between the goal posts and it has been last touched by an attacking player, a goal throw is awarded to the defending goalkeeper. who makes the throw from the goal line between the posts. When the ball goes over the goal line outside of the goal posts and is last touched by a defending player, a free corner throw is awarded to an attacking team player from two yards out from the goal line at the side of the pool. All goals count one point. In deciding the winner of a championship tournament the highest goal average rule is applied whenever two or more teams are tied in games won and lost.

Interest in water polo as both a player and spectator sport increased with international competition, notably in Europe and Central and South America. Water polo enjoys a particular advantage over most other team sports in that it requires only limited space and relatively inexpensive equipment and facilities. In the United States its rise to prominence was phenomenal on the Pacific coast, where all colleges and athletic clubs have teams. Elsewhere in the United States, the failure of colleges and universities to include water polo in their athletic programs has resulted in a lag in interest, but several old established athletic clubs (*e.g.*, in New Tork. Chicago and St. Louis) maintained interest and competition in the national annual tournaments, both indoor and outdoor, and in Pan-American and Olympic championship teams (*see* OLYMPIC GAMES).

A fundamental change in rules was made shortly after the 1948 Olympic games, when the old rule whereby a player mas not allowed to move when the referee blew his whistle was changed to permit freedom of swimming at all times. The purpose of this change was to eliminate stoppages and to make the game faster.

For complete rules *see* the current edition of the Amateur Athletic Union of the U.S., *Official Swimming Handbook;* and the *1957 Rules of Water Polo* issued by the International Water Polo Board. (J. J. CN.; E. J. ST.)

WATER RIGHTS. By the law of England the property in the bed and water of a tidal river is presumed to be in the crown or as a franchise in a grantee of the crown, and to be extra-parochial. The bed and water of a nontidal river are presumed to belong to the person through whose land it flows, or, if it divide two properties, to the riparian proprietors, the rights of each extending to midstream *(ad medium filum aquae)*. In order to give riparian rights, the river must flow in a defined channel, or at least above ground. The diminution of underground water collected by percolation, even though malicious, does not give a cause of action to the owner of the land in which it collects, it being merely *damnum sine iniuria,* though he is entitled to have it unpolluted unless a right of pollution be gained against him by prescription. The right to draw water from another's well is an easement (*q.v.*) not a *profit à prendre,* and is therefore claimable by custom. As a general rule a riparian proprietor, whether on a tidal or a nontidal river, has full rights of user of his property. Most of the statute law will be found in the Fishery Harbours act. 191j, and the Salmon and Freshwater Fisheries act, 1923. In certain cases the rights of the riparian proprietors are subject to the intervening rights of other persons. These rights vary according as the river is navigable or not, or tidal or not. For instance, all the riparian proprietors might combine to divert a nonnavigable river, though one alone could not do so as against the others, but no combination of riparian proprietors could defeat the right of the public to have a navigable river mantained undiverted. We shall here consider shortly the rights enjoyed by, and the limitations imposed upon, riparian proprietors, in addition to those falling under the head of fishery or navigation. (See also FORESHORE.)

The right of use of the water of a natural stream cannot be better described than in the words of Lord Kingsdown in 1858: "By the general law applicable to running streams, every riparian proprietor has a right to what may be called the ordinary use of water flowing past his land—for instance, to the reasonable use of the water for domestic purposes and for his cattle, and this without regard to the effect which such use may have in case of a deficiency upon proprietors lower down the stream. But, further, he has a right to the use of it for any purpose, or what may be deemed the extraordinary use of it. provided he does not thereby interfere with the rights of other proprietors, either above or below him. Subject to this condition, he may dam up a stream for the purposes of a mill, or divert the mater for the purpose of irrigation. But he has no right to intercept the regular flow of the stream, if he thereby interferes with the lawful use of the water by other proprietors, and inflicts upon them a sensible injury" (*Miner* v. *Gilmour,* 12 Moore's P.C. Cases, 156). The rights of riparian proprietors where the flow of water is artificial rest on a different principle. As the artificial stream is made by a person for his own benefit, any right of another person as a riparian proprietor does not arise at common law, as in the case of a natural stream, but must be established by grant or prescription. If its origin be unknown the inference appears to be that riparian proprietors have the same rights as if the stream had been a natural one *(Baily* v. *Clark,* 1902, *1* Ch. 649). The rights of a person not a riparian proprietor who uses land abutting on a river or stream by the licence or grant of the riparian proprietor are not as full as though he were a riparian proprietor, for he cannot be imposed as a riparian proprietor upon the other proprietors without their consent. The effect of this appears to be that he is not entitled sensibly to affect their rights, even by the ordinary as distinguished from the extraordinary use of the water. Even a riparian proprietor cannot divert the stream to a place outside his tenement and there use it for purposes unconnected with the tenement (*McCartney* v. *Londonderry and Lough Swilly Rly. Co.,* 1904, A.C. 301).

The limitations to which the right of the riparian proprietor is subject may be divided into those existing by common right, those imposed for public purposes and those established against him by crown grant or by custom or prescription. Under the first head comes the public right of navigation, of anchorage and fishery from boats (in tidal waters) and of taking shellfish (and probably other fish except royal fish) on the shore of tidal waters as far as any right of several fishery does not intervene. Under the second head would fall the right of eminent domain by which the state takes riparian rights for public purposes, compensating the proprietor, the restrictions upon the sporting rights of the proprietor, as by acts forbidding the taking of fish in close time and the Wild Birds Protection acts, and the restrictions on the ground of public health, as by the Rivers Pollution act, 1876, and the regulations of port sanitary authorities. The jurisdiction of the state over rivers in England may be exercised by officers of the crown, as by commissioners of sewers or by the board of trade, under the Crown Lands act, 1866. These powers were later transferred to the ministry of transport. Rivers are frequently controlled by conservation under special acts, upon which their powers mainly depend (see *Thames Conservators* v. *Kent,* 1918, 2 K.B. 272). A bridge is erected and maintained by the county authorities, and the riparian proprietor must bear any inconvenience resulting from it. An example of an adverse right by crown grant is a ferry or a port. The rights established against a riparian proprietor by private persons include the right to land, to discharge cargo, to tow, to dry nets, to beach boats, to take sand, shingle or water, to have a sea wall maintained, to pollute the water (subject to Rivers Pollution act), to water cattle, etc. Where the river is navigable, although right of navigation is common to subjects of the realm, it may be connected with a right to exclusive access to riparian land, the invasion of which may form the ground for legal proceedings by the riparian proprietor (see *Lyon* v. *The Fishmongers' Company,* 1876, 1 A.C. 662). There is no common-law right of support by subterranean water. A grant of land passes all watercourses, unless reserved to the grantor.

A fresh-water lake appears to be governed by the same law as a nontidal river, surface water being *pars soli.* The preponderance of authority is in favour of the right of the riparian proprietors as against the crown. Most of the law will be found in *Bristow* v. *Cormican,* 1878, 3 A.C. 648.

Unlawful and malicious injury to sea and river banks, towing paths, sluices, floodgates, milldams, etc., or poisoning fish, are crimes under the Malicious Damage act, 1861.

A mill may be erected by anyone, subject to local regulations and to his detaining the water no longer than is reasonably necessary for the working of the wheel. But if a dam be put across running water, the erection of it can only be justified by grant or prescription, or (in a manor) by manorial custom. On navigable rivers it must have existed before 1272. The owner of it cannot pen up the water permanently so as to make a pond of it.

Batkzng — The reported cases affect only sea bathing. but Hall (p. 160) is of opinion that a right to bathe in private waters may exist by prescription or custom. There is no common-law right to bathe in the sea or to place bathing machines on the shore. Prescription or custom is necessary to support a claim, whether the foreshore is the property of the crown or of a private owner (*Brinckman* v. *Matley,* 1904, 2 Ch. 313). Bathing in the sea or in rivers is now often regulated by the bylaws of a local authority. (*See* also FERRY.)

Scotland. — The law of Scotland is in general accordance with that of England. The crown has: (1) a right of property in the *solum* and salmon fisheries of the sea — and tidal navigable rivers — within the three-mile limit, which is *inter regulia minora* and may be alienated by express or implied grant; and (2) a right of navigation and white fisheries in the same which is *inter regalia majora* and inalienable. A crown charter of lands "bounded by the sea" is a habile title to prescribe a right to the *solum* of the foreshore, between high- and low-water mark of ordinary spring tides, and if the charter contain a clause *cum piscationibus* it is a habile title to prescribe a right to the salmon fishing *ex adverso* of the lands. Where the foreshore is acquired under a crown grant it remains subject to public uses incidental to navigation and white fishing. Persons engaged in the herring fishery off the coast of Scotland have, by 11 Geo. III. c. 31, the right to use the shore for 100 yd. from high-water mark for landing and drying nets, erecting huts and curing fish. The right of ferry is one of the *regalia minora* acquirable by prescriptive possession on a charter of barony. Sea greens are private property. The right to take seaweed from another's foreshore may be prescribed as a servitude. The riparian proprietors have several rights in the *solum* of a fresh-water loch and a right in common to use its surface for boating, fishing and shooting (*Mackenzie* v. *Banks,* 1878, 3 App. Cas. 1324). As between opposite riparian proprietors the *medium filum* is only of importance in determining rights of property in the *solum,* or the exercise of fishing rights, where the opposite proprietors have each rights of fishing but neither has had exclusive possession. *See* the Salmon Fisheries (Scotland) acts 1828 to 1868. In Ireland the lam is similar to that of England. In *R.* v. *Clinton,* I.R. 4 C.L. 6, the Irish court went perhaps beyond any English precedent in holding that to carry away drift seaweed from the foreshore is not larceny. The Rivers Pollution act, 1876, was re-enacted for Ireland by the similar act of 1893.

United States. — In the United States the common law of England was originally the law, the state succeeding to the right of the crown. This was no doubt sufficient in the 13 original states, which are not traversed by rivers of the largest size, but was not generally followed when it became obvious that new conditions, unknown in England, had arisen. Accordingly the soil of navigable rivers, fresh or salt, and of lakes is vested in the state, which has power to regulate navigation and impose tolls. The admiralty jurisdiction of the United States extends to all public navigable rivers and lakes where commerce is carried on between different states or with foreign nations (*Genesee Chief* v. *Fitzhugh,* 12 Howard's Rep. 443). And in a case decided in 1893 it was held that the open waters of the great lakes are "high seas" within the meaning of s. 5346 of the revised statutes (U.S. v. *Rodgers,* 150 U.S. Rep. 249). A state may establish ferries and authorize dams. But if water from a dam overflow a public highway, an indictable nuisance is caused. The right of eminent domain is exercised to a greater extent than in England in the compulsory acquisition of sites for mills and the construction of levees or embankments, especially on the Mississippi. In the drier country of the west and in the mining districts, the common law as to irrigation has had to be altered, and what was called the "arid region doctrine" was gradually established. By it the first user of water has a right by priority of occupation if he give notice to the public of an intention to appropriate, provided that he be competent to hold land. (*See* EASEMENT; FISHERIES, LAW OF.)

WATERS, TERRITORIAL. In international law, territorial waters are generally defined as that area of the sea immediately adjacent to the shores of a state which is subject to the territorial jurisdiction of that state. Territorial waters in this sense, sometimes called the marginal belt or coastal sea, are thus to be distinguished on the one hand from the high seas, which are common to all nations, and on the other from inland waters, such as lakes wholly surrounded by the national territory or certain bays and estuaries penetrating into the land. It became universally agreed that this marginal belt, together with the sea bed and subsoil beneath it and the airspace above, constitutes territory of the coastal state. subject only to a right of innocent passage for merchant vessels of other nations. A similar right probably exists for foreign warships in time of peace, but this is not wholly free from doubt. A state may insist that foreign vessels comply with reasonable navigation and police regulations during passage; and to a limited degree it probably may also interdict passage through particular areas for defense or security reasons, provided that no important international sea routes are thereby interfered with. The right of innocent passage does not apply to submerged submarines or to aircraft, nor does it extend to inland waters.

Historically, the concept of territorial waters originated in the controversy over the status of the sea which mas conspicuous during the formative period of modern international law in the 17th century. One point of view, that large areas of the open sea might rightfully be subject to the dominion of a single state, received its most effective exposition in the *Mare clausum* (published in 1635) of the English writer John Selden. The contrary doctrine, that the sea by its nature must be free to all. was upheld most notably in the *Mare liberum* (1609) and *De jure belli et pacis* (1625) of the Dutch publicist Hugo Grotius. The Grotian view was eventually to prevail, but Grotius himself recognized the practical need of a coastal state to exercise some jurisdiction in the waters adjacent to its shore. In 1703 another distinguished Dutch jurist. Cornelius van Bynkershoek, gave classic form to a solution foreshadowed somewhat earlier; that the jurisdiction of a coastal state should extend seaward as far as the effective range of land-based weapons. Toward the end of the 18th century some effort was made to define this range in terms of a fixed distance. and it was at this time that the three-mile limit was first mentioned (apparently without much expert knowledge of the still limited range of guns) as the equivalent of cannon shot. The Italians Ferdinando Galiani (1782) and Domenico Azuni (179j) were among the first to suggest this equivalence; and in 1793 three miles was adopted by the United States as the limit of its jurisdiction for neutrality purposes. During the 19th century many maritime states, inspired by British and U.S. practice, came to use the same limit, but it never won enough universal acceptance to become a rule of international law. It was settled, however, that the belt of territorial waters appertained automatically to the adjacent coast without any affirmative act of acquisition being required. Some theoretical dispute long continued whether the belt was actually territory of the coastal state or whether it was merely an area of the high seas in which that state enjoyed special jurisdictional rights; the former view later prevailed overwhelmingly.

In the absence of any uniform state practice with respect to the width of territorial waters, modern international law can be said to lay down no rule on the matter except that every state is entitled to claim at least three nautical miles (one marine league or 3.45 land miles). Claims in excess of 12 to 15 mi. commonly meet such widespread opposition from other states that they are probably untenable. Within these limits there is considerable variation. The United States during most of its history has adhered to the three-mile limit in its own practice and has generally declined to accept more extensive claims by other nations; the limit has received judicial recognition in many cases, notably by the supreme court in *Cunard* v. *Mellon,* 262 U.S. 100 (1923) and *United States* v. *California,* 332 U.S. 19 (1947). A similar stand has been taken by Great Britain since the 19th century. and was given parliamentary sanction with respect to criminal jurisdiction in the Territorial Waters Jurisdiction act of 1878. Belgium, France, Germany, Japan, the Netherlands, the nations of the British Commonwealth and some other states have also followed the three-mile standard for most purposes. On the other hand, the Scandinavian countries have long claimed a 4-mi. limit; Egypt, Greece, Italy, Spain, Yugoslavia and other states have claimed 6 mi.; Mexico, g mi.; and the U.S.S.R. and several smaller states, 12 mi.

The determination of the base line from which territorial waters are to be measured is another problem on which there are variations in practice. There is substantial agreement that off simple coasts the base line should be the low-tide mark along the shore, together with an artificial line across such bays and inlets as are considered to be inland waters. Various geometric techniques for ascertaining such bays and fixing the limits of territorial waters have been proposed, but none is wholly satisfactory and none has attained the status of a rule of law. With heavily indented coasts and those having many off-lying islands the base-line problem is more complex; in such cases some states have resorted to artificial straight lines connecting specified points along the coast and islands. Norway's adoption of such a method off its rugged northern coast was upheld by the International Court of Justice in the Anglo-Norwegian fisheries case in 1951 (I.C.J. Reports, 1951, p. 116), in which the court said that the method was proper if applied reasonably and in such a manner as to follow the general trend of the coast.

Bays, gulfs and estuaries along a coast are undoubtedly inland waters landward of the point (whether at or within the entrance) where they first narrow to six miles in width. Nations adhering to the three-mile limit, however, have generally relaxed the strict six-mile measure in favour of a ten-mile width similarly applied, in order to eliminate narrow tongues of high seas running down the centre of bays; this rule of convenience has been embodied in a number of international agreements, but it has been held by the International Court (in the fisheries case above cited) not to be such a rule of general international law as to preclude larger claims. States claiming more than three miles of territorial waters generally increase proportionately their claims to bays, and some states have declared all bays along their coasts to be inland waters regardless of size. Claims to particular bays of large dimensions are sometimes justified under the so-called "historic bays" doctrine on the ground of prescriptive rights acquired by long exercise of exclusive control. Straits passing through the territory of a single state present special problems; if important as international arteries they are usually governed by particular treaty arrangements, as has long been the case with the Turkish straits.

Distinct from territorial waters proper are zones in the adjacent high seas in which coastal states claim no territorial rights but assert rights of jurisdiction for one or more special purposes. These "contiguous zones," generally extending 6 to 12 mi. beyond territorial waters, are most commonly claimed in connection with the enforcement of customs and sanitary regulations; but in some instances they may be established for fishery conservation or for security purposes. Also distinct from territorial waters are the claims made after 1945 by many states to the continental shelf off their shores, the shelf being generally regarded as the shallowly submerged margin of the continent extending outward to about the 600-ft. depth line in which oil or other resources may exist. Insofar as these claims were confined to the shelf itself, without affecting the status as high seas of the waters above, they met with little opposition. Actions by some states, however (*e.g.,* Chile and Peru), which asserted jurisdiction over waters as well as shelf, evoked wide protest as amounting to unwarranted extensions of territorial waters.

Efforts to codify the international law governing territorial waters and to give greater precision to its content have been persistent but unsuccessful. The subject was exhaustively discussed at the Conference on the Codification of International Law held under League of Nations auspices at The Hague in 1930. The conference proceedings served chiefly to emphasize the great differences of view among the states represented on such matters as the width of the marginal belt and the permissibility of contiguous zones; it proved impossible to reach agreement on a draft convention designed to lay down rules of universal application. After World War II, the International Law commission organized under the auspices of the United Nations general assembly selected in 1949 the regime of the territorial sea as one of its topics for study and report. The commission's deliberations on the subject disclosed, however, that many of the difficulties encountered in 1930 still presented major obstacles to agreement.

WATER SCORPION, an aquatic insect of the order Hemiptera (*q.v.*), family Nepidae, so called from its superficial resemblance to a scorpion, the likeness being caused by the modification of the anterior pair of legs for grasping and by the presence of a long slender process, simulating a tail, at the posterior end of the abdomen. The common British species (*Nepa cinerea*) lives in ponds and stagnant water. The common genus in the U.S. is *Ranutra.*

WATERSHED is that area from which all precipitation flows to a single stream. Synonyms are "catchment area" and "drainage basin." The boundaries of a watershed are known as a drainage divide; precipitation falling on opposite sides of a drainage divide falls onto different watersheds. Thus, all the area drained by the Mississippi river constitutes the watershed of that stream. That part of the basin drained by the Ohio river is the watershed of the Ohio; that area of the Ohio watershed drained by the Wabash river of Indiana constitutes the watershed of the Wabash, part of which is drained by the White river, which has a segment of the Wabash river basin as its watershed, and so on up to the smallest tributary stream.

The regime of the stream that drains a watershed may be of great practical interest from the standpoint of flood control, hydroelectric power development, navigation, municipal or irrigational water supply or waste disposal. The regime of the stream, in turn, is largely controlled by the size, shape, surface configuration, surface materials, vegetation and climate of its watershed.

Only part of the precipitation that falls on a watershed ultimately gets into the stream: it is known as runoff and varies widely among watersheds. The rest of the precipitation is either evaporated back into the atmosphere directly, enters the ground and eventually migrates back to the surface where it is evaporated or enters the ground and is taken up by plants and evaporated from their leaf surfaces in the process called transpiration. These two processes are sometimes lumped together under the general term "evapotranspiration."

The quantity and time distribution of runoff from a watershed is probably determined more by the quantity, type and time distribution of rainfall than by any other factor. Extreme examples are offered by the precipitation conditions in some of the tributaries of the Colorado or Rio Grande rivers whose watersheds receive only 6 or 8 in. of precipitation annually, whereas the watersheds of some of the tributaries of the Tennessee river receive 60 in. or more. Some tropical watersheds may have an annual precipitation of more than 150 in. The type of precipitation is also important. For example, many of the headnater streams of the Columbia river of Washington and Oregon receive a considerable part of their annual precipitation as snow, which accumulates for several months in the winter and then runs off entirely in a few weeks in late spring and early summer. The intensity of precipitation also controls the regime of the stream. If rain falls as short intense storms, a high percentage of the water will run off in a very short time, causing the stream to flood, followed by long periods of very low water. Such a regime is characteristic of many streams in semiarid areas. Precipitation that is evenly distributed throughout the year in gentle showers may produce streams of very even regime, few floods and ample flow at low water. Many of the streams of western Europe are of this type.

Evaporation and transpiration also have important bearings on watershed characteristics. The rate of potential evaporation is directly proportional to temperature, wind movement and, to a minor extent, humidity. High temperatures and wind velocities increase the evaporation potential. Approximately the same relationships are true with respect to transpiration. The actual rate of evapotranspiration, however, is dependent upon the availability of water to be evaporated. There may be very little evapotranspiration in a hot windy desert because there is no water available to be evaporated.

The shape of a watershed also strongly affects the regime of its stream. A circular shaped watershed may produce extremely high floods in the lower part because much of the surplus water reaches the lower end of the basin simultaneously. Conversely, a long narrow basin may produce floods with a much lower peak flow but of longer duration.

The character of the vegetation on the watershed will also strongly influence the regime of the streams because of its effect on the rate of water flow off the area, because of its effect on evaporation by shading the ground and slowing down wind movement and by transpiration.

The nature of the terrain also influences stream regime. Commonly, a natershed of steep slopes will have more runoff than a somewhat flatter area. Depth and characteristics of the soil also influence the water conditions on a watershed.

WATER SKIING. In this sport the thrill of speed can be savoured without the usually accompanying danger. Since its inception in France in the late 1920s, the growing popularity of water skiing, especially after World War II, has paralleled that of motorboating.

Skis.—Typical, all-purpose skis are of solid or laminated wood 63 in. wide and 5 ft. 9 in. long, with a wooden stabilizing fin on the bottom near the heel. Tight-fitting rubber foot bindings stretch in case of a fall, releasing the skier's feet without injury. The skier holds onto a wooden handle attached by a 75 ft. towline to a motorboat. Speeds from 15 to 35 m.p.h. are used.

Water Ski Events.—In 1936 Dan Hains founded the American Water Ski association and categorized the sport into trick riding, slalom and jumping events. Since then annual national and international open competitions have been held in these events, except during the war years.

For trick riding, typical skis are 43 ft. long and 8 in. wide and have no fins, permitting them to be used for turning from frontward to backward and completely around while skiing. This phase of skiing is characterized by different kinds and numbers of turnarounds on one or two skis on the water, in the air and on the jumping ramp. Speeds of around 18 m.p.h. are generally used, and special tow bars with means for holding the line with the foot are employed.

Slalom competition is held in a course consisting of a specified array of buoys through which the skier must negotiate a sinuous path at increasingly higher speeds (up to 34 m.p.h.). For this, many skiers use a single ski tapered in the rear, with a large metal fin and bindings for both feet. Others use two conventional skis fitted with larger metal fins to facilitate sharp turning. This phase of the sport accentuates precise timing, ability to turn sharply and skill in crossing the boat wake.

Jumping for distance is done with heavy, conventional type skis on a 24 ft. long, waxed wood-surfaced ramp. For best distance the skier cuts sharply across the boat wake and hits the ramp as he swings far out to the side. From a 6 ft. ramp height and 35 m.p.h. boat speed, jumps of over 140 ft. are attained. Ladies and junior competitors jump at ramp height of 5 ft. and at speeds up to 28 m.p.h.

In ski races boats with skiers in tow compete at speeds up to 70 m.p.h. If a skier falls during a race, the boat may circle to pick him up again and resume, but the skier may not touch the boat. (J. AN.)

WATERSPOUT, the name applied to any narrow, rapidly spinning funnel-shaped cloud or column of water, similar to a tornado but occurring at sea. There are two types: (1) One is caused by a true tornado formed over land and passing over the water; this type has the usual causes, dimensions and behaviour of tornadoes (*q.v.*). (2) The other type is more common and often smaller, developing sporadically as funnel clouds from the bases of cumulus or cumulo-nimbus clouds over tropical and middle-latitude seas (and lakes) during the warm season. The lower tip of the funnel cloud, as it approaches the sea surface, first agitates the sea surface into a cloud of spray into the centre of which the funnel finally dips to reach the sea. Then the funnel draws up a vortex spout of sea water, probably in part still hollow, with a cloud of spray still flying out from the base. The spout may reach several hundred feet up the funnel cloud and last half an hour or more. It may twist and bend in a manner similar to that of tornadoes. Finally the spout thins and breaks away from the funnel and quickly vanishes or collapses into the sea. The wind nearby whirls around the spout with some violence, causing a rough and confused sea. (R. *G. SE.*)

WATER SUPPLY AND PURIFICATION. Water supplies, no matter how large or small, consist of a source, a means of conveyance from the source to the site of the consumers and a means of distribution. A supply for a farm, for example, may comprise a spring on a hillside above the house; a pipe carrying the water by gravity to the premises; and a system of pipes delivering the water to the dwelling and other farm buildings. If the source is a well, a pump may be used to lift the water from the well and deliver it through the supply pipe under pressure.

To give an example at the other extreme of size, in the Catskill water supply of New York city, water is collected from the uplands of the Esopus and Schoharie watersheds; uniformity of supply is assured by storing wet-weather runoff in two great reservoirs created by high masonry dams thrown across Esopus creek and the Schoharie river; the water is transported in an aqueduct that traverses over 200 mi. of varying landscape to the Kensico reservoir not far from the city; and the water is fed into the city through a tunnel in the rock of Manhattan Island, distributed into street mains from shafts rising from the tunnel and shared with the other boroughs of the city through great mains, one of which, for example, crosses the Narrows as a flexibly jointed pipe to reach Silver Hill reservoir, the service reservoir for the distribution system of Staten Island. Individual premises in New York tap the street mains through service connections. The connections supply water to pipes within the buildings either directly or, in the case of skyscrapers, with the help of pumps and water tanks.

Sources of Supply.—The selection of water sources is greatly dependent on the bounty of nature. Regional hydrology, geology and topography determine whether the water is best taken from a lake, stream or underground aquifer. Under favorable circumstances, communities do not have to reach out very far for their supply. Indeed, they may find its source at their own doorsteps, as do the cities on the Great Lakes of the U.S. and on the large river systems that drain the North American and European continents. Communities may seek their supply also from the ground at no great distance and, as in the case of a part of the supply of London, even from the geological formations on which the cities themselves rest On the other hand, less favorably situated communities, like those of southern California, may have to tap a source hundreds of miles away.

Upland sources are often superior to nearby lakes and rivers because their watersheds are sparsely inhabited. At the same time, upland sources, such as the Catskill supply of New York city, may be tapped at such elevation that their waters can be transmitted to communities and distributed within them by gravity; *i.e.,* without pumping. Power has become so widely available and relatively so cheap, however, that the search for a gravity supply is no longer quite so important as it once was. Means for water purification, furthermore, have been elaborated to such degree that pristinely pure waters need no longer be sought for their own sake. Nevertheless, there is general agreement among those concerned with conserving natural resources and protecting the public health that available water supplies should be kept as pure as possible and that the highest use of good water is to slake man's thirst. There is agreement, too, that growing competition for water requires that, wherever possible, water supply to communities be fitted into regional multiple-purpose developments of available water resources.

Classification of Sources.—A classification of water sources includes. (1) rain water from roofs stored in cisterns for small individual supplies or collected from prepared catchment areas called catches and stored in reservoirs for larger communal supplies; (2) surface water from streams, natural ponds and lakes of such size and replenishment that needed water can be withdrawn from them either continuously without major storage facilities or intermittently, seasonally or selectively in the presence of adequate storage basins or reservoirs; (3) surface water from streams with insufficient dry-weather flow but adequate annual discharge made available by impounding wet-weather flows in storage reservoirs behind dams constructed across the stream valley; (4) ground water from natural springs and from wells, infiltration galleries, basins or cribs penetrating to or lying within existing aquifers; (5) natural ground-water floas augmented by spreading waters from another source. such as a river, on the surface of the gathering ground whence it seeps into the soil, or by diffusing it into the ground through basins, ditches, galleries or wells; and (6) brackish or salt water freed from unwanted salinity by evaporation or by ion exchange, chemical precipitation or electrochemical processes.

Surface Waters.—For the collection of surface waters, intake towers are placed near the shore or at some distance from it in order to reach suitable depths or clean water, as in the Great Lakes. These vertical structures are usually provided with inlets at different depths so that water of the most suitable quality and temperature may be withdrawn. The water collected is led to pumping stations on the shore through pipes or tunnels.

Ground *Waters.*—Wells may be shallow or deep. Depending upon their size and depth, they may be dug by hand or machinery, driven into the soil as pipes under hammer blows, sunk as pipes with the aid of water jets, bored by simple augers or rotary machinery or drilled into rock. Water enters the well pipe or casing through perforations forming a strainer. Dug and bored wells are lined with suitable materials that include concrete and steel. Wells drilled in rock may be left unlined. Well strainers placed in oversized bore holes are surrounded with gravel in order to increase the yield of the well. A 10-ft. depth of watertight lining below the ground surface will usually prevent pollution by surface seepage. (See WELL.)

Infiltration galleries are horizontal collecting units constructed within deep ditches or driven through the ground as tunnels below the ground-water level. They frequently parallel watercourses in order to intercept the ground-water flow streaming to them and sometimes, too, in order to capture seepage flow from the watercourse. However, they may be blanked off against taking in river seepage if this water is unsatisfactory. In suitable formations, horizontally radiating collecting pipes may be forced into the ground from a central well shaft to extend the collection area of the well. Aquifers or water-bearing strata that lie below a confining layer of impervious material will yield water under pressure, in some cases sufficiently great to reach the ground surface as flowing wells. All such aquifers are described as producing artesian (named after the province of Artois, France) water. Fresh water can be withdrawn from suitable aquifers in contact with the sea to depths equaling approximately 40 times the height of the ground-water table above sea level, provided the rate of withdrawing fresh water does not exceed the rate of recharge from rainfall or other fresh-water sources. Much coastal intrusion of sea water into water-supply aquifers has been caused by overpumping. To oppose this encroachment on a needed resource, fresh-water barriers have been created, in southern California, for example, by the construction of lines of recharge wells and galleries that parallel the shore. Through these, surface or reclaimed water is diffused into the soil.

Although ground water is the most common source of public as well as private supplies in the United States, the number of people provided with water from municipal surface sources at the beginning of the second half of the 20th century was about three times that receiving ground water. In other parts of the world, too, expanding industry and population growth were generally making for wider adoption of surface-water sources. (See GROUND WATER.)

Quality of Water.—Desirable Qualities.—Whether water supplies need to be purified or treated in some manner and to what degree depends upon their quality at the source and the demands of the community. The community ordinarily asks that the water be: safe to drink; attractive in appearance, taste and odour; and usable for the many purposes to which it is put in household and industry. The community may demand further that the water be noncorrosive to metals and contain enough fluoride to satisfy the physiological needs of children for good dental health.

The waters from some surface and ground sources are satisfactory for all ordinary uses. They need no purification, but they may be chlorinated as a precaution against chance contamination. Other raw waters contain objectionable substances in varying degrees. These substances must be removed, reduced to tolerable limits, destroyed or otherwise changed in character to the point of acceptability. Impurities are acquired in the passage of water through the atmosphere, over the earth's surface or through the pores and channels of the ground. Impurities that cause pollution originate principally from the uses man makes of water, in particular from the waste waters he discharges into natural watercourses. Water can acquire some impurities also within the water-supply system. Among them are corrosion products of lead, zinc, copper and iron. There are opportunities, too, for the contamination of the communal supply through cross-connection with public or private industrial supplies or through backflow in domestic and industrial plumbing systems.

Important among the impurities of water are: (1) disease-producing organisms of enteric (intestinal) origin; (2) toxic substances, which are most frequently derived from industrial wastes but, in the case of lead, also can come from the lead or lead lining of old-fashioned water pipes; (3) colour, usually flushed from overflowing swamps; (4) turbidity, generally carried into suspension by the erosion of clay deposits; (5) organic materials that produce odours and tastes upon decomposition; (6) carbon dioxide, which enables water to take calcium, magnesium and, in certain instances, lead into solution; (7) iron and manganese, which are taken into solution in the absence of dissolved oxygen; and (8) algae, which release characteristic odours and tastes.

Water-borne diseases include typhoid fever, cholera, bacillary dysentery, amoebic dysentery, infectious hepatitis and a number of diseases caused by parasitic worms. Apart from certain toxic heavy metals, nitrate (NO,) is of some interest because it is toxic to infants, in whom it causes methemoglobinemia or the blood changes and cyanoses otherwise associated with nitrite (NO,) poisoning. Colour, turbidity, odour or taste, in high concentrations. can make water unattractive or unpalatable. Calcium and magnesium are the principal causes of hardness. Magnesium, furthermore, is laxative in high concentrations. Iron and manganese form, respectively, red and black precipitates when the water in which they are dissolved comes into contact with air. They also give water a metallic taste. (See also GEOLOGY: Erosion by *Ground Water;* HYDROLOGY: Ground Water.)

Prescribed *Qualities*.—In the United States, the public health service promulgates standards of water quality from time to time in connection with its responsibility for water supplied by common carriers, and these standards are widely accepted by other governmental bodies in that country. There are no standards of like scope and purpose in the United Kingdom, but the World Health organization (WHO) has proposed international standards for drinking water. In reference to chemical and physical quality, the WHO suggests permissible levels and indicates the magnitude of excessive amounts. The standards for bacteriological quality require, with some qualifications, that in 90% of the samples examined throughout the year the statistical average number of coliform bacteria shall be less than 1 per 100 millilitres in treated waters and less than 10 per 100 in untreated waters. The public health service has the single standard of less than 1 coliform organism per 100 millilitres for untreated as well as treated supplies.

The coliform standard of water safety rests on the following facts: (1) Many members of the coliform group of bacteria have their origin in the intestines of man. (2) Billions of the coliform organisms are excreted daily by man. (3) They are as hardy or more so than typhoid, cholera and dysentery bacteria. (4) They normally occur in a given population in far greater numbers than do the disease-producing bacteria and amoebic cysts. Numerically, therefore, both the U.S. and international standards imply a tremendous dilution or a high natural death rate, or both, of possibly dangerous bacteria within the water source or, otherwise, their equivalent removal or destruction by purification. Unfortunately, the numerical presence in water of the virus of infectious hepatitis and its death rate, removal and destruction are, as yet, poorly defined. (See also BACTERIOLOGY: Bacteria in Air and Water; BACTERIAL AND INFECTIOUS DISEASES: Infections via *the* Alimentary Tract)

U.S. and international committees have set the permissible level of radioactivity of public water supplies at 10^{-7} microcuries per millilitre for unknonn mixtures of isotopes and at one-tenth this amount when large population groups are exposed. Prescribed, in addition, are permissible limits for specific isotopes. These vary according to the isotope. Radioactive contamination originates in fall-out, the use of isotopes in medical therapy and research, and waste waters from nuclear power plants.

Because they narrow the required capacity range, purification or treatment plants are usually inserted in the water-supply complex at or near the source. The sequence of engineering aorks in a public nater-supply system usually is as follows: (1) the collection works at or forming the source; (2) the purification or treatment works; (3) the transmission conduits or aqueduct; and (4) the distribution system, including service reservoirs.

Purification and Treatment.— Historically, the purification of water began well in advance of the discovery of the role of water in the transmission of enteric diseases or the germ theory of disease itself. Noteworthy facts related to modern practice are: (1) that James Simpson built the first water-filtration plant for the purification of Thames river water in 1829; (2) that John Snow gave epidemiological proof that the London cholera epidemic of 1854 was traceable to water drawn from the Broad street well (or pump, as it was called); and (3) that the city of Altona. Ger., ahich took its raw water from the Elbe river, was protected by its filters against the cholera epidemic of 1892 that ravaged the neighbouring upstream city of Hamburg, which used unfiltered Elbe river water.

Opposing the degradation of water by pollution are certain natural purifying forces. Among them in surface waters are sunlight, which speeds the destruction of disease-producing organisms and bleaches colour; time, which causes pathogens to become devitalized and to die and organic matter to decompose and be stabilized; and sedimentation, which allows material held in suspension to settle out in quiescent river reaches, ponds, lakes and reservoirs. In ground waters, natural filtration is the most potent purifying force. However, crevices, large pore spaces and solution passage occur in some geological formations. In these, little if any purification takes place. The hygienic quality of waters from such sources is, therefore. always suspect.

There are three general categories of water-purification works: filtration plants, iron-removal plants and softening plants.

Filtration.—In the course of their history, filtration plants have been constructed in two forms: as slow filters and as rapid filters. The older slow filtration plants, generally speaking, have consisted of large beds of relatively fine sand of moderate depth. Through the beds of sand the water seeps vertically downward into a system of underdrains. Most of the suspended impurities are removed in the top inch or two of the sand. After operating for a month or so at a rate of downward flow of about 5 in. per hour, the resistance to further passage of water becomes so great that the top layer of sand must be removed or washed in place. Removed sand is cleaned at convenient times, and the bed is resanded when it has been reduced in depth from about 42 in. to not less than 24 in. For waters that are relatively free from turbidity and not too heavily polluted, filter performance is excellent. The effluent is clear and largely free of bacteria; the filter however, will remove only about one-third of the colour. In modern practice the effluent is chlorinated for safety.

In England, waters not suited for direct filtration have been strained through rapid filters or rotary drums covered with fine metal screens called microstrainers in order to reduce their content of clogging substances. Both turbidity and algae are removed by rapid filters, algae alone by microstrainers.

In the newer rapid filtration works, the water is treated with a coagulant, such as aluminum sulfate, ferric chloride or ferric sulfate. Flocculent precipitates are formed with the aid of stirring devices and carry down most of the suspended matter during the more or less quiescent flow of the treated water through sedimentation basins. The settled water is filtered through a group of small beds of relatively coarse but uniform sand at rates of 192 to 288 in. per hour (2 to 3 gal. per square foot per minute). The filtering bed, which is about 30 in, deep, is cleaned as a unit either by backwashing (upward-flowing water) alone or by air agitation followed by backwashing. The filtered water is disinfected with chlorine. Heavily polluted waters may be chlorinated both before and after filtration. Bad odours and tastes may be adsorbed on activated carbon or destroyed by high doses of chlorine or chlorine dioxide before filtration. In these ways a clear, colourless, palatable and safe water may be produced.

Iron and *Manganese* Removal.—Because iron and manganese are held in solution in water only in the absence of oxygen, their removal is generally accomplished by aerating the water to oxidize them to the insoluble state and by removing the resulting precipitates in slow or rapid filters. These metallic impurities are eliminated also by contact oxidation in beds of treated zeolite that are regenerated with potassium permanganate. Zeolites are natural or synthetic insoluble sodium-aluminum silicates. For iron and manganese removal, they are pretreated with manganous sulfate and potassium permanganate. (See also ION EXCHANGE: Applications.)

Softening.—Hard waters are softened either by the addition of precipitating chemicals or by passage through beds of ion-exchange media. Useful chemicals are lime for bicarbonate hardness and soda ash for chloride and sulfate hardness. Ion exchangers are beds of zeolites, carbonaceous materials or resinous substances. Depending upon their nature and that of the ions exchanged, the beds are regenerated with salt, acid, soda ash or caustic soda.

By the proper selection and protection of water sources and by rigourous treatment of the available waters, some countries have been able to wipe out epidemics of water-borne disease. To give but a single example, deaths from typhoid fever in Toronto, Ont., were 93.1 per 100,000 population in 1890, 43 in 1910 and 0 in 1945 and later. However, in many parts of the world, water-borne diseases remain among the leading causes of illness and death because sanitation in general and water supply and purification in particular lag behind attainable standards.

Transmission of Supply.—Conduits.—Large conduits through which water flows to the community by gravity are sometimes open channels, more often cut-and-cover aqueducts and sometimes tunnels. These structures are placed on grades that, although relatively flat, will overcome the frictional resistance to flow at reasonable velocities. Cut-and-cover aqueducts are normally constructed of reinforced concrete and given a horseshoe-shaped cross section for structural reasons. As their name suggests, they are built partly in cut, and the earth removed is employed to give them a protective cover. Grade tunnels are generally similar in shape. They are lined with concrete unless they serve only as passageways for one or more strands of pipe. Water-supply tunnels are driven through rock, clay or other geological formations in much the same way as vehicular and railway tunnels. Large conduits that transport water pressure are usually constructed as: (1) circular tunnels often driven beneath undulating terrain at considerable depth and of great length; (2) reinforced concrete pipe generally precast and prestressed; and (3) steel pipe in longitudinally welded 30-ft. sections joined in the field by bolted sleeves that compress rubber gaskets to seal the transverse joints.

Smaller pressure conduits are usually made up of cast-iron or cement-asbestos pipe. Cast-iron and steel pipes are protected against corrosion, internally by cement or bituminous linings, externally by bituminous paints or cloth impregnated with bituminous substances. Corrosion may be held in check also by adding lime, metaphosphates or other stabilizing chemicals to the water itself.

Pressure lines that transmit water over long distances usually are placed below the hydraulic grade line, a hypothetical line traced by the height to which water would rise from within the conduit if free to do so.

Pumping.—Water is usually lifted to desired elevations or placed under pressure by centrifugal or similar types of pumps. Pumps are generally electrically driven, with diesel engines provided as a secondary source of power where the electricity is not generated at the pumping station itself or where electric feeder lines cannot be supplied from more than one power source. Lake and river supplies that are to be purified at the source may include both low-lift pumps that raise the water to the treatment works and high-lift pumps that drive it to the community. Springs and flowing artesian wells may need no pumping. From all other groundwater sources, water must be lifted or pumped at least to the ground surface. Suction lifts must be kept well below atmospheric pressure (34 ft.). Deep-well pumps may be inserted into the well casing or bore hole at any desired depth, often below water level. If necessary, multiple-stage units can discharge water directly into distribution systems. Dug wells from which water is drawn by rope and bucket are the most primitive sources of ground water. If they must serve many users, their contamination cannot be avoided. Periodic chlorination, preferably daily, will offer some protection. If pumps are installed and the well tightly covered, pollution can be reduced.

Distribution of the Supply.—Piping.—Cast iron is the preferred material in most distribution systems. Pipes of this durable metal are centrifugally cast in lengths of up to 20 ft. and in diameters of up to 36 in. Lead and other calked joints have been superseded, very largely, by bolted compression joints with rubber gaskets. Only sizable feeder mains within the distribution system are normally made of steel. Fire hydrants, too, are usually cast in iron if they are to stand above ground; so-called flush hydrants provide an outlet to which a portable hydrant must be connected. Water mains and service pipes are laid below freezing depth. In the northern United States, this is about 5 ft. At least 2 ft. of cover is required to protect mains against street-traffic shock.

Pressure.—Water pressures in distribution systems are held at about 60 lb. per square inch (p.s.i.), even in districts where fire engines are capable of boosting hydrant pressures to adequate intensities. In order to assure a pressure of 75 p.s.i. for direct hydrant streams, the distribution pressure must be elevated to 100 p.s.i. or more. This makes for increased losses through leaks in public mains and in water systems in buildings. Pressures in residential areas are often but 40 p.s.i. and, sometimes, even less.

Booster Pumps.—Hilly communities sometimes are divided into service zones that differ in elevation by about 100 ft. The water is lifted to the high-lying areas by booster pumps. Each zone may have its own distribution reservoir or be served from a higher-lying district through pressure-reducing connections. Some communities, among them Boston, New York and Philadelphia, have separate fire-supply grids in which the pressure is raised, on call, by pumps standing by in power stations. Many factories and industrial complexes are given additional fire protection by private fire pumps, pipe grids, yard hydrants and sprinkler systems. When a fire breaks out, the pumps force water into the system from streams and other nearby bodies of water. Since these are often unsafe from a health standpoint, private systems should not be interconnected with municipal water mains. Rigid separation of the two systems is required by some public authorities; cross-connections consisting of at least two approved check valves tested for tightness at regular intervals are permitted by others.

Reservoirs.—Distribution or service reservoirs provide: (1) equalizing or operating storage; (2) fire reserve; and (3) emergency reserve. Equalizing or operating storage compensates for hourly and peak variations in demand; the fire reserve must be large enough to fight a serious conflagration; and the emergency reserve must be of such magnitude that reservoir inflow can be stopped while needed repairs are being made to supply conduits. In the interest of water sanitation, distribution reservoirs are covered wherever possible. Reservoirs that must be left open because of their large size are protected against surface drainage and human access. The water obtained from such reservoirs may be given secondary chlorination.

Service reservoirs are situated at sufficiently high elevation to provide water under adequate pressure. Where there is no suitable natural height of ground for them, they are constructed as standpipes or elevated tanks. All of the water supplied to a given area may pass through its service reservoir, or this unit may float on the line, filling through a connecting main at times of low draft and emptying through it at times of high water use.

Water-Supply Management.—Required Amounts and Capacities.—The over-all needs of the average United States community mounted at mid-20th century to about 140 gal. per person daily, divided about as follows: (1) 50 gal. each to residences and industry; (2) 20 gal. to commercial establishments; and (3) 10 gal. to public uses, such as public, buildings, fountains, swimming pools, street and sewer flushing and fire fighting. About ten gallons are lost in distribution or are otherwise unaccounted for. It is obvious that water consumption depends on the nature of the community: heavy industrialization and prosperous residential quarters, for example, can increase per capita consumption.

Representative over-all values for large cities in the United Kingdom are much lower than in the U.S. The London Metropolitan Water board, for example, in the 1960s registered a consumption of under 60 gal. per person daily. There, as well as in other growing countries of the world. however, the trend is toward higher consumption. In the United States, air conditioning, wider use of automatic household equipment and increasing numbers of fixtures, as well as industrial development, continued to push consumption upward.

The safe yield of surface waters is estimated from records of stream flow or water stage by suitable statistical methods The total length of surface streams in the United States is close to 3,000,000 mi., and their flow is recorded at about 10,000 sites. Impounding reservoirs, depending upon stream-flow conditions and degree of development, are economically useful when they store up to about 25% of the mean annual flow in well-watered regions and often more than two times the mean annual flow in semiarid regions.

The safe yield of ground-water supplies is determined by pumping tests. The volume of water in the interstices of the soil and rocks of the United States at depths less than 2,500 ft. is estimated to equal the total recharge of ground water during the last 150 years. It is for this reason that it has been possible to overpump many ground-water sources. Nevertheless, observed drops in ground-water levels in excess of 150 ft. between 1900 and 1950 are a warning that overpumping cannot be long continued with impunity. In the London area, flowing artesian wells no longer exist. Owing to overpumping, mostly of privately owned wells, the ground-water level has sunk to as low as 250 ft. below mean sea level.

The collection and transmission portions of public water supplies are generally dimensioned, for economic reasons, to deliver to the service reservoirs the maximum daily flow, or about 150% of the mean annual requirement. Pumping and purification works attached to these portions are given about the same capacity but with an allowance of one or more stand-by units to permit repairs to be made.

The distribution system and its feeder mains must care for needed fire flows and coincident draft. For the protection of the central community against runaway conflagrations, the National Board of Fire Underwriters in the U.S. required fire flows of 1,000 gal per minute for towns of 1.000 people, and up to 12 000 gal. per minute for populations of 200.000 or more, nith 2,000 to 8,000 gal. per minute for a second fire. Water must be available at these rates along nith the coincident rate of draft for at least four hours in small communities and ten hours in large communities.

The equalizing storage of distributing reservoirs usually amounts to about 15% of the average daily demand, but it may be as great as 50% when nater is pumped to storage during but 12 hours of the day. The fire reserve depends on the rates of flow and duration suggested by the National Board of Fire Underwriters. Needed emergency reserve depends greatly upon the nature of the supply. A five-day reserve at maximum flow is suggested by the National board. but, in practice, this value is rarely attained. The United Kingdom has similar fire-fighting requirements, but U.S. cities, because of the nature of their construction, much carelessness and wide necessity for winter heating, present greater fire risks and must be more fire ready.

The smallest pipes included in the distribution gridiron of U S. communities are six inches in diameter. In the United Kingdom pipes four inches or less in diameter are quite common. Distribution systems within d ellings are proportioned to meet fixture demands.

Depending upon expected rates of population growth and rates of interest on loans, large and important components of the water-supply system that are not easily increased in size or duplicated are designed to meet estimated requirements up to 50 years in the future Examples are dams, aqueducts and tunnels. The design period for wells, distribution systems and purification plants seldom exceeds 25 years. Laterals and secondary mains of distribution systems, however, are normally dimensioned to full development.

Costs and Charges.—The capital invested in the public waterworks of the U.S. at mid-20th century amounted to about $100 per person served. However, the cost of reproducing these works and of new construction was about $250 per person served. Of the various components of the system, the collection and transmission works normally cost about 33% of the total. the distribution system slightly more than 50% and the purification plant about 10%, the remainder being the cost of acquired real estate. There are wide variations from these values in individual supplies. Much of the investment in smaller communities is chargeable to fire protection.

Including interest and depreciation, as well as charges against operation and maintenance, water costs from $50 to $300 per 1,000,000 gal. to collect, purify and distribute. It is charged for accordingly. Common prices to the consumer usually range from 10 to 25 cents per 100 cu.ft. On a weight basis, this is generally four cents a ton or less delivered to the point of use, a remarkable bargain. There are a number of different methods of charging for water. In the United Kingdom, domestic water is paid for in proportion to the "rateable" or net annual value of the property supplied. The London rate is 10%, with additional charges for garden use. Industrial properties are metered, and the amounts used are billed at a rate of 14 cents per 1,000 gal. Many U.S. cities are almost fully metered and charge only for the water actually consumed. Others collect at a flat rate based either on the frontage of the premises served or the number, and sometimes also the kind, of fixtures installed. A single meter rate is applied by some communities, a sliding scale by others. The sliding scale reduces the unit cost above certain magnitudes. There may be a stand-by charge for the service whether water is drawn or not.

Organization and Ope?-ation.—Generally speaking, the organization and operation of water supplies has moved from private to public control. In metropolitan areas, multiple undertakings have been combined within single authorities. Water districts are sometimes formed by small neighbouring communities as co-operative ventures.

Not more than 15% of the community water supplies of the United States were in private hands in the 1960s. The private water companies received a return not only for water purchased by private consumers and public bodies, but normally also a hydrant rental, which is paid by the community as a ready-to-serve or fire-protection charge. In some countries, the Philippines, for example, a national water authority designs, constructs and operates all public water supplies.

Water mains are extended farther and farther into the countryside as communities spread. There comes a time, therefore, when rural networks can be constructed with good economy. The rural water supplies of the United Kingdom and Holland are examples.

Some communities, especially those with much industry, have installed dual water supplies that differ in the general acceptability but not in the safety of their product. Use of the supply of inferior quality is confined to suitable industrial purposes, sewer and street flushing, and the like; that of superior quality is used for drinking and the other needs of the people. Danger of interconnecting such supplies has kept most municipalities from adopting the dual scheme.

Large communities often recruit their own engineering force to plan and design major additions to their works. Consultants may be called in only to advise on specific matters. Smaller cities and towns often use the services of a consultant for planning and designing their entire project and for supervising its construction. By these practices, a high degree of competency can be marshalled for the development of effective water schemes.

A like degree of competency is called for in the operation of waterworks. Large sums of money are administered. There are heavy responsibilities, both ethical and legal, for the protection of the community against disease and fire. Adequate maintenance of all parts of the system is essential to their proper functioning and to the conservation of water. Good records of operation require the inclusion of recording meters on supply mains and of water-level recorders on reservoirs. Leakage or waste surveys will identify controllable water losses, including not only undetected breaks in pipes but also leaky fixtures on private premises.

WATERTOWN, a town (township) of Massachusetts, U S., in Middlesex county, is on the Charles river about 7 mi. W. of Boston. Founded and incorporated in 1630 by Sir Richard Saltonstall and the Rev. George Phillips. it was one of the four earliest Massachusetts bay settlements and the first inland farming town. The name may have derived from the fact that the area was well watered. Fishing in the Charles river proved of great importance in the early periods. For about 20 years, Watertown ranked as the most populous town in the colony, but gave way to Boston. Its area once included Waltham (*q.v.*) and Weston, most of Lincoln, and parts of Belmont and Cambridge (*q.v.*). Taxation without representation was protested in 1632 when its townspeople refused to pay a tax of f60 for the purpose of erecting a stockade fort in Cambridge, Mass. Watertonn lays claim to be the "cradle of the town meeting" as the first board of selectmen was elected there in Aug. 1634. The town, fermenting with anti-British sentiment, was highly involved in the revolutionary efforts. From there Gen. Joseph Warren left for Bunker hill The provincial assembly met in the town from April to July 1775; the Massachusetts general court from 1775 to 1778; and the Boston town meetings during the siege of Boston.

The first gristmill, built on the falls of the Charles river, was constructed in the early 1630s. The second mill, a cloth fulling mill, was established in 1662. This early industrial development continued, becoming more varied and adapted to the demands of the times, especially after 1830. One of the best known plants is the United States arsenal, started in 1820. Modern manufactures include clothing. measuring tools, heating apparatus, toys, paints and rubber goods. Watertown is the location of the Perkins Institution for the Blind (founded in Boston in 1829 and removed to Watertown in 1912), which possesses one of the largest Blindiana libraries in the world. For comparative population figures see table in MASSACHUSETTS: Population. (M. E. L.)

WATERTOWN, a city of northern New York, U.S., the seat of Jefferson county, located on the Black river 10 mi. E. of Lake Ontario, is a gateway to the Thousand Islands resort region, to northeastern Ontario, Can.. and to the St. Lawrence power and seaway projects. Founded in 1800 by New England pioneers attracted to the spot by the falls in the river. Watertown was incorporated as a village in 1816 and as a city in 1869. It is the trade, banking and cultural centre of a large dairy and resort region. Unlimited electric power is available. Chief among the manufactured products are hydraulic equipment. tool appliances, snowplows, paper, paper products and papermaking machinery. Points of interest are Public square, the business heart of the city, and the Roswell P. Flower library and museum, containing relics of Indian life and of French émigrés who settled in the region after 1802. F. W. Woolworth (*q.v.*) lived for a time in Watertown and there conceived the idea of the "five and ten cent store." For comparative population figures see table in NEW YORK: Population. (M. E. MA.)

WATER TURKEY: see SNAKEBIRD.

WATERVILLE, a city of Maine, U.S., in Kennebec county, is on the Kennebec river 19 mi. N. of Augusta. A trading post was established at Ticonic falls early in the 17th century and in 1754 Gen. John Winslow built Ft. Halifax on the east bank of the river. Waterville's early settlers came from Massachusetts and were mainly of English ancestry. They were followed by French-Canadians and in the late 19th century Syrian immigrants arrived. In 1802 Waterville was separated from Winslow to the east and in 1873 from Oakland to the west. It became a chartered city in 1888.

The chief manufactures are textiles, shirts, wood products, plastics and ice cream. Railway repair shops are maintained there. Waterville is a shopping and market centre for the nearby vacation regions of the Belgrade and China lakes. The city is the seat of Colby college. a liberal arts college founded in 1813, and of two private secondary schools, Coburn Classical institute and Thomas junior college. For comparative population figures see table in MAINE: Population. (H. B. R4.)

WATERWAYS, INLAND, include both natural channels maintained for navigation and artificial channels or canals that may be used for irrigation, drainage and water supply as well as for navigation. See LAND RECLAMATION. Traffic on inland waterways and international agreements affecting them are dealt with in the article INLAND WATER TRANSPORT. (See also the articles on particular rivers, canals and places; *e.g.,* KIEL; MEUSE; THAMES.)

Early History. — The earliest waterways in the form of level cuts and adapted river sections probably served for both irrigation and navigation. Many examples of these cuts remain in Mesopotamia. About 510 B.C. Darius undertook the construction of a canal linking the Nile with the Red sea—the forerunner of the modern Suez canal. Similar projects were promoted by the Romans. Early Chinese canals include the Ling Ch'u canal in Kwangsi (3rd century B.C.), the canal between Ch'ang-an to the Yellow river (Hwang-ho), built 133 B.C., and the Grand Canal of China, joining the Pei-ho, Hwang-ho and Yangtze rivers This had sections in use by the 7th century AD. In Europe Charlemagne planned an ambitious waterways system connecting the Main. Rhine and Danube. In England the oldest artificial canal, the Fossdyke. a relic of Roman occupation, connecting Lincoln with the Trent river, was originally built primarily for drainage but was later also developed for navigation. Similar canals were built in the Low Countries, Italy, Russia and India during the 13th, 14th and 15th centuries. Although it seems that some form of incline was used on the Grand Canal of China, it was not until the lock was invented to raise or lower boats between different water levels that inland navigation could be further developed. Some doubt exists as to who invented or first made use of locks. They may have been introduced in China and Holland as early as the 14th century, but undoubtedly considerable credit for them belongs to Italy. An early lock was built in 1373 at Vreeswijk in Holland. Filippo degli Organi and Fioravante di Bologna constructed at Viarenno, near Milan, a lock chamber enclosed by a pair of gates in 1438–39 and, half a century later, Leonardo da Vinci completed six locks uniting the canals of Milan. The first pound lock in England is thought to have been built for the Exeter canal about 1564–67. The introduction of the lock marked an important phase in the development of inland navigable systems. The locked Briare canal. connecting the Loire with the Seine. was completed in 1642 and was soon followed by the Canal du Midi, or Languedoc canal (1666–81). which is often regarded as the pioneer in modern Europe. It connects the Mediterranean with the Bay of Biscay. has 119 locks in a length of 148 mi. and rises to 620 ft. above sea level. In Sweden a canal with locks between Eskilstuna and Lake Malar was finished in 1606.

MODERN DEVELOPMENTS

Great Britain. — The first canal in the modern sense was the Bridgewater canal opened in 1761 to carry coal from the Worsley mines to Manchester. Its success inspired the Grand Trunk canal, which connected the Mersey with the Trent. A canal boom ensued and new routes spread all over the country. After 1830 this remarkable expansion was severely checked by the railways.

In the 20th century the canals were hit still further by road

BY COURTESY OF BRITISH TRANSPORT COMMISSION

FIG. 1.— DIVISIONAL ORGANIZATION OF BRITISH WATERWAYS UNDER THE BRITISH TRANSPORT COMMISSION

haulage. Successive government committees made proposals for their future. The most important was the royal commission (1906–09). which recommended central control and the standardization of the four main routes from the ports to the Midlands for 100-ton barges. All the reports stressed the urgency of co-ordination, but though some government control was introduced during World Wars I and II. nothing permanent was achieved until the Transport act of 1947. This transferred most of the canals and canalized rivers, excluding undertakings such as the Manchester Ship canal. Bridgewater canal and the Thames, to the British Transport commission.

Under nationalization a unified system of about 2,100 route miles at last became possible. Considerable rehabilitation of traffic routes was carried out and scientific research fostered The major routes include the Aire and Calder. Sheffield and South Yorkshire, and Trent Navigation. from the Humber to Leeds, Sheffield and Nottingham, respectively; the Weaver Navigation from the Mersey to Cheshire; the Gloucester Ship canal and Severn river from the Bristol channel to Worcester and Stourport-on-Severn; and the Grand Union and Lee Navigations serving the Midlands and London. A substantial part of the remaining mileage of waterways is virtually unused for navigation, though still in use for drainage. water supply, etc.

Europe. — In Europe the chief canal networks are in France. the Netherlands. Belgium. Germany and the Soviet Cnion. In some cases the routes are interconnected, thereby facilitating long through hauls for international traffic. They are mostly closely related to large navigable rivers such as the Rhine. Danube. Oder. Elbe. Scheldt. Seine and Volga. Inland water transport mas developed through regularizing such rivers by canalizing difficult sections, by building lateral canals or by connecting them with entirely new artificial canals.

France. — France developed an extensive inland waterways system in the 18th and 19th centuries. Though its inland waterways total about 8,000 mi., only 3,000 mi. of canals and 2,000 mi. of rivers were being worked in the early 1960s. These comprise three main groups: the main network in northern, eastern and central France, bounded by Le Havre, Dunkirk, Strasbourg, Lyons and Nevers; and two isolated secondary networks in Brittany and southern France. Major waterways include the Seine, the Rhbne and the Rhine. The Seine has a minimum depth of $10\frac{1}{2}$ ft. downstream from Corbeil. It is canalized upstream from near Rouen and is joined by the Havre-Tankarville canal and by the canalized Oise near Paris. The Rhône. with a normal depth of 63 ft.. connects with the Sabne and with the canals to Marseilles and Sète. The 300-ton waterways form the largest group, totaling about 1.300 mi. They comply with a law of 1879 to standardize principal routes for barges 126 ft. by $16\frac{1}{2}$ ft. carrying up to 340 tons at a draft of $10\frac{1}{2}$ ft. The minor canals in Brittany and southern France total about 1,720 mi. About 50.000.000 tons are carried on France's waterways annually in a fleet of 10.400 craft (total capacity about 3,750,000 tons). An improvement program was under way in the late 1950s in the Seine and Rhône-Sabne routes. A hydroelectric project for the Rhône involved the building of eight major navigable canals. The first. 18 mi. long, between Donzkre and Mondragon. was completed in 1952. It includes the Bollène lock. 640 ft. by 39 ft. Three 300-ton routes were to be improved — Dunkirk-Bauvin-Lille; Bauvin-Etrun-Paris and Abbécourt-Strasbourg.

New waterways projects in France included the following: (1) Canalization of the Moselle to take 1,350-ton barges. (2) Grand Canal d'Alsace between Basel and Strasbourg. Two sections between Basel and Ottmarsheim were completed in 1954 and the Fessenheim section was to be completed later. Locks are two-chamber, the largest 607 ft. by 82 ft. (3) Work was resumed again on the Canal du Nord. which was started in 1907 between the Sensée and the Somme canals. The completed portion was severely damaged in World War I and, though work had been resurned later. it was halted in 1932.

Belgium.—Belgium's inland waterways total about 1.100 mi., including approximately 600 mi, of canals. some of which rank as ship canals. The system has developed largely from the Scheldt and Meuse rivers. with Antwerp as a key point. Three main routes connect the port to industrial centres at Liège via the modern Albert canal; to Brussels and Charleroi; and to Ghent and the Borinage coal district. There are also two cross-country routes, one in the south connecting the French network with Liège, the other in the north linking the coastal ports to Ghent and Antwerp. Traffic on the Belgian waterways, much of it from the French and Belgian coal fields and industrial areas, amounts to more than 50.000.000 tons annually. Major developments were planned, particularly for large-craft.

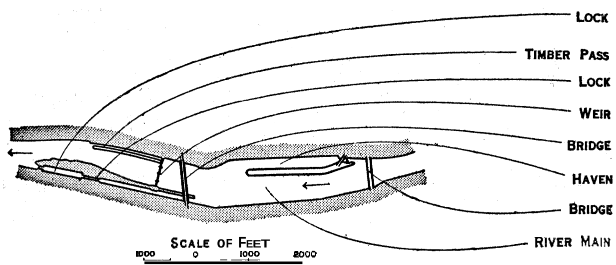

FIG. 2 — PLAN OF LOCKS, WEIR AND HAVEN ON THE RIVER MAIN NEAR FRANKFURT

Belgium's most up-to-date waterway is the Albert canal, started in 1930 and completed before the outbreak of war in 1939. Eighty mi. long. it connects the port of Antwerp with Liège on the largely canalized Meuse and it crosses a highly industrialized area. It has a minimum bottom width of 80 ft. and a middle depth of 16 ft. and can be navigated by vessels of 2.000 tons. Fast boats can do the passage in 15 hours. The authorized speed on the canal is six to seven miles an hour. There are six sets of triple locks, electrically operated, the two largest in each set being 446 ft. long and 52 ft. wide.

Improvements between Charleroi and Clabecq would enable the whole of the Brussels-Charleroi route (depth 10 ft.) to be used by 1.350-ton craft. In the Borinage area a new canal, also for 1,350-ton craft. was to link Nimy, Blaton and Péronnes. A circular canal around Ghent for 2.000-ton craft to link principally the tidal Scheldt. the Upper Scheldr and the Ghent-Terneuzen canal was also being built. The Upper Scheldt and the Ghent-Terneuzen canals were being improved.

Netherlands.—Waterways occupy a dominant position in inland transport in the Netherlands. which has the largest waterway fleet in Europe. Canal development in such a low-lying country originated partly for drainage and flood control. There are about 3,500 mi. of canals and 700 mi. of navigable rivers—nearly one-fifth of the total being usable by craft of over 1,500 tons capacity. Traffic carried by waterways is in excess of 95.000,000 tons annually—nearly four times as much as that by rail. There is a considerable network of canals in the north of the country, but the outstanding developments have been planned to enable large craft to penetrate farther inland from the seaports of Rotterdam and Amsterdam (see also Ship Canals, below). Canals were cut to link with such rivers as the Rhine. Maas (Meuse) and Scheldt, thereby serving numerous towns in the Netherlands and joining up with the waterway systems of Belgium. France and Germany. A number of projects were undertaken in the 20th century to provide

FIG. 3.— KEMBS SECTOR (NEAR BASEL, SWITZ.) OF THE LATERAL GRAND CANAL D'ALSACE PROJECT WHICH WAS PLANNED TO AVOID NAVIGATION DIFFICULTIES ON THE UPPER RHINE SUCH AS THE ISTEIN BAR

routes for barges of over 1.000 tons. Particularly notable were the developments of the route between Nijmegen and Maastricht connecting with the Rhine and Rotterdam in the north and with Belgium's Albert canal in the south. Designed for 2.000-ton barges, they comprised the Meuse-Waal canal, the canalization of the Meuse and the Juliana canal. The latter, which was opened in 1935, is about 20 mi. long, 16 ft. deep and 50 ft. wide (bottom). It has only four locks (446 ft. by $11\frac{3}{4}$ ft.). To eliminate a bottleneck at Lanaye, a better connection with the Albert canal, which is also navigable by 2,000-ton barges, was put in hand in 1958. The Wilhelmina canal (1915–23) was built to cope with expanding coal traffic from Limburg to the west of the country. and the Twente canal, opened 1936 and usable by 1,350-ton barges. connected the thriving industrial areas of the east Netherlands with the Rhine and mith the canals in the north. The ambitious Amsterdam-Rhine canal, 44 mi. long, was started in 1931 and opened in 1952. It incorporated the old Merwede canal from Amsterdam to Utrecht, considerably enlarged, but from there a new canal was built to join the Waal, a tributary of the Rhine. at Tiel. The channel from Amsterdam to Utrecht was deepened from $10\frac{3}{4}$ ft. to $13\frac{3}{4}$ ft. and widened from about 65 ft. to 164 ft. (bottom). The cut from Utrecht to Wijk bij Duurstede. where the canal crosses the Lek river, had a bottom width of $109\frac{1}{2}$ ft. and the remaining portion to Tiel $134\frac{1}{2}$ ft. The ship lock at Tiel, started in 1939 and completed in 1952, is one of the largest inland navigation locks in the world. It is 1,148 ft. long and 59 ft. wide and has two intermediate gates. The canal was designed for vessels of 2.000 tons.

Germany.—The number of large navigable rivers in Germany—the Rhine. Weser. Elbe and Oder—running southeast to northwest was conducive to the growth of canals as east-nest links to serve highly industrialized areas, and there was rapid development in the latter 19th century. Inland water transport remains most important. The waterways of western Germany (canals 690 mi. rivers 1.950 mi.) have a high traffic density, and more than a quarter of them can take craft over 1,350 tons. The large-sized German canals are intended for barges of 1.000 tons or more. mith length of 220 ft. to 262 ft., beam 27 ft. to $29\frac{1}{2}$ ft. and draft of $6\frac{1}{2}$ ft. to $8\frac{1}{2}$ ft. A notable example is the Dortmund-Ems canal (southern section). linking the Ruhr area with the North sea. It is about 70 mi long and $8\frac{1}{2}$ ft. deep. Between World Wars I and II a large-scale project to join the four rivers mentioned was undertaken. and the last link. the 250-mi. Mittelland canal giving Berlin connections with the North sea, Basel, the Oder and the Baltic, was opened in 1938. The Kusten canal from the Dortmund-Ems canal to Oldenburg, the Wesel-Datteln canal from the Rhine to the Dortmund-Ems canal, and the canalization of the Neckar as far as Heilbronn were also undertaken in the 1930s. Projects in progress in the late 1950s included a widening of the Dortmund-Ems canal: further canalization of the Main above Würzburg; the canalization of the Keckar south of Heilbronn toward Stuttgart; and further canalization of the hlittelweser between Minden and Bremen. All these projects were designed for 1.350-ton barges. Total traffic carried on waterways of the German Federal Republic was more than 110,000,000 tons annually.

U.S.S.R.—Inland waterways play a big part in Soviet economy. Flat country fostered the cutting of canals to link important rivers. The Volga is the key to the system. Since 1930 Moscow has become an inland port "of five seas," having five ship-barge canals linking it to European seas (see below). The waterways are much used for carrying passengers as well as goods.

BARGE CANALS

Choice of Line.—In laying out a line of canal the engineer is more restricted than in forming the route of a road or a railway. The canal must either be made on one uniform level or must be adapted to the general rise and fall of the country through which it passes by being constructed in a series of level reaches at varying heights, each closed by a lock or some equivalent device to enable vessels to be transferred from one reach to another. To avoid unduly heavy earthwork. the reaches must follow the bases of hills and the windings of valleys. but it may become necessary to cross a depression by the aid of an embankment or aqueduct, while a piece of rising ground may involve a cutting or a tunnel. Sharp bends must be avoided, the permissible radius of curves depending on the dimensions of the vessels for which the canal is designed and on the width of the waterway.

Aqueducts.—Brindley took the Bridgewater canal over the Irwell at Barton by means of an aqueduct of three stone arches. the centre one having a span of 63 ft., and Thomas Telford arranged that the Shropshire Union canal should cross the Dee valley at Pont-y-Cysyllte partly by embankrnent and partly by an aqueduct 1,007 ft. long and 120 ft. above the river. consisting of a cast-iron trough supported on iron arches with stone piers. In the building of the Manchester Ship canal it became necessary to replace Brindley's aqueduct at Barton, which was only high enough to give room for barges. by a swing aqueduct. the first of its kind, to allow shipping to pass in the canal under it. *(See* MANCHESTER SHIP CANAL.)

Tunnels. — In a hilly country such as England many canal tunnels were necessary. One of the earliest was completed in 1777 by Brindley at Harecastle on the Trent and Mersey canal. It was 2,880 yd. long, 12 ft. high and, being only 9 ft. wide, was suitable for one-way traffic only. Like many other tunnels it had no towpath. A second tunnel. parallel to this but 16 ft. high and 14 ft. wide, including a towpath, was finished by Telford in 1827. In tunnels without towpaths boats had to be "legged through" by men lying on their backs and propelling the boat by pushing their feet against the tunnel walls. Sometimes they were poled through or a fixed or endless chain was used. By the mid-20th century, as horses had largely disappeared, boats usually went through under their own power or with the aid of tugs. The largest canal tunnel in regular commercial use in England is the Blisworth tunnel on the Grand Union canal, completed in 1805. It is 3,056 yd. long, 15 ft. wide and $10\frac{3}{4}$ ft. high above water level.

Tunnels on European canals, especially in France, are also numerous and of much larger dimensions than those on English canals. One, on the St. Quentin canal, 6,200 yd. long, is $26\frac{1}{4}$ ft. wide and $22\frac{1}{3}$ ft. high. The Royaulcourt tunnel on the Nord canal (completed 1923) is 4,757 yd. long, 33 ft. wide and 28$ ft. high, with an enlarged passing place in the middle. The largest canal tunnel in the world is that at Rove, near Marseilles. (See below.)

Dimensions. — The dimensions of a canal, apart from considerations of water supply, are regulated by the size of the vessels which are to be used on it and. to some extent, by their speed. A good depth of water is particularly important. According to W J M Rankine (*Manual* of Civil Engineering, 24th ed. [1911]). the depth of water and sectional area of waterway should be such as not to cause any material increase of the resistance to the motion of the boats beyond what would be encountered in open water, and he laid down the following rules as fulfilling these conditions: (1) least breadth of bottom = 2 × greatest breadth of boat; (2) least depth of water = $1\frac{1}{2}$ ft. + greatest draught of boat; (3) least sectional area of waterway = 6 × greatest immersed midship section of boat.

Rankine was considering the small barges in use in his day, but his proportions are still very generally accepted. In large modern canals it is, however. usual to allow a greater clearance than 18 in. under the boat. the amount increasing with the size and the speed

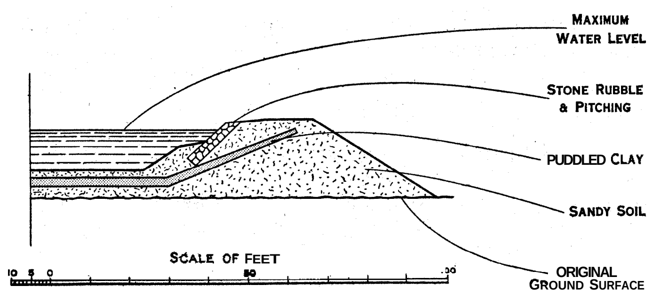

FIG. 4.— HALF CROSS SECTION OF A PORTION OF THE DORTMUND—EMS CANAL. BUILT ON EMBANKMENT OF PERVIOUS MATERIAL

of the vessels (see MECHANICS. FLUID). The ratio of wetted cross section of the canal to the immersed cross section of the boat varies in modern canals from 4:1 to 6.5:1. The larger the ratio, the less will be the erosion of the banks, which increases with the speed of vessels. The ordinary inland canal in England is commonly from 18 to 30 ft. wide at the bottom, 30 to 45 ft. at the water level. with a depth of $3\frac{1}{2}$ to 5 ft. The early continental canals were a little larger, being usually designed for boats of 100 tons or more. The tendency on all continental waterway systems has

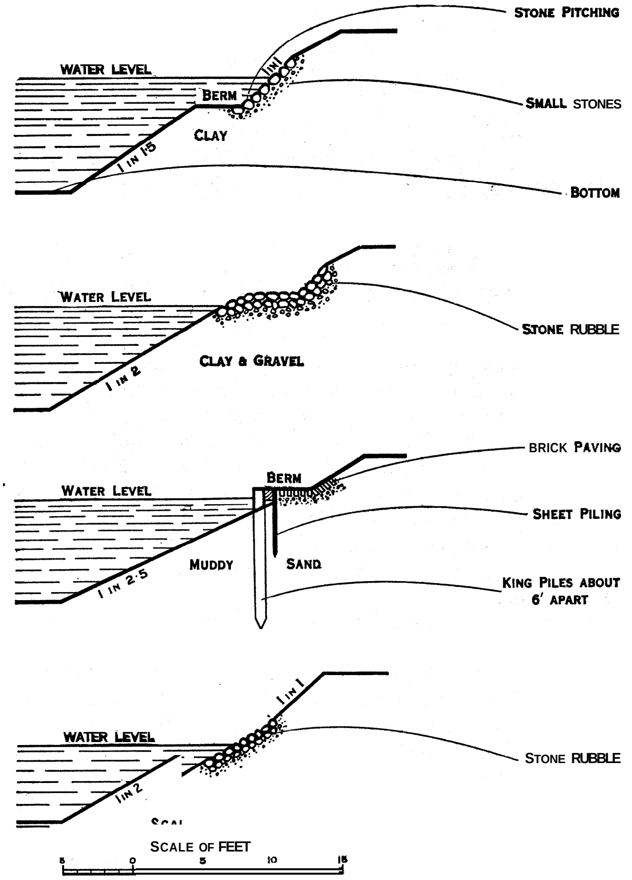

FIG. 5.— CROSS SECTION OF BARGE CANAL BANKS, SHOWING THE SLOPING SIDES. THE STONE RUBBLE TO PROTECT AGAINST WASH. AND THE BERM. A NARROW LEVEL STRIP THAT INCREASES THE CROSS-SECTIONAL AREA OF THE AVAILABLE CHANNEL IN CANALS LIABLE TO FLOOD WATER

been to increase the ruling dimensions of both canals and canalized rivers in order to allow a larger proportion of the craft using the great free rivers, such as the Rhine, to navigate the locked waterways In Germany, for instance, canals were constructed with a width of 69 ft. and more. Beyond Utrecht the Amsterdam-Rhine canal has a width of 109 ft.

Canal Banks. — To retain the water in porous ground, and especially on embankments, a watertight lining of puddle clay must be provided on the bed and sides of the channel. or some other means, such as a lining of concrete, adopted to prevent leakage (fig. 4). The difficulty of maintaining canals on embankments is always a serious one even on banks of quite moderate height.

The sides of canals are usually sloped, the angle varying with the nature of the soil from 1 in $1\frac{1}{2}$ to 1 in 3 or even flatter. In rock cuttings the sides are often nearly vertical. To prevent the erosion of the sides by the wash from boats it is usual to protect the banks at or near the water line by rushes, stone rubble or pitching, concrete or brick paving for fascine work, in some cases combined with continuous steel-sheet piling (figs. 4 and 5). A berm —a narrow, level strip along the bank at or just under the water level—is sometimes formed in the bank to minimize the effect of wash (fig 5). Such bank protection reduces cost of upkeep and prevents excessive silting.

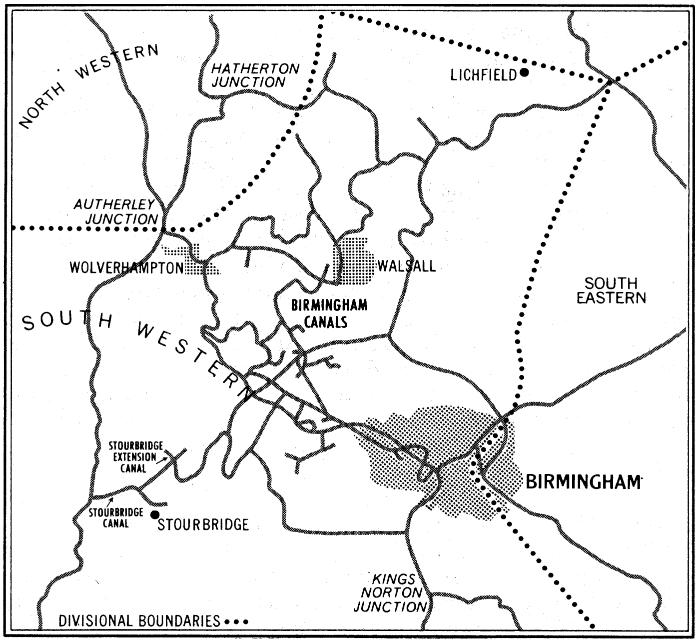
Water Supply and Consumption. — Canals may be fed from natural lakes and streams. but artificial reservoirs often have to be provided. They must be conveniently situated to enable water to flow through feeders, particularly to the summit level of the canal, whence it gravitates to make up the deficiency of water caused by evaporation, percolation, leakage and lockage. Additional feeders must also be provided for intermediate ponds. Water is lost every time a boat passes through a lock, and up traffic consumes more than down. An ascending boat entering a lock displaces a volume of water equal to its submerged capacity. The water so displaced flows into the lower reach of the canal and. as the boat passes through the lock, is replaced by water flowing in from the upper reach. A descending boat also displaces a volume of water equal to its submerged capacity, but in this case the displaced water flows back into the higher reach where it is retained when the lock gates are closed. An insufficient water supply may affect the density of traffic and prevent the enlargement of locks to accommodate more economical craft. Hence economy of water consumption is most important. This is often aided by side ponds into which part of the water from the lock being emptied is discharged and stored instead of flowing into the lower reach. It can be returned to the lock when refilling takes place. Up to half the lockage water may thus be saved. Even greater economy is possible with shaft locks by the use of side ponds placed one above the other and operated in turn. A double lock, where one acts as a side pond. inclines and lifts also facilitate economy. With some canals, however, pumping back of the water is required to compensate for losses, particularly in dry weather and on summit levels, and there are a number of electrically operated canal pumping installations in England and on the European continent.

Wasteweirs and Stop Gates.—An essential adjunct to a canal is a sufficient number of wasteweirs to discharge surplus water accumulating during floods. The wasteweirs are placed at the top water level of the canal, so that when a flood occurs the water flows over them and thus relieves the banks. Culverts, when constructed under a canal embankment to pass streams and floodwater, must be of ample dimensions (see WEIR). Safety or stop gates are necessary at intervals for the purpose of dividing the canal into isolated reaches so that, in the event of a breach, the gates may be shut and the discharge of water confined. In broad canals these stop gates may be formed like lock gates; in small works they sometimes consist of thick planks slipped into grooves. Stop gates consisting of a horizontally framed steel shutter of the width of the canal, suspended from an overhead bridge and counterbalanced, are used on some modern canals; these can be lowered by means of gearing into grooves built in the canal sides.

Locks.—A lock is a watertight chamber, generally rectangular in shape, which by means of gates at either of its ends affords communication between two reaches of a canal at different levels. A boat wishing to ascend from one reach to the next enters through the bottom or downstream gates of the lock, and these gates are then closed. The water level is raised to that of the higher reach, and the top or upstream gates are opened to allow the boat to proceed out of the lock. In descending from a higher reach the procedure is reversed, the water in the lock being drained until it corresponds with the level of the lower reach. The lock chamber is filled and emptied through sluices fitted to the lock gates, or in the side of the chamber from a culvert built in the ground, or both. Locks may be built of timber, brick or stone, but nowadays concrete and steel piling are largely used.

Water supply, changes in levels and the type of craft using the waterway all influence the size of locks, and wide variations are shown in their dimensions. Apart from ship canals, in England they range from the smaller: narrow boat locks, about 75 ft. long, 74 ft. wide and 5 ft. deep, to the longest locks on the Aire and Calder Navigation canal. 460 ft. long. 214 ft. wide and 9 ft. deep. On the European continent the range is greater. There are exceptional locks like the Tiel lock (see below), or the Ruhr lock (Rhine-Herne canal) 1.148 ft. by $42\frac{1}{2}$ ft. by $11\frac{1}{2}$ ft. On the canalized Meuse (the Netherlands) the largest measure 853 ft. by 46 ft. by $12\frac{1}{2}$ ft. Standard locks on many principal French canals are about 126 ft. long and 17 ft. wide. To economize water, canal locks are made only slightly larger than the largest vessel they have to accommodate. In many modern canals they may provide for a train of barges, and long locks for the purpose have sometimes intermediate gates so that only one section of the lock need be used if a single vessel is passing. The 1,148-ft. lock at Tiel on the Amsterdam-Rhine canal is divided into three such sections.

Lock gates may be built of oak or, in large modern canals, of steel. A pair of gates when closed meet at an obtuse angle pointing toward the higher reach of the canal so as to withstand the pressure of the water. The ends of the gates are finished with vertical mitre posts which meet and make a watertight joint. The base of the gates rests against a sill in the lock floor and also forms a watertight joint. When open, the gates fit into recesses in the walls. The timber uprights nearest the lock walls are called heelposts; they work on a pivot in the lock bottom and are rounded to enable them to rotate tightly in a hollow quoin in the wall. Iron straps round the head of the heelpost let into the coping stone support the gates, which are often operated by balance beams projecting over the lock side. With many small locks, however, hand gearing



BY COURTESY OF BRITISH TRANSPORT COMMISSION

FIG. 6—MAP SHOWING INLAND WATERWAYS IN THE AREA OF BIRMINGHAM, ENG.

is employed. On many modern canals the opening and closing of the gates and the sluices are electrically operated. Tumbling, rolling, floating. sector and lifting gates are sometimes used instead of mitre gates, sector and lifting gates being particularly suitable with steel-piled locks. Shaft locks have the upper part of the bottom gates fixed. with only the lower part opening.

Locks may be built in flights ("risers") in which the bottom gates of one lock act as the top gates of the one below. Time and water can be saved if a boat passes in the same direction through the flight. In certain later canals locks were built in groups, leaving long reaches between the groups. For example, the Albert canal in Belgium has six sets of triple locks in a length of 80 mi. The lift of canal locks rarely exceeded 12 ft. up to the end of the 19th century. The modern tendency, where physical conditions and water supply permit, is to build one lock with a high lift in preference to a number of shallow locks. Lifts of 20 to 40 ft. are not uncommon in U.S. and European canals, and the lock on the Donzère-Mondragon canal at Bollkne, which is 640 ft. long and 39 ft. wide, has a lift of 85 ft.. the highest in Europe.

Lateral Canals.—The name "lateral canal" is given to an artificial navigable locked waterway, constructed at the side of or near to the course of a river which may be unsuitable for canalization or improvement. A lateral canal can draw its supply of water from the river with which it is connected and is. in fact. a by-pass, vessels entering it at the higher end and re-entering the river at its lower end or vice versa.

Inclines.—Economy of water and time can be effected by the

Some Representative Barges on European Canals and Canalized Rivers

Type	Length (ft.)	Beam (ft.)	Draught (ft.)	Carrying capacity (metric tons)
England				
Narrow boat	71½	6%	3%	25–30
Barges	61–90½	14½–20½	4–9½	50–190

use of inclined planes or vertical lifts in place of locks. In China rude inclines appear to have been used at an early date, vessels being carried down a sloping plane of stonework by the aid of a flush of water or hauled up it by capstans. On the Bude canal (England), now abandoned, this plan was adopted in an improved form for small boats. In some cases, as on the Morris canal, New Jersey, and between the Ourcq canal and the Marne, near Meaux, France, boats were conveyed on a wheeled trolley or cradle running on rails. Heavy-loaded barges are apt to be strained in this way, however, and to overcome the objection, inclines carrying tanks on wheels, but filled with water on which the boat floated, were introduced. Inclines of this kind were in use in England on the old Chard canal and on the Monkland canal. In 1900 a modern type was installed at Foxton on the Grand Union canal to replace a staircase of ten locks. The two balanced tanks, each capable of carrying two 30-ton boats or a 70-ton barge, moved in opposite directions on 16 wheels and eight rails up and down an incline 307 ft. long, representing a vertical rise of 75 ft. Power was provided by a steam engine. Because of high cost and difficulty of operation, however, the incline was abandoned a few years later.

Lifts.—Vertical lifts can be used instead of locks only where a marked difference in level occurs in a short length of canal, since otherwise long embankments or aqueducts would be necessary to obtain sites for their construction. An early example was built in 1809 at Tardebigge on the Worcester and Birmingham canal. At Anderton a lift was erected in 1875 to connect the Weaver Navigation with the Trent and Mersey canal, which at that point is 50 ft. higher than the river. The lift is a double one and can deal with barges up to 100 tons; the vessels are waterborne in a wrought-iron tank 75 ft. long and 15½ ft. wide. Until 1908 the tanks were raised and lowered by means of hydraulic rams, but in that year electric power was substituted, each of the two tanks being counterbalanced by weights and operated by electric winches. A similar hydraulic lift, completed in 1888 at Fontinettes on the Neuffossé canal in France, raises vessels of 300 tons 43 ft.; and a still larger example on the Canal du Centre at La Louvière in Belgium, built in 1888, has a rise of 50 ft., with tanks that will admit vessels up to 400 tons. This lift, and three others of the same character, were completed in 1921; they overcame the rise of 217 ft. which occurs in this canal in the course of 4⅓ mi. In 1899 the Henrichenburg lift on the Dortmund-Ems canal was opened. It raises 600-ton barges 46 ft. and is operated by an ingenious arrangement of balancing floats immersed in deep tank shafts. Two other notable German lifts are the Niederfinow (1933), with a rise of 117 ft. from the Oder to the Hohenzollern canal, and the Rothensee (1938), with a rise of 60 ft. between the Elbe and the Mittelland canal. They are operated by cables and counterweights and by floats, respectively, and both have single tanks 276 ft. long, 39 ft. wide, with a depth of water 8 ft.

At Peterborough, Ont., there are two hydraulic barge lifts constructed about 1908. Neither lifts nor inclines are in use in the United States. Generally speaking, canal constructors, both in the U.S. and on the continent of Europe, have for many years shown a decided preference for high-lift locks to either mechanical lifts or inclines.

Canal Barges.—The accompanying table gives an idea of the range in size of craft on European canals and canalized rivers.

Towage and Haulage.—With the increasing use of diesel-engined power craft on the waterways between World Wars I and II, haulage by horses on the towpath was largely superseded. Self-propelled craft, tugs and mechanical traction are predominantly used. Barges, self-propelled by steam power, were first tried on the Forth and Clyde canal as early as 1789, and after 1910 the use of internal-combustion engines for propulsion made rapid strides. Self-propelled diesel barges and boats are common, some of them also acting as tugs, towing one or more unpowered or "dumb" craft.

Towage by steam tug was first employed on the Forth and Clyde canal in 1802, when two barges were drawn 19½ mi. in six hours by an engined tugboat. Tugs, steam and diesel, have since been extensively employed to pull one or several barges, but they are most economically used where there are no locks, as on the Bridgewater canal in England, or where the locks are well spaced and can admit the tug and its train of barges simultaneously. For example, on the Aire and Calder Navigation canal, also in England, the largest locks have a length of 460 ft. and pass together a tug with its train of 19 coupled compartment boats carrying in all 700 tons of coal for shipment at Goole on the Humber.

Mechanical haulage by tractors on the towpath has long been practised, particularly in France and Germany, and was introduced in England. An early attempt was made with a steam locomotive on the French Bourgogne canal in 1873. Electric tractors running on rails were used on the continent after the beginning of the 20th century. They are used extensively in France, where about 1,100 of them serve nearly 600 mi. of canals: this compares with more than 600 diesel oil tractors serving about 1,600 mi. The cost of installing and working a system of electric rail traction is justified only where, as on some of the canals in the north of France, the traffic is very heavy.

Mechanical traction did not develop so markedly as towage; generally, its results do not show any considerable decrease in cost compared with other haulage or towage, nor has the speed of craft been increased materially by it. Though the hor'sepower needed for haulage by tractor is about a quarter of that needed for propeller propulsion, bank erosion is reduced and cargo capacity of the dumb craft is greater, the system is generally less adaptable.

Other means of traction include pushing tugs which, coupled close to dumb barges! convert the barges temporarily into a self-steering, self-propelled unit. Tugs fitted with winches that unwind submerged chains fixed to either end of a canal reach are also in use in France on particularly narrow canals or in one-way tunnels (St. Quentin canal). By this means a tug with a convoy of many barges can be hauled along canal sections. In the Mont de Rilly tunnel at the summit level of the Aisne-Marne canal, a system of cable traction was established in 1893, the boats being taken through by means of an endless travelling wire rope supported by pulleys on the towpath. Electric capstans are often used to facilitate the passage of boats through locks, particularly where they have difficultyin entering under their own power.

Horse traction craft on canals was a slow method, but even though by the mid-20th century boats were mostly moved me-

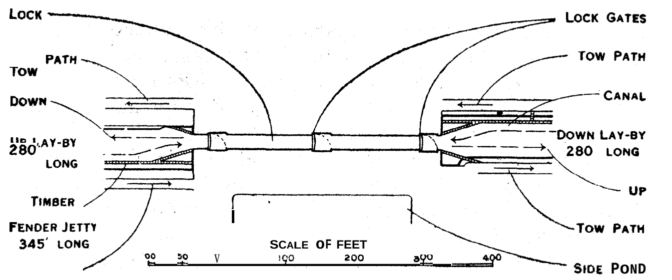

FIG. 7.—PLAN OF TYPICAL LOCK ON THE CANAL DU NORD, FRANCE

The lock is 279 ft. long, but an intermediate gate, shown in the centre of the drawing, is used when a short lock chamber suffices for the passage of barges chanically. the speed was still necessarily restricted on many canals to avoid erosion. At speeds of more than three miles an hour the wash of the craft and propeller vibration begin to cause erosion of the banks. and bank protection schemes are often necessary. The tractive effort required to haul a barge increases at a considerably greater ratio than the speed, and tests have shown that speeds much over three miles per hour are uneconomical in haulage and maintenance costs.

Speeds on British canals vary from three to six miles an hour. In France self-propelled barges are usually limited to $3\frac{3}{4}$ m.p.h., and a tug or tractor with a tow of barges may cover up to 18 mi. a day. including passage through locks. Canals of modern construction usually incorporate bank protection measures. which. with the greater depths provided, facilitate faster speeds. On the Albert canal in Belgium, the maximum authorized speed is six to sex-en miles an hour. There was a growing tendency to increase speed on Dutch waterways.

Inland Ports.—Apart from those important terminals on ship canals which rank as ocean ports, such as blanchester or Ghent, there are many other intermediate wharves and inland ports associated with canalized rivers and canals. These range from waterheads such as Worcester on the canalized Severn, small yet well equipped with landing: discharging. storing and distribution facilities, to extensive, well-developed inland ports such as Strasbourg, which is a focal point for a number of important waterways and has an international trade of 5,000,000 metric tons a year. Such ports. in an industrial environment, must have modern quays and be equipped with the latest cranes and other discharging appliances. warehouses. transit sheds. lay-bys, dry docks and rail and road access. Their terminal works. sea approaches and locks are akin to dock and harbour constructions.

CANALIZED RIVERS

A river whose discharge is liable to become quite small at its low stage. or which has a somewhat large fall, as is usual in the upper part of rivers, cannot be given an adequate depth for navigation by regulation works alone; and its ordinary summer level has to be raised by impounding the flow with weirs at intervals across the channel (*see* RIVER AND RIVER ENGINEERING), while a lock has to be constructed alongside the weir. or in a side channel. to provide for ships (fig. 2). A river is thereby converted into a succession of fairly level reaches rising in steps upstream and providing a comparatively still-water navigation like a canal; but it differs from a canal in the introduction of weirs for keeping up the water level and in the provision for the regular discharge of the river at the weirs. Canalization secures a definite available depth for na igation, and the discharge of the river is generally ample for maintaining the impounded water level. as well as providing the necessary water for locking. The navigation. however, is liable to be stopped during the descent of high floods. which in many cases rise above the locks (fig. 3); and it is necessarily arrested in cold climates on all rivers by long, severe frosts, and especially on the break-up of the ice. (This also applies to canals, even in England: and the suspension of traffic during prolonged frosts is one of the disadvantages under which canals have to operate.)

Many small rivers: such as the Thames above its tidal limit, have been rendered navigable by canalization: and several fairly large rivers have thereby provided a good depth for vessels for considerable distances inland. Thus the canalized Seine has secured a navigable depth of $10\frac{1}{2}$ ft. from its tidal limit up to Paris, a distance of 135 mi.. and a depth of $6\frac{1}{2}$ ft. up to Montereau. 62 mi. higher up. Regulation works for improving the Main river. from its confluence with the Rhine opposite Mainz up to Frankfurt, failed to secure a minimum depth of three feet at the low stage of the river, and canalization works, carried out between 1883 and 1900 by means of six weirs in the $26\frac{1}{2}$ mi. between the Rhine and Offenbach, above Frankfurt. provided a minimum depth of $8\frac{1}{4}$ ft. On ascending a river it becomes increasingly difficult to obtain a good depth by canalization because of the progressive inclination of the river bed. Thus, even on the Seine. with its moderate fall, a depth of $10\frac{1}{2}$ ft. was obtained on the lower Seine by weirs placed on the average $13\frac{1}{2}$ mi. apart, but on the upper Seine weirs were required at intervals of only about 43 mi. to attain a depth of 64 ft. (L. A. Gs.)

UNITED STATES AND CANADA

U.S. Inland Navigation.—The total length of federally improved navigable rivers in the United States is about 28,500 mi. At least 40 distinct and separate rivers have been improved by canalization. (See *Annual Report of the Chief of Engineers,* U.S. Government Printing Office.) After 1900 an immense amount of improvement of the inland waterways, both natural and artificial. was accomplished. As a rule. canalization is well inland. the lower and middle reaches of the great rivers being open to navigation. For instance. on the Hudson, the first lock is at Troy, N.Y., 153 mi. from the sea; on the Mississippi, at St. Louis. Mo., 1,375 mi.; and on the Missouri there is open navigation to Sioux City. Ia., 2,146 mi. from the Gulf of Mexico. The construction of locked waterways near seaports to connect ocean traffic with inland navigation is comparatively infrequent, although the St. Lawrence seaway (*q.v.*), the New Orleans Industrial canal and the Lake Washington Ship canal at Seattle (*see* below) are important examples.

When traffic on U.S. rivers began to be intense, recourse was had to extensive canalization in cases where shallow water and limited flow gave rise to difficulties either seasonal or continuous. Among the rivers so improved were the Ohio, with its tributaries the Allegheny and Monongahela; the Kanawha in West Virginia; the Kentucky in Kentucky; the Cumberland in Kentucky and Tennessee; the Tennessee in Kentucky, Tennessee and Alabama; the Black Warrior and Tombigbee in Alabama; the Columbia in Oregon and Washington; and the Mississippi above St. Louis.

The locks on the Ohio are among the largest on the great rivers of the United States. Between Pittsburgh, Pa.. and Cairo, Ill.. a distance of 981 mi., there are 47 locks. Four of these locks. being higher, replaced nine obsolete locks. The cost of the improvements exceeded $130.000.000. Each lock is 110 × 600 ft. internally, and in addition auxiliary locks are provided at five locations—56 × 360 ft. at Emsworth. Dashields, Montgomery and Dam 41 and 110 × 360 ft. at Gallipolis. Dashields is a fixed dam while Emsworth. Montgomery and Gallipolis are fixed dams with movable crests. The remaining dams are of the movable-crest type, which permit open river navigation during higher flow conditions. The depth over the sills varies from 9.5 to 37 ft., with the lift of the majority of the locks varying from 6 to 12 ft.

Canalization of the upper Mississippi river was completed in 1938 when the last of 24 locks and dams were opened to navigation. The project provides for a nine-foot channel between Alton. Ill., and Minneapolis, Minn.. a distance of 650 mi. Lock 19. at Keokuk. Ia.. was constructed in conjunction with a hydroelectric power dam in 1913; its dimensions are 110 × 358 ft. Upon completion of the 110 × 1.200 ft. lock under construction in the early 1950s. the older lock mas used as a stand-by unit. All other structures are provided with 110 X 600 ft. locks. with auxiliary locks of shorter length at Locks 1, 2, 15 and 26. In 1953 the Chain of Rocks canal at St. Louis, Mo., extended the canalized section of the river downstream 19 mi. Lock lifts vary from 5.5 ft. at Lock 5A (near Winona, Minn.) to 38.2 ft. at Lock 19 (Keokuk). The dams are non-navigable, with movable crests. usually Taintor gates.

Apart from the river improvements effected by the federal government. which controls all navigable rivers. several of the states undertook canal work; the most notable instance being the reconstruction by New York of the old Erie canal. which now forms the New York State Barge canal. This work, carried out between 1905 and 1918 at a cost. including branches and terminals completed subsequently, of more than $170,000.000, connects the Hudson river at Troy with Lake Erie at Buffalo. (*See* N. E. Whitford, *History of the Barge Canal of New York State,* and the *Book of Plans* [1921–22].) Altogether including branch canals and the Lake Champlain section. there are 525 mi. of canal proper, with 57 locks. Ships and barges up to 300 ft. in length and $43\frac{1}{2}$-ft. beam can navigate the canal. Some of the barges

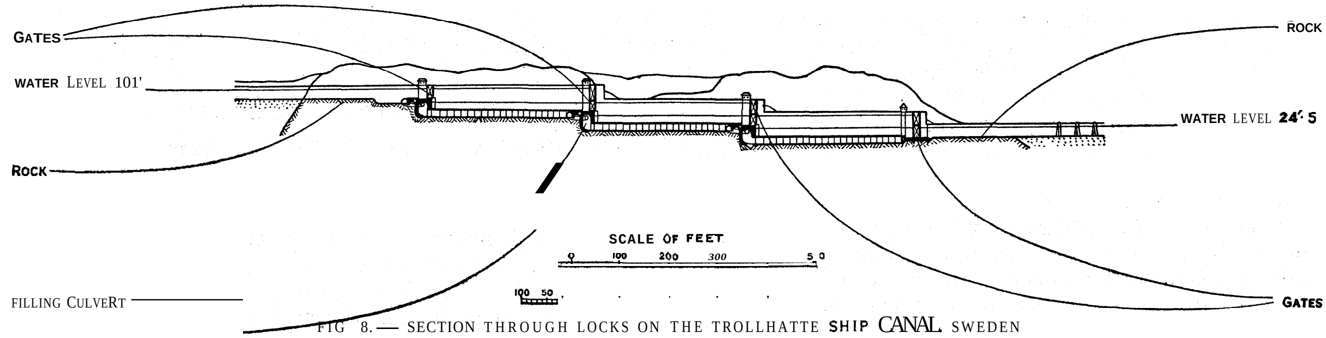

FIG. 8.— SECTION THROUGH LOCKS ON THE TROLLHATTE SHIP CANAL. SWEDEN

Completed in 1916, canal connects Goteborg with Lake Vaner. The three locks shown overcome a total rise of 77 ft. and are $321\frac{1}{2}$ ft. by 45 ft. internally

using it have a cargo capacity of 2.500 tons. All the locks have a depth of 13 ft. over sills. and the maximum lift in any one is $40\frac{1}{2}$ ft. All lock and other machinery is operated electrically. and the canal and its terminal ports are equipped in lavish manner with mechanical appliances. There is at Oswego, on this canal, a novel and interesting system of siphons for emptying and filling the lock chamber.

Locks and **Weirs in the U.S.**—After 1910 practically all locks on inland waterways in the United States were constructed of concrete. No mechanical lifts or inclined planes are in use. and no provision is made at any of the locks for mechanical haulage of vessels through them. Electric locomotives for rack traction, however. are employed for towing ships through the locks of the Panama canal. The large majority of the navigable waterways of the states being rivers of very variable flow. the provision of dams or weirs with sluices has usually been necessary in conjunction with lock construction. and many of these works are of considerable magnitude. Steel lock gates of the double-leaf mitred type are adopted generally for new works; but rolling caisson gates are also used for closing many of the river locks. particularly at the upper end. of wide locks on rivers. The silting up of the caisson chambers. however. gave trouble in some cases. and their use was abandoned in works carried out after 1916. "Tumbling" or flap gates ("bear trap") hinged on a horizontal axis have also been used in a fen. instances. Sluice valves are constructed in the lock walls and are irequently of the "butterfly" type, but Stoney gate sluices, Taintor gates and cylindrical valves predominate. The practice of placing sluice valves in the gates has been abandoned. Movable weirs of the Chanoine and needle types were formerly much used. but in the dams and weirs of later construction some form of sliding or hinged sector gates has often been adopted. The Stoney sluice is typical of the first class and the Taintor gate of the second (see WEIR).

Canadian Inland Navigation.— The-splendid inland navigation system of Canada mainly consists of natural lakes and rivers. Most of the artificial waterways are lateral canals cut in order to enable vessels to avoid rapids in the rivers. The earliest locked canal in America. completed in 1783. was made to avoid rapids on the St. Lawrence river between Lake St. Francis and Montreal. (See SAINT LAWRENCE SEAWAY; GREAT LAKES.)

(N. G. G.; G. J. Z.)

SHIP CANALS

Ship canals are of two classes. those which connect two seas or lakes and those which provide access for seagoing vessels to inland ports. The Suez canal between the Mediterranean and the Red sea. the Panama canal between the Atlantic and Pacific oceans and the Welland canal joining lakes Erie and Ontario in Canada are examples of the first class. and the hlanchester Ship canal. giving access to the great inland port of Manchester. represents the second class. An earlier though smaller British example of this second class is the ship canal between Sharpness and Gloucester, completed in 1827. Though ship canals are used by larger and seagoing vessels and cost more to construct. no rigid distinction can always he drawn between them and barge canals. The modern Albert canal in Belgium. and the Amsterdam-Rhine canal. for example. are suitable for both seagoing vessels and barges.

The four most famous ship canals with a large international trade are the Suez. Panama. Manchester and Riel. The Suez represents the canals on one level without locks. and the Panama those at varying levels that require locks. To keep pace with the increasing size of modern ships, it became necessary in some cases to enlarge the dimensions of ship canals and their locks. For example. the Suez was successively increased from a depth of 26 ft. and bottom width of 72 ft. to minima of $42\frac{1}{2}$ ft. and 197 ft. respectively. The enlarging of a locked canal is more complicated, especially if reconstruction of the locks is involved. In connection with the enlargement of the North sea canal connecting Ymuiden to Amsterdam the original entrance lock was 394 ft. by 60 ft. A much larger sea lock had to be added later, and another new lock. the largest in the world. was opened in 1930. It is 1,312 ft. long. 163 ft. wide and 50 ft. deep.

Apart from the Manchester and the Gloucester ship canals: the only other noteworthy British ship canals are in Scotland. The Caledonian canal (opened 1822), the first through ship canal in the country. connects the North sea and the Atlantic. It consists of artificial cuts (22 mi.) linking natural locks (38 mi.). The 9-mi. Crinan canal (completed 1801) crosses Kintyre. The use of both canals is limited to small ships.

The Forth and Clyde canal (completed 1790) had a great success in its earliest years, but after the beginning of the 20th century was little used. Periodically proposals were made for a mid-Scotland deep-water ship canal, the proposal of 1946 being unfavourably reported on by a government committee because of enormous cost and limited strategic value.

Belgium and the Netherlands are favourably placed for the development of ship canals. and both countries have built a number of them. The Ghent-Terneuzen canal. 22 mi. long, originally constructed 1825–27 and since enlarged to $28\frac{2}{3}$ ft. deep and up to 163 ft. bottom width, is half Dutch and half Belgian. It converted the city of Ghent into an extensive and well-equipped inland port. Bruges and Brussels similarly became inland ports through, respectively. the Bruges ship canal (1896–1907), $6\frac{1}{4}$ mi. long and 26 ft. deep. and the Rupel canal (1922), 18 mi. long and $21\frac{1}{4}$ ft. deep.

Two notable ship canals in the Netherlands are the North sea canal to Amsterdam. 15 mi. long, and 39 ft. deep, already referred to. and the "New Waterway" between the Hook of Holland and Rotterdam. which has been developed from an older waterway and which gives access to the Rhine system. The navigation channel has been improved to a width of 328 ft. and a low-water depth of 36 ft.

France has no really large ship canals. Rivers such as the Seine were canalized and some canals were built. however. for small ships as well as barges. The so-called Marseilles-Rhône Ship canal. which is about 48 mi. long. is really intended to open up the port of Marseilles to barge traffic and the whole waterways system of France. The canal is level throughout but has regulating locks. It is about ten feet deep. A remarkable feature is the Rove tunnel. $4\frac{1}{2}$ mi. long. which. with a width of 72 ft. and height of 50 ft.. has the largest tunnel cross section in the world. The lockless Corinth canal, a 3-mi. cut across the isthmus dividing the gulfs of Corinth and Aegina, was built 1882–93 and obviates a 200-mi. sea voyage. It was blocked in 1944 by the Germans but was fully reopened in

1948. It has a bottom width of 72 ft. and depth of $26\frac{1}{4}$ ft. for vessels up to 10,000 tons.

Russia. which in 1884 had completed the Kronstadt canal to open up St. Petersburg (later Leningrad) to seagoing ships, in later years promoted a number of ambitious ship canal projects. The most notable was the plan to link five seas—White, Baltic, Black, Caspian and Azov. This has made Moscow a great inland port connected to these seas by the Marie. Stalin, Moscow-Volga and Volga-Don canals. The White sea–Baltic, or Stalin canal, 141 mi. long. was completed in 1933. the Moscow–Volga canal. 79 mi. long, in 1937. The last stage in the plan, the Volga–Don canal, 63 mi., was completed in 1952 and connects the Black, Azov and Caspian seas. It has 13 locks, each with a rise of 32–42 ft. This development formed part of an immense project covering reservoirs, irrigation, hydroelectric power, soil erosion and drainage.

Sweden, a country of many lakes and rivers, also developed some ship canals. Two of the most interesting, the Göta and the Trollhatte canals. enable small sea vessels to cross Sweden between the North and Baltic seas. The Gota canal, begun in 1716 and finally completed in 1832, extends from the Baltic to Lake Vaner, which is also connected to Goteborg by the Trollhatte, 52 mi. long, completed in 1916. (L. A. Gs.)

U.S. and Canadian Ship Canals.—Important ship canals, in addition to the Panama canal (opened to traffic in Aug. 1914), were completed after the beginning of the 20th century. The New Orleans Industrial canal connects the Mississippi river with Lake Pontchartrain, $5\frac{1}{2}$ mi. distant. It was completed in 1923 at a cost of more than $25,000,000, and its construction was brought about mainly by the desire to provide increased waterside frontage at the port of New Orleans. Moreover, it forms part of the Gulf-Intracoastal waterway (see below), for connecting New Orleans with the Gulf of Mexico by way of a land cut through the marsh south of Lake Pontchartrain into Lake Borgne. The lock at the entrance to the canal is constructed on a foundation of 24,000 piles driven through a bed of very fine quicksand. The usable dimensions of the lock are 640 × 75 ft., with 31-ft. depth over sills at lowest water in the Mississippi river. The canal at its minimum section is 30 ft. deep, 150 ft. wide at bottom and 300 ft. wide at water level. The Gulf-Intracoastal waterway provides a 12 × 150 ft. channel for more than 1,100 mi., from Brownsville, Tex., to Xpalachee bay, Fla. Most of the canal is excavated from marshy land inland from the coast. Locks have been provided at certain locations to facilitate crossing streams intersecting the canal or for exclusion of salt water to adjacent agricultural areas. The Atlantic-Intracoastal waterway provides for a 12-ft channel from Key West, Fla., to New York city, a distance of about 1.700 mi. Widths vary from 90 to 250 ft. The canal was completed between Jacksonville, Fla., and Chesapeake bay, and certain sections between the bay and New York also were at project dimensions. A lateral canal across Florida through Lake Okeechobee also was completed, and a second canal starting at Jacksonville was proposed. Locks were constructed in Okeechobee lateral and in the main canal at various points to provide for differences in head and exclusion of silt and salt uater.

The Lake Washington Ship canal, eight miles long, extending from Puget sound to Lake Washington, was opened in 1916. The sea entrance at Seattle. Wash., has two locks, the larger of which has a usable length of 760 ft., with intermediate gates, and is 80 ft. wide. The depth over the sill varies from 25 to 44 ft. according to the state of the tide. Flood water is provided for by the construction of a dam with movable crest gates.

The Cape Cod canal, connecting Cape Cod bay on the east with Buzzards bay on the west of the Cape Cod isthmus, is $7\frac{2}{3}$ mi. in length with dredged approaches which make the total length of the cut $17\frac{1}{2}$ mi. Its construction was begun in 1909 and the waterway was first opened to traffic in 1914, after which the works were completed to give a depth of 32 ft. at low water. There is no regulating lock on the canal. and because of the difference in sea levels at the two ends there is. at times a considerable current flowing through it. It provides a shorter route than the exposed open sea route between New York and Boston.

For the St. Mary's Falls canal or, more correctly, canals connecting lakes Superior and Huron at Sault Ste. Marie, and the Welland Ship canal connecting lakes Erie and Ontario in Canada, see GREAT LAKES, THE. (N. G. G.; G. J. Z.)

WATERWAYS, INTERNATIONAL. International waterways comprise international rivers and inland canals, straits and interoceanic canals. An international river or inland canal is one that flows through or separates the territory of two or more nations. While a strait in a geographical sense is any passage connecting two portions of the high seas (*q.v.*) or of the waters adjacent thereto, in its legal sense the term refers to any passage between two areas of the high seas where the territorial seas of the littoral states meet and overlap in such a way that no stretch of the high seas extends through the geographic strait. An interoceanic canal is an artificial waterway connecting two sections of the high seas.

Rivers and Inland Canals.—International rivers possess importance for navigation, fisheries, the generation of hydroelectric power. the carrying away of wastes and consumptive use for irrigation and domestic purposes.

When an international river constitutes the boundary between two or more countries, it is usual to subject the waterway to joint regulation by the riparians. Both under treaties and in the absence of treaties, the boundary line between the two riparian states is normally fixed at the middle point of the principal channel, or *thalweg*, of a navigable river, and at the middle point of a nonnavigable river.

In the 19th and 20th centuries a number of navigable rivers running through the territory of two or more nations were opened by treaty to free use by the shipping of the riparians and of other nations. The principle of free navigation by ships of all nations of certain major European rivers was first enunciated in general terms at the congress of Vienna of 1815. The Rhine was opened to free navigation by the treaty of Mayence (Mainz) of 1831, but it was not until the Act of Mannheim of 1868 that the river was opened on a nondiscriminatory basis to vessels of all nations and certain impediments to free navigation were removed. The Danube and its mouths were opened to ships of all nations by the treaty of Paris of 1856. By the treaty of Versailles (*q.v.*) of 1919, parts of the Elbe, Moldau, Oder, Niemen and Danube were declared to be international rivers upon which the shipping of riparians and nonriparians was to be treated on a basis of equality. Following World War II, the domination of the Danube by the U.S.S.R. and its satellites brought to an end for practical purposes the international regime which had hitherto existed for the river. By the general act of the Berlin conference of 1885, navigation on the Congo and Niger rivers was declared "free for the merchant ships of all nations equally." The 1885 act was substantially revised. however, by the treaty of St. Germain of Sept. 10. 1919.

In the absence of a treaty, there is no general right of free navigation by riparians and nonriparians, even in cases in which a river affords access to the sea for a landlocked state. Despite the recognition in principle by a treaty of a right of free passage, practical impediments to navigation may be created through measures of control by the riparians. For the most part tolls. other than charges for special services rendered, are no longer charged on international rivers.

The administration of international rivers used for navigation, irrigation and the generation of power is frequently entrusted to an international organization representing the riparians and, in a number of instances, nonriparians as well. The oldest of these is the Central Commission for Rhine Navigation, established in 1815 and charged with the co-ordination of works on the river and the maintenance of free navigation. Prior to World War II, free navigation on the Danube was facilitated by the International Danube commission on the portion of the river entrusted to its care. International bodies charged with supervision of the consumptive uses of international rivers (*e.g.,* irrigation and generation of power) include the Canadian–U.S. International Joint commission; the Committee for Co-ordination of Investigations of the Lower Mekong Basin; and the Spanish-Portuguese International commission, having competence with respect to the Douro (Duero) river.

Various attempts to establish a common regime of navigation for international rivers, in substitution for special arrangements for individual waterways, were not, as of the late 1950s, successful. The Barcelona convention of 1921 on the regime of navigable waterways of international concern, by which the parties agreed to accord the right of free navigation on their waterways to other contracting nations, was not ratified by a sufficient number of states to be of substantial importance. The proposal of Pres. Harry S. Truman at the Potsdam conference of 1945 that the Black sea straits, the Kiel canal, the Danube, the Rhine and other international waterways of Europe be opened to "free and unrestricted navigation" under common international supervision was not carried into effect.

The extent of the legal obligation of an upper riparian under customary international law to maintain the flow of an international river for the benefit of a downstream riparian is controverted. The rights of upper and lower riparians, and of adjacent riparians on a boundary river, to divert water are usually regulated by treaties apportioning the flow. Examples of these are the treaty of 1944 between the United States and Mexico regarding the Rio Grande and the Colorado river and the Nile Waters agreement of 1929 between Great Britain and Egypt. Agreements of this nature frequently also regulate pollution and fisheries and state what priority, if any, is to be accorded various uses of the river. During the period following World War II, international disputes over the employment of the waters of the Jordan, the Indus (split apart by the partition of India), the Helmund and other international river systems reflected an enhanced demand for the waters of these rivers for irrigation.

Straits. — Under customary international law, as enunciated by the International Court of Justice in the Corfu channel case, both merchant ships and warships have, unless otherwise prescribed by treaty, a right of free passage "through straits used for international navigation between two parts of the high seas without the previous authorization of a coastal state, provided that the passage is *innocent."* In time of war, a neutral riparian may enforce reasonable measures to protect the neutrality of its territorial sea within a strait. Such measures may include the laying of mines and compulsory pilotage, but must keep the strait open to free navigation When a coastal state is at war, it may close the strait to enemy shipping and vessels carrying contraband to the enemy and may take all belligerent measures which it would be authorized to employ in its other territorial waters or on the high seas. Because of exceptional geographical and political circumstances, passage through certain straits is restricted by treaty. The most notable instance of such regulation is the Montreux convention of 1936, which controls the passage of warships through the Turkish straits and permits the closing of the straits when Turkey is at war.

Interoceanic Canals. — In the second half of the 20th century the three major interoceanic canals, Suez, Panama and Kiel, were operated and maintained by the states through whose territory the canals passed. The three were opened to common usage by treaties which dedicated them to free navigation by the ships of all nations on a nondiscriminatory basis. Freedom of navigation through the Suez canal was secured by the Convention of Constantinople of 1888, reaffirmed by the Egyptian government in its declaration of April 24, 1957; through the Panama canal by the Hay–Pauncefote treaty of 1901 between the United States and Great Britain and the Hay–Bunau-Varilla treaty of 1903 between the United States and Panama; and through the Kiel canal by the Versailles treaty of 1919. So long as the administering state is not at war, these canals must be left open to navigation by the warships and merchant ships of all nations. The passage of the shipping of belligerents is not, in the view of the Permanent Court of International Justice in the case of the S S. "Wimbledon," inconsistent with the neutrality of the nation operating the canal. In case of a war to which the proprietor nation is a party, the canal may lawfully be closed to enemy vessels and ships carrying contraband to the belligerents. Passage through canals is at all times subject to the payment of tolls which under the treaties mentioned must be equal for all states. They are fixed by the proprietor state, which assumes responsibility for the operation and maintenance of the waterway.

See J. P. Chamberlain, *The Régime of the International Rivers* (1923). (*R. R.* Br.)

WATERWEED (Water Thyme; *Anacharis canadensis* or *Elodea canadensis*), a submersed aquatic herb of the frogbit family (Hydrocharitaceae), native to America. It was introduced into Ireland about 1836, and soon spread and became a weed in waterways, ditches, streams and ponds in England and on the continent. The staminate and pistillate flowers are borne on separate plants. If, as in England, only one kind of plant is present, the species produces no seeds but spreads by vegetative propagation. The allied *A. occidentalis* is a common native species of the northern United States; *A. densa,* native to Brazil, is cultivated as an aquarium plant for its showy petals.

WATFORD, a market town and municipal (1922) and parliamentary borough of Hertfordshire, Eng., 15 mi. N.W. of Marble arch, London, by road. Pop. (1951) 73,130. Area 8.3 sq.mi. The rivers Colne and Gade (on the east and west) and the Grand Union canal pass through the borough, which is mainly a residential and shopping town, many of its inhabitants working in London. In 1931 the Essex almshouses (1580) were restored but the mansion of Cassiobury park, the home of the earls of Essex, was demolished, though a part of the park was acquired for the public. Watford has a technical college, many schools and other educational centres, a thrice-weekly market (the first market charter was from Henry I), printing works (the biggest industry), paper mills, breweries, engineering, chemical and other works.

WATKINS GLEN, a village of New York, U.S., at the south end of Seneca lake; the seat of Schuyler county. A settlement was begun in 1791; after several changes in name, it became Watkins in 1852 in honour of Samuel Watkins, an early promoter, and in 1926 Watkins Glen. Salt production, from brine wells, is an important industry, and the annual Watkins Glen Grand Prix automobile race is held there. The entrance to Watkins Glen State park, established 1863, is on the main street. A creek flowing 2 mi. through the gorge of the 604 ac. park, descends 700 ft. to the village, forming spectacular pools, rapids and cascades. Primarily a resort, the permanent population is about 3,000. (C. C. Ma.)

WATLING STREET, the Early English name for the great road made by the Romans from London past St. Albans (Roman Verulamium) to Wroxeter (Roman Viroconium) near Shrewsbury and used by the Anglo-Saxons, just as a great part of it is used today. According to early documents the name was at first Waeclinga (or Waetlinga) straet; its derivation is unknown, but an English personal name may lie behind it. After the Conquest the road was included in the list of four royal roads which the Norman lawyers recorded or invented. (*See* Ermine Street.) Later still, in the Elizabethan period and after it, the name Watling street seems to have been applied to many Roman or reputed Roman roads in various parts of Britain. In particular, the Roman "North road" which ran from York through Corhridge and over Cheviot to Newstead near Melrose, and thence to the Wall of Pius, and which has largely been in use ever since Roman times, was not infrequently called Watling street, though there was no old authority for it and throughout the middle ages the section of the road between the Tyne and the Forth was called Dere street.

WATSON, HEWETT COTTRELL (1804–1881), British botanist, authority on the geographic distribution of British plants, was born at Firbeck, Yorkshire, on May 9, 1804. He received his scientific education at Edinburgh. About 1835 he settled in Thames Ditton, Surrey, where he died on July 27, 1881.

Beginning in 1832, Watson's publications extended over a period of more than 40 years. His most notable work, *Cybele Britannica* (1847–60), was the first serious attempt to put British geographical botany on an exact basis. His *Compendium* (1868–70) is essentially a condensed and emended edition of the *Cybele.* In these works the distribution of British plants is traced through the 18 provinces into which Watson divided Britain. In the *Supplement to the Compendium* (1872) distribution is traced through 38 subprovinces. His last large-scale work, *Topographical Botany* (1873–74), records distribution in even greater detail through 112 counties and vice-counties.

Bibliography.—Memoirs of Watson's life and works are found in *J. Bot., Lond.,* 19:257–265 (1881); *Watsonia,* vol. i (1949). For a list of his publications see *Botanisches Centralblatt,* 7:254–255 (1881).

(J. W. Tt.)

WATSON, JOHN BROADUS (1878–1958), U.S. psychologist who codified and forcefully publicized the theoretical program of behaviourism, was born at Greenville, S.C., on Jan. 9, 1878. He studied at Furman university, Greenville (M.A., 1900), and The University of Chicago (Ph.D., 1903), and was professor of psychology at Johns Hopkins university from 1908 until 1920, when he entered private business. He made many experimental contributions, especially to animal and child psychology.

Behaviourism as expounded by Watson sought to make psychology "a purely objective experimental branch of natural science" by restricting it to study of the relations between environmental events (stimuli) and behaviour (responses). Mental phenomena, as analyzed by the introspective psychologies dominant in the early 20th century, were held unverifiable in that they are directly observable only by their owners, and the abandonment of introspective methods was urged. Within the Watsonian program certain special hypotheses and judgments stand out: (1) the view that learned behaviour derives by the principles of the conditioned reflex (Pavlov) from a limited repertory of innate reflexes; (2) the theory that thinking and imagery reduce to "faint reinstatements" of the original muscular responses involved in speech and other motor behaviour; and (3) extreme environmentalism, as evidenced by the judgment that a "healthy, well-formed baby" may be made to develop in any specifiable direction and degree by appropriate environmental influence. After the early 1920s the program of behaviourism, in broad outline if not in specific Watsonian detail, was dominant in U.S. psychology, though from roughly the late '40s its influence declined.

Among Watson's books are *Behavior: an Introduction to Comparative Psychology* (1914); *Psychology From the Standpoint of a Behaviorist* (1919); *Behaviorism* (1925). He died in New York city on Sept. 25, 1958. *See* also BEHAVIOURISM.

WATSON, JOHN CHRISTIAN (1867–1941), first Labor prime minister of Australia (April to August 1904), was born at Valparaiso, Chile, on April 9 when his parents were on voyage as immigrants to New Zealand. He received his primary education at Oamaru, N.Z., and began work as a compositor. In the early 1880s he immigrated to New South Wales. He became active in trade union affairs and was president of the Sydney Trades and Labor council in 1890. He was elected to the New South Wales parliament in 1894, in Labor's turn to politics after the "great strikes," but resigned in 1901 when he was elected to the first Australian commonwealth parliament and became leader of the Labor party. He was active in gaining Labor support for "New Protection," and a majority for the tariff protectionists over free traders. He retired in 1908 and died on Nov. 18, 1941. (J. F. C.)

WATSON, SERENO (1826–1892), U.S. botanist, one of its leading plant taxonomists of the 19th century, was born on Dec. 1, 1826, at East Windsor Hill, Conn. Graduating from Yale in 1847, he subsequently taught school, farmed, studied and practised medicine, and worked in insurance and banking. In 1866 he re-entered Yale to study chemistry and mineralogy, and in the following years, in California, became botanist to the United States geological exploration of the 40th parallel, under the direction of Clarence King (*q.v.*). Watson's association with the Gray herbarium of Harvard university began in 1870, and he was appointed curator there in 1874. He died on March 9, 1892, at Cambridge, Mass.

Watson described many new genera and species, particularly of plants of western North America. Outstanding among his publications are *Botany* (1871), the report on plants of the King expedition; *Botany of California* (1876–80), done in collaboration with W. H. Brewer and Asa Gray; *Bibliographical Index to North American Botany* (1878); and *Contributions to American Botany* (1873–91), a series of taxonomic papers. The sixth edition of Asa Gray's *Manual of the Botany of the Northern United States* (1890) was revised by Watson and J. M. Coulter.

See an account of Watson and a list of his publications in Proc. ***Amer.*** *Acad. Arts Sci.*, 27:403–416 **(1893).** (J. W. TT.)

WATSON, THOMAS (*c.* 1557–1592), English poet who exemplifies the spirit of the Renaissance in his use of Italian poetic forms and his facility in Latin versification. He was born in London, probably in 1557, was educated at Oxford, and while quite a young man enjoyed a reputation, even abroad, as a Latin poet. His earliest surviving work (1581), a Latin version of the *Antigone* of Sophocles, was followed by his first work in English, the *Hecatompathia or Passionate Centurie of Love* (1582). This is a collection or cycle of 100 pieces, in the manner of Petrarch, celebrating the sufferings of a lover and his long farewell to love. Although they profess to be sonnets, they are really written in triple sets of common 6-line stanza, and therefore have 18 lines each. The metre has had no imitators.

At this time, Watson was regarded, as the testimony of Thomas Nashe and others proves, as the best Latin poet of England. In 1590 he published, in English and Latin verse, his *Meliboeus,* an elegy on the death of Sir Francis Walsingham, and a collection of *Italian Madrigalls,* put into English by Watson and set to music by William Byrd. Of the remainder of his career nothing is known, except that on Sept. 26, 1592, he was buried in the Church of St. Bartholomew the Less, London. His latest and best book, *The Tears of Fancie, or, Love Disdained* (1593), posthumously published, is a collection of 60 competent 14-line sonnets.

WATSON, THOMAS EUGENE (1892–), U.S. marine corps officer, a prominent commander in the Pacific theatre during World War II, was born Jan. 18, 1892, in Oskaloosa, Ia., attended Penn college there and enlisted in the marine corps in 1912. Commissioned a second lieutenant on Oct. 20, 1916, he advanced through the various ranks to lieutenant general. Watson distinguished himself in command of the force that captured Eniwetok atoll, in the Marshall Islands, in February–March 1944. He commanded the 2nd marine division on Saipan and Tinian later in that year, and again distinguished himself in the capture of those islands of the Marianas group. After the war, he commanded Camp Lejeune, N.C., prior to his retirement in July 1950. (J. B. HN.)

WATSON, WILLIAM (*c.* 1559–1603), English conspirator, was born in the north of England, probably on April 23, 1559. In 1586 he became a Roman Catholic priest in France, and during the concluding years of Elizabeth I's reign he paid several visits to England; he was imprisoned and tortured more than once.

He became prominent as a champion of the secular priests in their dispute with the Jesuits, and in 1601 some writings by him on this question appeared which were answered by Robert Parsons (*q.v.*). When Elizabeth died, Watson hastened to Scotland to assure James I of the loyalty of his party and to forestall the Jesuits, who were suspected of intrigue with Spain. The new king did not, however, as was hoped, cease to exact the recusancy fines, and Watson became involved in the "Bye plot" or "Watson's plot," in which connection his name is best known, and in its sequel the Main or Cobham's plot.

Watson discussed the grievances of his coreligionists with another priest, William Clark, with Sir Griffin Markham and Anthony Copley and with a disappointed Protestant courtier, George Brooke. They took another Protestant, Thomas, 15th Lord Grey de Wilton, into their confidence.

It was arranged that James should be surprised and seized, while the conspirators talked loudly about capturing the Tower of London, converting the king to Romanism and making Watson lord keeper. One or two of the conspirators drew back; but Watson and his remaining colleagues arranged to assemble at Greenwich on June 24, 1603, and under the pretense of presenting a petition to carry out their object. The plot was a complete failure; Henry Garnet and other Jesuits betrayed it to the authorities, and its principal authors were seized, Watson being captured in August at Hay on the Welsh border. They were tried at Winchester and found guilty; Watson and Clark were executed on Dec. 9, 1603, and Brooke suffered the same fate a week later. Grey and Markham were reprieved, and Copley, who had made a full confession, was pardoned.

Before the executions took place, however, the failure of the Bye plot had led to the discovery of the Main plot. Brooke's share in the earlier scheme caused suspicion to fall upon his brother Henry

Brooke, Lord Cobham, the ally and brother-in-law of Sir Robert Cecil, afterward earl of Salisbury. Cobham appears to have been in communication with Spain about the possibility of killing "the king and his cubs" and of placing Lady Arabella Stuart on the throne. He was seized, tried and condemned to death; though he was led out to the scaffold he was not executed. It was on suspicion of being associated with Cobham in this matter that Sir Walter Raleigh was arrested and tried.

See the article *by* A. F. Pollard in *Dictionary of National Biography* (1885–1901).

WATSON, SIR WILLIAM (1858–1935), English poet, born on Aug. 2, 1858, at Burley-in-Wharfedale, Yorkshire, was brought up at Liverpool. In 1880 he published his first book, *The Prince's Quest,* but he first made a name in 1890 with the publication of *Wordsworth's Grave.* Besides *Wordsworth's Grave* the volume contained *Ver tenebrosum* (originally published in the *National Review* for June 1885), a series of political sonnets indicating a fervour of political conviction that was later to find still more impassioned expression. There followed: *Lacrymae Musarum* (1892); *The Eloping Angels* (1893); *Odes and Other Poems* (1894); *The Father of the Forest* (1895); *The Purple East* (1896), sonnets on the Armenian question; *For England* (1903); *New Poems* (1909); *A Hundred Poems* (1922); *Poems Brief and New* (1925), and other verse. *Collected Poems* were published in 1898 and 1905. Watson is said to have been considered for the laureateship when Tennyson died. In 1917 he was knighted.

Except in Watson's political verse there is more thought than passion. Bearing trace enough of the romantic epoch, his poetry recalls the earlier classical period in its epigrammatic phrasing and Latinized diction.

See William Archer, *Poets of the Younger Generation* (1902).

WATT, JAMES (1736–1819), Scottish engineer, the inventor of the modern condensing steam engine, was born at Greenock on Jan. 19, 1736. He made his way to London, at the age of 19, to be apprenticed to an instrument maker, but the hard work and frugal living forced him at the end of a year to seek rest at home. However, he had gained a fair knowledge of the trade and became handy in the use of tools, and upon his return to Scotland in 1756 he tried to establish himself as an instrument maker in Glasgow, only to find that the city guilds would not recognize a craftsman who had not served the full term of apprenticeship. The college, however, took him under its protection, and in 1757 he was established in its precincts with the title of mathematical instrument maker to the university.

Joseph Black, the discoverer of latent heat, then lecturer on chemistry, and John Robison, then a student, afterward professor of natural philosophy at Edinburgh, became his intimate friends, and with them he often discussed the possibility of improving the steam engine, the best type of which was at that time the Newcomen engine. It was then applied only to pumping water—chiefly in the drainage of mines; and it was so clumsy and wasteful of fuel that it was little used. Some early experiments by Watt in 1761 or 1762 had no direct result, but in 1764 his attention was seriously aroused by having a model of Newcomen's engine, which formed part of the college collection of scientific apparatus, given him to repair. Having put the model in order, he was at once struck with its enormous consumption of steam. After some unsuccessful efforts to remedy this difficulty Watt began a scientific examination of the properties of steam, studying by experiment the relation of its density and pressure to its temperature, and concluded that two conditions were essential to the economical use of steam in a condensing steam engine. One was that the temperature of the condensed steam should be as low as possible, 100° F. or lower, otherwise the vacuum would not be good; the other was, to quote his own words, "that the cylinder should be always as hot as the steam which entered it."

Early in 1765, the idea struck him that, if the steam were condensed in a vessel distinct from the cylinder, the temperature of condensation could be kept low and that in the cylinder high. Without delay Watt put his idea to the test, and found that the separate condenser acted as he had anticipated. To maintain the vacuum in it he added an air pump to remove the condensed steam and injection water with any air gathered in the condenser.

To further his object of keeping the cylinder as hot as the steam that entered it, Watt supplemented his great invention of the separate condenser by several less notable but still important improvements: a tighter packing over the piston, lubricated by oil; a steam-tight stuffing box for the piston rod, which allowed steam instead of air to press on top of the piston; an insulated casing for the cylinder; and a steam jacket that provided a layer of steam between the cylinder proper and an outer shell.

All these features were specified in Watt's first patent *(see* STEAM: *Steam Engine),* which was obtained in Jan. 1769, nearly four years after the inventions it covered had been made. In the interval Watt had been striving to demonstrate the merits of his engine by trial on a large scale. His earliest experiments left him in debt, and he agreed that John Roebuck, founder of the Carron ironworks, should take two-thirds of the profits of the invention in consideration of his bearing the costs. An engine was then erected at Kinneil, near Linlithgow, and this gave Watt the opportunity of overcoming many difficulties in details of construction. Meanwhile he was gaining reputation as a civil engineer. In 1767 he was employed to make a survey for a Forth and Clyde canal, which failed, however, to secure parliamentary sanction. During the next six years he made surveys for several canals and prepared plans for several harbours, for deepening the Clyde and for building a bridge over it at Hamilton.

In 1768 Watt met Matthew Boulton, who owned the Soho engineering works at Birmingham. Boulton agreed to take Roebuck's share in the invention, and to apply to parliament for an act to prolong the term of the patent. The application was successful, and in 1775 an act was passed continuing the patent for 25 years. By this time Watt had settled in Birmingham, where the manufacture of steam engines was begun by the firm of Boulton & Watt. Boulton left the work of inventing to Watt, in uhose genius he had the fullest faith, while he attended to the business side.

Watt's second steam-engine patent, dated 1781, describes five different methods of converting the reciprocating motion of the piston into motion of rotation, so as to adapt the engine for driving ordinary machinery. A third patent, in 1782, covered the invention of the double-action engine; that is to say, both ends of the cylinder, instead of only one, were alternately put in communication with the boiler and the condenser. This patent also described the system of expansive working, in which the admission valve is closed after only a portion of the stroke is completed, and the steam enclosed in the cylinder is then allowed to expand during the remainder of the stroke, doing additional work upon the piston without making any further demand upon the boiler until the next stroke. Recognizing that this would cause a gradual reduction of the force on the piston, Watt devised a number of contrivances for equalizing the effort throughout the stroke. He found, however, that the inertia of the pump rods in his mine engines, and the flywheel in his rotary engines, served to compensate for the inequality of thrust sufficiently to make these contrivances unnecessary. His fourth patent, taken out in 1784, describes an arrangement of links by which the top of the piston rod is connected to the beam so that it may either pull or push, and is at the same time guided to move in a straight line.

A still later invention was the centrifugal governor, by which the speed of rotary engines was automatically controlled. This is now recognized as one of the earliest applications of feedback, an essential element in automation. Another of Watt's contributions to the development of the steam engine is the indicator, which draws a diagram of the relation of the steam's pressure to its volume as the stroke proceeds. The eminently philosophic notion of an indicator diagram is fundamental in the theory of thermodynamics; the instrument itself is to the steam engineer what the stethoscope is to the physician.

By 1783 all but one of the Newcomen pumping engines in Cornwall had been displaced by Watt's. The mines were then far from thriving; many were even on the point of being abandoned through the difficulty of dealing with large volumes of water; and Watt's invention. by its economy, gave many of them a new lease of life.

His engine used no more than a fourth of the fuel that had formerly been needed to do the same work, and the Soho firm usually claimed as royalty a sum equivalent to one-third of the saving.

Watt's first patent made the steam engine quick in working, powerful and efficient, but still only as a steam pump. His later inventions adapted it to drive machinery of all kinds. Subsequent improvements consisted chiefly in the use of high-pressure steam and in the introduction of compound expansion. Both of these improvements the firm of Boulton & Watt strongly resisted.

On the expiration in 1800 of the act by which the patent of 1769 had been extended, Watt gave up his share in the business to his sons, who carried it on with a son of Boulton for many years. The remainder of Watt's life was quietly spent at Heathfield hall, near Birmingham, where he devoted his time to mechanical pursuits and inventions. He died at Heathfield on Aug. 19, 1819.

WATTEAU, (JEAN) ANTOINE (1684–1721), the great French painter whose *fêtes galantes* ushered in the art of the 18th century, was born at Valenciennes on Oct. 10, 1684. His father, a tiler, apprenticed him to a local painter. Almost penniless, Watteau departed for Paris in 1702, where he worked in a shop in which small devotional pictures and copies of popular Dutch painters were turned out wholesale. In 1704 he entered the studio of Claude Gillot, an accomplished draftsman and a man of lively intelligence with a passionate love for the theatre, especially the Italian comedy, which became an element of Watteau's art. In 1708 Watteau went to Claude Audran, a fashionable decorative painter and keeper of the Luxembourg palace. While with Audran, he attained a mastery of arabesque and *chinoiserie* decoration and was also greatly influenced by the Rubens paintings of "The Life of Marie de' Medici," then in the Luxembourg. He executed sketches from life in the palace gardens, sharpening and elaborating his remarkable fluency of draftsmanship.

ALINARI

"GILLES" BY ANTOINE WATTEAU. IN THE LOUVRE, PARIS

In 1709 he entered for the Academy's Prix de Rome but only obtained the second prize. Disappointed by this failure, Watteau, having sold his first military picture to Pierre Sirois, decided to return to Valenciennes, where he continued his long and successful series of camp pictures. These show both the influence of Rubens' technique and the artist's own vivid observation of life. In 1710 Watteau returned to Paris and in 1712 was made an associate of the Academy on the presentation of "Les Jaloux" (National gallery, Melbourne, Austr.). From this date until 1715 there is no certain information concerning his life. He was already stricken with tuberculosis which perhaps accounts for his restless and difficult moods and his constant change of residence as well as the feverish haste to achieve as much as possible in various styles and techniques. Thanks to Pierre Crozat, one of the great financiers and collectors of his time, Watteau entered the most intelligent and artistic society of the day. In 1715 Crozat had recently returned from Italy bringing with him many drawings from which Watteau gained an immense knowledge of the old masters, especially of the Venetian and Flemish schools. He was also to hear a great deal of music, a most potent influence on his art, and to study landscape both in the gardens surrounding Crozat's house in Paris and at his country property at Montmorency. From this period onward Watteau was constantly busy with commissions. With the help of his sketchbooks, on which he relied for his apparent improvisations, he produced a series of splendid and individual works.

Group pictures of friends, often dressed in the costume of the theatre, nudes, portraits. landscapes and above all *fêtes galantes*, his unique contribution to European art, followed in quick succession, culminating in his diploma picture, "The Embarkation for Cythera" (1717, Louvre, Paris). In this work Watteau realized the perfect fusion between his own dream world and acute observation of nature and the human figure. In 1719 he decided to visit England, where he hoped to obtain further commissions and to consult Richard Mead, a well-known doctor and a keen collector who already possessed "L'Amour Paisible" (Potsdam) and for whom the artist then painted "The Italian Comedians" (National gallery, Washington, D.C.).

In 1720 Watteau returned to Paris for the wedding of his friend Jean de Jullienne, for whom he executed the "Rendez-vous de Chasse" (Wallace collection, London). He stayed with his friend and biographer E. F. Gersaint for six months and in eight mornings painted for him the "Enseigne de Gersaint" (Berlin), a signboard depicting the interior of the dealer's shop. In this picture, so perfectly composed, each stroke is filled with supreme confidence and here. Watteau realized the world of pure beauty which lies behind everyday things. The great portrait of "Gilles" (Louvre) is perhaps Watteau's last painting before, harassed by restlessness and ill-health, he moved to Nogent-sur-Marne. He sent for his former pupil J. B. J. Pater, with whom he worked on some unfinished pictures until his death in Gersaint's arms on July 18, 1721.

Watteau was a painter endowed with remarkable technical facility and unique in the combination of poetic sensibility and the passionate observation of reality. He swept away the last vestiges of the official art of the age of Louis XIV, uniting in his works not only the germ of all 18th-century art but foreshadowing many of the discoveries of later schools, especially the Impressionists. Largely as a result of the influence of the *Recueil Jullienne,* four volumes of Watteau's drawings and paintings engraved by the best artists of his time and published by Jullienne in 1735, Watteau's art remained popular all over Europe until swept away, for a time, by the revolutionary doctrines of J. L. David. The Louvre owns nine paintings of supreme quality and over 30 drawings, and Watteau is splendidly represented in the Wallace collection, which contains nine of his finest paintings, and at the British museum by a remarkable collection of drawings. In Germany some of Watteau's best works, originally purchased by Frederick the Great from Jullienne, can be seen in Berlin and at Potsdam, and there are also two fine *fêtes galantes* at Dresden. The Hermitage museum, Leningrad, contains five paintings including two of the best military pictures. In the United States, Watteau is well represented in Washington, D.C., New York city, Boston and Cleveland. *See* also PAINTING: *France: 17th and 18th Centuries;* CRAYON DRAWING.

WATTERSON, HENRY (1840–1921), U.S. journalist, and newspaper editor, one of the great figures in a bygone era of personal journalism, was born in Washington, D.C., where his father was serving as a member of congress from Tennessee, on Feb. 16, 1840. As a youth he had literary ambitions, and after attending an academy in Philadelphia turned to journalism, becoming for a brief time editor of the *Nashville* (Tenn.) *Republican Banner* in 1861. During the Civil War he was attached to the staffs of the Confederate generals Nathan B. Forrest, Leonidas Polk and John B. Hood; was chief of scouts in the Johnston-Sherman campaign and edited the *Rebel* in Chattanooga. After further newspaper work and the first of many trips abroad, he became editor of the *Daily Journal* at Louisville, Ky. In 1868, with Walter N. Haldeman, he founded and became editor of the *Louisville Courier-Journal*, a consolidation of the *Courier*, the *Democrat* and the *Journal*. Haldeman and Watterson adopted a policy of business integrity and interest in the public service which soon made the *Courier-Journal* one of the most influential of southern newspapers. It had its unpopular days, however, in such times as the Reconstruction period, when it stood for conciliation between the two sections, and during the free silver and greenback agitations when it advocated a sound currency. Watterson was largely responsible for the Democratic nomination of Gov. Samuel J. Tilden of New York for the presidency in 1876. He was Democratic representative in congress for a short term (1876–77), where he served as Tilden's floor leader during the Tilden-Hayes electoral contest. In Aug. 1918 he sold his interest in the paper and became "editor emeritus." In April 1919 he resigned from the paper because of its support of the League of Nations. He died at Jacksonville, Fla., on Dec. 22, 1921. He wrote *History of the Spanish American War* (1898), *The Compromises of Life and Other Lectures and Addresses* (1903), and *"Marse Henry"; an Autobiography* in two volumes (1919). *Editorials of Henry Watterson* was compiled by Arthur Krock in 1923.

See Isaac F. Marcosson, *"Marse Henry"* (1951); Joseph Frazier Wall, *Henry Watterson: Reconstructed Rebel* (1956).

WATTLE AND DAUB (DAB), a term in architecture applied to a wall made with upright stakes with withes twisted between them and then plastered over. It is probably one of the oldest systems of construction. The Egyptians employed the stems of maize for the upright stakes; these were secured together with withes and covered over with mud, the upper portions of the maize stems being left uncut at the top, to increase the height. These uncut tops were bent out by the weight of the mud roof, and were probably the origin of the later cavetto cornice, the torus molding below representing the heavier coil of withes at the top of the wall (*see* MOLDING). Vitruvius refers to wattle and daub; in the middle ages it was employed as a framework for clay chimneys, and for the filling in of half-timber work.

WATTMETER, an instrument for the measurement of electric power or the rate of supply of electric energy to any circuit. Wattmeters are of three types: electrostatic, used only in standardizing laboratories; dynamometer instruments based on the principle of the Siemens electrodynamometer; and induction instruments. *See* INSTRUMENTS, ELECTRICAL MEASURING.

WATTS, GEORGE FREDERIC (1817–1904), English painter and sculptor of grandiose allegorical themes, was born in London on Feb. 23, 1817, the son of an unsuccessful piano manufacturer. From the age of ten he frequented the studio of William Behnes, the sculptor, who introduced him to the Elgin marbles. Although on the roll of the Royal Academy schools from 1835 to 1837, his attendance was irregular. Among his first three Academy exhibits were "The Wounded Heron" and "Miss Hopkins" (1837, both Watts gallery, Compton, Surrey), which display a precocious technical mastery based chiefly on William Etty and Sir Thomas Lawrence. In the Houses of Parliament competition of 1843, Watts won a first prize of 1300 for his cartoon "Caractacus," and that year left for Florence as the guest of Lord and Lady Holland, accompanying them on visits to Rome and Naples. This cultivated existence was a liberating experience deeply to affect the artist, but here also began that hothouse tending of Watts as a tame genius which was continued by Mr. and Mrs. Henry T. Prinsep at Little Holland house from 1851 to 1875. While abroad he painted "Story From Boccaccio" (Tate gallery, London), which shows his aptitude for vast mural designs. Entering his "Alfred Inciting the Saxons" ior the 1847 Houses of Parliament competition, he again won a first prize, of 1500.

In 1852 Watts unsuccessiully offered to decorate the great hall of Euston station for the cost of the materials alone, but the following year be began the fresco "Justice" in the new hall of Lincoln's Inn, completed in 1859. A much grander scheme depicting a symbolic history oi mankind, sketched out in 1848 as "The House of Life," never matured, but its subject matter, conceived in terms of vague abstract ideals, is characteristic of Watts's imprecise philosophical outlook. An agnostic, fatalistic and pessimistic, he yet believed that art should preach a universal message independent of current dogmas. Appalled by the materialism of his age, he nevertheless accepted its benefits while shunning to identify himself with its victims. Soon after his return to England in 1847, he painted a bitter comment on society in "Life's Illusions," and again in "Mammon" (1884–85, both Tate gallery).

Apart from a disastrous, short-lived marriage with the 16-year-old Ellen Terry, Watts's domestic life remained uneventful; he married Mary Fraser-Tytler in 1886. He was elected royal academician in 1867, and had begun experimenting with monumental sculpture. A small, Michaelangelesque marble "Clptie" (bronze version, Tate gallery) was in the 1868 Academy, and in 1870 he began the large equestrian statues "Hugh Lupus" (finished 1883, Eaton hall, Cheshire) and "Physical Energy" (finished 1904; second, revised cast Kensington gardens, London). The discipline of this medium influenced Watts's later paintings, which became more solidly and simply constructed; *e.g.*, "For He Had Great Possessions" (1894, Tate gallery). His technique broadened and was nearer to that of Tintoretto than Titian. The most iamous of his later works, "Hope" (1886, version in Tate gallery), is ambiguous and perhaps ironical in meaning. In addition to some excellent landscapes, Watts completed many shrewdly observed portraits of his famous contemporaries, notably that of Cardinal Manning (1882, National Portrait gallery).

Watts presented over 50 works to the Tate gallery; and there is a permanent collection at Compton, Surrey, his home from 1891 until his death on July 1, 1904. Having twice refused a baronetcy, he accepted an Order of Merit in 1902.

(D. L. FR.)

WATTS, ISAAC (1674–1748), English theologian and hymn writer, son of a clothier, was born at Southampton on July 17, 1674. The father, who afterward had a boarding school at Southampton, also wrote poetry, and a number of his pieces were included by mistake in vol. i of the son's *Posthumous Works*. Isaac Watts studied at the Nonconformist academy, Stoke Newington, London. On leaving the academy he spent over two years at home, and began to write his hymns. In the autumn of 1696 be became tutor in the family of Sir John Hartopp at Stoke Newington, where he probably prepared the materials of his two educational works—*Logick, or the Right Use of Reason in the Enquiry After Truth* (1725), and *The Knowledge of the Heavens and the Earth Made Easy, or the First Principles of Geography and Astronomy Explained* (1726). In his 24th year Watts became assistant pastor of the Independent congregation in Mark Lane, London, and two years later, pastor. In 1712 he went to live with Sir Thomas Abney of Abney Park.

Watts preached only occasionally, devoting his leisure chiefly to the writing of hymns (*see* HYMNS), the preparation of his sermons for publication, and the composition of theological work. In 1706 appeared his *Horae Lyricae*, of which an edition with memoir by Robert Southey forms vol. ix of *Sacred Classics* (1834); in 1707 a volume of *Hymns;* in 1719 *The Psalms of David;* and in 1720 *Divine and Moral Songs for Children.* His Psalms are free paraphrases, rather than metrical versions, and some of them ("O God, our help in ages past," for instance) are among the most famous hymns in the language. Isaac Watts died on Nov. 25, 1748, and was buried at Bunhill Fields.

Among the theological treatises of Watts, which are far from conventional orthodoxy, are: *Doctrine of the Trinity* (1722); *Essay on the Freedom of the Will* (1732); and *Useful and Important Questions Concerning Jesus, the Son of God* (1746). He was also the author of a variety of miscellaneous treatises. His *Posthumous Works* appeared in 1773, and a further installment of them in 1779. *The Works of . . . Isaac Watts* (6 vol.), ed. by Jennings and Doddridge, with a memoir compiled by G. Burder, appeared in 1810–11. His poetical works were included in Johnson's *English Poets*, where they were accompanied by a *Life*, and they appear in subsequent similar collections.

WATTS-DUNTON, WALTER THEODORE (1832–1914), English man of letters, was born at St. Ives, Huntingdon, on Oct. 12, 1832. His article on "Poetry" in the ninth edition of the *Encyclopædia Britannica* was the principal expression of his views on the subject. Watts-Dunton was in later years Rossetti's intimate friend. He was the friend of Swinburne (*q.v.*), who shared his home for nearly 30 years before he died in 1909. In 1897 he published a volume of poems under his own name, *The Coming of Love.* His prose romance *Aylwin* (1898) attained immediate success, and ran through many editions in the course of a few months. Both *The Coming of Love* and *Aylwin* set forth, the one in poetry, the other in prose, the romantic and passionate associations of Romany life, and maintain the traditions of Borrow, whom Watts-Dunton had known well in his own early days. He edited George Borrow's *Lavengro* (1893) and *The Romany Rye* (1900); his *Studies of Shakespeare* appeared in 1910; in 1903 he published *The Renascence of Wonder*, a treatise on the romantic movement, as a preface to the third volume of Chambers' *Encyclopaedia of English Literature*, and in 1916 this, with his *Encyclopædia Britannica* article—both enlarged—was republished in book form as *Poetry and the Renascence of Wonder.* He died at Putney on June 6, 1914.

WAUGH, BENJAMIN (1839–1908), English social reformer and one of the founders of the London Society for Prevention of Cruelty to Children (S.P.C.C.), was born at Settle, Yorkshire, on Feb 20, 1839. After spending several years in business he entered the Congregational ministry in 1865. Settling at Greenwich he devoted himself especially to children and served on the London school board from 1870 to 1877. As a result of his information a clause, giving magistrates power to take the evidence of children too young to understand the nature of an oath, was included in the Criminal Law Amendment act of 1885. The same year Waugh gave up pastoral work. He died at Westcliff, Essex, on March 11, 1908.

In 1884 Waugh was one of those responsible for founding the S P C.C., which was established nationally in 1889 and granted a charter of incorporation in 1895. In 1889 he saw his society justified by the act for the prevention of cruelty to children, the first steppingstone to the act of 1908. (See CHILDREN, LAWS CONCERNING) The society's financial administration was attacked in 1897; an inquiry was demanded by Waugh and the commission, which included Lord Herschell, vindicated both Waugh and the society. Waugh was an honorary director from 1889 to 1895, when he became a paid director until 1905 and consulting director from 1905 until his death. Waugh edited the *Sunday Magazine* from 1874 to 1896 His *The Gaol Cradle: Who Rocks It?* (1873) was a plea for the abolition of juvenile imprisonment.

See R Waugh, *Life of Benjamin Waugh* (1913).

WAUKEGAN, a city of northeastern Illinois, U.S., the seat of Lake county. stands on a high bluff above Lake Michigan about 40 mi. N of Chicago. The alternation of highland and ravine creates a pleasant contrast. It was designated on 18th-century maps as Little Fort. The first American white settler arrived in 1835, and the name was changed to Waukegan, the Potawatomi equivalent of Little Fort, in 1849 at the time of incorporation. It was chartered as a city in 1859. As a part of the Chicago-Milwaukee industrial complex, it manufactures a wide variety of products, including wire, chemical and pharmaceutical preparations, asbestos roofing, outboard motors and steel castings. To the south is the Great Lakes naval training station, and a little farther removed, Ft. Sheridan Both help colour the life of the city and use it as a residence area. Transportation is provided by a harbour (with coal docks) on Lake Michigan, a number of major highways and railways. Pop. (1960) 55,719. For comparative population figures ***see*** table in ILLINOIS: *Population.* (E. G. HI.)

WAUKESHA, a city of Wisconsin, U.S., 16 mi. W. of Milwaukee on the Fox river; the seat of Waukesha county. First settled in 1834, it was incorporated as a village in 1852 and as a city in 1896; its name was derived from the Potawatomi Wauktsha meaning "fox." From about 1870 to 1905 it was a popular summer resort. Lying in a region of intensive dairy farming, it is a centre for the sale of superior dairy cattle. Its industries are mainly metal working, led by the manufacture of motors, jacks and castings. and also include wood products, food and beverage processing and mineral spring water bottling. Carroll college, a Presbyterian coeducational institution, was incorporated in 1846. The city has a symphony orchestra. For comparative population figures ***see*** table in WISCONSIN: *Population.* (W. *S* GR.)

WAUSAU, a city in north-central Wisconsin, U.S., seat of Marathon county, is on the Wisconsin river about 140 mi. N. of Madison. Huge forests of white pine and the water power of Big Bull falls brought settlers in the late 1830s. A settlement was established and named Wausau (an Indian word meaning "far away place") in 1850. Early population was predominantly German. Dubbed the "Lumberjack City," it was incorporated in 1872.

The chief manufactures include wood and wood products such as food package containers, fibreboards, paper, veneers and doors. Wausau is also an important agricultural and distribution centre. It is the home office of one of the country's largest writers of workmen's compensation insurance, and the headquarters of the Wisconsin Valley Improvement company, a privately owned but state-regulated enterprise which stores the water of the Wisconsin river in reservoirs and releases it on a toll basis to operating plants.

Its river situation, nearness to the upper lake country and towering Rib mountain on the city's border make Wausau a favoured area for fishing, hunting, and summer and winter sports. For comparative population figures ***see*** table in WISCONSIN: *Population* (AL. E. SM)

WAUTERS, ÉMILE CHARLES MARIE (1846–1933), Belgian painter, mainly of historical subjects, was born in Brussels on Nov. 29, 1846. He studied under Portaels and Gérôme and in 1868 produced a striking work, "The Battle of Hastings: the Finding of the Body of Harold by Edith." As his youth disqualified him for the medal of the Brussels Salon, he was sent, by way of compensation, as artist-delegate to Suez for the opening of the canal (1869). In 1870 Wauters exhibited his picture of "Mary of Burgundy Entreating the Sheriffs of Ghent to Pardon Her Councilors Hugonet and Humbercourt" (Liège museum), which created a great sensation. Even more celebrated was the "Madness of Hugo van der Goes" (1872, Brussels museum), a picture that gained for Wauters the grand medal at the Salon and led to the commission for two large works decorating the Lions' staircase of the Hôtel de Ville. His 380-by-49 ft. panorama, "Cairo and the Banks of the Nile" (1881), was exhibited with extraordinary success in Brussels, Munich and The Hague. Wauters also painted some portraits, sometimes using pastel as a medium. He died in Paris on Dec. 11, 1933.

WAUWATOSA, a city of Wisconsin, U.S., in Milwaukee county and a suburb of Milwaukee, which borders it on three sides, is on the Menomonee river. The Potawatomi Indians relinquished their title to the region in 1833, and New England and New York settlers began arriving in 1835, followed by German and Irish immigrants. First known as Hart's Mill, Wauwatosa became a village in 1892 and a city in 1897. The name Wauwatosa is a modification of an Indian word meaning "firefly."

With the extension of street railways in the mid-1880s, workers in Milwaukee and West Allis began establishing their homes in Wauwatosa; other civic developments, such as the adoption of a zone ordinance in 1921, increased this trend. Between 1930 and 1960 the population increased by 168.6% to 56,923. Industry is limited, and includes the manufacture of iron castings, interior woodwork, steel scaffolding, chemicals, cement blocks, screws and bolts. For comparative population figures ***see*** table in WISCONSIN: *Population.* (AL. E. SM.)

WAVE LENGTH, in radio, the distance traveled in one period or cycle by a periodic disturbance. The distance between corresponding phases of two consecutive waves of a wave train. The quotient of velocity by frequency. For a discussion of theory ***see*** ELECTROMAGNETIC WAVES; for wave lengths in broadcasting and wireless ***see*** RADIO.

WAVELL, ARCHIBALD PERCIVAL WAVELL, 1ST EARL (1883–1950), British army officer, a leading figure of World War II who defeated the Italians in east Africa and liberated Ethiopia, was born at Colchester on May 5, 1883. He was educated at Winchester and joined his father's regiment, the Black Watch. After war service in South Africa, India, Flanders and Palestine, he was recognized as an exceptional trainer of troops and in July 1939 was appointed to the new middle east command, in which he reached (as a full general) the high-water mark of his military career by routing in Dec. 1940–Feb. 1941 greatly superior Italian armies in Libya and liquidating the Italian empire in east Africa (Jan–May 1941). But in July 1941 after unsuccessful fighting against the Germans in Greece, Crete and Libya he was superseded and appointed to command in India. When Japan entered the war, as Allied commander in the southwest Pacific and against great odds Wavell could not prevent the loss of Malaya and Burma. As a field marshal and viceroy of India (June 1943–Feb. 1947) he had to cope first with famine and then with intractable political controversies. He died in London on May 24, 1950.

Wavell was famous for his knowledge of languages, phenomenal memory and literary gift, as shown in his life of his former chief, *Allenby* (1940–43), and his love of poetry; also for his taciturnity, which handicapped him in discussion. His sterling character, in which his uncomplaining loyalty was conspicuous, won him general respect and confidence. Wavell's only son was killed in Kenya on Dec. 24, 1953, in an attack on Mau-Mau terrorists.

Wavell's writings included *The Palestine Campaigns* (1928); *Other Men's Flowers,* an anthology (1944); *The Good Soldier* (1948); *Soldiers and Soldiering* (1953). (J. R. M. B.)

WAVELLITE, a mineral consisting of hydrated aluminum phosphate. Distinct crystals are of rare occurrence, the mineral usually taking the form of hemispherical or globular aggregates with an internal radiated structure. It is translucent and varies in colour from gray or white to greenish, yellowish, etc. The formula is $Al_3(OH)_3(PO_4)_2 + 4\frac{1}{2}H_2O$ and it crystallizes in the orthorhombic system. The hardness is 3.5, and specific gravity 2.32. It was first found, at the end of the 18th century, by W.

Wavell near Barnstaple, Devon, where it lines crevices in a black slaty rock. In the United States it has been found in Pennsylvania and near Hot Springs, Ark.

WAVE MECHANICS, a particular form of quantum mechanics which was developed as the result of researches by Louis de Broglie and Erwin Schrodinger in 1925–26. As loosely used, the term wave mechanics is practically synonymous with quantum mechanics.

See the article on **QUANTUM MECHANICS,** especially the section entitled Wave Mechanics. (J. H. V. V.)

WAVE MOTION. The study of wave motion is concerned with the propagation of disturbances in physical systems. The system may be a body of fluid, a structure or even a procession of automobiles; the disturbance may be characterized by changes in velocity of the fluid particles, distortion of the structural material, changes in automobile speed or variations in any physical quantities which contribute to the time-dependent description of the system.

As an aid to discussion, the subject is frequently subdivided into categories according to the intensity of the disturbance, its periodicity or lack thereof, the manner of its initiation and, as in the following, the type of medium in which the waves are propagating.

Waves in a Liquid.—Perhaps the most frequently observed waves are those which propagate on the surface of a body of liquid. The study of a particular example of such waves provides some insight into the manner in which the fundamental laws of physics can be invoked to provide a quantitative account of wave motion phenomena. A channel of unit width with vertical plane walls contains a layer of fluid whose initial depth distribution is defined by the solid line of fig. 1. Consider the circumstances under which

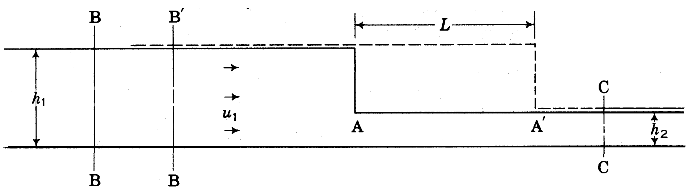

FIG. 1.— SEQUENTIAL POSITIONS OF SURFACE OF LIQUID DURING BORE PROPAGATION

the successive configurations of fig. 1 can occur. The velocity of the fluid to the left of A at time t_1 (and to the left of A' at a later time t_2) is denoted by u_1, and its depth is denoted by h_1. The depth of the motionless fluid into which the wave is advancing is called h_2. The two physical laws which must be invoked are those which state that: (1) no fluid materializes or disappears during the process; and (2) the rate at which the momentum of any element of the fluid increases must be equal to the net force externally applied to that element. If the element of fluid to which these laws are to be applied is one initially lying under the solid line of fig. 1 between B-B and C-C, it will, after a time interval t, lie under the dotted line between B'-B' and C-C; the distance from B-B to B′-B′ will be u_1t. Since the deeper fluid is moving to the right at speed u_1, the first law stated above requires that the distance L over which the formerly quiescent fluid has been accelerated during this time interval be given by

$$(hi - h_2)\ L = hi\ u_1t$$

In order to apply the second law, it should be noted that the average fluid pressure (taking atmospheric pressure as a reference) in the fluid of depth h_1 is $\rho gh_1/2$, and that the average pressure over C-C is $\rho gh_2/2$. Here, g is the acceleration of gravity and p is the density (mass per unit volume) of the fluid. The net horizontal force exerted on the fluid element under consideration during this time interval is, then, composed of two parts: (1) a force of magnitude $\rho gh_1^2/2$ exerted by the fluid on the left of the element; and (2) one of magnitude $\rho gh_2^2/2$ exerted by the fluid on the right of C-C. The net force is directed to the right and has magnitude $\rho g(h_1^2 - h_Z^2)/2$; thus, the second law states that

$$\rho g(h_1^2 - h_2^2)/2 = (\rho h_2L/t)u_1$$

where ρh_2L is the mass of fluid which has been accelerated from rest to speed u_1 during the time t, and $(\rho h_2L/t)u_1$ is therefore the rate at which momentum has been acquired by the fluid element during that time interval. These two quantitative statements now imply that

$$u_1^2 = g(h_1 - h_2)^2\ (hi + h_2)/2h_1h_2$$

and

$$L/t = \sqrt{g(h_1 + h_2)\ h_1/2h_2}$$

L/t is the speed at which the front of the deeper layer encroaches on the shallow layer; *i.e.*, the wave speed. Here, as in almost all wave phenomena, the wave speed differs from, and is greater than, the material particle speed. It must be noted that dissipative effects, variations of velocity with depth, and the difficulties associated with the determination of the detailed shape of the front have been ignored. Despite these simplifications this quantitative picture of the encroachment of a deep layer of liquid into a more shallow layer is an excellent macroscopic description of the tidal bores which occur in many of the rivers of the world. In the application of these results to such cases, speeds must be measured relative to an observer moving with the undisturbed speed of the river in which the bore is to be propagated.

The foregoing phenomenon can be observed on a small scale by allowing water to flow from a faucet into a basin. The speed can be adjusted so that two zones surround the point at which the water meets the basin; the inner zone consists of a thin flat layer of water moving rapidly outward, and the outer zone is a thicker more slowly moving layer. The size of these zones can be controlled by adjusting the faucet.

In order to relate this observation to fig. 1, the reader should imagine that he views that figure as he moves to the right at a speed equal to L/t as calculated above; *i.e.*, he moves at the speed of the bore. From this reference system the bore is stationary, the thin layer on the right is moving to the left at speed L/t and the thick layer is moving to the left at speed L/t-u_1. The leftward motion so described agrees precisely with the radial motion of the observation.

Considerations similar to the foregoing can be used to indicate the manner in which a gentler disturbance is propagated. Ordinarily, a wave whose height is very small compared with the ambient fluid depth, h, and whose extent in the direction of propagation is large compared with h, will propagate in an otherwise

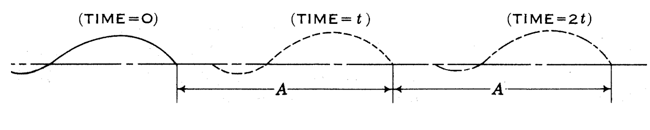

FIG. 2.— SURFACE POSITION AT TIMES O, t AND $2t$, OF A NONDISPERSIVE WAVE TRAVELING AT SPEED A/t. A DENOTES THE DISTANCE TRAVERSED IN TIME t BY THE WAVE

quiescent fluid at speed $\sqrt{gh}$ (this is consistent with the foregoing formula for L/t). This propagation speed is independent of the details of the wave shape, and the wave must propagate without change of shape (fig. 2). However, if the wave height is an appreciable fraction of the depth, so that the wave speed is significantly greater at positions of greater depth than it is at shallow spots, the propagation must occur in the manner illustrated in fig. 3. The argument presented here to account for this is by no means complete, but it does indicate the considerations which help make possible a correct prediction of the steepening of such waves and formation of bores discussed earlier. In particular, by the time configuration C of fig. 3 is reached, a bore starts to form; configuration corresponding to later times can be deduced only from a more precise theory.

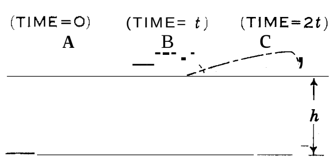

FIG. 3.— SEQUENTIAL POSITIONS OF INTENSE WAVE MOVING TO RIGHT (see TEXT)

The propagation of surface

waves in deep water provides a different picture. If the extent of the surface distorted by the wave is small compared with the water depth, only the fluid near the top moves, and the depth plays no role as it did in the foregoing. There is, in fact, no single propagation speed for low intensity waves appropriate to all wave shapes as there is in shallow water, and, with isolated exceptions, waves cannot travel without change of shape. The wave motion in systems such as this is said to be dispersive.

A study of the disturbance left behind by a motorboat first in shallow water and then in deep water affords some insight into the implications of this contrast. In shallow water of depth h, the motorboat proceeds from position O to A to B to C (in fig. 4) at a constant speed, V, which here is greater than $\sqrt{gh}$. The times of arrival of the boat at these points are 0, t_1, t_2, t_3, respectively. When the boat arrives at point O, it initiates a disturbance there which propagates outward from O at speed $\sqrt{gh}$; therefore, by the time the boat arrives at C (whose distance from O is Vt_3), this disturbance which has spread out at speed $\sqrt{gh}$ is confined within a circle of radius $t_3\sqrt{gh}$. Similarly, the wave initiated at B at time t_2 has, at time t_3, spread into a circular region of radius $\sqrt{gh}(t_3 - t_2)$. The outline or envelope of the region into which all such disturbances have spread is the wedge shown in fig. 4; in particular, the angle θ shown there is such that sin

$$\theta = \sqrt{gh}/V$$

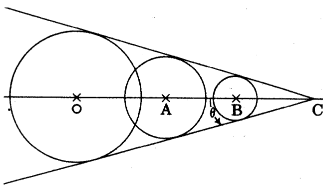

FIG. 4.—DISTURBANCE CREATED BY MOVING BOAT. POINTS O, A, B, C REPRESENT LOCATIONS OF BOAT AT SUCCESSIVE TIMES O, t_1, t_2, t_3; θ IS ANGULAR CO-ORDINATE OF ANY POINT IN FLOW FIELD (see TEXT)

Thus, the geometry of the disturbed region depends on the speed of the boat.

In deep water, on the other hand, no such elementary construction can be carried out. It happens, however, that the geometry of the wave generated by the boat depends on the boat's speed in such a way that the most rapidly propagating significant contributions to the wave pattern propagate at a speed proportional to the speed of the boat. The proportionality constant is always the same and is such that $\theta = 19°28'$. In the foregoing arguments the words shallow and deep have been (and must be) used in a relative sense. In a wave motion discussion, water is shallow whenever the distances (other than wave height) characterizing the wave geometry are large compared with the depth. When these distances are small compared with the depth, the water is said to be deep. The discussion of the intermediate case requires subtler tools and will not be discussed here.

An example of wave motion in which the surface tension of the liquid plays an important role can be observed when a stream of water about one-tenth of an inch in diameter flows from a faucet into the basin below. This stream of fluid would ideally be a slowly tapering column whose shape did not change with time, but when the stream diameter is small such a configuration is almost never observed. Even if the steady column could be temporarily established, the minute disturbances which are always present in the room would initiate a distortion of the column, and the wave so initiated would grow in magnitude until, at some position, the column would break up into droplets. The dynamics of this phenomenon are dominated by the effects of surface tension and fluid particle accelerations, and the reason that this droplet formation in the faucet experiment can be observed only for small streams is the following: The surface tension, T, has units m/t^2 (m = mass; t = time); the density p has units m/l^3 (l = length); and the stream diameter, d, has dimension l. If it is agreed that no other physical parameters play a role in the wave amplification, then the only combination of pertinent physical quantities having the physical dimension time is $\sqrt{\rho d^3/T}$.

Since relationships between physical quantities can be meaningful only when the physical dimensions involved are self-consistent (*e.g.*, the force required to lift an object must be equal to something having the physical dimension force), the droplet formation time, τ, must be equal to something having the dimension time. Since no other time-dimensional quantity is available, τ must be proportional to $\sqrt{\rho d^3/T}$. This implies that the breakup time, τ, increases rapidly with increase in stream diameter; however, τ must be a shorter time than that required for each particle of fluid to reach the bottom (roughly $\sqrt{2L/g}$, where L is the distance from faucet to sink, and g is the acceleration of gravity), and this will be the case only when d is small enough. Systems such as this, in which the initial wave motion becomes more intense with time without the aid of external excitation, are said to be unstable in the presence of such waves. The gross character of the ocean currents, the atmospheric circulation, the flow past airplane wings and the flight of a baseball would each be very different indeed were it not that their flow configurations are drastically modified as a consequence of such instabilities.

The foregoing experiment can be extended if a person will place a finger in the stream at such a position that the column assumes a stationary but wavy shape above this obstruction. When this condition is achieved the wave which is present is one which travels upward relative to the fluid at precisely the speed, V, with which the fluid in this wavy region is falling. The resulting picture is one in which the wave is stationary relative to the observer, and the ratio of the wave length, λ (distance from crest to crest), to the diameter can readily be estimated. Arguments much like those by which the droplet-forming time was estimated will indicate that this ratio should depend on the quantity $\rho dV^2/T$. A careful analysis shows that

$$\lambda = \pi d \div (1 + \rho V^2 d/T)^{1/2}$$

A sequence of such experiments with various stream speeds and diameters will confirm this result.

Shock Waves in a Gas.—The science of acoustics is concerned with the propagation of sound waves, particularly in air. Sound waves are usually defined to include only those waves whose intensity is so small that the changes in pressure and temperature which characterize them are a very small fraction of the ambient pressure and temperature. These waves travel at sound speed, a speed which depends only on the ambient state of the air. Situations are frequently encountered, however, in which larger disturbances are generated, and some of the most fascinating of these are concerned with the formation and propagation of shock waves. Whenever an object moves through a gas at a speed greater than sound speed, a shock wave will be present. As indicated in fig. 5, this shock wave is an exceedingly thin region separating undisturbed gas from gas that has already been set into motion. The flow between the dotted lines near the point A in fig. 5 is closely analogous to that discussed in conjunction with fig. 1. In fact, fig. 1 is precisely applicable when h_1 and h_2 are interpreted as gas density rather than as liquid depth. Actually, as the shock propagates into the gas, it is the density, temperature, pressure and velocity of the gas that change abruptly. In order to deal quantitatively with this wave phenomenon, one must invoke not only the mass and momentum conservation laws used above but also the law requiring the conservation of energy and a knowledge of the thermodynamic properties of the gas. The use of these laws leads to the quantitative description which follows.

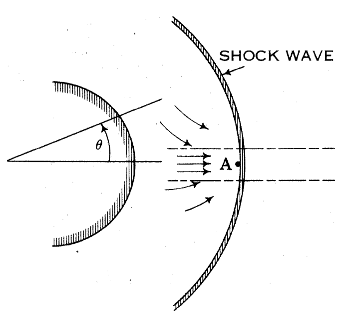

FIG. 5—SHOCK WAVE GEOMETRY
Speed of object A in supersonic flight (to the right), which is equal to speed at which shock wave advances, is somewhat greater than speed of air particles. Horizontal scale is greatly exaggerated. Arrows indicate roughly air velocity distribution; θ is angular co-ordinate of any point in flow field

When an object is flying at speeds comparable to those of meteorites or artificial satellites entering the Earth's atmosphere (say 25,000 ft. per second), the characterizing features of the shock wave are these: In the gas through which the point A on the wave has just passed, the pressure is about $.9\rho_1 U^2$, the gas velocity is about $.9U$, the density is about $10\rho_1$ and the temperature is several thousands of degrees Kelvin. Here ρ_1 is the ambient density of the air and U is the wave speed (the speed at which the shock wave encroaches upon the still gas). The gas will be compressed to a lesser extent behind the oblique part of the wave; the pressure distribution, in fact, will be well approximated by $.9\rho_1 U^2 \cos^2\theta$. It should be noted that this isolated information concerning strong shock waves for which the pressure rise is large compared with the ambient pressure is all that is needed to estimate the early motions of objects of known size and velocity entering the atmosphere.

Strong shock waves also occur when explosive charges are detonated in gas, liquid or solid. The details are very involved, largely because the relevant properties of the materials entail complicated descriptions. Once again, however, a somewhat idealized study provides a clear picture of the dominant features of the wave motion. Imagine that all of the energy, E, of the explosion has been released instantaneously at a single point in space at time 0 and that at time t the shock wave has traveled a distance R and is advancing with speed U through the gas. The only relevant quantities that enter the problem are the energy E (units ml^2/t^2) and the ambient density p (units m/l^3). Information is wanted on the history of the distance R (unit l), the pressure p (units m/lt^2), the speed U (units l/t) and the time t. The only physically meaningful relations among these must have consistent units, and the only such relations would state that R is proportional to $(Et^2/\rho)^{1/5}$, that U is proportional to $(E/\rho t^3)^{1/5}$ and that the pressure just behind the shock wave is proportional to $(E^2\rho^3/t^o)^{1/5}$. Thus, the wave starts out at very high speed but quickly slows down, and the pressure in the gas just behind the shock decreases even more quickly as the wave expands. A more detailed analysis has shown that, for explosions in air, the distance traveled by the shock in time t is $R = .97(Et^2/\rho)^{1/5}$, and that the pressure just behind the shock is $p_2 = .17(\rho^3E^2/t^6)^{1/5}$, the values of R and p_2 being centimetres and dynes/cm.^{2}, respectively. These figures are accurate only until p_2 is about three times the ambient pressure.

See also SOUND.

Traffic Waves.—When a reasonably uniform stream of traffic is traversing a long road, the flow pattern is described by a specification of the density, p (number of cars per car length of road), and the automobile speed, q. Disturbances in such a pattern are frequently introduced by traffic lights. debris, accidents, etc. The wave (characterized by change in density and velocity) which propagates through the traffic stream can be readily estimated by invoking two laws similar in character to those used earlier in this article. The first law requires that no cars materialize or disappear; the second, based on empirical observation,.postulates a specific relation between speed and density. Such observations have been made, and this relation, with sufficient accuracy for our purposes, is

$$q = q_0\,(1 - \rho)$$

'The speed q_0 may be regarded as the maximum safe speed for the road; thus, the possible speeds range from 0 when the cars are bumper to bumper to q_0 when the cars are very far apart. The first law requires that the number of cars emerging from a given segment of road per unit time subtracted from the number entering the segment per unit time should equal the time rate of density increase in the segment times the length of the segment. Those familiar with the differential calculus will recognize the mathematical statement of this equality to be

$$\partial(\rho q)/\partial x + \partial\rho/\partial t = 0$$

They will also be able to verify that these laws are satisfied by any density distribution p which changes with x (the distance along the road) and t (the time) according to the rule (the more general equality is not needed in what follows)

$$x = q_0(1 - 2\rho)\,t$$

The implications of this particular density variation can most readily be seen by plotting the positions of constant density on a picture in which the horizontal co-ordinate is distance along the road, and the vertical co-ordinate represents the time of observation (fig. 6A). This figure corresponds to a situation in which a long string of cars has stopped behind a traffic light at $x = 0$. There, at the time $t = 0$, when the light changes to "go," the density to the left of x = 0 is unity and that to the right is 0. According to the foregoing equation, the density is constant on each radial line through the origin. Thus, at the later time t, the velocity distribution is that shown plotted in fig. 6B.

When an obstruction appears in a stream of traffic in such a way that the cars must change speed abruptly a shock wave can form. To apply the first law to the flow across such a shock wave, it must be written in the form

$$\rho_1(q_1 - U) = \rho_2(q_2 - U)$$

where ρ_1 and q_1 are the values of p and q just to the left of the shock. and ρ_2 and q_2 are those just to the right of the shock; U is the speed at which the shock wave advances into the fluid, and the equality implies that the number of cars which enter the shock per unit time is equal to the number which leave per unit time.

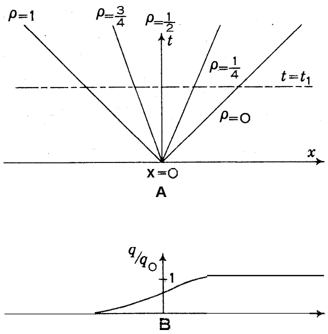

FIG. 6.—(A) LINES OF CONSTANT DENSITY WHICH FORM WHEN LINE OF TRAFFIC IS RELEASED SUDDENLY. (B) TRAFFIC SPEED (PLOTTED AS FRACTION q/q_0) V. DISTANCE x (see TEXT)

Consider now the situation in which, until time 0, the flow of traffic is essentially uniform at speed $q_1 = (\frac{3}{4})q_0$ and density p, $= \frac{1}{4}$. At time 0, an obstruction suddenly appears at x = 0, so that each car must pass it at speed $q_2 = q_0/8$ (and, according to the first equation of this section, at density $\rho_2 = \frac{7}{8}$). Fig. 7A indicates the manner in which the road chokes up in this situation. There is uniform flow at density ρ_1 approaching the obstruction, until it encounters a shock wave whose speed U is $-q_0/8$ by a region of uniform flow at density ρ_2. When the cars have just passed the obstruction, they immediately accelerate to a speed $7q_0/8$ and maintain this speed until they·catch up to the traffic stream moving at speed $3q_0/4$. This encounter occurs at $x = 5q_0t/8$, and thenceforth the stream proceeds at the unobstructed speed. Fig. 7B shows the car speed as a function of distance at time t_1. This piecing together of different speed regimes may seem arbitrary, but it is the only combination of density and speed distribution which satisfies the relation between q and p and which conserves the number of cars.

The foregoing phenomena are analogous to certain phenomena in gases. When the two ends of a long cylinder are separated by a diaphragm, one end is evacuated and the diaphragm subsequently is suddenly removed, the gas density distribution which develops is very much like the traffic density distribution of fig. 6. On the other hand, when a partial obstruction is suddenly inserted into a cylinder through which gas is flowing at high speed, the flow to the left of the obstruction may be like that of fig. 7, but the flow to the right will be quite different. This difference arises because the molecules of gas are influenced bv the neighboring molecules behind them as well as those in front, but the car speed is influenced only by the proximity of the cars ahead.

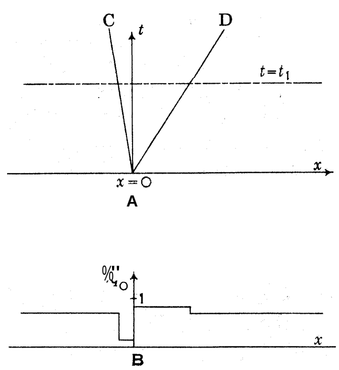

FIG. 7.—(A) SHOCK WAVE LOCATIONS IN x-t PLANE FOLLOWING SUDDEN, PARTIAL OBSTRUCTION OF ROAD. IN REGION TO LEFT OF LINE C, DENSITY IS 1/4; BETWEEN C AND VERTICAL IT IS 7/8; BETWEEN VERTICAL AND LINE D IT IS 1/8; TO RIGHT OF D IT IS 1/4. (B) TRAFFIC SPEED V. DISTANCE x

Waves in Elastic Solids.—When one end of a long cylindrical rod of homogeneous, isotropic elastic material is suddenly twisted about the axis of symmetry, the displacements which characterize the ensuing wave correspond to rigid body rotations of the successive circular cross sections. The distorting elements of material do not change volume, and the wave proceeds at the speed $\sqrt{G/\rho}$, where G is the shear modulus of the medium (for steel, G is about 6.000 tons per square inch, and the transverse wave speed is somewhat greater than 10,000 ft. per second). The particle displacements are all perpendicular to the direction in which the disturbance is progressing, and such waves are called transverse waves. If, however, a uniform pressure were suddenly applied to the surface of a spherical chunk of the same material, the wave which propagated toward the centre of the sphere would involve changes in volume of the material, and the displacements would be in the direction of propagation. Furthermore, this longitudinal wave would proceed at a speed which for most metals is $\sqrt{2(1-v)/(1-2v)}$ where v is Poisson's ratio of material. (*See* MATERIALS, STRENGTH OF: *Elasticity.*) In most structures (ranging in size from small piezoelectric crystals and machine elements to the planet earth itself), the wave propagation phenomena of interest involve both kinds of waves. This stems largely from the fact that when either a transverse or a longitudinal wave encounters any nonhomogeneity (a crack or void, a force-free surface, an inclusion of a different material, etc.) the transmitted and reflected waves necessarily are made up of both transverse and longitudinal contributions In general. a longitudinal wave exhibits a coincidence of the direction in which the wave propagates nith the direction associated with the disturbance characterizing quantity; *e g*, displacement, velocity, surface traction, electric-field intensity, etc. In a transverse wave, however, the propagation direction is perpendicular to the direction associated with the disturbance characterizing quantities.

The presence of one particular nonhomogeneity, an extended surface on nhich the externally applied force is negligible, *e.g.*, the surface of the earth, gives rise to one especially interesting phenomenon. When a disturbance occurs near the surface, *e.g*, an earthquake, some of the energy associated with the wave so generated spreads out spherically away from the point and thus diminishes in intensity in proportion to R^{-2} uhere R is the distance from the inception point However, a substantial fraction of the energy remains near the surface as it propagates, because of the manner in which the presence of such a surface requires the longitudinal and transverse waves to interact. The volume over nhich this energy spreads is smaller by a factor R than the former contribution, and it can be detected at greater distances; it is this wave, in fact. which is so frequently detected after earthquakes. When such a disturbance occurs in an unpopulated area, its source is usually located by a comparison and analysis of the particle displacement time histories collected by various seismographs throughout the world. Once again, of course, the appropriate detailed analysis requires the invocation of the laws implying the conservation of mass and of momentum and implies a knowledge of the relation between distortion and loading for the material under consideration.

See also EARTHQUAKES.

General Remarks.—The range of physical situations in which nave motion plays a vital role and the degree of sophistication with nhich such phenomena may be investigated extend far beyond the content of the foregoing examples. However. the understanding of all such wave phenomena rests on the deduction of the implications of the fundamental laws of physics and the properties of the media in the system being studied.

BIBLIOGRAPHY.—J. W. S. Rayleigh, *Theory of Sound* (1945); J. J. Stoker, *Water Waves* (1957); F. W Sears, *Mechanics, Wave Motion and Heat* (1958); C. A. Coulson, *Waves,* 7th ed. (1935). (G. F. C.)

WAVES AND SHORE CURRENTS are continually changing the shores of lakes and oceans. The most important are caused by winds and tides. Others, such as waves caused by earthquakes and volcanic eruptions (the so-called tidal waves) are so infrequent that their work in shaping shores is comparatively unimportant. In their beginning, wind-caused water waves are boundary waves such as develop at the contact between moving bodies of gases or liquids of differing densities. Once started, the energy of these boundary waves is further built up and their forms are somewhat changed by the pressure of the wind against their sides.

Water waves are of two kinds, waves of oscillation and waves of translation. Waves of oscillation are the ordinary deepwater waves in which all the particles of water within the wave move in circular orbits. At the surface, these orbits have a diameter equal to the height of the wave. They decrease rapidly with depth until. at a depth equal to the length of the wave. the movement is practically zero. In a wave of translation, the whole body of water moves forward and does not return.

Much has been written regarding ocean waves, and numerous formulas have been developed giving the relations existing between wind velocity and the length, height, velocity and energy of ocean waves.

See also WAVES OF THE SEA.

Breakers and waves of translation form when waves of oscillation enter shallow water. The rate of forward movement of the waves decreases, their height increases and they croud closer together. Along nith this decrease in length and increase in height is an increase in the diameter of the orbit of the wave until it is too large to be completely filled by the amount of nater present. It then falls forward and becomes a breaker. As the wave breaks, a part of the nater in it is thrown forward and does not return. This is a wave of translation. The action can best be seen where the uaves are breaking against a submerged ridge, the uater in the upper part of the breakers being thrown forward across the ridge top, carrying the sand with it thus forming a subaqueous dune.

Shore Currents result from the combined action of waves of translation and the drag of the wind across the water surface. During storms. the water may pile up on the shore or flow at an angle with it, depending on the direction of wind and waves and the shape of the bottom. Some of the water piled on the shore moves outward beneath the surface in a current called the undertow. However, much of its escapes here and there along the shore in a series of outward-flowing currents knoun as rip currents. These sometimes attain a velocity of 3 to 5 mi per hour and may be very dangerous to snimmers. Near shore, their width is usually 50–100 ft. Farther out, they niden and the velocity lessens until they disappear at 1,000–3,000 ft However. beyond the breaker zone, with an onshore wind there is a slow outward movement of water several feet beneath the surface and with offshore winds, a similar deep current moves slowly in toward shore. Rip currents are strongest with the, wind blowing squarely onshore, but if the wind blous toward shore at some lesser angle, a current is set up running parallel with the shore. This is the longshore current. It may reach a velocity of several miles an hour, especially uhen combined with the tidal flow. Such currents continue along shore until they encounter an outward-flowing rip current or are turned offshore by a curving shore line.

Shore Structures form along the shore as the result of transportation and deposition of sediment by the naves and currents. When a wave reaches shore. part of its nater is thronn forward on the beach as a wave of translation, producing the swash. This water. running back down the beach under the force of gravity, is the backwash. The forward movement in the swash throns the sand and other material up into a ridge just above the water line. This is the beach ridge. If the waves come in perpendicular to it, the water in the snash and backwash moves up and back in a straight line and there is no lateral movement of the material. But if the waves come in at some other angle, the movement in the swash and backwash approaches that of a distorted parabola and causes the material in the beach ridge to move along the shore. At the same time, the longshore current picks up and transports material in much the same way a river does, but with the added advantage that sediment from the bottom is stirred up and kept in suspension by the breakers. This transportation of material along the shore by the combined action of longshore current and the swash and backwash is called shore drifting.

As the material transported by shore drifting is again deposited, some of it is formed into structures such as spits, bars and cusps. A spit is an embankment of sediment having one end attached to the land and the other terminating in open water. Its crest, for some distance outward. rises above the water. The most usual place for a spit to form is on the windward side of a bay entrance. Its formation begins with deposition of sediment by the longshore current. After the current reaches the turn of the bay entrance, it continues past it in a straight line. On entering the quiet water, its velocity is reduced and it drops its load. Thus, a ridge is formed on the bottom extending part way across the bay mouth. While this ridge is building, its shore end receives material brought to it along the front of the beach ridge by the swash and backwash: Thus. the part of the spit above the water is an extension of the beach ridge superimposed on the subaqueous embankment built by the longshore current. The shape of the spit, whether long and slim or short and wide, depends on the amount of sediment available and the direction and size of the waves. Sometimes a spit is curved at the end, forming a hook. This curving is caused by wave refraction. When waves move into shore at an angle, the end that first enters shallow water is retarded while the end in deeper water continues on. This causes the waves to curve around the end of the spit and, if they are relatively strong as compared with the amount of sediment, it produces a turn at the end of the beach ridge Hooks nearly always turn toward the land, since the stronger waves come from the open water. A bar is an extended spit that closes, or nearly closes, a bay mouth. It may build from only one end. or it may result from two spits building from opposite directions. Geologists have never agreed as to the size of this opening, but it is generally assumed that it may be large enough for the passage of such vessels as navigate the waters.

Beach cusps are triangular-shaped projections of sediment extending out into the nater along a shore line. They are of various forms and sizes and may occur either singly or in series. They form in several ways. One common type that occurs in series is caused by the breaking of a beach ridge by a wave system larger than that which originally formed it. The breaks in the ridge crest are not all of the same size nor evenly spaced, but the uniform parabolic movement of the water in the swash and backwash intensifies the larger openings and closes the smaller ones until there is produced a fairly uniform series of triangular cusps. Their size and spacing depend on the size of the waves and the height and width of the ridge from which they are formed.

A rather rare shore structure that sometimes forms on sandy beaches having a very gentle underwater slope is the cuspate spit. It is started by the overloaded shore current dropping some of its load at a small obstruction or irregularity in the shoreline. This deflects the current outward and causes a small cusplike structure to form. The swash and backwash adds material and a spit is built out over the shallow bottom. On small' lakes, these often occur in series and may extend out several hundred feet. Along the shores of large bodies of water, as on the west side of Lake Huron north of Saginaw bay, they appear as fairly permanent sand structures reaching out several hundred yards from shore.

Offshore Structures, unconnected with the shore, such as barrier beaches, low and ball and ripple marks, are formed by the waves and currents on the underwater terrace. Barrier beaches are ridges of sandy sediment lying parallel to the shore and reaching above the water but not attached at either end. In North America they are numerous and large along the coasts of Texas and the Carolinas, and in Europe along the coasts of the Netherlands and the southeastern Baltic sea. Their method of formation is not well understood. Some physiographers think they'are the result of the waves throwing up ridges of sand from the bottom. Others think they may be long spits in shallow water built parallel with the shore, cut through at the neck and later widened by the addition of beach ridges on the seaward side. As they seldom or never form on lakes or inland seas, it is possible that the rise and fall of the tide is a factor in their building. Low and ball designates a series of subaqueous troughs and ridges lying parallel with the shore. Their spacing and size varies with the depth of water and the slope of bottom. In some localities, as on the gentle slopes of the bottom of Chesapeake bay and the Gulf of Mexico, they occur in a series of a dozen or more, increasing in size with distance from the shore. They are also numerous along the shore of the Great Lakes and on the south and southeast coasts of the Baltic sea. Along the east side of Lake Michigan, the bottom slope is such that they usually occur in series of three. Their spacing varies. but their average distances from shore are about 200. 600 and 1,200 ft. From the shore line outward, the trough depths average about 5, 11 and 18 ft., and the depths of the crests, 4, 8 and 12 ft.

The ridges are caused by piling up of sediment stirred up from the bottom by the downward-plunging water in the breaking waves. The effect in shallow water is to dig a depression as a waterfall does in a stream. But because of the orbital movement in a wave, the sediment stirred up from the bottom, instead of going toward the shore in the direction of wave travel, is moved a little distance in the opposite direction. This material accumulates as a ridge on the lake bottom. Theiposition of the lows (troughs) and balls (ridgesj is fixed by the average size of the storm waves. After once forming, the structures'remain nearly constant in position as long as the water level remains the same, moving only a little toward the shore or away from it with changing wave conditions. However, if the water level falls, breaks sometimes occur in the ridge nearest shore and the ends are pushed in toward shore by the waves of translation. In long continued periods of low water, the inner ridge may move in as a subaqueous dune and unite with the beach ridge.

Ripple marks (*q.v.*) are common on shallow, sandy bottoms, along the shores of oceans, lakes and on the bottoms of streams. They are formed in two ways—by the forward and backward movement produced on the bottom by the passage of waves of oscillation, or by currents in which the water moves steadily in one direction. The underwater terrace on which the above features are formed is. itself. a product of the work of the waves and currents. They take the material from the shore and work it out toward deep water. but the movement ceases at the depth at which 'the waves are incapable of moving material. Thus, a terrace is formed. Its outer edge is usually at a depth equal to about one-third the length of the average storm waves.

Closely related to the underwater terrace is the sea cliff. It forms where the sea advances against a high shore. The vertical distance that waves can cut is limited by their height. So, when they break against the face of a high cliff they undercut it until the overhanging rock is brought down by its own weight. This material is then moved away from the shore by the waves and currents, spread out and made a part of the underwater terrace. As the process continues, the terrace becomes wider and wider. A cliff formed as the result of wave cutting is a sea cliff. Where cut in solid rock, sea cliffs may endure for a long time after uplift of the land or lowering of sea level has shifted the shore line seaward. Perhaps the best known of these are the cliffs of Dover and the opposite shores of Calais on the English channel. They are also numerous at various places along the coasts of Scotland and Ireland.

The total effect of the waves and currents, over a long period of time, is to take more sediment from the land than they bring back. During storms, great quantities are torn from the shores and thrown into suspension by the waves along with that stirred up from the bottom by the plunging breakers. At such times, the rip currents are strong and great quantities are rushed offshore to deep water. But with gentle currents and waves of small size, much of this is returned to the land by the travel of the asymmetrical ripples toward shore and the work of the waves of translation. The final shape of the shelf depends on the relation between the strength of the waves and currents and the amount of sediment available. With an excess of sediment the shelf is wide with a gentle slope; with less sediment and stronger waves and currents it is narrower and steeper. *See* also LAND RECLAMATION; SEDIMENTARY ROCKS: *Sedimentology.*

WAVES OF THE SEA. Whenever the wind blows over water, the surface is formed into waves. These grow under the influence of the wind and form a most irregular surface pattern known as "sea." When wind-raised waves travel out of a storm area they advance as "swell." and after having traveled large distances becomes a series of long, low and fairly regular undulations. These may be all but hidden by short irregular waves, newly formed on the surface, until the swell travels into shallow water. There each wave crest rises sharply from the water surface, grows steeper and steeper until it breaks, and foaming white "surf" advances toward the shore line and rushes up the beach. The terms sea, swell and surf describe, therefore, different stages of the same phenomenon, and the waves of the sea caused by wind are discussed below under these headings.

Not all waves of the sea are caused by wind. Destructive waves caused by earthquakes, submarine landslides or volcanic eruptions beneath the sea occasionally inundate low-lying coasts and cause enormous damage. Such waves are popularly known as "tidal waves," although they have nothing in common with the tides. They are discussed under *Other Ocean Waves*, below. True tidal waves are caused directly or indirectly by the attracting forces of the sun and moon and, although strictly speaking they belong to the waves of the sea, they are usually treated as a separate subject (*see* TIDES).

WAVES CAUSED BY WIND

History of Investigations.— Waves have been observed for thousands of years, yet knowledge of them is most incomplete and many fundamental questions remain unanswered. This lack of knowledge is probably due to the fact that the subject has been studied from two different points of view, each failing to take into account the results achieved by the other. To the mathematician wave motion has presented a fascinating field of study, but he has not often been concerned with the practical application of his studies to waves of the sea. To the seafaring observers waves have long been a source of keen interest but mariners have been unable or unwilling to utilize the tools developed by the mathematicians. Until about 1925 few attempts had been made to bridge the gap.

The literature dealing with ocean waves is so large that only a few of the more important works can be mentioned. The first systematic mathematical study of wave motion appears to have been made by Sir Isaac Newton (1642–1727), but not until the 19th century was the study of wave motion put on a sound mathematical basis. Among the important contributions were those by G. G. Stokes (1847), J. Boussinesq (1872) and Lord Rayleigh (1876). The first accounts of careful observations of waves were those by Leonardo da Vinci (1452–1519). Observations in wave tanks seem to have been initiated by the Weber brothers in 1825. A "Report on Waves" submitted by J. Scott Russell in 1844 to the British Association for the Advancement of Science exercised a profound influence upon all subsequent wave studies. Observations at sea were published by T. Stevenson (1850), A. Paris (1871), G. Schott (1893), V. Cornish (1934) and A. Schumacher (1928). The effect of waves on engineering structures was studied by D. D. Gaillard (1904). The first successful attempt to bridge the gap between theory and observation was made by Harold Jeffreys in 1925. H. U. Sverdrup and W. H. Munk developed a series of dimensionally complete empirical relationships on the basis of which it was possible to forecast wave height and period from weather maps. Such forecasts were made to assist amphibious landings in World War II. Thereafter much progress was made to give more complete statistical descriptions of the sea surface. In England, G. E. R. Deacon, N. F. Barber, M. S. Longuet-Higgins and F. Ursell in 1946–48 developed methods for recording the spectrum of ocean waves, and Willard F. Pierson, Jr., at New York university, developed in 1950–52 relationships for forecasting the spectrum. Carl Eckart in 1953 gave the first statistical theory of wave generation.

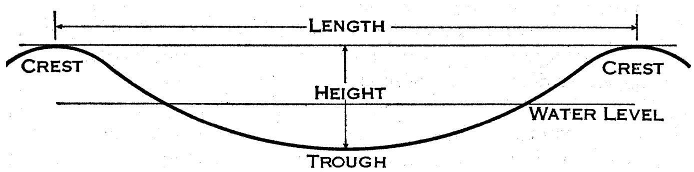

FIG. 1.— DIAGRAM OF A WAVE SHOWING HOW THE LENGTH AND HEIGHT ARE MEASURED. THE VERTICAL SCALE IS EXAGGERATED

Definitions.— The height of a wave, H, is the vertical distance from crest to trough. The length, L, is the horizontal distance between adjacent crests (fig. 1). The wave period, P, is the time interval between the passage of successive crests at a fixed point. The velocity, V, of a wave is the speed with which the wave form travels along the sea surface.

Theory.— The derivation of the basic properties of wave motion according to the classical wave theory is next indicated, but a knowledge of theory is not essential for the reader's understanding of the rest of this article.

The usual procedure for dealing with short waves in deep water is to solve the hydrodynamic equations of motion and the equation of continuity for an incompressible medium, subject to the following conditions: (1) all motion is irrotational, that is, a velocity potential ϕ exists; (2) the pressure along the surface is constant; (3) the motion ceases at great depth. Neglecting second-order terms, the simplest solution satisfying these conditions is

$$\phi = \frac{gH}{2\sigma} e^{kz} \cos (kx - \sigma t) \qquad (1)$$

where z is the vertical co-ordinate directed upward from the undisturbed sea surface, x the horizontal co-ordinate positive in the direction of wave motion, t time, g the acceleration caused by gravity, a $= 2\pi/P$, $k = 2\pi/L$. Equation (1), assumption (2) and the identity $V = L/P$ lead to the equations $L = gP^2/2\pi$, $V = gP/2\pi$ or, with good approximation,

$$L = 5P^2,\ V = 3P \qquad (2)$$

where L is the wave length in feet, P the period in seconds, V the velocity in knots. Equations (1) and (2) apply only to deep water but are approximately correct when the depth is larger than one-half the wave length. Derivations of these equations. together with a complete discussion of the entire subject of wave theory, are included in chapters 8 and 9 of Horace Lamb's *Hydrodynamics* (1932).

Wave Motion and Water Movement.— The wave velocity is the speed with which the wave form travels along the surface. The water, on the other hand, advances very little. This was known to Leonardo da Vinci, who compared water waves to waves traveling across a wheat field where the wheat itself remains rooted. There is. however, a slight surface drift in the direction of wave movement which amounts to about 1% only of the wave velocity. Although too small to be of general importance, it does affect the drift of life rafts, causes floating objects to wash ashore and contributes, in heavy surf, toward an abnormal rise of the water level against shore. the latter known as "storm tide."

Within the traveling wave any small volume of water moves in a vertical circle. At the surface the diameter of the circle equals the wave height. An object on the crest of the wave moves forward with the wave. When the object lies in the trough it moves in a direction opposite to that of the wave. In front of the crest the object rises; behind the crest it falls. The circular movement is completed during one wave period. If an object were suspended beneath the surface it would still describe circles; but the deeper the object, the smaller the circle. At a depth of a quarter of a wave length the diameter of the circle is only 10% of that at the surface, and at twice that depth practically all wave motion ceases. For that reason submarines can escape wave motion by diving to greater depth.

Wave Observations.—The theoretical relationships between wave length, velocity and period (equation [2]) have been confirmed by careful observations. The wave period is best measured by recording the time interval between successive appearances on a wave crest of a well-defined patch of foam or a floating object at a considerable distance from a ship. The wave length can be estimated by comparison with the ship's length; the wave velocity, by timing the passage of a crest between the ship's bow and stern. However, experience has shown that the wave length and velocity measured in this manner are likely to be far too small because one tends to take the crest of a wave at a point short of its actual summit. If wave length and velocity are desired it is better to measure the wave period and compute length and velocity according to equation (2).

Unlike the length and velocity, the wave height does not bear any definite relationship to the wave period. Heights of large waves can be estimated by waiting until the ship is in a trough and taking a station from which the crest coincides with the horizon. The wave height then equals the distance from the eye height to the ship's water line.

Sea.—If there were no wind there would be no waves. A small gust of wind blowing over a calm stretch of water will ripple the surface. Each little wave presents a slight obstacle to succeeding gusts of wind. As the wind blows on the waves, the pressure on the windward side exceeds on the average the pressure on the lee side, and this pressure difference brings about a transfer of energy from wind to waves: the sea grows. At the same time, by some mechanism not yet understood, the most prominent waves become successively longer. Length and height both increase, but at first their ratio remains approximately the same at 13:1. At the later stages of wave generation, the height will increase less rapidly, and the waves accordingly become flatter. In the trade-wind belt, where the wind blows steadily over large distances, a long rolling sea is generated. These long waves may eventually travel faster than the wind.

When the wind velocity exceeds 10–12 knots, some of the smaller waves grow so rapidly that their height reaches one-seventh of their length. When this critical ratio is reached, the water at the crest moves faster than the crest itself, causing the water to topple forward into whitecaps.

A heavy sea is raised when strong winds blow for many hours over large ocean areas. The height of the sea is determined, therefore, by three factors:

Fetch ....Distance over which wind blows.
Wind velocity ....Average speed of wind over fetch.
Wind duration ....How long the wind blows.

Over landlocked areas, such as bays and small lakes, the wave height is usually limited by wind velocity and fetch (distance from the windward shore); thus, in a small body of water high waves cannot be formed. Over large ocean areas the height of the sea is usually limited by wind velocity and wind duration. So, in general, the wave height may be limited either by fetch or duration. When wind velocity, fetch and duration are known, the wave height can be determined from Tables I and II, and the lower of the two values will be applicable.

The highest sea ever reliably reported consisted of 55-ft. waves. To produce such waves a 60-knot wind would have to blow about 24 hours over a fetch longer than 500 mi. Waves consistently higher than this are not found because gales do not blow over sufficiently large fetches for a sufficiently long time and because at hurricane velocities the tops are blown off.

TABLE I.—Wave Height in Feet for Various Wind Velocities and Fetches

Fe[redacted] in nautical miles	Wind velocity in knots					
	10	20	30	40	50	60
10	2	3	5	[illegible]	[illegible]	[illegible]
20	2	4	7			
50	2	6	10	14		
100	2	7	13	17	25	30
500	2	10	20	31	45	55
1,000	2	10	21	35	50	70

Sea coming from different quarters of a storm will run in different directions and a cross sea results. When two crests intersect, peaks are formed. When two troughs intersect, hollows are formed. Instead of long crests and troughs the sea surface then consists of apparently unrelated peaks and hollows. Isolated peaks up to 80 ft. have been reported; but these freaks, caused by the coincidence of two or more crests, rise high above the general water level. To a ship passing through a cross sea formed by high waves these peaks spell danger. Steep cones of water may crash over the ship causing extensive damage to superstructure and loss of personnel. A full gale sometimes tears the tops off these peaks and flying sheets of water are thrown against the ship.

TABLE II.—Wave Height in Feet for Various Wind Velocities and Durations

Wind duration in hours	Wind velocity in knots					
	[illegible]	20	30	40	50	60
6	2	5	10	14	20	25
12	2	7	13	20	30	35
24	2	9	17	30	40	55
48	2	10	22	35	45	70

Swell.—Waves leaving their storm area are known as swell. Their length, velocity and period increase as they travel away from the storm area while their height decreases because of the resistance offered by the air. Table III shows approximately how the wave height decreases. The first column gives the height of waves just as they emerge from the storm area, the other columns the height at distances of 500, 1,000, 2,000 and 3,000 mi.

TABLE III.—Approximate Height of Swell in Feet at Various Distances From the Storm Area

Distance from storm area in nautical miles				
0	500	1,000	2,000	3,000
40	25	20	12	8
30	19	14	8	5
20	12	8	5	3
15	8	5	3	2
10	5	3	2	1
5	2	1	0.5	—

This decay of wave heights is assisted by an opposing wind and lessened by a following wind.

Seafaring men learned to judge the distance of a storm from the approaching swell. In general, an irregular short and high swell comes from a nearby storm, while a regular long and low swell comes from a distant storm. But even the most regular swell is composed of alternate groups of high and low waves. These are caused by interference between trains of swell from different quarters of the storm. Alternate groups of high and low swell result, and these have been responsible for the popular but incorrect belief that every seventh wave is highest. Waves vary in height but without regularity.

One of the longest s ell periods ever recorded was 23 sec. According to equation (2) its length in deep water would equal 2,650 ft., about half a mile, and its velocity 69 knots. This swell was observed at Ascension Island after it had traveled across the equator from its generating area near Iceland. The rollers of Ascension are famous. Accounts of their destructive power date back to 1846 when 13 vessels were driven from their moorings and totally wrecked. The swell reaching Rio de Janeiro, Braz., is equally famous and locally known as the resaca. A 28-sec. swell which was generated in the roaring forties of the South Atlantic was recorded at the Cape of Good Hope. According to equation (2) its length must have been almost three-quarters of a mile and its speed, 84 knots.

Each ocean region has its own characteristic swell conditions which are related to the general atmospheric circulation. Along the North American west coast the swell is often the result of storms traveling south of the Aleutians into the Gulf of Alaska.

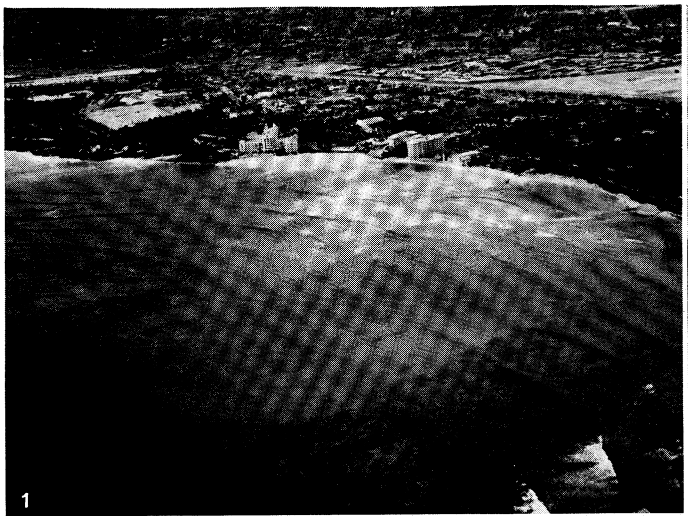
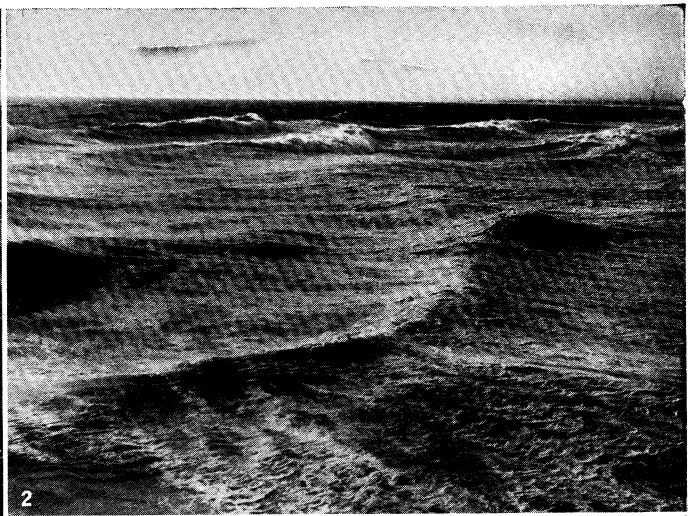
WAVES OF THE SEA





BY COURTESY OF (1) U S. NAVY, (2 3) PAUL WILLIAMS; PHOTOGRAPH, (4) CAPT. BEATON

1. Swell bends into Waikiki beach, Honolulu, Hawaii
2. Surf resulting from near-by storm. The top of the wave spills over gradually, and breaking continues over a long period
3. Surf resulting from distant storm. The crests curl and break with great intensity — with all the energy going into the initial plunge
4. Towing a sailing ship over a river bar. The wave conditions arc accentuated by the presence of the near-by bar, but are a good illustration of the severe wave conditions often found in open sea

Conditions are similar along the European and African west coasts which receive smell from storms traveling toward Iceland. Along the Oregon. Washington and Canadian coast, and in Scotland, North Ireland and Norway the swell, although heavy, is usually overshadowed by the high sea generated in local storms.

Because of the prevailing westerly winds the east coast, or lee side, of continents in the northern hemisphere does not experience a long swell, and high surf is usually the result of local storms. This applies to the American east coast as well as to the coast of eastern Asia. Swell in the southern hemisphere can be expected to be longer than in the northern because the area occupied by ocean is proportionally larger.

Surf. — All the energy which the waves have accumulated from the wind for many hours over long fetches is thrown into a narrow surf zone. High breakers can do much damage. At Ymuiden, the Netherlands, the harbour entrance to the Amsterdam canal, a wave in a gale lifted a 20-ton concrete block 12 ft. and deposited it on top of the pier which was about 5 ft. above high water. Waves breaking against cliffs and embankments may impel water skyward and cause damage high above sea level. In one instance, damage was reported 132 ft. above high water.

The transformation of a seemingly harmless flat swell into steep, plunging breakers had been thought to be primarily brought about by friction, but investigations made during the period 1943–45 indicated that the restricting effect of the sea bottom upon the water movement is the primary factor. In deep water, waves set up a circular motion which extends to a depth of about one-half the wave length. In shallow water this circular motion is squeezed into elliptical motion and at the bottom is distorted into back-and-forth movement shoreward under the crest and out to sea beneath the trough. The distortion of the water movement is associated with a decrease in wave velocity. When the depth becomes less than 15 ft., the velocities of the waves of periods longer than 8 sec. depend only upon the depth of the water as shown in Table IV.

Table IV.—Wave Velocity in Shallow Water

Depth of water in feet	Speed of wave in knots
15	13
10	11
5	8

As waves pile into the shallow water there is also a decrease in wave length as if the wave train were being compressed accordion fashion. Unlike the wave velocity, the wave length in shallow water depends not only upon the water depth but also upon the wave period. The longer the wave period, the longer will be the wave length. The wave period remains unchanged throughout

The direction of the waves also changes. Waves approaching a straight coast line at an angle tend to swing parallel to shore because the portion of the crest nearer shore is in shallower water and moves slowly while the portion of the crest in deeper water races ahead. Thus, waves turn in such a manner that the outline of the crest tends to take the shape of the bottom contours. Waves bend into bays, around headlands, points and jetties, but in doing so they lose height because they must stretch.

Bent crests give evidence of bottom features which are not apparent from configurations of the coast line. In the case of submarine canyons, the parts of the crests that advance over the centre of the canyon are in deeper water and move ahead faster than those on either side. As a result the crests are stretched and the wave height decreases. Fishermen anchor near the heads of these canyons because the waves are low there. Underwater ridges near shore have the opposite effect. When waves pass over them the crests are squeezed and the wave heights increase. Many instances have been noted of unusually violent breakers over under water ridges.

Waves entering shallow water also undergo a change in shape which depends chiefly upon whether the surf is caused by a distant swell or a local sea. A swell which is almost symmetrical in deep water, with flat long crests and flat long troughs, turns into a series of narrow steep crests isolated by flat long troughs (fig. 2). This "peaking" or "humping" is noticeable even to the casual observer when a long swell rolls in toward a smooth beach. As the wave is about to break it becomes steep, the shoreward face becomes concave and the water plunges from the top, momentarily enclosing an air space and striking the water surface in front with great force,

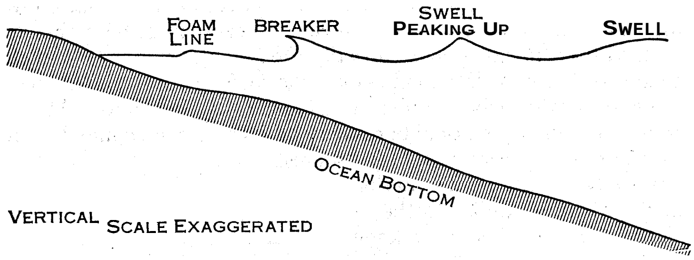


FIG. 2.— IN DEEP WATER THE SWELL IS LOW AND ROUNDED. BUT AS IT ADVANCES INTO SHOAL WATER THE CRESTS BECOME STEEPER AND THE TROUGHS FLATTER, SO THAT CRESTS APPEAR TO PEAK UP SUDDENLY JUST BEFORE THEY BECOME UNSTABLE AND BREAK

often throwing up a spray higher than the original wave. Onshore winds lessen the tendency to curl and reduce possibility of spray. Offshore winds cause the back of the wave to continue well rounded up to the point of breaking, and its front may become so deeply hollowed that a swimmer about to dive through it just as its crest is falling can look back for an instant through a sheet of falling water. These sheets of falling water have been observed to enclose and compress pockets of air which, in turn, give rise to miniature geysers of water.

As a wave breaks it appears much higher than it did in deep water, principally because it has shortened and steepened. Actually, the breaker height rarely exceeds the wave height in deep water by more than 50%. Plunging breakers occur at depths approximately equal to the breaker height.

If the surf is caused by local storms, whitecapping continues all the may to the surf zone. The top of the wave spills down the front, producing white foam and "boiling" on the leading slope, but no real plunge of water. Spilling breakers occur at depths larger than their wave height.

Statistical Waves Theory. — In the vears following World War II it became clear that because of the irregularity of ocean waves simple descriptions dealing with wave height, period and length were inadequate for many purposes. In fact, it appears that predictions based on the mathematical theory of random noise are well supported in observations of ocean waves.

OTHER OCEAN WAVES

Earthquake Waves. — Earthquakes on the ocean bottom may produce shock waves similar to those caused by depth charges. These travel in the sea at the velocity of sound, about 5,000 ft. per second. They will be felt on board ship as a shock which violently rocks the vessel. The shock may be so severe that the sailors believe their vessel has struck a rock. On early charts several such reported "rocks" were indicated in waters where recent soundings have shown the depth to be several thousand yards. These shocks are accompanied by loud noises like thunder or cannon fire. Only in exceptional cases will they cause damage.

Far more destructive are the waves caused by vertical displacements along earthquake faults on the sea bottom, by submarine landslides and by volcanic eruptions beneath the sea. A series of high so-called tidal waves (more correctly designated by their Japanese name, tsunami) may result. The velocity of these waves in the open sea is large and depends upon the depth of water in the following manner:

Depth in feet	500	1,000	2,000	5,000	10,000	15,000
Velocity in knots	75	100	150	240	340	420

The average depth of the Pacific ocean was estimated for the first time from the velocity of tsunamis and turned out to be only one-third of the previously assumed value. These computations were later confirmed by soundings. Tsunamis quickly lose height and become exceedingly long, sometimes up to 500 mi., and in the open sea they can be observed only in the immediate vicinity of their origin. Their period may lie between 10 min. and 60 min.

The tsunami is usually led by a small rise, followed by a distinct trough. On shore the arrival is first noticed by a fall in the sea level for a number of minutes, as if there were an abnormally low tide, followed by a rapid rise to levels far exceeding the high-tide level. Tsunami waves do not usually break in the manner in which sea and swell break, but coming over the reefs of coral islands they give rise to extremely turbulent and dangerous conditions. At the mouths of large rivers tidal bores may be formed, which may travel many miles upstream as solitary waves.

Seiches.—Periodic fluctuations of the sea level are also caused by disturbances similar to the sloshing back and forth of water in a large dishpan. These are known by the Swiss word, seiches, because they were first observed in lakes in Switzerland. Seiches are most likely to occur in bays and lagoons but have also been observed along the open coast The period of oscillation may vary from minutes to hours and depends largely upon the dimensions of the moving mass of water.

Internal Waves.—In the oceans, internal waves, or boundary waves, have been observed at the boundary between layers of light (warm and low-salinity) water and heavy (cold and high-salinity) water. Although internal waves may displace the boundary by as much as 50 ft.. they cannot be noticed at the surface and their velocity rarely exceeds two knots.

In the time of sailing vessels there were many reports of "dead water." The vessel appeared to stick in the water, behaving sluggishly and making little headway. This experience was common in arctic water where, by melting of ice. there was formed a layer of nearly fresh water about as thick as the draft of vessels. In such a case the power is used to produce an internal wake at the boundary between the fresh water and the salt water in addition to the ordinary wake at the sea surface, and in one instance a vessel was slowed from five knots to one knot. In extremely old sailing accounts internal waves were mistaken for sea monsters which were holding the ships back.

WAX FIGURES. Beeswax is possessed of properties which render it a most convenient medium for preparing figures and models, either by modeling or by casting in molds. At ordinary temperatures it can be cut and shaped with facility; it melts to a limpid fluid at a low heat; it mixes with any colouring matter, and takes surface tints well; and its texture and consistency may be modified by earthy matters and oils or fats.

Wax figures of their deities were used in the funeral rites of the ancient Egyptians, and deposited among other offerings in their graves; many of these are now observed in museums. That the Egyptians also modeled fruits can be learned from numerous allusions in early literature. Among the Greeks during their best art period, wax figures were largely used as dolls for children; statuettes of deities were modeled for votive offerings and for religious ceremonies, and wax images to which magical properties were attributed were treasured by the people. Wax figures and models held a still more important place among the ancient Romans. The masks (*effigies* or imagines) of ancestors, modeled in wax, were preserved by patrician families; they were exposed to view on ceremonial occasions and carried in their funeral processions. The closing days of the Saturnalia were known as *Sigillaria,* because of the custom of making, toward the end of the festival, presents of wax models of fruit and waxen statuettes which were fashioned by the *sigillarii* or manufacturers of small figures in wax and other media. The practice of wax modeling can be traced through the middle ages, when votive offerings of wax figures were made to churches, and the memory and lineaments of monarchs and great personages were preserved by means of wax masks as in the days of Roman patricians. In these ages malice and superstition found expression in the formation of wax images of hated persons, into the bodies of which long pins were thrust, in the confident expectation that thereby deadly injury mould be induced to the person represented; and this belief and practice continued until the 17th century. Indeed the superstition still survives in the Highlands of Scotland. With the renaissance of art in Italy, modeling in wax took a position of high importance, and it was practised by some of the greatest of the early masters. The bronze medallions of Pisano and the other famous medalists owe their value to the art qualities of wax models from which they were cast by the cire-perdue (lost wax) process (see BRONZE AND BRASS ORNAMENTAL WCRK); and indeed all early bronzes and metalwork were cast from wax models. A figure in the Wicar collection at Lille is one of the most lovely examples of artistic work in this medium in existence. Wicar, one of Napoleon's commissaries, brought this figure from Italy. It represents the head and shoulders of a young girl. It has been claimed as a work of Greek or Roman art, and has been assigned to Leonardo da Vinci and to Raphael, but all that can be said is that it probably dates from the Italian Renaissance. In Spain beautiful wax figures of saints, distinguished in form and colouring, were achieved in the realm of religious art. Until toward the close of the 18th century modeling of medallion portraits and of relief groups, the latter frequently polychromatic, was in considerable vogue throughout Europe. About the end of the 18th century John Flaxman executed in wax many portraits and other relief figures which Josiah Wedgwood translated into pottery for his jasper ware. The modeling of the soft parts of dissections, etc., for teaching illustrations of anatomy was first practised at Florence. Such preparations formed part of a show at Hamburg in 1721, and from that time waxworks, on a plane lower than art, have been popular attractions. Such an exhibition of waxworks with mechanical motions was shown in Germany early in the 18th century, and is described by Sir Richard Steele in the Tatler.

The most famous exhibition is that of Marie Tussaud (*q.v.*) in London.

WAX MYRTLE (CANDLEBERRY), popular names of species of Myrica, especially M. cerifera and *M. pensylvanica* (bayberry or waxberry), small shrubs native to eastern North America. The fruits have a waxy covering and are utilized as a source of vegetable wax, used especially in New England for making candles. Sierra wax myrtle or sweet bay (M. *hartwegi*) is a similar shrub, found in the Sierra Nevada mountains; the western wax myrtle (M. *californica*), a large evergreen shrub with resinous wax-covered fruit, occurs along the coast from Los Angeles to Washington. M. gale is the native British gale or sweet gale (*q.v.*). Toxicodendron succedanum is the wax tree of Japan.

WAXWING. The three species of waxwing are among the most beautiful of the smaller birds. Their sleek plumage has an exquisite silky texture and is generally brownish or grayish but with some black around the eyes and throat edged with white. The name "waxwing" is given because of the red, waxlike tips of the shorter wing feathers (secondaries). The cedar waxwing (*Bombycilla* cedrorum) of North America averages seven inches in length and has shades of soft brown fading to yellowish underneath. The Bohemian waxwing (B. garulla) of the colder regions of North America, Europe and Asia is larger, about eight and one-half inches long. It is grayer with the wing quills edged with yellow and white. The Japanese waxwing (B. *japonica*) is about six and one-half inches long and is of a warmer shade of brown. It lacks the curious waxlike tips

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

CEDAR WAXWING. OR CEDAR BIRD, (BOMBYCILLA CEDRORUM) but the feather itself is tipped with red as is the tail, unlike the other two species which have the tail tipped with yellow. It is found in Japan and adjoining parts of Asia.

The waxwings are attractively crested. They feed on berries so ravenously at times that they are unable to fly; they are also avidly fond of potato bugs and other insects. Their voices have a lisping quality; they are not songbirds. Waxwings often nest in coniferous trees, building rather bulky nests of twigs, rootlets and grasses lined with soft material. They lay from four to six neutral-tinted eggs spotted with blackish. (K. P.)

WAYCROSS, a city of southeast Georgia, U.S., and the seat of Ware county, is situated on the coastal plain 60 mi. from the Atlantic ocean. In colonial days, the site was the hub of stagecoach roads and pioneer trails. Settlers moved into the land around Kettle creek in 1818, to build forts for protection against Indians but as late as 1870 the village had only 50 inhabitants. The area developed rapidly as a commercial centre after the coming of the railroads. Bee culture, production of naval stores, tobacco warehousing and pecan shelling are leading industries in the city and area. Waycross was incorporated in 1874. The name signifies the city's strategic location at the junction of six rail lines.

Seven miles south of Waycross is the entrance to the Okefinokee swamp (*q.v.*), a 700 sq mi. wildlife refuge. The name, Okefinokee or "land of trembling earth" was given to the swamp by the Seminole Indians because of the quaking nature of its soil. The Suwannee river, immortalized by Stephen Foster, and the St. Mary's river rise in the Okefinokee. For comparative population figures see table in GEORGIA: *Population.* (J. N. A.)

WAYLAND, FRANCIS (1796–1865), U.S. educator, fourth president of Brown university, Providence, R.I., was born in New York city on March 11, 1796. He graduated from Union college in 1813 and subsequently studied medicine and theology. He was a tutor at Union college, 1817–21, pastor of the First Baptist church of Boston for five years, and was elected professor of mathematics and natural philosophy at Union in 1826. He held that post for only a very short time, being called in 1827 to take over the presidency of Brown university. During his 28 year administration Wayland became famous for introducing electives, developing the library and emphasizing science. His textbooks on ethics and economics were widely used, and his Thoughts on the Present Collegiate System in the United States (1842) and Report to the Corporation of Brown University (1850) promoted educational reforms. They proved to be more influential elsewhere than at Brown, where later administrations reversed his policies. He was a leader of the "law and order" group during the Dorr rebellion of 1842 (see RHODE ISLAND).

Wayland died on Sept. 30, 1865.

His son, also FRANCIS WAYLAND (1826–1904), was for 30 years dean of the Yale law school.

BIBLIOGRAPHY.—Francis and Heman Lincoln Wayland, *The Life and Labors of Francis Wayland,* 2 vol. (1867); James O. Murray's short sketch in the "American Religious Leaders Series" (1891); Theodore Collier in *Dictionary of American Biography.* (HY. M. W.)

WAYLAND THE SMITH, hero of romance (Scand. Volundr, Ger. Wieland). The legend of Wayland probably had its home in the north, where he and his brother Egill were the types of the skilled workman, but there are abundant local traditions of the wonderful smith in Westphalia and in southern England. His story is told in one of the oldest songs of the Edda, the *Völundarkviða,* and, with considerable variations, in the prose *Þiðrekssaga* (Thidrek's saga), while the Anglo-Saxon *Beowulf* and Deor's Lament contain allusions to it. The first part of the tale contains obviously mythical features connected with his parentage and marriage. The second part concerns Volundr, lord of the elves, the cunning smith, who, with his sword Mimung, made famous in German epic poetry, defeated in fight at the court of king Niþoþr, the smith Amilias. Niþoþr, in order to secure Völundr's services, lamed him and established him in a smithy. The smith avenged himself by the slaughter of Niþoþr's two sons and the rape of his daughter Bodvildr, then soared away on wings he had prepared. The story in its main outlines strongly resembles the myth of Daedalus, but the denouement of this tale, which first appeared in European literature in the De obedientia (Opera, Venice, 3 vol., 1518–19) of Jovianus Pontanus (d. 1503), is different. The Aaron of Shakespeare's Titus Andronicus was derived from this source. King Rhydderich gave a sword fashioned by Wayland to Merlin, and Rimenhild one to Child Horn. English local tradition placed Wayland Smith's forge in a cave close to the White Horse in Berkshire.

The earliest extant record of the Wayland legend is the representation in carved ivory on a casket of Northumbrian workmanship of a date not later than the beginning of the 8th century. The fragments of this casket, known as the Franks casket, were presented to the British museum by Sir A. W. Franks. One fragment is in Florence.

See also Vigfússon and Powell, *Corpus poet. bor.,* i, pp. 168–174 (1883); A. S. Napier, *The Franks Casket* (1901); G. Sarrazin, *Germanische Heldensage in Shakespere's Titus Andronicus,* Herrig's *Archiv.,* xcvii (1896); P. Maurus, *Die Wielandsage in der Literatur* (1902); C. B. Depping and F. Michel, *Véland le Forgeron* (1833). Sir Walter Scott handled the Wayland legend in *Kenilworth;* there are dramas on the subject by Borsch (1895), English version by A. Comyn (1898); August Demmin (1880); H. Drachmann (1898); and one founded on K. Simrock's heroic poem on Wieland is printed in Richard Wagner's *Gesammelte Schriften,* vol. iii, 2nd ed. (1887).

WAYNE, ANTHONY (1745–1796), U.S. army officer, was born at Waynesboro, Pa., on Jan. 1, 1745. After a trial at surveying he operated the tannery on his father's estate and later inherited the property. He was commissioned a Continental colonel Jan. 3, 1776. His regiment was sent to reinforce Benedict Arnold's retreating Canadian expedition, and he later commanded Ft. Ticonderoga. He was promoted to the rank of brigadier general early in 1777 and took a prominent part in the battles of Brandywine and Germantown. After being defeated at Paoli he spent the winter at Valley Forge. At Monmouth courthouse on June 28, 1778, he led the attack on the British. The storming of Stony Point, July 16, 1779, was his most dramatic stroke. The name "Mad Anthony" rose from a deserter's complaint. When the treason of Benedict Arnold was discovered, Wayne moved promptly to safeguard West Point. In 1781 he was sent south to help Lafayette. At Green Springs, Va., on July 6, he took on Cornwallis' larger army, but extricated himself with small loss. He was present at the siege of Yorktown and then was dispatched to join Gen. Nathanael Greene's southern army. He served largely in Georgia, recovering the state and defeating the enemy Indians.

The Georgia legislature elected him to the U.S. house of representatives in 1790, and he served nearly two years before his seat was declared vacant because of state election frauds. President Washington then appointed him commander in chief of the small U.S. army, which had suffered defeat in Ohio by Indians. Wayne trained his enlarged army for two years before advancing slowly north of the Ohio river. At the battle of Fallen Timbers, Aug. 20, 1794, near modern Toledo, he routed the British-inspired Indians. This defeat and the Jay treaty (*q.v.*) with England enabled Wayne to negotiate, with the Indians, the treaty of Greenville, 1795, by which the Indians agreed to open a large part of Ohio for peaceful settlement. The next year the British yielded their posts on the U.S. side of the Great Lakes. Wayne died at Erie, Pa., on Dec. 15, 1796 while on duty.

WAYNFLETE (WAINFLEET), **WILLIAM OF** (WILLIAM PATYN; 1395?–1486), English lord chancellor and bishop of Winchester, founder of Magdalen college, Oxford, took his name from his birthplace, Wainfleet-All-Saints, in Lincolnshire. Little is known about his early years, but he evidently established a reputation as a scholar before he became master of Winchester college in 1429. In 1442 he went to Eton where he is believed to have acted as master; it is known that he was provost in Sept. 1443. In 1447 he was consecrated bishop of Winchester, which office he retained until his death at Bishop's Waltham, Hampshire, on Aug. 11, 1486.

In 1448 he began his great work, the establishment of the College of St. Mary Magdalen, Oxford, but the wars hindered the completion of his plans and it was not until 1480 that the college was fully working. The statutes of the college were modeled on those of William Wykeham for New college, but with some important differences. Waynflete's 70 scholars were divided into 40 fellows and 30 junior scholars. Waynflete attached great importance to grammar as a foundation for further studies. A master and usher were in charge of the grammar teaching and three readers were appointed to lecture on theology and different branches of philosophy. Their stipends were on a generous scale and they were the first endowed teachers of the university. Magdalen college took a leading part in Renaissance studies. Waynflete's suppression of religious houses to increase the endowment of his college set an example for Cardinal Wolsey. In 1484 it is thought that Waynflete began building Magdalen college school, Brackley, Northamptonshire.

When Jack Cade's rebellion occurred in 1450 Waynflete was employed with Archbishop Stafford, the lord chancellor, to negotiate with the rebels. A full pardon was promised, but afterward he was one of the special commissioners to try the rebels. In 1457, as chancellor, Waynflete took part in the trial and condemnation for heresy of Reginald Pecock, whose books were then burned. He resigned the chancellorship upon the Yorkist success in 1460, but came to no harm in the changing fortunes of the Wars of the Roses.

See H. A. Wilson, *Magdalen College,* pp. 1–48 (1899). (S. J. C.)

WAYS AND MEANS COMMITTEE. The traditional name in English-speaking countries for the committee responsible for revenue legislation in the lower house of the national legislative body. The nature of the committee, however, is different in Great Britain and other countries with the parliamentary form of government from what it is in the United States.

In Great Britain, the committee on ways and means consists of the entire house of commons, meeting under somewhat different rules from those prevailing for the house itself. This practice formally originated in 1707, but had actually developed on an informal basis at an earlier date. It developed primarily because the speaker of the house was at that time a designee of the crown, and parliament wished to increase its independence of the crown and its privacy in acting on revenue measures by meeting under the chairmanship of one of its own members. At first the term "committee of the whole house" was used. By the middle of the 17th century the practice had developed of using two designations for the house meeting as a committee — supply, and ways and means. The former dealt with expenditures, the latter with voting the money to meet the expenditures, and providing for methods of financing.

When the house meets as the committee on ways and means the chancellor of the exchequer presents his budget statement. The committee immediately votes on the proposed resolutions to authorize continuation of existing taxes, make changes in taxes or add new levies. The resolutions passed by the committee are then submitted to the house itself, meeting under its normal rules, and their contents are incorporated into the finance bill. This bill is subject to debate on second reading, and is open to amendments which may reduce taxation but not increase it.

The Canadian version of the ways and means committee is similar to the British. The committee consists of the entire membership of the house of commons meeting in this capacity and thus under less formal rules than those applying to the house itself. However, unlike the British practice, each paragraph of the resolutions relating to tax changes is explained, discussed and debated while the house is in committee. When the resolutions relating to the changes have been approved by the committee on ways and means, a report is made to the house itself. Amending bills are then introduced, debated and enacted.

In the United States, the ways and means committee, consisting in the late 1950s and early 1960s of 25 members of the house of representatives, handles all measures in the house relating to the raising of revenues, including taxes, tariffs, social security levies and debt policy. This was one of the earliest committees established in the house, first as a select or special committee in 1795, and then as a permanent or standing committee in 1802. The committee originally handled both appropriations and revenue measures, but this placed a heavy work load on the committee and concentrated too much power in its hands. To remedy this situation control of expenditure measures was transferred to an appropriations committee, established in 1865. Since the constitution provides that all revenue legislation must originate in the house of representatives, the ways and means committee occupied a somewhat more strategic position than its senate counterpart, the finance committee. Gradually, however, the senate adopted the practice of making drastic changes in tax measures approved by the house, and the position of the two houses is now in practice more nearly equal. The ways and means committee, however, makes more detailed examination of tax questions than does the senate committee.

Under practice as evolved by 1960, most changes made in tax legislation originate in the committee itself, initiated either by recommendations of the president and the secretary of the treasury, or by the work of the committee. The committee holds lengthy and detailed public hearings on proposed tax legislation, with testimony from various business, farm, labour and other organized groups, the treasury and interested individuals. Next, meeting in executive session, the committee reaches its decisions and brings forth a measure to the house. Under usual rules of the house, debate is limited and amendments are not permitted. The house can, of course, reject the measure, but it rarely does so. The bill as passed by the house then follows the usual procedure for legislation. Bills on revenue matters introduced by individual house members are referred to the committee but rarely receive serious consideration.

The distribution of membership on the committee is established roughly in proportion to the relative membership of the two parties in the house. The senior majority member is chairman. This position is one of great influence, both with regard to the selection of measures on which committee action is to be taken and the actual contents of the revenue measures.

WAZIRABAD, a municipality and tehsil (subdistrict) in Gujranwala district, Lahore division, West Pakistan. The town, near the left bank of the Chenab river, is 62 mi. N. of the city of Lahore.

The population of the town was 33,027 in 1951.

It is an important railway junction. The main line of the North-Western railway there crosses the Chenab by the Alexandra bridge, opened in 1876. Boat building and manufactures of steel and iron are carried on. Wazirabad tehsil had a population of 217,198 in 1951.

WAZIRISTAN, a mountain tract in West Pakistan, between Dera Ismail Khan, Bannu and Kohat districts (Dera Ismail Khan division) and the Afghanistan frontier, which was there demarcated in 1894; total area 4,473 sq.mi. The tract is controlled as two agencies—NORTH WAZIRISTAN (pop., 1951, 128,235) and SOUTH WAZIRISTAN (pop., 1951, 135,784) — administered by the central government through an agent (ex officio the commissioner of the Dera Ismail Khan division, to which for all practical purposes they are attached).

The central range of Waziristan is enclosed on the north by the Tochi valley and on the south and west by that of the Gomal; it is connected with the great limestone ranges of the Suliman hills to the south, and dominated by the great peaks of Shuidar (Sheikh Haidar) and Pirghal, both of them between 11,000 and 12,000 ft. above the sea. From these peaks a view is obtained westward across the grass slopes and cedar woods of Birmal and Shawal to the long, serrated ridges of the central watershed which shuts off the plains of Ghazni. To the eastward several lines of drainage strike away toward the Indus, and are, as usual, the main avenues of approach to the interior of the country. They are the Khaisora and the Shakdu on the north, which, uniting, join the Tochi south of Bannu, and the Tank Zam (which is also called Khaisor near its head) on the south. The two former lead from the frontier to the military station of Razmak and the village of Makin, situated on the slopes of Shuidar, and the latter leads to Kaniguram, the Waziri capital and the centre of a considerable iron trade. Kaniguram lies at the foot of the Pirghal mountain.

The Waziri tribes are the largest on the frontier, but their state of civilization is very low. Neighbouring Mohammedan tribes, seem inclined to deny their title to belong to the faith.

Except in a few of the highest hills, which are well wooded, the Waziri country is a mass of rock and stones, bearing a poor growth of grass and thinly sprinkled with dark evergreen bushes.

The Waziris are divided into two main sections, the Darwesh Khel. referred to as "Wazirs," and the ilfahsuds.

The Darwesh Khel are the more settled and civilized of the two, and inhabit the lower hills bordering on Kohat and Bannu districts and the ground lying on both sides of the Kurram river. between Thal on the north and the Tochi valley on the south. The Mahsuds, who inhabit the tract of country lying betneen the Tochi valley on the north and the Gomal river on the south, have earned for themselves an evil name as the most confirmed raiders on the border. The Mahsud country is more difficult even than Tirah. The Tochi valley is inhabited by a degraded Pathan tribe, known as Dauris, who placed themselves under British protection in 1895.

Following the independence of Pakistan in 1947, and the accession of the tribal areas to the new dominion, attempts were intensified to foster education, industry and agriculture in those areas.

Campaigns in Waziristan.—British expeditions were needed against various sections of the Waziris in 1852, 1859, 1860, 1881, 1894, 1897, 1902, 1917, 1919–20, 1922, 1936–37 and during World War II.

There is no need to recount in detail the course of the earlier expeditions into Waziristan. In 1860, after some sharp minor actions, a column of all arms occupied Kaniguram and Makin, the centres of population in the Mahsud country; and the success of Sir Robert Sandeman (*q.v.*) in subduing the Baluchi tribes after 1866 subsequently led to similar attempts to open up Waziristan to British civilization. In 1879, however, the Mahsuds had to be subjected to an economic blockade, and in 1893 a well-conducted expedition under Sir W. Lockhart overran Waziristan. The Pathan was much more democratic and much less subject to the influence of his maliks than was the Baluchi to the authority of his chiefs, and the policy of civilization by influence finally broke down in 1894, when the Waziris made a night attack upon the camp of the British delimitation commission at Wana. The attack was delivered with such determination that the tribesmen penetrated into the centre of the camp, and it was only with the greatest difficulty that friend could be distinguished from foe. A force of 11,000 British troops subsequently traversed the tribal country, destroyed the toners and dictated terms. one of which was that the Tochi valley should be occupied by British garrisons. In 1896 Wana was occupied at the request of the Wazirs themselves. But still there was trouble. leading to the Tochi expedition of 1897. In 1900 a second blockade of the illahsuds was initiated, but dragged on for over a year until several columns had devastated the most fertile of the Mahsud valleys. In 1902 attempts to "Sandemanize" Waziristan were given up by Lord Curzon. In 1917 a brief expedition penetrated up the Shahur river and effected a temporary submission of the Mahsuds.

The close of World War I was followed in May 1919 by the outbreak of the third Afghan War. For some time past Wazirs and Mahsuds alike, excited by Afghan propaganda. had been growing bolder in their brigandage. The climax came when the evacuation of the military posts maintained in the Tochi and Gomal valleys was effected. These trade routes had in the past been guarded by fortified posts garrisoned by native forces known as the Northern and Southern Waziristan militia respectively. These forces. composed of tribesmen under British officers, with few exceptions deserted early in 1919, and thereby provided their Mahsud compatriots with an invaluable stock of rifles and ammunition; while, more serious still. they formed a nucleus of skilled leaders for the *lashkars*. However, in Nov. 1919 an expeditionary force was placed under the command of Maj. Gen. S. H. Climo. This force amounted to 30,000 combatants, figures later augmented.

On Nov. 17, General Climo received unconditional surrender of the Tochi Wazir tribes at Datta Khel. It was now decided to move the striking force to the Tank Zam valley and to advance in one column by that route to Kaniguram and Makin in the heart of the Mahsud country. The force was completely assembled at Jandola on the Tank Zam by Dec. 13, whereupon a beginning was made to picket the valley on either flank by crowning the heights with small fortified works.

On Dec. 17 the Mahsuds made a fierce onslaught on the advanced troops of the striking force, or "Derajat column," under cover of a parley. They were driven back and the column moved next day. An attempt to seize Mandanna hill, made on the 19th, failed. A second attempt. on the 20th, conducted by stronger forces and supported by aircraft, met with negligible resistance. Leaving 100 men to complete the fortification of a detached post on the hill, the troops returned to camp. No sooner had they withdrawn than a fierce Nahsud attack swept away the remaining detachment, and the hill was lost again. A similar attempt to seize Tarakai or Black hill on the 22nd eventually succeeded. The Mahsud losses, occasioned by some close-quarter fighting and artillery fire: proved very heavy for this class of warfare. Tarakai was held as the enemy retired.

On Dec. 25 Mandanna hill was occupied afresh and permanently. An advance of four miles was made to Kotkai where the column remained until Jan. 7, preparing to force a precipitous defile known as the Ahnai Tangi. Three attempts, on the 7th, 9th and 10th, failed. In view of this situation, now daily growing more unsatisfactory, Gen. Andrew Skeen ordered a night march for the small hours of the 11th. On the 14th the entire column passed through the defile.

The task was still formidable. The eastern bank of the Tank Zam was formed by two long ridges, the nearer being christened Flathead Left and the farther Flathead Right, while to the north of a deep depression came yet another height dubbed Marble Arch. The right flank guard soon became heavily engaged on Flathead Left while the advanced guard met with a heavy fire from Marble Arch and was checked. After a savage action at close quarters, Flathead Left was taken and held throughout the day, aircraft contributing to this result. After a night march on the 28th, the column passed through the gorge.

Although the Mahsud resistance was on the wane, Afghan emissaries were busy stirring them to further efforts. Two Afghan mountain guns arrived to reinforce moral persuasion. On Feb, 1 General Skeen once more ordered a night march against the Mahsud position, held in great strength, near Aka Khel. A striking success resulted; the enemy's resistance collapsed with no seeming hope of its reviving; Afghan help did not materialize, while the two mountain guns proved a dismal failure. But the Mahsuds showed no sign of accepting the government's terms and so the column marched farther up the Tank Zam valley. A coercive policy was now enforced. appropriate measures being taken for the destruction of hfahsud property.

On Feb. 16 the column arrived at Tauda China, 2 mi. from Makin, which centre of population and agriculture. failing submission by the Mahsuds, was to be ravaged. According to the terms of an ultimatum, the days of grace expired on Feb. 19. when, until the 29th, the fortified Mahsud villages were systematically shelled or raided. On March 2 the column moved to Kaniguram, the only so-called "town" of the Mahsud country. The place itself was not occupied, the troops being kept within a fortified camp constructed at Ladha close by the town. A certain number of rifles were surrendered, but as a whole the Mahsuds remained untamed and hostile. The column remained at Ladha when, on April 6, it carried out an important punitive operation northwest of Kaniguram. This showed the tribesmen to be still as contumacious and bellicose as ever. Ladha was consequently converted into a standing camp connected with Tank by a strong series of posts down the Tank Zam valley. The Waziristan force was reduced, the Derajat column as such was broken up; one brigade remained at Ladha while another guarded the road to Tank. Then finally, in the autumn, the long-deferred expedition to Wana was organized as the Wana Wazirs had failed to comply with the government's demands for reparation for the outrages of 1918–19. Moreover, the Wazirs were then undoubtedly harbouring Afghan agents who were intriguing against the government of India.

On Nov. 12 the Wana column, commanded by Maj. Gen. W. S. Leslie, left Jandola for Sarwekai where a lengthy pause was made. Then, on Dec. 15, the troops moved again and reached Wana on Dec. 22. The only incident of the advance was a spirited little affair at the pass of Granai Mara Narai where a night march once more dislodged the Wazirs from their position virtually without fighting. The beginning of 1921 thus found a brigade of Indian troops at Ladha and Wana respectively with every prospect of a permanent occupation of Waziristan. But a great circular motor road was now to be constructed from Bannu up the Tochi valley; thence across the passes to Razmak and so down the whole Tank Zam valley to Tank. This road would allow of military operations being conducted under very different conditions to those prevailing in 1919–20. Moreover, the royal air force was now in possession of a new aerodrome at Dardoni in the Tochi valley. Lastly, two 6-in, howitzers were to be stationed at Ladha.

At the close of 1922, on the impending completion of the new motor road, the garrison of Ladha was ordered to move into the new and more salubrious camp of Razmak. The Mahsuds, mistaking this change for a symptom of weakness, committed acts of open hostility. The situation grew so bad that punitive operations became inevitable. The plan of operations was for one brigade to advance from Razmak and to unite with the brigade from Ladha in the Makin area. Before this could be effected the last stages of the motor road had to be completed and this proved an arduous task. Starting from Idak in the Tochi valley the 7th brigade reached Razmak on Jan. 23, then effecting a junction with the 9th brigade from Ladha on Feb. 4 at Tauda China. The Makin area was once more devastated; aeroplanes, 6-in. and 3.7-in. howitzers were all employed in the task. By the 12th enough destruction had been accomplished, and on the 22nd the last recalcitrant tribes made their submission.

After many years of peace, serious fighting once more took place in 1936–37 because of the anti-British activities of the fakir of Ipi. Punitive operations were also necessary during World War II.

WAZZAN, a small town: 60 mi. N.W. by N. of Fez, Morocco, on the slopes of the Djebel Bu-Hallal. Pop. (1952) of Wazzan, chief town of a territory, 21,353. It manufactures a coarse woollen cloth, from which the hooded cloaks (called *jellábs*) are made. There is Dar D'manah — "House of Safety" — as it is sanctuary for any who gain its limits, on account of the tomb of a sainted Idrisi Sherif who lived there in 1727 and was the founder of one of the important religious brotherhoods of the Moslem world, called the Taibiya. After the conquest of Algeria the sherifs of Wazzan, chiefs of the brotherhood, were placed under the protection of France. French troops occupied Wazzan in 1920. (P. W. I.)

WEADOCK, THOMAS ADDIS EMMET (1850–1938), U.S. lawyer, legislator and jurist, was born in Ballygarrett, County Wexford, Ire.. on Jan. 1, 1850. He was brought to the United States in infancy, his family settling on a farm near St. Marys, O. He was educated there and taught in the district schools nearby before receiving his L.L.B. degree from the University of Michigan, Ann Arbor, in 1873.

Admitted to the Ohio and Michigan bars in that year, he began practice in Bay City, Mich., was prosecuting attorney (1877–78) and mayor (1883–85), and served as a Democratic representative in the 52nd and 53rd congresses (1891–9j), refusing to try for re-election in 1894. He resumed law practice in Detroit, mas appointed professor of law at the University of Detroit in 1912 and served as a justice of the supreme court of Michigan in 1933–34. He died in Detroit on Nov. 18, 1938.

WEAGANT, ROY ALEXANDER (1881–1942), U.S. electrical engineer and inventor, who helped solve the problem of static in radio, was born on March 29, 1881, in Morrisburg, Ont. His great-grandfather had gone to Canada from Baltimore, Md., early in the 19th century. In 1884 the Weagants moved to Derby Line, Vt.. and after the death of the father, the widow's marriage to a U.S. citizen gave her and her son U.S. citizenship. Weagant studied two years at Stanstead college and received his B.S. degree from McGill university (Montreal. Que.) in 1905.

He worked successively for the Montreal Light, Heat and Pomer company (1906); Westinghouse Electric and Manufacturing company in Pittsburgh. Pa. (1907); De Laval Steam Turbine company, Trenton. N.J. (1908): and National Electric Signaling company (1908–13). He was chief engineer of the Marconi Wireless Telegraph company (1915–20), and in 1919 completed the invention which reduced static and also reduced power needed and eliminated the need for tall steel towers. He was consulting engineer for the Radio Corporation of America, successor to the Marconi company (1920–24). After 1924 he was chief engineer and vice-president of the De Forest Radio company and consultant patent expert for the Radio Corporation of America. He received the Morris-Liebman prize for his static-reducing invention.

Weagant died in Newport, Vt., on Aug. 23, 1942.

WEA INDIANS, a subtribe of the Miami, a tribe of North American Indians of Algonkin stock.

The name Wea was probably contracted from *Wawiaqtenang,* the name for place of the round, or curved, channel; or from *Wayahtónuki,* "eddy people," from *wayaqtonwi,* or eddy.

The Jesuit Relation (1673) reported the tribe in eastern Wisconsin; they later lived in western Wisconsin. In 1719 their chief village, Ouiatenon, which became a French trading centre, was on the Wabash river near Wea creek, Ind. The Wea, also representing the Piankashaw Indians, signed the treaty of Greenville, O., Aug. 3, 1795. By 1820 they had sold all their land in Indiana and, with the Piankashaw, went to Illinois and Missouri. In 1832 they sold their claims there and followed other members of the group to Kansas. The Wea and Piankashaw joined the Illinois, known then as the Kaskaskia and Peoria. in 1854, the consolidated group totalling only 259. They went to northeastern Oklahoma in 1868.

WEAKFISH (Cynoscion regalis), an important North American food fish, so-called from its tender mouth. It inhabits sandy shores of the Atlantic coast from Cape Cod to Florida and is greenish-brown above, silvery below, with brown markings. The weakfish is known as squeteague in New England, as weakfish in New Jersey, and as sea trout in Chesapeake bay and to the south. It rarely reaches a weight of 30 lb. (average 5 lb.). The commercial fishery centres in Chesapeake bay, to which fish spawned in waters both to the north and to the south migrate. It is a popular sport fish, especially from Long Island to Chesapeake bay.

WEAKLEY, ROBERT (1764–1845), U.S. soldier and legislator, who was active in the founding of the state of Tennessee, was born in Halifax co., Va., on July 20, 1764. He attended schools in Princeton, N.J., until at the age of 16 he entered the Revolutionary army and served to the end of the war. In 1785, with the horse he rode and $1.75, he went to the territory west of the Alleghenies which North Carolina later ceded for the creation of the state of Tennessee. Weakley fought in the wars with the Creek and Cherokee Indians under James Robertson, rising to the rank of colonel.

In 1789 when he was 22, Weakley was a member of the North Carolina convention that ratified the Constitution of the United States. He was elected to the house of representatives in the first Tennessee general assembly in 1796, and served as a representative from Tennessee in the 11th congress from 1809 to 1811. He served in the senate of the general assembly in 1811, 1819 and 1823-24, in the last two cases being the speaker. In 1819 he was U.S. commissioner in negotiations with the Chickasaw Indians. In 1834 he was a member of the convention which wrote the second of Tennessee's constitutions.

He died near Nashville. Tenn., on Feb. 4, 1845, and was buried at his estate, "Lockland," near there.

WEALD, THE, an area about 100 mi. long and 40 mi. broad in southeast England, enclosed by the continuous chalk escarpment

(180 mi. long) of the North and South Downs. Within the chalk, forming roughly concentric rings, are outcrops of Upper Greensand, Gault, Lower Greensand, Weald Clay and, in the centre, the Hasting Sands which stretch from Horsham to Hastings and rise in places to 800 ft. It is drained by rivers running through gaps in the Downs (*q.v.*): the Wey, Mole, Darent, Medway and Stour to the north and the Arun, Adur, Ouse and Cuckmere to the south. The Forest Ridges (High Weald), running east to west in the centre of the area, divide the Yale of Sussex from the Vale of Kent. The total area under forest about 1660 was more than 200,000 ac.; the chief remains are Ashdown, St. Leonard's and Tilgate forests. The Weald is stil! heavily wooded, though the area is mostly agricultural and. in parts, residential.

The National trust owns about 100 areas (including historic buildings) within the region.

There are Mesolithic, Neolithic, Bronze and Iron Age sites. The Romans called the great forest Sylva Anderida (the Roman port Anderida is now Pevensey, the coast being then different in outlinej and the Anglo-Saxons named it Andredsweald. The forests were used extensively for fuel in the ironworks of Sussex, which were worked by the Romans and earlier! became important in the 16th and 17th centuries and died out early in the 19th century. Stane street was built by the Romans across the Weald from Chichester to London. In 477 the South Saxons descended from over the sea upon the Sussex coast, to which they gave their name, and populated it. Name endings of towns and villages bear witness to early settlements: those ending in *-ing* are the oldest; *-ham* is also early; *-ton* is later and *-hurst* and *-den* later still.

See S. W. Wooldridge and F. Goldring, *The* Weald (London, Toronto, 1953).

WEALE, JOHN (1791–1862), English pcblisher, born in 1791, issued many technical books and educational works; particularly in the field of architecture.

He published *Catalogue of Works on Architecture and the Fine Arts* (1854), a bibliographical work; *A Series of Examples in Architectural Engineering and Mechanical Drawing* (London, 1841); *Designs of Ornamental Gates, Lodges, Palisading, and Ironwork of the Royal Parks Adjoining the Metropolis, Edited by John Weale* (London, 1841); *The Theory, Practice, and Architecture of Bridges of Stone, Iron, Timber, and Wire, Edited by Jolzn Weale,* 2 vol. (London, 1843); *Letter to Lord John Russell on the Defence of the Country* (London, 1847); *Rudimentary Dictionary of Terms Used in Architecture, Building, and Engineering* (1849–50; jth ed., 1876); *Designs and Examples of Cottages, Villas, and Country Houses* (London, 1857); *Old English and French Ornaments, Comprising 244 Designs. Collected by John Weale* (London) 1858). Weale was editor of *Weale's* Quar*terly Papers on Engineering* (London, 1843–46) and *Weale's* Quar*terly Papers on Architecture* (London, 1843–4j).

He died in London on Dec. 18. 1862.

WEALTH AND INCOME. The term "wealth" commonly refers to the stock of economically significant objects or items owned by a particular unit—a nation, a class or an individual. When applied to the individual the concept appears to be relatively clear and free from ambiguity. It denotes his holdings of various assets—real property, securities, intangibles such as copyrights and patents and money—minus his debts or obligations. Even in this case questions can arise as to the inclusion and valuation of certain assets. When dealing with the wealth of a nation, these questions are more insistent, and they can be answered in various ways depending upon the precise use to which the concept or measure is to be put. Nevertheless, despite possible differences in meaning, the different wealth concepts will have. as we shall see, a common feature: the idea of a *stock* or *inventory* existing at a certain date or point in time.

The term "income," by contrast. is concerned with a *flow* over a period of time: a flow of earnings, or purchasing power, or economically significant items for any period of time—usually a year. Even if we could determine the income level for a certain day. or for one minute or one second of that day, it would still have to do with a flow of "economically significant" iteins during the relevant period of time. The analogy is frequently used of wealth as a lake and income as a stream flowing into it, or through it, at a certain rate per unit of time. More concretely, the stock of wheat (so many bushels) would then be a component of wealth; the production of wheat (so many bushels a year, or a month) would be a part of income.

Many of the questions that arise about whether to include and if so how to value items in the measure of wealth arc bound to come up again in estimating income. However, there is not an exact parallelism in the answers given. Certain items which are commonly included in income have no place in wealth, and vice versa, and it follows that the analogy set out above is by no means exact. The water which fills the lake is not of precisely the same composition as the water that runs down the stream.

NATIONAL WEALTH

The determination of what to count in wealth is necessarily arbitrary, chiefly because the decision as to what items are economically significant depends upon the nature of the inquiry. Items which possess no value in the market presumably do not qualify, for the fact that they are free is an indication either that they are not wanted or alternatively that, like air, though useful they are available in amounts that exceed requirements. In either case, such items would not be economically significant for they are not economized. Items which though desired and relatively scarce are not marketed—for instance, labour in any but a slave economy—would normally be omitted too because there is no way to set a value upon it. But what about durable goods in the possession of consumers—say, vacuum cleaners and refrigerators? What about nondurable goods owned by business firms, or their intangible assets, like patents and good will? And what about items which cannot be reproduced—for instance, subsoil wealth, or a Gutenberg Bible? And finally, to illustrate the complexity of the problem with one more example, what should be done with items which have only a military value—long-range jet bombers; for instance? No simple rule can be laid down that would be appropriate in all circumstances. If we are interested in measuring aealth because it provides one indication of the economy's capacity to produce, we should probably not find it advisable to include consumer durables or military equipment, though we should want to cover the value of such nonreproducible items as land and subsoil wealth. If, instead, our concern is with wealth as an index of economic growth, we might exclude the category of nonreproducible items which, after all, are not created when the economy progresses, while we would include most of the other categories.

Unfortunately the decision as to whether items of a certain kind are to be included in the concept or not must rest in many cases on a quite different ground—namely, whether adequate data can be secured. In most cases, for instance, it is quite impracticable to collect reliable information as to the value of the various intangible assets of business firms—their good will, patents and so on—because firms typically set down only a nominal figure for such assets in their balance sheets.

It will be noticed that no mention has been made of holdings of securities—government bonds, for instance—and money. When we are dealing with the wealth of an individual or a particular group in the economy, such an ornission would be a mistake. Quite properly an individual's bank deposit and cash holdings are counted as a part of his wealth. But the situation is somewhat different when we are dealing with the wealth of a nation.

This is not because the value of the money or securities suddenly disappears as our interest is transferred from the individual to the nation. The reason is, instead, that though their value to their holders continues to be recognized, so too must the obligations they impose upon their issuers. Just as they are clearly assets to their owners, so are they liabilities of an equal amount to the firms: government bodies or banks which have created them. Thus, when individual wealth accounts are consolidated to form the nation's account, these assets are offset by matching liabilities. There is no such offsetting for the other items of wealth noted earlier. Hence, in determining a nation's wealth. holdings of money and securities (and other evidences of debt) are commonly neglected.

There is one exception to this rule which it is worth while to note. There may be assets owned in one country which represent a debt of residents of another. Confining our attention to the mealth of either country, the worth of these assets is not offset by liabilities. Holdings of Canadian government bonds in the United States would then be counted as an item in the wealth of the Cnited States, while U.S. holdings of the bonds of its own government would have to be ignored. Likewise, Canadian-owned deposits in a United States bank would be a part of Canada's wealth, while Canadian holdings of deposits in Canadian banks would not be included. We conclude then that financial assets, apart from those which are international in scope, do not constitute part of a nation's wealth. Only real assets, perhaps together with such intangibles as patents (if their value can be estimated) and selected intangibles would make up a nation's wealth.

A highly regarded estimate of United States national wealth! prepared by Raymond W. Goldsmith (*A Study of Saving in the United States*, vol. iii, Princeton, N.J., London, 1956), illustrates the composition of U.S. mealth. In 1949 the total stood at more than $950,000,000,000 in prices of that date. The components of this total (in such prices) follow, in billions of dollars:

Reproducible tangible durable wealth (except consumer durables)	$593.7
Durable consumer goods	99.3
International assets	45.3
Land and subsoil wealth	160.0
Military tangible durable assets	70.4
Total	$968.6

This is perhaps as broad an estimate as could ever be required. For most purposes, one or more of the items listed here would be dropped. Incidentally, it should be pointed out that the accuracy of some of these estimates is distinctly questionable.

There is an inclination to regard a nation's wealth as synonymous with, or at least a very good index of, the economic well-being of its residents. This tendency should be resisted. While a country with great wealth is likely to provide its residents with a high level of living, such a result is by no means a certainty. Other factors, notably the size and ability of its labour force, the level of their employment and the technical skill with which its productive factors are administered, help to determine the economic results, and their influence may be predominant. A country with immense stores of mineral resources but with an inadequate technology or a serious shortage of skilled labour would be unable to provide a high level of economic well-being. An adequate national wealth is a necessary but not a sufficient condition for real prosperity.

Recognizing this fact, some economists have sought to extend the concept over a wider range. Some discussions of national wealth refer to gifts of nature — climate, rivers, coast line and so on; to a country's labour force, as the living depository of skills and productive power; and to the moral characteristics of the population. All these, and many other conditions under which a nation lives and thrives, are important in determining its productive capacity. But if the concept of national wealth is to have a measurable counterpart and is to be useful in economic analysis, it must be limited to goods external to members of the nation, goods that enter into economic transactions and find a measurable value on the markets of the economy.

The problem of measuring or valuing the components of the national wealth must be considered briefly. These components include a wide variety of goods reducible to a common denominator only through the yardstick of the market price. But of all these goods, only a small percentage changes hands and passes through the market during the year. For this reason, special difficulties are encountered in establishing realistic current valuation indices for most of the components of the national wealth. The prices of the new additions to wealth can usually be recorded, but the reassessment of durable items (which have in all likelihood depreciated too) in a period of changing prices is bound to raise serious problems.

The national wealth total as a stock of tangible commodities usually includes: (1) land for various uses (agricultural, industrial plant location, houses, etc.) and the stock of mineral resources in the land; (2) construction and various types of improvement attached to land (houses, plants, roads, bridges, etc.); (3) durable equipment in the hands of enterprises (machinery, tools, rolling stock, etc); (4) inventories of goods in the hands of business enterprises and other producing agencies; (5) stocks of goods, mostly durable and semidurable, in the hands of ultimate consumers (automobiles, furniture and clothing. in the households). The sum total of values for these five categories is wealth located within the boundaries of the country. In order to convert it into national uealth, *i.e.*, wealth owned by the nation's members, either individually or collectively. one must add: (6) the excess (positive or negative) of claims by the nation's members against foreign countries over the claims by foreigners against the members of the nation (usually designated the net balance of foreign claims).

Referring again to the data already supplied on the national wealth of the United States in 1949, and to the source there noted for further details. we find that on the broadest possible concept (nhich includes military assets) wealth in structures (housing, business plant and government buildings) came to 42% of the total; wealth in equipment (including consumer durables but excluding military items), to 21% of the total; in inventories, to about 8.6%; in military items, about 7.25% of the total; in the form of nonreproducible assets (land and subsoil wealth), to 16.5%; and in international assets, to about 4.75%. Reproducible wealth, that is, the total excluding land and irreproducible resources. was about $808,600,000,000 (in 1949 prices) and the relative weight of its various components — structures, equipment, inventories and so on — is shifted accordingly.

Naturally, the physical assets composition of national wealth differs from country to country, and for the same ,country from time to time — largely with the stage of economic development. In countries that are not developed industrially and in which the per capita income level is relatively low, land and irreproducible resources are naturally a much larger percentage of total wealth; reproducible wealth is proportionately less significant; stocks of goods in the hands of consumers tend to be relatively low; and the net balance of foreign claims is likely to be negative rather than positive. In countries in which agriculture is proportionately less important than in the United States, *e.g.*, Great Britain, the relative weight of land is smaller; and, before World War II the net balance of foreign claims loomed larger in total wealth.

Control Over **Physical** Assets. — The physical assets constituting national wealth can also be classified by the type of economic agent that has direct control over them (who or what makes use of them). The most common basis of classification distinguishes business enterprises (as unincorporated, nonfinancial corporations and various forms of financial institutions); households (nonfarm and farm); government (federal, state and local and government corporations); and nonprofit institutions. This kind of classification must be distinguished from a related one, that in which the assets are shown in accordance with their ultimate owners. The obvious purpose of this present scheme is to relate the existing stock of mealth to the various types of use to which it is put.

Such a classification can be illustrated for 1949; once again the results are R. W. Goldsmith's. Of the approximately $880,000,000,000 of tangible assets (nonmilitary) in the country (in 1949 prices) in 1949, nonfarm households had about 38%; farm households. 14%; nonfinancial corporations, 23%; financial institutions, 3%; government (including nonprofit institutions), 16%; and unincorporated business, 6%. Naturally, the kinds of assets each sector held had their own special features, nonfarm households having very nearly 60% of their holdings of tangible assets in the form of residential structures, while farm households held only 10% in this form.

The basic tripartite division among consumers, business and government, and the industrial distribution within the business sector, are likely to vary from country to country and from time to time. In the United States the share of government increased perceptibly in the 1930s and 1940s so that at mid-century it was nearly double what it had been 50 years before; it was much less than 10% in the 19th century. Likewise, with the rise in the level of living and increased use of durable goods, the share of consumer wealth may have been higher in later decades than in the 19th century Shifts in the industrial structure of an economy over time or differences in structure among different countries are naturally reflected in the industrial attachment of wealth within the business sector proper. However, industries differ in their ratio of capital or wealth to output, so that shares of industries in total wealth are not necessarily identical with their shares in total output.

Ownership of Wealth. — Attaching values to the various physical items that enter the stock of wealth is not the only way of estimating its value. An alternative approach can be followed which leads to a different system of classification and to a different set of insights. Each item of wealth is owned by somebody, either an individual or a collective, and that ownership. certified as it is in some overt form, can ordinarily be valued. By adding the values of all the ownership claims of private individuals, whether to commodities used by them directly or to those used by firms. and to this subtotal adding the value of the wealth owned by collectives, net of any claims by individuals (since these are already counted), one should get an alternative figure for national wealth. The classification suggested by this ownership or claims approach is between privately and collectively owned wealth; and within the former class; by type of private owner. classified, for instance, by size of holdings or level of income. Instead then of looking at the objects owned, one may study the owners and the amounts they hold.

The claims approach will not necessarily yield a total for national wealth identical with. or as reliable as. the totals derived from taking an inventory of physical assets. The market value of an indirect claim to a physical asset, in the form, for instance: of a share of common stock in a business firm, is subject to violent fluctuations and sometimes does not appear to be closely related to the values oi the underlying physical assets estsblished by independent methods, say cost or reproduction value. Since the market value of such claims is so unstable, this method of estimating national wealth may not give a very reliable picture of the country's productive power. or of its past investment or prospective capital needs. And yet for certain purposes, notably when the behaviour of agents is influenced by what they regard as the value of their holdings, the claims approach is a sound one. Even when it is desirable, however, the investigator may have to face technical difficulties in getting reliable information on holdings of claims from individuals, since individuals are usually reluctant to provide such data, and they are not likely to be well informed: in any event, about the value of their holdings.

Nevertheless, the claims approach has been widely used in several countries, based either directly upon some current statistics of ownership by living persons. or more often upon data on estates of decedents. The former must always be supplemented by data on physical assets, to check on underreporting, to cover cases of direct owner use and to include assets by collectives not offset by private claims on them. The estates data involve the difficult problem of passing from wealth of the decedent to that of the living population. The derivation of the necessary conversion coefficients is difficult, since accurate data on mortality rates among different economic groups in the population are not usually available. Only once was a census of wealth based on a direct questionnaire survey of the population (in Australia in 1917).

Distribution of Wealth by Size of **Holdings.**—The claims approach to national wealth. although of limited value in estimating the total, is useful in describing the distribution of wealth among individuals by the size of their holdings, or their income, or by some other variable. For the United Stares, information on the distribution of wealth by households has been gathered periodically for the survey of consumer finances. The results for early 1950 were brought together in vol. iii of A *Study* of *Saving in the United States*. Although there is obvious underreporting for some categories, and there are serious problems in proceeding from results based upon a relatively small sample to the whole population, the results are nevertheless suggestive. The households' total asset holdings as covered in the survey came to $613,000,000,000—about two-thirds of the amount which the alternative method of estimating national wealth indicated. Households with more than $60,000 of wealth held about 32% of the total wealth; these households constituted about 3% of all families. The approximately 8% of families whose wealth was between $25,000 and $50,000 had about 23% of the total wealth. The 17% of all families whose wealth amounted to less than $400 had among them negative wealth amounting to 1.5% of the total. And finally, the 50% of all families which had wealth of less than $4,900 owned only 6% of all household wealth.

Another approach to the question of the distribution of wealth can be obtained from reports on the distribution of income from property (dividends, rent and interest). On the basis of reasonable assumptions, it can be inferred that the distribution of property incomes by size among individuals reflects the distribution of wealth by size of holdings, at least of income-yielding wealth (excluding stocks of consumer goods, although the size of such holdings is likely to be positively associated with the size of property in income-yielding wealth).

The distribution of wealth among individuals is much more unequal than is that of income. Thus during the period between World Wars I and II. the top 5% of the income population of the United States received from 25% to 30% of total income. During the same period, they received about 77% of all dividends paid to individuals, 42% of all interest and about 38% of all rent—a total of about 54% of all property incomes. These percentages are measures of the minimum rather than the true inequality in the distribution of income-yielding wealth by size of holdings. In England and \Vales, 1% of the population 2j years and over owned 55% of the total property in private hands in 1936, and 60% of that property in 1925–28.

National and Group Balance Sheets. — Describing and analyzing the structure of claims and obligations attached to the physical assets that comprise the national wealth is an aspect of the claims approach which was still in its early development in the 1950s. The machinery, buildings and inventories used by a business firm are the subject of clainis of the firm's stockholders and creditors; and these claims may be in part overlaid by the claims of their creditors — for instance. claims of depositors in banks which have made loans to the firm. When national wealth is estimated by adding net claims: only the residual figure enters; claims and counterclaims partially offset one another. But in order to analyze and understand the behaviour of groups of enterprises and ultimate consumers, it may be important to establish for each group or subgroup the full complex of assets, real and financial: and obligations to which each is subject, without any cancelling and netting. This is because we can probably expect economic units with the same net worth but with different structures of assets and liabilities (for instance, assets of different liquidity) to behave differently.

Probably the greatest value of the claims approach to the determination of national wealth lies just here; not that it provides a superior estimate of the total, but rather that, almost as a by-product, it supplies detailed information about the multiple structure of claims and obligations, assets and liabilities of particular groups of enterprises and ultimate consumers. Data available for these purposes are of rather recent origin. and were not fully adequate for the task in the latter 1950s. A start had been made, however, and Raymond Goldsmith set out both national and sector balance sheets for a number of years between 1896 and 1949 in vol. iii of his *Study of Saving in the Cnited States.*

Uses of National Wealth Estimates. — Estimates of national wealth reach at least as far back as those for national income — in some countries to the late 17th century (Great Britain) and in increasing numbers during the 19th century. Indeed, in the latter century more attention mas paid to estimates of national wealth than to those of national income. The reasons, which can only be conjectured, lay partly in the emphasis on the need for accumulation of capital (business and consumers') to satisfy the demands of a growing industrial system and a rapidly growing population; partly in the concern in some countries about the size of the national debt; and partly in the greater ease with which the scanty statistical data could be used to identify the major blocks of tangible wealth, as contrasted with the difficulty of getting an adequate picture of the flows constituting national product. Only in the years after 1920 did the emphasis definitely shift toward national income, with comparative neglect of work on national wealth totals.

In considering the uses of national wealth estimates, two qualifications already indicated must be reiterated. First, the estimated total of national wealth. being limited to alienable economic goods, falls far short of measuring the sum total of a country's productive capacity, of revealing the variety of factors that condition the latter. Second, the valuation of national wealth is a difficult problem because only a small proportion of it, often under atypical conditions. passes through and is evaluated on the markets of the economy in any given year.

Within these major qualifying limitations national wealth estimates serve t o important groups of uses—corresponding to the real assets and claims approaches respectively. The first group comprises uses of estimated stocks of goods as elements in the framework of a producing economy. Comparisons of stocks of plant, equipment and inventories used by producing enterprises with their output of current product, or the amount of labour they use, for industrial sectors in the same country over time or for various countries at a given time. even for national aggregates, shed light on the ways in which technological and other changes affect the demand for accumulated capital. Comparisons of stocks of consumers' capital (houses, durable goods, etc.) with the demand for their services illuminate factors in the structure of current and prospective production and suggest the role of saving in this particular investment process. Value of land and other nonreproducible assets, in comparison with other factors, provides light on the dependence of production on natural resources in different countries and in different times. In these ways. data on wealth as a stock of tangible commodities are indispensable for analysis of the operation of the productive system, and particularly of the extent to which accumulation of capital is a prerequisite of levels of productive performance, in their changes over time or in their differences across space. Current discussions of capital needs of underdeveloped countries, or of the presumptive slackening of demand for capital in the mature economies, are conspicuous examples of the uses to which estimates of national wealth and their physical components are put.

Somewhat less developed, but of obviously equal importance, is the type of use connected with the claims approach. The influence of the structure of assets and liabilities on the behaviour of enterprises and of individuals is obvious, particularly for the short run. The extent to which the real assets of the economy are controlled by productive enterprises, or by financial institutions that serve as intermediaries between the ultimate savers and the ultimate users of capital funds, or by government either as a fund supplier or guarantor, is important in understanding the functioning of the economy. This and related aspects of national wealth as a network of claims and obligations call for tracing the latter from their attachment to real assets in the hands of producers to claims in the hands of ultimate savers.

Naturally, effective use of the national wealth estimates, like that of any empirical measure, is contingent upon adequate knowledge both of the statistical characteristics of the estimates and of the system of analysis that provides the framework within which the estimates must be built. Progress in understanding of the wealth aspect of economic structures is made by a continuous interplay of empirically grounded hypotheses nith proper absorption of additional data relating to an increasing variety of historical periods and types of national economies.

NATIONAL INCOME

The concept of individual income is a relatively familiar one.—the earnings per unit of time. The very notion of earnings implies that the payments received are payments for something; presumably for productive services rendered. We associate wage and salary income with the payment for work performed; rent and interest income, with the payment for the use of property and liquid assets; and profit with the payment for entrepreneurial services. When we move from a consideration of the individual to the nation we find a counterpart to income regarded as a total of earnings which corresponds to real assets as the wealth counterpart to the value of claims. It is the value of the economy's production, which is merely another way of indicating the total value of all services rendered by the economy's factors of production. By looking at the national income from these two different aspects, a good deal of significant information can be secured.

A number of questions, somewhat analogous to those already considered in connection with wealth, must first be dealt with.

If the national income corresponds to the value (appropriately measured) of the nation's production: only payments for co-operating in "production" are to be counted. What about. then, payments made to the unemployed, under an unemployment insurance scheme? It is agreed, generally, that since such payments are not made for a productive service, they should not be included. In most countries a similar ruling has been adopted for payments of interest on government debt. There is certainly no suggestion that these payments are undeserved; whether they are a part of the national income or not has nothing at all to do with that question. But they do not correspond to an act of production, and as a result they are not counted as earned income. (To make matters more confusing, they are a part of what is called personal income.) Unlike them, payments of interest on private debt, as for instance on corporation bonds, are commonly treated as payments for productive services, and hence do constitute a part of the national income.

The value of goods or services which are priced on the market is recorded at the price the market actually sets. In an economy like that of the United States or Great Britain, the greater part of output is so valued. But even in so preponderantly private an economy as the former. some output does not pass through the ordinary market. As an example, consider the services of schoolteachers engaged in the public-school system. How should their output be valued? Or the output of military personnel? Or policemen? The usual procedure is to suppose it to be equal to the earnings of those who render the service. Then the national income and its counterpart, the value of the economy's production, include the pay of government employees, including those in the armed forces.

As a rule, production can only proceed at the cost of "using up" existing wealth. Stocks of raw materials are of course consumed when production goes on. If we are to have a meaningful concept of the nation's production, we are bound to allow for this. The gross national product, a measure in frequent use. actually takes the value of the economy's production after allowing for the consumption of raw material and other inventories.

But there is another kind of capital consumption to be taken into account too—the depreciation of capital assets. Depending upon the purpose of the measure, we may wish to subtract this figure from the gross national product. If we do, we have what is technically known as the net national product. The brevity of this account should not suggest that the determination of either of these allowances—the using-up of goods in inventory and the wearing out of more durable assets—is a simple matter. Serious problems, not only of statistical methodology but even of principle, frequently arise.

The value of the output, whether gross or net, is measured by what a market is willing to pay (the purchase price). But that price includes sums that are to be paid directly to the government for either sales or excise taxes. Since these payments cannot constitute income in any sense, output is often valued instead at its market price minus the payments for these taxes—the indirect business taxes as they are called. The net national product valued in this way (at factor cost, to use the technical term) is the output counterpart of the national income.

There is one further point to notice. Allowance is commonly made in output, and hence in the income generated by its production, for certain services for which no transaction occurs. The most important example of this is the use of a house occupied by its owner. Had the house been occupied by a tenant, his rental would have measured the value of the service he purchased; that sum would have entered into the national income, and also the net national product. at factor cost. When the house is not rented but instead provides accommodation for the owner, it is now the common practice to set a value for the service it provides and to add this both to income and output. Certain other imputations are made too; for example, the value of agricultural product consumed on the farm.

It can be argued that the value of housework done by the housewife should be regarded as a part of the national product and of national income. If any payment is made for the work, its value is counted; in principle. But the line is usually drawn at this point. If the work is not paid for it is not included in the total.

It might also be argued that if the value of the use of existing houses is treated as a part of the national product and income, a similar allowance should be made for the use of the stocks of durable consumer goods: home furnishings, refrigerators. automobiles, etc. But again. the rule that has been followed allows these entries only if payment is received for their use—for taxis or rented furniture. for example. but not for the nonbusiness use of an automobile by its owner. It cannot be denied that these rulings are somewhat arbitrary. They can perhaps find some justification in the fact that almost all countries, except for the Soviet bloc, follow them.

Source of Income, by Sector.—We may briefly note that various aspects of the national income, rather like those already considered in connection with the national wealth, may be described. We may. for instance, secure data on the relative importance of the different sectors of the economy as sources of income. The United States department of commerce, responsible for the "official" estimates of the national income, presented the data given in Table I for 1929 and 1953. The changes in the relative standing of each sector should be noted.

TABLE I.—*Sources of U.S. National Income*
(in $000,000,000)

Source	1929	1953
Total U.S. national income	87.4	305.0
Originating in agriculture	8.0	16.8
in mining	2.1	5.5
in contract construction	3.7	15.2
in manufacturing	22.0	97.3
in trade	13.1	52.3
in transportation	6.6	16.0
in communications and public utilities	2.9	10.2
in service	10.2	28.8
in government	5.1	33.9
in finance	13.1	26.4
in rest of the world	0.6	1.5

Distribution of Income, by Function.— The division of income between labour and property and then among different kinds of property holders can also be described. Official data for 1954 is given in Table II.

TABLE II.—*Division of U.S. National Income, 1954*
(in $000,000,000)

National income	$299.7
Compensation of employees	207.9
Property income	91.8
Proprietors and rental	40.4
Corporate profits (before taxes)	33.8
Net interest	9.6

Distribution of Income, by Income Class.—A great deal of information has become available on the share in total income of the different income classes or occupational groups. Much of this information is secured by the federal reserve board's annual survey of consumer finances (results of these surveys are generally carried in several numbers of *The Federal Reserve Bulletin,* beginning in the spring). Reference should also be made to the report of the U.S. department of commerce: *Income Distribution in the United States* (1953).

One form in which the data are presented is especially familiar, though it can be somewhat misleading. From it we can learn that in 1935–36, 43.5% of families had incomes of less than $1,000. and their income totalled $9,150,000,000. In 1953 only 5.7% of the families were in this category, and they earned a total of $1,430,000,000. The danger in using statistics in this form is that, with changing prices, an income of $1,000 in 1935–36 would have to be matched against one of nearly $2,000 in 1953. With no change in the real distribution of income, in a period of rising prices there would be a decrease in the number receiving less than some low figure, and an increase in the number who got more than a specified relatively high figure.

TABLE III.—*Percentage Shares of Family Personal Income*

percentage group	1953	1947
Lowest 20%	5.0	5.0
Second quintile	11.3	11.0
Third quintile	16.5	16.0
Fourth quintile	22.3	22.0
Top 20%	44.9	46.0
Top 5%	20.7	20.9

A more satisfactory procedure is to set the share of aggregate income received by a particular percentage of income recipients —say by the top 5% or the lowest quintile. Table III, adapted from U.S. department of commerce statistics, illustrates the form.

A slight tendency to more nearly equal incomes can be observed between 1947 and 1953. Comparing post-World War II data with those for the years before the war (1935–36 or 1941), a more pronounced shift in the direction of equality can be seen.

NATIONAL WEALTH AND INCOME COMPARED

National wealth and income do not cover exactly the same things, as we have seen. Moreover, their components necessarily have to be valued differently. For this reason caution must be exercised in comparing the two totals.

Nevertheless, the significant relation between the national wealth and income totals warrants comparisons despite qualifications imposed by the difficulties of establishing full statistical comparability. If national wealth is limited to reproducible goods that can ordinarily be duplicated in the process of production, the origin of the stock is exclusively in the past process of production; and one can calculate. by comparing it with national income as a measure of total annual output; how many years' supply national wealth represents. Comparisons for several countries in 1914 and for a much smaller number of countries in later years (largely just before World War II) show that the ratio of reproducible wealth to annual national income ranges from four to one to six to one; in other words, it equals the nation's total output for about four to six years. In general, the higher ratios characterize the older countries. like the United Kingdom, France and Germany; and the lower ratios the younger countries with somewhat higher per capita income levels: like the United States and Australia.

It may at first seem surprising that the total stock of wealth (excluding land and irreproducible mineral resources) should equal only four to six years' output. But this obviously does not mean that it could be recreated in four to six years. Most annual output goes into current consumption and not into saving and accumulation of wealth. If we assume an investment-income ratio of roughly 10%, it would take 40 to 60 years, not 4 to 6, to recreate the existing stock of reproducible wealth. Even this interpretation is unrealistic because in the absence of the existing stock of wealth, the given level of national income could not be attained. All that the comparison means is that given the ratio indicated above, the stock of reproducible national wealth existing at any given moment is the result of accumulation of a past period certainly exceeding 40 to 60 years (to allow for the smaller average size of national income over the decades preceding the point of comparison)—in other words, the savings of at least two generations.

The Real Income.— In periods of rapid price change. the figure for money income for any year can be misleading if set beside the figure for another year. The fact that the price level is different means that even if the real income is unchanged, income expressed in money will be different. For this reason income (and product) and wealth estimates are often prepared on the basis of constant prices—say the prices ruling in 1929 or 1947. There is no room here to suggest the many problems that arise in recomputing these values in prices of another period. It is enough to urge that the results have to be treated with caution.

Statistics of Wealth and Income.— National income estimates have been prepared, with varying degrees of detail. by government agencies of a number of countries, and many of these are published periodically as official documents. Of about 50 or more such estimates assembled by the statistical office of the United Nations at mid-20th century (covering figures back to 1938 when available. and released in reports under the general title *National Income Statistics*) considerably more than half are prepared and published by government agencies. Of the remainder quite a number are prepared by semipublic institutions. Uses of national income estimates as comprehensive records of a country's economic activity. as bases for government policy and economic planning and as indices for allocation of contributions and for policy making by international agencies warranted active interest by governments in their preparation and publication in an increasing number of countries. It should be noted, however. that some governments prepared estimates without releasing them; this was true after World War II of the U.S.S.R. and countries in the Soviet bloc! as they began to view such data as having strategic importance to be withheld for presumptive security reasons.

No such widespread information was available at mid-20th century on national wealth. Apparently periodic estimates of the stock of goods are considered less useful than annual measures of the current flow of total output. Even in the United States the decennial census of wealth. a long-standing practice. had been abandoned partly because of a clearer realization of the difficulties involved in securing reliable figures, partly because the availability of annual national income figures had lessened the need for wealth estimates. The last census of wealth in the United States was taken for 1922; those that would ordinarily have been taken for 1932 and 1942 were omitted, the former because it was felt that the depressed conditions of the time would yield atypical values and the latter because of the pressure of war problems. In other countries. interest in estimates of national wealth was also lagging, although some pressure for them had been stirred by attempts to gauge damages caused by World War II (with resulting rough figures, not widely released, for China, Japan, the Netherlands and France).

This contrast between the emphasis on income estimates and the neglect of wealth estimates might well be a passing phase. Because of the technical and analytical relations between the two measures, the development and use of the income estimates were likely to be hindered by a complete neglect of the wealth side of the economic picture. Once the current estimates of national income reached the stage of development where they became directly useful in the study of saving, investment and capital accumulation. pressure would arise for better and more current estimates of at least reproducible wealth. Indeed, interest in national wealth had already been revived and exploration of wealth estimates renewed by national income analysts in the United States and elsewhere.

The long history of national income and wealth statistics goes back to the late 17th or early 18th century in some of the western countries. Government interest and responsibility for national income estimates are quite modern. Even in the Cnited States and the United Kingdom, no official estimates were available before the 1930s and the 1940s respectively (except for some sporadic cases). Preparation of national income estimates for the most part had been the labour of individual scholars. The same was largely true of national wealth estimates: except for the official decennial series in the United States and occasional government estimates elsewhere. This origin in work by individual scholars meant that the national income and wealth estimates were not prepared regularly and were diverse in quality — reflecting differences in the supply of data and the statistical skill, diligence and imagination of the individual authors.

Because of this diversity in quality. compilations of the results would be most useful if made with a critical review of each author's work and with full knowledge of the statistics for the country and for the period to which the figures apply. Such a task, especially if attempted on an international scale. would demand on the part of the compiler omniscience, critical thoroughness and unusual diligence. Naturally, the compilations of available past estimates (see *Bibliography* below) fall short of this ideal. They are useful, however, as reference lists and as preliminary summaries, even though they must be supplemented in any serious work by references to the original writings.

Methods of Estimating. — Effective understanding and use of income and wealth statistics depend upon some knowledge of the methods that can and have been used in arriving at the totals and their components; of the questions of definition and valuation that must be answered in the process of estimation; and of the character of the basic data used.

In estimating national income. one or several of four approaches can be employed. (1) For each industry the gross income (value of sales, total revenue or a similar gross volume total) is estimated; then capital depreciation and consumption of products of other industries (materials or services) are subtracted to yield net income originating in each industry. The sum of these incomes, plus net balance of income receipts across the boundaries, is the national income total. (2) For each industry, net income originating is derived directly by totalling employee compensation, entrepreneurial income, dividends, interest, rent and undistributed profits of corporations (including, or in some variants excluding, such profits for government). The total of these, plus net balance of income flows across the boundaries. is the national income. (3) From data on income receipts by individuals, the total of all individuals' incomes can be derived, either directly or by supplementing data on income receipts with data from enterprises (using a variant of method 2). To this total of individuals' incomes the undistributed profits of business firms and other producing enterprises (including, or in some variants excluding, those of government) are added, to yield the national income total. (4) The sum of expenditures on consumers' goods by individuals and households, expenditures on net additions to capital goods by business and other producing enterprises (including government, although some variants include expenditures by government on all goods) and net changes in claims against foreign countries will also yield the national income total. Method 1 was used to derive estimates for Sweden for a period extending from 1860 to the later 1930s. Methods 2 and 4 are used to derive estimates for the United States; formerly only method 2 was used. Method 3 has been employed in preparing the estimates for the United Kingdom.

The two basic approaches to estimating national wealth are, as we have already seen, the inventory of physical assets and the valuation of claims. The inventory method has been followed in the census of wealth estimates in the United States. A combination of the two found frequent application in the western European countries in the 19th century. It should be noted that since the estimates of national income by method 4 provide information on current net additions to reproducible wealth, an inventory of physical assets once arrived at in approximating national wealth can be kept perpetual by the addition of net changes derived from the national income estimates for the following periods.

Questions of Definitian and Valuation. — No matter which method is used in deriving income and wealth estimates, questions of definition and valuation are bound to arise. There is first the problem of deciding what activities are to be regarded as economic or what are economically significant goods. Then there is the problem of defining the net output, or income, by allowing for the consumption of capital goods and perhaps, too, for the services to production rendered by government. Finally, there are the many problems of valuation: market value or cost? valuation of goods and services which do not pass through the market? These and other questions like them have already been discussed in some detail.

It is clear from the mere listing of the questions of definition and valuation that national income and wealth totals are synthetic aggregates involving many decisions necessary to render them precise in scope and unequivocal as to the value base used in weighting the numerous components. While, by and large, there is agreement on the answers to these questions, differences in definition and valuation among countries and among periods do exist, and such differences must naturally be examined in any comparison of the resulting figures.

Value of Income and Wealth Statistics. — Despite the margins of error and the controversial questions of definition and valuation, the usefulness of national income and wealth estimates should not be minimized. With all their faults, these estimates indicate important orders of magnitude which are fundamental to any intelligent view of the structure and operations of a national economy. The study and analysis of the economic development of nations and of their adaptations to short-term changes (such as business cycles or wars) are well nigh impossible without national income and its components as measures of total activity and national wealth as the measure of capital stock and of the complex of claims and obligations. Furthermore, public policy on economic problems finds in estimates of national income and wealth valuable means for testing any specific decision by placing it within a broad framework of the operating economy as reflected in these measures. The limitations of the estimates should be recognized and studied as a condition of their effective use and, in the hands of active scholars, as a basis for their further improvement. But they should not lead to a disregard of the high value of these measures, or to a reluctance to use them effectively to narrow the area of ignorance and of disagreements resulting from lack of knowledge.

BIBLIOGRAPHY.—The most complete account of national wealth (U.S.) is to be found in Raymond W. Goldsmith, *A Study of Saving in the United States*, 3 vol. (Princeton, N.J., London, 1955–56). *See* also *Income and Wealth*, series i–iv, published by Bowes and Bowes (Cambridge); Kational Bureau of Economic Research, *Studies in Income and Wealth*, various volumes.

Simon Kuznets *et al.*, *National Product Since* 1869, National Bureau of Economic Research (New York, 1946), and *Long-Term Changes in the National Income of the United States of America Since 1870*, in series ii, *Income and Wealth*.

The most complete listing oi later literature on both national income and wealth is the bibliography prepared by the International Association for Research in Income and Wealth (with headquarters at the National Institute for Economic and Social Research, London). The bibliography which is published by Bowes and Bowes, Cambridge, covers in the first volume, published in 1951, the years from 1938 through 1949, and is kept up to date by annual or biennial volumes.

Statistics on national income for a number of countries are assembled in most convenient iorm in compilations by the Statistical Office of the United Nations. Published volumes are: *Kational Income Statistics, 1938–1947* (1948) and *National Income Statistics, 1938–1948* (1950), both with extensive bibliographies. Several additional surveys and special studies were published by the Statistical Office of the United Nations. Estimates for the United States are published in the *Survey of Current Business*, usually in the July issue of the following year. A most useful assembly oi series and explanatory notes is in "National Income and Product oi the United States, 1929–1953," 1954 supplement to the *Survey of Current Business*. Those for the United Kingdom are released in an annual White Paper.

Of compilations oi past estimates, a later work is Colin Clark, *Conditions of Economic Progress* (New York, London, 1940). An earlier compilation, relating to 1914 but still of value, is that in an article by Lord Stamp, "The Wealth and Income of the Chief Powers" (originally in the *Journal of the Royal Statistical Society*, 1919, and reprinted in *Current Problems of Finance and Government*, London, 1924). For compilation of past estimates of national wealth, Corrado Gini, *L'Ammontare e la Composizione della richezza delle nazioni* (Turin, 1914), while old, is still indispensable. *See* also Richard Stone, *Measurenzent of Sational lnconze and the Construction of Social Accounts*, United Nations (Geneva, 1947). (L. Ts.)

WEAPON, any instrument of offense or defense, more usually a term confined to offensive or attacking instruments.

The word is derived from the Old English *wǣpen;* compare the Dutch *wapen*, the German *Wappe*, also *Wappen*, a coat of arms, heraldic shield.

See AMMUNITION, ARTILLERY; ARMS AND ARMOUR; GUN, MACHINE; HALBERT; LANCE; ORDNANCE; PISTOL; SMALL ARMS, MILITARY; SWORD.

WEAPONS, PRIMITIVE. Among primitive peoples it is often impossible to say of any object whether it is a weapon of war or an implement of agriculture or the chase. Thus in Assam the knife or *dao* fells trees, kills animals, defends its owner against human aggression and takes heads for him. A bow and arrow may be used for war or for hunting only. Instruments of war may be roughly classified as those of offence and defence.

Stones.—The earliest missiles which man or sub-man used were the untrimmed stick or stone, hand-thrown. (For BOWS AND ARROWS, BLOWGUN, and the weapons of civilized peoples *see* separate articles.) To give greater force and carrying power to stones, devices such as the sling and pellet-bow have been constructed. By far the most common sling is the *cord sling*, found sporadically throughout the world. It consists of a wide, short strip of material, which forms a pouch to hold the stone, to the ends of which one or more strings are fastened for grasping in the hand. The *pellet-bow*, a more elaborate contrivance found in India, is a bow fitted with two strings; between these, about half-way down, is a small pouch for holding the stone or clay pellet.

Throwing-sticks and Clubs.—The stick thrown by hand has also become a specialized weapon. As an object for piercing it has developed into the dart, javelin, spear and arrow; as an object for stunning or crushing into the throwing-stick and throwing-club. As an implement of the chase the throwing-stick was used in ancient Egypt and is still found in Abyssinia, India and among the Hopi of North America; as a weapon of war, however, the flat throwing-stick is practically confined to Australia, though two specimens have also been found in the island of Santo (New Hebrides, West Pacific). In Australia the fighting *boomerang* (*q.v.*) is rather long and narrow and curved within the plane of the flattened sides. It differs from the better known returning *boomerang*, which is of lighter build and curved out of the plane of the sides, which propeller-like twist gives it its returning powers. This latter is used exclusively for fowling or as a game. The Australian *waddy*, and the *ulas* of Fiji are throwing-clubs; the former has typically a flat triangular head, the latter is short with a spherical head and a handle carved to make the grip more sure. Other clubs are sometimes thrown without being specially designed for the purpose. The many-bladed throwing-knives of certain tribes in the Sudan, of those throughout the Congo basin and north to Lake Chad are metal derivatives of the African wooden throwing club.

Throwing-spears.—As to piercing missiles, such as darts, javelins and throwing spears, the variety is endless. The simplest are composed of a single piece of wood one end of which is pointed and often hardened in the fire. More usually there is a separate shaft and fore-shaft of which the latter is often heavily barbed by means of carving or the attachment of separate pieces of bone or wood. Heads of obsidian or other stone, bone and—especially in Africa—metal are often added. To give greater range to the throwing spear certain tribes use mechanical aids, of two main varieties, the *spear-thrower* and the *beckett*. The former, constructed of wood or bamboo, performs the function of an extra joint in the arm. The spear lies along the spear thrower, with its butt resting against a projecting peg, or, where the thrower is of bamboo, in the slight socket made by the septum of the node. This device is typical of Australia; it is also used in parts of New Guinea and in some of the islands of Micronesia, and was formerly used in Central and South America, whether in the chase or war is not clear. The Eskimo and tribes of the northwest coast of America also use it for discharging harpoons and fish-spears.

The *beckett* consists of a short length of cord with a knot at one end. It is wrapped once round the spear, the knot passing under the free end and being thereby kept in place. The free end of the cord is then wrapped round the index finger of the throwing hand. The resultant action when the spear is thrown is on the same principle as that of the sling, and the spear is given greater force in its flight than if thrown by hand, and is made to spin as it flies. For use in warfare the *beckett* appears to be restricted to Oceania, but as a toy it is found both in Australia and Europe. A similar contrivance was used by the soldiers of ancient Greece and Rome and also by some North African peoples who may well have borrowed it from them. It differs from the *beckett* in that the cord is attached to the spear and is not retained in the hand.

In East Africa an unusual form of spear-thrower is found. A shaft of wood terminating in a swollen head has this part hollowed out; into it is fitted the butt of the spear. The man then manipulates the thrower as though it were a part of the spear-shaft, but it does not leave his hand.

Bolas.—An unusual missile now used almost exclusively for hunting or as a game is the *bolas*. Among the Patagonians and the Gauchos of La Plata, who formerly used it in warfare, it is composed of three (less commonly two) balls of stone connected with each other at a common centre by thongs several feet long. One ball is usually smaller than the rest, and this is held while whirling the *bolas*. The aim is to entangle the victim in the thongs rather than to kill him. Among the Ho of Togoland, West Africa, a long cord with a stone attached at either end is similarly used for hindering an advancing enemy. Elsewhere a few tribes in Central and East Africa use the same instrument as a toy. The Eskimo uses a many-thonged *bolas* for catching birds.

Thrusting-spears and Clubs. — These are the most important weapons used in hand-to-hand fighting. The former are very similar to the throwing-spears, though usually heavier, and, since nicety of balance is not necessary more often made without a separate foreshaft. Many of them are heavily barbed as in the beautiful specimens found in Fiji. Clubs are of diverse kinds. Primarily they are for bruising or crushing, but some, such as the bird-headed clubs which are used in New Caledonia are well adapted for piercing. A distinction can also be made between those which are all of one piece and those having a head of different material from the shaft — usually of stone. Among those of the former type the business end is usually considerably thicker than the shaft and carved with spikes or rugosities (sometimes in imitation of its prototype the torn-up sapling) which make it more effective; but in the W. Pacific bat-shaped clubs, called by the early travellers "swords," are also found, though to-day they seem to be used more often for ceremonial than for military purposes. Clubs made entirely of any material other than wood are not very common, but the nephrite *mere* and bone *patu* of the Maoris are examples, and also the rhinoceros horn clubs of the Bechuana. These former are not only striking but also thrusting weapons, and are supplied with sharpened edges for the latter purpose.

Poisons. — The art of poisoning their weapons is known to many tribes. The poison is extracted from plants, as the upas tree in Indonesia. and also sometimes from reptiles and insects. In many parts of the world, however, weapons are said to be poisoned but are not, for deaths due to tetanus which so often followed wounds from these have frequently been mis-attributed to poison. The belief arose partly from the statements of the natives themselves, partly from the presence (in the West Pacific) of a green gummy substance at the base of the arrow or spear-heads. The latter is, however. only the vegetable cement fastening head to foreshaft, while the former refer to the magical power supposed to be given the weapon by using human instead of animal bone for the head or barbs.

Primitive Armour. — With the exception of shields, weapons of defense are not common among primitive peoples, though some have armour of a sort. In New Guinea, a few tribes wear a body-covering of basket work, sometimes with a high back to protect the neck and head. In the Gilbert Islands, owing to the dearth of timber, native weapons of the ordinary kind are not found, but in their stead, slender spears and many pronged "swords" edged with sharks' teeth; as a protection against these, armour of coconut fibre is worn often covering the whole person, including the head. From West Africa and among the Baggara of the northeast occasional suits of chain mail have been recorded, probably the result of Arab influence. Plate armour is found in northeast Asia and on the northwest coast of America, and among the Haida cuirasses of wooden or bone slats are used, whose form is reminiscent of this. In Indonesia corselets of hide or basketry and wadded coats covered with feathers give protection, and helmets of cane or skin are also found in this area and in Indo-China, and Assam.

Shields. — Shields vary greatly in material and form. In Africa hide and basketry are much used, the former mainly in the east and south among the cattle-rearing people. In Indonesia, Australia and the Pacific region those of wood are more common, though basketry ones are also found. The Australian shields are small and light, suitable for parrying blows, and in this are similar to those of the Dinka and Mundu of the Sudan; elsewhere they are mostly for covering the most vital parts of the body. The shield is essentially the means of defense for those who use the club and spear and who fight mainly in the open. It is not convenient for a bow and arrow people. since it interferes with the free use of both hands. In New Guinea, however, this difficulty has been overcome. Among the Tapiro pygmies of Netherlands New Guinea a small shield is hung around the neck in a net bag in such a way as to protect the chest. Among the Gulf tribes of Papua a large wooden shield, which has in its upper edge a deep slot for the passage of the left arm, is suspended over the shoulder.

See Horniman Museum Handbook, *Weapons of War and of the Chase.* (C. H. W.)

WEAR, a river in Durham, Eng., rising in the Pennines, and traversing a 65-mi. valley to the North sea. The stream flows east to Bishop Auckland, then, turning northeast, it meanders past the bold rock which bears the cathedral and castle of Durham. Before the Ice Age it joined the Tyne at Newcastle, but now it turns east to Sunderland (*q.v.*) where, near its mouth, the steep banks are lined with shipyards, engineering works and coal-loading and timber-landing wharves.

WEASEL (*Mustela nivalis*), the smallest European species of the group of mammals of which the polecat and stoat are well-known members (*see* CARNIVORA). The weasel has an elongated slender body, head small and flattened, ears short and rounded, neck long and flexible, limbs short, five toes on each foot, all with sharp, compressed, curved claws, tail rather short, slender, cylindrical, and pointed at the tip, and fur short and close. The upper-parts are reddish brown. the under-parts white. In cold regions the weasel turns white in winter, but less regularly and at a lower temperature than the stoat, from which it is distinguished by its smaller size and the absence of the black tail-tip. The length of the head and body of the male is about 8 in., that of the tail $2\frac{1}{2}$ in.; the female is smaller. The weasel is distributed throughout Europe and northern and central Asia; and is represented by closely allied animals in North America. It possesses all the active, courageous and bloodthirsty disposition of the rest of the genus. Mice, rats. water-rats, moles and frogs constitute its principal food. It can pursue its prey not only through holes and crevices and under dense herbage, but can follow it up trees, or into the water, swimming with ease. It constructs a nest of dried leaves and herbage, placed in a hole in the ground or hollow tree, in which it brings up its litter of four to six young ones. The mother will defend her young with the utmost desperation. Instances are known of weasels being met with in packs.

Among the American species may be mentioned the pygmy weasel (*M. rixosa*), probably a race of the true weasels and the long-tailed weasel (*M. frenata)* of the United States, which is chocolate-brown above and may turn white in winter. The short-tailed weasel (M. *cicognani)* is about 5 in. shorter than the last and is darker in summer. It inhabits Canada and the northern United States and the fur is an important source of ermine.

WEATHER FORECASTING is the application of the principles of physics, supplemented with a variety of statistical and empirical techniques, to the problem of prognosticating the weather. The term weather is used here in its widest meaning and includes all atmospheric phenomena which substantially affect man's activities. Included also are certain changes in the earth's surface which are caused by atmospheric conditions. Thus, forecasts of soil frost, snow cover, travel conditions, swell and surf, storm tides and floods are usually referred to as weather forecasts.

After a short section on terminology and time scales, this article is presented in the following major sections:

See also METEOROLOGY and CLIMATE AND CLIMATOLOGY for more general discussions of weather matters. *See* also articles on specific weather phenomena such as CLOUD; FOG; HUMIDITY, ATMOSPHERIC; THUNDERSTORM; TORNADO; and WINDS, GENERAL CIRCULATION OF, etc.

The term weather forecasting was introduced by Robert Fitzroy about 1860 in order to avoid the use of the stricter term prediction and to discourage the use of the looser term prophecy. By mid-20th century what were called numerical predictions (see Forecasting Based on *Physical* Theory and Time-Series Analysis, below) had become possible; these are skeleton prognoses of the large-scale motion and weather systems of the atmosphere by strict numerical processes.

By the late 1950s weather forecasts were provided on a variety of time scales. Warnings of severe local weather, such as tornadoes. destructive gusts and hailstorms, are usually issued 6 to 12 hours in advance and are valid for a period of about 6 hours. The routine forecasts issued to the general public usually cover a period of 24 to 48 hours. Forecasts ranging from a few hours to about two days are referred to as short-range forecasts. In the United States and certain other countries general outlooks for periods covering a week or a month are provided as a public service, and these are referred to as medium-range forecasts. The term long-range forecast is commonly reserved for general and broad outlooks covering one or more seasons or years. The techniques underlying long-range forecasting were in an experimental stage, and the success had not been adequately documented.

I. HISTORICAL

1. Weather Lore.—Long before science began to take form, man noted the characteristics of the seasons, watched the sky and tried to arrange his activities as well as he could according to the changing ueather. Undoubtedly many astute observers were able to gain considerable knowledge of the more typical weather sequences and to formulate rules which were useful on occasions. In the ancient cultures of the near east the weather was believed to be controlled by the gods and the stars. In the Babylonian writings the idea of an astral control was prominent, while the Hebrews expressed strong beliefs in a divine influence. The thought of an extraneous control weakened under the influence of the Greeks and the Romans, and although religious undertones have been strong until modern times there are few reflections of them in the weather lore and proverbs found in the writings of the western world. On the whole. western weather lore may be divided into four main groups in which the future weather is related to: (1) the phases of the moon; (2) the reactions of people and animals to the changing weather conditions; (3) such optical phenomena as rainbows and halos; and (4) certain weather sequences.

The weather proverbs belonging to the first group are generally void of scientific substance; analyses of observations have failed to reveal any lunar influence on the weather processes. and there is no theory to suggest the existence of such influences. A few of the ueather sayings relating to human and animal reactions seem to lend themselves to scientific explanation, in the sense that people and animals react to the existing weather, and the coming weather is often related to that which exists. Some of the sayings relating to optical phenomena are meaningful. For example. the proverb: "When the sun is in its house (halo; q *v.*), it will soon rain," reflects the fact that halos form as a result of refraction of the direct light from the sun or the moon in ice crystal clouds at high levels, and such clouds are often the forerunners of rain-producing weather systems. Some of the weather' proverbs belonging to the group relating to weather sequences reflect sound principles, though most of them cannot be substantiated on scientific grounds. For example, the proverb: "Thunder in spring, cold will bring," reflects the well-known fact that spring thunderstorms in middle latitudes most frequently occur along the forward side of an advancing mass of cold air.

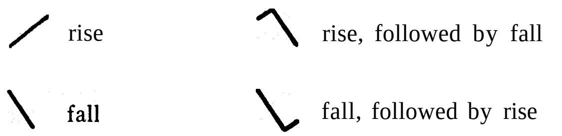
Although some of the weather sayings can be explained in the light of scientific knowledge. their value in forecasting is negligible. On the whole the substance of the weather proverbs falls far short of the considerable weather wisdom possessed by mariners. particularly during the time of sailing ships. By watching the changing sky, the drift of the clouds, the winds, the swell, etc., and by keeping and preserving accurate logs, the mariners accumulated much useful information and used their knowledge to take advantage of the winds and, as far as possible, to avoid devastating storms. After some major sea disasters in Europe in the middle of the 19th century the feasibility of providing a storm warning system became the subject of investigation.

2. Technological Advances.—Although meteorology is as old as the other branches of the physical sciences. weather forecasting as a public service is only about 100 years old. It was only after the invention of the electric telegraph (about 1840) that it became possible to establish a communication system suitable for the rapid collection of weather reports. The first systematic experiments in weather telegraphy and forecasting began about 1860 and were conducted by Robert Fitzroy in England, Urbain Jean Joseph Leverrier in France, and the Smithsonian institution in the United States. A decade later forecasting services had been established in several other countries. Initially, the meteorologists were concerned mainly with the forecasting of major storms. Many of these came from the oceans, and forecasting services were hampered by lack of observations from the high seas. The next advance came from 1900 to 1920 after the invention and development of radiotelegraphy. As radio became standard equipment on ships it became possible to collect weather reports also from ocean areas. At the same time, and particularly after World War I, aircraft equipped with instruments began to provide information on the state of the atmosphere at higher levels: A major advance was made about 1930. At this time development of the radiosonde (see UPPER AIR SOUNDINGS) permitted soundings of temperature, pressure and humidity through the troposphere and lower stratosphere (see ATMOSPHERE). During World War II, the radiosonde was improved to provide also observations of the winds. At the same time radar was developed and used to provide information on clouds and precipitation. In the late 1950s it was much used in locating and tracking thunderstorms, tornadoes and tropical, revolving storms (see RADAR METEOROLOGY). The most recent technological advance affecting weather forecasting is the invention of the electronic computer. Such machines, in a variety of types, have contributed greatly to improvement in the processing of meteorological data, and made it possible to solve many mathematical problems which could not readily be tackled by customary techniques.

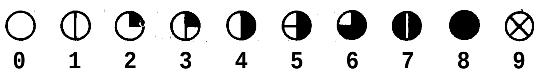
II. BASIC PRACTICES

1. Observations and Reports.—The early experiments in weather telegraphy and forecasting were based upon reports from a few land stations observing once or twice a day. The number of observing stations and the frequency of reports grew slowly until about 1920. With advances in meteorological theory and the development of aviation came demands for denser networks, more frequent observations, upper-air soundings and facilities for rapid exchange of reports between continents. Although much progress was made prior to the outbreak of World War II, it was only after the end of this war that world-wide networks of surface and upper-air stations and meteorological telecommunication channels became established. The international network of observing stations and the telecommunication services continued in a state of expansion, particularly in the regions which were undergoing rapid technological development. In the late 1950s there were about 10.000 ordinary land stations which provided surface reports, and about 1,000 stations which made soundings of temperature. pressure, humidity and wind through the troposphere and lower part of the stratosphere. About 3.000 commercial ships and about 50 specially equipped weather-observing ships provided observations from ocean areas. Several squadrons of aircraft equipped with meteorological instruments and radar engaged in meteorological reconnaissance over ocean areas where ship observations were absent or sparse. Much of the improvement in the forecasting of tropical storms (*q.v.*) resulted from information provided by meteorological reconnaissance. Commercial aircraft provided much useful information on the cloud and wind systems aloft. and a steadily growing network of radar stations gave detailed reports on severe local weather.

To ensure uniformity in the observations and the reporting procedures throughout the world, sets of definitions, scales, standards and codes were adopted in the 1950s by international agreements under the auspices of the World Meteorological organization. Instrumental observations (*e.g.*, pressure and temperature) are reported as numbers, and visual observations (*e.g.*, types of clouds, rain and snow) are translated into numbers according to internationally adopted specifications. The observations are then composed into coded messages and transmitted through established communication networks to all forecasting centres, where the instrumental observations are decoded and plotted as numbers, while visual observations are represented by symbols. An important element in weather forecasting is the barometric tendency, or the change in pressure over the three-hour period preceding the observation. The amount of change is plotted in millibars (mb.) (unit of pressure), and the trend of the barograph trace is indicated by such symbols as

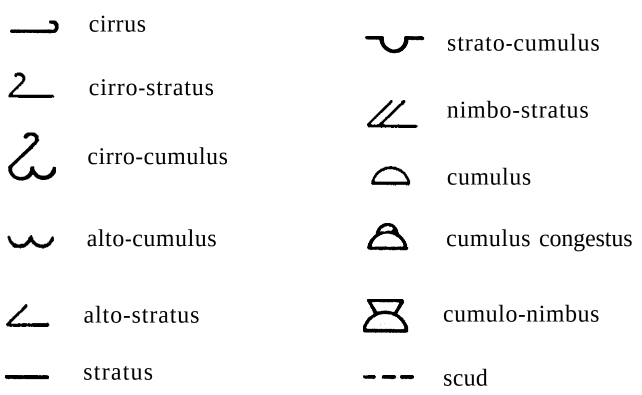


The wind direction and speed art: indicated by an arrow (), the shaft of which indicates the direction from which the wind blows, and the barbs signify the number of knots. A short barb indicates 5 knots, a long barb 10 knots, and a filled triangle 50 knots. The state of the sky, the weather elements, etc., are represented by symbols which, as far as possible, are constructed on mnemonic principles. The observing station is represented by a circle, and the amount of cloud cover is represented on an octadic scale by proportional filling. Thus:

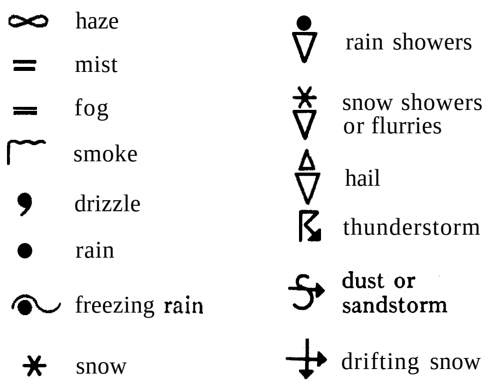


where o means clear sky, and g indicates that the sky is obscured (*e.g.*, by smoke).

The cloud forms are represented by combinations of the following symbols:



The forms of precipitation and the impurities of the air are represented by combinations of symbols, the more important of which are:



The various weather elements are plotted as shown in fig. 1, so that each element occupies a fixed position in relation to the station circle.

2. Analysis. — The weather charts for any extensive region in middle and high latitudes show well-defined pressure systems, the horizontal dimensions of which are generally of the order of a few thousand kilometres. These systems are represented by isobars, or lines which connect the points having the same sea-level pressure. The wind blows nearly along the isobars with low pressure to the left in the northern hemisphere, and low pressure to the right of the wind in the southern hemisphere (*see* also BUYS BALLOT'S LAW). The primary types of such pressure configurations are shown in fig. 2. They are: (1) Areas of low pressure surrounded by closed isobars, commonly called lows, depressions or cyclones. (2) Areas of high pressure surrounded by closed isobars, commonly called highs or anticyclones. (3) Troughs of low pressure along which the direction of the isobars and the accompanying winds change either gradually or abruptly. (4) Ridges or wedges of high pressure along which the direction of the isobars and the accompanying winds change gradually. (5) Cols, or saddle-backed regions, between pairs of highs and lows.

Early experiments in weather forecasting showed that stormy and rainy weather was normally associated uith cyclones and troughs, while fair weather was characteristic of the anticyclones and wedges of high pressure. It is this experience that is reflected in the construction of the aneroid barometer (*see* BAROMETER), where weather notations are affixed to the pressure scale. Furthermore, it was found that the centres of low pressure normally drifted toward the east or northeast, while the high-pressure centres drifted to the southeast or east. Until about 1920 the forecasters were concerned mainly with the charting of the pressure systems and extrapolating the past movements of the systems 24 hours into the future. By using the normal relation between pressure configurations and weather, and by using a number of empirical rules derived from past experiences, forecasts were obtained.

A major advance in weather analysis. with far-reaching effects on modern forecasting procedures. began at the end of World War I when Vilhelm Bjerknes. assisted by Jakob Bjerknes, Tor Bergeron and Halvor Solberg, undertook systematic investigations of the more important weather and motion systems in middle and high latitudes. The research group became widely known as the Norwegian school of weather forecasting, and the techniques developed are generally known as the air-mass and polar-front methods. Bjerknes and collaborators found that the cyclones in middle latitudes were made up of two distinct air masses (*see* AIR MASS) separated by a shallow and sloping layer of transition. One of the masses was found to be cold or cool air of polar origin, and the other was warm and moisture-laden air from the subtropics. The zone of separation between the air masses was called a front (*see* FRONT). Of primary importance is the polar front, or the front that separates the polar and tropical air masses. Important also is the arctic front which separates arctic air from the less extreme air masses in subpolar latitudes.

In normal cases a cyclone would form as an unstable wave disturbance on the polar front; the wave amplitude would grow and the disturbance would gradually develop into a large vortex surrounded by closed isobars. During the development the warm air would ascend over the frontal surface and be replaced by colder air at low levels. The ascending air would cool by expansion, with the result that part of its water vapour content would condense and fall out as precipitation.

The internal processes in the air masses were found to be important also. Thus, a polar air mass would absorb heat and moisture when streaming southward over a warmer surface. As a result, the stratification would become unstable; vertical overturnings would set in, leading to the development of cumulus clouds, showers and, in severe cases. thunderstorms. Conversely. a tropical air mass streaming northward would be cooled by the underlying surface: the air mass would become increasingly stable and part of its water vapour content would condense at low levels, producing low stratus clouds, fogs and drizzle.

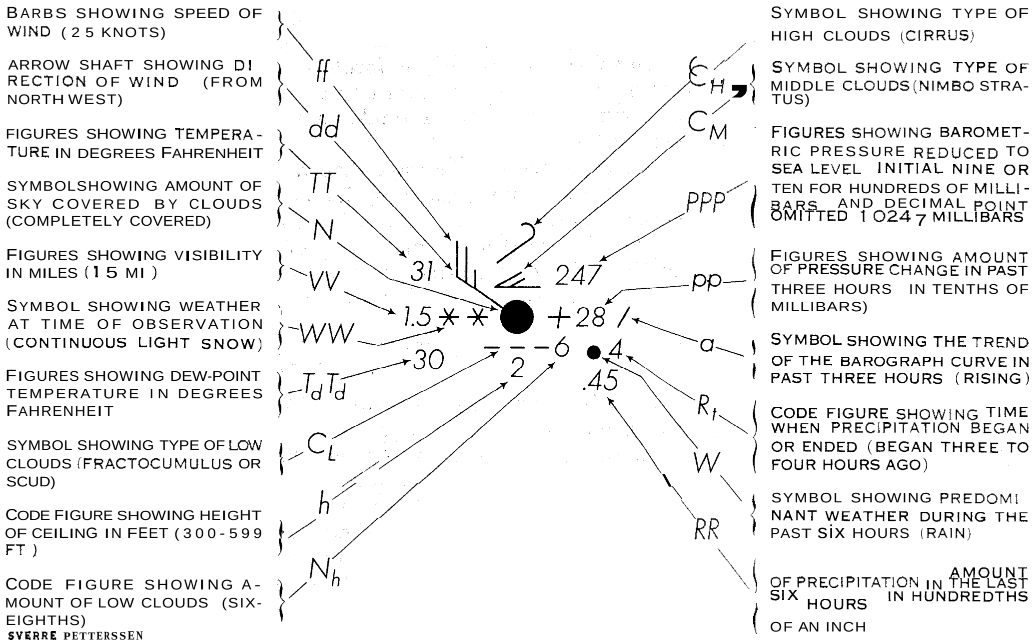


FIG. 1.— PLOTTING MODEL FOR WEATHER OBSERVATIONS

In the scheme developed by the Norwegian school the results of the analyses of the motion and weather systems in the lower atmosphere are represented by a set of symbols, the more important of which are shown in fig. 3. Here, a warm front is one along which warmer air replaces colder air, a cold front is one along which colder air replaces warmer air and an occluded front results when a cold front overtakes a warm front. The motion systems are represented by isobars, and the weather systems are referred to such principal processes as general ascending motion (notably along frontal surfaces), orographic upglide motion and exchange of heat and moisture between the air masses and the underlying surface. The methods of analysis have found world-wide acceptance and their application may be illustrated by reference to fig. 4 (see also SYNOPTIC WEATHER CHART). The low-pressure area near Iceland is recognized as a cyclone in the decaying stage. The warm air has been displaced to higher levels and cooled by expansion; the vortex has become surrounded by cold air which, when streaming southward over the warm Atlantic waters, produces showers and squally weather. The low-pressure area over the eastern part of North America is recognized as a young developing cyclone consisting of a cold and a warm air mass separated by a distinct front. The extensive belt of precipitation is interpreted as being the result of warm air ascending over the frontal surface. Furthermore, the warm air that streams northeastward along the east coast of North America surrenders heat to the underlying surface and produces low stratus clouds and fog. During the following 24-hour period (see fig. 5) the old cyclone near Iceland weakened while the young cyclone over North America moved northeastward, intensified and carried its weather systems with it. At the same time, showers and squally weather developed in the cold air mass that moved from the North American continent onto the warm Atlantic waters.

The analysis techniques developed by the Norwegian school are described in terms of models which represent stages in the evolution of the large-scale motion and weather systems, and these models are used by the forecasters to identify the observed states with stages in evolutionary processes, the broad aspects of which are well understood. In the late 1950s Horace Robert Byers and Tetsuya Fujita developed similar techniques for analyzing small-scale weather systems of the type commonly known as squall lines and clusters of thunderstorms.

The analyses of the conditions of the upper atmosphere are represented in isobaric surfaces, or surfaces in which the atmospheric pressure is constant. The horizontal pressure force is proportional to the slope of an isobaric surface, and the slope is represented by the isohypses (lines connecting points of equal height) of the surface concerned. The wind blows very nearly along the isohypses (fig. 6), with decreasing height to the left of the wind in the northern hemisphere, and decreasing height to the right in the southern hemisphere. The speed of the wind is very nearly inversely proportional to the distance apart of the isohypses. In routine analyses the isohypses are taken to represent the wind. In more detailed analyses the wind field is represented by streamlines, or lines which everywhere are tangent to the wind direction, and isotachs, or lines connecting the points having the same wind speed. This latter type of analysis is widely used in low latitudes where the relation between the wind and the horizontal pressure force is less firm. Methods of analysis suitable for application in the intertropical belt were developed during the 1950s, notably by Clarence E. Palmer and Herbert Riehl. Outside the equatorial belt routine analyses containing isohypses, isotherms and isopleths of moisture content are provided for the levels 850, 700, 500 and 300 mb. The conditions at intermediate levels can normally be obtained with satisfactory accuracy by interpolation. In regions where aircraft operate above the 300 mb. level, additional analyses are provided. At levels above about 100 mb. observations are generally sparse and the analyses less complete.

While the sea-level charts (see fig. 4 and 5) are generally dominated by centres of high pressure and centres of low pressure, surrounded by closed isobars and moderate winds, the predominant feature in the middle and upper troposphere and lower stratosphere is a strong westerly current (see fig. 6) between slowly moving air in the tropical and polar regions. The strong circumpolar current aloft is often concentrated in a narrow meandering band with four or five major waves upon which minor waves are superimposed. Much evidence has accumulated to indicate that the movement and development of such upper waves are closely related to the

development of weather and motion systems near the earth's surface.

III. TECHNIQUES USED IN SHORT-RANGE FORECASTING

The immense complexity of the atmospheric processes is reflected in the methods used in prognostication. It is typical of weather forecasting in the mid-20th century that the methods vary over a wide range. At the one end of the range, use is made of mathematical and statistical operations so complex that high-speed electronic computers are needed to solve the-equations. At the other end, reliance is placed on vaguely formulated experience which has accumulated in the minds of the forecasters after several years of practice. Weather forecasting commenced long before any theory was developed that could explain, even in broad outline, the evolution of the weather and motion systems. Until about 1920 the prognostication was based almost exclusively on practical experience. From 1920 to 1930 the air-mass and frontal methods of analysis were developed. Although these methods did not deal specifically with prognostication, the increased understanding of the large-scale weather processes and the greatly improved analyses that resulted therefrom contributed greatly to improvement in weather forecasting and formed a basis from which specific forecasting techniques could be developed. Most weather forecasts are produced as a compromise between the results of several techniques in which experience and judgment play an important part. In broad outline, distinction may be made between five groups of general techniques used in the preparation of prognostic charts.

1. Computation of Displacements. — In 1933 Sverre Petterssen provided a set of kinematical formulas by the aid of which the rate of movement of well-defined pressure systems could be computed. The types of systems to which the formulas apply are shown in fig. 2. For example, in the case of a trough of low pressure the x-axis, or the axis along which the speed is to be computed, is chosen at right angles to the trough line. If p denotes atmospheric pressure, and *t* denotes time, the formula for the speed (C) of the trough line is

$$C = -\frac{\partial^2 p/\partial x \partial t}{\partial^2 p/\partial x^2} \qquad (1)$$

The rate of movement can thus be computed from the observed distribution of the pressure and the local time rate of change of pressure. Similar formulas hold for the other pressure configurations shown in fig. 2, and other formulas provide estimates of the rate of intensification of pressure systems. In the case of well-defined pressure systems the formulas give fairly accurate results for periods of 12 to 24 hours into the future, but the errors tend to accumulate and the formulas are of little value for longer periods.

The movement of the wave-shaped flow patterns in the upper atmosphere was investigated by Jakob Bjerknes (1937) and Carl-Gustaf Rossby (1939). By using some plausible assumptions Rossby showed that the movement of the long waves aloft was controlled, to a large extent, by the mean zonal speed of the wind (U) and the length (L) of the wave, such that

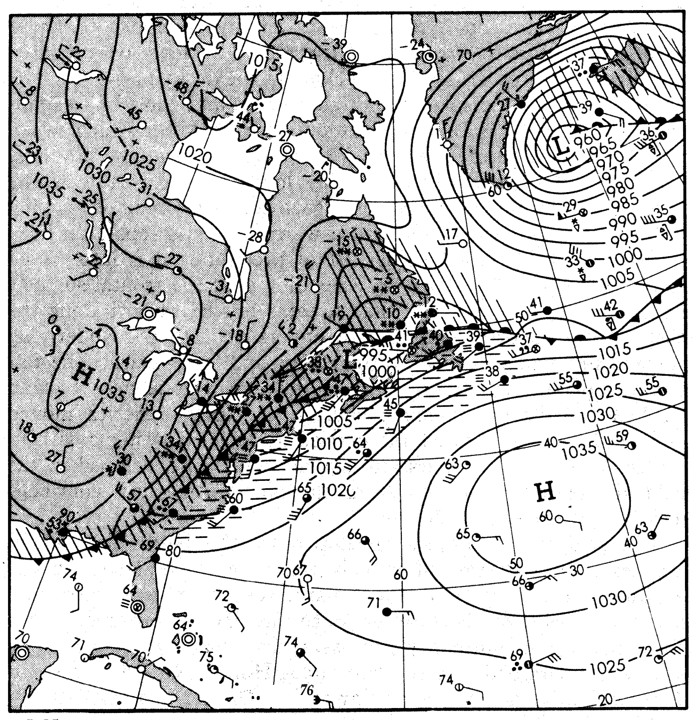
$$C = U - \beta\left(\frac{L}{2\pi}\right)^2 \qquad (2)$$

Here, β is a factor that depends on the earth's rotation and is a function of latitude only. On account of the underlying assumptions, the formula is applicable only at intermediate levels, such as the 500 or 600 mb. surfaces. Rossby's theory was applied extensiveiy by George Cressman, Riehl, and others, who developed a number of rules concerning the influence of the long waves aloft on the development of motion and weather systems at low levels. Rossby also developed a technique for predicting the trajectories of the air in the upper waves. While this technique lacks precision in detail. it has been found useful for estimating changes in the number of waves around the hemisphere.

Rossby's formula was extended by Petterssen, who found that

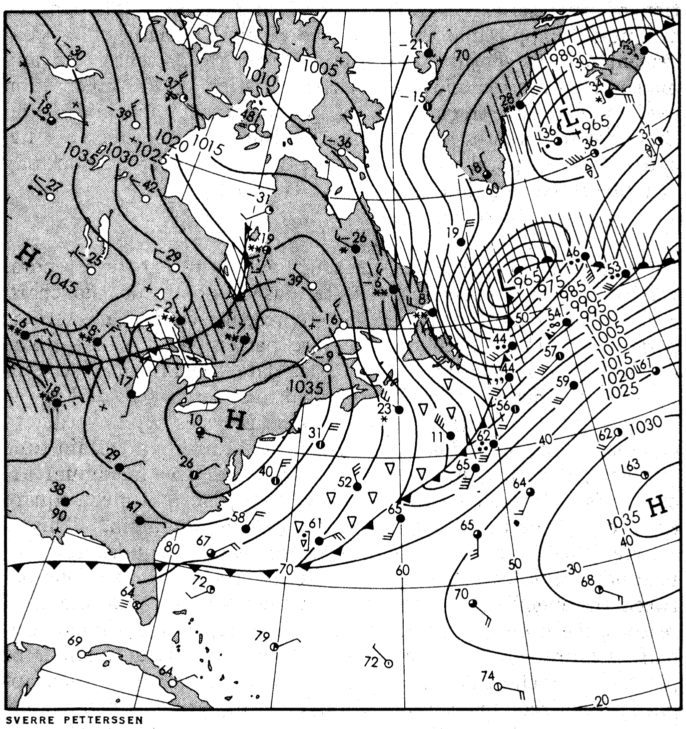
$$C = \frac{U_{max} - \beta\left(\frac{L}{2\pi}\right)^2}{1 + \left(\frac{L}{2\pi B}\right)^2} \qquad (3)$$

Here, U_{max} is the maximum wind speed and B is a measure of the concentration of the current. This formula is applicable to long waves as well as to short waves, and tests have shown that it is capable of predicting the 24-hour displacements of waves with an average error which is about 15% of the observed displacement. Formula (2) is not highly demanding in regard to observations



SVERRE PETTERSSEN

FIG. 4.— AN EXAMPLE OF A WEATHER MAP AT SEA LEVEL: JAN. 23, 1957, 1200 G.C.T. (GREENWICH CIVIL TIME). L AND H REPRESENT CENTRES OF LOW AND HIGH PRESSURE. THE PRESSURE DISTRIBUTION IS REPRESENTED BY ISOBARS AT INTERVALS OF FIVE MILLIBARS. EXPLANATION OF THE OTHER SYMBOLS MAY BE FOUND IN FIG. I AND 3. MUCH OF THE DATA USED IN OBTAINING THE ANALYSIS HAVE BEEN OMITTED



SVERRE PETTERSSEN

FIG. 5.—THE GENERAL WEATHER SITUATION 24 HOURS LATER THAN THAT OF FIG. 4

and is therefore well adapted to general uses. Formula (3), on the other hand, is more demanding and can be used only where the network of upper air observations is relatively dense.

Though the foregoing formulas are simple, several difficulties are encountered in their application. In formula (1) the differential quotients have to be replaced by finite differences, and this may introduce errors, particularly when the systems are small and of irregular shape. All three formulas give only the instantaneous rate of movement, and allowances must be made for accelerations. Furthermore, the formulas can be applied only to special lines and points, and they do not provide information on the movement of the field in general. A far more elaborate technique which, at least in principle, is capable of predicting the changes of continuous fields can be obtained by seeking more complete solutions to the equations of physics.

2. Forecasting Based on Physical Theory.—From the point of view of theoretical physics, weather forecasting may be regarded as an initial-value problem. If, in any physical system, an initial state and the laws that govern its changes are known, the future behaviour can be predicted by mathematical deductions, provided that mathematical techniques are available for obtaining solutions to the governing equations. In the atmosphere none of these prerequisites is fully satisfied. Although the general laws of hydrodynamics and thermodynamics are well established, two formidable difficulties are encountered. In the first place, the structure of the equations that govern the atmospheric processes is so complex that solutions can be obtained only on the basis of several simplifying assumptions. Secondly, and perhaps more restrictive, is the absence of adequate observations, particularly over the oceans and in the polar and equatorial regions.

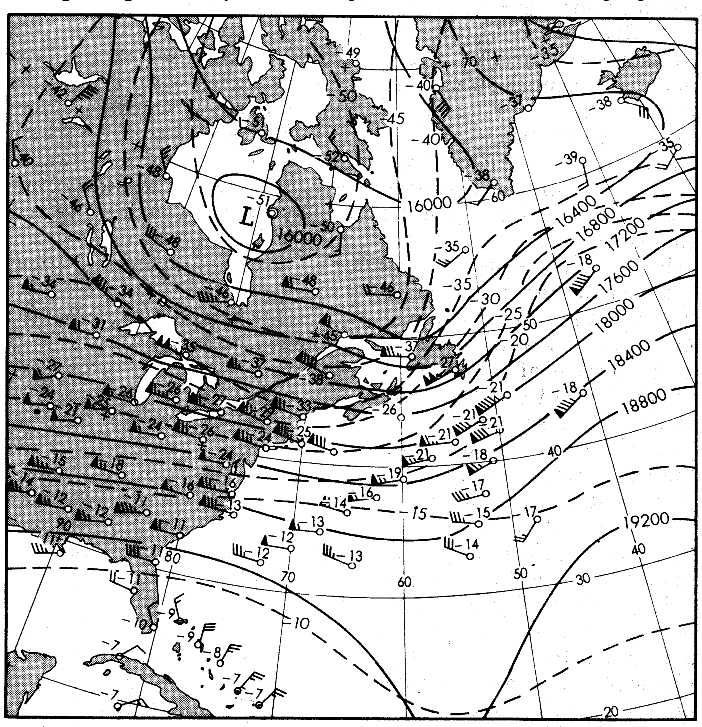
The formulation of weather forecasting as an initial-value problem was first enunciated by Vilhelm Bjerknes in 1904. The first attempt at producing a forecast by this method was made by L. F. Richardson during World War I. Although the results were disappointing from a practical point of view, Richardson's work brought to light some of the difficulties involved and indicated a direction which proved fruitful after upper-air observations and high-speed electronic computers became available.

In 1947 Reginald Cockcroft Sutcliffe outlined a theory for the development of cyclones and anticyclones which lends itself to prognostic application in connection with conventional weather charts. At the same time Jule Gregory Charney devised a scheme for filtering out the effects of inertial and gravitational oscillations, and thus provided a set of simplified differential equations which are capable of representing the changes resulting from the large-scale motion systems with which the predominant weather systems are associated. The basic equations are: (1) the Newtonian equations of motion, which relate the acceleration to the forces; (2) the equation of continuity, which states that the mass is conserved; (3) the thermodynamic energy equation, which relates the supply or removal of heat to the changes in the internal energy and the work done in expansion; and (4) the Boyle-Charles law, which describes the physical state of gases.

This set provides a number of equations equal to the number of unknowns, and solutions are possible in principle. In application to forecasting certain simplifications are used, and the more important ones may be outlined as follows. In the first place, terms representing frictional stresses are omitted. Secondly, the effects of heat and cold sources are ignored, so that the changes of state are assumed to be adiabatic (see ADIABATIC PROCESSES IN ATMOSPHERE). Thirdly, in certain terms which are not highly sensitive, the actual wind is replaced by the geostrophic wind, or the wind that would result if the horizontal pressure force were balanced by the force resulting from the earth's rotation. In the more sensitive terms the characteristics of the wind field are obtained from the equation of continuity.

The structure of the atmosphere is represented by model structures and expressed by a set of equations the number of which depends upon the number of levels for which prognoses are required. Together with suitable boundary condition, the equations are solved by relaxation techniques, using either electronic computers or a graphical procedure developed by Ragnar Fjörtoft. The computations commence with a set of analyzed charts which represent the initial state of the atmosphere at a given time, say t_0. Next, small increments of the pertinent variables are computed for a future time interval At. The increments are then added to the initial values at t_0, and this provides an approximation to the state at the time $t_1 = t_0 + At$. The process is then repeated in small time steps until the end of the forecast period is reached.

Beginning about 1950 several prediction models were proposed



SVERRE PETTERSSEN

FIG. 6.—THE ANALYSIS OF THE CONDITIONS AT THE 500 MB. LEVEL. JAN. 24. 1957, 1500 G.C.T. FULL LINES SHOW THE ISOHYPSES OF THE 500 MB. SURFACE EXPRESSED IN FEET. BROKEN LINES ARE ISOTHERMS EXPRESSED IN DEGREES CENTIGRADE. OTHER SYMBOLS ARE EXPLAINED IN FIG. 1 AND 3

for application to the large-scale motion systems of the atmosphere. The simplest and most thoroughly tested one is the barotropic (*q.v.*) model which is capable of providing prognoses at only one level which must be chosen in the middle troposphere where the divergence of the wind normally is small. Other models provide predictions for two or three levels, one of which may be chosen at or near the earth's surface. The computational work increases rapidly with the number of levels, and models involving more than three levels had not been tried by the late 1950s. Predictions based on physical models were produced on an experimental basis in several countries. In the United States such predictions mere provided routinely and distributed to the forecasting centres, where they were used together with results obtained by other forecasting techniques. The theories and techniques based upon physical prediction models were in a state of rapid development. Experience indicates that these models are capable of providing useful forecasts of the behaviour of the large-scale motion systems in the middle and upper troposphere, while they are less able to account for the changes associated with the smaller and more irregular systems near the surface of the earth.

3. Analogues and Types. — Numerous attempts have been made to classify past weather charts for the purpose of establishing systems of analogues or types which can be used in forecasting. The thought underlying these endeavours has been that if two atmospheric states are similar their evolutions must also be similar. The current weather charts are matched against established types until a maximum of similarity is found, and a forecast is provided on the assumption that the evolution of the current situation will be similar to that indicated by the analogue. Though forecasts based on analogues have been remarkably successful on occasions, failures have been frequent. The selection of pictorial analogues and matching by inspection involves a considerable amount of subjectivity. Furthermore, the variety of atmospheric states is so great that it is not often possible to find within the period for which historical weather charts are available, two situations which are similar in all respects over a sufficiently large area. While analogues and types have proved useful as background information and for broad classification, provision of specific forecasts based on analogues alone has not proved feasible.

4. Regression Equations and Diagrams. — In an endeavour to establish objective forecasting techniques a search has been made for simple statistical relations between past and future events. In the first place, certain parameters, which theory or experience has shown to be importantly related to the weather element to be predicted. are chosen. These parameters are called predictors, while the weather element is called the predictand. Next, a long series of past data is analyzed, and a multiple regression equation between the predictand and the predictors is established. 4 more flexible scheme is to seek graphical relations between the predictors and the predictand. For example, if X_1, X,, X_3 and X_4 are the predictors, the predictand may be plotted in one diagram as a function of X_1 and X_2, and in another diagram as a function of X_3 and X_4. If the predictors are meaningful, the analyses of the diagrams will normally result in the establishment of two separate first approximations (Y_1 and Y_2) to the predictand. A second approximation is then sought by plotting the predictand, in a third diagram, as a function of Y_1 and Y_2. The prediction diagram thus prepared is then tested on an independent set of data to determine its stability.

Prediction diagrams of this type have proved useful in the forecasting of certain weather phenomena in places where a few local influences are so pronounced that a small number of well-chosen parameters suffice to establish useful relationships. For general application the procedure has severe limitations, for most atmospheric phenomena are governed by a complex set of equations, and only solutions to simple equations can be approximated by diagram analyses of this kind.

5. Time-Series Analysis. — A far more ambitious and promising scheme for application of statistical theory to meteorological prediction was initiated by Thomas Francis Malone and collaborators in the mid-1950s. Essentially it consists in an extrapolation of time series as applied to weather charts. Though the technique is applicable to any meteorological variable, it is convenient here to consider only the atmospheric pressure. In any meteorological prediction, the characteristics of the air motion over an extensive region are of predominant importance, and these are well represented by the pressure distribution (*see* fig. 4–6). The temporal variation of pressure at a given station may be represented by a time series $f(t)$. If we let

$$F_i(t) \quad (\text{with } i = 1, 2, 3, \ldots\ldots n)$$

denote a group of such series, the group will represent the temporal variations of the pressure at n stations or points on the chart. Each member of the group will represent some characteristic parameter pertaining to the pressure pattern as a whole. The problem then is to extract from past data the information contained in the history of each individual time series $f(t)$ and in the group $F_i(t)$, from a time as far back as is necessary, in order to extrapolate the individual time series forward over a certain time interval *At*, with a maximum of accuracy. The maximum accuracy is determined by demanding that the root-mean-square error of the extrapolated values shall be a minimum. This is accomplished by establishing an operator which includes autocorrelations within each time series as well as cross correlations between the members of the group of such series. For practical reasons, the pressure distribution, as indicated by continuous isobars, is represented by the pressure values at a large number of points in a rectangular grid. A screening procedure is then applied so that redundant information, or information of little value, is eliminated. The end result is an operator which establishes a relation between the past history of the time series, the current weather charts and the future weather situation.

While forecasts based on physical theory are deterministic, in that they provide one, and only one, solution, the forecasts based on statistical theory are probabilistic, in that they indicate the most probable value and certain limits within which the actual value may be found. Since weather forecasts are used, essentially, for the purpose of minimizing a risk, the probabilistic forecasts are particularly suited to operational needs.

The development of forecasting techniques based upon statistical operators began only in the 1950s, and in the late 1950s such forecasts were provided only by one private organization in the United States. It is evident that this technique incorporates all that can be accomplished by the more limited procedures described in the sections on *Analogues and Types* and on *Regression Equations and Diagrams.*

IV. EXTENDED-RANGE FORECASTING

The time interval for which forecasts can be provided by operations on individual weather charts is limited to about 48 hours. Beyond this range the behaviour of individual weather systems cannot be accounted for by present techniques except in special cases. It is possible, however, to provide general outlooks which indicate the broad aspects of the predominant weather patterns for longer periods. An elaborate scheme for the provision of such outlooks was developed in the U.S. weather bureau by Jerome Namias after 1940. Essentially, the scheme is built around extrapolation of meteorological charts which are averaged over a period of several days. As compared with long-term normals, these charts exhibit well-defined anomalies, the movements of which can be traced and extrapolated. On account of the averaging process, the small and usually fast-moving systems become largely eliminated, while the large centres of action, the main zonal current and the long waves aloft retain their identity. Rossby's theory, to which reference was made earlier, shows that the motion of the long waves aloft is controlled by the wave length and the mean zonal wind. The zonal current averaged around the world is called the zonal index, and empirical evidence shows that the zonal index undergoes certain quasi-rhythmic changes which can be foreshadowed. Rossby's formula (2) is used to compute the movement of the mean long waves, with such empirical corrections as experience has shown to be appropriate. The average weather patterns at sea level, and particularly the anomalies in temperature and rainfall, storm tracks, etc., are related to the positions of the centres of action, the variations in the zonal index and the movement of the long waves, and from various analyses of the mean states, general outlooks for periods from 5 to 30 days are obtained.

V. SPECIAL WEATHER FORECASTS

In all countries weather forecasts for periods of 24 to 48 hours are distributed over customary channels for the information of the general public. Since these forecasts are highly generalized and intended to refer to relatively large areas, they do not readily lend themselves to specific applications, particularly where critical limits and timing of events are involved. Far more useful are the forecasts prepared for operations or conditions the specifications of which are known to the forecasting team. During World War II all major military operations were planned on meteorological advice, and the launchings were timed on the basis of weather forecasts. Of major importance were the highly specialized forecasts prepared for massive air operations in darkness, amphibious operations, etc. The largest of all operations, namely the assault on the continent of Europe by the Allied forces in June 1944, was successfully postponed for 24 hours on the basis of weather forecasts which had to satisfy a number of operational specifications. The importance of military weather forecasting has increased greatly with the increase in military technology, and forecasting services have become integral parts of the military establishments.

After the end of the war, industry and business, particularly in the United States, developed an increasing interest in the application of weather forecasting to their operational problems. In the late 1950s several companies employed weather forecasters, and others obtained services from meteorological consultant firms. The problems in industrial forecasting cover a wide range and include warnings of local floods and storms which may interrupt operations or cause damage; warnings of sea, surf and swell for offshore oil drilling; forecasts of cloud cover, light conditions, etc., for outdoor photography; forecasts for scheduled and nonscheduled aircraft; and forecasts of temperature for shipping of sensitive goods, scheduling of fuel deliveries and regulation of pipeline loads. In general, the special industrial forecasts are based on the public forecasts, supplemented in detail to satisfy the needs of the client.

The types of forecasts issued by the national weather bureaus vary greatly from one country to another. Most varied are the forecasts provided in highly industrialized countries which are sufficiently large to span over several climatic regions. In addition to the general prognoses mentioned above, special warnings and forecasts are provided by the U.S. weather bureau in the categories indicated below, and similar services are provided in most other countries where a need is present.

1. Marine forecasts and warnings. These provide information on all weather conditions that affect shipping. A similar service is established for the Great Lakes.

2. River and flood forecasts and warnings. These indicate runoff potentials, icing conditions and flood stages for the principal rivers.

3. Agricultural forecasts. These include information on the weather elements that affect the growing of crops and livestock. Of special importance are the fruit-frost forecasts which are used for the scheduling of frost prevention operations.

4. Fire-weather forecasts. These give information on the conditions, such as excessive dryness, which are generally favourable for forest and brush fires, thunderstorms which may initiate fires, and the winds which may spread fires.

5. Cold waves, blizzards and related warnings. These serve all interests which are affected by severe cold, snowstorms, icing storms and blizzards.

6. Severe local storm warnings. These include general alerts and specific warnings of destructive thunderstorms, gusts, hailstorms and tornadoes.

7. Hurricane warnings. On the basis of general meteorological observations and aircraft reconnaissance, general alerts and specific warnings are issued to all threatened areas.

8. Aviation forecasts. These provide regional information on the conditions that affect flying in general, and specific information on terminal and route conditions.

WEAVER, JAMES BAIRD (1833–1912), U.S. lawyer, political reformer and presidential candidate of the Populist party, was born at Dayton, O., June 12, 1833. He took a degree at the Cincinnati, O., Law school, and entered practice at Bloomfield, Ia. An adherent of Free-Soil ideas and active in local Republican politics, he volunteered shortly after the outbreak of the Civil War and saw active service in the Union army. In March 1865 he was brevetted brigadier general. In 1866 he was elected district attorney of the 2nd Iowa judicial district and held the appointive office of federal assessor of internal revenue. 1867–73. His hostility to the railroads and other corporations and his inflationist views, however, blocked his further advancement in the Republican party, and he turned to the Greenbackers, on whose ticket he was elected to congress in 1878, 1884 and 1886. He was the Greenback candidate for president in 1880. He was nominated for president by the People's or Populist party in its first national campaign in 1892. After a vigorous campaign he received 1,027,000 votes, 8.5% of the total.

Weaver died at Des Moines, Ia., Feb. 6, 1912. (R. HR.)

WEAVERBIRD, the name by which a family (Ploceidae) of birds are usually known, from their often elaborately interwoven nests. They are small sparrowlike birds, but the males are often conspicuously coloured. Perhaps the most remarkable is the African sociable grosbeak (Philetaerus *socius*); some 100 or 200 pairs build their grass nests together in one tree, forming a gigantic mushroom-shaped mass. Each nest is entered from below.

The subfamily of the widow birds (Viduinae) have long tail feathers, reaching in Vidua *paradisea,* a bird the size of a sparrow, a foot in length. This decoration is confined to the males. The Ploceidae are closely related to the Fringillidae (see FINCH), and are distributed over Africa, Australia and the warmer parts of Asia.

WEAVING. The process of weaving consists in interlacing, at right angles, two or more series of flexible materials, of which the longitudinal are called warp and the transverse weft. Weaving, therefore, embraces only one section of the textile industry, for felted, plaited, netted, hosiery and lace fabrics lie outside this definition.

Felting consists in bringing masses of loose fibres, such as wool and hair, under the combined influences of heat, moisture and friction, when they become firmly interlocked in every direction. Plaited fabrics have only one series of threads interlaced, and those at other than right angles. In nets all threads are held in their appointed places by knots, which are tied wherever one thread intersects another.

Hosiery fabrics, whether made from one or many threads, are held together by intersecting a series of loops; while lace fabrics are formed by passing one set of threads between and round small groups of a second set of threads, instead of moving them from side to side.

The invention of spinning (*q.v.*) gave a great impetus to the introduction of varied effects; previously the use of multi-coloured threads provided ornament for simple structures, but the demand for variety extended far beyond the limits of colour, and different materials were employed either separately or conjointly, together with different schemes of interlacing. Eventually the weaver was called upon to furnish articles possessing lustre, softness and delicacy; or those that combine strength and durability with diverse colourings, with a snowy whiteness, or with elaborate ornamentation.

To meet the requirements the world has been searched for raw materials. From the animal kingdom, wool, hair, fur, feathers, silk and the pinna fibre have long been procured. From the vegetable kingdom, cotton, flax, hemp, jute, ramie and a host of other less known materials are derived. Among minerals there are gold, silver, copper, brass, iron, glass and asbestos. In addition, strips of paper, or skin, in the plain, gilt, silvered and painted conditions are available. Finally, artificial fibres are used, especially artificial silk, which has come into very extended use.

The processes of bleaching (*q.v.*), mercerizing (*q.v.*), dyeing,. printing (*see* TEXTILE PRINTING) and finishing (*see* COTTON MANUFACTURE) contribute to the resultant product.

FABRIC STRUCTURE AND DESIGNING

The following classification will be adopted: Group 1, to include all fabrics made from one warp and one weft, provided both sets of threads remain parallel in the finished article and are intersected to give the requisite feel and appearance. Group 2, to include *(a)* fabrics constructed from two warps and one weft, or two wefts and one warp, as in those that are backed, reversible and figured with extra material; *(b)* two or more distinct fabrics built simultaneously from two or more warps and wefts, as in two, three and other ply cloths; (c) fabrics built by so intersecting two or more warps and wefts that only one texture results, as in loom-made tapestries and figured repps. Group 3, to include fabrics in which a portion of the weft or warp rises vertically from the ground-work of a finished piece, as in velveteens, velvets, plushes and piled carpets. Group 4, to embrace all fabrics in which one portion of the warp is twisted partially, or wholly, round another portion, as in gauzes and lappet cloths.

The structure of a cloth, and its ornamentation by weaving, is worked out by the cloth designer on squared paper. Successive vertical lines of squares are taken to represent the warp threads, whilst horizontal lines similarly represent weft threads. A filled-in square then indicates that the warp thread it represents is above the weft, whereas a blank means weft above warp. This can be seen clearly in fig. 1. When two or more warps or wefts are used in a cloth, different colours or kinds of marks are generally used to show the working of the different warps or wefts. Thus, in fig. 15 the crosses represent ground warp above ground weft, whereas the filled squares show ground warp above the extra or figuring weft.

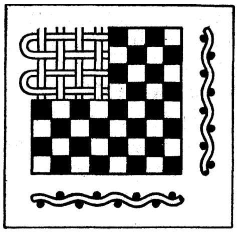

FIG. 1.—PLAIN CLOTH

Fabrics in Group 1.—These are affected by the nature and closeness of the yarns employed in their construction, by colour, or by the scheme of intersecting the threads. The most important section of this group is *Plain cloth,* in which the warp and weft threads are approximately equal in thickness and closeness, and pass over and under each other alternately, as in fig. 1, which shows a design, plan and two sections of plain cloth. Such a fabric would, therefore, appear to admit of but slight ornamentation, yet this is by no means the case, for if thick and thin threads of warp and weft alternate the resultant fabric may be made to assume a corrugated appearance on the face, while beneath it remains flat, as in poplins, repps and cords. A plan and a longitudinal section of a repp cloth are shown in fig. 2. Colour may also be employed to ornament plain fabrics, and its simplest application produces stripes and checks. But colour may convert these fabrics into the most artistic productions. Tapestries only differ from simple plain cloth in having each horizontal line of weft made up of numerous short lengths of parti-coloured thread. Many fine specimens of this art have been recovered from ancient Egyptian and Peruvian tombs, and many are still produced in the Gobelins and manufactories of Europe.

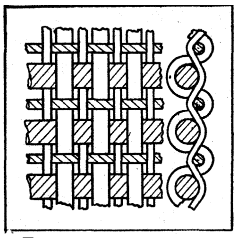

FIG. 2.—REPP CLOTH

Twills are next in importance to plain cloth on account of their wide range of application and great variety of effects; in elaborately figured goods their use is as extensive as where they provide the only ornament. Twills invariably form diagonal ribs in fabrics, and these are due to the intervals at which the warp and weft are intersected; thus two or more warp threads are passed over or under one or more than one weft thread in regular succession. Twills are said to be equal when similar quantities of warp and weft are upon the face of a fabric, unequal when one set of threads greatly preponderates over the other set. Fig. 3 shows the design for an equal, and fig. 4 that for an unequal twill, each of which requires four warp and weft threads to complete the scheme of intersections. If the ribs form angles of 45 degrees, the warp and weft threads per inch are about equal in number, but for an unequal twill the material most in evidence should be closest and finest. The angle formed may be greater or less than 45 degrees, as in figs. 5, 6, which are both derived as shown from the same base weave.

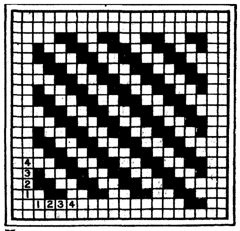

FIG. 3.—FOUR-THREAD 2/2 TWILL

Twills are *simple* and *fancy;* both terms refer to the schemes of intersecting. In the former the same number of warp threads are placed successively above or below each weft thread, and the ribs are of uniform width, as in figs. 3, 4. In the latter more warp threads may be above one pick than another, the ribs may vary in width and small ornament may be introduced befween the ribs, as in figs. 5, 6 and 7. Twills may be broken up into zig-zags, lozenges, squares and other geometrical designs, all of which may be produced by reversings in the diagonal lines, or by reversing the weave of an unequal twill. Fig. 8 is a zigzag, nameiy, a twill reversed in one direction. Fig. 9 is a diamond, or a twill reversed in two directions, and fig. 10 is a diaper, which gives a warp face in one place and a weft face in another.

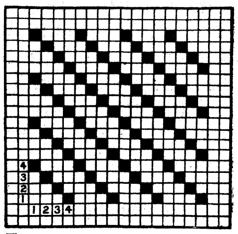

FIG. 4.—FOUR-THREAD 1/3 TWILL

Satins and *sateens* form another important section of Group 1. In a satin the bulk of the warp, and in a sateen the bulk of the weft, is on the face of a fabric. If perfect in construction both present a smooth, patternless appearance, which is due in part to the scheme of intersections, in part to using fine material for the surface threads and placing it close enough together to render the points of intersection invisible; the threads of the other set being coarser and fewer in number. Satins differ from twills in having each warp thread lifted, or depressed, separately, but not successively. From five to upwards of 30 threads of warp and weft are required to complete the various schemes of intersecting. If the intervals between the intersections are equal the weave is said to be perfect, as in fig. 11, but if the intervals are irregular it is said to be imperfect, as in fig. 12. In *Damasks* a satin is combined with a sateen weave, and since any desired size and shape of either weave may be produced, great facilities are offered for ornamentation. But in combination neither the satin nor the sateen can be perfect in construction, for one requires a preponderance of warp, the other a preponderance of weft; it follows that every point of intersection is distinctly visible on both surfaces.

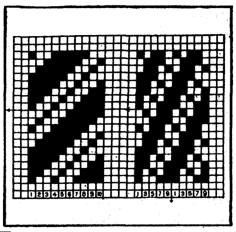

FIG. 5.—UPRIGHT TWILL

Brocades are fabrics in which both sets of threads may be floated irregularly upon the surface to produce ornamental effects, and they may be taken as typical of all one, warp and one weft fabrics that are figured by irregularly floated materials, whether the threads are uniformly or irregularly distributed, and whether one weave or several weaves be employed.

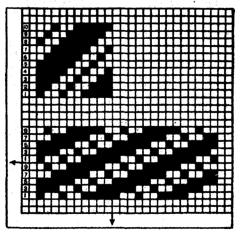

FIG. 6.—RECLINING TWILL

Group 2.—This group includes all backed and reversible fabrics, as well as those ornamented with extra material and compounded. Cloths intended for men's wear are often *backed,* the object of which is to give weight and bulk to a thin texture without interfering with the face effects. Either warp or weft may be used as backing; in the former there are two series of warp to one series of weft threads, while in the latter there are two series of weft to one series of warp threads. The face material is superposed upon that of the back, but the ratio of face threads may be one or two to one of back.

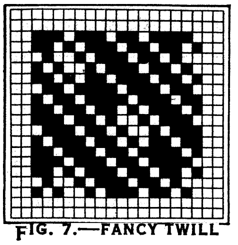

FIG. 7.—FANCY TWILL

In order to avoid disturbing the face weave, only those threads are used to bind the backing that are hidden by the face, as in fig. 13, which gives the design and a transverse section of a backed fabric. A is face weft, B back weft, and the circles are warp threads; of the latter C, D are beneath both B and A. This diagram will serve equally as a longitudinal section of a warpbacked fabric, if **A** represents a thread of face warp, B a thread of back warp and the circles are weft threads. Weft backing is capable of giving a more spongy feel to a fabric than warp, because softer materials may be used, but in these fabrics the length output of the loom is reduced by reason of the wefts being superposed.

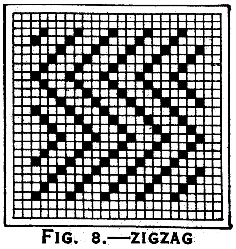

FIG. 8.—ZIGZAG

Warp-backed fabrics, whether uniformly coloured or striped, do not materially reduce the output of a loom, for every weft thread adds to the cloth length. *Reversible* fabrics may have either two series of differently coloured wefts or warps to one of the other series, in which event they may be similarly figured on both sides by causing the threads of the double series to change places, as in the design and transverse section, fig. 14; or, by allowing one series to remain constantly above the other, as in backed cloths, both sides may be similar or dissimilar in colour and pattern.

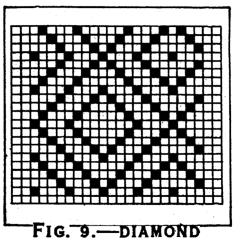

FIG. 9.—DIAMOND

Fabrics figured with extra material may have two series of warp or weft threads to one series of the other set, and they may yield reversible or one-sided cloths. The figuring may be done entirely by the extra material placed above or below a ground texture, as in fig. 15, or ordinary and extra materials may be used conjointly for figuring. In fig. 15 the waved lines and circles represent a section of the plain cloth ground which shows a thread of extra material.

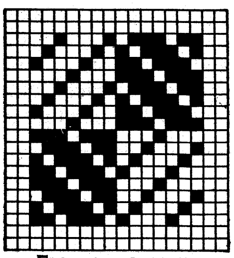

FIG. 10.—DIAPER

Compound cloths must have at least two textures, both as distinct in character as if woven in separate looms. They have many advantages over backed cloths, thus: the same design and colouring may be produced on both sides; where bulk and weight are required a fine surface texture may be formed over a ground of inferior material, and soft weft be passed between the upper and lower textures; the fabric is more perfect and admits of either simple or elaborate patterns being wrought upon the surface, with simple ones beneath, as in piqués and matelassés. One texture may be constantly above the other and connected at the selvages only, as in hose pipes and pillow slips; or at intervals a thread may pass from one texture into the other, in which event both are united, as in many styles of bedcovers and vestings. As many as from three to twelve textures may be woven simultaneously and united, as in woven beltings. It differently coloured, the textures may change places at pleasure, as in Kidderminster carpets.

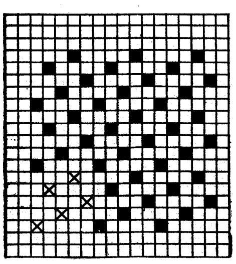

FIG. 11.—FIVE-THREAD SATEEN

There may be from one to three threads of face warp to one of back, and the wefting may or may not correspond with the warping. Fig. 16 shows the face and back weaves, the design, and a transverse section of a compound cloth with two threads of face warp and weft to one of back, and both are stitched together. The circles in the upper and lower lines represent face and back warps respectively, and **A**, B, C are weft threads placed in the upper and lower textures. In the design, filled squares show face warp lifted above face picks, crosses show back warp lifted over back picks, dots indicate face warp lifted over back picks, and the oblique marks show the binding of the two fabrics by back warp lifted over a face pick.

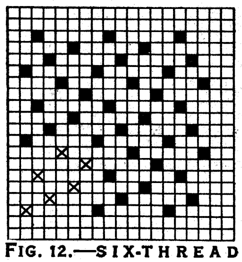

FIG. 12.—SIX-THREAD SATEEN

Loom-made tapestries and figured repps form another section of Group 2. As compared with true tapestries, the loom-made articles have more limited colour schemes, and their figured effects may be obtained from warp as well as weft, whether interlaced to form a plain face or left floating more or less loosely. Every weft thread, in passing from selvage to selvage, is taken to the surface where required, the other portions being bound at the back. Some specimens are reversible, others are one-sided, but, however numerous the warps and wefts, only one texture is produced. When an extra warp of fine material is used to bind the wefts firmly together a plain or twill weave shows on both sides.

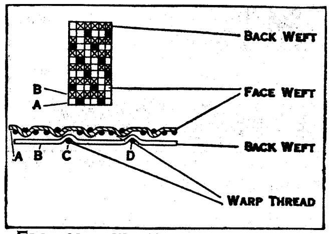

FIG. 13.—WEFT BACKED FABRIC

If a single warp is employed, two or more wefts form the figure, and the warp seldom floats upon the surface. Where warps do assist to form figure it rarely happens that more than three can be used without overcrowding the reed. Fig. 17 gives the design, and a transverse section of a reversible tapestry in four colours, two of which are warps and two wefts. If either warp or weft is on the surface, corresponding threads are beneath. The bent lines represent weft and the circles warp. In this design the marks indicate the colours showing on the surface of the cloth, and *not* the lifting of the warp. Thus, crosses show No. 1 warp on the surface, filled squares show No. 2 warp, dots show No. 1 weft and oblique marks No. 2 weft on the face of the fabric.

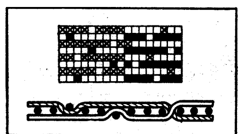

FIG. 14.—WEFT REVERSIBLE FABRIC

Each vertical line of squares represents one thread of each warp and each horizontal line represents one thread of each weft. *Figured repps* differ from plain ones in having threads of one, or more than one, thick warp floated over thick and thin weft alike; or in having several differently coloured warps from which a fixed number of threads are lifted over each thick weft thread; the figure is due to colour.

Group **3. Piled** Fabrics.—In all methods of weaving hitherto dealt with the warp and weft threads have been laid in longitudinal and transverse parallel lines. In piled fabrics, however, portions of the weft or warp assume a position at right angles to the surface of the cloth.

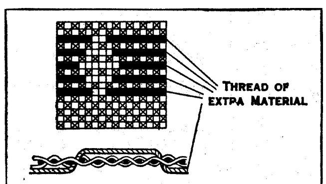

FIG. 15.—FIGURING WITH EXTRA WEFT

If the former there are two series of weft threads, one being intersected with the warp to form a firm ground texture, the other being bound into the ground at regular intervals, as in the design and transverse section of a velveteen, fig. 18; the circles and waved lines form plain cloth, and the loose thread **A** is a pile pick. After leaving the loom all threads A are cut by pushing a knife lengthwise between the plain cloth and the pile. As each pick is severed both pieces rise vertically and the fibres open out as at B. Since the pile threads are from two to six times as numerous as those of the ground, and rise from an immense number of places, a uniform brush-like surface is formed. Raised figures are produced by carrying the threads **A** beneath the ground cloth, where no figure is required, so that the knife shall only cut those portions of the pile weft that remain on the surface. The effect upon the face varies with the distribution of the binding points, and the length of pile is determined by the distance separating one point from another. When *chenille* is used in the construction of figured weft-pile fabrics, it is necessary to employ two weaving operations, namely, one to furnish the chenille, the other to place it in the final fabric. Chenille is made from groups of warp threads that are separated from each other by considerable intervals; then, multi-coloured wefts are passed from side to side in accordance with a predetermined scheme. This fabric is next cut midway between the groups of warp into longitudinal strips, and, if reversible fabrics such as table-covers and curtains are required, each strip is twisted axially until the protruding ends of weft radiate from the core of warp, and form a cylinder of pile. In the second weaving this chenille is folded backward and forward in a second warp to lay the colours in their appointed places and pile projects on both sides of the fabric. If chenille is intended for carpets, the ends of pile weft are bent in one direction and then woven into the upper surface of a strong ground texture. *Warp-piled fabrics* have at least two series of warp threads to one of weft, and are more varied in structure than weft-piled fabrics, because they may be either plain or figured, and have their surfaces cut, looped or both. *Velvets and plushes* are woven single and double. In the former case both ground and pile warps are intersected with the weft, but at intervals of two or three picks the pile threads are lifted over a wire, which is subsequently withdrawn; if the wire is furnished with a knife at its outer extremity, in withdrawing it the pile threads are cut, but if the wire is pointed a line of loops remains, as in terry velvet. Fig. 19 is the design and two longitudinal sections of a Utrecht velvet. The circles are weft threads, and the bent line is a pile thread, part of which is shown cut, another part being looped over a wire. The circles are repeated to show how the groundwarp intersects the weft. In the design the filled squares show the pile warp lifted over the wires. *Double plushes* consist of two distinct ground textures which are kept far enough apart to ensure the requisite length of pile. As weaving proceeds the pile threads are interlaced with each series of weft threads, and passed from one to the other. The uniting pile material is next severed midway between the upper and lower textures, and two equal fabrics result. Fig. 20 gives three longitudinal sections of a double pile fabric. The circles A, B are weft threads in the upper and lower fabrics respectively; the lines that interlace with these wefts are pile warp threads which pass vertically from one fabric to the other. At C, D the circles are repeated to show how the ground warps intersect the wefts, and at E the arrows indicate the cutting point. *Figured warp-pile fabrics* are made with regular and irregular cut and looped surfaces. If regular, the effect is due to colour, and this again may be accomplished in various ways, such as *(a)* by knotting tufts of coloured threads upon a warp, as in Eastern carpets; *(b)* by printing a fabric after it leaves the loom; (c) by printing each pile thread before placing it in a loom, so that a pattern shall be formed simultaneously with a pile surface, as in tapestry carpets; *(d)* by providing several sets of pile threads, no two of which are similar in colour; then, if five sets are available, one-fifth of all the pile warp must be lifted over each wire, but any one of five colours may be selected at any place, as in Brussels and Wilton carpets. Fig. 21 is a longitudinal section of a Brussels carpet. The circles represent two tiers of weft, and the lines of pile threads, when not lifted over a wire to form loops, are laid between the wefts; the ground warp interlaces with the weft to bind the whole together. When the surface of a piled fabric is irregular, also when cut and looped pile are used in combination, design is no longer dependent upon colour, for in the former case pile threads are only lifted over wires where required, at other places a flat texture is formed. In the latter case the entire surface of a fabric is covered with pile, but if the figure is cut and the ground looped the pattern will be distinct.

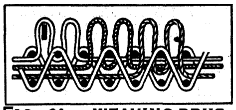

FIG. 21.—WEAVING BRUSSELS CARPET

Group 4. **Crossed** Weaving. — This group includes all fabrics, such as gauzes, in which the warp threads intertwist amongst themselves to give intermediate effects between ordinary weaving and lace. Also those, such as Lappets, in which some warp threads are laid transversely in a piece to imitate embroidery. *Plain gauze* embodies the principles that underlie the construction of all crossed woven textiles. In these fabrics the twisting of two warp threads together leaves large interstices between both warp and weft. But although light and open in texture, gauze fabrics are the firmest that can be made from a given quantity and quality of material. One warp thread from each pair is made to cross the other at every pick, to the right and to the left alternately, therefore the same threads are above every pick, but since in crossing from side to side they pass below the remaining threads, all are bound securely together, as in fig. 22, which shows a longitudinal section and also a plan of gauze. *Leno* is a muslin composed of an odd number of picks of a plain weave followed by one pick of gauze. In texture it is heavier than gauze, and the cracks are farther apart transversely. *Fancy gauze* may be made in many ways, such as *(a)* by using crossing threads that differ in colour or count from the remaining threads, provided they are subjected to slight tensile strain; *(b)* by causing some to twist to the right, others to the left simultaneously; (c) by combining gauze with another weave, as plain, twill, satin, brocade or pile;

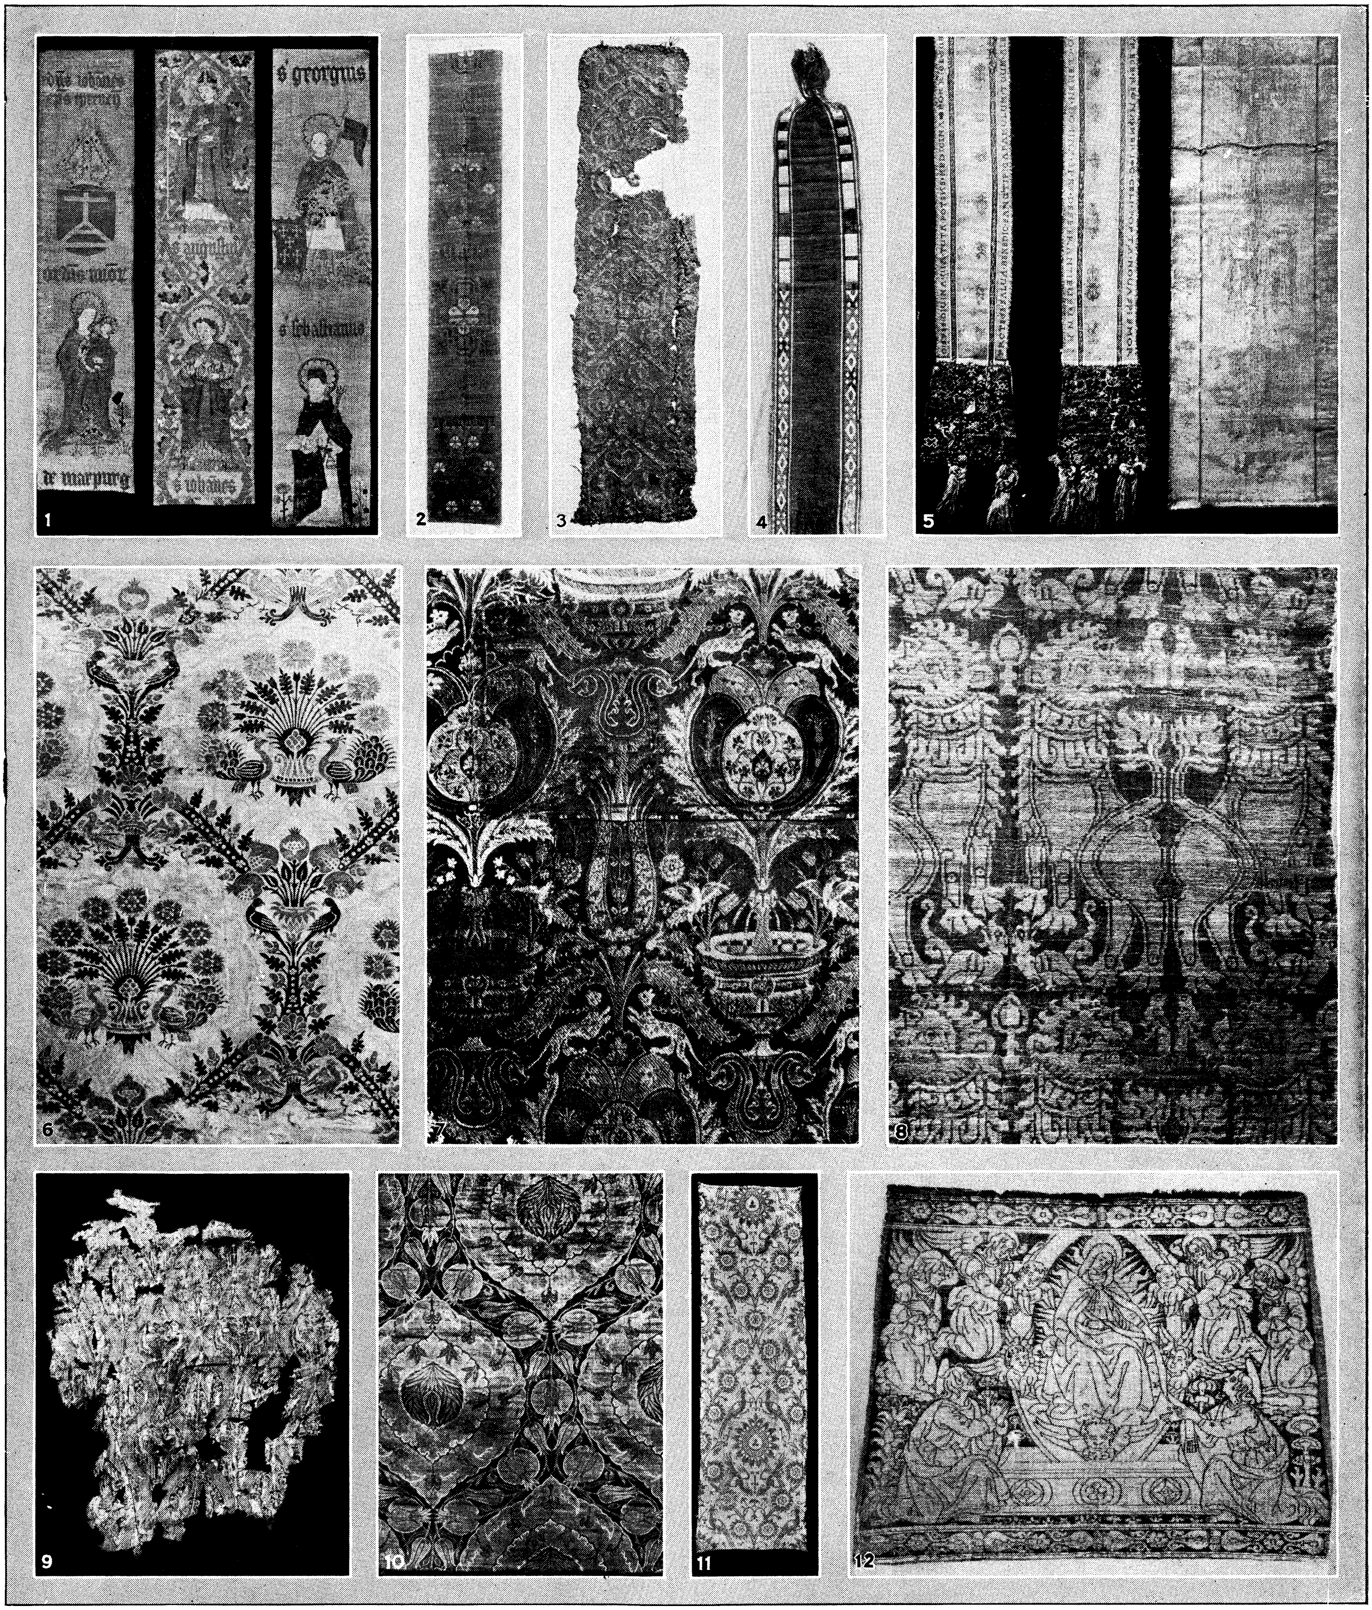
SPECIMENS OF ANCIENT WEAVING

1. Fragment of fabric woven by the Incas. Taken from a grave in Pachacamac, Peru. 2. Portion of the silk wrapping of tomb of Charlemagne with fanciful elephant and sacred tree device in a roundel. Possibly of Baghdad manufacture, 9th century. 3. Syrian or Anatolian silk weaving of the 5th century depicting Samson slaying the lion. 4. Inca woven fabric with figures of persons. Discovered in an ancient grave in Ancon, Peru. 5. Syrian or Persian silk weaving of the 5th oentury, showing mounted hunters engaged in the chase. 6. Syrian and Coptic flax weaving of the 5th or 6th century. Discovered at Akhmin, upper Egypt. 7. Long narrow strip of Inca fabric with typical design found in a grave in the Nasca valley. 8. A wider strip of Inca woven fabric that was also discovered in one of the Nasca valley graves

WEAVING



BY COURTESY OF THE VICTORIA AND ALBERT MUSEUM, LONDON

EXAMPLES OF MEDIAEVAL WEAVING

1. Cologne orphreys woven in silk and gold threads. Faces of the Virgin and Child are embroidered, (1425–1450). 2. Another specimen of Cologne orphrey also woven with gold and silk threads and bearing Latin inscriptions, late 15th century. 3. Part of a narrow band with chevron spaces filled with delicate scroll ornament. Woven in silk and gold thread, 13th century. 4. Portion of Clavus or narrow band from a Coptic tunic of the 9th or 10th century. 5. (Left) German late 12th or early 13th century orphrey woven in gold and silk threads with Latin inscription along the edges. (Right) part of broad band or orphrey woven in gold and silk threads and bearing figures of the Crucifixion and Annunciation. German work of the 13th century. 6. Italian damask or brocade silk fabric of 15th century manufacture. 7. Example of Venetian silk weaving. Design shows Ottoman influence, 16th century. 8. Byzantine weaving, 11th century. Red silk and gold thread used. 9. Fragment of Byzantine silk of the 12th century. 10. Ottoman silk and gold thread weaving of the 16th century, with ogival framed ornament. 11. Piece of north Italian silk weaving, 14th century, pattern planned on original basis with fantastic birds. Cone forms contain sham Arabic inscriptions. 12. Apparel of a Dalmatic woven in Venice late in 15th century. The pattern depicts the Virgin in glory

(d) by varying the number of threads that cross, and by causing those threads to entwine several ordinary threads; (e) by passing two or more weft threads into each crossing, and operating any assortment of crossing threads at pleasure.

Lappet weaving consists in diapering the surface of a plain or gauze fabric with simple figures This is done by drawing certain warp threads into a transverse position and then lifting them over a thread of weft to fix them in the texture, after which they are moved in the opposite direction and lifted over the following pick, the cloth being generally woven with the face side down. The material between one binding point and another must float loosely, and this limits the usefulness of lappet figuring. In fig. 23 the thick lines show a lappet spot upon a plain texture.

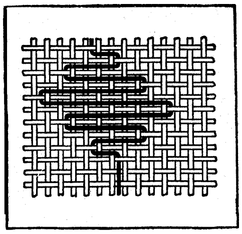


FIG. 23.—LAPPET FABRIC

Notwithstanding diverse structure, intricate machines are not essential to the production of either simple or complex textures; the most elaborate and beautiful specimens of the weaver's art have been manufactured upon simple machinery.

WEAVING MACHINERY

The longitudinal threads of a fabric are called warp, caine, twist and organzine, and the transverse threads are weft, shoot, woof, filling and tram. A loom for weaving these threads into cloth must provide for: *(1)* Shedding, *i.e.,* raising and lowering the warp threads in a predetermined sequence so as to form two lines between which the weft may be passed. *(2)* Picking, or placing lines of weft between the divided warp. *(3)* Beating-up, or striking each weft thread into its appointed position in the fabric. *(4)* Letting-off, or holding the warp tense and delivering it as weaving proceeds. (5) Taking-up, or drawing away the cloth as manufactured. (6) Temples, for stretching the fabric widthwise in order to prevent the edge threads of a warp from injuring the reed, and from breaking. Fig. *24* illustrates these operations. Shedding is generally done by controlling the warp threads by eyed healds, which are lifted or lowered to form the shed. The weft is inserted by the shuttle after the shed has been formed, and beating-up is done by the reed which is moved forward by the slay or batten. Intermittently driven rollers take up the cloth and a frictional drag, applied to the warp beam by a weighted rope or chain, regulates the let-off and warp tension. Power looms require the above-named contrivances to act automatically; and, in addition, (7) a weft-fork, to stop the loom when the weft

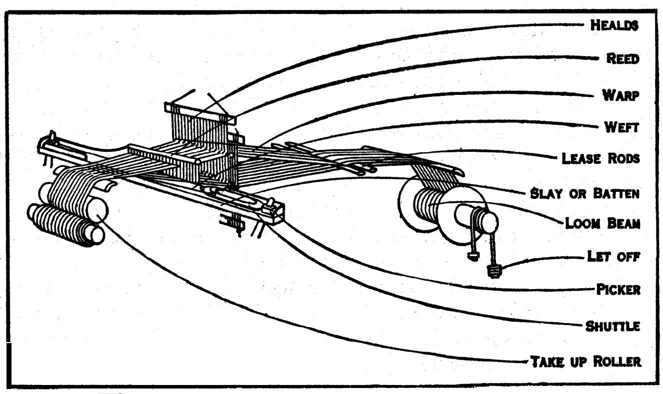

FIG. 24.— DIAGRAM OF VARIOUS PARTS OF A LOOM

becomes exhausted or breaks. (8) Mechanism for stopping the loom when the shuttle fails to reach its appointed box. (9) For weaving cross stripes, multiple shuttle boxes are needed to bring different colours, or counts of weft, into use at the proper time. (10) In some looms a device for automatically ejecting a spent cop, pirn or shuttle, and inserting a full one is requisite. (11) If a weaver has to attend to a greater number of looms than usual, a device for stopping the loom when a warp thread fails is essential. In addition to the loom itself, weaving machinery includes preparatory machines required to get the warp and sometimes the weft threads ready for the loom. Warp thread—or rather yarn—generally requires re-winding from the spinning frame bobbins or cops on to larger bobbins; warping a number of these yarns side by side on to a beam or into an untwisted rope; sizing the yarn to lay projecting fibres and to strengthen the

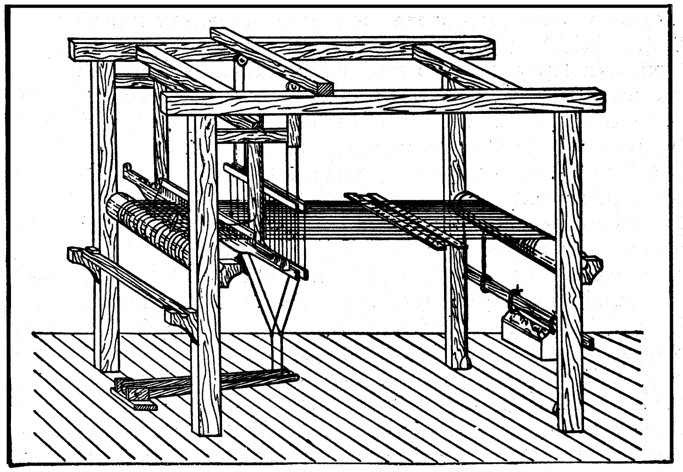

FIG. 25.— DIAGRAM OF HAND LOOM

yarn for weaving; finally, winding the sized yarn on to the loom beam and getting it ready for weaving in the loom.

The Hand-loom.— During the 17th and the first half of the 18th century it was observed that wherever any branch of the textile industry had been carried to a high state of excellence the looms used to manufacture a given fabric were similar in essentials, although in structural details they differed greatly. Prior to the invention of the fly shuttle by John Kay, in 1733, no far-reaching invention had for generations been applied to the hand-loom, and subsequently the Jacquard machine and multiple shuttle boxes represent the chief changes. A hand-loom as used in Europe at the present time *(see* fig. *25)* has the warp coiled evenly upon a beam whose gudgeons are laid in open steps formed in the loom framing. Two ropes are coiled round this beam, and weighted to prevent the warp from being given off too freely. From the beam the threads pass alternately over and under two lease rods, then separately through the eyes of the shedding harness, in pairs between the dents of a reed, and finally they are attached to a cloth roller. For small patterns healds are used to form sheds, but for large ones a Jacquard machine is required. Healds may be made of twine, of wire or of twine loops into which metal eyes, called mails, are threaded. But they usually consist of a number of strings which are secured above and below upon wooden laths called shafts, and each string is knotted near the middle to form a small eye. From two to *24* pairs of shafts may be employed, but the healds they carry must collectively

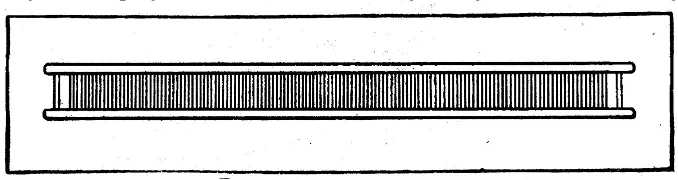

FIG. 26.— WEAVER'S REED

The warp threads are passed, generally in pairs or threes, through the dents or spaces between the reed wires

equal the number of threads in the warp. These healds will be equally or unequally distributed upon the shafts according to the nature of the pattern to be woven, and the threads will be drawn through the eyes in a predetermined order. The upper shafts are suspended from pulleys or levers, and the lower ones are attached directly or indirectly to treadles placed near the floor. The weaver depresses these treadles with his feet in a sequence suited to the pattern and the scheme of drawing the warp through the healds. When the treadle is pressed down, at least one pair of shafts will be lifted above the others, and the warp threads will ascend or descend with the healds to form a shed for the shuttle to be passed through. The reed (fig. 26) is the instrument by which weft is beaten into position in the cloth; it also determines the closeness of the warp threads, and guides a moving shuttle from side to side. It is made by placing strips of flattened wire between two half round ribs of wood, and binding the whole together by passing tarred twine between the wires and round the ribs. Such a reed is placed in the lower portion of a batten, which is suspended from the upper framework of the loom. In front of the reed, and immediately below the warp, the projecting batten forms a race for the shuttle to travel upon from side to side. Before Kay's invention a shuttle was thrown between the divided warp and caught at the opposite selvage, but Kay continued the projecting batten on both sides of the warp space and constructed boxes at each end. Over each box he mounted a spindle and upon it a driver, or picker. Bands connected both pickers to a stick which the weaver held in his right hand, while with the left hand he controlled the batten. A treadle is pressed down by one foot to form a shed; the batten is pushed back till a sufficient portion of the shed is brought in front of the reed and the depressed threads lie upon the shuttle race; a clear way is thus provided for the shuttle. A quick movement of the stick tightens the cord attached to a picker and projects the shuttle from one hox to the other. The batten is now drawn

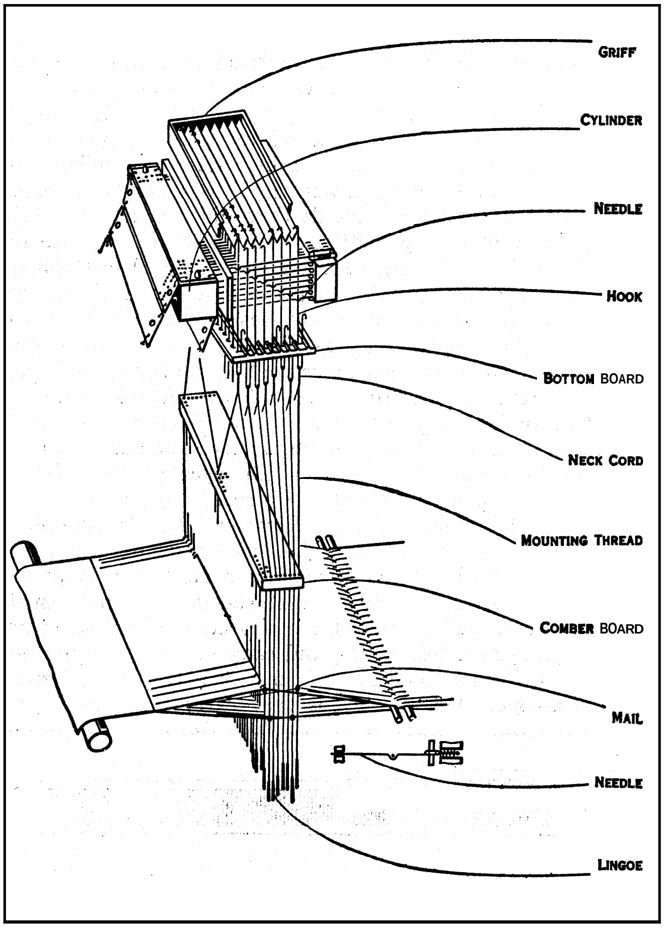

FIG. 27.—JACQUARD MACHINE AND HARNESS
This method of shedding is required for the production of all fabrics ornamented by woven floral designs

forward, and the reed beats up the weft left by the shuttle. As the next treadle is depressed to form another division of the warp for the return movement of the shuttle, the last length of weft is enwrapped between intersecting warp threads, and the remaining movements follow in regular succession.

In cases where the weft forms parti-coloured stripes across a fabric, also where different counts of weft are used, shuttles, equal in number to the colours, counts or materials, must be provided. By Robert Kay's invention of multiple shuttle boxes, in 1760, much of the time lost through changing shuttles by hand was prevented. His drop boxes consist of trays formed in tiers and fitted into the ordinary shuttle boxes. Each tray is capable of holding a shuttle, and by operating a lever and plug with the forefinger and thumb of the left hand the trays may be raised and lowered at pleasure to bring that shuttle containing the colour next needed into line with the picker.

The **Draw** Loom.—Large figured effects were formerly produced in draw looms, where the warp threads were so controlled by separate strings that any assortment could be lifted when required. To the lower end of each string a dead weight, called a lingoe, was attached, and a few inches above the lingoe a mail was fixed for the control of a warp thread. The strings passed through a comber board which held the mails and warp threads facing the proper reed dents. Still higher up, groups of strings were connected to neck cords; each group consisted of all strings required to rise and fall together constantly If, for example, in the breadth of a fabric there were 12 repeats of a design, 12 strings would be tied to the same neck cord, but taken to their respective places in the comber board These parts of a draw loom harness are clearly shown in fig. 27 which represents a Jacquard machine and harness. Each neck cord, after being led through the perforated bottom board and over a grooved pulley, was threaded through a ring on the top of a vertical cord called the simple, and passed horizontally to, and tied upon, a bar rigidly fixed near the ceiling of the weaving room. The simple cords were similarly attached to a bar placed near the flbor. From one hundred to several thousands of neck and simple cords could be used in one harness. The design to be reproduced in cloth was read into the parallel lines of the simple by looping a piece of string round each cord that governed warp threads to be lifted for a given shed; after which all the loops were bunched together. By pulling at a bunch of loops the simple cords were deflected and they caused all warp threads controlled by them to be lifted above the level of those undisturbed. Similar bunches of loops were formed for every shed required for one repeat of a design, and they were pulled in succession by the draw-boy, while the weaver attended to the batten and picking.

The Jacquard Machine.—This is the most important invention ever applied to the hand-loom, but it is not the work of one man; it represents the efforts of several inventors whose labours extended over three-quarters of a century. This apparatus has taken the places of the simple, the loops, the pulleys and the draw-boy of the older shedding motion, but other parts of the harness remain unchanged. In 1725 Basile Bouchon substituted for the bunches of looped string an endless band of perforated paper by which the simples for any shed could be selected. In 1728 M. Falcon constructed the machine since known as the Jacquard and operated it through the medium of perforated cards, but it was attached to the simple cords and required a draw-boy to manipulate it. In 1745 Jacques de Vaucanson united in one machine Bouchon's band of paper and the mechanism of Falcon. He placed this machine where the pulley box previously stood, and invented mechanism for operating it from one centre.

In a Jacquard machine the warp threads are raised by rows of upright wires called hooks (fig. 27). These are bent at both extremities and are normally supported upon a bottom board which is perforated to permit the neck cords from the harness beneath to be attached to the hooks. Each of a series of horizontal needles—one of which is shown enlarged and detached at the foot of the drawing—is provided with a loop and a crank; the former to permit of a to-and-fro movement, the latter to receive a hook. The straight ends of the needles protrude about one-quarter of an inch through a perforated needle board, but the looped ends rest upon bars placed in tiers. A wire passed through all the loops of the needles which form one vertical line limits the extent of their lateral movement, and small helical springs impinge upon the loops of the needles with sufficient force to press them and their hooks forward. A frame called a griff, is made to rise and fall vertically by a treadle which the weaver actuates with one foot. This frame contains a blade for each line of hooks, and when the blades are in their lowest position the hooks are free and vertical with their heads immediately over the blades, hence an upward movement given to the griff would lift all the hooks and thereby all the warp threads. Only certain hooks, however, must be lifted with the griff, and the selection is made by a quadrangular block of wood, called a cylinder. and cards which are placed upon it. Each face of the cylinder has a perforation opposite each needle, so that if the cylinder be pressed close to the needle board the needle points will enter the holes in the cylinder and remain undisturbed. But if a card, which is not perforated in every possible place, is interposed between the cylinder and the needles, the unpunctured parts of the card close up some of the holes in the cylinder and prevent corresponding needles from entering them. Each needle so arrested is thrust back by the advancing card; its spiral spring is contracted and its hook is tilted. If at this instant the griff ascends, its blades will engage the heads of all vertical hooks and lift them, but those that are tilted will remain unlifted. So soon as the pressing force of a card is removed from the needles the springs restore both needles and hooks to their normal positions. Cards are perforated by special machinery from a painted design, after which they are laced into a chain and passed over conical pegs upon the cylinder; the number required to weave any pattern equals the number of weft threads in that pattern The cylinder is generally drawn out and turned by each upward movement of the griff, and restored to the needles by each downward movement, so that each face in succession is presented to the needles, and each rotatory movement brings forward a fresh card. As the griffe rises with vertical hooks a shed is formed, and a thread of weft is passed across the warp. The griff then descends and the operation is repeated but with a new combination of lifted threads for each card. A Jacquard may contain from 100 to 1,200 hooks and needles, and two or more machines may be mounted upon the same loom.

The Power-loom. — Little is known of the attempts made before the beginning of the 17th century to control all parts of a loom from one centre, but it is certain the practical outcome was inconsiderable In the year 1661 a loom was set up in Danzig, for which a claim was made that it could weave four or six webs at a time without human aid, and be worked night and day; this was probably a ribbon loom. In order to prevent such a machine from injuring the poor people the authorities in Poland suppressed it, and privately strangled or drowned the inventor. M. de Gennes, a French naval officer, in 1678 invented a machine whose chief features consisted in controlling the healds by cams, the batten by cams and springs and the shuttle by a carrier. From 1678 to 1745 little of importance appears to have been done for the mechanical weaving of broadcloth, but in the last-named year M. Vaucanson constructed a very ingenious, self-acting loom, on which the forerunner of the Jacquard machine was mounted; he also adopted de Gennes' shuttle carrier.

During the last quarter of the 18th century it was generally believed that, on the expiry of Arkwright's patents, so many spinning mills would be erected as to render it impossible to consume at home the yarns thus produced, and to export them would destroy the weaving industry. Many manufacturers also maintained it to be impossible to devise machinery which would bring the production of cloth up to that of yarn. It was as a protest against the last-named assertions that Dr. Edmund Cartwright, a clergyman of the Church of England, turned his attention to mechanical weaving. More fortunate than his predecessors, he attacked the problem after much initial work had been done, especially that relating to mechanical spinning and the factory system, for without these no power-loom could succeed. In 1785 Dr. Cartwright patented his first power-loom, but it proved to be valueless. In the following year, however, he patented another loom which has served as the model for later inventors to work upon. He was conscious that for a mechanically driven loom to become a commercial success either one person would have to attend several machines or each machine must have a greater productive capacity than one manually controlled. The thought and ingenuity bestowed by Dr Cartwright upon the realization of his ideal were remarkable. He added parts which no loom, whether worked manually or mechanically, had previously been provided with, namely, a positive let-off motion and warp and weft stop motions; and he planned to size the warp while the loom was in action. With this machine he commenced to manufacture fabrics at Doncaster, and by so doing discovered many of its shortcomings, and these he attempted to remedy: by introducing a crank and eccentrical wheels to actuate the batten differentially; by improving the picking mechanism; by a device for stopping the loom when a shuttle failed to enter a shuttle box; by preventing a shuttle from rebounding when in a box; and by stretching the cioth with temples that acted automatically. In 1792 Dr. Cartwright obtained his last patent for weaving machinery. This provided the loom with multiple shuttle boxes for weaving checks and cross-stripes. But all his efforts were unavailing, and it became apparent that no mechanism, however perfect, could succeed so long as warps continued to be sized while a loom was stationary. His plans for sizing them while a loom was in operation, and also before being placed in a loom, both failed. Still, provided continuity of action could be attained, the position of the power-loom was assured, and means for the attainment of this end were supplied in 1803 by William Radcliffe and his assistant, Thomas Johnson, by their inventions of the beam warper and the dressing sizing machine.

For upwards of 30 years the power-loom was worked under numerous difficulties. The mechanism of the loom itself, the preparatory processes and the organization of the industry were all imperfect. Textile workers were unused to automatic machinery, and many who had been accustomed to labour in their own homes refused employment in mills, owing to dislike of the factory system and the long hours of toil which it entailed. Yet improvements in every branch of the textile industry followed each other in quick succession, and the loom slowly assumed its present shape. By using iron instead of wood in its construction, and centring the batten, or slay, below instead of above the warp line, the power loom became more compact than the hand-loom.

In the modern power-loom (figs 28 and 29), motion is communicated to all the working parts from a main shaft A, upon which two cranks are bent to cause the slay to oscillate; by toothed wheels this shaft drives a second shaft, C, at half its own speed. For plain weaving four tappets are fixed upon the second shaft— two, D, for moving the shuttle to and fro, and two others, E, for moving the healds, L, up and down through the medium of treadles M, M. For other schemes of weaving shedding tappets

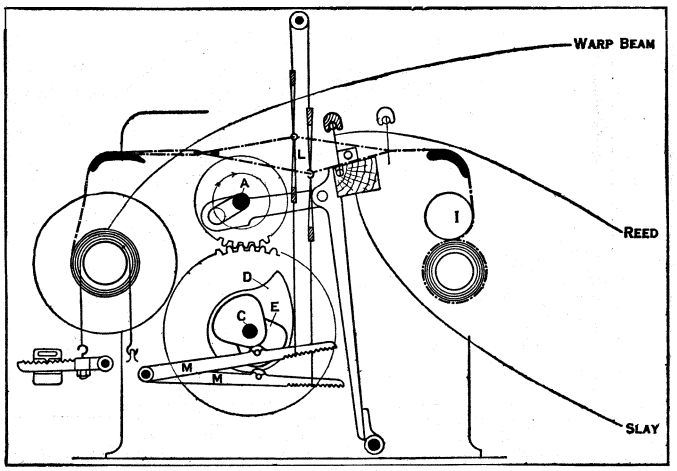

FIG. 28.—VERTICAL SECTION OF A POWER LOOM

are more numerous, and are either loosely mounted upon the second shaft or fixed upon a separate one. In either event they are driven by additional gearing, for the revolutions of the tappets to those of the crank shaft must be as one is to the number of picks in the repeat of the pattern to be woven. The warp beam is often put under the control of chains instead of ropes, as used in hand looms, and the chains are attached to adjustably weighted levers, whereby the effectiveness of the weights may be varied at pleasure. In the manufacture of heavy fabrics, however, it may be necessary to deliver the warp by positive. gearing, which is either connected, or otherwise, to the taking-up motion. The cloth is drawn forward regularly as it is manufactured by passing it over the rough surface of a roller, I, and imparting to the roller an intermittent motion each time a pick of weft is beaten home. This motion is derived from the oscillating slay, and is communicated through a train of wheels. The loom is stopped when the weft fails by a fork-and-grid stop motion, which depends for its action on the lightly balanced prongs of a fork, N. These prongs come in contact with the weft, between the selvage of the web and the shuttle box each time the shuttle is shot to the side at which the apparatus is fixed. If the prongs meet no thread they are not depressed, and being unmoved a connection is formed with a vibrating lever by which the loom is stopped. On the other hand, if the prongs are tilted, the loom continues in action. If more than one shuttle is used it may be necessary to feel for each, instead of alternate threads of weft. In such cases a fork is placed beneath the centre of the cloth and lifted above a moving shuttle; if in falling it meets with weft it is arrested and the loom continues in motion, but if the weft is absent the prongs fall far enough beneath the shuttle race for a stop to act upon a lever and bring the loom to a stand. To prevent a complete wreck of the warp it is essential to arrest the loom when a shuttle fails to reach its appointed box. For this purpose there are two devices, which are known respectively as fast and loose reed stop motions. The first was invented in 1796 by Robert Miller, and its action depends upon the shuttle, as it enters a box, raising two blades, K, which if left down would strike against stops and so disengage the driving gear. The second was invented in 1834 by W. H. Hornby and William Kenworthy; it is an appliance for liberating the lower part of a reed when a shuttle remains in the warp, thus relieving it, for the time being, of its function of beating up the weft. On the release of a reed from the motion of the slay a dagger stops the loom. Temples must keep a fabric distended to the breadth of

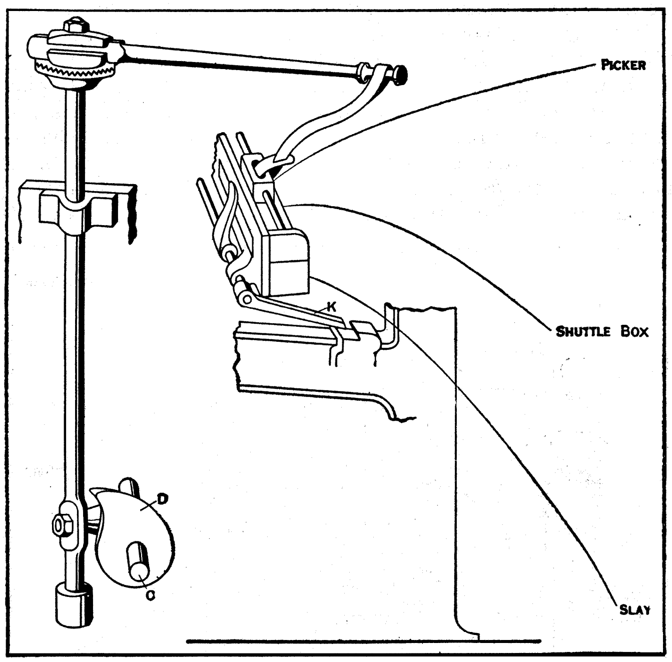

FIG. 29.— PICKING PARTS OF POWER LOOM
The illustration shows the cone overpick motion, the type generally used on the cotton looms of Lancashire and the jute looms of Dundee

the warp in the reed, and be self-adjusting. This is usually accomplished by small, rollers whose surfaces are covered with fine, closely set points. The rollers are placed near the selvages of a web which is prevented from contracting widthwise by being drawn tightly over the points.

Looms are varied in details to suit different kinds of work, but as a rule fabrics figured with small patterns are provided with healds for shedding as at L, while those with large patterns are provided with the Jacquard and its harness. Healds may be operated either by tappets or dobbies, but the range of usefulness in tappets is generally reached with 12 shafts of healds and with patterns having 16 picks to a repeat; where they are unsuitable for heald shedding a dobby is used. A dobby may resemble, in construction and action, a small Jacquard; if so the selection of healds that rise and fall for any pick is made by cards. In other types of dobbies the selection is frequently made by lags, into which pegs are inserted to pattern in the same manner that cards

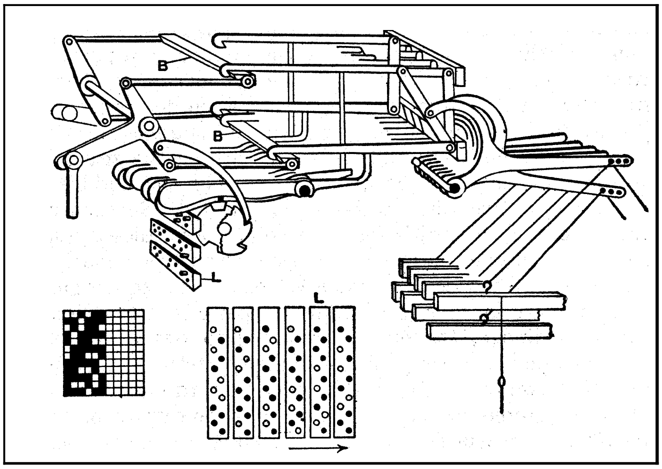

FIG. 30.— DOBBY SHEDDING MOTION. WIDELY USED FOR LIGHT CLOTHS REQUIRING SMALL PATTERNS. AS STRIPED SHIRTINGS AND DRESS FABRICS

are perforated. A dobby of this type is illustrated in fig. 30, which shows detached the pegging of the pattern lags for a small design, filled in circles representing pegs. The pattern lags, L, act on levers which lower hooks into contact with the oscillating griff bars B, and these lift the required heald shafts. The figure shows a double acting dobby, one lag, with two rows of pegs, serving for two picks. Some dobbies are made single acting and some have rollers instead of pegs to form a pattern. When multiple shuttles are required for power looms one of two types is selected, namely, drop or rotating boxes; the former are applicable to either light or heavy looms, but the latter are chiefly confined to light looms. As previously stated, Robert Kay invented drop boxes in 1760, but they were not successfully applied to the power-loom until 1845, when Squire Diggle patented a simple device for operating them automatically. Since his time many other methods have been introduced, the most successful of these being operated indirectly from the shedding motion. Revolving boxes were patented in 1843 by Luke Smith.

Many devices have been added to power looms with a view to reduce stoppages, among which those for the automatic supply of weft are probably the most important. These efforts originated with Charles Parker, who in 1840 obtained the first patent, but no marked success was achieved until 1894, when J. H. Northrop patented a cop changer. By his plan a cylindrical magazine, placed over one shuttle box, is charged with cops or pirns. When fresh weft becomes necessary the lowest cop in the hopper is pressed into a shuttle from above, the spent one is pressed out from beneath and the new weft is led into the shuttle eye, while the loom is moving at its normal speed. The mechanism is controlled by the weft fork, or by a feeler which acts when only a predetermined quantity of weft remains inside a shuttle. Many inventions are designed to eject an empty shuttle and introduce a full one; others change a cop, but differ in construction and action from the Northrop. By relieving a weaver of the labour of withdrawing, filling, threading and inserting shuttles it was seen that a large increase might be made in the number of looms allotted to one weaver, provided suitable mechanism could be devised for stopping a loom on the failure of a warp thread and for automatically maintaining a constant tension on the warp. With these devices as many as 100 looms have been supervised by one weaver.

Warp stop motions date from 1786, when Dr. Cartwright suspended an Independent detector from each warp thread until a fracture occurred, at which time a detector fell into the path of a vibrator and the loom was stopped. The demand for warp stop motions was, however, small until automatic weft supply mechanisms were introduced, and the majority of those devices now in use are constructed upon similar lines to the invention of Dr. Cartwright.

Smallware Looms.—A loom, which was for a long period operated manually, but to which mechanical power could be applied, was brought into use more than a century before Dr. Cartwright's invention. It was known as the Dutch engine loom, and was designed to weave from eight to upwards of 40 tapes or ribbons simultaneously. This machine may be regarded as a series of looms mounted in one frame, each having a complete set of parts, and as the first practical effort to connect and control all the motions of weaving from one centre. The place and date of its invention are uncertain, but it is known that in some districts its use was entirely prohibited, that in others it was strictly limited, and that it was worked in Holland about 1620. In England the first patent was obtained by John Kay and John Snell, in 1745, for additions which enabled it to be worked by hand, by water, or other force, and in 1760 John Snell appears to have added the draw harness for weaving flowered ribbons. In 1765 a factory in Manchester was filled with ribbon looms which were either invented by M. Vaucanson, or Kay and Snell, but one weaver could only attend to one machine. When worked by hand it was known as the bar-loom, because the weaver oscillated by hand a horizontal bar that set in motion all parts of the machine. The shuttles and reeds are actuated from the batten, the former originally by pegs, but later by a rack and pinion arrangement, which in action shoots the shuttles simultaneously across a web, to the right and left alternately, each into the place vacated by its next neighbour. One small warp beam is required for each web, but tappets, dobbies, or Jacquards are available for dividing the threads. Where differently coloured wefts are needed in one web the shuttles are mounted in tiers and all raised or lowered at once to bring the proper colour in line with the shed.

In *Swivel weaving,* shuttles, similar to those described above, are added to the battens of broad looms in order to diaper small figure effects, in different colours or materials, over the surface of broad webs. Weft from an ordinary shuttle forms the ground texture with the warp, and after the passage of this shuttle the small swivel shuttles place the figuring weft where required on the surface of the fabric.

Pile Weaving.— Looms for weaving piled fabrics differ in certain important respects from those employed for ordinary weaving; they are also made to differ from each other to suit the type of fabric to be manufactured, as, for example, double and single, plain and figured, textures. In *Double pile looms* the special features are those that control the pile threads and those that sever the vertical lines of pile. Two ground warps are required, and unless they are kept a uniform distance apart the piled effects will be irregular. For plain goods the pile threads are wound upon two or more beams, and as they move from web to web cloth-covered rollers deliver them in fixed lengths. Meanwhile, a shuttle passes twice in succession through each ground warp, and the pile threads in moving above or beneath the wefts are bound securely. Both fabrics are furnished with taking-up rollers which draw the pieces apart and so stretch the uniting pile in front of a knife, which severs it, thus forming two pieces at once.

The chief feature which renders most *single pile looms* dissimilar from others is the mechanism by which wires are woven upon, and withdrawn automatically from, a ground texture. Wires are of two kinds, namely, without and with knives. The former, being flattened and somewhat pointed, are woven above the weft of a ground texture, but beneath the pile, so that by withdrawing them looped pile is formed. A wire terminating in a knife with a sloping blade, on being withdrawn, cuts the pile and produces a brush-like surface. The mechanism for operating the wires is placed at one end of a loom and consists of an arm which moves in and out; at each inward movement a wire is inserted, and at each outward movement one is withdrawn. In weaving tapestry carpets, and certain other fabrics, a wire and a shuttle move simultaneously, but the shuttle passes through the ground warp, while the wire passes beneath the pile. After several wires have been woven upon the ground texture the one first inserted is withdrawn by the vibrating arm, and at the next inward movement the same wire enters the warp near the reed, where it is beaten up with the weft, and from this point the operation is continuous. Tapestry carpets require three warps, one for the ground texture, a second, or stuffing warp, to give bulk and elasticity to the tread, and a third to form the pile. The last named is printed upon a large drum, thread by thread to the colour-scheme of the design, then, when the colours have been fixed and the threads accurately placed, they are wound upon a beam, and all the warps are operated by healds. For figured velvets, and Brussels and Wilton carpets, the pile warp beam is replaced by a creel, in order that each thread of pile may be wound upon a bobbin and separately tensioned. This is essential, because, in the weaving of a design, it is probable that no two threads of pile will be required in equal lengths. Creels are made in sections called frames, each of which usually carries as many bobbins as there are loops of pile across a web, and the number of sections is the same as the number of colours. In weaving these fabrics healds are used to govern the ground warp, but a Jacquard is needed for the pile. It must form two sheds, the lower one to receive a shuttle, the upper one to make a selection of threads beneath which the wire is to pass.

Terry looms for weaving piled textures, of the Turkish towel type, have the reed placed under the control of parts that prevent it from advancing its full distance for two picks out of every series that separate one line of loops from another. At such times the weft is not beaten home but a broad crack is formed. So soon as the reed again moves through its normal space three picks of weft are simultaneously driven home, thus closing the gap and causing part of the pile to loop upward, the remainder downward. The system is available for plain and figured effects.

Gauze textures are woven in looms having a modified shedding harness, which, at predetermined intervals, draws certain warp threads crosswise beneath others and lifts them while crossed. There is also a tensioning device to slacken the crossed threads and thus prevent breakages due to excessive strain. At other times the shedding is normal.

Lappet looms have a series of needles fixed upright in laths, and placed in a groove cut in the slay, in front of the reed. Each needle carries a thread which does not pass through the reed. The needles are lifted for each pick and lowered after the passage of the shuttle, which is guided, not by the reed but by a series of pins in front of the needles and lifted and lowered along with the latter. After being lowered the needles are moved sideways the width of the figure and again lifted for the next pick. The edges of the figure are bound in this way to the ground texture by the weft.

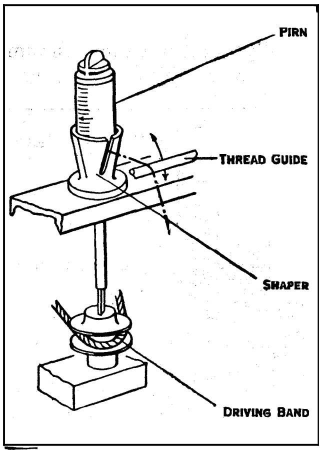

FIG. 31.—PIRN WINDING MACHINE, FOR WINDING COLOURED, AND SOMETIMES GREY, WEFT YARNS ON PIRNS FOR THE LOOM SHUTTLE

Preparing Warp and Weft for Weaving. — The power loom is only one of a series of machines which revolutionized weaving. Although early inventors of the power loom did much to perfect its various movements, the commercial results were disappointing> chiefly because means had not been devised for preparing warp and weft in a suitable manner for such a machine. William Radcliffe, of Stockport, perceived these shortcomings, and concluded that, by division of labour, weaving could be brought into line with spinning machinery, then recently invented. He therefore set himself the task of solving the problems involved, and by inventing the beam warper, the dressing sizing machine, the shuttle tongue, and the pin cop, he enabled the power loom to become a factor in the textile industry.

Weft yarns invariably receive simpler treatment than warp yarns; in many cases none at all. Cops and ring spools pass direct to the loom unless their dimensions are unsuited to the shuttles, in which case they, together with wefts bleached or dyed in hanks or used in a saturated condition, require winding upon pirns, or into cops of suitable sizes. Weft for use with automatic weft supply mechanism is frequently re-wound on to pirns, which hold much more than the cops or ring spools. This reduces the number of changes, lengthens the life of the changing mechanism and makes less work for the magazine fillers.

Pirn winders differ greatly in construction but a common type is illustrated in fig. 31. The spindles are driven at constant speed and the pirn is built up by the accumulation of yarn inside the shaper cup. The rubbing of the yarn against the cup is a disadvantage, and many winders have shapers which reduce rubbing to a minimum. These machines generally have horizontal spindles, running at constant speed, but often the speed is varied to keep constant rate of winding on to the varying diameter of the pirn.

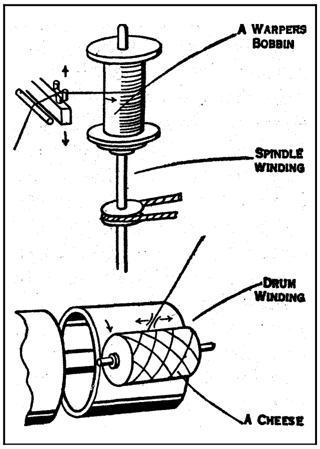

FIG. 32.— DIAGRAM OF WARP WINDING PROCESS

Warp winding consists in transferring yarn from cops, ring spools or hanks, either to warpers, bobbins or cheeses. Machines for this purpose are of two kinds, which are known respectively as spindle and drum winders (fig. 32). In the former each bobbin is placed upon a vertical spindle and rotated by frictional contact; a yarn guider meanwhile rises and falls far enough to lay the threads in even coils between the bobbin flanges. In the latter each bobbin, or tube, is laid upon a rotating drum and a thread guide moves laterally to and fro, slowly for a bobbin but quickly for a tube.

Warping. — Number of longitudinal threads in a web varies according to their closeness and its breadth. It is the function of a warper to provide a sufficient number of parallel threads for a web, all of equal length, and to retain their parallelism. Warpers are of three types, viz., mill, beam and sectional.

Mill *warping* (fig. 33) is the oldest type now in extensive use. A mill warper has a creel in which from 50 to upwards of 300 bobbins or cheeses are supported horizontally upon pegs, and the mill has a vertical axis which carries a reel from 5 to upwards of 20yd.

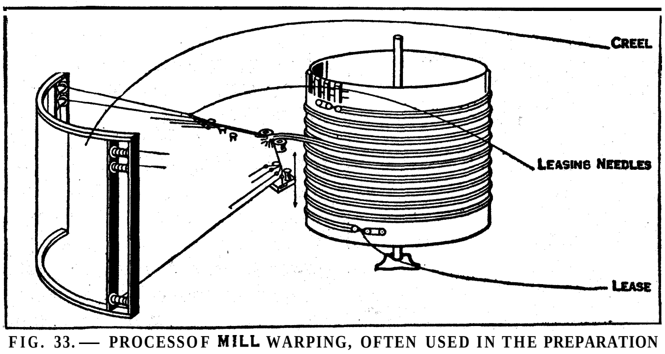

FIG. 33.— PROCESS OF MILL WARPING, OFTEN USED IN THE PREPARATION OF STRIPED COLOURED WARPS

in circumference. The threads from the creel are threaded in succession through leasing needles, then passed in groups of four to 20 threads between runners, and finally fastened by a peg to the mill staves. The needles are mounted alternately in two frames which may be lifted separately, one to elevate odd threads, the other even ones, and both separations thus formed are retained upon separate pegs; this is the lease which enables a weaver to fix readily the position of a broken thread. As the mill rotates the threads form a tape about 1in. wide, and the leasing appsratus slides down a post to coil the threads spirally upon the reel. When the full length of warp has been made the mill is stopped, a lease known as a half-beer lease is picked by hand from the divisions formed by the runners and is also retained upon pegs. The mill next reverses its direction of rotation, and as the leasing apparatus ascends the threads are folded back upon themselves. Hence, if a reel is 20yd. in circumference, and 200 threads are in use to make a warp 600yd. long, and containing 2,000 threads, the reel will

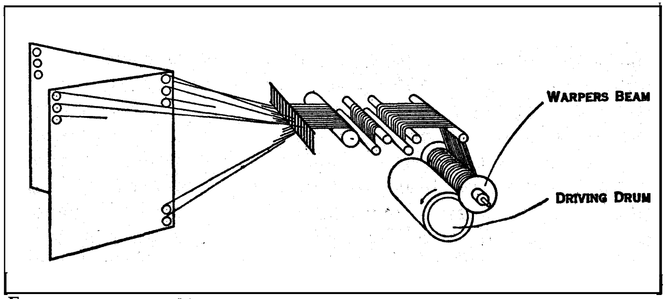

FIG. 34.— BEAM WARPING MACHINE. THE USUAL PROCESS FOR PREPARING THE WARP YARN FOR THE SLACKER SIZING MACHINE

make 30 revolutions (600÷20=30) and ten reversals, for at each reversal 200 additional threads will be added (2,000÷200=10).

Beam *warping* is the system most extensively used in the cotton trade. The creels for these machines have an average, capacity of about 600 bobbins, and are often V-shaped in plan. In each leg of the V the bobbins are arranged in tiers of 16 to 20, and row behind row. The threads are drawn separately between the dents of an adjustable reed, then under and over a series of rollers; from here they are dropped amongst the teeth of an adjustable comb and led down to a warper's beam, which rests upon the surface of a drum. As the drum rotates the threads are drawn from the bobbins and wrapped in even coils upon the beam. On most of these machines mechanism is attached for arresting motion on the breaking of a thread, and also for accurately measuring and recording the lengths of warp made. When full, a warpers beam holds threads of much greater length than are needed for any warp, but they are insufficient in number. Thus, if 500 threads are in use, and warps of the above-named particulars are required, four similar beams must be filled (2,000÷500=4) and the threads from all are subsequently united. The chief parts of a beam warper may be used as a substitute for a mill warper, provided that mechanism be employed to contract the threads to the form of a loose rope and coil them into a cylindrical ball, which will be subsequently treated as a mill warp. Or, one of these warpers may be furnished with parts which link the roped threads loosely into a chain.

Sectional warping is chiefly employed for coloured threads and its outstanding features consist in contracting the threads to form a ribbon of from 3in. to 12in. wide. This ribbon is coiled upon a block placed between flanges, and when completed is set aside until a sufficient number of similar sections have been made; after which they are slipped upon a shaft and by endlong pressure converted into a compact mass. All the threads are then collected and transferred in the form of a sheet to a loom beam, each section contributing its own width to that of the warp. Sectional warps are also made upon horizontal mills by superposing the coils of a ribbon of yarn upon a portion of the staves. When the first section is formed a second is wound against it, and the operation continued until all the sections have been made; after which the yam is run upon a loom beam.

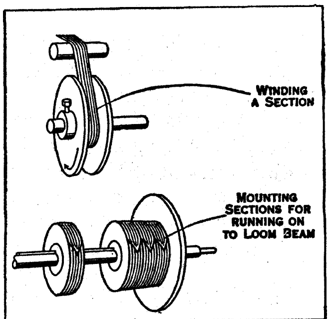

FIG. 35.—SECTION WARPING, SHOWING WARP YARN WOUND INTO SECTIONS (TOP), AND SECTIONS MOUNTED SIDE BY SIDE TO RUN YARN OFF ON LOOM BEAM (BOTTOM)

Yorkshire Dressing and Scotch Dressing — These systems are used to make striped warps from balled warps which have been dyed in different colours. The operation of Yorkshire dressing is as follows: The requisite number of threads of any colour is split from a uniformly dyed ball and set aside until warps of the remaining colours have been similarly treated. The split sections from the several balls collectively contain as many threads as are needed for a warp, but those threads have still to be placed in their proper sequence. This is done by drawing them in groups of two or four between the dents of a reed to a predetermined colour-scheme, then all are attached to a loom beam which is supported in a frame. The beam is rotated and winds the threads upon itself, but in order to hold the threads taut they are passed between weighted rollers and deflected by bars arranged ladder-wise, whilst in passing from one part of the machine to another they are gradually opened out to the width of the beam. Scotch dressing is an alternative system of making striped warps from dyed balled warps. Here, instead of being taken direct to the dressing frame, the required number of threads of each colour are first wound on to a beam. The threads from these differently coloured beams are then combined at the dressing frame and wound on to the loom beam according to the colour pattern, the yarn being wound on under considerable tension and the beam consolidated by a presser roller. This method gives a firmer beam than Yorkshire dressing, and the system is well suited to the preparation of several similar loom beams which can all be run from one set of coloured beams.

Sizing.—In cases where single yarns are made from short fibrous materials, smooth surfaces are obtained by laying outstanding ends of fibres upon the thread and fastening the fibres together to impart sufficient strength to resist the strains of weaving. This is accomplished either by coating the threads or by saturating them with an adhesive paste. In hand-loom days the paste was applied by brushes to successive stretches of warp while in a loom. But with the advent of mechanical weaving it was found necessary to size a warp before placing it in a loom. Two systems were evolved. One, invented by William Radcliffe, sizes, dries and beams a warp in one operation, the yarn being made to pass in the form of a sheet between a pair of rollers, the lower one being partly immersed in warm size. This roller carries upon its surface a film of size which it deposits upon the threads, while, by pressure, the upper roller distributes the size evenly, Brushes, acting automatically, smooth down the loose fibres and complete the distribution of size. As the yarn advances it is separated by reeds and lease rods, so that in passing over steam-chests and fans the moisture contained in the threads may be quickly evaporated. This machine is a duplex one, for the warpers beams are divided into two sets and placed at opposite ends of the machine, both sets receiving similar treatment as they move to the centre, where the loom beam is placed.

While efforts were being made to perfect Radcliffe's dressing machine a system of sizing ball warps was being gradually evolved and this system is still largely employed. The machine consists of a long trough, inside which a series of rollers are fitted, either in one horizontal plane or alternately in two horizontal planes, whilst over the front of the trough a pair of squeezing rollers are mounted. The trough contains size, which is maintained at a boiling temperature and in sufficient quantity to submerge the rollers. Two warps, in the form of loose tapes, may be simultaneously led over, under and between the rollers. As the warps advance, the threads become saturated with size, and the squeezing rollers press out all but a predetermined percentage, the latter being regulated by varying the pressure of the upper roller upon the lower one If more size be required than can be put into the threads during one passage through the machine, they may be similarly treated a second time. This process does not lay all the loose fibres, but the threads remain elastic. After sizing, the warps are passed round a set of steam-heated cylinders by which the moisture contained in the threads is evaporated; they are next either reballed or wound upon a loom beam.

For sizing cotton yarns Radcliffe's dressing machine has to a large extent been displaced by the slasher, but in some branches of the textile industry it is still retained under various modifications. In a slasher the threads from a number of warping beams are first combined into one sheet, then plunged into a trough filled with size which is kept at a boiling temperature by perforated steam pipes. The threads are next squeezed between two pairs of rollers mounted in the trough. The under surfaces of the sizing rollers are in the size, and the upper squeezing rollers, which are covered with flannel, rest by gravitation upon the lower ones. On leaving the size trough the sheet of yarn almost encircles two steam-heated cylinders which quickly expel moisture

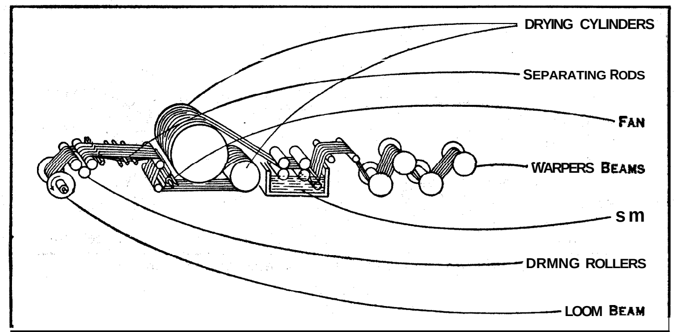

FIG. 36 —SLASHER SIZING MACHINE, FOR APPLYING SIZE TO THE WARP YARN AND FOR WINDING IT ON THE LOOM BEAM, ESPECIALLY IF CLOTH IS TO BE GREY OR ALL OF ONE COLOUR

from the yarn, but so much heat is retained that fans have to be employed to throw cool air amongst the threads. The yarn is next measured, passed above and below rods which separate threads that have been fastened together by size, smeared with piece marks, and coiled upon a loom beam.

Hank sizing is chiefly, but not exclusively, employed for bleached and coloured yarns. Machines for doing this work consist of a tank which contains size, flanged revolving rollers and two hooks. One hook is made to rotate a definite number of times in one direction, then an equal number the reverse way; the other has a weight suspended from its outer end and can be made to slide in and out. Size in the tank is kept at the required temperature by steam pipes, and "doles" of hanks are suspended from the rollers with about one-third their length immersed in size. As the hanks rotate all parts of the yarn enter the size, and when sufficiently treated they are removed from the rollers to the hooks where they are twisted to cause the size to penetrate the yarn and to wring out excess size. If sufficient size has not been added by one treatment, the wrung-out hanks are passed to a similar machine containing paste of greater density than the first and are treated a second time; if necessary this may be followed by a third passage. On the completion of sizing the hanks are removed either to a drying stove or a drying machine.

Drawing-in, or *entering,* is the operation of passing warp threads through the eyes of a shedding harness, in a sequence determined by the nature of the pattern to be produced, and the order of lifting the several parts. It is effected by passing a hook through each harness eye in succession, and each time a thread is placed in the hook by an attendant it is drawn into an eye by the withdrawal of the hook. The operation is generally done by hand, but for the simpler cloths, and particularly for repetition work, mechanical drawing-in is often used.

Twisting consists in twisting, between the finger and thumb, the ends of a new warp separately upon those of an old one, the remains of which are still in the eyes of the shedding harness. The twisted portions adhere sufficiently to permit of all being drawn through the eyes simultaneously.

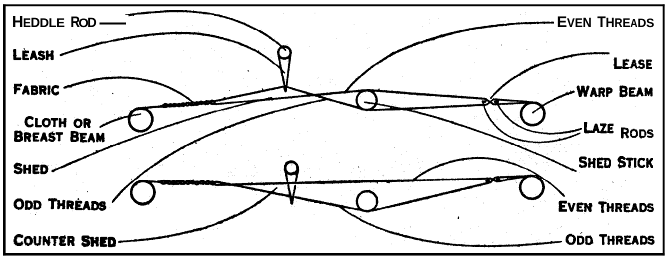
PRIMITIVE

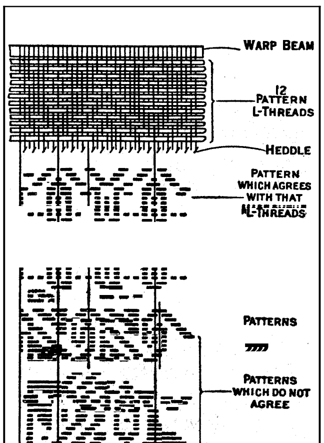
True weaving consists "of the interlacing at right angles by one series of filaments or threads, known as the *weft* or *woof,* of another series known as the *warp,* both being in the same plane." The *warp* threads are stretched from a *cloth-* or *breast-beam* to another beam known as the *warp-beam.* The process of weaving is then carried out by raising the odd threads, leaving the even ones



FROM ROTH, "STUDIES IN PRIMITIVE LOOMS" (ROYAL ANTHROPOLOGICAL SOCIETY)

FIG. 37

in position and passing the *woof* through the opening thus made. The odd threads are then lowered, the even ones raised, and the woof again passed between them. This is continued until the warp is full. The space between the odd and even threads when the former are raised is known as a *shed,* when the latter are raised as a *counter-shed.* The passing of the woof through either is termed *making* a *pick.* After each *pick* is made the woof is pressed home into position by a *beater-in* or *sword* usually a flat slat of wood. In some primitive looms the odd and even threads are laboriously raised by hand, but more commonly a *heddle* and *shed stick* are used. The simplest heddle consists of a bar of wood to which the odd warp threads are attached—this, the *rod heddle,* is always worked by hand. The *frame heddle* is composed of two parallel rods connected by a number of thin bars or strands, each with an eye or loop in the centre through which the odd warp threads pass (fig. 37). In Africa and Indo-China this is worked with the feet by means of treadles. The *shed stick* is a rod, usually of some thickness, which passes over the odd and under the even threads. When the heddle is not raised the thickness and weight of the shed-stick depresses the odd threads and so makes the *counter-shed* (fig. 38). *A* more efficient form of shed-stick is a lath which is set on edge to form the counter-shed. To prevent the warp threads from becoming entangled, either two slender laths are passed close to the warp-beam, one over the even and under the odd, the other over the odd and under the even threads; this prevents the warp threads from moving laterally or a *warp-spacer* is employed, *i.e.,* two parallel rods united by a number of rigid bars between which the warp-threads are passed in varying quantities. In many Indonesian and some African looms this is placed on the cloth-beam side of the heddles and serves as a *beater-in* as well. It is similar to the *reed* of a European hand-loom. An appliance which is sometimes used is the *temple,* usually a slender rod with a point at either end, inserted in the fabric horizontally close to the portion under construction, serving to keep the width of the web even. Except where the weft threads are discontinuous, as in the raffia looms of West Africa, the weft is wound upon a *spool.* The arrangement is either as on a European bobbin or the threads may pass lengthwise as on a netting needle. Where the former method is employed, the bobbin is usually encased in a shuttle, but among primitive peoples the latter is the more common. In Indonesia and Indo-China the material used in weaving is generally cotton, and this is also



FROM ROTH, "STUDIES IN PRIMITIVE LOOMS" (ROYAL ANTHROPOLOGICAL SOCIETY)

FIG. 38

widely used in Africa; but here and in the west Pacific vegetable fibre and the filaments of shredded leaves are utilized.

Variants.—Outside Africa the *horizontal loom* is most common. In this the warp beam is fixed a short distance off the ground. The cloth-beam is then either similarly fixed (as in the African specimens) or to it is fastened a girdle which passes behind the back of the weaver as she sits at work. By adjusting the position of her body she is able to regulate the tension on the warp threads. The looms of ancient Mexico and modern West Africa differ from other horizontal looms in that they lack a warp beam; instead the warp-threads are bunched together and anchored to a pole or to the ground.

The *vertical loom* is now found among primitive peoples in Africa, India and parts of North America. It was used in ancient Egypt and a special variety, with weights instead of a warp beam, in classical Greece. The African vertical loom has two varieties, that for weaving cotton and that for working raffia. They are probably related historically, possibly to the ancient Egyptian form. In them the warp-beam is the upper, the cloth-beam the lower; that is, the weaver begins his work at the bottom. A sloping loom is used by the Bushongo, wherein the warp is stretched at an angle of about 60° and the weaver sits underneath it, working from the bottom upwards.

Distribution. — The art of weaving occurs sporadically among primitive peoples. The vertical loom is found in Africa, India and among the Zuni, Navaho and kindred tribes of North America. The horizontal loom with fixed cloth-beam is mainly African; that with a back-strap is found in Farther India, Indo-China, in parts of Indonesia, Micronesia and north, central and south America, among the Ainu of Japan and in a few islands of Melanesia. In this last area its presence is almost undoubtedly due to Micronesian influence. In some islands, such as the Banks group and Santo (New Hebrides), it appears to have become a lost art, since there is evidence of its having been practised there formerly.

Sociological and Religious Aspect of **Weaving.**—Weaving is often the prerogative of one or other of the sexes. In Africa all the weavers are men, and though women may spin they are often prohibited from touching a loom. With the exception of Oceania the horizontal loom with the back-strap is worked mainly by women. Weaving may be restricted to villages or families, and among the Tangkhul Nagas of Assam, if a woman of a weaving village marries and goes to live elsewhere, she usually ceases to ply her craft. Even certain designs may be owned. In olden days in Ashanti the king appeared to hold "copyright" of all new designs, which were treated as a "tartan." Among the Sema Sagas a woman may not weave while her husband is away hunting, trading or fighting. The Ashanti hold it wrong to break or burn any part of a loom, and they therefore throw those which are past service into a stream. If a man weaver commits adultery with the wife of a weaver a sheep must be sacrificed in atonement to the loom as well as to the ancestral stools.

Rattray, *Religion and Art in Ashanti* (1927), contains a very detailed account of the technical processes and the manifold designs; richly illustrated. (C. H. W.)

WEAVING, HAND. One of the most ancient crafts, hand weaving is a method of forming a pliable plane of threads by interlacing them rectangularly. Invented in a preceramic age, it has remained essentially unchanged to this day. Even the final mechanization of the craft through introduction of power machinery has not changed the basic principle of weaving.

Other techniques had been devised to the same end: single element techniques—looping, netting, knitting, crocheting—and mul-

WOMEN WEAVING WOOL ON WARP-WEIGHT LOOM AS SHOWN BY A PAINTING ON LEKYTHOS (SCENT BOTTLE); ATHENIAN. ABOUT 560 B.C.

tiple element techniques—knotting, coiling, twining, braiding. In weaving, in the latter group, one system of threads, the warp, crosses another one, the weft, at right angles and the manner of intersecting forms the different weaves.

Gradually the various phases of manipulating warp and weft were mechanized until the technique of weaving surpassed all others in efficiency.

Whereas single-thread methods can be handled with few tools, weaving needs more complicated equipment since the warp has to be given tension. The device giving such tension is the loom. Weaving, then, is the process of passing the weft between taut, alternately raised warps, as in the basic plain weave, or between other combinations of selected warps, and pressing it into place.

Earliest weaving was done on the warp-weight loom where warps were suspended from an upper bar and weighted at bottom. Weaving here progressed downward, unlike other weaving. It was used in ancient Greece and, more recently, by Indians of the North Pacific American coast. Next came the two-bar loom, with warp stretched from bar to bar, or, for extended length, wound onto the bars. Used either vertically or horizontally, the warp was held taut by a framework or stakes in the ground. Early Egyptian records show weaving on such a loom which, in vertical position, is also the tapestry loom of today.

FAMILY OF FLEMISH WEAVERS USING SHAFT LOOM; FROM "BOOK OF **TRADES," YPRES, BELG.; 14TH CENTURY**

Another loom, allowing for subtly adjustable tension, therefore finer weaving, is the back-strap loom, in which the lower bar is attached to a belt around the waist of the weaver, who, leaning forward or backward can tighten or slacken the warp. This loom made possible the extraordinary textile achievements of pre-Columbian Peru and is still found in remote regions of Asia and parts of Central and South America.

The intersecting weft, crossing between raised and lowered warps, was first inserted without tool, the extra length being wound into little bundles, as today in tapestry weaving; *i.e.*, pictorial weaving. Later the weft was wound onto sticks and released as it traversed the warp. Finally, to introduce the weft faster and in greater length, it was wound on bobbins, inserted into boat-like shuttles, and thrust across the opened warp (the shed) in hand as well as in power looms.

To beat the weft into place, a weaver's sword of wood was an early instrument. Later a comblike "reed" was introduced, combining warp spacing with pounding of the weft. Suspended from the loom framework, the reed swings against the woven fabric pressing successive wefts against it.

A first device for speeding up the selection of warps between which the weft passes was the shed-rod, carrying raised warps. To raise the opposite warps, an ingenious device, called a heddle, was introduced. The warps running under the shed-rod were tied with string-loops to a second rod! the heddle-rod, and they now could be raised past those on the shed-rod with one upward motion. Later, series of heddle-rods replacing the shed-rod facilitated the production of weaves based on more complex warp operation than that demanded for the plain weave, based on the principle of opposites.

In the medieval loom the heddle-rods! now called shafts or harnesses, were suspended from the framework, similar to the pounding device, and were attached to foot treadles, as they are on hand looms today. They are still found on power looms. Though of incalculable value in saving time, this invention limited the thus far unlimited, primitive, warp selection.

To regain some of the early freedom, the highly developed draw-loom was devised. Chinese in origin, developed for elaborate pattern weaving, such as brocades and damasks, it was later adopted in Europe. It was superceded by a further mechanized warp-selection method, Jacquard weaving, still in use today, though transferred during the past century to power-driven machinery.

Among high achievements in hand weaving, Coptic as well as early Peruvian weaving must be recognized, the latter surpassing perhaps in inventiveness of weave structure, formal treatment, and use of colour, other great textile periods. In fact practically all known methods of weaving had been employed in ancient Peru, and also some types now discontinued.

Today, hand weaving is practised mainly on the medieval shaft loom with few harnesses. No longer of consequence as a manufacturing method in an industrial age, it concerns itself chiefly with fabrics for decorative use. Increasingly, though, industry is turning to hand weavers for new design ideas, worked out on hand looms, to be taken over for machine production. Hand weaving is included in the curriculum of many art schools and art departments of colleges and universities, as an art discipline able to convey understanding of the interaction between medium and process that results in form. It has survived through the ages as an art form in tapestry.

Hand weaving has also been taken up in the field of occupational therapy, having, though, as its aim there neither an educational nor an artistic end but solely that of rehabilitation.

It should be realized that the development of weaving is dependent also upon the development of textile fibres, spinning and dyeing, each a part of the interplay resulting in a fabric. Recent advances in the production of synthetic fibres and new textile finishes are having profound effect upon the weaving of cloth. (AN. A.)

WEBB, MATTHEW (1848–1883), English endurance swimmer popularly known as "Captain Webb," was the first person to swim the English channel. Born at Dawley, Shropshire, Jan. 18, 1848, he first attracted international attention when, on July 3, 1875, he swam the Thames from Blackwall pier, East London, to Gravesend, Kent (20 mi.) in 4 hr. 45 min., a record which stood for 24 years. Seven weeks later, on Aug. 24–25, he swam the channel, from Dover to Calais, in 21 hr. 45 min.

Captain Webb died on July 24, 1883, attempting to swim the whirlpool rapids below Niagara falls. *See* also SWIMMING: *Channel Swimming.* (J. D. McC.)

WEBB, PHILIP SPEAKMAN (1831–1915), British architect of the Gothic school, was born at Oxford on Jan. 12, 1831. He was educated at Aynho, Northamptonshire, and entered the office of G. E. Street, Oxford, where he met William Morris. In 1856 he set up for himself in London and after the establishment of the firm founded by Morris produced for them many designs for varied purposes. house decoration, tiles, jewelry, furniture, etc. Webb designed many country houses and one church, at Brampton, Cumberland (1875). His first house was built for William Morris (Red house, Upton, 1859). He also made additions to old houses; for example, Berkeley castle and Pusey house, Berkshire. Webb was the inventor of a method by which old buildings were strengthened by filling the interior of the walls with new material. This procedure was often used by the Society for the Protection of Ancient Buildings, which Webb and Morris jointly organized and founded in 1877. Webb died at Worth, Sussex, on April 17, 1915.

WEBB, SIDNEY JAMES, 1ST BARON PASSFIELD (1859–1947), and **BEATRICE** (née POTTER) (1858–1943), English leaders of social and economic reform, for half a century exercised far-reaching influence on the outlook of their time. Their books had world-wide circulation; the effect of their joint action was not less notable.

Sidney Webb was born on July 13, 1859, in London, of East Anglian stock. His father was an accountant; his mother carried on a hairdressing business. Educated on the continent and at the City of London and Birkbeck colleges, he left school at 16 and in 1878, after a brief period of commercial employment, won a place in the war office. Successful in a series of competitive open examinations, he passed from the clerical to the administrative grade in 1881 and spent ten years in the colonial office. In 1885 he was called to the bar; in the same year he joined the Fabian society (*q.v.*), where Bernard Shaw was a lifelong friend. His contribution to *Fabian Essays* (1889) was read by Beatrice, one of the nine daughters of Richard Potter, a wealthy and enterprising industrial magnate in Tadcaster. Born in Gloucester, Jan. 22, 1858, and privately educated, Beatrice shared her father's work, traveled widely with him and acted as his London hostess. In 1887 she entered the field of social work as assistant to her cousin Charles Booth (*q.v.*), in the inquiry published as *Life and Labour of the People in London* (17 vol., 1891–1903). At the time of her first meeting with Sidney Webb, she was engaged on *The Co-operative Movement in Great Britain* (1891). In 1892 they married. Henceforward, resources and talents were fused. Their London home—41 Grosvenor road—became a workshop for a long series of books, a hive of intellectual activity and a serious social centre of a unique kind.

Leaving the civil service in 1891, Sidney was elected, on a forthright Fabian program, as a Progressive member of the new London county council (L.C.C.). He held his seat at Deptford, with increasing majorities at each election, until he resigned in 1910. Much of his L.C.C. activity was devoted to education; he has been called the parent of London's educational system *(see* EDUCATION, HISTORY OF). The Webbs were the power behind the Balfour Education acts of 1902 and 1903; they did much to give London a teaching university; and they promoted the development of the London School of Economics. Sidney served on many royal commissions, including that of 1903–06 on trade unions; Beatrice was a member of the commission on the poor law.

Its famous minority report (1909) challenging the basis of the entire poor-law system, signed by Beatrice, was written, as usual, jointly by herself and her husband *(see* POOR LAW: *Reports of the Royal Commissions, 1909).* They organized a great crusade in favour of the minority report; its failure, at the time, brought them into party politics, hitherto eschewed. In 1913 they founded the *New Statesman;* in 1914 Sidney became a member of the war emergency committee set up by the Labour party and largely directed its domestic policies. He wrote the manifesto *Labour and the New Social Order,* on which the party fought the elections of 1918, 1922 and 1924; he was, from 1915 to 1925, a member of the party's national executive. In 1918 he stood as member of parliament for London university; in 1922 he was elected M.P. for Seaham Harbour. In the 1924 Labour government he was an adequate president of the board of trade. He resigned his seat in 1928, but in the government of 1929 he came back, under strong pressure, to be secretary of state for the colonies, with a seat in the house of lords as Baron Passfield—a title his wife never used. The name was derived from the pleasant house, Passfield Corner, in Liphook, Hampshire, to which they had retired in 1928, giving up their London home but not their contacts. In 1932 they visited the U.S.S.R. and in 1935 published their last major book, *Soviet Communism,* in which the doctrine of "gradualism," to which they had been so long devoted, seemed to be thrown over. In 1944 Sidney Webb was awarded the Order of Merit. Beatrice died in Liphook on April 30, 1943; he died four years later, on Oct. 13, 1947, also in Liphook. Their ashes are interred in Westminster abbey.

The most important works by the Webbs are: *The History of Trade Unionism* (1894; rev. ed., 1920); *Industrial Democracy* (1897; new ed., 1920); *English Local Government,* 9 vol. (1906–29; includes *English Poor Law History,* 3 vol.); *The Break-up of the Poor Law* (1909); *English Poor Law Policy* (1910); *A Constitution for the Socialist Commonwealth of Great Britain* (1920); *The Consumers' Co-operative Movement* (1921); *The Decay of Capitalist Civilization* (1923); *Soviet Communism: a New Civilisation?* (1935; 3rd ed., 1945).

Beatrice Webb also wrote *My Apprenticeship* (1926) and *Our Partnership* (ed. by B. Drake and Margaret I. Cole, 1948). Her *Diaries, 1912–1924* were also edited by Cole (1952).

WEBB, WILLIAM HENRY (1816–1899), U.S. naval architect and the leading shipbuilder in New York for over 30 years, was born in New York city on June 19, 1816. He began shipbuilding at the age of 20, and by 1869 he had built more tonnage than any other U.S. builder. Bold and versatile in his designs, he built packets, clippers and side-wheelers, sailing vessels and steamships, wooden ships and ironclads. He also built war vessels for Russia, Italy and France.

Webb closed his shipyard in 1869, due to the shift from wood to iron construction, but continued his shipping interests until 1872 when he retired because of ill-health. He died in New York on Oct. 30, 1899.

Webb's most permanent and important contribution was the founding, building and endowing of Webb Institute of Naval Architecture at Glen Cove, N.Y., in 1889. (F. E. HA.)

WEBER, ALBRECHT (1825–1901), German orientalist, one of the most outstanding Sanskrit scholars of his generation, who contributed greatly to the development of European knowledge in ancient Indian studies, was born at Breslau on Feb. 17, 1825. In 1856 he was appointed teacher of Sanskrit at the University of Berlin and in 1867 he became professor of ancient Indian languages and literature, which appointment he held until his death in Berlin on Nov. 30, 1901. It was chiefly in the field of Vedic literature, especially in the old Vedic ritual texts, that he excelled as a scholar. He contributed largely to the Vedic portions of the great Sanskrit dictionary of O. von Bohtlingk and R. Roth. Although his principal work was on Sanskrit, he also took a keen interest in Prakrit: his edition of the Prakrit poems ascribed to Hala and his study of the Jaina Prakrit manuscripts in the Berlin Royal library are his most important works in this field.

Among Weber's important publications are: *White Yajurveda* (1849–59); *Akademische Vorlesungen über indische Literaturgeschichte* (1852); *Indische Studien* (1849–98), a review which Weber started and edited and to which he largely contributed; and *Verzeichnis der Sanskrithandschriften der kgl. Bibliothek zu Berlin* (1853–92). (J. BR.)

WEBER, CARL MARIA FRIEDRICH ERNEST VON (1786–1826), German composer, was born at Eutin, near Lubeck, on Dec. 18, 1786, of a family long devoted to art. His father, Baron Franz Anton von Weber, a military officer in the service of the palgrave Karl Theodor, was an excellent violinist, and his mother once sang on the stage. In 1778 Franz Anton was appointed director of the opera at Liibeck. In 1779 the prince-bishop of Eutin made him his *Kapellmeister,* and five years later he went to Vienna. placed two of his sons under Michael Haydn, and in 1785 married the young Viennese singer Genovefa von Brenner. In the following year Carl Maria was born—a delicate child, afflicted with congenital disease of the hipjoint.

Carl Maria von Weber became familiarized with the stage from his earliest infancy. Franz Anton hoped to see him develop into an infant prodigy, like his cousin Mozart. The child was taught to sing and place his fingers upon the pianoforte almost as soon as he could speak, though he was unable to walk until he was four years old. Happily his powers of observation and aptitude for general learning were so precocious that he seems, in spite of all these disadvantages, to have instinctively educated himself. In 1798 Michael Haydn taught him gratuitously at Salzburg. In April the family visited Vienna, moving in the autumn to Munich. There the child's first composition—a set of "Six Fughettas"—was published, with a pompous dedication to his half-brother Edmund; and there also he took lessons in singing and in composition. Soon afterward he began to play successfully in public, and his father compelled him to write incessantly. Among the compositions of this period were a mass and an opera—Die *Macht der Liebe und des Weins*—now destroyed. A set of "Variations for the Pianoforte," composed a little later, was lithographed by Carl Maria himself, under the guidance of Alois Senefelder, the inventor of the process. In 1800 the family moved to Freiburg. where Ritter von Steinsberg gave Carl Maria the libretto of an opera. *Das Waldmädchen,* which the boy (not yet 14) at once set to music, and produced in the following November at Freiburg.

Carl Maria returned with his father to Salzburg in 1801, resuming his studies under Michael Haydn. There he composed his second opera, *Peter Schmoll und seine Nachbarn,* which was unsuccessfully produced at Nuremberg in 1803. In that year he again visited Vienna, where, though Joseph Haydn and Albrechtsberger were both receiving pupils, his father preferred placing him under Abt Vogler. Through Vogler's instrumentality Carl Maria was appointed conductor of the opera at Breslau, before he had completed his eighteenth year. He began a new opera called *Riibezahl,* the libretto of which was "romantic" to the last degree, and Weber worked at it enthusiastically, but it mas never completed, and little of it has been preserved beyond a quintet and the masterly overture, which was rewritten in 1811 under the title of *Der Beherrschcr der Geister.* Quitting Breslau in 1806, Weber removed in the following year to Stuttgart, where he had been offered the post of private secretary to Duke Ludwig, brother of Frederick. king of Wiirttemberg. He worked hard, and in 1809 remodeled *Das Waldmadchen,* under the title of *Sylvana.* Weber removed to Darmstadt in order to be near his old master Abt Vogler. and his fellow-pupils Meyerbeer and Gänsbacher. On Sept. 16. 1810, he reproduced *Sylvana* at Frankfort, but with very doubtful success. His new comic opera *Abu Hassan* was completed at Darmstadt in January 1811.

Weber started in February 1811 on an extended artistic tour, during which he made many influential friends, and on June 4 brought out *Abu Hassan* with marked success at Munich. His father died at Mannheim in 1812. In 1813 Carl Weber's wanderings were brought to an end by the unexpected offer of an appointment as *Kapellmeister* at Prague, coupled with the duty of entirely remodeling the performances at the opera house. He retained this post till 1816. He composed no new operas. but he had already written much of his best pianoforte music, and played it with never-failing success, while the disturbed state of Europe inspired him with some of the finest patriotic melodies in existence. First among these stand ten songs from Körner's *Leyer und Schwerdt,* including "Vater. ich rufe dich," and "Lützow's wilde Jagd"; and in no respect inferior to these are the splendid choruses in his cantata *Kampf und Sieg,* which was first performed at Prague. on Dec. 22. 1815.

Weber resigned his office at Prague on Sept. 30, 1816. and on Dec. 21, Frederick Augustus, king of Saxony, appointed him *Kapellmeister* at the German opera at Dresden. Weber had previously meditated turning *Der Freischiitz* into an opera, and, with the assistance of Friedrich Kind, he produced an admirable libretto, under the title of *Des Jagers Braut.* He had dealt with the supernatural in *Riibezahl,* and in *Sylvana* with the pomp and circumstance of chivalry; but the shadowy impersonations in *Riibezahl* are scarcely less human than the heroine who invokes them; and the music of *Sylvana* might easily have been adapted to a story of the 19th century. But Weber now knew better than to let the fiend in *Der Freischiitz* sing; with three soft strokes of a drum below an unchanging dismal chord he brings him straight to us from the nether world

Weber wrote the first note of the music of *Der Freischiitz* on July a—beginning with the duet which opens the second act. But nearly three years elapsed before the piece was completed. In the meantime the performances at the opera house were no less successfully remodeled at Dresden than they had already been at Prague, though the work of reformation was far more difficult. Having, after much difficulty, broken off his liaison with Margarethe Land, Weber married the singer Carolina Brandt, a consummate artist. The new opera was completed on May 13, 1820. He had engaged to compose the music to Wolff's gypsy drama, *Preciosa.* Two months later this also was finished, and both pieces ready for the stage.

It had been arranged that both *Preciosa* and *Der Freischütz*—no longer known by its original title, *Des Jagers* Braut—should be produced at Berlin. *Preciosa* was produced with great success at the old Berlin opera house on June 14, 1821. On June 18, the anniversary of the battle of Waterloo, the opening of the new *Schauspielhaus* was celebrated by the production of *Der Freischütz.* Its success was triumphant, and it was received with equal enthusiasm at Vienna on Oct. 3 and at Dresden on Jan. 26, 1822. Yet Weber's position as *Kapellmeister* was not much improved by his success. For his next opera Weber accepted a libretto based, by Frau Wilhelmine von Chezy, on the story of *Euryanthe,* as originally told in the 13th century, in Gilbert de Montreuil's *Roman de la Violette,* and repeated with alterations in the *Decameron,* in Shakespeare's *Cymbeline,* and in several later forms. The work was produced at the Karntnerthor theatre in Vienna, on Oct. 25. 1823. and received with enthusiasm.

Weber's third and last dramatic masterpiece was an English opera. written for Covent Garden theatre. upon a libretto adapted by Planché from Wieland's *Oberon.* It was disfigured by the spoken dialogue abandoned in *Euryanthe;* but in musical beauty it is quite equal to it, while its fairies and mermaids are as vividly real as the spectres in *Der Freischiitz.* Though dying of tuberculosis Weber began to compose the music on Jan. 23, 1825. Charles Kemble had offered him £1,000 for the work, and he could not affordto rest. He finished the overture in London, at the house of Sir George Smart, soon after his arrival, in March 1826; and on April *12*, the work was produced with triumphant success. Weber was found dead in his bed on the morning of June 5, 1826. Besides his three great dramatic masterpieces and the other works already mentioned, Weber wrote two masses, two symphonies, eight cantatas, and a large number of songs, orchestral and pianoforte pieces, and music of other kinds, amounting altogether to more than 250 compositions.

Weber's style rises, in his three greatest works, to heights which show his kinship with the great classics and the great moderns. His intellect was quick and clear; but yet finer was the force of character with which he overcame the disadvantages of his feeble health, desultory education and the mistakes of his youth. With such intellect and character, every moment of his short life was precious; and it is impossible not to regret the placing of his training in the hands of Vogler.

Weber's master was an amiable charlatan, whose weakness as a teacher was exposed, in perfect innocence, by his two illustrious pupils Meyerbeer wished to be famous as the maker of a new epoch in opera. Weber could not help being so in reality. But all his determination could not quite repair the defects of his purely musical training, and though his weaknesses are not of glaring effect in opera, still there are moments when even the stage cannot explain them away. Thus the finale of *Der Freischütz* breaks down so obviously that no one thinks of it as anything but a perfunctory minding-up of the story, though it really might have made quite a fine subject for musical treatment.

In *Euryanthe* Weber attained his full power, and his inspiration did not leave him when this work needed large musical designs. But the libretto was full of absurdities; especially in the last act, which not even nine remodelings under Weber's direction could redeem. Yet it is easy to see why it fascinated him, for, whatever may be said against it in regard to probability and literary merit, its emotional contrasts are highly musical: it is through them that the defects invite criticism.

WEBER, ERNST HEINRICH (1795–1878), German anatomist and physiologist, a pioneer in the field of psychophysiology, was born in Wittenberg. June 24, 1795, the oldest of three brothers, all of whom achieved distinction in science *(see* WEBER, WILHELM EDUARD) From 1818 until his death Weber held a chair at Leipzig. Though he conducted many investigations on the internal organs, he is known chiefly for his work on touch, a field in which he conducted many original experiments and published two books: *De tactu: annotationices et physiologicae* (1834); and *Der Tastsinn und das Gemeingefühl,* first as a section of Rudolf Wagner's *Handwörterbuch der Physiologie* (1846) and later as a separate book (1851). Weber died in Leipzig on Jan. 26, 1878.

Weber's experiments on cutaneous localization and the two-point threshold led to his theory of sensory circles—small regions of common innervation that are projected upon the brain—a forerunner of R H Lotze's theory of local sign and of the doctrine of isomorphism of Gestalt psychology

From the localization of touch Weber went to the localization of sound. but these experiments attracted little attention. His measurement of sensibility—the just noticeable difference between sensations—might also have been neglected had his results not attracted the attention of G. T Fechner (*q.v*), who made them the basis of psychophysics Weber discovered the principle that ratios. not absolute differences, are required for the discrimination of least perceptible differences. Fechner saw the significance of these results for his own theory, gave mathematical form to the empirical relationship and called the formulation Weber's law. (K. M. D.)

WEBER, MAX (1864–1920), influential German sociologist and political economist, was born at Erfurt on April 21, 1864, and died in Munich on June 14. 1920. He was a professor at the universities of Berlin (1893), Freiburg (1894), Heidelberg (1897) and Munich (1919). As a student of legal and economic history, his first important work in this field was *Dze romische Agrargeschichte in ihrer Bedeutung fur das Staats- und Privatrecht* (1891). Later he turned to the study of sociology; the main challenge to his mind was the Marxist idea of economic determinism. In a thorough historical study *Die protestantische Ethik und der Geist des Kapitelismus* (1904–05; Eng. trans.. *The Protestant Ethic and the Spirit of Capitalism,* 1930), he tried to prove that, in this case at least, religious and ethical ideas were of overwhelming significance. The problem of historical causation developed into an even broader question: in view of the failure of other cultures to produce a capitalized economy. what factor in the spiritual history of the western world is responsible for capitalism? *(See* CAPITALISM) Weber found an answer only by thoroughly studying the religious and social history of India, China and the Jews His results were published in three volumes, *Gesammelte Aufsatze zur Religionssoziologie* (1920–21; Eng. trans., "The Religions of the East Series," 1952–58) His *Wirtschaft* und *Gesellschaft* (1921; Eng. trans.. *On Law in Economy and Society,* 1954) is a systematic presentation of the sociological factors (economic and noneconomic) that shaped history—a grandiose attempt to show that world history lends itself to systematic treatment. *(See* ECONOMICS: *The Critical Schools.)* In his contribution to scientific methodology, *Gesammelte Aufsatze zur Wissenschaftslehre* (1922; Eng. trans.. *Methodology of the Social Sciences,* 1949), Weber argued that human studies are different in nature from science because sympathetic understanding *(Verstchen)* and valuations play a decisive role, and the elaboration of the typical leads to the creation of specific concepts (*Idealtypus*). The great political thinker of the Weimar republic, he was a firm believer in the democratic ideals of the west.

Weber also wrote *Gesammelte Aufsatze zur Sozial- und Wirtschaftsgeschichte* (1924; Eng trans., *Theory of Social and Economic Organization,* 1947); *Gesammelte Aufsätze zur Soziologie und Sozialpolitik* (1924); *Gesammelte politische Schriften* (1921); *Wirtschaftsgeschichte* (lecture notes), ed by S. Hellman and M Palyi (1923; Eng trans., 1927). *From Max Weber: Essays in Sociology* was translated and edited by Hans H. Gerth and C. Wright Mills (1946).

See Marianne Weber, *Max* Weber: *ein* Lebensbild (1926), with a full bibliography (K. MM.)

WEBER, WILHELM EDUARD (1804–1891), German physicist noted for his contributions to the study of electricity and electromagnetism, was born at Wittenberg on Oct 24, 1804, a younger brother of Ernst Heinrich Weber, author of Weber's law. He studied at Halle and Gottingen, was one of the seven professors who were expelled for protesting against the action of the king of Hanover (Ernest Augustus, the duke of Cumberland) in suspending the constitution (1837). He was professor at Leipzig (1843) and in 1849 returned as professor at Göttingen.

There was at that time no system either of stating or measuring electrical quantities; but Weber showed, as his colleague C. F. Gauss did for magnetic quantities, that it is both theoretically and practically possible to define them, not merely by reference to other arbitrary quantities of the same kind, but in terms in which the units of length. time and mass are involved. Weber's theory of electricity was founded on the views of Gustav T Fechner, who considered that positive and negative charges move in a conductor with equal and opposite velocities. From this he worked out the law of forces between charges. Weber's work on electricity did much to stimulate mathematical physicists. He also carried on extensive researches in the theory of magnetism and developed Michael Faraday's ideas regarding the explanation of diamagnetic phenomena. In his observations in terrestrial magnetism he not only employed an early form of mirror galvanometer but, about 1833. devised a system of electromagnetic telegraphy, by which a distance of about 9,000 ft. was worked over. In conjunction with his brother Ernst h e published in 1825 a well-know: treatise on waves, *Die Wellenlehre auf Experimente gegründet;* and in 1836 he collaborated with his younger brother. the physiologist Eduard Friedrich Weber (1806–71), in an investigation into the mechanism of walking.

He died at Gottingen on June 23, 1891.

WEBER AND FIELDS, U.S comedians and theatrical managers. JOSEPH M. WEBER was born Aug. 11,1867, and LEW (Lewis Maurice) FIELDS, Jan. 1, 1867, both in New York city. In 1877 they made their first appearance in public, enacting together a juvenile sketch. They perfected their comedy teamwork over the next eight years, appearing chiefly in Dutch sketches. In 1885 they formed their own company and ten years later took over management of the Broadway Music hall, which thereafter was popularly called "the Weber and Fields." Their shows consisted chiefly of informal song, dance and comedy routines; and their burlesques of popular plays of the period, under such titles as *The Great Decide* and *Without the Law*, were featured. In 1904 Fields left the partnership and opened Fields' theatre. The team reunited in 1912 to produce *Hokey-Pokey* at the Broadway theatre, which Weber had continued to manage. Fields died in Los Angeles, Calif., July 20, 1941; Weber, May 10, 1942, also in Los Angeles. (S. W. H.)

WEBERN, ANTON (1883–1945), Austrian composer, was born in Vienna on Dec. 3, 1883. He studied at Vienna university, taking the degree of Ph.D. in musicology, and was one of the first disciples of Arnold Schönberg, whose principles he adopted in his own works. In concentration and intensity he even exceeds Schönberg, and fragmentariness and almost complete absence of tangible melody or effective rhythm are characteristics of his later compositions. A typical feature is his use of pianissimo. Webern died on Sept. 15,1945, near Salzburg.

His works include: choral cantatas; two string quartets, op. 5 and 9; pieces for violin and piano, op. 7; *passacaglia,* symphony and variations for orchestra; *Geistliche Lieder* for soprano with five instruments, op. 17; other vocal and instrumental chamber music; and five sets of songs.

WEBER'S LAW: *see* PSYCHOPHYSICAL METHODS.

WEBSTER, DANIEL (1782–1852), American statesman and lawyer, was born in Salisbury (area now in Franklin), N.H., Jan. 18, 1782. His parents were rugged New England farming people. Daniel was the delicate one of the family, and not particularly inclined to farm work. From childhood, however, he loved out-of-door life, was exceedingly fond of hunting and fishing, and unusually skilful at them, and this taste, which became strong in his youth, clung to him through all his long career.

His early schooling was primitive. But he had a passion for books of all sorts. Bits of the poets and illustrations from the great historians were always ready to his hand when he needed them and came out with singular appropriateness in later years. It has been urged that he was indolent. So was Sir Walter Scott. But Scott could do more work in a day than other men in a week; and so could Webster. His mind seized the essence of things.

These intellectual gifts were so manifest that Webster's father made great sacrifices to send the boy to Phillips academy, Exeter, and then to Dartmouth college. His college record was good, but not remarkable; like many men of genius, he preferred other things to the appointed task. It is said that in early days he was reluctant to speak in public, but toward the end of his college career he was known as something of an orator and debater, and when he was 18, a year before his graduation in 1801, he was invited to deliver the Fourth of July address for the town of Hanover. Some of these early speeches have been preserved, and while crude, they suggest what was to come.

With a mind like Webster's the law seemed the inevitable vocation, and the little teaching he did was merely a means to an end. As was the custom in those days, he went into the office of a practising lawyer in Boston, and the invaluable training of Christopher Gore no doubt went far in making his pupil the great lawyer that he afterwards became. He was admitted to the bar in 1805, and in 1807 settled himself to practise in Portsmouth. His reputation in law is quite as great as, perhaps more unclouded than, in statesmanship. His clear, massive, gorgeous, overwhelming eloquence carried juries with him as well as parliaments, and no estimate of his eloquence is complete that does not allow for the superb personality that gave it weight and vigour. He was a notable presence, even to those who passed him unknown in the street. The dignity of his solid figure, the rich and varied music of his voice, above all the penetrating splendour of his eyes, gave his spoken words a glory which we cannot recover, effective as his speeches often are in print. Of his jury triumphs the best known is that in the White murder case. His most celebrated plea before the Supreme Court in Washington is that for Dartmouth college, in 1818, when the personal touches, notably, "It is, as I have said, a small college, and yet there are those who love it," so affected all present that it was said of Chief Justice Marshall that "the deep furrows of his cheek expanded with emotion and his eyes suffused with tears."

Party passions, together with the power of his tongue, naturally took Webster into politics. It is said that even in childhood he began to study the Constitution as printed on a cotton handkerchief. From 1813 to 1817 he was a member of the House of Representatives. New England at that time was bitterly opposed to the Madison Administration, to the Democratic Party, and especially to the war with England, and Webster's eloquence was used unsparingly to express these New England prejudices, though he cannot be connected with the more or less disloyal Hartford Convention. At this early period, in curious contrast to his later views and arguments, he was hostile to a protective tariff, feeling that it would complete the ruin of the New England shipping interests, already sufficiently imperilled by the cost of the war.

While he was out of politics, from 1817 to 1823, Webster devoted himself energetically and profitably to the practise of law. During these years he was making his great reputation as a historical orator. In 1820 he delivered the bi-centennial speech at Plymouth, celebrating the landing of the Pilgrims, and it is probable that in the line of general eloquence he never reached a greater height than this. The significance of America, the political, social and religious principles that America stood for, and the splendid development and prospects of the Anglo-Saxon race, were portrayed with a dignity and amplitude which good judges consider worthy to be compared with Demosthenes or Burke. Webster's impressive delivery, his intense, magnetic hold upon his audience, were never more fully manifested than upon this occasion. Ticknor, who was present, gives a vivid account of his own experience: "I was never so excited by public speaking before in my life. Three or four times I thought my temples would burst with the gush of blood. . . . When I came out I was almost afraid to come near to him. It seemed to me as if he was like the mount that might not be touched and that burned with fire. I was beside myself, and am so still." The address delivered on the anniversary of the battle of Bunker Hill, in 1825, was another of these historical tributes, equally successful and well known. On Aug. 2, 1826, Webster gave, in Faneuil hall, Boston, the eulogy on John Adams and Thomas Jefferson, who had both died on the Fourth of July previous. This speech contains the famous words, attributed to John Adams, "Sink or swim, live or die," etc., which have probably been repeated in school declamations as often as any piece of rhetoric in the English language. In 1823 Webster again appeared in the House of Representatives, and in 1827 in the Senate, in which he was to play so great a part for many years. The Missouri Compromise (*q.v.*) of 1820 had for the time apparently settled the question of slavery, but in reality the rift between the two sections of the country had been opened, and it was not ever really to be closed again until after the Civil War.

Webster's position with regard to slavery was taken at this time, and in spite of his conduct in later years, it cannot be said that his theoretical attitude was ever altered. He believed, as did so many good men and leaders, both North and South, that slavery was an evil, disastrous to the white race as much as to the black. The earlier great men of the South in the main held this view, and it was left for Calhoun and Jefferson Davis, under the controlling influence of cotton, to discover that the enslavement of the blacks was ordained by God for the benefit of everybody. But Webster believed first of all in the Constitution. The Constitution recognized slavery, and therefore it was impossible to meddle with it, except to see that its increase and spread were discouraged by every means that the Constitution would permit.

On the other sectional issue, that of the tariff, which some persons consider even more vital than slavery, inasmuch as it meant the growing triumph of the industrial North over the agricultural South, Webster was more aggressive, and distinctly advocated the high protection which the Southern leaders felt to be fatal to their prosperity. But above all Webster ranged himself on the side of those who opposed sectional division and disunion tendencies altogether. In 1830 a comparatively minor debate as to the public lands brought on the Southern attack upon New England, and Webster, in defending his native state, replied to Hayne with the, glorification of the Union, which probably did more to unify the country than any single utterance of any man. Hayne and his followers often had the technical interpretation of the Constitution on their side, but Webster had common sense behind him, he was himself the incarnation of common sense, and he gave the common sense of a united country a superb, an enduring dignity of expression which has never been forgotten and never can be. In his arguments with Calhoun over nullification, in 1833, there is the same striking contrast. Calhoun was perhaps more sound as regards mere technical logic, but Webster had the weight and the enduring substance of human truth.

In this nullification quarrel with South Carolina Webster heartily supported Andrew Jackson. But there was no sympathy between the two. Webster was an aristocratic Whig of the old school, Jackson an aggressive Democrat of the America to come, and over the bank and other things they came into violent conflict. It should be added that Webster's most serious contributions to political thought are to be found in his discussion of strictly financial matters. Moreover, when Jackson went out, in 1836, Webster would have liked to come in, and this was one of the acute crises in the fever of his presidential desires. It is amusing to see how many of his biographers deny his ambition. He wanted to serve his country, they say; he wanted to be where he could be of the greatest use. It is the old story, and no one has ever yet succeeded in disentangling the personal from the patriotic motive in these matters. The Presidency is the final seal of success in American politics, and no man who has given his life to those politics has ever been willing to see the Presidency slip from him without a sigh of despair. "I would rather be right than be President," said Henry Clay. But Clay and Webster and many another have persuaded themselves that the road to being President was the road to being right. Where will you find a more ingenuous avowal of ambition than in Webster's words to his friend Plumer: "I have done absolutely nothing. At 30 Alexander had conquered the world; and I am 40."

But Van Buren was elected, and Webster passed by, and for a time he turned his thoughts to private life. His affairs needed more attention than he could give them. He had been twice married, first in 1808, to Grace Fletcher, a love-match; second in 1829, to Caroline Le Roy. He had an expensive family, and his own tastes were expensive. He liked social life of all sorts, and social life was costly. He liked eating and drinking, especially the latter. He was happy on his great farms, in Franklin and at Marshfield.

But the farms and the country life were almost as ruinous as dissipation, perhaps more so. And the trouble was aggravated by Webster's business habits, or lack of them. He was a master of theoretical finance, but he could not keep his own private accounts, did not even try to keep them systematically. In consequence, he was always in trouble, always borrowing and renewing. When such business methods get mixed up with politics, there may not be corruption, but there is terrible danger of it. Webster's biographers insist that he was never personally dishonest. But there is a profound remark of Webster himself, which is worth remembering: "There are means of influence not generally esteemed positively corrupt, which are competent to produce great effects."

With the failure of his immediate political ambitions, Webster turned his attention to more general matters, and grew anxious to see something of Europe. The embassy to England had always tempted him, and it was even said that he had manoeuvred to get his friend Everett out of the position so as to succeed him. This came to nothing, but in 1839 Webster arranged a trip across the water and he was received by his English friends with every possible attention and courtesy. He wrote rather extensive letters home, but it is curious to note, with these, as with all his correspondence, the singular lack of intimate personal revelation. In reading these lengthy epistles, we may be driven to wonderwhether Webster's external life was so active and varied that it left the inner life somewhat jejune and bare.

Returning from abroad, Webster found the election of 1840 impending, but his own hopes and aspirations were completely submerged in the spectacular success of Harrison, with the log-cabin and hard cider and Tippecanoe campaign furore. Again it was evident that, widely as Webster was esteemed and respected, he had not the faculty of personal leadership. Men praised him, but they did not vote for him. Instead of the Presidency, he was forced to put up with the secretaryship of State, which was given him by Harrison, and at first continued by Harrison's successor, Vice-president Tyler. Tyler soon got into trouble with his Whig cabinet, and they all left him but Webster, who incurred some odium by remaining. His plea was that he wished to complete the negotiation with England about the north-eastern boundary. This was settled with Lord Ashburton by the treaty of 1842, an arrangement which was entirely satisfactory to neither party, and was therefore probably as fair a compromise as could have been devised. This is notable as being almost the only great constructive achievement of Webster's career. With all his intellectual and oratorical powers, the working of circumstances was such that he was almost always in opposition, and had no opportunity to show how well he could build for permanence, though the sure logical action of his genius would seem to have adapted him peculiarly for such work.

After the treaty was disposed of, Webster retired from the cabinet and for a time again disappeared into private life. The clouds seemed to be gathering about him in many ways. The deaths of his children, culminating in that of his daughter Julia, were a terrible grief to him. His money complications increased, and though his earning power was as great as ever, his gift for spending more than kept pace with it.

When he returned to the Senate in 1845, the political world was as dark as his own surroundings. He was personally attacked by Ingersoll, with charges of dishonesty during his secretaryship. Congressional investigation cleared him of all but carelessness, yet men always spoke of him with a slur or an apology from the financial point of view. The menace of the Mexican War was confusing everything, and making the issue of slavery more threatening and more difficult to deal with. Webster, like Clay and Calhoun, opposed the war, but he sent his son to fight and die, as did Clay also.

The vast accession of territory that resulted from the defeat of Mexico brought all sorts of slavery complications with it. Webster took an active part in these, being in the main anxious to have slavery repressed and limited, so far as this was compatible with the Constitution. But when, in 1850, Clay brought forward his compromise measures, in the desperate attempt to avert actual civil conflict, Webster joined him, and the combined influence of the two, after months of heated debate, prevailed to have the compromise accepted. Webster's course was abused with the utmost violence by the anti-slavery section of the North, and Whittier's wail over Ichabod gave the abuse literary dignity and permanence. The senator was accused of having betrayed every high principle, in the vain hope of getting the South to support him for the Presidency. Recent historians have come more and more to reject this view. They argue that without the compromise, the Civil War would have been precipitated at that time, and that by postponing it for ten years, until the North was strengthened by the immense accession of the growing West, the whole course of American history was changed. In this view Webster became, not the destroyer but the saviour of his country, and it must at least be believed that such salvation was mainly what he aimed at.

Under Fillmore, he had to be content with the secretaryship of State, and he filled this office until the condition of his health became so critical that work of any kind was out of the question. Perhaps the most notable of his later official acts was his sharp correspondence with the Austrian *chargé* Hulsemann in regard to the affairs of Hungary. Webster died on Oct. 24, 1852.

The details of Webster's death have been recorded with curious minuteness by his biographer, Curtis. The dying statesman first delivered a senatorial oration on religious matters, perhaps, like most of his talk on such subjects, more eloquent than convincing. The exhaustion of this prostrated him for the moment. When he again came to himself, his words were: "Have I—wife, son, doctor, friends, are you all here?—have I, on this occasion, said anything unworthy of Daniel Webster?" And the audience unanimously answered, "no." It would be hard to find a more fitting final utterance for a man who had lived for 50 years in the statuesque pose.

Yet it is fair also to remember that Webster's last preoccupation on the less personal side was with his country, and he directed that the American flag should be kept flying at the masthead of his little yacht, with a light cast upon it at night, so that he could see it as long as he could see anything.

Webster's writings are best studied in the complete edition, 18 vols., 1903. This includes the two volumes of correspondence published earlier by his son. A large amount of further correspondence was published by Van Tyne in 1902. The two-volume Life, by Curtis (1869), is a storehouse of material, but is eminently partial to the subject. H. C. Lodge's "Life," in the American Statesman series, is brilliantly written, but under strong Republican and anti-slavery prejudices. *The* True Daniel *Webster,* by Fisher (1911) is sympathetic, and defends Webster where he most needs it. The Life by Ogg (1914), is critical and dispassionate. The Reminiscences of Lanman and Harvey are suggestive, but not always reliable. The writer of this article, whose grandfather was Webster's law partner, possesses a desk and a dispatch box which belonged to Webster. In the desk are a number of unpublished documents tending to support the statements made above as to Webster's financial habits. *See* also Allan L. Benson, *Daniel* Webster (1929). (G. B.)

WEBSTER, JOHN (fl. 1602–1624), one of the greatest tragic writers in English literature. Of his life almost nothing is known. It is said that he was the son of a London tailor; and we learn from his own Preface to the pageant called Monuments of Honour that he was a member of the Merchant Taylors' Company and "born free" of it. But this does not prove that either he or his father ever actually plied the needle. It might be gathered from the ambiguous classical knowledge exhibited in his writings that he was educated at some school of repute; but his close association with so good a scholar as Heywood gave him many opportunities of picking up the scraps of Martial and Horace which adorn his pages. Reasons have been given for placing his birth about 1580; and, as we hear nothing of him after 1625, he may have died in that year. These uncertainties are intensified by the fact that several persons of that time are known to have borne his name.

At what date he "commenced playwright" is uncertain. We learn from Henslowe's diary that he collaborated with Drayton and others in Caesar's Fate, 1602, and with Chettle, Dekker and Heywood in Christmas comes but once a year. Somewhat later his name appears with that of Dekker as part-author of Westward Hoe and Northward Hoe and in 1604 he contributed the induction to Marston's Malcontent. In 1607 "Mr. Dickers and Mr. Webster" appear on the title-page of The Famous History of Sir Thomas *Wyat,* a play which had no fewer than five authors and at least two titles (it is an abridgment of Lady Jane).

This habit of collaboration perplexes the critic who endeavours to appraise merit or mark progress in style. One collaborator may easily fall into the manner of the other, and it is not impossible that the authors themselves, after a few years, would be unable to name their own portions. Unerringly to trace the hand of Webster through Elizabethan drama is now impossible, though students still essay the task. Mr. Sykes thinks he had a share in Anything for a Quiet Life, usually ascribed to Middleton, and in the Fair *Maid* of the Inn, perhaps by Massinger and Ford but printed as Beaumont and Fletcher's. Mr. Sykes may be right, and has the weighty support of Mr. Lucas; but it is certain that others have been wrong. Thus in 1661 *A* Cure for a Cuckold and *A Thracian* Wonder were ascribed by the publisher Kirkman, probably without the slightest traditional justification, to Webster and Rowley. The former, as a whole, seems to bear rather the mark of Heywood than of either of the assigned authors; but there is in it an episode easily detachable from the rest and of some merit, which Gosse and Spring Rice, in 1885, printed separately under the title of Love's Graduate, with the wish rather than the assurance that it might be "a piece of silver-work by the sculptor whose other groups are all of bronze." As The Guise and The Late Murther of the Sonne upon the Mother (this latter partially by Ford) are alike lost, conjecture may here disport itself without danger either of proof or of confutation.

The case of *Appius* and Virginia is more important, for on the decision as to its genuineness must rest our idea of the width and range of Webster's genius. Except for a few remarkable passages, this excellent play differs in every way from Webster's certain work. The only external evidence is the statement of an unknown publisher in 1654, repeated by Humphrey Moseley in 1659; but Webster's authorship was never doubted till in 1911 Rupert Brooke submitted the play to a careful analysis and finally, on grounds of style and vocabulary, ascribed it to Heywood. The present writer, after carefully considering Brooke's arguments, and comparing the play with Heywood's undoubted works (especially with the Rape of Lucrece) is inclined to believe that Brooke has made out his case. If so, we are, in forming our judgment on Webster's powers, limited to the three undoubtedly genuine works, The White Devil, the Duchess of Malfy, and the Devil's Law Case.

The last, though considerably the latest of the three—it is dated 1619 or 1620—may be taken first, and can be easily dismissed. It is a clumsy, involved, inartistic tragicomedy, in which the happy ending is brought about by the violation of all probability. With many reminiscences of the older and better time, it marks the transition to the later and worse fashion of the Caroline drama. Its chief merits lie in occasional flashes of Webster's characteristic murky imagery and daemonic forcefulness of phrase. There are also some touches of a shrewd satirical observation which, though not always dramatic, is in itself exceedingly striking.

But it is on the two great tragedies that Webster's fame must always rest. The White Devil, based on actual events of then recent date, was published in 1612, with a preface that interests by its tersely-worded appreciations of contemporary writers; and, although we know Webster was a slow worker, may be dated 1611–12. The Duchess of Malfy, founded ultimately on a novel of Bandello's, cannot be later than 1614; for the researches of Charles Wallace have shown that William Osteler, who acted in it, died that year. The two plays, therefore, were written with the combined daring of youth and solid strength of manhood. They have been said to belong to the "Tragedy of Blood," and they certainly have much in common with Kyd's Spanish Tragedy on the one hand and with Hamlet on the other. But perhaps it would be better—if classify we must—to regard them as a fusion of the Blood-Tragedy with the "Machiavellian" type of which Othello is the supreme example—that type in which further use is made of the Elizabethan conception of a contemporary Italy, rich in all the resources of culture, and permeated with all the vices of decadence. In it the essential element is the villain, endowed with matchless cunning, a hatred of good for its own sake, and a plentiful lack of conscience. To the exhibition of this conception Webster brought a certain Juvenalian indignatio which informs the work from beginning to end. The dramatic technique, coldly considered, is often lamentable; whole scenes are irrelevant, characters start up at random, and description too often takes the place of action. With every allowance for the fact that the plays were greatly shortened for the stage, these defects are serious, and go far to explain the repugnance of such critics as William Archer. But they are far outweighed by stupendous merits—in fact by the irresistible power of genius, often it is true "sufflaminandus," but conquering every obstacle like a rushing torrent. There is nothing of the icily regular about Webster. He dares all, and either vanquishes or fails. The main secret of his lasting appeal (an appeal perhaps stronger than ever to-day, to a generation that has supped full of the horrors of war) is his accumulation of catastrophe on catastrophe, his sense of the ghastly in little things, his power of symbolic hinting, and what we may call his sublimation of the pathetic into the portentous. To convey all this he has, when at white heat, a gift of brief expression, charged with the fullest meaning, unmatched except in Shakespeare. The famous "Cover her face, mine eyes dazzle, she died young," is only a supreme instance out of scores. In the face of this, criticism has to hold its peace; or, if it speaks at all, takes the form of such imitation as Shelley gives us in the Cenci.

Webster's works were edited by Dyce (4 vols., 1830) and inaccurately; W. C. Hazlitt (4 vols., 1857), but all previous editions are superseded by that of F. L. Lucas (4 vols., 1927, bibliog. in vol. i). *The White Devil* and *The Duchess of Malfy*, Symonds (1888) and Sampson (1904).

Criticism, Lamb, *Specimens* (1808); Swinburne, *Age of Shakespeare* (1908); Sidney Lee, *Dict. Nat. Biog.* (1899) (needs correction as to facts); Gosse, *Seventeenth Cent. Studies* (1883); Symonds, *Italian By-Ways* (1883). On the story of Vittoria Accoramboni *see* Trollope in *All the Year Round*, 1860. (E. E. K.)

WEBSTER, NOAH (1758–1843), U.S. lexicographer whose name became a virtual synonym for the word "dictionary," was born at West Hartford, Conn., Oct. 16, 1758. He entered Yale college in 1774 and, though his third year was interrupted by Revolutionary War service, graduated in 1778. He taught school, did clerical work and studied law, being admitted to the bar in 1781.

While teaching school in Goshen, N.Y., in 1782, he began his work on the English language, publishing in 1783 as part one of A *Grammatical* Institute of the English *Language*, a speller, *The* American *Spelling* Book, which ultimately sold more than 70,000,000 copies and provided much of his income throughout his life. To protect his copyright, he traveled through the states, lobbying at the legislatures for copyright laws, teaching, giving singing lessons and lecturing. Part two of the Institute, a grammar (1784), was based on a principle later enunciated in his famous American Dictionary of the English Language, 2 vol. (1828): "... grammar is formed on language, and not language on grammar." Part three, a reader (1785), was made up mainly of American selections. In 1789 he published his lectures as Dissertations on the English *Language*, stating "Customs, habits and language, as well as government, should be national." He spoke of American English as "Federal English."

He founded the short-lived *American Magazine* in New York city in 1788. After his marriage in 1789 he practised law successfully in Hartford until 1793, when he founded in New York the pro-Federalist daily newspaper, the American *Minerva*, and a semiweekly newspaper, the *Herald*. He went to New Haven, Conn., in 1798 and sold the papers in 1803.

Though his *Compendious Dictionary of the English Language* (1806) contained 5,000 more words than Dr. Johnson's (1755), it was merely a preparation for his later one, on which he started work in 1807. In 1824–25 he traveled to France and England to find sources unavailable to him in the U.S. The dictionary, attacked for its "Americanisms," its unconventional preference for U.S. usage and pronunciation to British and its inclusion of nonliterary words, contained about 70,000 entries and between 30,000 and 40,000 definitions that had not appeared in any earlier dictionary. The first edition (U.S., 2,500 copies; England, 3,000) sold out in little more than a year. Subsequent revised editions appeared in 1841, 1847 (including Webster's revised appendix finished a few days before his death in New Haven, May 28, 1843), 1856, 1864, 1879 and throughout the 20th century, those after his death being under the ownership of G. & C. Merriam Co.

Webster wrote on many subjects: politics (*Sketches of American Policy*, 1785, sometimes described as the first statement of the principles of the U.S. constitution), economics, medicine, physical science, in addition to writings on language. He noted the living language as he traveled. Early enthusiasm for spelling reform was modified somewhat in his later works, but he is largely responsible for the differences between British and U.S. spelling forms.

WEBSTER, a town of central Massachusetts, U.S., in Worcester county, is situated on the French river about 16 mi. S.W. of Worcester. Nearby, to the southeast, is Lake Chaubunagungamaug (full name, Chargoggagoggmanchaugagoggchaubunagungamaug), a three mile-long resort on the Connecticut line. Settlement began about 1713; the town was incorporated in 1832 and named for Daniel Webster. It was noted for its early textile mills built by Samuel Slater (1768–1835), regarded as the founder of the U.S. textile industry. Modern manufactures include textiles, shoes, machine tools, optical goods, paper goods and chemicals. Webster, like several other towns in the state, was still governed by town meeting in the second half of the 20th century. For comparative population figures see table in MASSACHUSETTS: Population. (A. B. So.)

WEBSTER GROVES, a suburb of St. Louis, Mo. (*q.v.*).

WEDDING: see MARRIAGE.

WEDEKIND, FRANK (1864–1918), German dramatist, was born in Hanover on July 24, 1864. In 1883 he took up journalism. Afterward he became an advertising manager and then, in 1890, secretary of a circus. In 1897 he set up as an actor and producer acting in his own dramas. His dramatic works include: *Frühlings Erwachen* (1891), *Erdgeist* (1895), Der *Marquis von Keith* and *Die Kammersänger* (1900), *Die Büchse der Pandora* (1903), *Schloss Wetterstein* (1910) and *Franziska* (1911). Wedekind's plays are written in a difficult symbolic style. Their preoccupation with erotic themes awoke much opposition, and he served a term of imprisonment in Munich for lese majesty. Wedekind also wrote poetry (Die Vier *Jahreszeiten*), novels, Mine-Haha (1906), etc., and essays. He died in Munich on March 9, 1918.

His *Works* were published in 8 vol. (1912–19). Certain plays were translated into English by S. A. Eliot, Jr.

See A. Kutscher, *Frank Wedekind* (1922–24).

WEDGWOOD, JOSIAH (1730–1795), British pottery manufacturer, whose most lasting influence resides in his scientific approach to pottery making, was the youngest child of Thomas Wedgwood, a potter of Burslem, Staffordshire, and came of a family whose members had been potters since the 17th century. After his father's death in 1739 Josiah was put to work in the family business, becoming exceptionally skillful at the potter's wheel. In 1744 he was apprenticed to his eldest brother, but an attack of smallpox seriously curtailed his work. The consequent inactivity, however, enabled him to devote thought to other aspects of his craft. After brief participation in a pottery at Stoke he entered into partnership in 1754 with Thomas Whieldon of Fenton, probably the leading potter of his day. These two experiences made Wedgwood master of current pottery techniques, while his experimental turn of mind led him to new discoveries. After inventing an improved green glaze, in 1759 he set up for himself at Burslem, first at the Ivy House pottery and subsequently also at the Brick House (or Bell works). There he perfected a cream-coloured earthenware which, because of Queen Charlotte's patronage in 1765, was called "Queen's ware." This, by virtue of its durable material and serviceable forms, became the standard domestic pottery and enjoyed a world-wide market.

In 1762 Wedgwood met Thomas Bentley, a Liverpool merchant, who in 1768 became his partner in the manufacture of ornamental wares. These were primarily unglazed stonewares in various colours, formed and decorated in the then resurgent classical style, to which Wedgwood's wares lent great impetus. Chief among these "dry bodies" were "black basaltes," which by the addition of red encaustic painting could be used to imitate Greek red-figure vases, and jasper ware, a fine-grained stoneware for copying classical cameos. For his ornamental wares Wedgwood built near Hanley a factory called Etruria (Greek vases were currently thought to be Etruscan), to which the manufacture of useful wares was also transferred (*c.* 1771–73). There his descendants carried on the business until 1940, when the factory was relocated at Barlaston, near Stoke.

Wedgwood's exhaustive researches into materials, his logical deployment of labour, his business organization and his promotion of improved communications make him one of the great leaders of the Industrial Revolution. He died at Etruria, Jan. 3, 1795. His daughter Susannah was the mother of Charles Darwin.

WEDNESBURY, a municipal and parliamentary borough of Staffordshire, Eng., 8 mi. N.W. of Birmingham. Pop. (1951) 34,-

759. Area 3.2 sq.mi. The borough includes the urban district of Darlaston (pop. 1951, 22.012). Wednesbury is an ancient market and industrial town. The foundation of modern Wednesbury was the rich "ten-yard" coal seam close to the surface and having near it ironstone, lime and fire clay. Pits are no longer worked in the borough but industries are still mainly metallurgical. It is the traditional centre of the manufacture of tubes The Church of St. Bartholomew is supposed to occupy the site of a place of the worship of Woden or Odin—hence Wednesbury (Wodensbeorgh). There Aethelflaed in 916 constructed a castle. After the Conquest it became a demesne of the crown, and was bestowed by Henry II on the Heronvilles. It became a parliamentary borough (1867) returning one member and a municipal borough (1886).

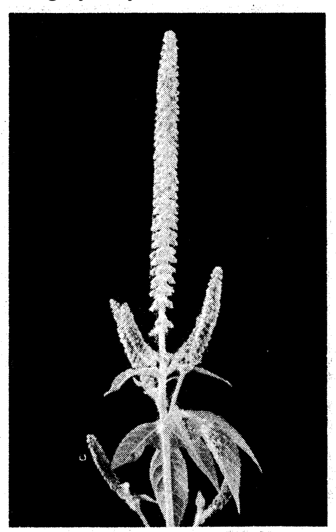
WEED, THURLOW (1797–1882), U.S. journalist and politician, was born at Cairo. N.Y., on Nov. 15, 1797, and began learning the printer's trade at the age of 12. As a member of the New York legislature, he was influential in placing his state behind John Quincy Adams in the 1824 presidential canvass.

He became a leader in the Anti-Masonic party (*q.v.*) in 1828; when the Masons forced him out of his management of the Rochester Telegraph, he started an anti-Masonic campaign paper. Soon convinced that anti-Masonry was an inadequate issue for a national party, Weed uas active in forming the Whig organization in New York. His paper, the Albany Evening Journal, founded in 1830 to support anti-Masonry, then became a chief Whig spokesman and Weed the leading political manipulator of the new party. Weed's alliance uith William H. Seward (q v.) was a strong factor in the latter's election to the governorship, and he was Seward's chief manager in his unsuccessful campaign for the Republican presidential nomination in 1860. As secretary of state, Seward in 1861 sent Weed as a special agent to England, where he was a successful propagandist for the United States. But his wish to compromise the war issues put him out of step with his party; and in 1863, tired and discouraged. he sold his paper and retired from politics. He later wielded some political influence, however, and was briefly editor of the *New* York Commercial Advertiser.

Weed's *Autobiography* (1883) and Thurlow Weed Barnes' *Memoir of Thurlow Weed* (1884) were published together as *The Life of Thurlow Weed* in 2 vol. *See* also Glyndon G. Van Deusen, *Thurlow Weed, Wizard of the Lobby* (1947). (F. L. MT.)

WEED. A weed is an unuanted plant. Ever since man first attempted the cultivation of plants he has had to fight the invasion by weeds of areas he has chosen for crops. Some unwanted plants later were found to have virtues not originally suspected and so were removed from the category of weeds and taken under cultivation. Other cultivated plants. when transplanted to new climates, escaped cultivation and became weeds. The category of meeds thus is ever changing, and the term is a relative one.

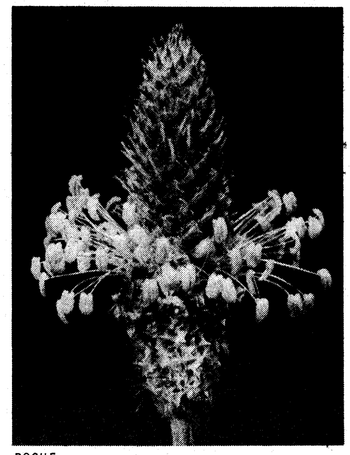
It has been estimated that the average yearly loss due to weeds in meadow and crop lands is greater than that due to animal and plant diseases. A large proportion of the farmer's work goes into the struggle with weeds. If he falters they gain control, and only through a much greater effort is he able to regain it. According to the adage. "one year's seeding means seven years' weeding." The reason is that agriculture disturbs the natural association of plants and sets in motion the ecological succession. This is the ever-present tendency of vegetation to return by ascending steps to the climax stage, which is its culmination. The climax is characterized by great permanence; if destroyed, whether by fire, floods or human agency, it always tends to return. The farmer seeks to replace this balanced natural vegetation with plants that for the most part do not belong to the climate and that in themselves have little power to impede the climb back to the climax association; hence his never-ending battle with weeds.



BY COURTESY OF ROGER P. WODEHOUSE

GIANT RAGWEED (AMBROSIA TRIFIDA)

When a piece of land has been denuded of vegetation and left unprotected against the sun, wind and rain, it is in jeopardy. Unless it is quickly covered, the soil is likely to be washed or blown away long before grass, shrubs or trees can become re-established. This provides an opportunity for the nearby weeds; they move in and auicklv clothe the soil. protecting it against destruction by rain and wind. (See below, Value *of* Weeds.) However, cultivated fields, with domesticated plants in rows three or four feet apart, similarly present open territory, which weeds attempt to pioneer. In this they are much more efficient than the cultivated plants, which struggle with an alien soil and climate and are assailed by an endless variety of insects and fungus and virus diseases. In this hostile environment cultivated plants would succumb promptly without constant attention from man.



ROCHE

BUCKHORN PLANTAIN (PLANTAGO LANCEOLATA)

The cost of maintaining cultivated fields against the onslaught of weeds and their concomitant effects is generally reckoned as the loss to agriculture from weeds. It represents the burden that agriculture assumes in arresting, in its earliest and most unbalanced stages, the ecological succession.

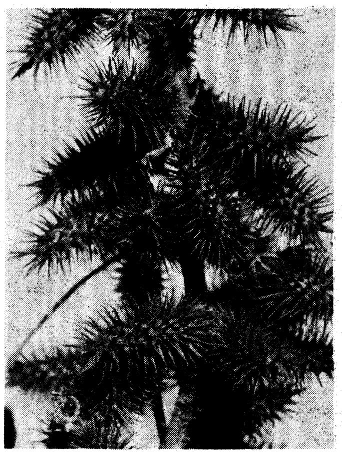
Pioneer Plants. — In spite of the fact that no plants are always weeds, many habitually are so classified. These are plants that in the climax association occupy a subservient position and almost go unnoticed, but that in the early pioneer stage of the ecological succession are dominant. Most are annuals, fast-growing and shallow-rooted, capable of quickly occupying denuded areas. Familiar examples are the weedy grasses such as foxtail (Setaria), barnyard grass, crabgrass, cheat (Bromus secalinus) and sandbur (Cenchrus). Also familiar are the short, tall and slender ragweeds, pigweed, lambs-quarters, marsh elder weed, cocklebur, Indian hemp (Cannabis), purslane, Russian thistle, wild sunflower and Galinsoga.

Most weeds, including all except the last four of the examples cited above, are wind pollinated. This is more than a matter of chance, for outside this ecological group wind pollination is relatively uncommon among the flowering plants. In fact, most of the wind-pollinated nonwoody flowering plants are pioneers. Wind pollination enables them to invade new areas in enormous numbers without the limitations imposed by an unreliable fluctuating population of pollinating insects. Wind pollination, however, is no assurance of success.

These plants must also be able to survive in the stable climax in scattered distribution, and thus enormous quantities of pollen per individual plant are required to bridge the gaps between the members of a species.

The ragweeds, false ragweeds, marsh elders, careless weeds, water hemps and some of the weedy grasses also belong to the pioneering group. These are not aggressive invaders, are easily crowded out by more permanent vegetation and so are relatively easily controlled The most obvious method of control is clean cultivation — preventing them from seeding. If, however. they are allowed to go to seed, a large proportion of their seeds are likely to become dormant. germinating at intervals, as opportunity arises, for 40 years or more. Once well in, therefore. they are likely never to be eradicated except by nature's way or at least some compromise with it.

In addition to the annuals, a large number of perennials also participate in the pioneer stages. Familiar examples are the field



JOHN H. GERARD

COCKLEBUR (XANTHIUM)

and hedge bindweeds of the morning glory family, in many places reckoned as the worst of all weeds; and Johnson grass, quack grass, Bermuda grass. curly dock, sorrel dock, nild onion. several species of plantain, nut grass. bur ragweed. western ragweed, knapweed, Canada thistle, horse nettle and common mallow. These are generally deep rooted and spread both by seeds and by runners above and belon ground. They belong to the next higher stage in the ecological succession and are more permanent than the annuals and more difficult to eradicate.

Origins of Weeds.—It is generally believed that weeds are introduced plants; in fact, this characteristic is often cited as their first qualification. It is not strictly true. however; so far as the number of different kinds is concerned. more weeds are native than introduced. All the ragweeds, false ragweeds, cockleburs and marsh elders. which are the most troublesome hay fever plants in North America, are native Americans. Some of these have been introduced into Europe and Australia. where they have failed to become weeds of any importance. Quack grass and Bermuda grass. troublesome weeds throughout much of North America. are both native. So also are Galinsoga and nut grass, poison ivy and poison sumac. On the other hand, the commonest and most pernicious American weeds are introductions from Europe. so that the impression based on numbers of individuals is most decidedly in favour of introduced species. The reason why the flora of America is so strongly tinged with that of Europe is, of course, that Americans came originally from Europe and brought their weeds with them or had them sent over later together with various European commodities.

When a plant or animal is transplanted into a new and favourable locality. it is likely to spread with great rapidity because of the absence of competition and its accustomed enemies. This was especially true of America, where large areas were made available to weeds by the heedless activities of men, who destroyed the native vegetation by plowing and overgrazing. The invasion of the western American ranges by Russian thistle was a result of such careless treatment. The American prickly pear, introduced into Australia, became a pestiferous weed there in overgrazed areas: as indeed it has become in America to a lesser degree.

Competition.— The harm that weeds do lies in their competition with more desirable plants for space. water, sunlight and nutrients. Under natural conditions the development of plants is closely related to the degree of competition that they have to endure, whether with each other or with other species. For example, it was shown by J. E. Weaver and F. E. Clements that 12 ragweed plants growing per square metre reach a height of 11.3 ft. with a stem diameter of 19.0 mm.; growing 64 to the square metre the figures are 8.4 ft. and 7.4 mm.; and growing at 154 plants, they are 5 ft. and 3.4 mm. Likewise corn that averaged 46 bu. per acre when weeds were kept down yielded only 7 bu. where weeds were allowed to grow.

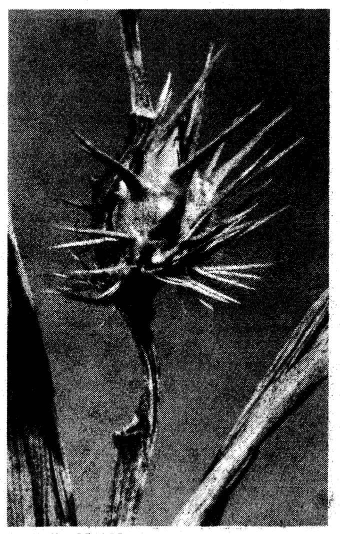
In an experimental competitive culture of tall panic grass (genus *Panicum*) and evening primrose (genus *Oenothera*) it was found that the evening primrose, being slightly taller than and extending its roots deeper than those of the grass, soon gained the ascendancy. The grass became attenuated and yellowish as a result of shading by the broad leaves of the evening primroses. By autumn. 25% of the panic grass had died. Only a few of the grass leaves ever managed to overtop the competitor and receive enough sunlight to perform full photosynthesis. By the end of the second season the evening primrose had seeded and died. which is normal. since its life cycle is biennial. It failed to reproduce in the area the following spring, however; the few starved grasses that remained tillered abundantly and soon had complete and permanent possession of the area. It is important to note that although this contest was very nearly fatal to the panic grass, this perennial weed finally won over the biennial evening primrose because the latter had to start again from seed. This it could not do in competition nith the grass, which had the advantage of starting from its tough perennial rhizomes. The outcome of the contest could have been made more certain for the grass by a single mowing or possibly grazing during the first or second year, for this is always much more injurious to broad-leaved annuals or biennials than it is to perennial grasses. This method is the easiest nay to convert a weed patch into grassy turf; land may be maintained indefinitely in this desirable condition, yielding a sustaining crop of hay or forage until the plot is needed for something else.

Value of Weeds.—Although needs should be replaced wherever possible by more desirable plants, they afford valuable service in the control of erosion, especially on abandoned or temporarily idle land. In controlled experiments a volunteer cover of miscellaneous weeds has been shown to be one-third more effective in reducing aater runoff and twice as effective in reducing the accompanying soil erosion as an ordinary stand of corn in the same kind of soil. Russian thistle as a volunteer cover crop is even more effective in conserving water and protecting the soil. Wild sunflouers are sometimes seeded in regions of low rainfall as an aid to restoring grass in a windswept soil. Wild mustard is sometimes sown from airplanes after destructive fires have removed all soil cover. This makes a dense stand the first year and then is gradually replaced by more permanent vegetation. Weeds. like true pioneers of the human race, do not thrive under crowded conditions, even of their onn making. and readily give way to more tolerant plants.

Control of Weeds.——Weeds are best controlled by good cultivation Experimental evidence shows that among both field and garden crops the only value of tillage is in weed control. Indeed, tillage generally results in some injury to the crop plants, but of course this is more than offsetby the removal of need competition.

Chemical herbicides offer a substitute for tillage in controlling weeds. These are of two kinds, nonselective and selective Examples of the former are common salt, iron sulfate, copper sulfate and sodium chlorate These are generally used at high concentration and sterilize the soil against all plant growth so that no plants can be grown on it for several or many years.

With the introduction of selective herbicides. weed control is rapidly being developed into an exact science. Many selective herbicides are in use, and more are continually being developed They are contact poisons of the nature of hormones and depend for their success upon the principle of selectivity. That is to say. in proper concentrations they destroy certain weeds without permanently injuring the desirable plants associated with them. The first of these to be developed were 2.4-D (2,4-dichlorophenoxyacetic acid) and 2,4,5-T (2,4,5-trichlorophenoxyacetic acid). The former kills herbaceous (soft-stemmed) and the latter woody plants, without injuring grasses. Used separately or in combination. they are particularly valuable in controlling weeds along roadsides; herbicide spraying may reduce necessary mowings to one per season. thus eliminating two or three mowings and reducing the cost of roadside maintenance by as much as 90%. Selective herbicides also give excellent control of ragweed and poison ivy From lawns and turf they remove such undesirable weeds as plantains and dandelions without injuring the grass; they must be used with discretion, however, if clovers are compo-



JOHN H. GERARD

MAT SANDBUR (CENCHRUS PAUCIFLORUS)

nents of the lawn, for these are very susceptible to such herbicides.

For the control of weeds in vegetable crops and among ornamentals the choice of herbicides depends on the plants grown and on the weeds to be killed.

Furthermore, the concentrations to be used must be carefully adjusted, because there is often only a small differential between lethal doses for the weed and the crop. Since the more refined methods of weed control vary widely with locality, it is advisable that the farmer or gardener consult his agricultural college or county agent for local recommendations.

Proper weed control always means replacing weeds by more desirable plants without leaving the soil unprotected against erosion. Without the protective soil-binding influence of the weeds or their substitutes, the life span of human civilization would be greatly shortened.

See also articles on the individual plants mentioned.

WEEK, the name given to periods of time, varying in length in different parts of the world, but shorter than a "month" (from A.S. *wicu,* Germanic *wikôn,* probably "change," "turn"). The month may be divided in two ways: a fractional part may be taken (decad or pentad), as in east Africa or ancient Egypt (moon-week), or the week may be settled without regard to the length of the month (market-week, etc.).

The seven-day week (see CALENDAR) originated in west Asia, spread to Europe and later to north Africa (Mohammedan). In other parts of Africa three, four (especially in the Congo), five, six and eight (double four) day weeks are found, and always in association with the market.

In ancient Scandinavia a five-day period was in use, but markets were probably unknown. That the recurrence of the market determined the length of the week seems clear from the Wajagga custom of naming the days after the markets they visit, as well as from the fact that on the Congo the word for week is the same as the word for market.

Among agricultural tribes in Africa one day of the week, which varies from place to place, is often a rest-day, visiting the market being the only work allowed.

WEELKES, THOMAS (1577?–1623), English composer, was one of the best and most individual of the English composers who took up the Italian madrigal form so eagerly in the closing years of the 16th century. An allusion to his "yeeres yet unripened" in Weelkes's book of *Balletts* and *Madrigals,* published in 1598, is the only evidence for the date of his birth. He had already published a set of madrigals for three, four. five and six voices in the previous year, and two more books of madrigals, one for five and the other for six voices: followed in 1600. For a brief period Weelkes had been organist of Winchester college, and in July 1602 he took the degree of Mus.B. at New college, Oxford. Shortly after, he was appointed organist of Chichester cathedral, which post he appears to have held until his death.

Although his madrigal publications had established his reputation, Weelkes produced only one more volume, the *Ayeres or Phantasticke Spirites* (1608) for three voices. There is no sign of any further secular music dating from later than 1608, but numerous scattered fragments (and some complete works) suggest that Weelkes composed a considerable amount of church music, including at least ten Anglican services. He died in London, about Nov. 30, 1623.

Weelkes's madrigals have all been edited and printed by E. H. Fellowes in *The English Madrigal School,* vol. ix–xiii (London, 1913–24). Fellowes and others have also printed a number of Weelkes's sacred works, and the surviving keyboard works have been edited by Margaret Glyn. The most complete studies of Weelkes's compositions occur in Fellowes's *English Madrigal Composers* (Oxford, 1921) and *English Cathedral Music* (London, 1941). (J. J. N.)

WEENIX, JAN BAPTIST (1621–1660), Dutch painter, whose paintings show great diversity, in quality as well as in subject matter, though at his best he was a fine artist, was born in Amsterdam, where Jan Micker was his first master. He later studied under Abraham Bloemart in Utrecht and Nicolaes Moeyaert in Amsterdam. He married Josina d'Hondecoeter in 1639 and had two sons, Jan (see below) and Gillis.

In 1643 Weenix traveled to Italy and stayed there four years, mostly in Rome. While there he was much employed by Giovanni Battista Cardinal Pamphili, who became Pope Innocent X in 1644.

After returning to Amsterdam in 1647 Weenix soon settled in Utrecht, where he was elected a commissioner of the painters' guild in 1649.

Before his Italian period Weenix seems to have used the single Christian name of Jan or Johannes, and he probably adopted the second in honour of his patron. In signing his pictures he always used the Italian form—Gio[vanni] Batt[ist]a Weenix. Characteristic subjects are landscapes (usually italianate) with peasants and animals, seaports, still-life compositions with dead game; he also painted a number of competent portraits. His pupils included, besides his son Jan, his nephew Melchior d'Hondecoeter and Nicolaes Berchem.

His son JAN WEENIX (1640?–1719) was born in Amsterdam, where he worked for most of his life, though he appears in the Utrecht painters' guild in 1664 and 1668. He specialized in large still-life paintings of dead game, which, with the elaborate bird paintings of Melchior d'Hondecoeter, were in great demand for the decoration of private houses in Amsterdam and elsewhere. (R. E. W. J.)

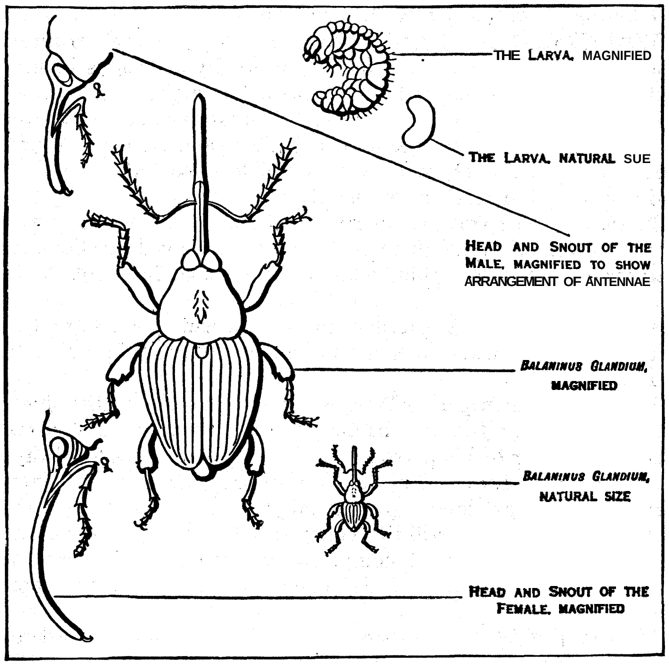
WEEVER, or WEAVER. The weevers (*Trachinus*) are small marine fishes common on the coasts of Europe. They belong to a family of spiny-rayed fishes (Trachinidae), and are distinguished by a long low body with two dorsal fins. the anterior of which is composed of six or seven spines only, the posterior being long and many-rayed. The ventral fins are placed in advance of the pectorals. The upper surface of the head is bony, without skin.

Several species are known, but two only occur on the British coasts, viz., the Greater Weever (*Trachinus* draco) and the Lesser Weever (T. *vipera*); the former is frequently found of a length of 12 in., while the latter grows only to about half that length. The coloration of both is plain, but the short first dorsal fin is always deep black. The weevers are bottom fish, burying and hiding themselves in the sand or shingle—the lesser species living close inshore and the greater preferring deeper water. They inflict wounds by their dorsal and opercular spines. The spines are deeply grooved, and the poisonous fluid lodged in the grooves is secreted by glands at their base. The flesh is not bad eating.

See Jordan, *Guide to the Study of Fishes.*

WEEVIL, the name applied to beetles of the division Rhynchophora of the order Coleoptera. They are characterized by the prolongation of the head into a rostrum or snout which bears the mouth-parts at the apex. The antennae are usually elbowed and clubbed, with the basal portion frequently lodged in a depression on each side of the rostrum. The tarsi have four evident segments and there is a single median or gular suture beneath the head. Their larvae are usually white, curved, fleshy grubs, generally without legs; the head is darker and well developed, with strong jaws; eyes are absent or very rudimentary. Both the adults and the larvae are exclusively vegetable feeders.

The true weevils or Curculionidae form the largest natural family in the animal kingdom and include over 35,000 known species, but probably several times that number still await discovery. More than 400 species occur in the British Isles, and upwards of 2,500 species inhabit America N. of Mexico. Their most characteristic organ is the rostrum: its function in the female is often that of a boring instrument, a hole being drilled by it for placing the eggs, but its significance in the male is not understood. As a rule the rostrum is better developed in the female than in the male, a feature that is well seen in the nut weevils. The majority of weevils are sombrely coloured but



ACORN-WEEVIL (BALANINUS GLANDIUM), ADULT AND LARVA

A nut-weevil closely allied to the common nut-weevil (Balaninus nucum) of Great Britain. The female of the various species drills holes in green hazel-nuts acorns or similar nuts and deposits eggs singly within the kernels upon which the larvae later feed

others are attractive objects. In the brilliant green Phyllobius and *Polydrusus,* so common among herbage in Britain, the colour lies in the covering scales. The Papuan *Eupholus* is sky blue. and the diamond-beetles (*Entimus*) of Brazil are probably the most resplendent of all. In their larval stages weevils may feed upon any part of a plant from the roots to the seed: the vast majority are internal or subterranean feeders, but some feed openly and a few live in tunnels formed of rolled leaves. A large number of species are highly injurious either as larvae or as adults also. The granary weevil (*Sitophilus granarius*) destroys the grains of corn (maize), wheat and barley, and has become widely distributed through commerce. The cosmopolitan rice-weevil (S. *oryza*) affects, besides rice, a great variety of other dry food products. The cotton-boll weevil (*Anthonomus grandis*) is the most serious enemy of the American cotton crop, causing immense damage to the bolls. The allied apple-blossom weevil (*A. pomorum*) is very destructive to unopened blossom buds in England and other parts of Europe. The palm-weevil (*Rhynchophorus ferrugineus*) affects toddy and coco-nut palms, and the pine-weevil (*Hylobius* abietis) is a European enemy of young conifers. The alfalfa-weevil (*Phytônomus posticus*) entered the U.S. from Europe in 1904 and is' a serious enemy of alfalfa and clovers. Mention must be made of the North American plum curculio (*Conotrachelus nenuphar*), a most destructive pest of stone fruits, of the nut-weevils (Balaninus) and of species of *Sitona* which attack leguminous crops. In addition to the Curculionidae, the Rhynchophora include the families Scolytidae, Platypodidae, Anthribidae and Brentidae.

WEFT: see WARP AND WEFT.

WEIDENREICH, FRANZ (1873–1948), German anatomist and physical anthropologist, an expert on the reconstruction of prehistoric human remains, well known for his work on *Sinanthropus* (Peking man) and for his studies in human evolution. Born June 7, 1873, at Edenkoben, in the Rhineland-Palatinate, he received a medical degree from the Cniversity of Strasbourg in 1899, where he became professor of anatomy in 1903. His publications reflected a growing interest in skeletal anatomy that eventually found expression in studies of locomotion, posture and bone structure as related to problems in primate evolution. He became professor of anatomy at the University of Heidelburg (1919); he was professor of anthropology at Frankfurt (1928–33) and visiting professor at The University of Chicago (1934). His most valuable contributions were made after his appointment (1935) as professor of anatomy at Peking Union Medical college, China, uhere he carried on investigations begun by D. Black on the Sinanthropus fossils (also termed Peking man or Pithecanthropus *pekinensis*)—one of the earliest known groups of human fossils. Weidenreich's classic descriptions. of Sinanthropus gained in importance when the fossils were lost during the Japanese invasion of Peking. In 1941 he went to the American Museum of Natural History, New York city. where he concentrated on the newly found Pithecanthropus (Java man) fossils and "giant" teeth discovered by G. H. R. von Koenigswald. (See also MAN, EVOLUTION OF.) His last project, a major study of Solo man (a later fossil from Java), was interrupted by his death on July 11, 1948, in New York city.

Among his works are *Apes,* Giants and Man (1946), a collection of scholarly but popular lectures; and Anthropological Papers, published posthumously (1949).

WEIERSTRASS, KARL THEODOR WILHELM (1815–1897), German mathematician, one of the founders of the modern theory of functions, was born at Ostenfelde on Oct. 31, 1815. He studied jurisprudence at Bonn and later went to Miinster to study under C Gudermann, who was interested in the theory of functions. Weierstrass wrote a paper on the development of modular functions for his teacher's examination and so started the aork in mathematics with which his name is associated. He became a teacher of mathematics at the gymnasium at Deutsche-Krone (1842–48) and then at the Collegium Hoseanum in Braunsberg (1848–56). In 1856 he was appointed extraordinary professor of mathematics at Berlin and lecturer at the school of technology. He was appointed ordinary professor in 1864. He died in Berlin on Feb. 19. 1897.

Weierstrass' work on the theory of functions was the most notable work on this subject since that of N. H. Abel and K. Jacobi. He published relatively little himself, but embodied his works in his lectures, which were collected in *Gesammelte Abhandlungen* (1894–1927); vol. i, ii and iii contained his lectures, vol. iv (1902) on Abelian functions, vol. v and vi (1915) on elliptic functions, vol. vii on the calculus of variations and vol. viii on analytic functions. He worked on the functions of real variables, devised tests for the convergence of series and dealt with converging infinite products. All his mathematical work is characterized by his emphasis on clarity and logical stringency. His example of a continuous function without a derivative at any point is famous in the history of mathematics. He also dealt with the theory of bilinear and quadratic forms.

Weierstrass developed the theory of functions of a complex variable to such an extent that he put his subject on a fresh basis. He also made notable contributions to the theory of periodic functions, elliptic functions, Abelian functions and the calculus of variations. Although his work was on pure mathematics, he was interested in its applications and influenced a number of his students to work on applied mathematics. He edited J. Steiner's *Gesammelte Werke* (2 vol, 1881–82) and was co-editor with E. Kummer of *Crelle's* Journal. See also FUNCTION. (O. OE.)

WEIGALL, ARTHUR EDWARD PEARSE BROME (1880–1934), British Egyptologist and author, was born on Nov. 20, 1880, and educated at Hillside school, Malvern. and at Wellington college. After a short time at New College, Oxford (1900), he joined the Egypt Exploration fund as assistant to Prof. Flinders Petrie, and later (1905) was appointed inspector general of antiquities under the Egyptian government He retired in 1914, hut continued to write on archaeological subjects. He received several foreign decorations for his archaeological work.

His many publications include A Report on the Antiquities of Lower *Nubia* (1907); *Travels* in the Upper Egyptian Deserts (1909); The Life of Akhnaton, Pharaoh of Egypt (1910, revised 1922); The Life of *Cleopatra,* Queen of Egypt (1914, revised

1924); *Egypt from 1798 to 1914* (1915); *Ancient Egyptian Works of Art* (1924); *A History of the Pharaohs*, vol i (1925), vol. ii (1926); *Wanderings in Roman Britain* (1926); *The Grand Tour of Norman England* (1927).

WEIGHING MACHINES. This article deals with mechanisms used for weighing goods and commodities, or used for technical purposes other than those for which the fine balance is constructed. The latter instrument is fully dealt with in the article BALANCE. and to that article the reader is also referred for a discussion of the principles which underlie the construction of the balance beam and determine its accuracy, sensitivity, period of vibration and so forth. The beam scale. or simple balance is, however, used for commercial as nell as for scientific purposes; hence a brief account of the principal forms is given.

The Beam Scale: Its History.—It seems certain that the balance originated in predynastic Egypt. and in the opinion of some Egyptologists its invention dates back to over 5,000 years before the Christian era.

The earliest balances of which we have knowledge were of the cord pivot type, the beam being suspended at its centre by a cord attached to a fixed support and the scale pans similarly suspended from the ends of the beam. At first. to effect these attachments, holes were drilled diametrically through the beam, but at a period which may be as early as 2000 B.C., a great improvement was initiated which enabled balances of considerable precision to be constructed. The end pivot was formed by drilling a hole into the upper surface of the beam and connecting it with one drilled longitudinally into the end. The suspension cord issuing from the latter and secured above the former hole was always held by the weight of the scalepan in definite contact with the end of the beam. Any inequality of arm length could be quickly corrected. The central pivot. or fulcrum. was either constructed by drilling diametrically through the beam, or by wrapping the suspension cord round the beam. or by attaching the cord to a metal ring secured to the upper surface of the beam. The better type of Egyptian balance, as early as 1500 B.C., and possibly much earlier. was always suspended from a bracket projecting from a substantial standard. From this bracket a plumb line was hung, the heart-shaped plumb bob of which was placed immediately below the tip of a downward depending tongue (finger or pointer) of triangular shape, secured to the bear- at its centre.

At a later date. and for ordinary commercial purposes, a more portable type of beam was used, like that depicted on the *kylix* of Arcesilas, a Spartan vase dating from about 550 B C. The lotus-shaped ends of the beam are here retained, but the beam is depicted as hung, by a simple sailors' device, from the lowered yard of the ship, on the deck of which the king is seated superintending the weighing and loading of a cargo of silphium. This balance is equipped with neither tongue nor plummet. The ancient method of constructing the cord pivot beam has survived in India and China to the present day.

The balance used in classical times was often constructed on Egyptian lines. but those examples nhich have survived are almost entirely of bronze, and are of a quite different type nhich possibly originated at Alexandria in Ptolemaic times. The pivots in these instruments may best be described as hole or ring pivots, and were formed by linking hooks or rings through holes pierced through the beam. These ring pivot instruments stand for a gain in portability and convenience, but for a retrograde step in accuracy of weighing.

At first no fork (gallon-s, shears, or cheeks) was used, as this device had not been invented. In its place a metal hook or loop of cord was attached to a ring linked through a central hole.

Later. probably about the beginning of the Christian era—but the date is quite uncertain—the fork was invented, and, being itself suspended, enabled an upward pointing tongue to be fitted. In all these classical balances the middle, or fulcrum pin, was apparently never secured to the beam. but to the fork. The beam turned loosely on a pin attached to the fork.

It is a remarkable fact that in the case of the steelyard in some surviving examples (of which one is now in the British Museum) we find a fixed fulcrum pin secured between lugs shaped in the body of the beam. It would appear that it was not till towards the close of the middle ages that such a pin, approximating to the modern knife-edge, was used in equal-armed balances.

Bullion Balances.—The finest type of large balance constructed in 1929 is used for weighing gold and silver. It is really a large precision balance and the principles of its construction need not here be detailed. Great care in design is necessary because of the magnitude of the stresses to which the parts are subjected. In particular, the design of the relieving cam and the whole of its connected parts demands technical skill of a high order.

In the modern form of bullion balance care is taken to preserve the structural rigidity of the beam by causing the continuous plane bearing piece to pass through an aperture in the framework of the open trussed beam. and thus give support to the continuous fulcrum knife-edge. This means that the bearing piece has to bridge over a space between tno supporting columns, and, in order to ensure freedom from distortion under load, great transverse rigidity is necessary.

For ordinary commercial purposes, box end, Dutch end. and "brass agate" beams are still often used. but the continuous knife-edge with continuous bearing is gradually displacing less accurate forms of pivot.

Counter Machines, or Small Linked Mechanisms.—It is convenient for most commercial purposes to use scales in which the scalepans are placed above the beam. In the United States such machines are known as counter trip scales. To effect this end. linked mechanisms have had to be devised which maintain the pans always in a horizontal position, and give accurate neighing irrespective of the position thereon of the load and weights. This means that each pan must be supported so that a load, wherever it is placed, will exert the same turning moment round the centre of oscillation of the main beam. This may be effected in various ways, the object in all cases being to give to every part of a pan or platform the same virtual velocity.

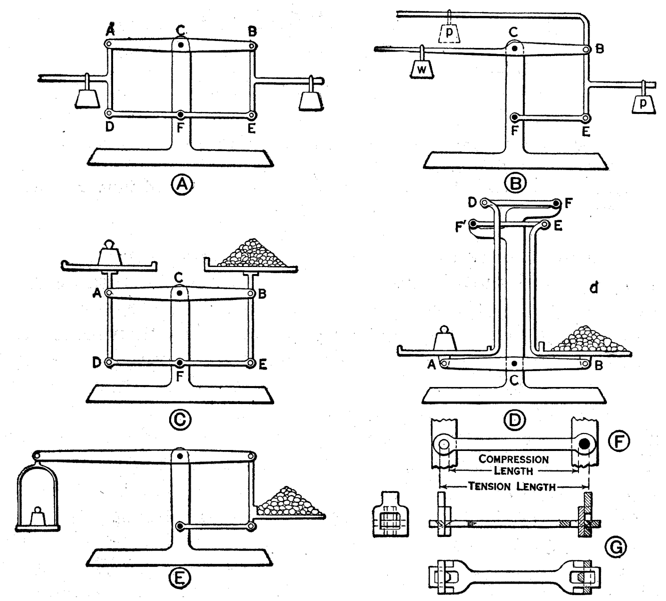

FIG. I.—THE ROBERVAL ENIGMA AND DERIVED MECHANISMS
(A) The Roberval Enigma; (B) Modified form; (C) Ordinary Roberval Counter Machine; (D) Inverted type of Roberval Balance; (E) Balance designed to avoid reversal of stress in stay; (F) Diagram showing change in stay length due to reversal of stress; (G) French stay designed to maintain constant length in tension or compression

Two chief groups of mechanisms may be recognized: (1) Those directly derived from the *énigme statique* (fig. 1*a*) of the French mathematician. Gilles Personne de Roberval, and (2) those consisting of a combination of load carrying levers adapted to support the scalepans in such a manner as to comply with the specified conditions (fig. 2). Roberval invented his static enigma in 1669, but no completely satisfactory explanation of its action appears to have been formulated until Louis Poinsot published the 3rd edition of his *Éléments de Statique* in 1821. His explanation is based on the theory of couples, and has the advantage of being immediate and self-contained.

J. d'Alembert, in his article on the lever in the *Encyclopédie* of 1750, had attempted a similar type of solution without complete success. On the other hand, Isaac Newton had long previously, by the enunciation of his principle of virtual velocities, provided all the data for solving the problem, though he left no note on the subject. J. T. Desaguliers applied Newton's principle to the enigma in his Course of Experimental Philosophy (2nd ed., London, 1745), and showed that in such a balance the turning moments exerted by the weights on each side of the centre are proportional to their virtual velocities multiplied by their mass, and not proportional to their distance from the centre of rotation. The original form of the enigma is shown in fig. 1*a,* while b shows a modified form using one parallelogram only.

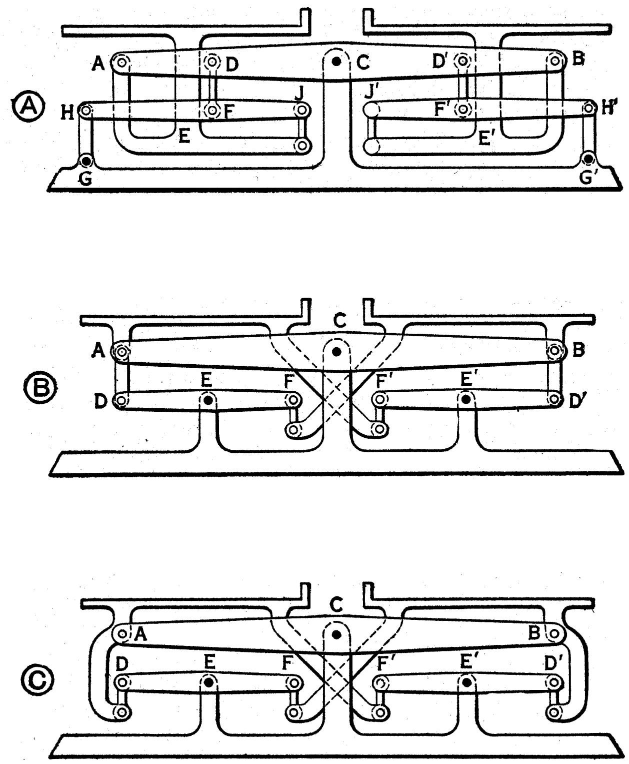

FIG. 2.— OUTLINE DIAGRAMS OF COUNTER MACHINES HAVING MORE THAN ONE WEIGHING LEVEL
(A) Béranger Balance; (B) Phanzeder Balance; (C) Modified form of Phanzeder Balance in which the links are all in tension

In fig. 1*a,* AB is an equal-armed beam pivoted on a knife-edge at C. AD and BE are vertical members pivoted with as little friction as possible to the beam and also to the link DFE, which latter is pivoted to the frame at F, the whole linkage forming two parallelograms. To the vertical legs are rigidly secured two bars from which equal weights are adapted to hang. These bars need not be fastened to the middle of the legs, nor need they project horizontally. If the parallelograms are truly equal. the balance will remain in equilibrium no matter what the position of the equal weights on the bars. It is obvious that, since the legs rise and fall vertically, the virtual velocities of the weights for any given change of inclination of the beam AB are independent of the distance of the weights from C, and are equal to each other; and it can be shown that, this being so, the balance of the system must remain undisturbed when the positions of the weights are changed. Considering the problem in the light of the principle of work, it is clear that, for a given inclination of the beam the vertical displacement of the weights is irrespective of their distance from the fulcrum C of the beam. Under such conditions equilibrium is not disturbed by moving the weights along the bars.

Any divergence of the linkage from perfect parallelism destroys the characteristics of the balance; and it is important to observe that the susceptibility to derangement through lack of equality in the lengths of the parallel members is much greater as regards the vertical legs than as regards the horizontal lever arms and links.

Fig. 1*b* shows a form of the device in which both weights may be placed spatially on the same side of C, though kinematically *p* is on the opposite side to *w.* A balance based on this form was made by Phitzer of Oschatz. The two principal counter machines which have been constructed on the basis of the Roberval enigma are indicated in outline in figs. 1*c* and 1*d,* and do not require detailed description. Type 1*d*—the inverted Roberval—is the better form, as the long vertical legs reduce the magnitude of the alternating tensional and compressive stresses in the stays or links DF and EF'.

In order to ensure that the parallelograms retain their true shape under load it is important that the attachment of the leg to the scalepan supports should be very rigid. In fact, good weighing with this type of balance depends on thoroughly sound design and construction.

Reference has been made to the alternation of stress in the stays or checks caused by varying positions of the load or weights. Unless a special type of pivot is employed, providing line contact on one and the same line irrespective of whether the stay is in tension or compression, a reversal of stress will always be accompanied by a change in the effective length of the stay, and, consequently, by a distortion of the parallelogram in question. This is shown in fig. 1*f.* The beautiful kinematic pivot by which this distortion is prevented is shown in diagram in fig 1*g.* Such stays require to be made with great accuracy to give satisfactory service in modern self-indicating balances, where any minute differences of load effect caused by variation in the position of the load are directly visible on the chart. To avoid reversal of stress in the stays the form of balance shown in fig. 1*e* has been devised and occasionally manufactured. Other forms have been constructed. A pointer attached to the beam to indicate over or under is useful as an aid in proportioning the weighed material for balance. U.S. counter machines are also generally equipped with a graduated steelyard, called a side beam, placed parallel to the scale beam and carrying a suitable poise. By moving this poise to the appropriate notch a balance may be obtained without the use of small fractional weights. A 16-lb. capacity scale would have a side beam of 1 lb. capacity graduated in $\frac{1}{4}$-oz. subdivisions. The use in retail trade of such counter scales is not allowed in England.

Of counter machines in which more than one load carrying lever is employed to keep a scalepan always parallel to itself throughout its permitted range of movement, the most typical is probably that of Joseph Béranger, a French scale manufacturer, who patented his device in the United Kingdom in 1849. This beautiful linkage is represented diagrammatically in fig. 2*a,* where ACB is the main beam, of which, as in all these diagrams, only one of the two side members is shown. At D and D' are pivots equally spaced from the fulcrum C. To the links DF and D'F' are suspended the subsidiary levers HFJ and H'F'J', anchored to the base plate respectively by links HG and H'G', and serving to support, by means of the links hanging from J and J', the cradles E and E', which latter are also suspended from pivots A and B of the main beam. By pillars rigidly attached to the cradles the scalepans are conveniently supported above the levers. Considering the left half of the beam, the short arm DC bears the same ratio to the long arm AC, as the short arm HF of the subsidiary lever HFJ does to the long arm HJ of the same. Hence it follows that, when the balance vibrates, if D falls 1 in, and A 2 in., J will also fall 2 in.; consequently, the cradle E, together with its scalepan, will move parallel to itself, and the load, or any part thereof, will produce the same turning moment about C whether it be transmitted directly to the main beam through A or indirectly through J, F and D. Precisely the same considerations hold in respect of the other half of the mechanism.

Another type of balance, very similar in principle to the Béranger, and much used in European countries, is the Phanzeder. In fig. 2*b* the earlier type, using compression links AD and BD'. is shown. The subsidiary levers DEF and D'E'F' are equal-armed, and it will be observed that each scalepan has one leg

VARIOUS TYPES OF WEIGHING MACHINES

1. Bullion and testing balance, a sensitive beam weighing machine used for precious stones and metal
2. Portable unit counting scale used to count the number of uniform pieces in an unknown quantity or to count a predetermined number of pieces
3. Phantom view of the load compensating and indicating mechanism found inside a dial scale. (The scale is shown at three-fourths capacity)
4. Dial with adjustable photoelectric control which provides an impulse at any desired weight to control material flow in any sort of batching operation
5. Dial scale and weight printer which indicates the weight and then prints on tape or tickets, or both, the weight plus any combination of numbers or symbols as set up on the keys, as well as the time, date and consecutive numbering of items weighed
6. Plate fulcrum track scale showing movable end section
7. Electric instrument which interprets and indicates weights received in the form of an electric current from the load cells of an eiectrical scale
8. Conveyor scale indicating mechanism which records the accumulated weight of material passing along a conveyor belt. The chain couples the speed of the moving belt with load being applied at the left through the rod and hook
9. Understructure or lever system of a heavy-duty two-section industrial scale

supported by a pivot, A or B, of the main beam, and the other leg supported by a link from a pivot of the subsidiary lever on the opposite side of the fulcrum.

Obviously, to avoid friction. since the arcs described by A and D, or B and D′ are of different radii. AD and BD' must be pivoted links, and not rigid projections from the scalepans. Obviously, too. they are in compression. British practice, as also in the U S., is generally opposed to the use of such compression links, which, nevertheless. when correctly designed and constructed. are quite reliable. A form of the Phanzeder balance in which only links in tension are used is shown in fig. *2c*.

The Steelyard.—This instrument. designed as a portable weighing device dispensing with the necessity for using a large number of weights, must be regarded as in all respects of a secondary or derivative nature when compared with the balance. The English word has probably nothing whatever to do with either steel or yard, being derived from the M.L.German word *stâlhof,* sample courtyard, the name for the London depot of the Hanseatic merchants. where they displayed samples of their goods, and where numbers of such instruments were in use. In the U.S., and in the British commonwealth, steelyards, especially when suspended from a tripod, are often known as weighmaster beams.

The principle of operation of the modern or Roman steelyard may be gathered from the diagram, fig. 3. AB is the steelyard freely suspended by its fulcrum knife-edge C from the fixed support D. E is the load knife-edge, and *p* the poise. shown suspended at a point F, such that the turning moments about the pivot C due to the weight of the steelyard and its parts, together with those due to the poise and the load (not sho n). are of equal magnitude on each side of C. Under these conditions the yard is in equilibrium. Supposing then, with the poise in zero graduation G. and no load except the shackle and its parts depending from E, the instrument is in equilibrium. then it is clear that the centre of gravity of the unloaded steelyard is under the suspension knife-edge C. The weight of the steelyard and its parts, under such conditions. exerts no turning moment about C. If, then, a load L be suspended from E. it will exert a turning moment $L\times CE$, and obviously this can only be balanced by moving the poise *p* away from the centre until, at a point F, the turning moment $p\times CF=L\times CE$. Since CE and *p* are constants the load varies directly as CF. Hence the graduations of the steelyard mill be of equal magnitude for equal increments of load. It is desirable that steelyards should be constructed so that the unloaded beam is in balance when the poise is in zero graduation.

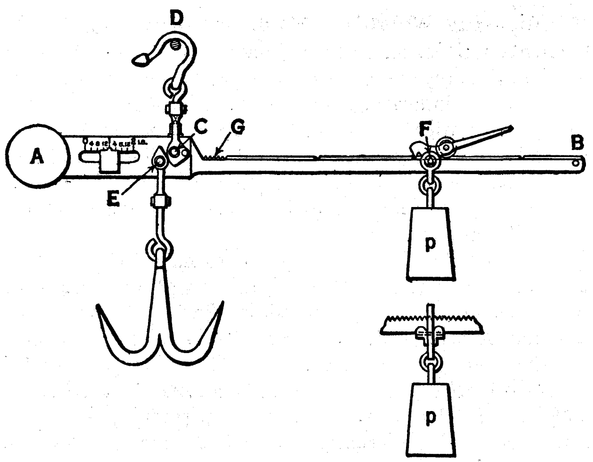

FIG. 3.— MODERN TYPE OF BUTCHERS' STEELYARD

A more primitive method of suspending the poise from the graduated yard is also shown

The Roman steelyard is an Italian invention, and probably originated about zoo B.C. in Campania, or in Magna Graecia. It was apparently unknown to Xristotle, who. in his "Mechanics," describes the so-called Danish steelyard, which we now know preceded the Roman type in classical antiquity, as also throughout the greater part of Europe and western Asia. The Danish steelyard consisted of a beam heavily weighted at one end, and provided at the other with a hook or pivot to which the load

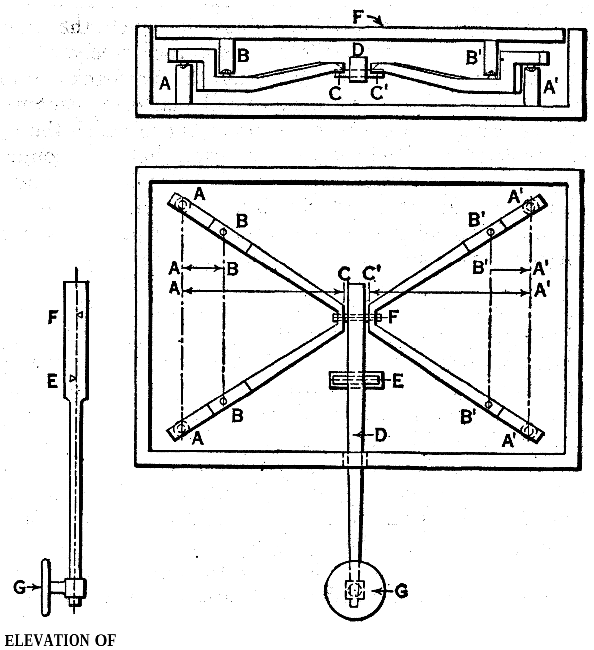

FIG. 4.— WYATT'S WEIGHBRIDGE

This first compound lever platform scale (about 1744) was the brilliant invention of John Wyatt of Birmingham

could be suspended. A loop of cord generally constituted the fulcrum. the graduated beam being moved through the loop until the load was balanced. The graduations were not equal, but formed a harmonic series. The Shetland *bismar,* the Indian *dhari,* and other instruments found throughout the east, conform to this type. The device was probably a Wiro invention, and was carried by those invaders into western and southern Europe, just as by the Aryans proper it was taken into India.

The modern Roman steelyard, still largely used by butchers, is a reliable and accurate instrument. The best makes are provided with devices to prevent undue wear of the graduation notches, and the yard proper, or blade, is made of noncorrosive steel. The notches are cut by a specially constructed dividing engine to a degree of accuracy quite unattainable by other means.

Compound Lever Platform Machine.—The usual method of weighing heavy loads is on some form of platform machine. Before John Wyatt's brilliant invention of the compound lever, about the year 1744, it was necessary to use immensely heavy and inconvenient steelyards for the weighing of loaded carts, and the operation, even in the case of a small two-wheeled hay cart, was a laborious one. Wyatt was a master carpenter or mechanic. Apparently most of his weighbridges were built when he was in the employ of the great Matthew Boulton. He died in 1766. Fig. 4 is a drawing, necessarily somewhat diagrammatic and lacking in detail, which probably represents rather closely the original scheme of Wyatt's mechanism. It has been constructed from early descriptions and illustrations. (See the 3rd edition of the Ency. Brit. [1797], under STEELYARD; John *Wyatt, Master* Carpenter and *Inventor* [1885, published anonymously, but compiled by Henry Pooley. of Liverpool], and the Wyatt manuscripts in the Birmingham reference library.)

The two triangular levers are pivoted at **A** and A', and receive the load transmitted by the stool legs of the platform F on pivots B and B'. The arms AB and X'B' are equal, as are also the arms AC and A′C′. The pivots C and C' transmit the load to the first order transfer lever D at the same distance FE from its fulcrum E. G is a table for weights to counterbalance the load. Such a combination of levers—crude as it is in construction, being devoid of links and originally having conical points instead of knife-edges —ensures the transmission to the counterpoising lever or steelyard of the same load effect by the same load, irrespective of its position on the platform. Before the close of the 18th century English builders were making machines of which the transfer levers pulled down on the ends of first order steelyards, very much in the modern manner. Whether the Fairbanks brothers of Vermont were the first to make small platform machines in which no separate transfer lever was used, but in which the upper triangular lever was provided with an extension arm connected to a steelyard, is difficult to ascertain; but their platform machines dating from the year 1831, undoubtedly marked an advance in construction and convenience of operation, and had a far-reaching effect on the development of platform machines throughout the world.

A medium capacity weighbridge of British design is shown in fig. j. The linkage consists of two triangular levers, link suspended from the framework, and connected by a central link to the upper lever, which has an extended arm. knife-edge connected to the counterbalancing and indicating device—a steelyard or automatic indicator. U.S. practice is to use a lever system composed of straight levers, with possibly some torsion levers. A torsion lever is a pipelike member with a fitting on each end which contains a load pivot and a fulcrum pivot. The load transmitted through these offset pivots twists the pipe, which is balanced at the end of a member extending perpendicular to the pipe. Thus a section composed of one torsion member and extension at each end of a

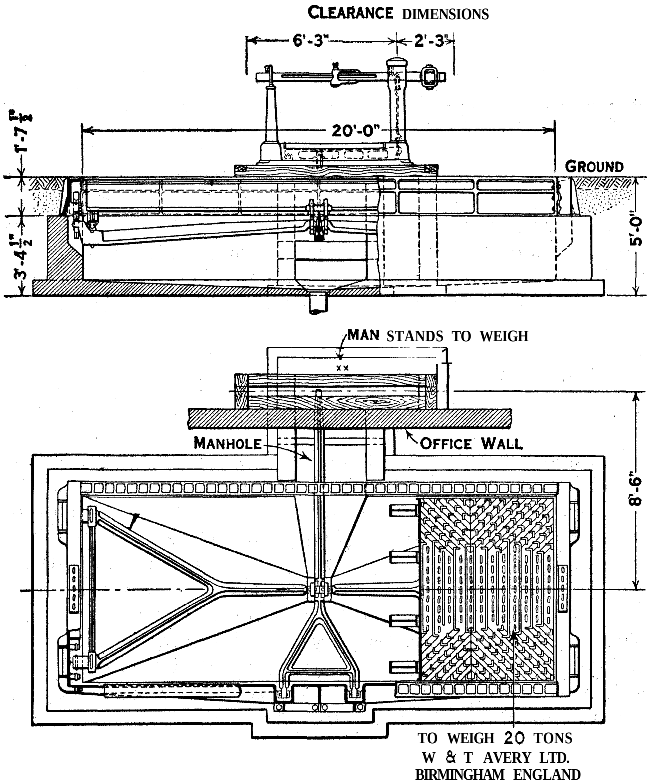

FIG. 5.— PLAN AND ELEVATION OF A BRITISH WEIGHBRIDGE CONNECTED TO A "NO-LOOSE-WEIGHT" STEELYARD

These bridges are sometimes connected to automatic dials, the load capacity of which can be multiplied several times by the use of counterpoise weights

weighbridge serves the same purpose as a section of two main straight and one extension levers, but requires one less fulcrum support. U.S. practice is to support fulcrums on pedestals from the concrete foundation. Vehicle scale linkages consist of two or four sections, depending on the length of platform and capacity of scale. Motor truck platforms 10 ft. wide and up to 60 ft. long, with weighing capacities to 50 tons, use four sections, all connected to one transverse extension lever for carrying the load to steelyard or other indicator. Railroad linkages are similar to those of motor truck scales and are made up to 110 ft. long, usually with four sections of capacities to 200 tons per section. Railroad track scales can weigh moving cars at the rate of about 5 per minute, whereas spotting for stationary weighing would allow about 18 per hour. The minimum indicator graduations may be 20 lb. The accuracy of such scales in heavy exposed service should be 0.1% to 0.2%. The use of long levers tends to minimize loss of accuracy by dulling pivots from heavy shock loads. Automatic printing devices attached to vehicle scales give quick proof of reading. Three seconds after the wheels of the freight car are on the scale a printed ticket is available. Heavy scales provided for weighing vehicles are subjected to considerable shock by approaching and suddenly stopping loads, and hence must have generous excess capacity. Suspensions to allow motion of the aeighbridge and checks to limit travel are built in, allowing horizontal motion and protecting the pivots. Another suspension system uses steel balls between cups on the weighbridge and loading pivot, providing freedom of motion and restoring action as well. The weight of railroad cars is transmitted to the weighbridge through sections of track isolated from the connecting track. If locomotive passage over this section transmits forces too great for the capacity of the system dead rails may be provided. These rails parallel the live rails and are supported by transverse beams bearing directly on the foundation, thus protecting the pivots of the weighing machine.

Plate Pivot Machines.—Of recent years there has been developed, in the United States, a type of weighbridge in which knife-edges are replaced by thin plates or laminae used in compression. These are all derived from the work of A. H. Emery, who, in the year 1875, successfully applied this type of pivot to the construction of a remarkably fine testing machine. There is no doubt that some admirably reliable and sensitive weighbridges have been constructed with plate fulcrums; but their cost at present prevents their general adoption. It is claimed that weighbridges built on this principle remain in accurate and sensitive adjustment even if subjected to severe conditions of use. The plate fulcrums and load pivots are made of chrome-vanadium steel, and their cross sectional area is sufficient to provide an ample margin of safety. The amount of flexure to which they are subjected in use is extremely small. The platform is restrained from horizontal movements by the tension of horizontal plates or rods sufficiently flexible to permit the minute vertical movement required for weighing. The lever system is similar to that of knife-edge lever machines. E. and T. Fairbanks and company, of St. Johnsbury, Vermont, constructed the first plate fulcrum railway track scale in 1915.

Self-indicating Weighing Machines.—The most important developments in the science of weighing instruments in recent years have, unquestionably, been associated with the evolution of the modern automatic indicating weighing machine. In these machines the load is automatically balanced by a resistant counterforce accompanied by a means of indicating the load. The variable counterforce is applied by helical springs or a pendulum (a bent lever with a large mass at the free end) whose effective moment arm varies with its displacement.

The first self-indicating scales appear to have been invented by Leonardo da Vinci (1452–1519). They are described and drawn in one of his notebooks preserved at Paris. (Manuscripts in Bibliothèque de l'Institut. See *Les Manuscrits de Léonard de Vinci, publiés en fac-simile,* etc., par C. Ravaisson Mollien, 6 vol. [1881–91]. *See* also *The Mechanical Inventions of Leonardo da Vinci,* by I. B. Hart [1925].) His description appears to make it certain that he had actually constructed one of these instruments. A semicircular dial, suitably weighted, is suspended, at the middle of its diameter, on a pivot from which also hangs a plumb line, situated so as to serve as an indicator. A scalepan hangs from one end of the diameter. The design has a remarkable characteristic not shared by many modern instruments, *i.e.,* the accuracy of the indications is not affected by any divergence from horizontality of the surface on which the instrument is placed.

A pendulum or bent lever resistant does not give equal chart divisions on a circular or segmental chart unless a cam or other equivalent device is used in the application of the load to the resistant, so as to counteract what has been called the circular error of the pendulum.

4s the pendulous mass is raised by the fall of the load, its resistance increases as the sine of the angle of displacement from the vertical. At the same time, unless the load has been applied by a strap passing around a circular arc concentric with the centre of rotation. the effective length of the arm to which the load is applied will vary. Supposing, in the most simple case. that when the instrument is unloaded the load arm is horizontal and the centre of gravity of the pendulous mass vertically beneath its pivot then the application of a load will deflect the system until a position of equilibrium is attained. During this movement the effective load arm will become shorter in the ratio of the cosine of the angle of deflection. and the resistant arm will increase from zero in the ratio of the sine of the angle. Hence, the load in all balanced positions will vary as the tangent of the angle of deflection, and a pointer attached to the pendulum will not indicate equal chart graduations for equal load increments Generally if the load arm makes an angle ϕ with the horizontal. and the pendulum an angle θ with the vertical, the applied load being L, the following relationship will hold:

$$\mathbf{L} \propto \frac{\sin\theta}{\cos\phi}.$$

Obviously, with a small angle of deflection the graduations will be approximately equal to each other, for the arc traversed will be nearly proportional to the trigonometrical function of its angle. Weighing machines have been constructed using such small angles of rotation in order to get virtual equality of subdivisions. as is required by the regulations of the various national weights and measures authorities. Where a machine is permanently and securely positioned, and extreme sensitivity is not required, little exception can be taken to this method of construction, which has the great advantage of extreme simplicity and robustness of design.

The sensitivity of a pendulum resistant is, however, within limits imposed by technical considerations, a function of the amplitude of the angle of rotation; and furthermore, the larger the angle the less the derangement that will result from such minute differences of level as may supervene after installation. Hence has arisen a multitude of designs for utilizing a considerable angle of rotation, as 55° for instance, while still obtaining equality of subdivisions. Various parallel motion and tangent bar devices have been constructed, but the most generally employed method makes use of a cam formed by eccentrically displacing a circular arc in respect of the axis of rotation. To the periphery of this cam the load is applied by means of a flexible metallic strap. *(See* fig. 6. *a* and b.) A close approximation to absolute equality of subdivisions is possible if the best geometrical configuration is adopted. Fig 6a is a diagram of the mechanism of the well-known fan type of self-indicating counter machine. The combined counterbalancing and indicating unit is pivoted on a knife-edge housed in V-shaped bearings. Fig. 6b is a diagram designed to show that the rate of change of the products of the "circular cam" arm lengths and their respective loads closely approximates to the rate of change of the pendulum moment arms, nhich latter, as has been stated above, conform to a sine law. The two rates of change are made to counteract each other in just the measure necessary to permit of the use of equally divided charts. The dimension d indicates the linear displacement of the cam circle from the centre of oscillation.

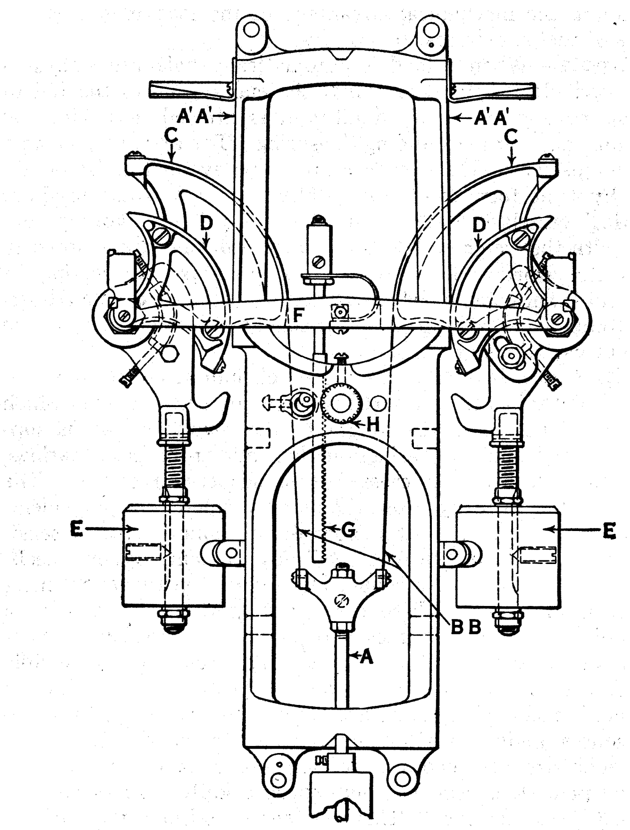

FIG. 7.— MECHANISM OF THE "TOLEDO" SELF-INDICATING PLATFORM MACHINE

(A) Connecting rod attached to weighing levers. Yoke connected by steel straps (BB) to the cams (CC), which are attached to segments (DD) and to pendulums (EE). Segments are suspended from the frame by straps (A'A'). The bar (F) sensitively pivoted to the centres of the circular segments (DD) is raised together with the elastically supported rack (G) which rotates the pinion (H)

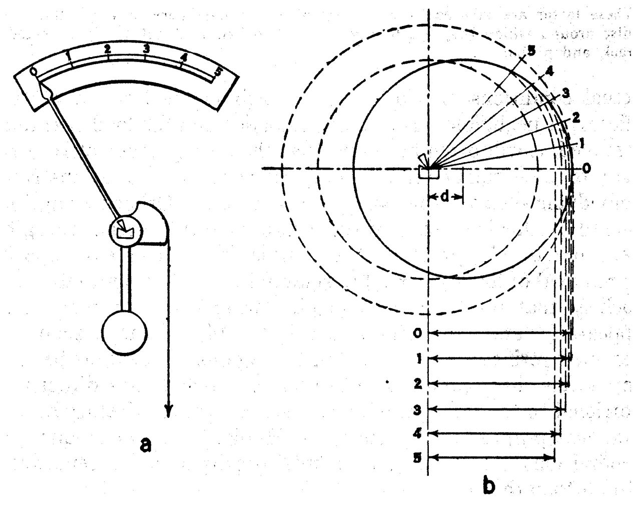

FIG. 6.— THE PENDULUM RESISTANT

(a) Diagram of the mechanism of the Fan Scale used for weighing small quantities in retail shops; (b) Diagram showing how the arm lengths of the cam vary with the angle through which the pendulum moves

The well knonn cylindrical computing scale embodies a resistant of this type, the cylinder itself being carried on antifriction uheels. and rotated by a pinion engaging with a vertically moving rack connected pivotally with the neighing lever. Some types of dial mechanism employ a resistant consisting of two pendulums rotating in opposite senses, thus eliminating the effects of out-of-level disturbances In a nell known U.S. type of mechanism. floating fulcrums replace stationary knife-edges. *(See* fig. 7.) The load is transmitted by straps to the load cams to which are attached cams supported from the frame by straps As the load is applied through tapes, the suspension cams roll about their strap contacts at the frame producing an upuard advancing pivot as the pendulum arms rotate outward. The use of two weights offsets the effect of uneven setting of base. The upward movement of the pendulum cam centres is transmitted through a rack meshing with a pinion to sneep the pointer around an indicator dial. Accuracy is dependent upon carefully cut gear teeth, good tooth contact and freedom from wear. The rack may be held in controlled mesh with the pinion by means of spring, roller or magnet. One redesigned scale dispensed with the rack pinion drive by substituting straps around multiplying drums.

A three-cam system whereby the leverage of the weight is varied by cam contour is illustrated in fig. 8. The load is transmitted by straps to the load cam and rotates the cam system about the suspension cam pivot at its tape contact point. This has the effect of diminishing the mechanical advantage of the load in raising the weights of the pivoted resistant levers.

Dashpots. — When a load is automatically balanced against a simple variable resistant, only half the energy due to the fall of the load to a position of equilibrium is utilized in raising the pendulous mass, or in extending the spring. The remaining energy, if violent oscillations and shocks are to be avoided, must be absorbed by some form of dashpot. The devices generally used are cylindrical vessels containing oil. in which pistons pivotally connected with the weighing levers by suitable linkage are adapted to reciprocate. Ports, in the piston, or in a tubular part connecting the upper and lower ends of the oil-containing chamber, enable adjustments to be made to compensate for changes in the viscosity of the oil due to variations of temperature.

Antifriction Devices. — In those self-indicating machines in which a pointer has to be rotated round a circular dial, or in which a moving dial is used, the weight of the revolving part is supported on frictionless bearings — either miniature ball bearings, antifriction wheels, or a crossed-strap suspension device. The first of these is, in many cases, the most commercially convenient, but does not permit the attainment of the same degree of sensitivity that is possible with really well-designed antifriction wheels.

Crossed-strap Device, introduced by Avery, constitutes the most frictionless method yet discovered of supporting and rotating a large indicating unit. No rack and pinion is necessary. A rotational angle of about 300° is possible. The weight of the spindle carrying the rotating part is entirely supported by two pairs of thin steel bands. These pairs are secured to, and wrapped in opposed senses about, a small drum attached to the spindle. Their upper ends are attached to the opposite ends of an inverted weighted pendulous segment, pivoted on a knife-edge working in V-shaped agate bearings. This segment constitutes the variable resistant, and carries a cam or displaced circular arc so disposed eccentrically to the fulcrum as to give equal chart subdivisions for equal fractions of the total load. The load effect or pull is transmitted from the main weighing lever to this cam by means of a long flexible steel strap. As the segment rotates on its knife-edge it unwinds one pair of straps and winds up the other pair at exactly the same rate, thus rotating the drum mounted on the floating chart-carrying spindle, while maintaining it in exactly the same position.

Other resistants beside the bent lever or pendulum have been and are used in weighing mechanisms. Of these the chief is the spring. The most commonly used form is the helical spring. For some purposes its employment is quite legitimate; nevertheless, the chief constructors of self-indicating weighers throughout the world have, with few exceptions, abandoned it as a resistant in entirely automatic weighing mechanisms. It has three outstanding defects, two of which result from its susceptibility to changes of external temperature. The substance of all steel springs expands or contracts in length with variations of temperature, and this generally affects the zero indication of the balance. It can be shown that, in the case of a properly proportioned helical spring in the unloaded state, the change in length of the wire caused by temperature change makes practically no difference in the actual length of the helix; but in a weighing instrument such a condition of no-load never occurs in practice. Temperature also affects the specific elasticity of springs. When a spring is warm it extends more under a given load than when cold. Hence, even if the scalepan is empty, the greater extension of the spring under its initial load resulting from the weight of necessary parts, displaces the zero indication. To a still greater extent the whole range of indications is affected. In a large measure this defect can be compensated for by means of a thermostatic device made of two dissimilar metals, so disposed that the transmitted load-effect can, by means of a change of leverage, be given a greater or less mechanical advantage before its application to the spring resistant or by using a special metal alloy unaffected by temperature.

The third source of error is more serious and cannot be completely eliminated, though it is proper to note that, under the actual conditions in which many weighing machines operate, its effects are negligible. If a spring is loaded and the load is gradually removed, it will often be found that the spring does not return exactly to its original conformation; hence. the zero of an instrument embodying such a spring will not be constant. Other derangements caused by this hysteresis of the elastic material of the spring have been noted. In practice, the gradual and shockless deposition or removal of loads referred to seldom takes place, and vibration—such as that resulting from neighbouring traffic or machinery—appears generally to eliminate this trouble in the case of well-designed spring-operated machines. Against these drawbacks the spring has the great advantage of giving deflections directly proportional to the load, thereby producing without alteration. for all practical purposes, conformity to Hooke's law, *i.e.,* equal chart subdivisions. Moreover, it is intrinsically a more sensitive resistant than the pendulum.

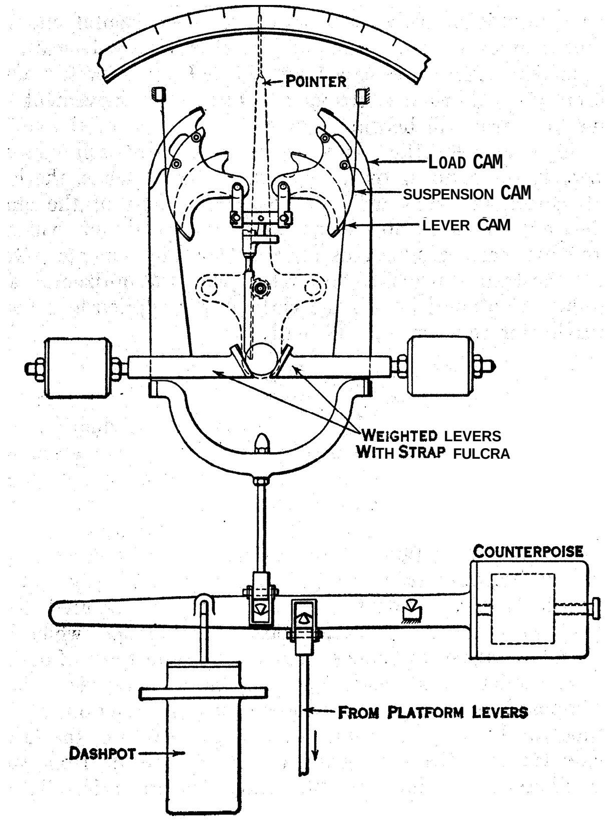

FIG. 8.—AVERY CAM-RESISTANT MECHANISM

A variable resistant is obtained without the use of pendulums, two sets of suspended triple cam contours so designed as to give to an increasing load a diminishing mechanical advantage in its efforts to raise the weighted levers. These latter are pivoted by steel straps to the periphery of a small circular disc around which they are free to roll. The balanced pointer is operated by rack and pinion

The hydrostatic resistant has been made in various forms. It depends on the buoyancy of a float and its resistance to vertical displacement. A mercury resistant embodying the same principle has also been extensively used.

Computing Scales. — Entirely automatic self-indicating counter scales are very generally adapted to indicate, not only the weight of the goods, but the particular value of the weight corresponding to a large number of different unitary prices. Collinear with each weight graduation is a series of price indications — the respective unitary prices, as, for instance, prices per pound avoirdupois being marked either on the pointer, if the dial is of the stationary type, or on the revolving chart itself.

Automatic Feed Scales.—This name is given to a large class of mechanisms by means of which granular and liquid materials may be automatically weighed off in predetermined amounts. It is possible to weigh in this manner practically all materials which can be induced to flow through a port or valve of reasonable dimensions. Thus modifications of the same general type of scale will weigh flour and the most finely ground cement, while others will weigh coal and ores broken up in lumps not exceeding say 2 or 3 in. in diameter. In general terms such a machine—one form of which is illustrated in fig. 9—may be defined as consisting of a hopper I, or box terminating a feeding spout, and equipped at its lower end with a pivoted gate D, or gates, adapted, when opened, to permit a flow of material into a scale hopper C, placed immediately beneath it. This receptacle depends from one end of an equal-armed balance beam A. the other end of which carries a weight box B. When the scale is empty the weighted end of the beam causes the hopper end to rise, and by contacting with a part pivotally connected by links to the above mentioned gate or gates, forces them to open, thus causing the rapid filling of the receptacle with the material being weighed. The bottom of the scale hopper is closed by a large discharge valve E, to which is connected linkage so designed that, when this door is closed, the linkage forms a locked dead centre. This device, often called a toggle, is indicated at the right of the receptacle in the illustration. Other and different devices, as detent mechanisms, are sometimes used to keep the bottom door securely fastened until the receptacle has received its proper load.

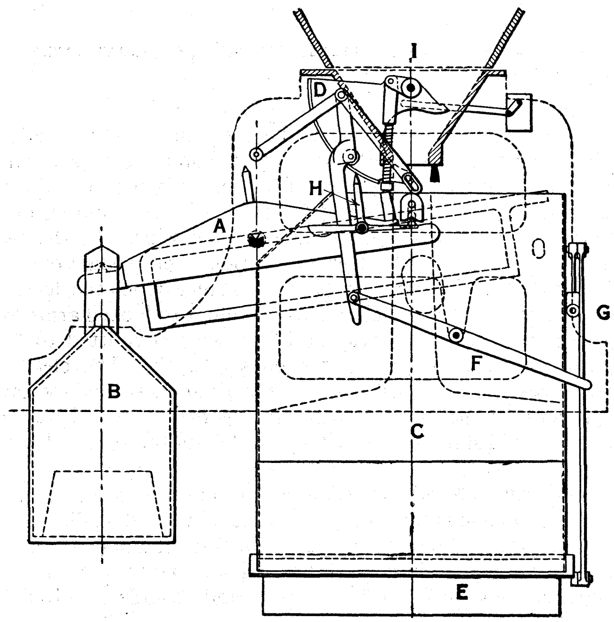

FIG. 9 — AUTOMATIC FEED SCALE

A diagram of a grain weigher for automatically weighing wheat and other grains. The material is stored in the hopper I, the gate D being opened by the upward pressure of the empty receptacle C due to the weights in the scale-pan B. When the load in the receptacle balances the weights the receptacle falls, closes the supply gate and 'opens the discharge valve E

As a state of equilibrium is approached, the weights no longer hold up the receptacle forcibly against the device which controls the opening of the hopper valve. Consequently. this valve gradually closes, and the final cutoff is arranged to take place just when a balance has been obtained. In some types of this mechanism the balanced beam, in falling aaay from the gate-opening mechanism, causes contact to be made between a lug or peg attached to the framework, and the linkage or detent system controlling the discharge valve; or, alternatively, as in fig. 9, a part connected with the feed gate is adapted to break the dead centre or toggle mechanism of the discharge valve linkage. at the moment when the hopper valve has completely closed. A small force, properly applied, suffices to effect this release. The moment this takes place the discharge valve E opens, and the weighed material falls into another receptacle, generally connected with a conveyor or elevator.

Such, in brief outline, is the principle on which practically all automatic feed weighers act. Many refinements are, however, necessary in practice. and to the chief of these some reference must be made. At the moment when the receptacle has received its true weight of material, and the beam is moving to the balanced position, there is a considerable weight of material in the act of falling from the closed feed port to the receptacle. To compensate for this amount, which would otherwise overload the balance: a compensating lever is employed. This lever is shown outlined in the illustration as lying parallel to the scale beam. It is pivoted to the frame, and adapted by means of an adjustable poise. not shown, to press upon the load receptacle: or some connected part, while the receptacle is being filled. Consequently, the receptacle tends to fall to the balanced position before it has obtained its full load, thus closing the feed port. The weight of material in the air at the moment of cutoff exactly compensates for this deficiency. If desired, the accuracy of the weighing can be immediately checked by raising the compensating lever before the hopper has had time to fall sufficiently far to cause discharge to ensue, or by preventing discharge in some other convenient manner. If the adjustments have been properly made, the beam will be found in perfect balance. In order to render the cutoff still more precise, in practically all larger weighers a small valve called a dribble valve is used in addition to the main valve or valves. The main valves are closed before the weighing is complete, but the dribble port continues open until closed by the release of a detent, or, in some mechanisms—as in the grain weigher illustrated in fig. 9—by the continued movement of the main valve. In some makes of machine, especially those used for weighing grain, the edge of the feed valve port is rimmed with a brush in close proximity to which the closing valve moves very smoothly and without risk of jamming.

The action of the particular type of weigher illustrated may be followed in a little greater detail. F is a lever connected to the feed valve linkage. When this valve is nearly closed, the little wheel shown on the vertical link is resting on the steel pin H, attached to a pivoted counterbalanced lever. Later, when the loaded receptacle falls to the balanced position, a pin contacts with the counterbalanced lever and throws H over to the right. The valve then closes completely, and the free end of the lever F rises and contacts with the pin G, thus breaking the dead centre and causing the discharge valve E to open.

Small automatic feed weighers, used for filling packets with standard quantities of material, are often operated electrically, as this enables great accuracy to be attained. In such devices, the instantaneous and energetic shutting of the feed port is actuated by the indicator through either a mercoid-magnetic switch, a high-voltage gap, or a photoelectric cell. Several adjustable cutoff positions are provided. A stepped interceptor of light to a photoelectric cell can give controlled dribble before cutoff.

Conveyor **Weighers.**—Of recent years various conveyor weighers have been developed, and have filled a useful place in the bulk weighing of materials where no great accuracy is required. The principle of operation of one form may be briefly outlined. If a conveyor belt is made to pass over rollers supported by a system of weighing levers, which system is in turn suitably connected to a variable resistant, the resistant will respond to the varying weight of material on the belt. If this weighing device, as regards its load indications, is connected with a device responding to the velocity of linear movement of the conveyor belt in such a manner that the one numerical magnitude is multiplied by the other, it is obvious the product may be evaluated to represent the weight of material passing along the conveyor in a given time. Various methods, some mechanical and others electrical, have been designed to effect this multiplication.

Totalizer. — This weighing machine is of the automatic moving poise type, and is generally used for the automatic weighing and recording of the total of the separate loads contained in a series of receptacles or trucks placed successively on the weighing platform. As each load is imposed an electrically propelled poise moves out along a steelyard connected to the weighing machine, and effects a balance, at the same time operating a counting device which records and adds on to the total of previous weighments the weight of the newly imposed load. Such mechanisms are capable of accurate and reliable adjustment. The divergence of the weight indications of the mechanical counters, when such a machine is working under reasonably good conditions, from the true weight of the total loads should not exceed about one-fifth of 1%. About the same standard of accuracy is often attainable with high-class automatic feed weighers.

Weighing as a Means of Counting.— A great extension of this convenient method of counting things of uniform weight has taken place in recent years. Immense numbers of small parts and finished articles are produced by modern methods of machining and fabrication under conditions which ensure that the weight of each piece will be approximately the same. Hence, if a balanced system of linked levers is constructed having two receptacles connected therewith, one large and one small, at points at which the mechanical advantage of a weight deposited in the small pan is 100 times greater than that of the same weight if deposited in the larger pan, it is obvious that equilibrium can only be obtained by placing 100 such weights in the large pan for every one deposited in the small pan. Hence if, for instance, it is desired to count bolts of uniform pattern in hundreds, one bolt is placed in the small pan and a quantity in the other, the number being rapidly adjusted until a balance is obtained.

Load Cells.—Where large beam machines are not suitable for weighing heavy or bulky objects, load cells are convenient. These are small, portable units that operate on electric, hydraulic or pneumatic principles. The electric cell consists of a load-carrying bar to which are attached four matched wire gauges electrically connected in a Wheatstone bridge circuit subjected to a direct current voltage. When the bar is loaded in tension or compression its deformation changes the resistance of the two loaded grids so that the circuit is electrically unbalanced proportionally to the load. The unbalance is amplified and transmitted to an indicating motor. Electric cells are available in sizes 0 to 200 lb. and up to 1,000,000 lb. Small size, excellent sensitivity and accuracy (better than 0.25%), small deflection and indifference to vibration along with high capacity and remote indication make it suitable for many applications, particularly automatic process control. Hydraulic cells utilize a thin film of oil between a piston and diaphragm. Pressure is generated by a short stroke and transmitted to an indicator with an accuracy of about 0.1%. Cells are extremely sensitive but are unsuitable for oscillating loads. Capacities are up to 5,000,000 lb. Pneumatic cells are supplied with air under pressure from an outside source to balance load applied on a piston. Principally used for light to medium loads over a limited range, these cells are more popular for control than for weight measurement.

Developments in transmitting readings electrically over long distances, optically magnifying and projecting readings for clear viewing, and refined automatic printing of weight recordings rapidly were being made in the mid-1950s. Application of dynamic weight control with prompt response and small movement are a requisite in the development of automation.

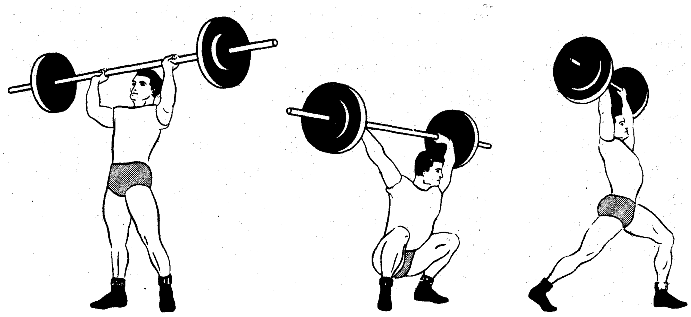
WEIGHT LIFTING. Weight lifting is a competitive sport, which is included in the Olympic games and governed by rules established by the International Weight Lifting federation. Champion weight lifters, like all champion athletes, must have co-ordinated speed and agility and a will to win. More than other sports, however, weight lifting requires strength.

Exercise similar to weight lifting, called weight training, is also practised by those who exercise with a bar bell (and dumbbells) to develop strength, to improve physical appearance, to increase power in order to succeed in other sports or to rehabilitate parts of the body weakened by illness or injury.

A bar bell is a steel rod handle to which removable cast-iron disks



A B C

AFTER J. A. MURRAY

THE THREE BASIC LIFTS: (A) PRESS. (B) SNATCH (SQUAT STYLE), (C) CLEAN AND JERK

are attached at the ends to vary the resistance. Dumbbells are simply short bar bells, used one in each hand. Competition involves a bar bell and three lifts. The winner is the one who lifts the highest total weight on the (A) press, (B) snatch and (C) clean and jerk. In case of a tie, the lighter man wins. In the press, the bar bell is lifted to the chest in one pull, then pushed overhead by the arms and shoulders without assistance from the legs. In the snatch, the bar bell is pulled from the floor to locked arms overhead in a single motion, with the lifter being permitted to lunge or squat under the weight as it travels upward. The clean and jerk is a two-movement lift, one to the chest and a second overhead, but leg action is not restricted, as in the press. The lifter may lunge, squat and start the bar bell upward from the chest with a leg drive.

Weights can be lifted for exercise in an infinite variety of ways. The main principle is that when a muscle is worked against gradually increasing resistance over a period of time. it becomes stronger (and to some extent larger). Pressing a weight overhead from the shoulders adds strength to the arms and shoulders. Holding a weight on the shoulders and doing knee bends strengthens the legs. Such basic exercises are usually done with five to ten repetitions. Scientific studies have shown that weight lifting does not slow the speed of muscular contraction and has a low incidence of injury.

For Olympic champions. see OLYMPIC GAMES.

WEIGHTS AND MEASURES. The U.S. customary system of weights and measures, the British imperial system and the metric system are treated in detail in this article, and the systems and units used in some other countries are briefly considered.

Some consideration is given to the materials used as standards, to the conditions necessary to specify in order that standards may correctly define the units, and to weights and measures administration. Reference should be made to the articles on METROLOGY and PHYSICAL UNITS for additional information about units and standards, and to the article on TIME MEASUREMENT for information about units of time.

Other related articles are those on GRADUATION AND CALIBRATION; DIMENSIONAL ANALYSIS.

The **U.S.** Customary System.—The weights and measures in common use in the American colonies at the time of the American Revolution were all of English origin and were the same as those then in use in Great Britain. As the system of weights and measures in Great Britain at that time was far from being on any scientific basis, it is not surprising that there was considerable lack of uniformity in the units in the colonies. The need for fixing the standards was recognized by the framers of the Articles of Confederation and of the constitution. The subject was often discussed but no definite action was taken for many years. On May 29, 1830, the senate passed a resolution directing the secretary of the treasury to cause a comparison to be made of the weights and measures in use in the principal customhouses and to report to the senate at its next session. The investigation was made and large discrepancies were found in the weights and measures in use. The average values of the several units were, however, all reasonably close to the corresponding values in the British system in 1776. Real progress was made toward the unification of weights and measures in the United States by the subsequent distribution of uniform standards to the customhouses based on the following: (1) the yard of 36 in., (2) the avoirdupois pound of 7,000 gr., (3) the wine gallon of 231 cu.in. and (4) the Winchester bushel of 2,150.42 cu.in. These units are still in use in the United States. The wine gallon, usually referred to as "the gallon" or "the U.S. gallon," is used only for liquid measures; and the Winchester bushel, usually referred to as "the bushel," or "the U.S. bushel," is used only for dry measures.

The yard is subdivided into three feet of 12 in. each. Five and one-half yards ($16\frac{1}{2}$ ft.) make a rod, pole or perch; 40 rods make a furlong; and eight furlongs (5,280 ft.) make a statute mile. Units of area and volume are simply the squares and cubes, respectively, of the units of length, except for the insertion of the acre, which consists of 43,560 sq.ft.

The avoirdupois pound is subdivided into 16 oz., or 256 drams or 7,000 gr. It should be noted that the grain is the same whether it is avoirdupois, troy or apothecaries' weight and that the avoirdupois ounce contains $437\frac{1}{2}$ gr. whereas the troy ounce and the apothecaries' ounce each contains 480 gr. One hundred pounds equals a hundredweight and 2,000 lb. equals one ton—designated as "net ton" or "short ton" to distinguish it from the "gross ton" or "long ton" of 2,240 lb.

The U.S. gallon is divided into four liquid quarts, or eight liquid pints or 32 gills. The gallon, quart and pint of the apothecaries' fluid measure are, respectively, the same as the corresponding unit of the ordinary liquid measure. The pint is subdivided in the apothecaries' fluid measure system into 16 fluid oz., or 128 fluid drams or 7,680 minims. The U.S. bushel is subdivided into four pecks, or 32 qt. or 64 pt.

For more complete information on units of the U.S. customary system reference is made to miscellaneous publication M233 of the national bureau of standards, entitled *Units of Weight and Measures (United States Customary and Metric)—Definitions and Tables of Equivalents,* and to Circular 570 of that bureau, entitled *Units and Systems of Weights and Measures—Their Origin, Development, and Present Status.*

It was not sufficient, however, that a decision was made in 1832 as to the units and measures for the United States; it was also necessary to adopt physical standards embodying those units. For the yard the length at 62° F. of the interval between the 27th and 63rd inch of a certain 82-in. brass bar known as the Troughton scale was adopted; for the pound, the troy pound of the mint was used, the avoirdupois pound being defined as $\frac{7{,}000}{5{,}760}$ troy lb. As already stated, the gallon and the bushel were defined in terms of the inch. For more than half a century those having the custody of U.S. weights and measures tried to keep the U.S. pound equal to the British pound and the U.S. yard equal to the British yard. But in 1893. after receipt of the metric standards, it was decided that a more stable basis for the system of customary weights and measures in the United States would be obtained by defining the yard in terms of the metre and the pound in terms of the kilogram using the U.S. prototype metre and the U.S. prototype kilogram, respectively, with their certified corrections as the primary standards of length and mass in this country. This is the present basis of the units. The U.S. yard was defined as $\frac{3{,}600}{3{,}937}$ m. and the U.S. pound as 0.4535924277 kg.

Effective July 1, 1959, the following exact equivalents were adopted by the national standards laboratories of Australia, Canada, New Zealand, South Africa, the United Kingdom and the United States: 1 yd. = 0.9144 m.; 1 lb. (avoirdupois) = 0.45359237 kg. From the first of these equivalents it follows that 1 in. = 25.4 mm. In the U.S. the survey foot, defined as $\frac{1{,}200}{3{,}937}$ m., will be used in connection with geodetic surveys for values expressed in feet.

It is to be noted that although the *mass* of a body, often defined as the quantity of matter in a body, remains constant everywhere and under all conditions as long as no portion of the body is taken away and no matter added to it, its *weight,* being a force equal to the product of mass of the body by the acceleration of gravity, varies with the locality in which it is measured *(see* MECHANICS: *Newton's Laws).* Where a standard or normal value for the acceleration of gravity is wanted in weights and measures work the value used is 980.665 cm./sec.^{2} (or 32.1740 ft./sec.^{2}) as adopted in 1913 by the fifth General (international) Conference on Weights and Measures.

The international prototype kilogram is defined as a standard of mass, and the U.S. pound is therefore regarded in weights and measures work as a unit of mass. The word *weight* has often been used in the sense of *mass* and critical reading is often necessary to determine in what sense this word has been used. This remark also applies to the French word *poid.*

The British Imperial System.—The British system of weights and measures evolved from units having many origins, many of the units having been introduced into Britain at the time of the Roman conquest. Some rather old standards are still in existence, as, for example, the Winchester bushel of Henry VII and the standard hundredweight of Elizabeth I. These and other standards are deposited in the Jewel tower at Westminster, London. At the council chambers at Edinburgh and Linlithgow there are some interesting standards of Scotland, including the Stirling jug or Scots pint, 1618; the choppin or half pint, 1555; the Lanark troy and trone weights of the same period.

By the beginning of the 19th century the units of length and mass for Great Britain had been fixed more or less approximately at their present values. Two different gallons were, however, in use: the wine gallon of Queen Anne containing 231 cu.in., and the ale gallon of 282 cu.in. Both these gallons were abandoned by the British in 1824 when the present British gallon (277.42 cu.in.) was adopted. When the houses of parliament were burned on Oct. 16, 1834, the standard pound and the standard yard were destroyed. The scientific studies and investigations in weights and measures which followed, the construction of new standards, the passage of weights and measures acts and the establishment of scientific laboratories, first the standards department of the board of trade, established in 1870, and later the National Physical laboratory in 1900, brought about a unified system of weights and measures.

The basic units of the British imperial system are the yard, the pound and the gallon.

The British imperial yard is defined (Weights and Measures act, 1878) as the distance, at 62 00° F., between two fine lines engraved on gold studs sunk in a specified bronze bar known as "no. 1 standard yard." This bar was cast by Troughton and Simms in 1845.

The British imperial pound is defined as the mass ("the weight *in vacuo*") of a cylinder of pure platinum about 1.35 in. high and

1.15 in. diameter. This is the only pound legal for use in Great Britain and is sometimes called the avoirdupois pound, the troy pound having been abolished with other troy weights from Jan. 1, 1879, by the Weights and Measures act of 1878, with the exception only of the troy ounce, its decimal parts and multiples, legalized in 1853 by the act of 16 Vict. c29, to be used for the sale of gold and silver articles, platinum and precious stones.

The British imperial gallon is the volume of ten pounds avoirdupois of pure water as weighed in air against brass weights, the temperature of the air and the water being 62° F. and the barometric pressure 30 in. of mercury. This legal definition is incomplete; for instance it does not state the density of the brass weights, but in official comparisons this density is taken as 8.143 g. per cm.[3]

The multiples and submultiples of the British yard are similar to the corresponding units of the U.S. customary system. The British pound is subdivided into 16 oz., or 256 drams or 7,000 gr. Fourteen pounds equals one stone; two stones = one quarter (28 lb.); eight stones = one hundredweight = 112 lb.; and 20 cwt. = one ton = 2,240 Ib. In the apothecaries' weight system 20 gr. make one scruple; three scruples make one drachm; and eight drachms make an apothecaries' ounce, the grain being the same as in the avoirdupois system.

The British gallon, as defined above, is by calculation equivalent to 277.42 cu.in. It is used as a unit of capacity, both liquid and dry. The British gallon is divided into four quarts. or eight pints, or 32 gills or 160 fluid oz. (the U.S. gallon being divided into 128 fluid oz., the result is that the British fluid ounce is smaller than the U.S. fluid ounce, whereas the other British units of capacity are larger than the corresponding U.S. units). Two gallons make a peck, eight gallons make a bushel and eight bushels make a quarter. In the British apothecaries' liquid measure system the fluid ounce is divided into eight fluid drachms, or 24 fluid scruples or 480 minims.

The Metric System.—The metric system is the international decimal system of weights and measures based on the metre and the kilogram. The essentials of the system were embodied in a report made to the French national assembly by the Paris Academy of Sciences in 1791. The definitive action taken in 1791 was the outgrowth of recommendations made along similar lines in the last half of the 17th century and the early part of the 18th century. Gabriel Mouton, vicar of St. Paul's church, Lyons, in 1670 first proposed a comprehensive decimal system having as a basis the length of an arc of one minute of a great circle of the earth. Jean Picard in 1671 and others made suggestions along similar lines.

The metric system as it was first set up by its founders differs in some details from the system as it exists today. The original scheme of the metric system will first be described and then the later changes will be discussed.

The metre, the unit of length, was to be the one ten-millionth part of meridional quadrant of the earth. Geodetic measurements for this purpose were made on an arc from Dunkirk, Fr., to Mont-Jouy, near Barcelona, Sp. A platinum end standard, the metre of the archives, was constructed and adjusted to be one metre in length as given by the above definition and measurements. This was the standard metre for most of the 19th century.

The gram, the unit of mass, was to be equal to the mass of a cubic centimetre (1 cm. = 0.01 m.) of pure water at the temperature of its maximum density (4° C.). A platinum cylinder known as the kilogram of the archives was made and declared to be the standard for 1,000 g.

The litre was defined as the volume equivalent to the volume of a cube, each side of which had a length of one decimetre (1 dm. = 0.1 m.).

The are was defined as the measure of area for land equal to a square ten metres on a side.

The stere was defined as the measure of volume, especially for cordwood, equal to a metre cube.

Names for multiples of the several units were to be formed by using Greek prefixes, and the names of subdivisions were to be formed by adding Latin prefixes. These prefixes are:

Prefix	**Signification**
deca	10
hecto	100
kilo	1,000
mega	1,000,000
giga	1,000,000,000
tera	1,000,000,000,000
deci	0.1
centi	0.01
milli	0.001
micro	0.000001
nano	0.000000001
pico	0.000000000001

The spelling of the metric prefixes as well as of the basic units is not uniform in all countries. In England the French forms *metre, kilogramme* and *litre* are retained, whereas in the United States the spellings *meter, kilogram* and *liter* are commoner. In Italy *kilo* becomes *chilo* and other similar changes are made to conform to the orthography of that country.

It took many years for the metric system to be adopted as the obligatory system for use in France. Its progress in most other countries has also been slow, but its desirability as an international system was recognized by geodesists and others. As a result of their efforts an international treaty was signed on May 20, 1875, providing for an International Bureau of Weights and Measures, thus assuring "the international unification and improvement of the metric system." This international bureau was established in Shvres, Fr., a suburb of Paris, on land ceded by the French government and declared to be international territory. An international conference, of a diplomatic nature, with the designation General Conference on Weights and Measures, meets nominally every six years. Between the meetings of the conference the general supervision of the international bureau is in the hands of an international committee. The treaty specifies the details as to the membership of the committee and the conference and also prescribes for the maintenance of the international bureau by the signatory nations.

The first task of the International Bureau of Weights and Measures was the construction of new standards for the metre and the kilogram, including the necessary measurements. As standards were constructed for distribution to the nations supporting the bureau, in addition to the international standards to be kept at Sèvres, the task was a large one. Since then important researches have been undertaken there. The scope of the work at the international bureau has been considerably broadened so that researches are carried on in the fields of electricity and photometry in addition to its former work in weights and measures with which were included such allied fields as thermometry and barometry.

At the first general conference in 1889 the work of the international bureau in constructing and comparing the standards was approved, new definitions of the metre and the kilogram in terms of the new standards were adopted, and the distribution of the national standards to the governments supporting the work was authorized.

The metre was redefined in terms of the bar of platinum-iridium, known as the international prototype metre, at the international bureau. This is a line standard of length made with a cross section known as the Tresca section, selected because of its great rigidity for a given weight, and having microscopic lines engraved on the plane of its neutral axis. The composition of the alloy is 90% platinum, 10% iridium. The distance between the central one of the group of three lines at each end when the bar, being subjected to normal atmospheric pressure, is supported on two rollers at least one centimetre in diameter placed symmetrically 572 mm. apart, and the bar is at a temperature of 0° C., is defined as one metre. Although measurements were made which showed the length of the bar to be equal to that of the metre of the archives, the metre is now defined in terms of the international prototype metre without reference to the metre of the archives or to the length of the earth's quadrant.

It was shown by Albert Abraham Michelson that a standard of length could be replaced by reference to the measurement of wave lengths of light (see INTERFEROMETER: The Michelson Interferometer) and measurements made by him in 1892–93 and later by Charles Fabry and Alfred Perot made this procedure possible. In 1927 the seventh General (international) Conference on Weights and Measures adopted provisionally a supplementary relation between the metre and the wave length of light. This relation for red cadmium light waves under specified conditions of temperature, pressure and humidity is

1 m. = 1,553,164.13 wave lengths.

The accuracy of this value is usually stated as being about 1 part in 10,000,000. A redefinition of the metre as 1,650,763.73 times the wave length of the orange light of isotopic krypton of mass 86 at 760 mm. pressure and 15° C. was adopted at an international conference in Paris in 1960.

The kilogram is the mass of a definite platinum-iridium standard, the international prototype kilogram, kept at the International Bureau of Weights and Measures. The composition of this cylinder, which has a height approximately equal to its diameter, is the same as that of the prototype metre, namely, 90% platinum and 10% iridium. When the first kilogram was constructed it was not possible to measure the volume of a cubic decimetre of water to 1 part in 1,000,000. Because of this there is not the simple relation between the metre, the kilogram and the litre that was originally intended, and if the volume of a quantity of water is found precisely by measuring linear dimensions and by weighing the water, using the assumption that one cubic decimetre of water at the temperature of its maximum density weighs exactly one kilogram, the two results are not exactly the same. According to the most precise determinations the difference is 28 parts in 1,000,000. For this reason the litre is a secondary or derived unit defined as the volume of a kilogram of pure water at the temperature of its maximum density and under standard pressure, and is equal to 1.000028 dm.3 Formerly the value 1.000027 cu.dm. was accepted as the best value. For most purposes the differences between the millilitre and the cubic centimetre can be safely neglected. In the graduation and test of volumetric apparatus and in the preparation of density tables for liquids, the unit employed is the millilitre (designated by the abbreviation ml.), the one one-thousandth part of the litre, even though it may be—and often is—incorrectly designated as c.c. If a volume is derived from linear measurements and is expressed in cubic centimetres, the correct abbreviation is $cm.^3$. The metric system is either obligatory or permissive in every civilized country. In the U.S. its use was legalized by the act of July 28, 1866. In Great Britain the Weights and Measures (Metric System) act of 1897 legalized its use in trade, although its use had previously been permitted from 1864 to 1878. In 1946 the metre-kilogram-second system of mechanical and electric units (m.k.s.), originally proposed by G. Giorgi in 1904, was adopted by the International Committee on Weights and Measures (see PHYSICAL UNITS: The M.K.S. *or* Giorgi System of *Units*).

Other Systems of Weights and Measures.—The Spanish, French and Portuguese systems of weights and measures were each somewhat analogous to the British and U.S. systems although there were many differences between these five systems. The Spanish, French and Portuguese systems were brought to America by the colonists and they survive to some extent, often in modified forms of the original, even where replaced by the metric system (South and Central America and Mexico) or by the British system (Canada).

In Europe prior to the 19th century each country had its own system or systems of weights and measures, and, although most if not all of these systems have given way to the metric system, use of the old systems often persists, at least in nomenclature.

Weights and Measures in General.—Materials for Standards.—It has already been stated that the international and national prototype metres and kilograms were made from an alloy of 90% platinum and 10% iridium. This alloy was chosen because it was believed to be the least liable to be affected by time or circumstance. Experience seems to have substantiated the wisdom of this choice. It is very costly, and therefore cannot be afforded for laboratory or shop use. It can be highly polished and fine lines can be ruled on it. Its coefficient of expansion is moderately high (8.7×10^{-6} per degree C.). Other materials are used for length standards in industry and in scientific laboratories. See METROLOGY.

Invar, an alloy of about 36% nickel and 64% iron discovered by Charles Edouard Guillaume, is often used for length standards where a low coefficient of expansion (about 1.0×10^{-6} per degree C.) is desired. A length standard made of this material needs to be checked against a more stable standard from time to time because invar is dimensionally unstable, so that the length of an invar bar changes with time. Although some improvement was expected in the use of so-called "stable invar" in which the small amounts of chromium have been added, there is instability even in this form of invar.

Fused quartz has been found to be very suitable for reference end standards of length. This material has a low coefficient of expansion (about 0.4×10^{-6} per degree C.), takes a high polish, and is very stable dimensionally.

The objection to platinum-iridium for use as a standard of mass, except as a primary standard where unusual precautions are always taken, is that because of its high density (21.57 g. per cm.3) the slightest abrasion will change its mass appreciably.

Brass weights, either lacquered or gold-plated are generally employed for the common sizes of commercial and laboratory weights. They frequently gain in weight for years without any visible alteration, and lacquered weights are liable to vary considerably with large variations in humidity (for example, by 0.2 mg. per 100 g.), Small weights are frequently made of platinum or aluminum.

Detailed information about materials for standards of weights and measures can be obtained from the national bureau of standards in the U.S. and other national standardizing institutions.

Effects of Temperature, Pressure and Gravity.—Because the dimensions of any standard change with temperature, it is necessary to state the temperature at which standards of length, area, volume, or capacity are to be used; if used at any other than standard temperature, then the coefficient of expansion must be stated. The standard temperatures most often used are: 0° C. (=32° F.), the standard temperature for the prototypes of the metric system, also used for some secondary metric standards and for some measurements; 20° C. (=68° F.), the internationally adopted standard temperature for gauges and the standard temperature which is being increasingly used for weights and measures work; 16.67" C. (=62° F.), the official temperature used in connection with the British imperial system; 4° C. (=39.20° F.), the temperature of maximum density of water, used in density and volumetric work in which water is directly or indirectly involved; 25" C. (=77" F.), a standard temperature used in some work in physical chemistry; and 15.56° C. (=60° F.), the standard temperature used in the petroleum industry for density and volume work.

If the expansion of the standard used in any measurements, a gauge for example, is the same as that of the piece being measured, it is only required that the standard and the object are both at the same temperature, not necessarily the standard temperature, the length of the gauge being known at the standard temperature.

Although the temperature of 62° F. used in the definition of the British units is numerically that used earlier, as for example, in 1845 in the construction of the imperial standards when Sheepshank's Fahrenheit thermometers were used, it is difficult to state how the true temperature then of 62" F. would compare with 62" F. of the present standard thermometric scale.

Changes in atmospheric pressure have very little effect on length standards, a change in pressure from 710 to 790 mm. causing a change in length of about 0.00005 mm. in the case of the prototype metre. Changes in atmospheric pressure are usually disregarded in measurements of length. Any changes in air pressure, as well as changes in the temperature and humidity of the air, are, however, of importance in any comparison of masses because these are factors affecting the buoyant effect of the air. Any definitions of weights that involve comparisons of the weights of bodies having different densities are incomplete unless the atmospheric conditions are specified together with the densities of the materials employed. In the United States most commercial weights are verified on the basis of apparent mass in air against brass standards of density 8.4 g./cm.^{3} at 0° C., no correction being made for the buoyant effect of the air, the values for the brass standards being their. true mass or weight in *vacuo*.

When weighing on an equal arm balance, if the body being weighed does not have the same density as the weights, a correction must be made.

The standard air pressure usually used in weights and measures work is 760 mm. mercury, at 20° C., mercury having a specified density of 13.5951 g. per cm.3, with gravity 980.665 cm./sec^2.

The effect of the force of gravity must be considered in precision length measurements because of the downward force acting on the standard and the resulting possible distortion of the standard. The length of the prototype metre bar would be slightly different if the supports were changed from the specified positions; this is because of the change in the deflections of the bar under the action of gravity. This difference has been made as small as possible first by the choice of the position for the two supports, and in the second place by the placing of the graduation lines in the plane of the neutral axis. If the graduation lines had been placed on the top of a rectangular bar, relatively large changes in length would be caused by a displacement of one or of both the supports.

Since a spring balance indicates weight and not mass, a constant mass suspended from a spring balance will produce different readings when measurements are made in a series of places having sufficient changes in the force of gravity, the indicated weights varying directly with the force of gravity, other conditions being equal. An equal arm balance likewise really compares weights rather than masses, but on the assumption that the two pans of the balance are acted upon by the same force of gravity, the result is an indirect comparison of masses. If other conditions remained constant. a balance would, on the same assumption, everywhere give the same balance between the same two bodies, no matter how the force of gravity varied from place to place.

Administration.—In the U.S., control of commercial weights and measures work, with the exception of a few special cases, is the function of state and local authorities. The organization of state and local work in weights and measures is not uniform in the several states. For information see National Bureau of Standards Handbook H26, Weights and Measures Administration.

In Great Britain the control of weights and measures is partly national and partly local. The Board of Trade regulates the denominations of weights and measures permissible for use, approves types of weighing and measuring devices as not being liable to facilitate fraud, and promulgates regulations for the guidance of the local inspectors of weights and measures. Local verification and inspection of weighing and measuring appliances in use in trade is undertaken by inspectors appointed by the local authorities, such as the county and county boroughs councils. An inspector is required to hold a certificate of qualification issued after examination by the Board of Trade and, to promote uniformity throughout the country, to follow the regulations prescribing the methods for testing weights, measures and weighing and measuring instruments. In most of the other important countries of the world, weights and measures control is either wholly government controlled or shared between central, state and local government in varying degrees.

Equivalents.—In the United States the following equivalents between the metric units and the customary units underlie all others:

1 yd. = 0.9144 m. (exactly)	1 m. = 1.093613 yd.
1 lb. = 0.45359237 kg. (exactly)	1 kg. = 2.204623 lb.
1 gal. = 3.785306 1.	1 1. = 0.264178 gal.
1 bu. = 35.2381 1.	1 1. = 0.028378 bu.

Detailed tables of equivalents are contained in national bureau of standards miscellaneous publication M233, Units of Weights *and Measures—Definitions* and Tables *of Equivalents*.

In Great Britain the equivalents corresponding to the above are:

1 yd. = 0.9144 m. (exactly)	1 m. = 1.093613 yd.
1 lb. = 0.45359237 kg. (exactly)	1 kg. = 2.204623 lb.
1 gal. = 4.5459631 1.	1 1. = 0.2200 gal.
1 bu. = 36.37 1,	1 1. = 0.02750 bu.

From these two sets of equivalents it will be seen that

1 U.S. yd. = 1 British yd.
1 U.S. lb. = 1 British lb.
1 U.S. gal. = 0.83267 British gal.
1 U.S. bu. = 0.9689 British bu.

or

1 British yd. = 1 U.S. yd.
1 British lb. = 1. U.S. lb.
1 British gal. = 1.20095 U.S. gal.
1 British bu. = 1.0321 U.S. bu.

However, when the National Physical laboratory, the national standards laboratory for Great Britain. adopted the above relations between the yard and the metre and between the pound and the kilogram, effective July 1, 1959, the British Board of Trade decided to retain the older equivalents for use in trade pending legislative action. These are: 1 British yd. = 0.914399 m.; 1 British lb. = 0.45359243 kg. The difierences are of legal implication but are not of practical importance in commerce.

Some selected equivalents between the units of other countries and the units of the U.S. system or the units of the metric system are given in a table appended to this article. The number of units of weights and measures used in modern times—as distinguished from ancient times—is very large, and the selection of the units to be included in a table is difficult. The purpose of such a table is taken to be that of giving the average reader some information about units with which he is not familiar, including the approximate size of units. For exact values one must necessarily resort to a source of more detailed information where exact values are given showing what changes have been made from time to time and how the values vary from place to place. Many of the units listed in the table are known to differ in these two ways, and the value shown is simply a representative one. A number of the units having simple relationships with the units of the metric system originally had values somewhat different.

Table of Selected Weights and *Measures*, Their Places of Use and Their Equivalents in *U.S. Customary* or in *Metric* Units

Acre	United States Great Britain	4,840 square yards = $\frac{1}{640}$ sq. mi.
Almude.	Portugal	16.7 litres.
	Spain.	4.625 litres = $\frac{1}{12}$ fanega (dry measure).
Ångström Unit (Spectroscopy)		10^{-10} metre = $\frac{1}{10,000}$ micron.
Anker	Latvia	38.256 litres, or 30 stoof.
Anoman (Ammomam, Amomam)	Ceylon	5.83 U.S. bushels.
Archin, or Arshin.	Turkey	1 new archin (Law 1881) = 1 metre (39.37 inches) = 10 parmaks (decimetres) = 100 khats (centimetres), 1 mill = 1,000 archins (kilometre). Pharoagh = 10 mills. hnothkr pharoagh = 2 hours' journey.
Archine, or chinne	U.S.S.R. (Estonia	28 inches, or 0.7112 metre.
Ardeb	Egypt	5.619 bushels (Customs).
Are		= 100 sq. metres = 119 6 sq.yds.
Arpent	France Canada	Legal arpent was equal to 100 sq. perches = 51 07 metric ares. In Quebec = 180 French feet.
hrroba	Portugal	14 68 to 15 kilograms.
	Spain	Wine = 16.14 litres; oil = 12.56 litres.
Artaba	Iran	66.0 litres.
Assay ton	United States	29 167 grams.
Aune	Belgium	1 metre. Formerly 1.2 metres.
	France	1.188 metres.
	Jersey	4 feet.
Barile	Rome	58.34 litres.
Bat, Baht, or Tical	Thailand	15 grams (= 231.5 grains).
Batman.	Iran	6½ lb. av.: varies locally.
	Turkestan.	125 kg. (variable).
Behar or Bahar	Arabia	450 lb. av.
Berri	Turkey	1.67 kilometres (1.04 miles) (old measure).
Boisseau	Belgium	15 litres.
Boutylka	U.S.S.R.	1.625 liquid pints (wine bottle).
Braça	Portugal	2.20 metres.

Braccio d'ara	Rome	0.7 metre.
Brasse	France	1.62 metres.
Braza	Argentina	1.732 metres.
Bu, or tsubo.	Japan	$\frac{100}{,0}$,, – 3.306 square metres (area). Also = $\frac{1}{100}$ shaku (length).
Bunder.	Netherlands	1 hectare.
Bushel	United States	2,150.42 cubic inches.
	Great Britain	1.032 U.S. bushels.
Cabot	Jersey	10 pots, or 19.75 litres.
Candy	Bombay	560 lb. av.
	Madras	500 lb. av.
Cantar or Kantar	Turkey	124.45 lb. av. (old weight).
Cantara	Spain	1 arroba.
Capicha.	Iran	2.63 litres.
Carat, metric		200 milligrams.
Catty	China	$1\frac{1}{3}$ lb. av. See Tael.
	Malaya	$1\frac{1}{3}$ lb. av.
	Thailand	2.67 lb. av.
Cawnie	Madras	1.322 acre.
Centigram		$=\frac{1}{100}$ gram.
Centilitre		$=\frac{1}{100}$ litre.
Centimetre		$=\frac{1}{100}$ metre.
Centimetre, cubic		0.061 cubic inch.
Centimetre, square		0.155 square inch.
Centner.	Austria	
	Denmark	50 kilograms.
	Switzerland	
Chain	Great Britain	66 feet.
Chain (Gunter's).	United States	66 feet.
Chang	China	10 ch'ih = 11 ft. 9 inches (*Treaty).
	Thailand	1,200 grams.
Chapah	N. Borneo.	1.8 lb. av.
Charka	U.S.S.R.	0.123 litre.
Chee. See *Tahil.*		
Chek	Hong Kong	14%inches.
Chenica.	Iran	1.359 litres.
Chetvert	U.S.S.R.	8 chetveriks, or 2.099 hectolitres.
Ch'ien	China	589 grains (silver weight).
Ch'ih	China	Varies throughout China from 11 to 15.8 inches. For Customs purposes the *Treaty ch'ih = 14.1 inches, and 5 ch'ih = 1 pu.
Chin or Catty	China	$1\frac{1}{3}$ lb. av. (*Treaty).
Ching	China	121 sq.ft. (*Treaty).
Ch'ing	China	72,600 sq.ft. (*Treaty).
Chittack	Bengal	5 tolas, or 900 grains.
Chô	Japan	As unit length = 360 shaku.
		As unit area = 3,000 bu. or tsubo.
Chuo	China	1,815 sq.ft. (*Treaty).
Chupah.	Singapore	3.125 lb. av. of water at 62° F., as a measure of capacity.
	Malacca	36 oz. av. of water.
Chupak.	Malaya	1 quart (British imperial).
Collothun	Iran	8.22 litres.
Cord (firewood)	United States	128 cubic feet.
Coss	India	1.829 kilometres.
Covado	Portugal	0.66 metre.
Covid, or Cubit	Madras	18 to 21 inches.
	Bombay	18 inches.
Covido	Arabia	19 inches.
Cuartillo	Spain	1.16 litre (dry); 0.504 litre (liquid).
Daktylos	Greece	25.39 millimetres.
Daribah	Egypt	15.84 hectolitres.
Decagram or dekagram		= 10 grams.
Decalitre or dekalitre		= 10 litres.
Decametre or dekametre.		= 10 metres.
Déçïatina	U.S.S.R.	= 2,400 square sagènes = 2.7 acres.
Decigram		=,dgram.
Decilitre		$=\frac{1}{10}$ litre.
Decimetre		$=\frac{1}{10}$ metre.
Decimetre, cubic		= 61.023 cu.in.
Decimetre, square		= 13.500 sq.in.
Denaro	Italy	1 gram.
Denaro	Rome	18.17 grains (old weight).
Deunam	Turkey	25 ares.
Diraa or Pik.	Egypt	0.58 metre.
	Turkey	0.7087 metre.
Dirhem	Egypt	1.761 dram av. (Customs).
		3.12 grams (Cairo).
Dito	Italy	1 centimetre.
Djerib	Turkey	1 hectare.
Dolïa, or Dola	U.S.S.R.	0.686 grain. 96 doli = 1 zolotnick.
Drachm	Great Britain	3 scruples (apothecaries' weight).
Drachm, fluid	Great Britain	0.961 U.S. fluid dram.
Drachma	Netherlands	3.906 grams (apothecaries' weight).
	Turkey	3.21 grams.
Drachma	Greece	3.2 grams.
Dram	Great Britain	$\frac{1}{16}$ avoirdupois ounce.
Dram	Iran	1 gram.
Dram, apothecaries'	United States	60 grains.
Dram, avoirdupois	United States	$27\frac{11}{32}$ grains.
Dram, fluid	United States	$\frac{1}{8}$ fluid ounce.
Ducat	Vienna	53.873 grains (gold weight).
Duim	hTetherlands	1 centimetre.
	U.S.S.R.	1 inch.
Eimer	Germany	29 to 307 litres.
El	Netherlands	1 metre. (Old el = 27.08 inches.)
Ell	Jersey	4 feet.
Ella	N. Borneo.	1 yard.
Elle	Latvia	0.537 metre.
	Switzerland	60 centimetres.
Estadio	Portugal (old)	258 metres.
Faden	Latvia	4.077 steres.
Faltche	Moldavia	143.22 ares.
Fanega	Argentina	137 litres.
	Portugal	55.364 litres.
	Spain	55.30 litres.
	Peru	55.50 litres.
		1.615 acre. but varies locallv.
Fass	Germany	1 hectolitr'e.
Fathom	United States	6 feet.
	Great Britain	
Feddan	Egypt	1.038 acre (Masri).
Fen	China	5.83 grains (silver weight).
Fjerding	Denmark	0.988 bushel.
Fod	Denmark	0.3138 metre = 1.0297 feet.
Foglietta	Rome	0.513 litre.
Foot	United States	$\frac{1}{3}$ yard.
	Great Britain	
	Canada	French foot = 12.8 inches.
	Amsterdam	11.147 in.)
	South Africa	12.356 in. old measure.
	Old Rhenish	
Fot.	Sweden	11.689 in. 10 fot = 1 stöng. 1 ref = 10 stänger. 1 mil = 360 ref.
	Norway	0.3137 metre.
Founte, or Funt	U.S.S.R.	0.90282 lb. av.
Foute, or Fut	U.S.S.R.	1 English foot.
Frasco	Argentina	$2\frac{3}{8}$ litres.
Funt	Poland	405.504 grams.
Furlong	United States	220 yards.
	Great Britain	
Fusz	Vienna	12 zolls = 1.037 feet.
	Switzerland	$3\frac{1}{3}$ fusz = 1 metre.
		See *Stab.*
Gallon	United States	231 cubic inches.
	Great Britain	1.201 U.S. gallon, or 0.129 U.S. bushel.
Gantang	Malaya	1 British imperial gallon.
	N. Borneo.	144 oz. av. weight of water as measure of capacity.
Garnetz.	U.S.S.R.	3.28 litres.
Gill	United States	$\frac{1}{4}$ pint.
	Great Britain	$\frac{1}{4}$ British pint.
Gin. See *Kati.*		
Gisla	Zanzibar	hfeasure of 360 lb. av. of rice.
Go	Japan	0.18 litre.
Grain	United States	$\frac{1}{7,000}$ avoirdupois pound = 0.065 gram.
	Great Britain	
	U.S.S.R.	0.960 grain (apothecaries').
Gram		15.432 grains.
		= 0.03215 oz. troy.
Grano	Rome	0.757 grain.
Grao	Portugal	0.769 grain; also measure 0.18 in.
Grein	Netherlands	= 0.065 gram.
Guz, or Gudge	India: Bengal	36 inches.
	" Bombay	27 inches.
	" Madras	33 inches.
	Iran	The guz, gueza or zer varies from 24 to 44 inches. A guz of 40.95 inches is common. By the law of 1925 the guz was made equal to the metre.
	Arabia	25 inches.
Hat'h, .or Moolum, or Cubit	India	18 inches.
Hectare.		= 100 ares, or 2.471 acres.
Hectolitre		26.418 gallons.

Hiyaka-me	Japan	5,797.198 grains.
Hiyak-kin	Japan	$132\frac{1}{2}$ lb. av.
Hoon. See *Tahil.*		
Hu.	China	51.77 litres.
Hulmit	Latvia	11.48 litres.
Hundredweight	Great Britain	112 lb.
Hundredweight, gross or long	United States	112 lb.
Hundredweight, net or short	United States	100 lb.
Immi	Switzerland	1.5 litre.
Inch	United States	$\frac{1}{36}$ yd.
	Great Britain	
Joch	Austria-Hungary	57.55 ares= 1.422 acre.
Kan	Ketherlands	1 litre.
	Hong Kong	$1\frac{1}{3}$ lb. av.
Kanne or Kanna.	Germany	1 litre, or formerly 1.06 liq. qt., or 0.91 dry qt.
	Sweden	2.62 litres.
Kantar; or Cantaro	Egypt	99.0492 lb. av.=100 rotls (Customs). 45 kilograms of cdtton. 44.5 kilograms other produce.
Karwar.	Iran.	100 batman.
Kassabah	Egypt	3.8824 yards (Customs).
Kati, Catty or Gin	Malaya	$1\frac{1}{3}$ lb. av.
Keddah.	Egypt	2.0625 litres.
Ken	Japan	1.82 metres=5.965 ft.
	Thailand	40 inches.
Kerbt	Turkey	$1\frac{1}{8}$ inch measure (old). 3.09 grains weight (old).
Kette, or Chain	Germany	10 metres.
Khat (New)	Turkey	1 centimetre.
Kileh	Turkey	1 bushel approx. (varies).
Kilogram		=1,000 grams=2.205 lb.
Kilometre		=1,000 metres=0.621 mile.
Kin	China	See Catty.
	Japan	0.600 kilogram= 1.323 lb.
Klafter	Austria	=2.0740 yards.
	Switzerland	1.9685 yard.
Koddi	Arabia	7.58 litres.
Koilon	Greece	33.17 litres.
Koku	Japan	180.39 litres=10 To.
Kon or Catty	Korea	$1\frac{1}{3}$ lb. av.
Korntonde	Norway	138.97 litres.
Korn-Topmaal	Norway	160 litres.
Korrel	Netherlands	0.1 gram.
Kouza	Cyprus	9 British imperial quarts.
Koyan	Malaya	$5,333\frac{1}{3}$ lb. av.
Krina	Bulgaria	20 litres.
Kung	China	78.96 inches (*Treaty).
Kup	Thailand	10 inches.
Kwan or Kuwan	Japan	3.75 kg.=8.267 lb. av.
Kwarta	Poland	1 litre.
Kyat	Burma	16.33 grams.
Last	Netherlands	30 hectolitres.
Latro	Czechoslovakia	1.917 metres.
League (land)	United States	3 statute miles.
Li	China	About $\frac{1}{3}$ mile=360 pu. Varies with length of ch'ih. 1 decigram.
Liang or Léang	China	1) oz. 16 liang=1 chin=$1\frac{1}{3}$ lb. avoirdupois.
Libbra	Italy	1 kilogram; 327 grams (old).
Libra	Argentina	1.0128 lb. av.
Libra (Castilian)	Spain, Mexico	1.0143 lb.
Libra, or Arratel	Portugal	1.012 lb. av.
Light Year (astronomy)		9.4627 × 10^{12} kilometres.
Line or Ligne	Paris	2.26 millimetres.
Liniya	U.S.S.R.	0.1 inch. 1 archine=280 liniyas.
Link, Gunter's or surveyors'.	United States	7.92 inches.
	Great Britain	
Litre		'0.908 dry quart, or 1.057 liquid quart.
Livre	Belgium	1 kilogram.
	France	0.4895 kilogram.
Loket	Czechoslovakia	0.593 metre (Prague); 0.594 metre (Moravia); 0.579 metre (Silesia).
Lot	Germany	New Lot=10 grams. Old lot, nearly $\frac{1}{2}$ oz. av.
	Switzerland	15.625 grams.
	Vienna	270.1 grains. Postal Lot 257.2 grains.
Maass	Germany	1.837 litres.
Maass	Switzerland	1.5 litres.
Maatze	Netherlands	0.1 litre.

Mace	China	58) grains.
	N. Borneo	$93\frac{1}{3}$ grains.
Mahud	Arabia	2.04 lb. av.
Marc, or Mark	France	0.2448 kilogram (old weight).
	Sweden	6.77 oz. troy.
	Vienna	9.02 oz. trov.
Marco	Portugal	=8 oncas=229.5 grams.
	Spain,	3,550 grains.
Maund	India	82.286 lb. av., Government. 28 Ib., Bombay. 25 lb.. Madras. Local maunds vary.
Metre		39.37 inches.
Metre, cubic		1.308 cubic yards.
Metre, square		1.196 square yards.
Metze	Austria	61.5 litres.
Microgram (y)		$\frac{1}{1,000,000}$ gram.
Micron (μ)		$\frac{1}{1\,000\,000}$ metre=$\frac{1}{1,000}$ mm.= 0 00004 inch.
Miglio	Rome	0.925 mile.
Mijle	Netherlands	1 kilometre.
Mil	United States	0.001 inch.
	Great Britain	
Mil, or Mill	Turkey	1,000 archins (new mil).
	Denmark	4.680 miles.
Mile, statute	United States	5,280 feet.
	Great Britain	
Mile, nautical	United States	6,080.20 feet (formerly).
Mile, nautical ("Admiralty").	Great Britain	6,080 feet.
Mile, nautical, International		1,852 metres.
Mile, square.	United States	640 acres.
	Great Britain	
Mile (postal)	Austria	4.714 miles.

Palm	Netherlands	1 decimetre.
Palmo	Portugal	0.22 metre.
	Spain.	0.229 metre.
Para	N. Borneo.	90 Ib. av.
Parah	Ceylon	25.4 litres.
Parasang. See *Persakh.*		

Parmak. See *Archin.*		
Parsec (astronomy)		3.084 X 10^{13} km.
Passeree	Bengal	5 seers.
PC	Portugal	$\frac{1}{3}$ metre.
Pecheus.	Greece	0.648 metre.
Peck	United States	8 dry quarts.
	Great Britain	8 British quarts = 1.032 U.S. pecks.
Pennyweight	United States	24 grains.
	Great Britain	
Perch	United States	1 rod.
	Great Britain	$30\frac{1}{4}$ sq. yd.
Perche	France	22 square pieds de roi. In Quebec 18 French feet.
	Canada	
Persakh	Iran	Probably 3.88 miles = 6,000 guz.
Pfund	Germany	= 16 unzen = 32 Lot; 1.01 to 1.23 lb. av. old weight.
		Zollpfund (1872) = 500 grams.
	Latvia	419 grams.
	Switzerland	500 grams = 16 unze.
		Apoth. pf. = 375 grams.
	Vienna	Pfund = 560 grams.
		Zollpfund (1871) = 500 grams
Pharoagh. See *Archin.*		
Pic or Pik	Cyprus	2 feet.
Picki, Pik or Pic	Greece	0.64 to 0.67 metre.
Picul	Japan	132.3 lb. av.
	Malaya, Hong Kong	$133\frac{1}{3}$ lb. av.
	North Borneo	A measure of 180 lb. weight of water.
Pie	Rome	11.73 inches.
	Spain	10.97 inches.
Pied	Belgium	11.81 inches = 10 pouces.
	Canada	12.79 inches.
Pied de Roi	Paris	0.3248 metre.
Pik. See *Diraa.*		
Pint	Great Britain	1.032 U.S. dry pints, or 1.201 U.S. liquid pints.
Pint, dry	United States	$\frac{1}{64}$ bushel.
Pint, liquid	United States	$\frac{1}{8}$ gallon.
Pinte	France	0.931 litre.
Pipa	Portugal	500 litres; 429 litres (old value).
Poide de Marc	France	0.2448 kg. = 8 ounces.
Point (typography)	United States	0.013837 inch, about $\frac{1}{72}$ inch.
Pole. See Rod.		
Polegada	Portugal	27.77 millimetres.
Pond	Netherlands	1 kilogram.
Pot.	Denmark	0.966 litre.
	Switzerland	1.5 litre.
	Belgium	$1\frac{1}{2}$ litre (dry). $\frac{1}{2}$ litre (liquid).
	Norway	0.965 litre.
Pouce	France	27.07 mm. = 1.066 inch (old measure).
Poud, or Pood	U.S.S.R.	36.113 lb.
Pound	Great Britain	1 U.S. avoirdupois pound.
Pound, apothecaries'[3]	United States	5,760 grains.
Pound, avoirdupois	United States	7,000 grains = 0.454 kilograms.
Pound, troy	United States	5,760 grains.
Pu	China	70.5 inches = 5 ch'ih.
Puddee	Madras	1.64 litres. 100 cubic inches = Government puddee.
Pulgada.	Spain.	0.914 inch.
Pund	Denmark	500 grams.
	Norway	500 grams.
		0.4981 kilogram (old value).
	Sweden	425.1 grams.
Quart	Great Britain	$\frac{1}{4}$ gallon = 1.032 U.S. dry quarts = 1.201 U.S. liquid quarts.
Quart, dry	United States	$\frac{1}{32}$ bushel.
Quart, liquid	United States	$\frac{1}{4}$ gallon.
Quarter.	Great Britain	28 lb.; 8 bu. = 8.257 U.S. bu.
Quarto	Rome.	73.6 litres.
	Portugal	3.46 litres.
Quintal	Spain.	100 libras (Castilian) = 101.4 lb.
	Portugal	58.752 kilograms. $129\frac{1}{2}$ lb. av.
	Argentina	100 libras, or 101.28 lb. av.
Quintal (metric)		= 100 kilograms = 220.46 lb.
Ralte	Iran	1 litre.
Ratel	Iran	1.014 lb. av.
Rattel, or Rottle	Arabia	1.02 lb. av.
Ri	Japan	2.440 miles.
Rod	United States	$16\frac{1}{2}$ feet.
	Great Britain	
Rode	Denmark	3.138 metres.
Roede	Netherlands	1 dekametre.

Rood	Great Britain	40 perches = $\frac{1}{4}$ acre.
Rotl, Rottolo or Ratel	Egypt	0.9905 lb. av. (Customs).
Rottol	Turkey	1.6 litres (old measure).
Sagène	U.S.S.R.	7 feet.
Scheffel	Germany	50 litres, formerly 16 metzen (Prussia).
Schepel	Netherlands	1 decalitre.
Schoppen	Germany	$\frac{1}{2}$ litre.
	Switzerland	0.375 litre.
Scruple	United States	20 grains.
	Great Britain	
Scruple, fluid	Great Britain	0.320 U.S. fluid dram.
Se	Japan	118.615 square yards (.9918 are).
Seer	India	Government seer = 2.057 lb. av.
		Bengal, 80 tolas weight of rice (heaped measure), about 60 cubic inches (struck measure).
		Madras, 0.617 lb. av.
		Bombay, 0.72 lb. av.
	Ceylon	1.06 litres.
	Iran	16 miscals, or 1,136 grains weight (Sihr).
	Note.—In India the seer, like the maund, varies considerably; usually 40 seers go to a maund.	
Seidel	Austria	0.354 litre.
Sen.	Thailand	40.6 metres.
Ser, Seer	India	1 litre.
Shaku	Japan	$\frac{10}{33}$ m., also 9.18273 square decimetres; also 18.039 cubic centimetres ($\frac{1}{100}$ shô).
Sheng	China	1.035 litre.
Shih	China	157.89 lb.
Shô	Japan	1.804 litre.
Skaal-pund	Sweden	425.1 grams, or 0.937 lb. av.
	Norway	0.4981 kilogram, or officially $\frac{1}{2}$ kilogram.
Skeppe	Denmark	17.39 litres.
Skjeppe.	Norway	17.37 litres.
Stab	Germany	1 metre, or 38 old fuss. but varied.
Stere		= 1 cubic metre.
Stone	Great Britain	14 pounds.
Stopa	Poland	0.288 metre.
Streep	Netherlands	1 millimetre.
Stremma	Greece	12.70 ares.
Strich	Germany	1 millimetre.
	Switzerland	$3\frac{1}{3}$ strich = 1 millimetre.
Stunde	Switzerland	4.8 kilometres.
Sultchek	Turkey	Cubic measure (1881) whose sides equal a parmak (decimetre).
Tael	Thailand	$936\frac{1}{4}$ grains.
	Hong Kong	$1\frac{1}{3}$ oz. av.
	China	Silver weight, 18 oz. av.
	Japan	10 momme.
Tahil	Malaya	$1\frac{1}{3}$ oz. av. = 10 chee = 100 hoon.
Tan	China	$133\frac{1}{3}$ lb. av., 25 gallons.
Tank	Bombay	68.1 grains (72 tanks = 1 seer).
Teng	Burma	Burmese measures of capacity depend on the teng or basket. Officially a basket is 2,218.2 cubic inches, but the teng varies locally:—
		Akyab = 23 lb. of rice.
		Bassein = 51 lb. of rice.
		Moulmein = 48 lb. of rice.
		Rangoon = 48 to 50 lb. of rice.
Thanan or Fanan	Thailand	1 litre.
Thangsat	Thailand	21.3 litres.
To	Japan	18.0391 litres = 4.77 U.S. gal. or 1.98 pecks.
Toise	France	1.949 metres.
Tola	India	180 grains. Legal weight of rupee.
Tomand	Arabia	187.17 lb. av. of rice.
Ton	Great Britain	2,240 lb.
Ton, long	United States	2,240 pounds.
Ton, metric		= 1,000 kilograms = 1.102 U.S. short tons.
Ton, short	United States	2,000 pounds.
Tonde	Denmark	131.4 litres (liquid measure).
		139.1 litres (dry measure).
Tonnelada	Portugal	793.15 kilograms.
Tonos	Greece	3,307 lb. av.
Tou	China	10 litres.
Tovar	Bulgaria	128.2 kilograms.
Township	United States	36 square miles.
T'sun	China	1.41 inch (*Treaty).
Tu	China	100.142 miles = 25 li.

Vara	Mexico	83.8 cm. (32.99 inches).
	Chile, Peru, Spain, etc.	83.59 cm. (32.91 inches).
	Argentina	86.6 cm. (34.09 inches).
	Portugal	1.1 metre (43.31 inches).
	Texas (u.s.A.).	33 33 inches (84.67 cm.).
Vat	Netherlands	1 hectolitre. 768 mingelen (old value). 1 mingelen = 1.20 to 1.237 litres.
Vedro	U.S.S.R.	10 schtoffs, or 12.3 litres.
	Bulgaria	12.8 litres.
Verchok	U.S.S.R.	1.75 inch.
Versta, or Verst	U.S.S.R.	0.66288 mile.
Vierkante Roede	Netherlands	1 are.
Viertel	Denmark	7.73 litres.
	Switzerland	15 litres.
Viss	Burma	3.60 lb. av. (3.65 lb. av. old value).
Wa or Wah	Thailand	2 metres.
Wichtje.	Netherlands	1 gram.
Wisse	Netherlands	1 stere.
Yard	United States	0.9144 metre.
	Great Britain	1 U.S. yard (almost exactly).
	Mexico	83.8 centimetres.
Zak	Netherlands	1 hectolitre.
Zar (metric)	Iran	1 metre.
Zer (Iran). See *Guz*		
Zoll	Switzerland	3 centimetres. Old zoll nearly one inch. (See also *Pfund*.)
Zolotnik	U.S.S.R.	65.8306 grains, or 96 doli.

*Values agreed on by China in treaties (1842–44 and 1858–60) with England and France and thereafter accepted by the Chinese maritime customs as standard values for all tariff duties, but not in general otherwise used.

(L. V. J.)

WEIGHTS AND MEASURES, ANCIENT.

WEIGHTS AND MEASURES, ANCIENT. The history of weights has been greatly extended by: (1) the discrimination of the ages of Egyptian weights by their forms; (2) the study of 3,400 weights and many capacity measures from Egypt; (3) the finding of the names and marks of four standards in Palestine which confirms their independent position; and (4) increased knowledge of prehistoric weights.

Such material supersedes most of the fragmentary and vague statements of ancient authors upon which we were formerly dependent.

The English standards of inches and grains are the most familiar and are here placed on the left side of the column; the equivalents in millimetres and grams are inset on the right side. Only the values actually found are here described without any theoretical amounts or assumed connections.

There is nothing easier than to frame systems of plausible relations between measures, but the exact amounts and the historic probability of descent must be ascertained before such theories can be valued.

LINEAL MEASURES. The units derived from 20.62 inches.

This standard of the cubit was used in Egypt

inches from the time of the predynastic royal tombs. mm.

20.62 The first accurate example yet published is in **524**

the size of the pyramid of Snefru (3rd dynasty) at 20.66, but still more exactly 20.62 in the pyramid of Khufu. The pure system of it was

n	100 = meh cubit	100 = khet
.206	20.62	2062 inches

But it was mixed with other systems as

zebo digit	4 = shep palm	7 = meh cubit	100 = khet reel	120 = ater or skhoinos
.737	2 947	20 62	2062	3.9 miles

This was termed the "royal cubit" throughout history. The Babylonian 20.89 of Gudea may be another form and probably the origin of this. It appears in Asia Minor as 20.55 to 20.94; in tombs at Jerusalem as 20.57; and in six English stone circles as 20.55. The eastern system was

uban	5 = qat	6 = ammat	6 = qanu	60 = sos	30 = parasang	2 = kaspu
.695	3.475	20.85	125.1	7506	225,180	450,360

The same cubit of 20.68 appears in stone buildings of New Mexico.

12.45 This foot is $\frac{3}{5}$ of the cubit of 20.75. It is found in Athens as 12.44; Aigina 12.40; Miletos **316**

12.51; Olympia 12.62; Etruria 12.45; and medieval England 12.47. The system was

foot	10 = akaina	10 = plethron	6 = stadion
12.45	124.5	1245	7470

From the foot was formed a cubit of 18.7 **474**

foot	$1\frac{1}{2}$ = cubit	4 = orguia	100 = stadion
12.45	18.7	74.7	7470

13.8 Another foot was formed of $\frac{2}{3}$ of the cubit adopted by Philetairos of Pergamon as a **350**

standard.

17.72 This was the short cubit of Egypt; actually found as a measuring rod and having 6 palms **450**

it was directly connected as $\frac{6}{7}$ of the 20.67 cubit. As 17.6 it is recognized as the early Jewish cubit.

The digit and derived measures.

inches This digit mas $\frac{1}{40}$ of the diagonal of the 20.62 mm.

.729 cubit. The diagonal of the cubit, 40 digits, is **18.51**

found as a wand of the middle prehistoric age, 29.1 long. Another multiple was the half of this, 20 digits, called the remen, used as a basis of land measure. By having two systems, one the diagonal of the other, it was possible to denote one square half the area of another.

digit	100 = orguia	10 = amma	10 = stadion: itinerary
.729	72.9	729	7290

inches mm.

18.23 25 digits = Greek cubit of 18.23 **463**

12.15 $\frac{2}{3}$ of 18.23 is the Greek foot of 12.15 from which was a decimal system. **309**

foot	10 = akaina	10 = plethron: agrarian
12.15	121.5	1215

This measure is rare in comparison with the 12.45 foot. It has been supposed to have been used for the Parthenon, but the 11.69 foot agrees more closely with that. The $\frac{2}{3}$ of 25 digits being a fractional amount was inconvenient, and the foot of 12.15 was divided binarily into 16 digits, of 96 to the orguia, or .759 inch. Such seems to have been the original connection of the different Greek systems, but much more dated material is needed.

11.613 From the digit of .729 on which the Greek measures were based, as for the Parthenon **294.9**

11.69, the Italic foot of 16 digits was formed of 11.66, or as it was later at Rome 11.613. The series was

digitus	4 = palmus	4 = pes	5 = passus	125 = stadium	8 = milliare
.726	2.90	11.61	58 06	7258	58,060

This was widely spread by Roman influence, varying up to 11.8. It has an earlier history, being used for the Parthenon and perhaps the Theseion as 11.69, as an Etruscan measure (**11.59**), in prehistoric times at Stonehenge **(11.68)** and probably in other stone circles and hill figures **(11.60).** Such are the linked systems of great extent from which have been derived many units.

13.3 This widespread measure is first found in Egypt as wooden cubit rods of 26.5 to 26.74 **338**

of the 12th dynasty: later a very accurate standard slab of this unit, divided in 7 palms, reaches 26.80. In Asia Minor it is found as 13.35 in buildings; in Greece 13.36; at Lachish 13.18 (900 B.C.); and in Syria (A.D. 620) as 13.22, carried on as the

Stambuli cubit of 26.6. Hultsch takes it as 13.1 and connects it with the Drusian foot of 2 digits longer than the Roman foot, or 13.10. This was the Belgic foot which Drusus had to adopt as a northern standard for the border settlements of the Agri Decumates. Hence it connects with the base of English land measure.

foot	6=fathom	10=chain	10=furlong	10=old mile
13 2	79.2	792	7920	79,200

It was the commonest building foot in medieval England (13.2), and its age is seen by its use as the measure for Silbury hill (13.0). It was also the basis for French architecture, the *canne* of 78.24, or six feet of 13.04. Unfortunately this old equivalent for the metre has now disappeared.

19.2 This unit is found in Persepolis (19.2) and modern Persia (2 × 19.3); the cubit of Gudea **488**
and of the tower of Babylon 119.5); in the west in Asia Minor (19.3); and as the Pythic foot (9.75, ½**19.5**). Two-thirds of this, a foot of 12.83, seems to bc a unit of buildings at Knossos.

20.0 The great U of 39.96 (Oppert) is possibly a variant of the preceding. found in some As- **507**
syrian buildings as 19.97.

21.6 By the recorded circuit of Khorsabad the U is 10.806, hence the series of multiples on the **549**
tablets is

susi	20=palm	3=U	6=qanu	2=sa	60=us	30=kasbu
18	3 6	10.8	64 8	129 6	7776	233,280

In Phrygia this mas 21.8 at Ushak; in Italy it was 21.86 in Lucania; and half of 21.7 or 21.9 as the Oscan foot. It may occur in square prehistoric earthworks in England. In Egypt there are late cubits of 21.11, 21.16 and 21 33 which may be the same. In Persia it was likewise a smaller form as

vitasti	2=arasni	360=asparsa	30=parathanha	2=gav.
10.7	21 4	7704	231,120	462,240

This important unit was used in Phoenicia; at
22.2 Byblos 11.10; for the Erechtheion 11.09; and 564
in Punic colonies, Carthage, Sardinia and the Hauran, 11.08–11.17. The double of 11.30 is the commonest unit of tombs at Jerusalem.

inches There are very few evidences of this measure. mm.
25.1 Divisions on a wall at Abydos give 25.13. The 638
contents of the brazen sea of Solomon taking the bath as 2380 c.c. would imply a cubit of 23.0 if cylindrical or 26.2 if hemispherical. This at least proves a cubit much longer than the Egyptian. Oppert concluded that Assyria had a cubit one-sixth longer than 21 6; *i.e.*, 25.2. Measures of buildings point to 25.28 in Palestine and 25.34 in Persia, where the *guerze* is 25 inches.

There are not included here some suggestive but debatable evidences of various units, such as the course heights of the pyramid of Khufu (*Anc.* Eg. **1925,39**) and the subsidiary marks of units on the standard cubits.

It may be noted how usually a stadium or furlong measure has been established. There are seven named above: 7258, 7290, 7470, 7506, 7704, 7776 and 7920 inches. These may result from convenient lengths for the plough furrow. It is easy to find coincidences with so many values to choose from.

Areas are passed by as they involve very uncertain factors of methods of cultivation, length of furrow, influence of measures of seed and varying ability of ploughing due to soil.

Capacity Measures

The approximate values of Egyptian capacities are anciently stated by the odd quantities that certain vases held, but as these were probably measured to some unknown point below the brim the result cannot be exactly defined. The standard vessels here described, intended for gauging, give better determinations than have been known before.

cubic inches The amount of the Egyptian hen by five regular measures (of metal or stone) averages c.c.
29.1 29.2 ± .5 cu.in., from ten bronze vessels 29.0 ± 477
.3, from eight marked vases 29.2 ± .6. So 29.1 may best be adopted. If it held 5 debens of water the deben weight would be 1,470 grains, which is nearly a middle value. The multiples are

ro	8=hen	4=hennu	10=apt	4=tama	25=sa
3.64	29.1	116.4	1164	4656	116,400

20.8 There is a double grouping of the Syrian kotyle 341
21.6 on 20.8 and on 21.6. This is supported by the 354
literary difference between the old Syrian 21 and Seleucidan 22 cu.in. (Hultscli). The cause for this change may have been that the old unit of 20.8 belonged to 25 beqa of water, and later it was raised so as to fall within the limit of 25 sela of water. The change would be caused by the sela superseding the beqa as a usual weight standard. In Egypt this was the commonest measure, of which there is a series of the 3rd dynasty and a stone cylinder standard from the 4th, of 20.8. The series of early and late values is

kotyle	2=xestes	18=sabitha or saton	3=bath, artaba
20 8	41 6	7488	22,161
21.6	43 2	7776	23,328

There was also the metretes of 5 saton, 37,440 to 38,880.

33.2 The Syrian log was not unusual in Egypt. Nearly in the midst of the values for it there 544
is a bronze cylinder measure with names of Ainenhetep III, of 33.26. If this log were to agree with 50 necef, the most usual Syrian weight, it would not be over 32.6 in early times and would only reach 33.2 in the 18th dynasty. The Phoenician, Babylonian and Jewish systems vary as follows, the Egyptian amounts being placed to the latter series.

P. log	4=kab		6=saton		30=kor	
31	123		740		22,200	
B. log	4=kapitha			18=epha	10=homer	6=akhane
33	132			2380'	23,800	142,800
J. log	4=kab	3=hin	2=seah	3=ephah	10=homer	
E. 33.2	132.8	398.4	796.8	2391	23,910	

17.4 The Attic kotyle is found in the size of six similar bronze bowls of late form in Egypt, **285**
from ½ to 2 kotyles. The mean is 17.15. This amount is too small for an Attic weight, for if the khous were 8 minae of water the largest bowl size would only agree with the lowest mina. But if the kotyle of water weighed half the mina of Chios or Persia (khoirine system), this would place it at 16.6 to 17.5. In this dilemma the Persian kapetis has some influence. According to Herodotus (1,192) the Attic kotyle: kapetis : : 12 : 51 or 4 : 17. The kapetis is shown by two bowls mentioned below to be 74.5 or 75.3; therefore, the kotyle would be 17.53 or 17.72. If we take 17.4 that would leave the 51 of Herodotus the nearest whole number, and the small difference would thus be divided among the three factors. The series is for

		Liquids			
kyathos	1½=oxybaphon	4=kotyle	12=khous	12=metretes	
2.9	4.35	17.4	208.8	25,056	
		Solids			
kpathos		6=kotyle	4=khoinix	8=hekteos	6=medimnos
2.9		17.4	696	5568	33,108

cu.in. Two bowls of Persian age from Egypt are of c.c.
74.5 74.5 and 75.26, clearly the Persian kapetis. 1221
Their relation to the kotyle value is stated above. The multiples were

kapetis	48=artaba	40= } akhane
74 5	3576	
	marıs	72= } 143,040
	1987	

58.5 A system found at Gythion (Rev. Arch., 1872) is based upon 58.5 cu.in., and seems to belong **958**
to the Egyptian hen, double of which is 58.2.

kotyle	4=hemihekton	4=khous	3=*n*
58.5	234	936	2808

1701 The most important Roman system is far from being established. The data are but few 27870
and discrepant.

	amphora	sextarius	amphora	sextarius
If amphora =cube ft.....	1569 cu.in.	32.7 cu.in.	25,709 c.c.	536 c.c.
Amphora 80 lib. water...	{1575	{32.8	{25,807	{538
	{1605	{33.4	{26,300	{548
By Farnese congius.....	1654	34.4	27,102	563
St. Genevieve congius...	1700	36.4	27,856	580

Naples measure........	1701 / 1703	35.44 / 35.48	27,872 / 27,905	581 / 581
Pompeian standard......	1732	36.1	28,377	623
Caervoran standard.....	1824	38.0	29,888	

There does not seem any course better than to accept the two accurately made measures in the Naples museum of 709.7 and 283.5 cu.in. as being 20 and 8 sextaria; this would give 1702 for the amphora, agreeing with the St. Geneviève congius. The Naples vessels are only measured by lineal gauging, but that cannot be far in error. The system was

quartarius	4 = sextarius	6 = congius	4 = urna	2 = amphora
8.86	35.44	212.6	850.5	1701

Of the above sources the first two may be only approximate, and the Farnese congius is not above suspicion of a Renaissance origin. The Pompeiian measures seem too rough internally and look as if they had held a beaten copper lining. The Caervoran measure is marked as $17\frac{1}{2}$ sextarii, and this yields 38.0 cu.in.

Weights

The whole subject of weights as treated here is based on Egyptian material as that is by far the earliest and best known historically, and in amount the largest published. The arrangement found in Egypt serves best to classify the standards of other countries. The broad view is that each people or tribe had a separate standard, and that these were brought into different countries by invasion or trade. Those standards which were most alike gradually approximated by errors of copying, and lost their individuality entirely before any of the literary records. Thus 17 standards in Egypt which had originally come from various foreign sources became simplified to 8. They are here described in the order of their amount.

grains 116, 121, 124 — grams 7.52, 7.86, 8.06

The peyem standard is marked P.Y.M. on three Palestine weights. The varieties named here were all known before the 6th dynasty; the two heavier were mixed at the 20th dynasty; the lighter one joined in the 26th. There are twelve weights known marked with numerals and the standard, called *shoti* in Egypt, is named on papyri as being 12 to the deben, or between 115 and 126 grains. The multiples were

n	4 = peyem	10 = noshem	10 = *r*	4 = *s*
30	120	1200	12,000	48,000 grains

The noshem was 1,225 grains according to a triply-inscribed weight, the shekel or peyem being 122.5.

grains 127.5, 131.5 — grams 8.26, 8.55

Two standards of the daric existed in the Old Kingdom, but they were blended in the 18th dynasty. The same separation is seen in the weights from Ur, with a light group at 126.1 and a heavy group at 129.4. The earliest in Egypt is of S.D.40, or the beginning of the eastern immigration of Gerzean age: these centre on 125.5. The early weight of Dungi is of 125.9. A maneh of 50 shekels at 126.0 was used in Syria and Knidos. In Italy it was divided into unciae and termed the litra. Italic bronze ingots of a talent are based on 126.0. On the heavier standard the Persian karasha was 10 shekels of 128.65. The coinage under the Persians (from which is taken the name daric) was of 129.2, and some coins reach 131. The heavy standard at Knossos is 131.8, 132.9. This daric standard spread over Asia Minor and across the Euxine, westward to Corinth, the Adriatic isles, south Italy and even to Ireland (gold work 128.0). The series is

um	60 = sikhir	6 = shekel	60 = maneh	60 = trade talanton
.36	21.5	129	7750	465,000

134.0, 135.8 — 8.68, 8.80

The Stater or Attic standard is the least prominent in Egypt. The forms are poor and only two examples bear numerals. The two standards were unified by the 18th dynasty, and the multiples are decimal. In Greece the system was

khalkous	8 = obelos	6 = drachma	100 = mina	60 = talanton
1.4	11.17	67	6700	402,000

In Greek use there was a lighter form for coinage, ,133, and a heavier form in trade, centring on 135. The names of obelos and drachma, or a dart and a handful (of darts), show how objects were used for weights in Greece. The names must have arisen in the use of iron or bronze weapons, and the silver coins were the exchange values. This standard passed into Italy where it was halved for the Etruscan and Sicilian libra, and divided into 12 unciae. It was the talanton of Antioch and the Ptolemies, and survived in Egypt as the rotl, divided duodecimally as in Italy and so producing the dirhem which was the standard coin of Arabic Egypt.

144 — 9.33

The qedet was the national standard of Egypt and was brought in by the dynastic people. There are very few marked weights because it was so usual. Though there were not distinct groups in early times, there were local differences, as weights "of Heliopolis" are on 140 unit, while one of Amasis is 150. Alabaster cones are the earliest, belonging to the 1st dynasty: they are multiples of a third of the qedet. From Ur are six small weights that are multiples of a twelfth of the qedet, so the division in thirds comes from Babylonia. There are many qedet weights from Gezer, Gerar, Knossos and Troy. A large knuckle-bone of bronze from Gela, inscribed "I am of the Gelonians," is 100 qedets. The unit, however, did not spread much in other countries nor start other standards.

b	4 = *c*	3 = qedet	2 = khenp deben	5 = deben	10 = sep	5 = *d*
12	48	144	288	1440	14,400	72,000

The deben a-as binarily divided in Ethiopia for the gold trade down to the *pek*, which was $\frac{1}{128}$. A set of measures for gold dust gives every stage of this division.

154.4, 162 — 10.0, 10.5

The necef is named on six Palestine weights; it may be the nusa weight mentioned in the Harris papyrus. It was first identified by the weight of Syrian tribute to Tehutmes III being in odd numbers of qedet but soluble as multiples of this amount. The two varieties of this unit did not blend till the 26th dynasty. The lighter was the Syrian standard of named weights and was the earlier one at Gezer. The system was decimal, multiplying up to 1,000 and halving down to $\frac{1}{8}$. By the tribute lists it was North Syrian and in later times is found at Berytus and Antioch, Cilicia (pre-Persian), Asia Minor and a bronze lion from Abydos of 2,500 necef. On going west there is a $\frac{1}{4}$ necef at Knossos. It appears in the jewelry of the 17th dynasty at Thebes, a collar of gold weighing 10 X 158.5, and bangles 2 $\times$ 161.3, 162.9. This collar is of the same form as the three Swedish collars weighing 60 $\times$ 158.2, 70 $\times$ 155.9 and 80 $\times$ 158.7, all on the necef basis. Where all this necef jewelry was made is unknown but it mas entirely foreign to both Egypt and Sweden. There are about 50 Irish gold objects on the heavy necef of 162 to 169. The Greek system was

stater	50 = mina	50 = talanton	60 = Greek talanton
160	8000	400,000	480,000

grains 171, 185 — grams 11.08, 12.00

A mark ♀ is often used for this unit but the name is not known in full. As many copies of cowry shells are on this (but on no other) standard, it is called the khoirine and perhaps the monogram is XO, as those letters were in use long before Greek writing. The bulk of the early examples is from 176 to 190; but there was a rarer form at 171–3, down to the 18th dynasty, and not blended with the majority till the 23rd. Three very fine numbered weights from Gerar closely agree in giving 179.3 to 179.8; the stone cowries are the same but rather more divergent, 177.7 to 180.0. The multiples in Egypt are decimal up to 1,000 and fractions down to $\frac{1}{10}$. In later times it became the Persian silver standard, but all the theories of the derivation of an 86 grain weight from the ratio of gold to silver, are blown away by the fact that this standard is thousands of years older. At Khorsabad silver plates are 40 khoirines in weight. As a monetary unit it is known at Arados, Cilicia, Lydia and Macedonia. It is known as the Chian standard, with a mina of 8,410 to 8,886. It was used on the Danube in Roman times and recognized as a mina of 20 unciae. The classical system was

obolos	6 = siglos	100 = mina	60 = talanton
14.3	86	8,600	516,000

196, 210 The oldest standard known is the beqa, found in early Amratian graves in Egypt (7000–8000 B.C.), and named upon three weights in 12.70, 13.61
Palestine. This is often called the gold standard because many of these weights bear the hieroglyph for gold. The names of kings are more frequent on this than on other standards. The lighter and heavier forms were not unified until the 23rd dynasty, though both were used before for royal weights. The system was decimal up to 2,000 beqa with fractions down to $\frac{1}{16}$. The earliest weights (Amratian) are short cylinders with domed ends; later (Gerzean) is a dome with convex base. From the marks, the variety of forms and fine work, this is the most attractive series of weights. Abroad the standard is often found at Gerar and there are several weights from Knossos (194–205); in the west are six double axes from Elbe and Rhine on a unit of 191, and 50 examples of Irish gold on 200 to 202. The iron currency bars found in Celtic England are stated to be on multiples of 191, though they vary rather widely. Some of these western forms are due to the Greek adoption of the beqa as the standard of Aigina (199) which was widely spread by trade in Asia Minor and Ionia, as well as in Greece (the old mina of Athens), and passed on to Italy. There as the Etruscan pound (it originated the Roman libra), which at its lightest was 25 X 187, divided into 12 unciae.

5050, 421 The heaviest value of the Roman libra is given by the early aurei as 5050, uncia 421. The influence of unification with other standards 327.24, 27.27
created many types of the libra, and it is instructive to see the groups at 393 (6 Attic coin drachma); 407 (6 Attic trade drachma); 412 (Roman trade); 417 (Roman solidi); 421 (Roman aurei); 427 (octodrachm Ptolemaic); and 435 (2 Phoenician staters). The Attic trade value was adopted for the average pigs of lead which are 250 librae of 4,900 grs.; the Attic coinage value influenced the Celtic weights; Mayence 4767, Glamorgan 4770. The system was

siliqua	6 = scripulum	4 = sextula	6 = uncia	12 = libra
2.9	17.5	70.1	421	5050

In later times the gold solidus, or sextula, was called the nomisma.

grains 220 The Phoenician or Alexandrian unit is best termed the sela which, though a later name, grams 14.26
serves to distinguish it from other shekels. It was a diffuse unit from the beginning, varying in the Old Kingdom from 214.7 to 227.0, and it gradually diminished to as low as 210. The multiples are decimal up to 4,000 and fractions to $\frac{1}{16}$. This is found as the unit of the Syro-Mesopotamian tribute under Tehutmes III, and later as one of the most usual coinage units, such as the Maccabaean shekel. It was carried by trade to Carthage and Spain and formed the Italic mina. Gold bars from Abukir of Roman age are each 25 shekels of 211.7, 212.9 and 213.0. The series is

drachma	4 = shekel	25 = mina	120 = talanton
55	220	5500	660,000

It extended widely into prehistoric Europe. At Knossos the great octopus weight shows a unit of 223.7, an ox-head from the Diktaian cave shows 227.2, a gold bar from Mykenai 233.1 and another irom Enkomi 222.6. The Vapheio cups are 20 sela of 213, and 216.5. Electrum jewelry from the temple of Ephesos is on a unit of 219.0. In Babylon the maneh of the age of Entemenna (2850 B.C.) is 50 of 210.1. The average of 19 ingots of bronze from Hagia Triada gives a talanton of 2,000 shekels of 226.0. Two double axes from the Rhine and four Ligurian ingots agree on 50 shekels of 225.4. The Irish gold has a large group agreeing with an average of 226.0. Thus there was a great spread of the unit, doubtless due to Phoenician trade.

(W. M. F. P.)

WEIGHT THROWING is the art, science and sport of throwing a weight for distance or height. Men of many nations have matched strength and skill at hurling objects of various weights for centuries. Such contests have always held particular appeal in what is now known as Ireland. As far back as 1829 B.C., the *roth cleas*, or wheel feat, was a major test of the Tailteann games. The competition involved various methods of throwing: irom shoulder or side; with one or two hands; and with or without run or follow. The implements used varied widely in weight and conformation. Early in the 20th century records nere listed for throwing weights of 14 lb., 28 lb., 35 Ib. and 56 lb., both for distance and height.

In 1904 at St. Louis, Mo., and in 1920 at Antwerp, Belg., 56-lb. weight-throwing contests for distance were held in the Olympic games. Etienne Desmarteau, a policeman from Montreal, Can., won the 1904 competition with a throw of 34 ft. 4 in. Pat McDonald, a New York policeman, won at Antwerp with a flip of 36 ft. $11\frac{1}{2}$ in.

By the second half of the 20th century there no longer was any international competition in weight throwing, and performances did not receive world-record listing by the International Amateur Athletic federation, the world governing body of track and field. The sport remained popular, however, in the northeastern United States. The 35-lb. weight throw is a standard event in the annual championship indoor meets of the Amateur Athletic union (A.A.U.) of the United States and the Intercollegiate Association of Amateur Athletes of America (I.C.4-A). Member I.C.4-A colleges include it in their dual meet programs. The A.A U. also had a 56-lb. weight throw on its list of outdoor championship events until 1959. when it was dropped.

The weight thrown today, either 35 lb. or 56 lb., is a ball molded of lead or a brass shell filled with lead. Affixed to it by an eye bolt or swivel coupling is a triangular handle of round iron or steel, $\frac{1}{2}$ in. in diameter. measuring no more than $7\frac{1}{4}$ in. a side, inside dimension. The throw must be completed from within a 7-ft. circle, without follow.

Top standards of performance in throwing for distance have risen to above 70 ft. nith the 35-lb. weight and 40 it. with the 56-lb. weight. Because there is little international competition, there no longer are listed world records for weight throwing but the A.A.U. publishes American records which, in effect, are world records since there are none better.

Method of Throwing.— Strength and bulk were once the main factors in weight throwing, but technique has been refined to a point nhere speed is now more important than mere weight and muscle. Because of their speed and perfection of technique, comparatively small men, such as Harold Connolly, have thrown the 35-lb. weight for distances undreamed of by the big men of earlier days. Connolly was the first thrower to exceed 70 ft.; the speed which he developed in training for the hammer throw, in which he has been a record-holder, more than compensated for his lack of size.

To throw for distance, the athlete takes a stance at the rear of the throwing circle with his feet well apart for balance and his back turned squarely toward the direction of the eventual throw. The weight is grasped by its triangular handle, palms up or donn or with the left palm down and right palm up. according to individual preference. The weight is lifted. swung to the right side and revolved around the head. With the completion of the revolution the thrower commences a tight-based, pivoting spin on his left foot. As he whirls nith arms fully extended the weight moves with him, square to his chest, in a wide arc. Another turn is taken with acceleration and then, at least by the good throwers, still another. On the completion of his third turn the throner should be in an approximation of his starting position, but in the forward portion of the throning circle. with the neight in rapid circular movement. With feet solidly planted he then whips all his strength into the release of the whirling ball, driving up with his legs, pivoting his whole torso and following through with his arms as he lets the ball fly over his left shoulder.

It has been well established through experimentation that there is no substitute for developing a high rate of speed on the turns. Weights as heavy as the 35-lb. or 56-lb. implements that are used must be moving at high speed at the release to travel long distances. Sheer strength or an explosive releasing snap is not enough to conquer the passive force of inertia.

While concentrating on attaining maximum spinning speed, the thrower must also maintain control and balance. The rules require that a competitor must not step from inside the circle until his throw has been measured and also that he must depart from the rear half of the ring. (J. M. Sh.)

WEI-HAI (formerly Wei-hai-wei), a city and port near the northern tip of the Shantung peninsula in Shantung province North China. The harbour faces eastward toward the Yellow sea but is protected on the east by 2-mi. long and 1-mi. wide Liukung Island which is urbanized along its south side. Wei-hai city on the mainland is backed by hills rising to 1,353 ft. The harbour takes vessels up to 33 ft. draft. Strong northwest winds in winter reduce safe depths by two feet. The southwest end of Liukung Island has a naval station with a number of piers, and Wei-hai is commonly linked with Port Arthur (*q.v.*) to form the naval gate ays guarding the entrance to the Gulf of Chihli (Po Hai). It was this strategic situation that caused Great Britain to lease the port from China as a naval base (Port Edward) in 1898, in part to counter Russia's lease of Port Arthur. The Wei-hai lease was surrendered voluntarily in 1930 when a special administrative area was established there by the Chinese government. Wei-hai was occupied by Japan from 1938–1945.

In 1949 following the Nationalist withdrawal, it was occupied by Chinese Communist forces, thereafter becoming a Communist naval base.

Wei-hai also is a secondary commercial and fishing port for Shantung. Small industries include vegetable oil pressing, silk and cotton weaving and ship repair, especially in the foundries and machine shops of the naval station. Highways connect Wei-hai with Chefoo (Yen-t'ai) in the west and Tsingtao (Ch'ing-tao) in the southwest. A submarine cable also provides communications with Chefoo. (H. J. Ws.)

WEILL, KURT (1900–1950), U.S. composer, was born in Dessau, Ger., March 2, 1900. He began to compose music while still in elementary school, prompted by his father, a cantor. At the age of 18 he began studying composition in Berlin with Engelbert Humperdinck. He moved to Ludenscheid in Westphalia, as operatic conductor, but shortly returned to Berlin to study with the pianist and composer Ferruccio Busoni until 1924. During these years Weill composed a variety of aorks, including symphonies and chamber music. He first adapted his composition to the theatre in the mid-1920s when he was commissioned to do a children's ballet for a Russian company visiting Berlin. In 1926 he collaborated with Georg Kaiser on the opera *The Protagonist,* and subsequently also collaborated with Kaiser, Ivan Goll and Bertolt Brecht on various operas including *Royal Palace, The Tsar Has Himself Photographed, The Three-Penny Opera* and *The Silver Lake.* The anti-Nazi overtones of *The Silver Lake* resulted in the banning of Weill's works in Germany, and he went to Paris where, in 1933, he composed the ballet *The Seven Deadly Sins.* In 1935 he went to the United States, where he was commissioned by producer Max Reinhardt to write the music for *The Eternal Road.* He also composed the music for *Knickerbocker Holiday* (1938), *Lady in the Dark* (1941), *One Touch of Venus* (1943), *Street Scene* (1946) and *Lost in the Stars* (1949). He died in New York city, April 3, 1950.

WEIMAR, a city of Germany, the chief town of the former *Land* of Thuringia, in the district of Erfurt. Pop. (1950) 64,452. It existed in the 9th century. Till 1140 it belonged to the counts of Orlamünde; it then fell to Albert the Bear. In 1247 Otto III founded a separate Weimar line of counts. In 1345 it became a fief of the landgraves of Thuringia, to whom it escheated in 1385. At the partition of Saxony in 1485 Weimar, with Thuringia, fell to the elder. Ernestine, branch of the Saxon house of Wettin. and was the continuous residence of the senior branch of the dukes of this line after 1572. Under Charles Augustus (1775–1828) and his successors, Weimar became a centre of liberalism as well as of German art. It was at Weimar, in July 1919, that the constitution of the new German republic was adopted by the national assembly.

Weimar still retains much of its medieval character because of the narrow winding streets of the older part of the town, the market place surrounded by houses with high-pitched gables and roofs, and the fragments of the walls, which still survive. Of the churches. the Stadtkirche is a Gothic building dating from about 1400, but much altered in detail under "classical" influences. The altarpiece is a triptych, the centrepiece representing the Crucifixion; beside the cross Luther is represented, with the open Bible in his hand, while the blood from the pierced side of the Saviour pours onto his head. The other church, the Jakobs- or Hofkirche (court church), is also ancient. The most important building in Weimar is the former palace, erected (1789–1803) under the superintendence of Goethe, on the site of one burned down in 1774. A remnant of the old palace, with a tower, survives. The interior is very fine, and in one of the wings is a series of rooms dedicated to the poets Goethe, Schiller, Herder and Wieland. Of more interest, however, is the house in which Goethe himself lived from 1782 to 1832. It is a complete example of a German nobleman's house at the beginning of the 19th century. Of more pathetic interest is the Schillerhaus, in the Schillerstrasse. containing the humble rooms in nhich Schiller lived and died. The theatre, built under Goethe's superintendence in 1825, memorable in the history of art not only for its associations with the golden age of German drama, but as having witnessed the first performances of many of Wagner's operas, was pulled down and replaced by a new building in 1907. The most beautiful monument of Goethe's genius in the town is, however, the park. Just outside the borders of the park, beyond the Ilm, is the "garden house," a simple wooden cottage with a high-pitched roof in which Goethe used to pass the greater part of the summer. Finally, in the cemetery is the grand ducal family vault, in which Goethe and Schiller also lie, side by side.

Among the other prominent buildings in Weimar are the Grunes Schloss (18th century), containing a library and a valuable collection of portraits, etc.; the old ducal dowerhouse (Wittumspalais); and the museum. In 1896 the Goethe-Schiller Archiv, on the height above the Ilm, containing manuscripts by Goethe, Schiller, Herder, Wieland, Immermann, Fritz Reuter, Mörike, Otto Ludwig and others, was opened. Weimar possesses also archaeological, ethnographical and natural science collections. About 2 mi. S. from the town is the château of Belvedere, with the open-air theatre, of interest because of its use in Goethe's day. A few miles northwest of Weimar was located the Nazi concentration camp of Buchenwald, where racial and political prisoners were confined from 1933 to 1945.

WEINGARTNER, FELIX (1863–1942), Austrian-born conductor and composer, was born in Zara, Dalmatia, on June 2, 1863. He studied music at the Leipzig conservatory and in 1883 went to work under Franz Liszt who arranged to have his first opera, *Sakuntala,* produced at the Weimar court theatre in 1884. He subsequently became *Kapellmeister* at the Konigsberg theatre. In 1891 he became *Kapellmeister* in the Berlin Royal Opera and conductor of the Berlin symphony orchestra. He first visited London in 1898, made his first appearance in the United States in 1905, as guest conductor of the New York Philharmonic orchestra, and toured the country the following year. His fame as a conductor grew steadily; he led the Vienna Opera (1908–10) and thereafter conducted the symphony concerts of the opera orchestra.

He became head of the Basel conservatory in Switzerland in 1927 and a naturalized Swiss citizen in 1931. He was director of the Vienna State Opera. 1935–36, but after 1937 lived in Switzerland. where he died. at Winterthur. on May 7, 1942.

His compositions included a number of operas and six symphonies and he edited many musical norks.

WEINHEIM, a town of Germany, in Baden-Württemberg, at the foot of the Odenwald, about 10 mi. N. of Heidelberg. Pop. (1950) 25,199. It is still in part surrounded by the ruins of its ancient walls. The Gothic town hall, the ruins of the castle of Windeck and the modern castle of the counts of Berckheim, the house of the Teutonic order, and three churches are the principal buildings. The town has various manufactures, notably leather, machinery and soap, and cultivates fruit and wine. It is a favourite climatic health resort and a great tourist centre for excursions in the Odenwald range. Weinheim is mentioned in chronicles as early as the 8th century, when it was a fief of the abbey of Lorsch. and it was fortified in the 14th century. In the Thirty Years' War it was several times taken and plundered, and its fortifications dismantled.

WEINMAN, ADOLPH ALEXANDER (1870–1952), C.S. sculptor, was born at Karlsruhe. Ger.. on Dec. 11, 1870. He emigrated as a child to New York city. where he studied sculpture under Augustus Saint-Gaudens. He opened his own studio in 1901 and first attracted notice for his group of American Indians at the St. Louis, Mo., world's fair of 1904. Well-known works oi his include a pediment of the national archives building. Washington, D.C.; a monumental frieze for the Elks National Memorial building, Chicago, Ill.; and figures for various state capitols. Weinman died at Port Chester, N.Y., on Aug. 8, 1952.

WEIR, J. (JULIAN) **ALDEN** (1852–1919), U.S. painter, who was among the earliest Americans to show the influence of Impressionism, was born on Aug. 30, 1852, in West Point. N.Y., the youngest of the 16 children of Robert Walter Weir (*q.v.*). After studying at the National Academy of Design in New York, he went to Paris to study with Gérôme. There he became a friend of Jules Bastien-Lepage, who was to become an important influence in his development. He became interested in the work of the Impressionists, particularly in their concern for light and colour, but he never fully adopted their manner. He helped form the Society of American Artists and was president of the National Academy of Design from 1915 to 1917. In 1898 he helped found the group known as the Ten American Painters, which consisted of J. H. Twachtman, F. W. Benson, Childe Hassam, E. C. Tarbell, W. L. Metcalf, E. Simmons. Robert Reid, Joseph De Camp. T. W. Dewing and, later. W. M. Chase. Weir died on Dec. 8, 1919, in New York city. His works are in the Metropolitan Museum of Art in New York, the Art Institute of Chicago, the Phillips collection in Washington. D.C.. and in several other galleries.

WEIR, ROBERT WALTER (1803–1889), G.S. portrait and historical painter, was born at New York, N.Y., on June 18, 1803. He was a pupil of John Wesley Jarvis, was elected to the National Academy of Design in 1829, and was teacher of drawing at the United States Military academy at West Point in 1834–46 and professor of drawing there in 1846–76. He died in New York city on May 1, 1889. Among his better known works are: "The Embarkation of the Pilgrims" (in the rotunda of the Capitol at Washington, D.C.); a portrait, "Red Jacket"; "Columbus Before the Council of Salamanca"; "Our Lord on the Mount of Olives"; "Virgil and Dante Crossing the Styx." Several portraits and "Peace and War" are at West Point.

His son, JOHN FERGUSON WEIR (1841–1926), painter and sculptor, became a member of the National Academy of Design in 1866, and was director of the Yale university art school in 1869–1913. Robert Weir was also the father of the painter J. Alden Weir (*q.v.*). (D. H. W.)

WEIR, WILLIAM DOUGLAS WEIR, 1ST VISCOUNT (1877–1959), British politician and businessman, was born May 12, 1877, the son of James Weir of Over Courance, Dumfriesshire. He was successively Scottish director of munitions (1915), member of the air board (1917), air minister (1918), and chairman of the advisory committee on civil aviation. He was director general of explosives and chemical supplies in 1939 and chairman of the tank board in 1942. He was knighted 1917, sworn P.C. and created a baron 1918. created G.C.B. 1934 and a viscount, 1938. He died July 2. 1959, in Eastwood Park, Scotland.

WEIR, a barrier of moderate height placed across a river or stream to control the flow of the water for navigation, irrigation, power or other purposes, discharging the water over its crest or through wide openings having movable gates. River weirs are frequently termed dams, particularly in the United States where the term weir is more generally applied to small barriers erected to measure the flow of water or to trap fish. The French term barrage is often applied to neirs. (See WATER SUPPLY AND PURIFICATION; IRRIGATION; DAM; RESERVOIRS; MECHANICS, FLUID.)

Rough neirs formed of stakes and brushwood were erected across English rivers in Saxon times for holding water and catching fish. Fish traps, with iron wire meshes and eel baskets, are still used sometimes at weirs. Similarly, weirs of brushwood weighted with stones are still being used in some parts of the world to divert the flon into a ditch leading to land to be irrigated or into a bucket-type water wheel that spills water into a flume leading to an irrigation ditch.

Weirs exhibit the greatest variety of form and construction in connection with the canalization of rivers. Navigation becomes impracticable at the shoals in many rivers during periods of low water. In early times boats had to be kept at such places until the discharge of storm water raised the river sufficiently to carry them over the shallows. An early method of remedying this trouble consisted in building low weirs upstream from the shallows to increase the depth of water. Openings in them could be temporarily closed by stanches usually consisting of planks supported by movable wooden beams. By removing these beams suddenly and thus releasing the stanch an artificial flood was produced which carried any boat waiting above the weir through the opening and over the shoals below. This process was called flashing. It remained in use on some rivers in England and France until the early 19th century. (N. G. G.; B. O. M.; X.)

WEIRTON, a city of Brooke and Hancock counties in extreme northern West Virginia, U.S.. and an important steel-producing centre, is situated on the Ohio river about 26 mi. N.N.E. of Wheeling and 39 mi. W. of Pittsburgh Incorporated in 1947. when several adjoining towns merged, the city sprawls across seven miles of the West Virginia panhandle from the river on the west to the Pennsylvania border on the east, and from King's creek on the north to Harmon creek on the south. Weirton is one of the largest cities in the state. (For comparative population figures see table in WEST VIRGINIA: *Population.*)

Originally settled by John Holliday and his family during the American Revolution, in the 1790s the area boasted one of the first iron manufactories west of the Alleghany mountains when Peter Tarr built a crude furnace on King's creek to smelt iron ore mined in the nearby hills. There were fashioned the cannon balls which the U S. fleet under Oliver Perry used to defeat the British in the battle of Put-in-Bay during the War of 1812.

Iron and steel have remained closely identified with the community's economic development. Both the city and its principal industry are named for Ernest Tener Weir, who, in 1909, with several associates, founded the Weirton Steel company. In addition to sheet steel and tin plate, Weirton is also noted for the production of Venetian blinds, steel furniture, automotive parts and electronic equipment. (P. R. S.)

WEISMANN, AUGUST (1834–1914), German biologist, whose outstanding contribution was the theory of the continuity of the germ plasm, was born in Frankfurt am Main on Jan 17, 1834. He studied medicine at Gottingen during 1852–56, and in 1863, after working for a short period under R Leuckart in Giessen, went to the University of Freiburg. where he later was professor of zoology until his retirement in 1912. He died in Freiburg on Nov. 5, 1914.

Weismann's early zoological work was in insect embryology. but as a result of deterioration of his eyesight he had to give up working with the microscope, and after 1864 he devoted himself mainly to theoretical problems. He proposed that living organisms contain a special hereditary substance (the germ plasm) which, unlike the perishable body of the individual (the somatoplasm), is transmitted from generation to generation. The germ plasm can never be formed anew, but is formed from pre-existing germ plasm It governs the development of every part of the organism, and is not, in Weismann's view. modified by the action of environment He vigorously opposed the doctrine of the inheritance of acquired characters, previously generally taken for granted.

Weismann saw that since the hereditary substances from the two parents became mixed together in the fertilized egg, there would be a progressive increase in amount of hereditary substances unless at some stage there was a compensating reduction. He therefore predicted that there must be a form of nuclear division at which each daughter nucleus receives only half the ancestral germ plasms contained in the original nucleus. The cytological work of E. Strasburger, O. Hertwig and others on meiosis proved the correctness of this prediction. and enabled Weismann, together with these others. to propose that the germ plasm was located in what were subsequently called the chromosomes of the egg nucleus. It should be remembered, however, that at this time (1885) no detailed information concerning the nature of the hereditary factors was available, since Mendel's work, though published, was lying in obscurity.

Many of Weismann's detailed speculations, such as his idea that cellular differentiation took place by some process of segregation of hereditary factors (ids). were not supported by later work. Moreover, his rigid distinction between germ plasm and somatoplasm could not be maintained once it was realized that both germ and somatic cells contain nuclei and chromosomes. Nevertheless, in broad outline his theory of the germ plasm remained the basis of much of modern genetics.

Weismann's writings include *Studien zur Descendenztheorie,* 2 vol. (1875–76), trans. as *Studies in the Theory of Descent,* with a preface by Charles Darwin (1882); *Aufsätze über Vererbung,* etc.. trans. as *Essays upon Heredity and Kindred Biological Problems,* 2 vol. (1889 and 1892); and *Das Keimplasma* (1892). trans. as *The Germ-Plasm, a Theory of Heredity* (1893). *See* also HEREDITY; LAMARCKISM.

See E. Gaupp, *August Weismann* (1917). (G. H. BE.)

WEISS, (CHARLES) ANDRÉ (1858–1928), French international lawyer, best known for his work in private international law. was born at Mulhouse on Sept. 30. 1858. He began as a lecturer at the University of Dijon. moving to the University of Paris in 1891, where he became professor in 1896. His wide range of interest embraced at various times civil, administrative. public and private international law. It was on the latter that he lectured at Dijon and published. in 1885. *Traité élémentaire de droit international privé,* expanded into the six volume *Traité théorique et pratique de droit international privé* (1907–13), a pioneering work which reflected a wide knowledge of foreign systems of law. In 1911. with Jules Roche and Louis Renault, he drafted the constitution of Monaco.

Weiss was legal adviser to the French foreign office (1908–22), was elected a judge of the Permanent Court of International Justice (1921) and served for a while as vice-president. He died at The Hague on Aug. 31, 1928.

See the tribute delivered by the president of the Permanent Court of International Justice. Sept. 13, 1928, in P.C.I.J. *Series* E, no. 5r.10; and E. Bartin in *Journal du Droit International Privé,* 55:849 (1928).

WEISSENBURG: *see* WISSEMBOURG.

WEISSENFELS, a town in the district of Halle, Ger. Pop. (1950) 47.967. It is a place of some antiquity, and from 1656–1746 was the capital of the small duchy of Saxe-Weissenfels. The body of Gustavus Adolphus mas embalmed at Weissenfels after the battle of Liitzen. The former palace, the Augustusburg (1664–90), lies on an eminence near the town. Manufactures include cardboard, rubber; boots, machinery, ironware and paper. In the area are large deposits of sandstone and lignite.

WEIZMANN, CHAIM (1874–1952), research chemist. Zionist leader and first president of Israel, was born Nov. 27, 1874, in the township of Motol in Russian Poland. After early upbringing in a traditional Jewish environment, he studied in Germany and Switzerland: becoming lecturer in biochemistry at the University of Geneva and in 1904 reader in the same subject in Manchester. His practical discoveries in organic chemistry gave him not only a wide reputation but also some degree of financial security. An eager Jewish nationalist, he was already prominent in the Zionist movement (*see* ZIONISM). In consequence, when World War I split Zionist leadership into two camps, he inevitably assumed the foremost role in England. In this he was aided by his engaging personality, his wide linguistic range and his important war work (1916–18) in the admiralty laboratories on acetone, which brought him into contact with some outstanding figures in national life. He was thus largely responsible for winning from the British government in 1917 the Balfour declaration favouring the establishment of a Jewish national home in Palestine.

Throughout the next generation Weizmann was the leading figure in the Zionist movement, being from 1920 almost without a break president of the World Zionist organization and from 1929 chairman of the extended Jewish Agency for Palestine. Convinced as he was of the reconcilability of British policy and interests in Palestine with the requirements of the Jewish national home. his influence was at all times moderating and conciliatory. This resulted in his temporary replacement as president from 1931 to 1935, when the emergency which resulted from the rise of Nazism made his return to office inevitable. He was the principal spokesman for the Jews before the successive British and international commissions of inquiry sent to Palestine in the following years. The tragic crisis which resulted from the Nazi persecutions and the necessity of finding a Jewish haven of refuge created a widening gap between the British and Jewish viewpoints on the Palestine situation. and Weizmann while condemning acts of violence could not condone the drastic restrictions now proposed by the British government.

Driven thus into resignation in 1946. Weizmann retired to Rehovoth in Palestine to work at the Institute of Science (later called the Weizmann institute) which he had helped to create. and to compose his vivid though somewhat idealized volume of memoirs, *Trial and Error* (1949).

When the state of Israel came into being in 1948 Weizmann was elected president of the provisional government, and in 1949 first president of the state. but largely owing to his poor health and failing eyesight took little part in active politics. He died at Rehovoth on Nov. 9, 1952.

See P. Goodman (ed.), *Chaim Weizmann, A Tribute on His 70th Birthday* (1945), containing appreciations and Eng. trans. of select speeches; O. K. Rahinowicz, *Fifty Years of Zionism: A Historiral Analysis of Dr. Weizmann's "Trial and Error"* (1932). (C. R.)

WELCH, WILLIAM HENRY (1850–1934), U.S. pathologist and educator. was born in Norfolk, Conn., on April 8. 1850. A graduate of Yale university (A.B., 1870), he studied medicine at the College of Physicians and Surgeons in New York city and graduated from that institution in 1875. After an internship at Bellevue hospital in New York he went to Germany in 1876 and spent two years there studying under well-known medical scientists. Returning to the United States in 1878, he was appointed professor of pathology and anatomy in Bellevue Hospital Medical college (later New York university), a post he held from 1879 to 1884, when he was called to the newly created professorship of pathology in the Johns Hopkins university in Baltimore. Md.

In his new post Welch had the opportunity to develop what was in reality the first true university department of pathology in the United States. When the school of medicine of the Johns Hopkins university was opened in 1893, Welch was appointed dean, a post which he held until 1898. He remained as professor of pathology in the university and pathologist to the Johns Hopkins hospital until 1916. when he was appointed director of the newly established school of hygiene and public health of the university. After organizing that school and seeing it operating successfully, he resigned to become the first professor of the history of medicine in the school of medicine (1926). He retired from that post in 1930.

Welch made a few original contributions to the sciences of pathology and bacteriology—notably the discovery, with G. H. F. Nuttall, of the so-called "gas bacillus," the cause of gas gangrene—but his chief contributions were to the development of medical science in general, of medical education and of public health. He was considered one of the foremost figures in U.S. medicine. He died at Baltimore on April 30, 1934. (A. M. CY.)

WELD *(Reseda luteola),* **a** herbaceous plant of the mignonette family (Resedaceae) formerly cultivated in France, Germany and Austria. It is the oldest European dyestuff known, and appears to have been used by the Gauls in the time of Julius

Caesar. Of all the natural yellow colouring matters, it yields the purest and fastest shades, but because of the small amount of dye which it contains, and its bulky nature, it has almost disappeared from the market. Weld contains the yellow colouring matter luteolin, which crystallizes in yellow needles and melts at 320° C. See ANTHOCYANINS AND ANTHOXANTHINS. (A. G. P.)

WELDING usually refers to a technique of joining metals by heating with or without the application of pressure and with or without a filler metal; cold welding is possible by means of high pressure or by hammering. The value of welding as a standard method of joining metals was not fully appreciated before World War I, when because of the need for speed of production in every metal-using and metal-fabricating industry, the older of the welding processes came into their own. During and after World War II new welding methods were developed, which further increased speed and facilitated the joining of the many special-purpose alloys that were developed during this period.

Limited in its early applications to small or less important parts, welding in the second half of the 20th century mas employed in fabrications too numerous to mention, such as ships, locomotives, railroad rails and cars. automobiles. pipelines. aircraft and household appliances. While all metal-using industries employ more or less nelding, some are completely dependent on this technique of joining metals. The petroleum industry is a classic example. The cutting edges of the bits used to drill oil wells consist of a hard weld metal fused to a tough backing. The oil is conducted to the surface through pipe sections fabricated from plate by welding, and these sections are in turn welded end-to-end to form a leak-proof casing. At the refinery the oil is processed in equipment of which every permanent joint is nelded. Transportation to and from the refinery is via all-welded pipelines, ships, tank trucks and drums And, ultimately, gasoline is pumped from nelded underground vessels into the nelded steel gas tank of the consumer's automobile, while heating oil is delivered into a welded tank in the consumer s basement.

Whenever a piece of apparatus is intended to contain a liquid or gas, melding is the logical method of fabrication. As such. it has almost completely replaced other methods. Water, fuel gas and a host of other fluids are, like petroleum and its products, stored, processed and transported in welded equipment. Poner boilers and other vessels built to contain fluid under high pressure are welded uith complete reliability.

Nuclear power reactors are of entirely nelded construction, from the small cans containing the' fuel elements to the huge envelopes designed to confine the radioactivity in the event of a leak. As a matter of fact, ease of nelding is one of the major criteria in the selection or development of construction materials for nuclear reactors.

Welding is of course by no means confined to applications where leak-tightness is involved. In the conventional body-on-frame automobile there are some 8,000 to 10.000 resistance welds and up to 40 ft of arc nelding. Even more nelding is employed in automobiles using the body as the primary load-carrying member. Arc welding is the basic means of fabrication of heavier vehicles such as trucks, locomotives and earth-moving equipment.

Welded construction is used in the aircraft industry to a somewhat lesser degree. Aluminum alloys used in airfoils and air frames derive their strength from a critical heat treatment, and the heat of welding causes some deterioration in properties. Turbine and rocket engines, however, are fabricated by welding. Further, trans-sonic aircraft develop skin and frame temperatures that preclude in many areas the use of aluminum. The alloys used in its stead are fabricated by welding.

Bridges and buildings can be erected by welding, with a saving of 10% to 20% in the amount of steel required. Erection costs and, particularly, design costs are somewhat higher than in riveted construction. The proportion of structures erected by welding was increasing in the second half of the 20th century and the trend appeared likely to continue. In the home, many thousands of welds can be found in such diverse places as refrigerators. washing machines, frying pans, heating plant, plumbing, window casings and vacuum cleaners. Frames of homes and similar small buildings have been erected by welding, and there are sound reasons to expect that this application will increase.

Processes. — The subject of welding may be divided into five

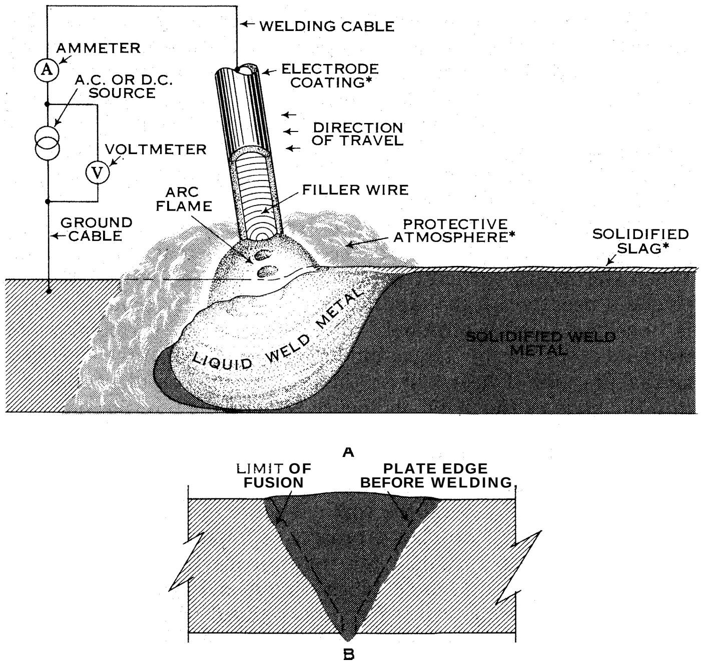

FIG. 1.—ARC WELDING WITH ROD ELECTRODES. (A) LONGITUDINAL SECTION THROUGH AN ARC WELD IN PROGRESS; (B) CROSS SECTION THROUGH COMPLETED WELD. COMPONENTS MARKED * ARE NOT PRESENT IN SOME ARC-WELDING PROCESSES

processes: (1) forge welding; (2) arc melding; (3) gas welding; (4) resistance welding: (5) aluminothermic welding.

Forge Welding. — From prehistoric times until about 1880 the only available method was forge welding. After properly shaping the two surfaces to be joined, the parts were heated to welding temperature in a forge or furnace and then hammered, rolled or pressed together, often with the aid of some fluxing material. In the manufacture of Damascan and samurai swords, wrought iron bars were hammered thin, then doubled back on themselves and forge welded. This procedure was repeated many times to ensure that all flaws in the original bar were drawn out in a longitudinal direction. The toughness of the neapon depended on how many times the bar was hammered out and nelded back on itself.

In modern practice, the heat is applied in *situ* by torches, induction coils or an aluminothermic mix (see *Aluminothermic Welding*, below). The parts are pressed rather than hammered to accomplish the weld. These modifications of forge welding are generally called pressure butt welding.

Cold nelding is the process by nhich ductile alloys can be welded at room temperature. if enough pressure and deformation are applied. Essentially, the process consists of drastically stretching the tno surfaces to be nelded together, while pressing them tightly in contact Strong joints in copper and the softer aluminum alloys can be made by this method.

Arc Welding may be divided as follows: (1) metal arc welding nith consumable rod electrodes; (2) inert-gas-shielded metal arc welding; (3) submerged melt nelding; (4) tungsten or carbon arc nelding; (5) atomic hydrogen welding. All of these methods can be automatized, and have been at one time or another. Important automatic installations are limited to (2), (3) and (4).

Metal Arc *Welding With* Rod Electrodes. — Tonnage-wise, this method is the most important. An arc burns between the electrode, a rod of suitable composition, generally coated nith a heavy cellulose or mineral coating and the parts to be welded. These should be properly shaped and are usually beveled on both edges when plates are to be joined in the same plane by a butt weld. The metal is fused at both ends of the arc and the fused electrode deposited in the joint in a series of layers until it is properly filled. After each layer the protective slag formed by the melting of the coating should be removed by chipping or peening. The arc should be as short as possible, particularly with bare wire welding, in order to avoid oxidation of the metal, the inclusion of harmful gases and to secure the proper penetration.

Welding may be done with direct or alternating current. The alternating current is usually supplied by a suitable transformer provided with taps to adjust the current. Several types of direct current arc welding equipment are available, An arc welding outfit consists of a welding generator or transformer, a control panel for varying the current, a voltmeter and ammeter, proper lengths of cable, an electrode holder and a suitable shield or helmet for protecting the eyes of the operator.

When direct current is used, one terminal remains positive and the greater portion of the total heat is liberated at this terminal. When alternating current is used, the terminals are alternately positive and negative so that approximately the same amount of heat is liberated at each terminal. Usually the piece of metal to be welded is considerably larger and has more mass than the electrode so that its loss of heat will be the greater because of conduction into the body of the metal and hence is made the positive side. In case very thin metal is being welded, it is frequently advisable to reverse the polarity to prevent the arc burning through the metal.

Coated electrodes have been used in some form since early in World War I. In general the coatings serve as a fluxing or deoxidizing medium and provide a protective vapour around the arc. They are used as a vehicle for transmitting desirable alloys in the deposited metal. Some types contain a large proportion of metallic iron. Components are always added which stabilize the arc by promoting ionization and thermionic emission. Low-hydrogen coatings, used on alloy steel rods, are compounded with a minimum of water or other hydrogen-producing substance. Some coated electrodes operate best with reversed polarity, *i.e.,* with electrode positive. Bare electrodes yield an inferior weld metal and are used only for tack welding and similar low-strength applications.

Inert Gas Metal Arc Welding.—The arc burns in a chemically inert atmosphere blown into the region of the weld. The electrode is fed automatically from a large spool of mire, through a tubular electrical contact, into the arc. The welding head, consisting of this contact, means for water or air cooling and means for conducting the inert gas to the weld, may be traversed either manually or automatically. Shielding gases commonly used are helium, argon and carbon dioxide. The last is not strictly inert to most engineering alloys.

The advantages of this process stem from its inherent high welding speed. A given size of wire can handle several times as much current as the same size of wire made into rod electrodes. Further, there is no need for the operator to stop frequently to change electrodes. The equipment costs more than that required for rod-electrode welding. The shielding gases, except where carbon dioxide can be used, are much costlier than rod-electrode coatings.

Submerged Melt Welding.—The apparatus is similar in many respects to that used in the last-described process. However, the wire is fed into a mound of flux rather than into a shielding atmosphere. Part of the flux melts, spreading over and protecting the molten weld metal. The flux is compounded to deoxidize and, if wanted, to add alloying elements to the weld metal.

Submerged melt welding is the most economical way to make long, straight seams in heavy steel plate in the flat position. In 1952 apparatus was introduced that makes possible submerged melt welding of horizontal and vertical seams in vertical plates.

Tungsten or *Carbon* Arc Welding.—The carbon arc was first applied to the welding of metals only a few years after its introduction as a smelting tool in 1881. The carbon resists the heat of the arc, but is gradually oxidized. The welding wire is fed into the arc, or into the molten pool formed on the work. The weld may be shielded against atmospheric contamination by means of granulated flux or an inert gas. However, submerged melt welding is a more satisfactory flux-shielded process.

Tungsten is nearly as resistant as carbon to the heat of an electric arc, but tungsten oxidizes more rapidly and is, of course. much more expensive. Of the two, tungsten is by far the better electrical conductor. Accordingly, tungsten has superseded carbon as a nonconsumable electrode for inert-gas-shielded arc welding. The shielding gas, argon or helium, is blown through an opening concentric with the electrode, thus serving to protect both the tungsten and the weld pool from oxidation.

Atomic Hydrogen Arc Welding.—A fine jet of hydrogen is forced through an arc formed between two tungsten electrodes. The high temperature of the arc breaks up the hydrogen molecules into hydrogen atoms, which recombine into molecules after passing through the arc, giving up the heat absorbed during dissociation in the arc. The result is a jet flame of hydrogen burning in a hydrogen atmosphere at a temperature higher than that of almost any other known flame, but lower than that of the arc. The welding mire is fused in this flame and deposited in the joint. The intensely reducing character of this hydrogen flame results in a nearly perfect weld practically as good as the parent metal, except in alloys that are embrittled or otherwise damaged by hydrogen absorption.

Gas Welding. — This process of fusion welding is generally carried out by the heat produced by the burning of acetylene in the presence of commercially pure oxygen, the flame temperature so attained being probably about 5,500' F, which, in view of the concentrated flame, is high enough to melt any metal locally, and so allows pieces to be easily fused together. It is necessary, when welding thick materials, to bevel the edges to be joined so they form a *v*, which is filled up by melting into it a rod of suitable composition, the weld metal also being fused to the base metal. The joint if well made is clean and sound, free from injurious defects. and usually as strong or stronger than the parts joined.

Torches. — Any oxyacetylene welding torch is an instrument that thoroughly mixes the two gases, oxygen and acetylene, in the proper amounts and that permits easy adjustment and regulation of the flame. A small flame and little heat are required for welding thin gauge metals and a large flame and much heat when welding heavy sections; thus interchangeable tips are furnished by the torch manufacturers. Broadly speaking, there are two types of torches—pressure and low pressure. In the pressure type of torch, both acetylene and oxygen are supplied to the torch under appreciable pressures, the pressures being increased for each larger size of tip used. In the low-pressure or injector type of torch, the oxygen only is under pressure. The mixing chamber is made on the same principle as an ordinary steam water injector so that the volume of acetylene going into the mixture is dependent upon the velocity, and not the volume of oxygen.

Flame Adjustment and *Manipulation.*—It is generally desirable that the welding flame be neutral, that is, that there be no excess of acetylene or oxygen. When there is an excess of acetylene the hot inner cone is ragged and poorly defined. When there is an excess of oxygen the inner cone is short and has a pale violet colour. The inner welding flame should not play directly on the welding rod but around it in a semicircular fashion, the rod being melted by the radiating heat of the flame. The heat should be evenly distributed on each side of the joint in order to melt down the walls and to secure thorough penetration and union of the adding material and parent metal. It is also essential that the torch oscillations be regular; otherwise fusion will be more thorough on one side of the joint than on the other.

Reinforcement.—As the weld proceeds, the rod metal should be added until the surface of the joint is built up a little above the edge of the plates. This reinforcement is customary in all welding on steel plate. The small amount of oxide that forms during welding and impurities remain on the surface as a scale and can be easily removed when cold, by grinding or machining.

Fluxes.—Except in the welding of wrought iron and steels, fluxes are usually required for satisfactory results. Impurities on the surface of the metal or impurities contained in the metal find their may into the weld and must be floated out as slag to prevent damage to the weld. The combination of a suitable flux with these impurities produces the slag.

Cutting.—The cutting torch differs from the welding torch in that in addition to having the oxyacetylene heating flame it also has another gas stream of pure oxygen under high pressure which does the cutting after the metal is raised to the ignition point by the heating flame. The iron and oxygen combine to form iron oxide, thus burning a narrow slit or kerf in the steel. It is a chemical process and should not be confused with melting. Sometimes hydrogen is used in welding and cutting operations instead of acetylene. Other fuel gases are sometimes used in conjunction with oxygen for cutting. The cutting torch may also be used for the beveling of plates and for machining operations.

Of the engineering alloys, only titanium, and the plain carbon and low-alloy steels. can be cut with a simple oxygen jet. Nickel- and copper-base alloys do not produce enough heat of combustion to maintain the cutting action. while highly alloyed steels yield too refractory a slag. To cut these alloys, iron powder is fed into the oxygen stream. The heat of combustion of the iron, plus the fluxing action of the oxide produced, makes possible the torch cutting of alloys that previously had to be sawed or sheared. The inert-gas-shielded tungsten arc is used for thermal cutting of aluminum alloys,

Resistance Welding.—In this method, invented in 1877 by Elihu Thomson, the parts to be joined, after proper shaping, are pressed together. A large current is then passed through the joint until it has reached welding temperature, when further pressure is applied, upsetting the joint and completing the weld. As the electrical resistance of the contact surface is much greater than that of the solid metal, most of the heat is generated at the joint surface where it is desired.

The voltage required is so low and the current so high that the only convenient source is a large-turns-ratio transformer built into the welder and as close as possible to the jaws, which hold the parts and transmit the current to them. For work of any considerable size, these machines are not readily portable; *i.e.*, the work must ordinarily be brought to the machine. The type of resistance welding described above is known as butt welding, and has been applied to join sections of widely varying shapes up to 36 sq.in. in a section.

Flush *Butt Welding.*—Parts to be welded are clamped, the primary circuit closed and the ends of parts brought together slowly. When these ends touch they will flash, that is, minute particles of molten metal will fly off; this flashing is continued until the entire faces of the abutting ends have reached a melding heat when heavy pressure is applied, forcing the ends together and completing the weld.

Spot *Welding.*—Where airtightness is not required, a lap seam may be welded in spots by clamping the seam overlap between two electrodes and passing the necessary current between them and through the overlapping edges of the plates. As the electrical resistance of the surface contact is least in the region under pressure, most of the current and therefore the weld is confined to a spot of about the same area as that of the electrodes. For relatively thin metal this method is much more rapid and economical than any other known method of making a joint where mechanical strength alone is the chief consideration. The mechanical strength obviously depends upon the number and size of the spots. Sometimes the spots are localized by raising one of the surfaces to be joined at convenient points or projections. Several spot welds may be made at one time by having one of the electrodes flat. This is called projection welding.

Seam Welding.—The overlapping edges of sheet metal are passed between two narrow roller electrodes, the speed, current and pressure being so adjusted as to produce a continuous seam or a series of overlapping spots. This method is usually limited to relatively thin sheets, but is readily applicable to straight seams or to circular seams. The process is widely used in manufacturing barrels. small transformer tanks and other containers.

Aluminothermic Welding.—Thermit and Exoweld are trade names for a mixture of finely divided aluminum and iron oxide, which when ignited reacts to produce a superheated liquid steel at 5,000" F. The underlying principle of the thermit process is the high chemical affinity of aluminum for oxygen. Up to a temperature of 2,800° F. thermit is an inert mixture. At that temperature however, the aluminum unites with the oxygen of the iron oxide, and the iron is set free and becomes a highly superheated liquid steel. It is obvious that if steel at this temperature is poured around the sections to be united, especially if the sections have previously been preheated to a bright red heat, it will melt those

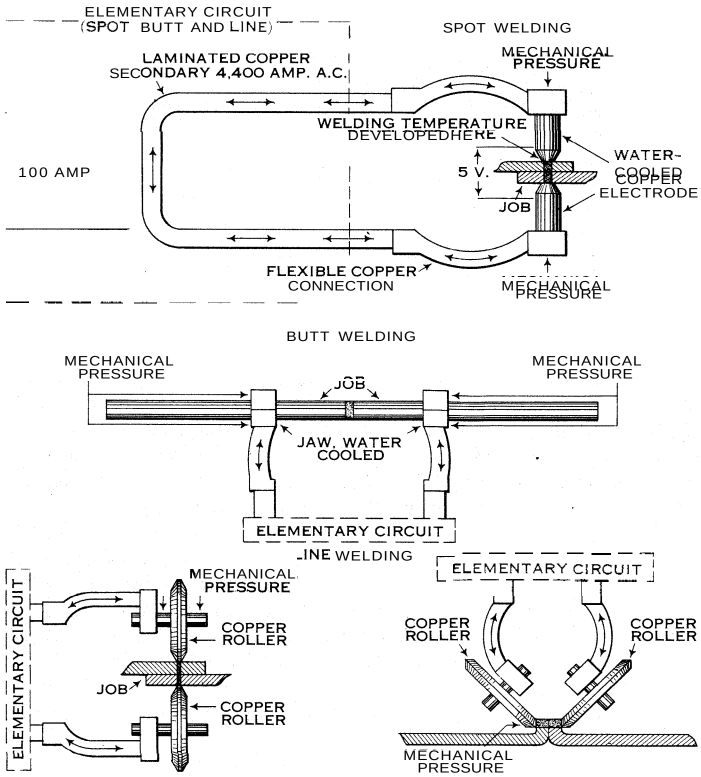

FIG. 2.—DIAGRAMS OF CIRCUITS OF VARIOUS WELDING MACHINES

sections and amalgamate with them so that the whole will cool to form a single homogeneous mass, or in other words a fusion weld.

Making a *Thermit Weld.*—In making a thermit weld, the parts to be united are first lined up with a space between the ends to be welded, the extent of which depends upon the size of the sections to be welded. The adjacent ends are then thoroughly cleaned by a sand blast or other suitable means. A wax pattern is then formed around the ends to be united of the exact shape of the thermit steel to be cast. A sand mold is next rammed around the wax pattern and inside a sheet iron box provided with pouring gates, heating gates and risers. A basin on the top of the mold serves to catch the slag when the pour is made.

The flame of a compressed air liquid fuel (gasoline or kerosene) heater. directed into the heating gate melts the wax pattern and leaves a space for the thermit steel. The heat is continued until the parts to be united have been brought to a good, red, workable heat. By that time the mold will have become dried out. In the meantime the charge of thermit is placed in a conical-shaped crucible supported over the pouring gate of the mold. When the sections are red hot and the mold dried. the application of heat is discontinued, the heating gate plugged up and the thermit charge in the crucible ignited. In 25 to 35 seconds the thermit reaction is completed and the thermit steel tapped from the bottom of the crucible into the mold where it flows around and between the sections to be welded, uniting them into one homogeneous mass.

APPLICATIONS

Every metal-using industry employs welding to a greater or lesser degree. Of the important families of engineering alloys. steel is welded by all the described processes. However, the tungsten arc and atomic hydrogen processes are rarely used on carbon and Ion-alloy steels, and stainless steel is seldom welded with the torch, and never with the carbon arc or aluminothermic process. Actually, the last process is used only on heavy sections of low-alloy and carbon steels. The accompanying table shows roughly

Applications of the Welding Processes

Process	Plain carbon and low-alloy steels	High-alloy and stainless steels	Nickel and cobalt alloys	Copper-base alloys	Aluminum-base alloys	Magnesium-base alloys	Titanium and zirconium alloys	Cast iron
Consumable rod electrode . .	A	A	A†	A†	B	C	D	A
Metal-inert-gas	A	A	D	A	A	D	D	B
Tungsten arc.	B	A	A	A	A	A	A†	B
Submerged melt	A	A†	D	D	D	D	D	D
Atomic hydrogen	C	B	B†	B	B	D	D	D
Oxyacetylene torch . . .	B	B†	B†	A†	A	B†	D	A
Aluminothermic	A	D	D	D	D	D	D	A†
Solid phase*	A	B†	B†	A‡	At:	C	D	D
Resistance flash	A	A	A	C	A	A†	A†	D
Spot, seam, projection . . .	A	A	A†	C	A	C	A†	D

*Includes modern forge welding and resistance butt welding. (A) preferred process. (B) yields sound melds, but is uneconomical except in special circumstances. (C) yields inferior welds unless special precautions are used. (D) not applicable. †Some members of the familv vield unsatisfactory welds by this process. ‡Only if the alloy can be cold welded. Otherwise (B)†.

to what extent each of the described processes is applied to the more important families of engineering alloys. Molybdenum, not included in the table, is used to some extent in jet aircraft and rocket-propelled missiles. It is joined by tungsten arc and resistance flash melding, but the welds are hrittle at room temperature. Zinc alloys and the precious metals are generally welded with the oxyacetylene torch. Lead is commonly welded with an air-hydrogen flame.

The welding of reactive and refractory metals and of those of ultra-high-strength steels which are sensitive to hydrogen can be accomplished in a high vacuum by use of an electron beam. A heated tungsten filament is the cathode from which electrons are emitted and accelerated toward the work by a potential of 5,000 to 150,000 volts.

See also Index references under "Welding" in the Index volume.

(WM. SP.; H. U.)

WELF or GUELPH, a German dynasty of princes. The 12th-century chronicler of the family recorded a tradition that its name was derived from the word meaning "whelp." The first member of the house of whom there is certain evidence was the Bavarian count Welf I, a contemporary of Charlemagne and of Louis the Pious. The kings of Burgundy who ruled until 1038 and the West Frankish magnate known as Hugh the Abbot (d. 886) were descended from him. The German line which had its chief seats at Altdorf and Ravensburg in Swabia died out with Welf III in 1055. Welf IV (d. 1101), a son of Welf III's sister Kuniza by Azzo of Este, was then summoned from Lombardy to take over the inheritance; he became the first Welf duke of Bavaria in 1070. Welf IV's son Henry the Black (d. 1126) married a coheiress of Magnus, the last Billung duke of Saxony. To the Saxon lands that she brought to her husband, their son Henry the Proud (d. 1139) added the entire fortune of the emperor Lothair of Supplinburg (see LOTHAIR II) by marrying his only child Gertrude. Henry the Proud's designs on the German crown were frustrated, but his son Henry the Lion (*q.v.*) kept the duchy of Saxony and regained Bavaria in 1156. Most of the family's south German lands passed to Henry the Proud's younger brother Welf VI (d. 1191), who was also enfeoffed with Tuscany, Spoleto and the Mathildine lands by his Hohenstaufen nephew, the emperor Frederick I Barbarossa; and Welf VI chose the house of Hohenstaufen to succeed him. When Henry the Lion had in 1180 forfeited his fiefs, only the Saxon patrimony round Brunswick and Liineburg remained to his descendants. In 1235 the emperor Frederick II turned these lands into a dukedom so that the Welfs should belong to the estate of princes. Later they frequently divided their reduced territories to endow new branches of their house. George Louis (1698–1727), elector of Hanover, who'came to the throne of Great Britain and Ireland as George I in 1714, belonged to the Liineburg line of the Welfs.

Otto IV (d. 1218), a son of Henry the Lion, fought against the Hohenstaufen for the imperial crown. His Italian supporters called themselves Guelphs, and this became the label of all who sided with the papacy against the adherents of the empire, or Ghibellines (see GUELPHS AND GHIBELLINES). The names of these factions long outlived their original meaning

(K. J. L.)

WELHAVEN, JOHANN SEBASTIAN CAMMERMEYER (1807–1873), Norwegian poet and critic, was born at Rergen. He first studied theology, but from 1828 onward devoted himself to literature.

In 1840 he became reader and subsequently professor of philosophy at Christiania (Oslo), Nor., and delivered a series of impressive lectures on literary subjects. In 1836 he visited France and Germany; and in 1858 he went to Italy to study archaeology.

Welhaven died at Christiania on Oct. 21, 1873.

In a violent attack on Henrik A. Wergeland's poetry, he opposed the theories of the extreme nationalists. He desired to see the Norwegian culture brought into line with that of other European countries, and he himself followed the romantic tradition, being closely influenced by J. L. Heiberg (*q.v.*). He represented clearness and moderation against the extravagances of Wergeland.

Welhaven gave an admirable practical exposition of his aesthetic creed in the sonnet cycle *Norges* Daemring (1834). He published a volume of Digte in 1839; and in 1845 Nyere Digte. His descriptive poetry is admirable. but his best work was inspired by his poems on old Norse subjects, in which he gives himself unreservedly to patriotic enthusiasm.

His critical work includes *Ewald og de norske Digtere* (1863), *On Ludwig Holberg* (1854). Welhaven's *Samlede Skrifter* were published in 8 vol. at Copenhagen (1867–69).

WELL, a pit or shaft generally excavated for the purpose of removing fluids from underground. In recent years some wells were constructed expressly for the purpose of putting fluids underground. In the U.S. (1960s) during a single year there were pumped from wells about 22,000,000,000,000 gal. of water, 2,600,000,000 bbl. of oil and about 15,000,000,000,000 cu ft. of natural gas. To maintain and increase these rates of extraction, about 500,000 water wells and 50,000 oil and gas wells were being drilled each year. It has been suggested that prehistoric man learned to dig for water by observing wild horses and wolves. It seems probable that the earliest wells were mere pits a few feet deep which, in times of progressive drought, were deepened as they became dry. By biblical times the digging of wells had become a common practice (Gen. xxvi, 17–23).

Types of Well.—Wells may be classified in many different ways according to purpose, method of construction, depth of excavation and depth to yield. The primary uses of wells are production, injection and observation.

Production Wells.—Although fresh water is the fluid produced in greatest quantity from wells, many other fluids are derived from underground sources. Wells drilled for oil are second in abundance only to fresh-water wells; such oil typically is mixed with natural gas and salt water. While the oil and gas are valuable products, the salt water is almost always a waste product. Rarely do oil-field brines contain sufficient concentrations of such valuable chemicals as iodine to justify extraction. Natural-gas wells mainly produce combustible gases, with only minor amounts of liquids. Other wells are drilled expressly to tap pools of highly concentrated and valuable brines. Such chemicals as table salt, magnesium salts, potassium salts, soda ash, bromine and iodine are extracted from these brines.

The recovery of sulfur by means of wells is a unique and espe-

cially interesting procedure. Native sulfur in solid form is found in the cap rocks of certain salt domes along the coasts of Texas and Louisiana in the U.S. In the Frasch process (see SULFUR), hot water is pumped down a well containing several concentric pipes to melt the sulfur. The liquid mixture of sulfur and water returns to the surface and is discharged to bins where the sulfur is allowed to solidify.

In a few areas of the world, usually near recently active volcanoes, wells are drilled to exploit the thermal properties of underground fluids. The well may flow (or is pumped) to produce hot water that can be piped to homes for hot-water taps or circulated through radiators as a source of heat. More commonly, the hot water is delivered to bathhouses and swimming pools. Many of these hot waters contain high concentrations of dissolved minerals and are unsuitable for drinking. Where underground temperatures are higher, the fluid coming from the well may be steam that is circulated for heating or directed through turbines for generating electricity. Formerly even nonthermal waters flowing from wells were used for power. In the 1880s the water from one well, flowing under high pressure, was discharged to a Pelton water wheel and developed enough power to grind 125 bbl, of flour per day.

Injection Wells.—Some wells are used to inject liquids or gases into underground layers. These wells may have been former production wells, or they may have been drilled expressly for injection use. The major objectives of injection are waste disposal, repressuring and terminal storage. Waste-disposal wells are utilized to dispose of large volumes of undesirable liquids where surface disposal would contaminate fresh water supplies or otherwise constitute a hazard. Chief among these liquids are oil-field brines, which are produced in large volumes in most oil fields; in certain areas these brines are more salty than ocean water. After being cleaned thoroughly, the brines are pumped into an injection well and enter a geological layer deep enough to avoid contamination of the generally shallower fresh waters. In inland areas it was expected that increasingly large volumes of atomic wastes would be disposed of in this manner. The disposal of storm waters into wells has been practised in a few areas where the geologic layers have large openings. Normally such waters are very turbid and will quickly clog disposal wells. Although most modern practices involve careful planning prior to waste injection, this was not true in the past when wastes were poured indiscriminately in abandoned wells, with disastrous consequences to underground fresh waters.

In older oil fields, brine injection may be used for water flooding, a method of secondary recovery of oil in which water is injected into partially depleted wells to push the remaining oil toward production wells. Injection of brine for such repressuring occurs at the lower levels in the reservoir layer, usually at the edge of the producing area. Simultaneously, natural gas may be injected through wells near the top of the underground oil reservoir also to rebuild pressures that have dropped with removal of oil.

To maintain the yields of aquifers (underground layers containing fresh water), some areas have ordinances requiring return of air-conditioning water to the layer from which it was pumped. Thus, each air-conditioning system would require two wells—one for production and one for injection. In certain coastal areas where fresh-water levels have been depressed far below sea level by heavy pumping, lines of injection wells are used to create a continuous ridge of fresh water. If this ridge can be maintained above sea level, the wells inland from the ridge can be pumped without causing intrusion of sea water into the aquifer.

From such areas of large natural gas reserves as the Texas Panhandle in the U.S.; the Stavropol oil fields in the U.S.S.R.; and Alberta, Can., the natural gas is piped for long distances. Demand for the gas in distant cities is very seasonal. If a pipeline were built to carry all the gas needed during the cold months, it would require an excessive diameter; while during the warm months, the pipeline would be carrying only a small part of its capacity. This problem was solved by terminal storage of large volumes of gas close to the centres of demand. The volume of storage required is much larger than can be accommodated economically in tanks, and so natural underground formations are used. During warm months the excess gas from a narrower, less costly pipeline is pumped to a suitable geologic layer through injection wells. During peak demand the gas is removed from the layer to supplement pipeline flow.

Observation Wells.—Observation wells are used for continuous or periodic collection of data. In studies of aquifers, an observation well is commonly an unused production well, although some are drilled especially for observation purposes. The well may be used for measuring depths to water, or water samples may be taken for chemical analysis. Some wells may be equipped with devices to give continuous records of the fluctuations of water or fluid levels. Flowing wells or natural-gas wells may be equipped with pressure gauges.

Methods of Well Construction.—The excavation of a well involves (1) loosening or breaking the soil or rock: (2) removing this loosened or broken material; (3) keeping the sides of the excavation from caving; and (4) preventing the entry of unwanted fluids into the hole or keeping the fluids in the hole from draining away. Ingenious procedures have been devised to deal with these problems in the history of well-sinking techniques. In many instances either a means was found to develop underground water, or the land had to be abandoned.

Dug *Wells.*—Dug wells are probably the oldest type, since they require a minimum of equipment. They must be of sufficient diameter to accommodate the labourers. Minimum diameter is about 3 ft.. with many in the range of 4 to 8 ft., and a few dug wells as much as 30 or 40 ft. across. Although most such wells are circular, some are square or rectangular. The depths of dug wells may be as much as 400 or 500 ft., but the overwhelming majority are less than 100 ft. Prior to the installation of central water-supply systems, towns usually had one dug well to which all residents came for water. The well served not only as a source of water! but had important functions as a social centre.

Dug wells are most often excavated in soft materials. The soil, loosened by pick and shovel, is usually placed in a container and lifted by a rope to the surface. Caving of the walls may become a severe problem, especially after water level has been reached, and walls may be curbed with wood, stone, bricks. concrete, tile or large pipes. In hard rock, though caving is much less a problem, blasting may be required. Hand digging flourishes in areas and times of inexpensive labour. Modern practice in more prosperous countries employs mechanized digging equipment, for there are places where the large-diameter dug well is the most advantageous. Modern digging utilizes a clamshell (see EXCAVATION) or orange-peel bucket which scoops the soft materials out of the hole. Sections of cylindrical curbing are allowed to settle as the material is removed. Mechanized digging is usually much more effective than hand digging below the water level where continuous pumping may be required to allow men to work. An important advantage of the large-diameter dug well, if the materials yield water slowly, is the large wetted surface exposed. This gathering area can be further enlarged by extending horizontal laterals radially outward from the well. Dug wells have relatively large storage capacity and can be pumped more efficiently than small-diameter wells in poorly yielding materials.

Dug wells are commonly associated with low production! usually no more than a few gallons per minute: but in certain rocks very large yields are known. Prior to 1900 dug wells usually yielded water at a greater rate than the existing equipment could remove it. Primitive methods for removal employed such things as a bag of hides on the end of a rope, and later a bucket and windlass. Increasing demands for high-yielding wells were generated by an expanding agriculture and the development of piped water supplies in towns and cities. Prior to 1900 centrifugal pumps were about the only types available for lifting water efficiently and in large volume. Although centrifugal pumps can push water considerable distances vertically, the pump itself had to be within suction lift (25 ft. or so) of the water. As heavy pumping continued and water levels dropped, centrifugal pumps had to be placed progressively lower in large diameter wells. This procedure of using a centrifugal pump near the bottom of a dug well was gradually superseded following the development of deep-well pumps (see PUMP).

Bored Wells.—In soft, noncaving materials, wells may be excavated with augerlike devices. The renowned flowing well that was started in A.D. 1126 at Lilliers. France, in the northern province of Artois. may have been bored. Wells excavated by boring are often called artesian wells after Artesium, the ancient name for Artois. Popular usage tends to reserve the term to such wells that flow without pumping. In the boring method a cutter at the end of a rod is rotated at the surface. When the auger or cutter is full it is raised to the surface and emptied. Casing or tubing probably was used even in early wells, since boring is difficult in badly caving materials. Boring was widely practised in Europe from the 12th to the 19th centuries, and was introduced (about 1823) to the U.S. from England. Early bored 11-ells were of small diameter, perhaps four inches or so, and reached depths of several hundred feet. Few small-diameter bored wells were being constructed in the 1960s, and in many areas. large truck-mounted power augers were being used to bore holes one to six feet in diameter. This equipment is used mainly for boring utility pole holes, foundation footing holes and residential cesspools, but is also used for boring water wells.

Driven *Wells.*—Small-diameter wells (one inch to four inches) may be constructed in favourable localities merely by driving a pointed piece of pipe into the ground. Such wells have been employed extensively where the surficial material is soft sand and where water is within suction lift of the ground surface. A hardened drive point is fixed to the bottom of the string of pipe. and above this is a screened section to admit the water. After a pitcher pump is attached to the top of the pipe the well is ready for production. This method is used much more rarely than in the past because of difficulties in preventing contamination of the shallow waters. Formerly, homever, batteries of driven wells connected to a common suction were used as water supplies for small towns. Such well systems are still used extensively for dewatering excavations.

Jetted *Wells.*—The jetting method involves washing down a hole with a stream of water under pressure issuing from the end of a small-diameter pipe. The cuttings are washed up in the space between the pipe and the wall of the hole. The washing action is supplemented by alternately raising and dropping a chisel bit, and also by turning the pipe at the surface. Casing is usually lowered into the hole, closely following the bit, and may be pounded down from the surface. Jetted wells are commonly about four inches in diameter, and depth may be as much as 500 ft. The earliest known jetting rig was built in about 1884 and by the end of the 19th century jetting was the chief method of sinking tubular wells on the Atlantic and Gulf coastal plains of the U.S. This method was adapted mainly for drilling water wells that would flow. Such small-diameter deep wells that did not flow were considered uneconomic because relatively expensive pumps had to be installed. If the water rose almost to the surface, it was sometimes allowed to flow through a pipe below the surface into an adjacent dug well of large diameter, simplifying the pumping problem. Because jetting is effective only in small-diameter holes, this method no longer is used extensively for water wells. The method, however is still commonly used as an inexpensive means of installing shallow observation holes.

Drilled *Wells.*—Most modern wells are constructed by drilling. The various drilling methods may be classified as percussion, rotary-hydraulic, reverse-rotary-hydraulic, rotary-air or gas, and rotary-air-percussion.

In percussion drilling, rock is pounded to fragments by lifting a heavy tool and allowing it to drop. At intervals the tool or bit is withdrawn from the hole and a special bucket or bailer is lowered into the hole to remove the debris. If the materials tend to cave, the hole should be lined with casing. Very primitive percussion drilling was employed by the ancient Chinese on the edges of the Gobi desert. Depths of 5,000 ft. were attained with bamboo tools and casing. Such wells sometimes required several decades of patient labour.

Percussion drilling started in the U.S. about 1808 and was developed almost to its modern form by the end of the 19th century, spurred by the completion (1859) of the Drake well in Pennsylvania, the first productive U.S. oil well. The earliest pre-Drake wells were drilled for brine along the Kanawha river in what is now West Virginia. In those days brine was sought as a source of table salt and the petroleum that occasionally appeared in small quantities was considered a nuisance. After observing the West Virginia drilling. Levi Disbrow built a rig and became the first well-drilling contractor in the U.S. His methods and tools were covered by patents issued in 1825 and 1830. Although he employed chisel bits that were raised by a windlass and allowed to drop, he also used augers where suitable.

In the earliest percussion rigs, the bit was suspended on a string of wooden poles connected by iron screw fittings. Because the poles broke excessively the bit was later suspended on a Manila rope. Modern percussion (cable-tool) drilling utilizes steel cable instead of rope. In hard rocks. where cable-tool drilling is standard procedure, no casing is needed unless a caving zone is encountered or a zone with unwanted fluid is reached. In oil wells, if water is encountered, a string of casing is inserted and drilling is continued with a smaller bit. Several strings of successively smaller casing may be required before the oil zone is reached. Where the cable-tool method is used in softer materials, casing may be required from the very start and pushed or driven down continuously as the hole is deepened. In cable-tool drilling the heavy chisel bit hits the bottom of the hole about 25 to 30 times per minute. At intervals the bit is quickly removed irom the hole and the bailer is lowered on a different cable. In soft materials a special bit-bailer combination ("mudscow") speeds drilling considerably.

Rotary-hydraulic drilling may be thought of as a combination of augering and jetting. At the bottom of a string of pipe (drill stem) a cutter (bit) is made to rotate by power applied at the surface. At the same time a liquid (commonly a mud slurry) is pumped down through the drill stem and continuously washes the cuttings to the surface. Casing is usually not needed because the mud cakes on the wall of the hole and prevents caving. Casing is normally not set in a water well until the desired aquifer is reached. In oil wells a shallow string of casing may be set to avoid contamination of shallow aquifers by oil and brine. The rotary-hydraulic technique was developed in the oil fields of Louisiana about 1890 but was given its greatest impetus during the oil boom in 1901 when the Spindletop well was discovered near Port Arthur, Tex. Gradually, rotary-hydraulic drilling replaced cable-tool methods in drilling oil wells, and cable-tool drilling tends to be restricted to shallow wells and special completion procedures. The deepest oil wells are drilled a-ith rotary-hydraulic methods, sometimes to depths over 20.000 ft. Cable-tool methods are much more widespread in water-\yell drilling, although in some areas rotary-hydraulic techniques have become relatively more important, especially for the deeper holes. A special variation of the rotary-hydraulic method is diamond core-drilling (with a hollow cylindrical bit armed with commercial diamonds!. A solid core remains undrilled and may be removed for examination. Although primarily for exploration holes, diamond core-drilling is occasionally used for small (1.5 to 3 in.) water wells in hard rocks; inclined or even horizontal wells are drilled this way.

In reverse-rotary-hydraulic drilling the water moves down the hole outside of the drill stem and the cuttings move up the drill stem, from which they are removed by high-capacity pumps. These are typically large-diameter wells (up to five feet or more) but usually no more than a few hundred feet deep. Reverse-rotary-hydraulic drilling is suited to soft materials, may be especially advantageous where small boulders are encountered, and is an increasingly popular recent modification of the more standard rotary-hydraulic method.

An even more recent modification of the rotary methods involves circulating air instead of water or mud. In this type of drilling excellent penetration rates have been obtained. Drilling must be through materials dense enough to prevent excessive loss of air, and only relatively small-diameter holes can be drilled. Since large quantities of water would prevent air circulation, water wells only of small yield can be drilled in this manner. For special purposes, rotary-air techniques have been very effective, but for most geologic conditions they will not replace rotary-hydraulic methods. For drilling in natural gas zones it has been found advisable to remove the drilling mud and circulate natural gas to avoid sealing gas zones with mud; drilling rates have been increased also, and bit life has been lengthened.

The most recent development in the 1960s was the rotary-air-percussion rig, combining rotating action and circulation of air with an air hammer just above the bit that delivers about 600 strokes per minute. In extremely hard rocks record drilling rates have been obtained, but small hole diameter and the limited volumes of fluid that can be handled are disadvantages for general use in drilling for water.

Typically. modern wells are drilled by rotary-hydraulic or cable-tool methods. Hard-rock water wells may be uncased: other wells usually are cased with wrought-steel pipe in convenient lengths welded or screwed together. Casing is perforated at points where fluids are to be removed or injected. In water wells, screens with accurately controlled openings are used extensively instead of perforated casing. Selection from among the wide variety of methods for adapting a drill hole to production or injection should be based upon a thorough knowledge of the geologic layers penetrated — their caving characteristics, the volume and nature of the contained fluids, and the fluid pressures in the various zones. The main objective in a production well is to extract the maximum amount of the fluid or fluids desired, and to exclude unwanted fluids and such suspended materials as sand and silt. A further consideration is the cost of lifting the liquids to the surface if the well does not flow. In water wells lifting efficiency is often improved by a sleeve of gravel (gravel pack) poured between the well screen or perforated casing and the wall of the hole. Special construction problems are encountered if the well penetrates high-pressure oil or gas zones.

The strings of casing should be cemented in place and high-pressure seals should be installed at the top of the pipe. In water wells the casing should be sealed to prevent the entry of polluted surface waters. *See* also references under "Well" in the Index volume.

WELLAND SHIP CANAL. This waterway provides for navigation of large vessels between lakes Erie and Ontario, and is an important link in the Great Lakes–St. Lawrence seaway. The difference in elevation between the two lakes is 326 ft. and the natural connection between them. the Niagara river (*q.v.*), is impassable because of its falls and rspids. The first canal. with a depth of 8 ft., was built by a private corporation, the Welland Canal company, at a cost of $7,700,000, and was opened to traffic in 1829. This n-as a ditch connecting Port Dalhousie. Ont. (3 mi. W. of the present canal outlet). with Port Robinson on Chippawa creek. which gave access to the Niagara river. In 1833 the canal was extended from Port Robinson to Port Colborne. Ont., on Lake Erie. The canal was enlarged by the government of Upper Canada (now Ontario) in 1871–87, at a cost of about $21.750.000. Further improveinents were begun by the Canadian government in 1912.and the official opening of the newer canal took place in 1932. This project cost about $130.000.000.

The modern Welland canal extends 27.6mi. from Port Colborne, Ont., on the north shore of Lake Erie. to Port Weller, Ont., on the south shore of Lake Ontario. It is 200 ft. wide at the bottom, 310 ft. at the water line with a lock width of 80 ft. and has a minimum depth of 27 ft. Eight locks provide for control of water level and flow. and they accommodate vessels 765 ft. long. The time required for transit of the canal generally is less than eight hours.

WELLER, THOMAS HUCKLE (1915–), U.S. physician and parasitologist, shared with J. F. Enders and F. C. Robbins (*qq.v.*) the Nobel prize in physiology and medicine in 1954 for cultivation of the poliomyelitis viruses in tissue culture. Weller was born in Ann Arbor. Mich., and received his education at the University of Michigan (A.B.. 1936: M.S., 1937) and Harvard medical school (M.D., 1940). While a medical student he became interested in tissue culture techniques and with Enders' group studied the propagation of the parasite causing trichinosis and also vaccinia or cowpox virus in living tissue cells. During World War II he served in the army as chief of the bacteriology, virus and parasitology sections of the Antilles Department Medical laboratory, Puerto Rico, n-here he studied various tropical diseases. After the war he completed his hospital training in pediatrics and in 1947 joined Enders in establishing a research laboratory at the Children's Medical centre, Boston. There, with Robbins, the viruses of poliomyelitis were successfully cultivated, leading to the development of poliomyelitis vaccine, new diagnostic methods and the isolation of many new viruses. In 1954 W'eller became professor of tropical public health at the Harvard school of public health, Boston.

(J. H. DE.)

WELLES, GIDEON (1802–1878), secretary of the navy in Lincoln's cabinet, was born at Glastonbury, Conn., July 1, 1802. He attended Episcopal academy. Cheshire. Conn., and spent three years at Norwich (Vt.) university. He then studied law for a time but. in 1826he became part owner and editor of the *Hartford Times*. For the next ten years his paper was the official spokesman for Jacksonian democracy in southern New England. He was elected to the Connecticut legislature in 1826 and served until 1835. He fathered legislation to end imprisonment for debt and to abolish property and religious requirements for voting. and was the author of the state's general incorporation law as part of the Jacksonian war against the Bank of the United States. Retiring from the legislature. Welles was three times elected state comptroller. served as postmaster of Hartford and then as chief of the bureau of provisions and clothing of the United States navy. He ran for congress in 1834and for the senate in 1850, but was defeated in each case.

Welles broke with the Democrats over slavery in 1854 and helped organize the Republican party. He also helped found the *Hartford Evening Press,* one of the first Republican papers in New England. In 1856 he was his party's candidate for governor. Although defeated, his activities led Abraham Lincoln to select him as New England's representative in the first Republican cabinet.

As secretary of the navy Welles proved efficient, loyal and honest. He increased the number of ships from 90 to 670, and the officers and seamen from 8,800 to 57,200. He made the blockade an effective factor in crushing the Confederacy and his support made possible the development of the ironclads which revolutionized naval warfare. Always a stickler for sound procedure, he opposed Lincoln's suspension of habeas corpus and the suspension of critical newspapers. He. however. backed the Emancipation Proclamation as a war measure and stood solidly behind Andrew Johnson in the impeachment proceedings. He supported the Liberal Republicans in 1872 but voted for Samuel Tilden in 1876. His diary is one of the most important documents of the Civil War period. He died at Hartford, Conn., on Feb. 11, 1878.

(AY. CN.)

WELLESLEY, RICHARD COLLEY WESLEY (or WELLESLEY). MARQUESS (1760–1842), eldest son of the 1st earl of Mornington an Irish peer. and brother of the famous duke of Wellington, nas born on June 20 1760 He nas sent to Eton and to Christ Church. Oxford By his fathers death in 1781 he became earl of Mornington, taking his seat in the Irish house of peers.

In 1784 Wellesley entered the English house of commons as member for Beeralston. Soon afternard he was appointed a lord of the treasury by Pitt. In 1793 he became a member of the board of control over Indian affairs and in 1797 accepted the office of governor general of India. Wellesley seems to have caught Pitt's large political spirit during his intercourse with him from 1793 to 1797. That both had consciously formed the design of acquiring empire in India is not proved, but the rivalry with France made Wellesley's rule in India an epoch of enormous and rapid extension of English power. Clive won and Warren Hastings consolidated the British ascendancy in India. but Wellesley extended it into an empire. For the details of Wellesley's Indian policy see INDIA: History.

He found the East India company a trading body, he left it an imperial power. He was an excellent administrator, and sought to provide, by the foundation of the college of Fort William, for the training of a class of men adequate to the great work of governing India. A firm free trader, like Pitt, he endeavoured to remove some of the restrictions on the trade between England and India.

Both the commercial policy of Wellesley and his educational projects brought him into hostility with the court of directors. and he more than once tendered his resignation, which, however. public necessities led him to postpone till the autumn of 1805. He reached England just in time to see his friend Pitt before his death. He had been created an English peer in 1797, and in 1799 an Irish marquess.

On the fall of the coalition ministry in 1807 Wellesley was invited by George III to join the duke of Portland's cabinet, but he declined, pending the discussion in parliament of certain charges brought against him in respect of his Indian administration. Resolutions condemning him for the abuse of power were moved in both the lords and commons, but defeated by large majorities.

In 1809 Wellesley was appointed ambassador to .Spain. He landed at Cádiz just after the battle of Talavera, and endeavoured, but without success, to bring the Spanish government into effective co-operation with his brother in Portugal. A few months later Wellesley became foreign secretary in Perceval's cabinet. He retired in Feb. 1812, partly from dissatisfaction at the inadequate support given to Wellington by the ministry, but also because he was convinced that the question of Catholic emancipation was urgent. With the claim of the Irish Catholics to justice he henceforward identified himself.

On Perceval's assassination he refused to join Lord Liverpool's administration, and he remained out of office till 1821, criticizing with severity the proceedings of the congress of Vienna and the European settlement of 1814. He was one of the peers who signed the protest against the enactment of the corn laws in 1815.

In 1821 he was appointed lord lieutenant of Ireland. Wellesley's acceptance of the vice-royalty was believed in Ireland to herald the immediate settlement of the Catholic claims. But the hope of the Catholics still remained unfulfilled. On the assumption of office by Wellington, who was opposed to Catholic emancipation, his brother resigned the lord lieutenancy. He had, however, the satisfaction of seeing the Catholic claims settled in the next year by the very statesmen who had declared against them. In 1833 he resumed the office of lord lieutenant under Earl Grey's brief ministry. He died on Sept. 26, 1842.

Malleson, *Wellesley* in the "Statesmen Series" (1895); *The Wellesley Papers: Life and Correspondence of Richard Colley Wellesley by* the editor of "The Windham Papers," 2 vol. (1914).

WELLESLEY, a college town (township) of Massachusetts, U.S., in Norfolk county, lies on 10.5 sq.mi. of rolling terrain 15 mi. W. of Boston. The township population in the 1960s was about 26,000.

Originally a part of Dedham, the Wellesley area was included in Needham when that town was set off in 1711, and comprised its western precinct until 1881 when it was incorporated as a separate town. Its place name was an adaption of the family name of Samuel Welles, who settled in the area in 1763 and whose grandson-in-law H. Hollis Hunnewell purchased the Welles estate and named it Wellesley. The natural beauty of the area and its easy access to Boston led to a steady population growth in the late 19th and early 20th century although strict zoning restrictions have kept the nature of the town residential. The town is governed by representative town meeting.

The character of the town was greatly influenced by the existence of the liberal arts women's college which bears its name. The campus of more than 400 ac. bordering on Lake Waban was once the country estate of Mr. and Mrs. Henry Fowle Durant, who decided in 1860 to establish a female seminary that would "offer to young women opportunities for education equal to those usually provided in colleges for young men." The college received its charter from the state in 1870, and in 1875 mas opened to 314 students. Its resources and size grew steadily and by the 1960s more than 40 buildings provided facilities for the intellectual and community life of approximately 1,700 students and 170 faculty members. Fourteen buildings are residence halls for undergraduate students, who come from every state in the union and several foreign countries. In 1959 the Jewett Arts centre; containing facilities for fine arts, music and drama instruction., was opened.

Despite its large physical growth the essential nature of Wellesley college as a liberal arts institution has remained constant. Classes are kept small and programs of individual study based on a student's particular interests are encouraged.

Wellesley is also the site of the Babson Institute of Business Administration (1919), the Dana Hall schools and the Academy of the Assumption.

WELLESLEY COLLEGE, a liberal arts college for women in Wellesley, Mass., chartered March 17, 1870, as Wellesley Female seminary. See WELLESLEY.

WELLHAUSEN, JULIUS (1844–1918), German Old Testament scholar, one of the most famous names in biblical criticism of the 19th century and promulgator of the Graf-Wellhausen theory, which after 1878 produced a revolution in Old Testament criticism, was born in Hameln, Westphalia, on May 17, 1844. He studied under G. H. A. von Ewald (*q.v.*) at Göttingen and began his teaching career there in 1870. He received a professorship at Greifswald in 1872, but in that stronghold of Lutheran conservatism his position became difficult after the appearance of critical works from his pen, and so he resigned in 1882. Beginning again as *Privatdocent,* this time in the field of Semitic languages, which freed him from ecclesiastical persecution, he became professor at Marburg in 1885 and at Göttingen in 1892. Sadly he thereby was robbed of the opportunity to draw large numbers of students. Nonetheless he gained a following almost without parallel by the convincing demonstration that the basic document of the Pentateuch (the Priestly Document or P, as he called it) was the youngest rather than the oldest element in that composite work. Only then did it become possible to understand the evolution of the Old Testament religion. His demonstration gave vast stimulus to Old Testament research, and a great number of younger scholars carried the task further.

Wellhausen was not only a master of literary criticism, he also contributed to textual criticism. He was a student of Islam and produced important works in that field. In pre-Islamic heathenism he saw the best parallel to Hebrew life and thought at the nomadic stage.

In his later years Wellhausen contributed important work to the New Testament field—to the criticism of the Gospels, Acts and Revelation. The search for Aramaisms in New-Testament Greek was begun by him. He wrote trenchantly and concisely, disdaining to set forth anew what others had dealt with sufficiently.

Perhaps the literary critical approach of Wellhausen's day and school was not the last word: it has subsequently been supplemented by other approaches; in detail many results formerly held secure have been softened; and the ancient orient was not resurrected until after his revolutionary works appeared. Nonetheless, Wellhausen may still be considered to occupy a place in biblical studies comparable with that of Darwin in biology. He died Jan. 7, 1918.

His major works included *Geschichte Israels* (1878), republished as *Prolegomena zur Geschichte Israels* (1882; Eng. trans. 1885); *Die*

Konzposition des Hexateuch und der historischen Bücher des Alten Testaments (1889); *Israelitische und jüdische Geschichte* (1894); ***Einleitung in die drei ersen Evangelien*** (1905). Wellhausen kept alive Friedrich Bleek's *Einleitung in das Alte Testament,* eds. 4–6 (1878–93), by extensive alterations and additions. (E. G. Kr.)

See E. G. Kraelinp, *The Old Testament Since the Reformation,* pp. 94 ff. (1955); W. Baumgartner, "Wellhausen und der heutige Stand der alttestamentlichen Wissenschaft," *Theologische Rundschau,* pp. 287 ff. (1930).

WELLINGBOROUGH, a market town and urban district in the Wellingborough parliamentary division of Northamptonshire, Eng., between the Nene and the Ise. 10 mi. N.E. of Northampton. Pop. (1961) 30,579. Area 13.7 sq.mi. In 1935 the area was extended to include the urban district of Finedon and other lands. In 948 Edred gave the church at Wellingborough to Crowland (or Croyland) abbey, and the grant was confirmed by King Edgar in 966. The town received the grant of a market in 1201. It was formerly famed for chalybeate springs. After a disastrous fire in 1738 on a "fry-day," the town was built on its present site on the hill. Wellingborough school, founded in 1595, was endowed with the revenues of a suppressed guild. The staple industry is leather, chiefly gloves, boots and shoes. Other industries are brewing, flour milling. iron smelting and founding and rubber, plastic and foodstuff manufacture. The name was said to come from the wells but, from forms such as Wendlingburgh in 1220, it has been shown that the name meant "burg of Wendel's people."

WELLINGTON, ARTHUR WELLESLEY, 1st Duke of (1769–1852), was the fourth son of Garrett (1735–1781) Wellesley or Wesley, 2nd baron and 1st earl of Mornington, now remembered only as a musician. He was descended from the family of Colley or Cowley, which had been settled in Ireland for two centuries. The duke's grandfather, Richard Colley, 1st Baron Mornington (d. 1758), assumed the name of Wesley on succeeding to the estates of Garrett Wesley, a distant relative of the famous divine. In Wellington's early letters the family name is spelled Wesley; the change to Wellesley seems to have been made about 1790.

Arthur (born in Ireland in 1769[1]) was sent to Eton, and subsequently to a military college at Angers. He entered the army as ensign in the 73rd Highlanders in 1787, passed rapidly through the lower ranks (in five ditierent regiments), became major of the 33rd (now the duke of Wellington's Regt.) and purchased the lieutenant-colonelcy of that regiment in 1793 with money advanced to him by his eldest brother. But in all these changes he did little regimental duty, for he was aide-de-camp to the lord-lieutenant of Ireland for practically the whole of these years. Before reaching full age he was returned to the Irish parliament by the family borough of Trim.

His first experience of active service was in the campaign of 1794–95. when the British force under the duke of York was driven out of Holland by Pichegru. In 1796 he was sent with his regiment to India, being promoted colonel by brevet about the same time. It was thus as a commanding officer that he learned for the first time the details of regimental duty. He mastered them thoroughly — it was to the completeness of his practical knowledge that Wellington ascribed in great part his later success. It is probable, moreover, that he at this time made a serious study of the science of war.

As soon as he landed in India he began to devote fixed hours to study, giving up cards and the violin. This study was directed chiefly to the political situation of India, and when on his advice his eldest brother, Lord Mornington, afterwards Marquess Wellesley. accepted the governor-generalship of India. he became his trusted though unofficial adviser. In the war with Tippoo Sahib the 33rd was attached to the Nizam's contingent. and Colonel Wellesley commanded this division in the army of General Harris. Though his military services in this short campaign were not of a striking character, he was appointed by his brother to the supreme military and political command in Mysore, in spite of the claims of his senior, Sir David Baird.

His great faculties now for the first time found opportunity for their exercise. In the settlement and administration of the conquered territory he rapidly acquired the habits and experience of a statesman, while his military operations against Doondiah, a robber chief, were conducted with extraordinary success.

When pressed in Mysore, Doondiah moved into Mahratta territory. whither Wellesley followed him. Here, negotiating and bargaining with the Mahratta chiefs, Wellesley acquired a knowledge of their affairs and an influence over them such as no other Englishman possessed.

Simple and honourable himself, he was shrewd and penetrating in his judgment of Orientals; and, unlike his great predecessor Clive. he rigidly adhered to the rule of good faith in his own actions, however depraved and however exasperating the conduct of those with whom he had to deal. The result of Wellesley's singular personal ascendancy among the Mahrattas came into full view when the Mahratta War broke out. In the meantime, however! his Indian career seemed likely to be sacrificed to the calls of warfare in another quarter. Wellesley was ordered with a body of troops to Egypt. But at Bombay he was attacked by fever, and prevented from going on. The troop-ship in which he was to have sailed went down with all on board.

He returned in May 1801 to Mysore, where he remained until the Mahratta War broke out. Wellesley, now a major-general, was placed in command of a division of the army charged with the task of restoring the Peshwa, overthrown by his rival, to power. Starting from Seringapatam, he crossed the frontier on March 12, 1803, and moved on Poona. The march was one unbroken success, thanks to Wellesley's forethought and sagacity in dealing with the physical conditions and his personal and diplomatic ascendancy among the chieftains of the district. A march of 600 m. was conducted without even a skirmish. The Peshwa was restored.

Sindhia and Holkar, with the raja of Berar, maintained a doubtful but threatening aspect farther north. It was uncertain whether or not a confederacy of the northern Mahrattas had been formed against the British Government. Wellesley was charged with "the general direction and control of military and political affairs in the territories of the Nizam, the Peshwa and the Mahratta states and chiefs." Armed with these powers, he required Sindhia, as a proof of good faith, to withdraw to the north of the Nerbudda. Sindhia not doing so, war was declared on Aug. 6, 1803, and Wellesley moved against the enemy. A second division was to converge from the east, but on Sept. 23 Wellesley suddenly found that the combined forces of Sindhia and the raja of Berar were close in front of him at Assaye. Weighing the dangers of delay, of retreat and of an attack with his single division of 4,500 men, supported only by 5,000 native levies of doubtful quality, Wellesley convinced himself that an immediate attack, though against greatly superior forces (30,000 horse, 10,000 European-drilled infantry and 100 well-served guns) in a strong position, was the wisest course. He threw himself upon the Mahratta host, and, carrying out a bold manoeuvre under an intense fire, ultimately gained a complete victory, though with heavy loss. In comparison with the battle of Assaye, all fighting that had hitherto taken place in India was child's play. Wellesley brought the war to a close by a second victory at Argaum on Nov. 29 and the storming of Gawilghur on Dec. 15. The treaties with Sindhia and the raja of Berar, which marked the downfall of the Mahratta power, were negotiated and signed by Wellesley—not yet 35 years old.

His ambitions now led him back to Europe, and in the spring of 1805 he quitted India. After being sent on the abortive expedition to Hanover, he was elected M.P. for Rye, in order to defend his brother in the House, and in the following year he was Irish secretary for a few months. He was then employed in the expedition against Copenhagen, in which he defeated the Danes in the action of Kjoge (Oct. 29). In 1808, however, began the war (*see* Peninsular War) in which his military renown was fully established. In April he was promoted lieutenant-general and placed in command of a division of the troops destined to operate against the French in Spain or Portugal. He landed at Mondego bay in the first week of August, moved southwards, and on the 21st won the battle of Vimeiro. In the midst of this

[1]At 24 Upper Merrion Street, Dublin, or at Dungan castle, Meath, on April 29 or on May 1; but both place and date are uncertain.

engagement, however, Sir Harry Burrard landed, and took over the command. Burrard was in turn superseded by Sir Hew Dalrymple, and the campaign ended with the convention of Cintra, which provided for the evacuation of Portugal by the French, but gave Junot's troops a free return to France. So great was the public displeasure in England at the escape of the enemy that a court of inquiry was held. After the battle of Corunna, Wellesley, who had in the meantime resumed his duties as Irish secretary, returned to the Peninsula as chief in command. He drove the French out of Oporto, and then prepared to march against Madrid. He had the support of a Spanish army, but his movements were delayed by the neglect of the Spanish Government, and Soult was able to collect a large force for the purpose of falling upon the English line of communication. Wellesley, unconscious of Soult's presence on his flank, advanced against Madrid, and defeated his immediate opponent, King Joseph, at Talavera de la Reina (*q.v*) on July 27–28. But within the next few days Soult's approach on the line of communication was discovered, and Wellesley, disgusted with his Spanish allies, had no choice but to withdraw into Portugal.

A peerage was conferred upon him for Talavera. He was also made marshal-general of the Portuguese army and a Spanish captain-general. But his conduct after the battle was sharply criticized in England, and its negative results were used as a weapon against the ministry. Even on the defensive, Wellington's task was exceedingly difficult. Austria having made peace, Napoleon was at liberty to throw heavy forces into the Peninsula. Wellington, foreseeing that Portugal would now be invaded by a very powerful army, began the fortification of the celebrated lines of Torres Vedras. (See FORTIFICATION.)

As summer approached Masséna moved against Portugal with 70.000 men. Wellington, unable to save Ciudad Rodrigo, retreated down the valley of the Mondego, devastating the country, and pausing to inflict a check on the French at Bussaco. Masséna continued to press forward but was held up definitely in front of the lines. It was with the utmost difficulty that he could keep his army from starving. At length, when the country mas exhausted. he fell back to Santarem. In the spring of 1811 Wellington received reinforcements and moved forward. Masséna retreated, but such were the sufferings of his army, both in the invasion and in the retreat, that the French, when they re-entered Spain, had lost 30,000 men. Public opinion in England, lately so hostile, now became confident, and Wellington, whose rewards for Talavera had been opposed in both Houses, began to be a hero.

In the meantime Soult, who was besieging Cadiz, had moved to support Masséna. But after capturing Badajoz, Soult learnt that Masséna was in retreat, and in consequence returned to the south. Wellington, freed from pressure on this side, and believing Masséna to be thoroughly disabled, considered that the time had come for an advance into Spain. The fortresses of Almeida, Ciudad Rodrigo and Badajoz barred the roads. Almeida was besieged, and Wellington was preparing to attack Badajoz when Masséna again took the field, and marched to the relief of Almeida. The battle of Fuentes d'Onoro followed, in which Wellington was only able to extricate the army from a dangerous predicament which "if Boney had been there" would have been a disaster. His attack on Badajoz and Ciudad Rodrigo failed.

Wellington had from the first seen that, whatever number of men Napoleon might send against him, it was impossible, owing to the poverty of the country, that any great mass of troops could long be held together, and that the French, used to "making war support war," would fare worse in such conditions than his own troops with their organized supply service. It was so at the end of 1811. Soult had to move southwards to live, and the English were again more than a match for the enemy in front of them. Wellington resumed the offensive early in 1812, took by storm Ciudad Rodrigo and Badajoz, although with terrible loss, and then advanced into Spain. Marmont, who had succeeded Masséna, fell back to the Donro, but there turned upon his assailant, and, by superior swiftness, threatened to cut the English off from Portugal. Wellington retreated as far as Salamanca (*q.v.*), and there extricated himself from his peril by a brilliant victory (July 22). Instead of immediately following the French, Wellington thought it wise to advance upon the Spanish capital. King Joseph retired, and the English entered Madrid in triumph. The political effect was great, but the delay gave the French northern army time to rally. "The vigorous following of a beaten enemy was not a prominent characteristic of Lord Wellington's warfare," as Napier says. Moreover, Soult, raising the siege of Cadiz, pressed towards Madrid. Wellington was compelled once more to retire into Portugal. During this retreat he announced in general orders that the demoralization and misconduct of the British army surpassed anything that he had ever witnessed. Such wholesale criticism was bitterly resented, but indeed throughout his career Wellington, cold and punctilious, never secured to himself the affections of officers and men as Marlborough or Napoleon did. He subjugated his army and gave it brilliant victories, but he inspired few disciples except the members of his own staff. For Salamanca his rewards included a marquessate.

He was now invested with the supreme command of the Spanish armies, and, after busying himself with preparations, in May 1813 the hour for his final and victorious advance arrived. The Russian disasters had compelled Napoleon to withdraw some of his best troops from the Peninsula. Against a weakened and discouraged adversary Wellington took the field with greatly increased numbers and with the utmost confidence. Position after position was evacuated by the French, until Wellington came up with the retreating enemy at Vittoria, and won an overwhelming victory (June 21). Soult's combats in the Pyrenees, and the desperate resistance of St. Sebastian, prolonged the struggle through the autumn, and cost the English thousands of men. But at length the frontier was passed, and Soult forced back into his entrenched camp at Bayonne. Both armies now rested for some weeks, during which interval Wellington gained the confidence of the inhabitants by his unsparing repression of marauding. his business-like payment for supplies. and the excellent discipline which he maintained. In Feb. 1814 the advance was renewed. The Adour was crossed, and Soult was defeated at Orthes. At Toulouse, after the allies had entered Paris, but before the abdication of Napoleon had become known, the last battle of the war was fought. Peace being proclaimed, Wellington took leave of his army at Bordeaux, and returned to England, where he was created duke of Wellington.

After the Treaty of Paris (May 30) Wellington was appointed British ambassador at the French capital. During the autumn and winter of 1814 he reported the mistakes of the restored Bourbon dynasty, and warned his Government of the growing hostility to it. His insight, however, did not extend beyond the circumstances immediately before and around him, and he failed to realize that the great mass of the French nation was still with Napoleon at heart. He remained in France until Feb. 1815, when he took part in the congress of Vienna. His imperfect acquaintance with French feeling was strikingly proved in the despatch which he sent home on learning of Napoleon's escape from Elba. "He has acted," he wrote, "upon false or no information, and the king (Louis XVIII.) will destroy him without difficulty and in a short time." Almost before Wellington's unfortunate prediction could reach London, Louis had fled, and France was at Napoleon's feet. The ban of the congress, however, went out against the common enemy, and the presence of Wellington at Vienna enabled the allies at once to decide upon their plans for the campaign. To Wellington and Blücher were committed the invasion of France from the north, while the Russians and Austrians entered it from the east. But Napoleon outstripped the preparations of his adversaries, concentrated his main army on the northern frontier, and on June 14 crossed the Sambre. The four days' campaign that followed, and the crowning victory of June 18, are described in the article WATERLOO CAMPAIGN. Wellington's reward was a fresh grant of £200,000 from parliament—he had already received £500,000 for the Peninsular War, the title of prince of Waterloo and great estates from the king of Holland, and the order of the Saint-Esprit from Louis XVIII.

Not only the prestige of his victories, but the chance circumstances of the moment, now made Wellington the most influential personality in Europe. The emperors of Russia and Austria were still far away at the time of Napoleon's second abdication, and it was with Wellington that the commissioners of the provisional Government opened negotiations preliminary to the surrender of Paris. The duke well knew the peril of delaying the decision as to the Government of France. The emperor Alexander was hostile to Louis XVIII. and the Bourbons generally; the emperor Francis might have been tempted to support the cause of Napoleon's son and his own grandson, who had been proclaimed in Paris as Napoleon II.; and if the restoration of Louis—which Wellington believed would alone restore permanent peace to France and to Europe—was to be effected, the allies must be confronted on their arrival in Paris with the accomplished fact. He settled the affair in his usual downright manner, telling the commissioners bluntly that they must take back their legitimate king, and refusing—perhaps with more questionable wisdom—to allow the retention of the tricolour flag, which to him was a "symbol of rebellion."

Further, it was mainly owing to the influence of Wellington, in conjunction with Castlereagh, that France escaped the dismemberment for which the German powers clamoured, and which was advocated for a while by the majority of the British cabinet. Wellington realized the necessity, in the interests not only of France but of Europe, of maintaining the prestige of the restored monarchy, which such a dismemberment would have irretrievably damaged. In the same spirit he carried out the trust imposed upon him by the allies when they placed him in command of the international army by which France was to be occupied, under the terms of the second peace of Paris, for five years. By the terms of his commission he was empowered to act, in case of emergency, without waiting for orders; he was, moreover, to be kept informed by the French cabinet of the whole course of business. If he had no sympathy with revolutionary disturbers of the peace, he had even less with the fatuous extravagances of the comte d'Artois and his reactionary *entourage,* and his immense powerful influence was thrown into the scale of the moderate constitutional policy of which Richelieu and Decazes were the most conspicuous exponents. Besides the complex administrative duties connected with the army of occupation his work included the reconstruction of the military frontier of the Netherlands, and the conduct of the financial negotiations with Messrs. Baring, by which the French Government was able to pay off the indemnities due from it, and thus render it possible for the powers to reduce the occupation from five years to three.

The events of the next few months considerably modified his opinions in this matter. The new chambers proved their trustworthy quality by passing the budget, and the army of occupation was reduced by 30,000 men. Wellington now pressed for the total evacuation of France, pointing out that popular irritation had grown to such a pitch that, if the occupation were to be prolonged, he must concentrate the army between the Scheldt and the Meuse, as the forces, stretched in a thin line across France, were no longer safe in the event of a popular rising. At the congress at Aix-la-Chapelle in the autumn of 1818, which settled the question, it was owing to his common-sense criticism that the proposal of Prussia, supported by the emperor Alexander and Metternich, to establish an "army of observation" at Brussels, was nipped in the bud. The definitive financial settlement between France and the allies was left entirely to him.

On Wellington's first entry into Paris he had been received with popular enthusiasm, but he had soon become intensely unpopular. He was held responsible not only for the occupation itself, but for every untoward incident to which it gave rise; even Blucher's attempt to blow up the Pont de Jéna, which he had prevented, was laid to his charge. His characteristically British temperament was wholly unsympathetic to the French, whose sensibility was irritated by his cold and slightly contemptuous justice. Two attempts were made to assassinate him. His work in Paris, however, was now finished, and on Oct. 30 he took leave of the international troops under his command. On Oct. 23, while still at Aix, he had received an offer from Lord Liverpool of the office of master-general of the ordnance, with a seat in the cabinet. He accepted, though with some reluctance.

He organized the military forces held in case of a Radical rising. It was his influence with George IV. that led to the readmittance of Canning to the cabinet after the affair of the royal divorce had been settled. It was only in 1822, however, that the tragic death of his friend Londonderry (Castlereagh) brought him once more into international prominence. Londonderry had been on the eve of starting for the conference at Vienna—later adjourned to Verona—and the instructions which he had drawn up for his own guidance were handed over by Canning, the new foreign secretary, to Wellington, whose official part at the congress is outlined elsewhere. (*See* VERONA, CONGRESS OF.) Unofficially, he pointed out to the French plenipotentiaries, arguing from Napoleon's experience, the extreme danger of an invasion of Spain, but at the same time explained, for the benefit of the duke of Angoulême, the best way to conduct a campaign in the Peninsula.

Wellington disliked Canning's aggressive attitude towards the autocratic powers, and viewed with some apprehension his determination to break with the European concert. He realized, however, that in the matter of Spain and the Spanish colonies the British Government had no choice, and in this question he was in complete harmony with Canning. This was also at first the case in respect to the policy to be pursued in the Eastern Question raised by the war of Greek independence. Both Canning and Wellington were anxious to preserve the integrity of Turkey, and therefore to prevent any isolated intervention of Russia; and Wellington seemed to Canning the most suitable instrument for the purpose of securing an arrangement between Great Britain and Russia on the Greek question, through which it was hoped to assure peace in the East. In Feb. 1826, accordingly, the duke was sent to St. Petersburg (Leningrad), ostensibly to congratulate the emperor Nicholas I. on his accession, but more especially—to use Wellington's own words—"to induce the emperor of Russia to put himself in our hands." In this object he signally failed. As a diplomatist the "Iron Duke"—whom Nicholas, writing to his brother Constantine, described as "old and broken (*cassé*)"—was no match for the "Iron Tsar." As for the Greeks, the emperor said bluntly that he took no interest in *ces messieurs,* whom he regarded as "rebels"; his own particular quarrel with Turkey was the concern of Russia alone. Under stress of the imminence of the peril. which Nicholas was at no pains to conceal, the duke was driven from concession to concession, until at last the tsar, having gained all he wanted, condescended to come to an arrangement with Great Britain on the Greek question. On April 4 was signed the Protocol of St. Petersburg, an instrument which—as events were to prove—fettered the free initiative not of Russia. but of Great Britain. (*See* TURKEY: *History;* GREECE: *History.*)

After the death of the duke of York on January 5, 1827, the post of commander-in-chief was conferred upon Wellington. His relations with Canning had, however, become increasingly strained, and when, in consequence of Lord Liverpool's illness. Canning in April 1827 was called to the head of the administration. the duke refused to serve under him. The effect of his withdrawal was momentous in its bearing upon Eastern affairs. Canning, freed from Wellington's restraint, carried his intervention on behalf of Greece a step further. and concluded the Treaty of London, whereby France, England and Russia bound themselves to put an end to the conflict in the East and to enforce the conditions of the St. Petersburg protocol upon the belligerents. Against this treaty Wellington protested, on the ground that it involved war. The battle of Navarino followed.

Canning died on Aug. 8. 1827. and was succeeded as premier by Lord Goderich. The duke was at once again offered the post of commander-in-chief. which he accepted on Aug. 17. On the fall of Lord Goderich's cabinet five months later Wellington became prime minister (Jan. 9. 1828). He had declared some time before that it would be an act of madness for him to take this post; but his sense of public duty led him to accept it when it was pressed upon him by the king. His cabinet included at first Huskisson, Palmerston and other followers of Canning. The repeal of the Test and Corporation Acts having been carried in the House of Commons in the session of 1828, Wellington, to the great disappointment of Tories like Lord Eldon, recommended the House of Lords not to offer further resistance, and the measure was accordingly carried through. In May Huskisson and Palmerston voted against the Government in the East Retford question; Huskisson resigned. and the other liberal members of the ministry followed suit. It was now hoped by the so-called

Protestant party that Wellington, at the head of a more united cabinet. mould offer a steady resistance to Catholic emancipation. Never were men more bitterly disappointed. The Clare election and the progress of the Catholic Association convinced both Wellington and Peel that the time had come when Catholic emancipation must be granted; and, submitting when further resistance would have led to civil war, the ministry itself brought in at the beginning of the session of 1829 a bill for the relief of the Catholics in the face of opposition from the king and from Wellington's own supporters. Wellington, who had hitherto always opposed Catholic emancipation, explained and justified his change of front in simple and impressive language. He had, however, to challenge the Earl of Winchelsea to a bloodless duel. No mischief resulted from the encounter.

As soon as Catholic emancipation was carried, the demand for parliamentary reform and extension of the franchise .agitated Great Britain from end to end. The duke was ill informed as to the real spirit of the nation. He conceived the agitation for reform to be a purely fictitious one, worked up by partisans and men of disorder in their own interest. Wholly unaware of the strength of the forces which he was provoking, the duke, at the opening of the parliament which met after the death of George IV, declared against any parliamentary reform whatever. This declaration led to the immediate fall of his Government. Lord Grey, the chief of the new ministry, brought in the Reform bill, which was resisted by Wellington as long as anything was to be gained by resistance. When the creation of new peers was known to be imminent, however, Wellington was among those who counselled the abandonment of a hopeless struggle. His opposition to reform made him for a while unpopular. He was hooted by the mob on the anniversary of Waterloo, and considered it necessary to protect the windows of Apsley House with iron shutters.

For the next two years the duke was in opposition. On the removal of Lord Althorp to the House of Lords in 1834, William IV unexpectedly dismissed the Whig ministry and requested Wellington to form a cabinet. The duke. however, recommended that Peel should be at the head of the government, and served under him. during the few months that his ministry lasted, as foreign secretary. On Peel's later return to power in 1841 Wellington was again in the cabinet, but without departmental office beyond that of commander-in-chief. He supported Peel in his Corn-Law legislation, and throughout all this later period, whether in office or in opposition, gained the admiration of discerning men and excited the wonder of zealots by his habitual subordination of party spirit and party connection to whatever appeared to him the real interest of the nation. On Peel's defeat in 1846 the duke retired from active public life. Nearly 80, his organization of the military force in London against the Chartists in April 1848 and his letter to Sir John Burgoyne on the defenses of the country proved that the old man had still something of his youth. But the general character of Wellington's last years was rather that of the old age of a great man idealized. He died on Sept. 14, 1852, and was buried under the dome of St. Paul's.

BIBLIOGRAPHY.—The *Wellington Despatches,* ed. by Gurwood; *Supplementary Despatches;* and *Wellington Despatches, New Series,* ed. by the 2nd duke of Wellington. Unlike Napoleon's dispatches and correspondence, everything from Wellington's pen is absolutely trustworthy. Almost all the political memoirs of the period 1830–50 contain more or less about Wellington in his later life. Those of Greville and Croker have perhaps most of interest. A good deal of information, from the unpublished Russian archives, is given in F. F. de Martens' *Recueil des traités conclus par la Russie. See* also Sir Herbert Maxwell, *Life of Wellington,* 2 vol. (1900); J. W. Fortescue, *Wellington* (1925); literature of the Peninsular War (*q.v.*), Waterloo Campaign (*q.v.*).

WELLINGTON, a market town and urban district in the Taunton parliamentary division of Somerset, Eng., 7 mi. W.S.W. of Taunton. Pop. (1961) 7,523. Area 3.5 sq.mi. The 1st duke of Wellington is commemorated by a monument (National Trust property) on the highest point of Blackdown hills. 23 mi. S. At its foot is Wellington school, founded in 1841. The town produces woolen goods, bedding and milk products. There is also a Wellington in Shropshire; Wellington college is in Berkshire.

WELLINGTON, capital of New Zealand, on the southern shores of the natural harbour of Port Nicholson in North Island. Area 27.6 sq.mi. Pop. (1961) 123.696. The harbour, one of the finest in the world, extends over 32 sq.mi., with depths varying from 6 to 14 fathoms. It was discovered early in the 10th century by Kupe, the celebrated Polynesian navigator, who landed but found the place uninhabited. Eight centuries later in 1773 Capt. James Cook sailed through the strait which now bears his name but did not enter the harbour.

Wellington was named after the 1st duke of Wellington and the first settlement of New Zealand colonists was founded in 1840 under the auspices of the New Zealand company. The capital of New Zealand was transferred to Wellington from Auckland in 1865. Politically. commercially and geographically Wellington is the most important city in New Zealand; it is a busy passenger and freight terminal as the greater part of rail, road, sea and air traffic passes through the city for redirection to other centres. As a chief port, Wellington vies with Auckland and the city contains the head offices of many banks, shipping companies, insurance companies and mercantile houses of the dominion. Main railway lines link Wellington with Auckland, Napier and New Plymouth and there are regular air services to various cities and towns in both North Island and South Island. There is a fast overnight steamer-ferry service to Lyttleton, the port of Christchurch, in South Island.

The principal public buildings include the houses of parliament, town hall, railway station, the National Art gallery and Dominion museum and many large modern structures housing government departments. Among the city's many fine educational institutions is Victoria university, one of the four universities of the dominion, established in 1897. The business section of the city is mainly situated on land reclaimed from the harbour after 1866. The residential suburbs extend over the surrounding hills and out to the seaside bays fronting Cook strait. Necessary open space, however, was retained in the form of 1,000 ac. of town belt skirting the hill tops and slopes and which, by the foresight of the early settlers, by statute was preserved for all time for the enjoyment and recreation of citizens. In addition, there are many public parks and recreation grounds. The Wellington City corporation, which is one of the largest combined local authorities in the southern hemisphere. owns the public transport, water supply and drainage systems and controls the electrical distribution. public libraries, cemeteries, recreation areas, public baths, abattoir, zoo and municipal airport, also the milk treatment and distribution service, the first in the world to be municipally established and controlled. (B. O. PN.)

WELLS, CHARLES JEREMIAH (1798?–1879), English poet, was born in London, probably in the year 1798. He was educated at Cowden Clarke's school at Edmonton, with Tom Keats, the younger brother of the poet, and with R. H. Horne. He met John Keats, but later quarreled with him.

In 1822 he published *Stories After Nature,* and in 1823, under the pseudonym of H. L. Howard, *Joseph and His Brethren.* For the next three years Wells saw Hazlitt, as he said, "every night," but in 1827 the two men were estranged. Wells was then practising as a solicitor in London. but he went to live in the country, first in south Wales and then at Broxbourne, Hertfordshire, on account of his health. In 1840 he left England for good. He settled at Quimper in Brittany, where he lived for several years. A story called *Claribel* appeared in 1845, and one or two slight sketches later, but several tragedies and a great deal of miscellaneous verse belonging to these years are lost. \Tells stated in a letter to Horne (Nov. 1877) that he had composed eight or ten volumes of poetry during his life, but that, having in vain attempted to find a publisher for any of them, he burned the whole mass of manuscripts at his wife's death in 1874 The only work he had retained was a revised form of *Joseph and His Brethren,* which was praised in 1838 by Wade, and again with great warmth, by Horne. in his *New Spirit of the Age,* in 1844. The drama was then once more forgotten, until in 1863 it was read and vehemently praised by D. G. Rossetti. The tide turned at last; *Joseph and His Brethren* became a kind of shibboleth—a rite of initiation into the true poetic culture—but still the world at large remained indifferent. Swinburne wrote an eloquent study of it in the *Fortnightly Review* in 1875, and the drama itself was reprinted in 1876. Between 1876 and 1878 Wells added various scenes, which are in the possession of Buxton Forman, who published one of them in 1895. After leaving Quimper, Wells went to reside at Marseilles, where he held a professorial chair. He died on Feb. 17, 1879.

The famous *Joseplz and His Brethren,* concerning which criticism has recovered its self-possession. is an overgrown specimen of the pseudo-Jacobean drama in verse which was popular in ultrapoetical circles between 1820 and 1830. Its merits are those of rich versification, a rather florid and voluble eloquence and a subtle trick of reserve, akin to that displayed by Webster and Cyril Tourneur in moments of impassioned dialogue.

In 1909 a reprint was published of *Joseph and His Brethren,* with Swinburne's essay and reminiscences by T. Watts-Dunton.

WELLS, DAVID AMES (1828–1898), U.S. economist, was born in Springfield, Mass., on June 17, 1828. He graduated at Williams college in 1847 and at the Lawrence scientific school, becoming assistant professor in 1851. In 1850–65 he published with George Bliss an *Annual of Scientific Discovery.* His essay on the national debt, *Our Burden and Our Strength* (1864), secured him the appointment in 1865 as chairman of the national revenue commission, which laid the basis of scientific taxation in the United States. In 1866–70 he was special commissioner of revenue and published important annual reports; during these years he became an advocate of free trade. The creation of a federal bureau of statistics in the department of the treasury was largely due to his influence. In 1871 he was chairman of the New York state commission on local taxation. He did good work in the reorganization of the Erie and the Alabama and Chattanooga railroads and on the board of arbitration for railroads. In 1877 he was president of the American Social Science association. He died in Norwich, Conn.. on Nov. 5, 1898. He edited many scientific textbooks, and wrote *Robinson Crusoe's Money* (1876), *Our Merchant Marine* (1882), *A Primer of Tariff Reform* (1884), *Practical Economics* (1885), *Recent Economic Changes* (1889), *The Relation of the Tariff to Wages* (1888) and *The Theory and Practice of Taxation* (1900), edited by W. C. Ford.

WELLS, HENRY (1805–1878), pioneer U.S. expressman, was born in Thetford, Vt., on Dec. 12, 180;. About 1841 he became agent for Harnden's express at Albany, N.Y. Within two years he established Livingston, Wells & Pomeroy's express, Albany to Buffalo, with himself as messenger. He carried letters for six cents each, one-quarter of the government rate. His services expanded, and with various partners he soon was operating from New York to St. Louis and to Bangor, Me. In 1850 he was a leader in merging several lines into the Xmerican Express company, and was its head for 18 years. In 1852, with William Fargo (*q.v.*), he organized Wells, Fargo & Company to serve the California gold fields and the growing west. Surviving a great panic in 1855, \\'ells, Fargo grew rapidly. It furnished a mail, courier, and banking service that came to include stagecoach lines from Sacramento to Salt Lake City, to Portland, Ore., and to many developing gold areas. In 1861 Wells and associates bought the famous pony express and operated it as a Wells Fargo enterprise in its closing months. In 1866 they added Ben Holladay's prairie and Rocky mountain section to Wells Fargo's overland stagecoach mail service.

In 1868 Wells founded Wells seminary, later Wells college for women, at Aurora. N.Y. He died in Glasgow, Scot.. on Dec. 10, 1878. (N. C. W.)

WELLS, HERBERT GEORGE (1866–1946), English novelist, journalist. sociologist and popular historian, a powerful influence in the movement which worked toward the breakdown of the 19th-century outlook in economics, moral and religious belief. He was born at Bromley. Kent. on Sept 21, 1866. His father. Joseph Wells. was the proprietor of a small china shop, nho for tno seasons had played professional cricket. and his mother had been a lady's maid. Wells grew up under the continual threat of poverty, and at the age of 14, after only the sketchiest education, he was apprenticed to a draper in Windsor, a position he liked so little that he ran away. Later he made several more false starts in life, as a chemist's assistant, as a draper again and lastly as an usher at Midhurst Grammar school. There he first found opportunity to read. so that at 18 he won a scholarship to study biology at the Normal School of Science. South Kensington. London. where Thomas Henry Huxley was one of his teachers. He graduated from London university in 1888.

For several years he lived in considerable hardship, first as a student and then as a teacher of science, his financial worries being increased by ill-health and by his marriage (1891) to his cousin Isabel Mary Wells. This marriage was not successful and in 1894 Wells joined Amy Catherine Robbins, who later became his second wife. Meanwhile, he had turned to journalism and in 1895 produced his first novel. *The Time Machine,* a story of travel into the remote future. The novel was successful at once, and soon he began to produce a series of scientific romances which established him as a writer of startling originality. *The Wonderful Visit* (1895), *The Island of Doctor Moreau* (1896), *The Invisible Man* (1897), *The War of the Worlds* (1898), *The First Men in the Moon* (1901) and *The Food of the Gods* (1904) followed. together with many short stories collected under such titles as *The Stolen Bacilius* (1895), *The Plattner Story* (1897) and *Tales of Space and Ttme* (1899). In all these Wells showed an immense fecundity of ideas. a virtuosity of biological and astronomical fancy that passed far beyond the comparatively mechanical inventions of Jules Verne.

Behind this virtuosity, moreover, lay a passionate concern for man and society, and it was this concern that eventually led him to abandon fantasy for the realistic comedy of lower middle-class life represented by *Love and Mr. Lewisham* (1900), *Kipps* (1905) and *The History of Mr. Polly* (1910). In these three novels, together with *Tono-Bungay* (1909), Wells reached his highest achievement as a novelist. Here. drawing on memories of his early life, he was able to make himself the spokesman for the inarticulate and the frustrated, revealing nith rare sympathy their aspirations and disappointments, their muddled tenderness and distorted dreams of beauty. Here, too, he made his liveliest and most persuasive comment on the social predicament which was soon to become his main preoccupation. For belief in the biological theory of the evolution of the species had led him to a vision of a society which was evolving, more or less inevitably, toward utopia—a conception presented in *Anticipations* (1901), *Mankind in the Making* (1903) and *A Modern Utopia* (1905). About this time, too. he became an active socialist, joining the Fabian society in 1903, though soon he began to criticize the methods of the Fabians and was led to present his own idea of socialism in such works as *New Worlds For Old* (1908) and *First and Last Things* (1908; rev. 1917).

From then onward, the pamphleteer and the novelist mere in conflict in Wells, and only *The History of Mr. Polly,* considered by many to be his masterpiece, and the lighthearted *Bealby* (1915) can be considered primarily as fiction. The rest of his novels are mainly discussions or illustrations of various social and intellectual problems. presented, nevertheless. with enthusiasm, humour and flashes of his old skill in portraiture. *Ann Veronica* (1909), *The New Machiavelli* (1911), *Marriage* (1912), *The Wife of Sir Isaac Harman* (1914), *The Research Magnificent* (1915) and *Joan and Peter* (1918) all belong to this category. while *Mr. Britltng Sees It Through* (1916), in spite of prejudice and shortsightedness, gives a brilliant picture of the English people during World War I. About this time Wells found himself turning to a belief in the transcendental—a belief nhich he afteraard renounced. *God: the Invisible King* (1917) and a novel. *The Soul of a Bishop* (1917), are the chief productions of this phase, together nith *The Undying Fire* (1919), a modernized version of the Book of Job.

The war had shaken Wells's faith in the inevitable progress of man and now, turning to his conception of the evolution of society. he put forth the proposition that man could progress only if he adapted himself to his changing environment. To help this adaptation, he began his great work of popular education. of which the main productions were *The Outline of History* (1920; rev. 1931), *The Science of Life* (1931), written in collaboration with Julian Huxley and G. P. Wells, and *The Work, Wealth and Happiness of Mankind* (1932). At the same time, he continued to produce fiction in which, however, his imaginative gifts were almost entirely subordinated to argument. *The World of William Clissold* (1926) carried the "discussion novel" to its furthest possible development, being little more than a huge collection of the tenets and opinions of its unamiable central character. Indeed, during this period Wells's literary powers are to be seen less in his novels than in the reminiscences of *Experiment in Autobiography* (1934).

In 1933 he published a novelized version of a film script, *The Shape of Things to Come,* which was a reversal to the utopianism of his earlier work, but. on the whole, his outlook grew less optimistic. Some of his later novels contained much that was bitterly satirical: *Mu. Blettsworthy on Rampole Island* (1928), for instance, and *The Autocracy of Mr. Parham* (1930). His *Experiment in Autobiography* appeared in 1934. In the succession of short novels and fables that appeared during the 1930s there was an increasingly pessimistic awareness of the tragic dangers of the future. *The Croquet Player* (1936), *The Brothers* (1938) and *The Holy Terror* (1939) are typical in various ways of this new development of Wells's thought. He was ill and aging and. with the outbreak of World War II, he lost all confidence in man. In *Tlze Outlook For Honzo Sapiens* (1942) and *Mind at tlte End of Its Tether* (1945) he depicted a bleak vision of a world in which nature had rejected man and was destroying him. He died on Aug. 13.1946.

In spite of the pessimism of his old age, Wells is remembered chiefly as the prophet of that period of optimism and experiment that preceded World War I. No other writer caught so vividly its energy, its adventurousness, its sense of release from the conventions of Victorian thought. His influence was enormous. both on his own generation and on that which followed. Few did more to incite revolt against Christian dogma or against the accepted codes of behaviour, especially in matters of sex, in which, both in his writings and in his personal life, he was a persistent advocate of an almost completely amoral freedom. In many matters Wells was hasty, ill-tempered and contradictory, yet he was undeviating and fearless in his fight for social equity, world peace and for what he considered to be the future good of mankind.

As a creative writer his reputation rests on his scientific romances and on the comic novels of his middle period. The first achieve a near poetry which make them part of the popular mythology of their age; the latter are among the finest contributions of the 19th century to the realist tradition of the English novel. Wells's style lacked grace, his psychology lacked subtlety. but the best of his work has a vitality, a verve. an imaginative compulsion unsurpassed by any of his contemporaries.

WELLS, HORACE (1815–1848), U.S. dental surgeon. was born at Hartford, Vt., Jan. 21, 1815. He studied dentistry in Boston, 1834. and began practice in Hartford, Conn. In 1840 he first expressed the idea that teeth might be extracted painlessly by the application of nitrous oxide gas. He tested the efficacy of the gas in this operation on his own person in 1844 and afterward frequently used it in his practice. He was long thought to have been the first to use an anesthetic in any operation. and, though he was preceded by Crawford Long (*q.v.*), he deserves the credit of an independent discovery, which through him was first brought to attention. He died in New York city, Jan. 24. 1848.

See "Life and Letters of Horace Wells, Discoverer of Anesthesia," *J.Am.Coll.Dentists,* vol. 4, no. 2, pp. 81–210 (June 1944).

WELLS (THEODUNUM, FONTICULI, TIDINGTON, WELLIAE, WELLE). a city and municipal borough in the Wells parliamentary division of Somerset, Eng., 21 mi. S. of Bristol by road. Pop. (1961) 6.691. Area 2.1 sq.mi. It lies below the Mendip hills and derived its present name from St. Andrew's wells, which during the middle ages were thought to have curative properties. There was a Roman settlement there.

During Saxon times Wells was one of the most important towns of Wessex. King Ine (688–726) built a church there, and in 909 Wells was made the seat of a bishopric by Edward the Elder. In 1088 John de Tours (or de Villula) removed the see to Bath. After struggles between the secular clergy of Wells and the regulars of Bath, it mas arranged in 1242 that the bishop should take the title of "Bath and Wells" and should be elected by representatives of the monks of Bath and of the canons of Wells. This arrangement continued until the suppression of the monasteries in 1539 when the election remained with the chapter of Wells, the bishop retaining his double title. Wells became a borough owned by the bishops before 1160, when Bishop Robert granted the first charter, and became a free borough by charter of King John in 1201. It was represented in parliament from 1295 to 1868. The theological college is well known. The diocese covers all Somerset escept Bedminster, Abbots-Leigh and Brislington.

The Cathedral.— The beautiful cathedral was executed principally by Bishop Reginald FitzJocelin (1174–91) and Bishop Jocelin of Wells (1206–42). The western part of the nave and also the lovely series of statues on the west front are attributed to Bishop Jocelin. With him was associated a famous architect, Elias de Derham (d. 1245), who was his steward in 1236. Early in the 14th century the central tower was heightened; the piers began to give way and to strengthen them the remarkable inverted arches were introduced. The beautiful octagonal chapter house on the north side and the Lady chapel at the extreme east were the nest important additions in the same century. The whole church is covered with stone groining of various dates, from the Early English of the choir to the fan vaulting of the central tower. Its plan consists of a nave (161 ft. long, 82 ft. wide) and aisles, with two short transepts, each with a western aisle and two eastern chapels. The choir and its aisles are of unusual length (103 ft.), and behind the high altar are two smaller transepts, beyond which is the very rich Decorated Lady chapel, with an eastern semioctagonal apse. On the north of the choir is the octagonal chapter house, the vaulting of which springs from a slender central shaft. The cloister, 160 hy 150 ft., extends along the southern wall of the nave. The length of the church from east to west is 383 ft.

On the south side of the cathedral stands the bishop's palace, a moated building, originally built in the form of a quadrangle by Bishop Jocelin, and surrounded by a lofty cirruit wall. The hall and chapel are beautiful structures, mostly of the 14th century. North of the cathedral are the deanery and archdeaconry (the latter now used by the theological college), the museum and the Chain gate, connecting the chapter house with the Vicars' hall and the charming 14th-century street known as Vicars' close.

The church of St. Cuthbert has a fine tower with spire at the west end. It is Early English and Perpendicular.

WELSH LANGUAGE: see CELTIC LANGUAGES.

WELSH LAWS or LEGES BRITANNIAE. The earliest and best manuscripts of these. whether in their original Welsh or Latin, do not date from before 1175–1200. Confessedly recensions and reflecting current politics. they hear notwithstanding so striking a general resemblance to one another that it is hard not to credit their common tradition, namely, that they hail from one original codification of British law and custom by King Howel (Hywel) Dda ("the Good"), who died 950. The Welsh manuscripts fall into three classes, each of which begins with its own type of preface: (1) Those which refer exclusively to the king of Aberffraw in northwest Wales and give other indications that they pertain to that kingdom: *i.e.*, Gwynedd or Venedotia. of which Aberffraw in Anglesey was the chief royal residence. The jurist Iorwerth ap Madog (*c.* 1200) would seem to be responsible for this recension. which Aneurin Owen in 1841 dubbed. not inappropriately. the "Venedotian code." (2) Those which refer exclusively to the king of Dinefwr (anglice Dynevor) in the "south." hut would seem from the preface to have prevailed in Powys. The jurists favoured are Morgeneu and his son Cyfnerth. Owen unfortunately called these the "Gwentian code" as pertaining to southeast Wales, of which the manuscripts provide no indication. (3) Those which refer to both the kings of Dinefwr and Aberffraw. stating expressly that of all the kings in Wales gold is payable only to these two.

But as they put Dinefnr before Aberffraw and refer to Rhyr ap Grufiudd (d. 1197). one of the Dinefwr kings, and contain a special section on Dyfed or Demetia in southwest Wales, they certainly pertain to the "south." Owen, however. called them insufficiently the "Dimetian code." The jurist named in the preface is Blegywryd. who is otherwise known as having intervened in a dispute in 95j, where he is described as "that most famous man" (Bk. of Llun *Dav,* 219). He is also known from some ancient Latin verses to have been a teacher of law in Howel's court and to have written a book of laws for the king. which book the king gave "ad partem dexteram"; *i.e.*, to the "south," in Welsh Deheubarth. which stands for "Dextera Pars Britanniae." the south part of Britannia or Wales (omitting Morgannwg, the country from Swansea to Chepstow).

That these three classes really represent law books in vogue in Gwynedd. Powys and Deheubarth, respectively. seems to be implied or reflected in the preface of the last-mentioned class. where we are told that "Howel ordered three law books to be made. one for the daily court to he always with him. another for the court of Dinefwr, the third for the court of Aberffraw, so that the three divisions of Wales. to wit, Gwynedd, Powys and Deheuharth should have the authority of law in their midst. at their need. always and ready." Readers for their guidance should bear in mind: (1) That the earliest manuscripts extant were written when the Norman French had long interfered in Welsh affairs and had already permanent possession of most of the petty kingdoms of south Wales; when also Geoffrey of Monmouth's History of *the Kings* of *Britain* was further confirming men's minds in the bizarre notions of the Welsh past, which had originally been set going by the book called Dc excidio *Britanniae* used by Bede. (2) That Howel Dda was not an original begetter of Welsh law; what Howel did was to "put together the laws of Britannia" (*i.e.,* Wales) with the consent and after the consideration of the wise men of his realm, assembled in one place. (3) That it is not conducive to sound knowledge to accentuate the "tribal" nature of the Welsh laws. No term for "tribe" appears. To read "tribes," therefore, into the Welsh laws is not only to force the text. but to obfuscate the emergence of Wales into the dark age from Romano-British Christian civilization.

Lloyd, *History of Wales*, pp. 283–356 (1912); G. Evans, *Facsimile of Chirk Codex* (1921); T. P. Ellis, *Welsh Tribal Law* (1926); *Aberystwyth Studies*, x (1928).

(A. W. W-E.)

WELSH LITERATURE. By Welsh literature is meant literature composed in the Welsh language. No account is here given of literature composed by Welshmen in English. to which the term Anglo-Welsh is more applicable. Welsh literature properly so called extends in an unbroken tradition from about the middle of the 6th century to the present day.

The Cynfeirdd or Early Poets (c. 550–c. 1100).—With the exception of two or three short pieces, all pre-Norman poetry has survived only in manuscripts written in the 12th, 13th, 14th and 15th centuries—*The* Black Book of *Carmarthen* (*c.* 1170–1230), *The* Book of Aneirin (c. 1250). The Book of *Taliesin* (*c.* 1275) and *The* Red Book of Hrrgest (*c.* 1375–1425)—and in a few others of even later date. Although their date is uncertain. it is clear that many of the poems are very much older than the manuscripts in which they have survived.

Welsh developed as a new analytic language from the older synthetic Brythonic by the middle of the 6th century. A note in the *additamenta* to the *Historia Britonum* attributed to Nennius, a disciple of Elfodd (d. 809), states that the poets Blwchfardd, Cian. Talhaern Tad Awen (the "father of the muse"). Taliesin and Neirin (later Aneirin) composed poetry in Welsh at a time roughly contemporary with Ida (547–559), son of Eobba. The first three are mere names, but *The* Book of *Taliesin* and The Book of *Aneirin* contain collections of verse which purport to be the works of Taliesin and Aneirin. All the poems in the former manuscript cannot be the work of the historical 6th-century Taliesin. but about a dozen of them appear to be authentic. In these. which may be described as heroic odes or lays. the poet praises the warlike deeds and generosity of his lord Urien of Rheged (the modern shires of Wigtown and Kirkcudbright in south Scotland) and moans the loss of Owein. son of Urien. *The* Book of Aneirin, on the other hand. contains a long poem called Y Gododdin, claimed to be the work of Aneirin. The extant text is very corrupt and contains many later interpolations, but the nucleus of it appears to have been composed (possibly in a form differing much from that in which it has survived) by Aneirin toward the close of the 6th century. It consists of series of verses, generally one for each hero, often linked together by the same initial phrase or line, and commemorates the ill-starred expedition of the war band of 300 men sent by their lord Mynyddawg Mwynfawr of Caereidyn (near Edinburgh) to recapture the old Roman stronghold of Catraeth (Catterick in Yorkshire) from the Saxons of Deira or to hold it against them. The background, inspiration and social conventions of the poems of Taliesin and Aneirin are typically heroic, the language is direct and simple, and the expression terse and vigorous. Among other technical adornments much use is made of alliteration and internal rhyme. which used in combination gradually developed by the 13th century into the intricate system of consonantal correspondences and internal rhyme called cynghanedd (*q.v.*). The later development of Welsh poetry owes much in form and matter to the continuance of the heroic mode of life. and to the pattern set by the works of Taliesin and Aneirin and those of other bards whose compositions have disappeared. It is kno n from Gildas that Maelgwn Gwynedd (d. *c.* 547), in northwest Wales, had court poets, but not a line of their compositions survived.

The connection between the Britons of Wales and those of north Britain. weakened by the battle of Chester in *c.* 61j was broken when Penda. with his British allies, was defeated in 654 or 655 by Oswiu (Oswin). king of Northumbria. Although Welsh survived as a spoken language for two or three centuries in North Britain and some interpolations in the text of Y *Gododdin*—in particular a stanza which refers to the death of Domnall Brecc in 642—show that the heroic tradition of eulogy and elegy was continued there, subsequent literary compositions in that region have disappeared. Early heroic poetry in Wales proper is first exemplified by a short poem in *The* Book *of Taliesin* in praise of Cynan Garwyn of Powys, whose son Selyf was slain in the battle of Chester. This poem strikes a note which remained constant in all Welsh eulogies and elegies down to the fall of the Welsh Bardic system: Cynan is the bravest in the field, the most generous in his home: all others are thrall to him and sing his praises.

The period between the 7th and 10th centuries is represented by a few scattered poems, most of them in the heroic tradition. Of poets there are references to Morfran, Meugan, Arofan (bard to Selyf ap Cynan mentioned above) and Afan Ferddig. whose patron Cadwallon ap Cadfan was killed in the battle of Hexham against Oswald of Bernicia in 634: The few authentic poems still extant include "The Eulogy of Cadwallon" (? by Afan Ferddig), "The Elegy of Cynddylan ap Cyndrwyn" of Powys in the first half of the 7th century and, less heroic in note and more peaceful in atmosphere. "The Eulogy of Tenby," by an unknown south Wales poet toward the end of the 9th century. Early vaticinatory poetry is represented by "The Great Prophecy of Britain." a stirring appeal c. 930 to the Welsh to unite with the Britons of the north, the Irish, the Norse of Dublin, the Cornish and the Bretons to oppose the Saxons and to refuse the unjust demands of their "great king." probably Athelstan of Wessex. Poetry outside the main bardic tradition is seen in nine *englynion* (stanzas of three or four lines) praising God; three englynion which are a monologue or part of a dialogue from a lost saga; a dialogue partly vaticinatory betneen Myrddin and Taliesin, c. 1050–1100; and "The Song of the Wind." a riddle poem which contains the germ of the later convention known as dyfaliad or comparison.

The poems associated with the name Llywarch Hen were once regarded as the work of the 6th-century leader of that name. It is clear, however, that they are the verse remains of at least two literary sagas composed toward the middle of the 9th century by an unknown but highly gifted storyteller of Powys, whose basic material was the traditions which had gathered around the historical Llywarch and Heledd, sister to Cynddylan ap Cyndrwyn. In these sagas prose was used for narrative and description, and verse for dialogue and soliloquy. The prose has been lost, and what the sagas were in their complete form can only be guessed from hints and references in the verse passages. The metrical form is the englyn embellished by alliteration, internal rhyme and incipient cynghanedd. The background is the heroic struggle of the Welsh of Powys against the Mercians, but the mode is elegiac: Llywarch bemoans the loss of his 24 sons fallen in defense of their land, and as he wanders lonely and poor from place to place he grieves at the desolation wrought by the enemy; Heledd. the other central figure. bewails the death of Cynddylan and her other brothers, and laments the passing of the glory which was once the pride of her and her family. The storyteller's mood and that of his people is relentlessly conveyed in stanzas of a haunting sadness and charm, rendered all the more effective by an extraordinary economy of words coupled with the device of incremental repetition. Both Llywarch and Heledd are portrayed as tragic, ill-starred figures (dzriaid) who envy the different fate of those born to a fortunate destiny (dedwydd), and now in their distress they call to mind the baneful pride (tmha) in word or deed which brought them to their low estate. The sheer poetry and artistic finish of these verses make regretful the loss of scores of other sagas referred to in the Triads, the "Stanzas of the Graves" and elsewhere, although they may never have received the consummate literary treatment which those of Llyuarch and Heledd received.

There are other fragments, inferior as poetry to the verses associated with Llywarch and Heledd, which were originally soliloquies or parts of dialogue in sagas. Such are the dialogues between Arthur and the porter Glewlwyd Mightygrasp. between Taliesin and Ugnach, between Gwyn ap Nudd and Gwyddneu Garanhir; the monologue of Ysgolan the Cleric; the verses praising Gereint son of Erbin (the Erec of medieval romance); and the tantalizing fragment of what appears to be an early native version of the Trystan and Esyllt (Tristan and Iseult) story. All these are found in The Black Book of Cmmarthen. Other groups of verses in the same manuscript show that there once existed in literary form a legend of Myrddin Wyllt, the wild man of the woods who went mad at the sight of a battle, a legend associated with Suibbne Geilt in Ireland, and with Lailoken in Scotland This Myrddin (later better known as Merlin) had the gift of prophecy, and so "prophecies after the event" came to be attributed to him. The historical poet Taliesin also became the central figure in a folk tale which was given literary form in the 9th or 10th century, but which has survived only in certain monologues spoken by some of the characters and preserved in The Book of *Taliesin,* and in a modernized and debased 16th-century text called *Hanes* Taliesin ("The Story of Taliesin"). As portrayed in the monologues Taliesin is the young bardic prodigy who surpasses everyone in his knowledge of the past, present and future. Hence he too, like Myrddin, came to be regarded as a prophet and many vaticinations mere attributed to him.

Nature, a source of similes in the heroic poetry and in the verse remains of the sagas, was sometimes a subject of song in its own right. Generally, the treatment of the subject is remarkable for its sensitive objectivity, its awareness of form, colour and sound and its concise expression which is often epigrammatic. In mood, matter and form (that of the englyn) it often overlaps with gnomic poetry, which consists of versified sententious sayings about man and nature. Most of the gnomic and nature poetry was probably produced in the 10th and 11th centuries by poets other than the professional bards. Toward the end of the pre-Norman period we have a few poems on religious and biblical subjects—"The Day of Judgement," "The Plagues of Egypt," "The Rod of Moses," "The Miraculous Harvest" and "The Dialogue Between the Body and the Soul"—and others which show acquaintance with nonnative legends such as those of Hercules and Alexander and that of the Irish Corroi Mac Dairi. They may be the work of inmates of the old Celtic monastic institutions.

Most of this early heritage of song—heroic, vaticinatory, nature, gnomic and religious—was developed by the medieval gogynfeirdd. Saga poetry gradually died out, for prose became the recognized medium for storytelling.

The **Gogynfeirdd or Poets of the Princes (c. 1100–c. 1350).**—With the consolidation of the principality of Gwynedd under Gruffudd ap Cynan (1054–1137) and his descendants, a new song suddenly appeared in that province. It is certain. however, that the poems of the first bards of this period are the culmination of long ages of literary activity of which there is now no record. The court poetry of the gogynfeii-dd was the direct and inevitable development of the work of the early poets (cynfeirdd) of North Britain and Wales.

The Bardic System.—The bards were divided into grades, the upper grade or pencerdd (chief of song) being a high officer of the court, whose duty it was to sing the praises of his lord and his family, and of God and the saints. He was forbidden to sing of love and nature, and his field of song was mapped out and prescribed. Under him came the bardd *teulu* (the bard of the king's war band) who did for the king's household what the pencerdd did for the king himself. He also was restricted as to subject, but he might sing of love and nature, and such songs as would please the ladies but be distasteful to the virile warriors. Last of all came many kinds of cerddorion (minstrelsj who might be permitted ribaldry and satire, and who told the *cyfarwyddyd* or oral tale which eventually developed into the Mabinogion.

Across this classification, which is somewhat analogous to a similar division in Ireland, cuts another, based on an entirely different principle—the grading of the bards according to degrees of proficiency. This classification was educational, and lay at the root of all learning in Wales. It was this latter classification which remained in Wales after the loss of its independence; its essential feature, the relation of disciple and teacher, persisting almost to modern times. In the time of Henry IV it led to the holding of an eisteddfod, or session of the bards, to confer certificates of proficiency and to prevent the lower orders from flooding the country and drifting into mere mendicancy.

One of the natural results of a bardic system of this type was an unparalleled conservatism in literature. Most of the 13th-century bards used a conventional diction which was consciously archaic in its vocabulary, grammar and idiom. It could not possibly be understood by any but those classes whose education included the study of poetry. This archaism was one of the means by which they produced that "exquisiteness," the aim of all bardism, and non-Celtic critics often find it extremely hard to appreciate an artistry the methods of which differ so widely from those of their own.

Bardism often went by families, and the first names of the new period are those of Meilyr, his son Gwalchmai and his grandson Meilyr ap Gwalchmai. who were attached to the court of Gwynedd at Aberffraw. Gwalchmai (*fl.* 1130–80) left on record his *Gorhoffedd* or "Boasting," a kind of spring song. In his Praise of *Owein* he displays one characteristic of all the gogynfeirdd, description of water, whether of river or sea. Nearly all the great poets of this period get their finest effects when they picture the waves red with the blood of their enemies. The traditional master of the archaic was Cynddelw (*fl.* 1155–1200), the court bard of the prince of Powys.

The official bards of this period all used the same material and used it in the same way. Song and its modes were prescribed for them, and to go beyond the stated limits was to be unbardic. The poetry of the bardic tradition was not measured by the depth and extension of its thought but by its exquisiteness. Its value was ornamental, and to be in a position to judge Cynddelw and his contemporaries one must think of a culture that sought not to interpret life but to adorn it. Two poet-princes, Owein Cyfeiliog of Powys (d. 1197) and Hywel ab Owein of Gwynedd (d. 1170), stand out in clear distinction from the contemporary bards. Cyfeiliog's most famous work is the *Hirlas,* "The Long Grey Drinking Horn:" in which he describes his warriors making merry over the mead after a victorious raid. Hywel ab Owein's departure from convention is even more striking than that of Cyfeiliog; for the first time in Welsh literature appears the love of country. He loved beauty. in the modern sense; land and sea and women and the Welsh speech spoken in cultured accents by his lady all awoke in him the emotion of awe and wonder. and he unifies in his own experience all these beautiful things. The *gogynfeirdd* alternated throughout this period between *marwnad* (elegy) and *moliant* (eulogy) until the time when the English conquest of Wales removed from Welsh life the occasion of both. The period ends with the most famous of all the Welsh *marwnadau,* sung by Gruffudd ab yr Pnad Coch, after the death of Llywelyn (Llewelyn) (d. 1282). the last prince of Wales.

The religious verse of the *gogynfeirdd,* comparatively small in bulk. is on the whole simpler in style than the eulogies and elegies. A set type of ode is the *marwysgafn* (deathbed song), in which the poet. sensing the approach of death, confesses his sins and prays for forgiveness. Other religious poems are in praise of God and the Trinity. to saints, on the torments of hell and on the birth of Christ. They illustrate the gradual widening of the bardic horizon but there is not much sacrifice of conservatism in diction.

The Later Gogynfeirdd.—With the princes and their pageantry, there passed away the older modes and conventions of Welsh poetry. The audience that could once accept and understand the intricate and involved *awdl* (a long stanza with a single rhyme throughout) of the old period could no longer find the means to educate themselves for the understanding of it. The old metres still remained, but the language became simpler. The poetical conventions which governed the old poetry having been thus in part relinquished. it was necessary to invent a new presentation of poetry. which contained some element that could be regarded as a substitute for them. The poets who sang in the years between the English conquest (1282) and Dafydd ap Gwilym ($. 1340–70) seem either to have returned to an earlier poetic fashion or to have been influenced by new ideas from other lands. The probability is that both suppositions are true; that is to say, the poets of the *bardd teulu* class. whose work has not been preserved, were greatly influenced in the 11th century by other trends in poetry, but this influence did not penetrate into the work of the *penceirddiaid* until the loss of Welsh independence had made them more directly dependent on what (to use an anachronism) might be called middle-class opinion.

Whereas in the early period exquisiteness was sought in archaic precision and in the suggestion of older modes. the new poets employed colour and form to an extent hitherto unknown in Welsh poetry and unparalleled in later times. Dress: jewels, armour, a lady's hair and cheeks, her form and gestures, even her silences are amply and precisely described in poetic words. The famous names in this period are those of Gruffudd ap Rlaredudd (*fl.* 1352–82), Gruffudd ap Dafydd (*fl. c.* 1300) and Casnodyn (*fl.* 1320–40) who all flourished in the first half of the 14th century.

Early and Medieval Prose (c. 900–c. 1500).—The earliest examples of Welsh prose are of a utilitarian nature: notes and glosses on Latin texts dealing with weights and measures. a record of an agreement made concerning the ownership of a piece of land and lists of dues to be paid to a church of St. Teilo's. A more substantial text is the 10th-century *Computus Fragment* of 24 lines which contains an incomplete commentary on a problem of astronomy. Their latinized vocabulary and syntax point to an ecclesiastical or monastic origin. Shortly before the middle of the 10th century Howel (Hywel) Dda (d. 950), according to the tradition recorded in the medieval law books, had the Welsh laws codified. The oldest extant version is in Latin, but the Welsh version in *The Black Book of Chirk* (*c.* 1200) derives from an earlier exemplar. It is difficult to assess how close this version may be to the original codification. However that may be, in the legal texts prose of a high order is used to describe, to define and to express precise distinctions in the organization of a complex society. Although there is no conscious effort at literary effect, there is a wealth of legal and technical terms, some of native and others of Latin origin, and a sustained clarity of expression.

The merits of the legal texts prepare one for the more conscious literary use of prose by the storytellers (*cyfarwyddiaid*) whose craft must be at least as old as that of the poets. They recited for entertainment oral tales of which the underlying material was a medley of mythology in decline, folklore and heroic. pseudo-historical and aetiological elements. Some of these tales were recorded in writing, whether by the *cyfarwyddiaid* or by others is not known. The most famous collection is that called the *Mabinogion* preserved in *The White Book of Rhydderch* (*c.* 1300–25) and *The Red Book of Hergest*. *Mabinogion,* long regarded as a plural of the authentic word *mabinogi* (youth, tale of youth) derives from a scribal error and so is a meaningless, but convenient! title for the collection of 11 tales. all anonymous. which range in date from the second half of the 11th century to the close of the 13th. These tales. it must be emphasized. are conscious literary compositions. based on older oral material. and not mechanical reproductions of the *cyfarwydd's* stock in trade. The greatest as literature are the four related stories "The Four Branches of the *Mabinogi,*" composed in the second half of the 11th century by an unknown writer from Dyfed, a fine artist in the use of description and dialogue. in the delineation of character and in investing incidents with a pathos and imagination which often transcend place and time. The author of "Culhwch and Olwen" (*c.* 1100), using basic material of the same kind as that which underlies the "Four Branches," appears to have kept closer to the oral *cyfarwyddyd*. He is less serious and on a lower artistic level. His delight in style for its own sake and his fondness for bravura and grotesque elements, together with his tendency to overcomplicate the story, prepare one for the later decadent *areithiau* (rhetorics) which are in part obvious parodies of the *Mabinogion*. "The Dream of Rhonabwy," composed in Powys late in the 13th century. forms an artistic whole. but again the style is consciously ornate and full of studied contrasts, and the action tends to become lost in the long and involved descriptions. It is significant that the colophon states that the story could not be told "without a book." Three of the *Mabinogion* tales, viz.. "Owein and Luned" (or "The Lady of the Fountain"). "Geraint and Enid" and "Peredur son of Efrawg," represent the transition from the purely native tales to those composed under Norman influence. The basic material of all three is largely native. but there is French influence in certain place and personal names. social conventions and general atmosphere. These tales correspond to the *Yvain*, *Erec* and *Perceval* of Chrétien de Troyes. and the exact relationship between the Welsh and French texts has long been a subject of debate. The weight of evidence shows that Chrétien's French versions and the Welsh tales derive independently from earlier French prose versions (now lost) which in turn were adaptations (possibly the work of Normanized Welsh or Breton *conteurs*) of pre-existing Welsh oral stories. Artistically these romances with their extreme sophistication and dreary *longueurs* show a decline from the native tales with their directness, restraint and disciplined selection of material.

Many translations from Latin and French played a part in the evolution of a prose which could express aspects of human thought and activities not often touched upon in the tales. Most of the translators are unknown by name, but they were probably monks and parish priests. Whether the medium of the original was prose or verse, the Welsh version is invariably in prose. Of the texts translated from Latin the following deserve mention: *Delw y Byt* (from the *Imago Mundi* of Honorius Augustodunensis); many lives of saints; *Gweledigaeth Bawl Abostol* (the *Visio Sancti Pauli)*; *Adrian ac Ipotis* (from the *Disputatio Hadrianz Imperatoris et Epicteti)*, *Cynghoreu Catwn* (the *Disticha Catonis)*. *Y Bibyl Ynghymraec* (the *Promptuarium Bibliae)*, three independent versions each of *Dares Phrygius,* of Geoffrey of Monmouth's *Historia Regum Britanniae,* and of the lost original Latin of "The Chronicle of the Princes of Wales"; and *Hystorya Gruffydd ap Cynan* (its Latin original disappeared). A Welsh version of the *Seven Wise Men of Rome* is a free retelling of the story rather than a close translation of any text. The translations from French, which are fewer in number, include: versions of the *Chanson de Roland;* the *Chanson d'Otinel;* the *Gestes* and the *Pelerinage* of Charlemagne; the *Queste del Saint Graal* and *Perlesvaus,* which form part i and part ii respectively of *Y Seint Greal.* Most of these translations uere produced in the 13th and 14th centuries. Their prose is to a large extent experimental and influenced in varying degrees by the language and style of their originals, but at its best, as in *Y Seint Greal* and *Seith Doethon Rufein,* it is not an unworthy development of the prose of the law tracts and native tales. Toward the end of the medieval period a few translations of religious, moralistic and allegorical texts from English appeared. some of them based on early printed books. These uere produced mainly in south Wales.

In summary, the development of medieval prose was hampered by a lack of alliance between the heirs of the Welsh literary tradition and those who cultivated the wider learning and culture of western Europe. The inspiration for the fashioning of a new prose, able to express all facets of human thought and activities, arose toward the middle of the 16th century from the joint upheavals of the Renaissance and the Protestant Reformation. As will be seen, it was the humanists, Protestant and Catholic, who laid the foundations of modern Welsh prose.

The Golden Age of the Cywydd, 1350–1450.—The conquest of Wales by Edward I did not put an end to the poetry associated with the royal courts of Gwynedd and Powys. Its effect was to transfer its patronage from the prince to the *uchelwyr* (landed aristocrats), and to diminish its prestige. Henceforth there was to be no legal recognition of the *pencerdd* and his particular department of song at the expense of the *bardd teulu.* The diminished prestige of the bards formerly associated with the native princes gave an opportunity to the lower orders nhose work had not hitherto been regarded as meriting preservation by the copyists. Indeed, in south Wales, where the Normans had been established for a whole century before the conquest of Gwynedd in 1282, the old song was gradually dying out, and the lower orders in the south were becoming more and more vocal.

While Gruffudd ap Maredudd and Casnodyn in Gwynedd were still, though in a simpler form. following old conventions of the *gwawd,* the *pencerdd's* song, the unknown bards of south Wales were developing an entirely new literature of which there is no trace in the manuscripts before the work of Dafydd ap Gmilym who, like his contemporary Chaucer in England, may be regarded in his own land as the father of modern poetry.

Dafydd ap Gwilym.—Dafydd was probably born about 1320. His family is associated with Dyfed, but he seems to have spent most of his time at his kinsmen's home in north Cardigan.

In the first of his periods he wrote according to two entirely distinct traditions. His *awdlau* to his patrons, his uncle Llywelyn and Ifor Hael, follow the strictest conventions of the later *gogynfeirdd;* he sang these as a *pencerdd.* At the same time, he produced a large body of poetry in what must be regarded as the tradition of the *bardd teulu.* These are *cywyddau* and *traethodlau.* The *cywyddau* are in couplets of seven syllables, one rhyme accented and the other unaccented; in his first period they are not regularly in *cynghanedd* as the rules of the *pencerdd's* song demanded. His other form, the *traethodl,* is also in couplets of seven syllables, but both rhymes are unaccented and there is no *cynghanedd* at all. From the fact that his *cywyddau* are the earliest known. and that his name was always associated with the *cywydd* by his contemporaries, he came to be regarded as the inventor of the *cywydd.* There is. however, ample reason to suppose that Dafydd's work was only the culmination of a long process of development among the *bezrdd teulu* in a part of Wales which. both politically and socially, had been for a century cut off from the main tradition of Welsh poetry.

Dafydd's important advance was in diction. In his *cywyddazc* he discarded the old archaisms and wrote in the ordinary language to the educated Welshmen of his own time. His successors followed his lead. and the old diction fell out of use. He thus established the standards of modern Welsh.

The substance of his poetry was also new. Up to his time, the bards were confined by regulation to a few well-defined subjects. Dafydd, however. listened to the songs which were then delighting the ordinary educated man in Europe, and he reproduced them in his *cywyddau.* The chief influences on his work were the songs of the *clerici vagantes* (wandering minstrels) and of the trouvères of France. The conventional divisions into which the poetry of the troubadours and trouvères is divided—aubade, serenade, tenson. *pastourelle* and so on—are faithfully and minutely reproduced in his work. Besides this, a large part of his poetry is derived from the uandering minstrels' popular songs in Latin, French and possibly in English. He has been hailed, without much discrimination, as the greatest of love poets. but of love poetry as such, he wrote very little. Love is a peg on which he hangs his exquisite nature poems, and it is in these that one finds his greatest achievement. In his nature poems he makes use of two conventions. that of the *llatai* or love messenger (already used by Llywarch ap Llywelyn, known as Prydydd y Moch, *fl.* 1173–1220) and that of the *dyfaliad* or descriptive poem. The first part of the poem is generally a conventional statement of his love for a lady, the second a short address to a bird or a fish or a natural feature, such as the cloud or the uave, praying it to take a message to the lady; the third and main portion is a minute description of the messenger. To Dafydd nature was purely external, and it had no mystical significance. But his treatment invested it with a new wonder.

Dafydd ap Gwilym's Contemporaries.—Dafydd's influence was twofold: not only was the *cywydd* established as the leading form, but the new subjects came to be recognized as themes fit for poetry. One of his oldest contemporaries, Gruffudd ab Adda *(d.* 1344?), wrote a *cywydd* "to a birch tree that had been made into a maypole at Llanidloes," which goes much further than Dafydd in the direction of the modern conception of nature. Iolo Goch *(c.* 1320–*c.* 1398) wrote a fine *cywydd* to the *llafurwr* (husbandman) which shows traces of contemporary English ideas as seen, for instance. in *Piers Plowman.* Llywelyn Goch Amheurug Hen (*fl.* 1360–90) wrote some of his earlier poems in the *gogynfezrdd* tradition. but his *Elegy to Lleucu Llwyd,* his best-known work, is a *cywydd* and combines nith striking success the Welsh tradition of the elegy with the imported form of the serenade. Other poets almost contemporary with Dafydd were Gruffudd Llwyd ap Dafydd (*fl.* 1380–1410), who sang two superb *cywyddau* to Omen Glendower, and Rhys Goch Eryri *(c.* 1365–*c.* 1448), who is chiefly famous for his literary quarrel on the nature of true poetry with Siôn Cent and Llywelyn ap y Moel (d. 1440), the author of a *cywydd* which gives a spirited description of a battle in which the poet fled. The most elusive figure in this period is Siôn Cent (d. *c.* 1430), to whom are attributed a number of *cywyddau brud* (semi-political songs) in the form of prophecies, and *cywyddau'r byd,* similar in every respect to the poems *du temps jadis* (of olden days), so popular in every country in Europe at the beginning of the 14th century and exemplified in the works of François Villon, William Dunbar, Michel Menot and Gómez Manrique. It is probable that these poems are by many hands. but the dominant thought of them all is so characteristic that they were attributed to the traditional name of Siôn Cent.

Dafydd ap Gwilym's Successors.—With the dawn of the 15th century the *cywydd* entered a new period. The poets purified the *cywydd* from the last traces of the old convention.

Dafydd Nanmor *(c.* 1420–*c.* 1490) in treatment of his subject and in imagination is inferior to most of Dafydd's contemporaries, but in his mastery of the cywydd form he had no equal. His poem "Llio's Hair" and his "Maiden's Elegy." among others, mark the zenith of that conception of poetic art which aimed at simplicity. Lewis Glyn Cothi (*fl.* 1447–86) and Guto'r Glyn (*fl.* 1433–93) show a further advance in the handling of the *cywydd* metre. In their work for the first time a real consciousness of nationhood among the Welsh is detected. Other poets of this period were Maredudd ap Rhys (*fl.* 1430–50), Hywel Swrdwal (*fl.* 1430–60), Tudur Penllyn (*fl.* 1470) and Dafydd Llwyd ap Llywelyn (c. 1420–*c.* 1500).

The Silver Age of the Cywydd, 1450–1650.—For a short time there arose a school of literary formalists. The chief of this school was Dafydd ab Edmwnd (*fl.* 1449–1500), who at the eisteddfod of the bards held at Carmarthen in 1451 rearranged the 24 canonical strict metres. The main characteristic of his poetry is its great ingenuity. His poetic heir was his nephew Tudur Aled (d. 1526) who made a further rearrangement of the rules of poetry, and whose poems in execution, mark the very zenith of the bard's craft as conceived in that age. His contemporary Gutyn Owain (*fl.* 1460–1500), though too much of his *moliant* consists of genealogical details, could in his dyfaliadau rival even Dafydd ap Gwilym.

In the latter part of this period, two events of supreme importance occurred—the Reformation and the accession of the Tudors. The former had little immediate influence on literature, except indirectly through its effect upon the language, since, with the decline of the old Catholic educational system, the general appreciation of literature was diminished. The Tudor policy of encouraging the spread of English at the expense of Welsh, and of inducing the Welsh aristocracy to emigrate to England, almost destroyed the old Welsh culture which was altogether bound up with the language. Yet for more than a century after Henry VII the bards plied their craft, though patronage was much diminished. Siôn Tudur (d. 1602) satirized the new aristocracy of profiteers. Edmwnd Prys (1544–1623), archdeacon of Merioneth, is best known for his "contention" with William Cynwal (d. 1587 or 1588) and for his biting satire on contemporary manners as well as for his version of the Psalms in the old ballad metre. William Llŷn (1535–80) and Siôn Phylip (c. 1543–1620) are among the great poets of the silver age of the cywydd.

The Rise of Modern Prose (c. 1550).—Traditional Welsh prose, which was becoming increasingly debased toward the end of the 15th century, was not an adequate medium of expression for the surging thoughts of the Renaissance and the Reformation. The humanists succeeded in fashioning a new prose with its accidence based on the language of the bards, its style and cadences on classical authors and its vocabulary enriched by new formations and extensive borrowings. Thus they laid the foundation of modern prose at a time when Welsh printed books began to appear.

The first Welsh book, Yn y Lhyvyr hwn, published in 1547, consisted of extracts in Welsh from the Scriptures and the Prayer Book. Probably in the same year was published William Salesbury's *Oll Synnwyr* Pen, a collection of proverbs. From this time Welsh prose literature began to take definite form, and may be studied under four headings: (1) the Reformation; (2) the Counter-Reformation; (3j the Welsh Renaissance; and (4) Puritanism.

The *Reformation.*—The most important name among this group of writers is that of William Salesbury (c. 1520–*c.* 1584). His work, begun in 1547, culminated in his translation of the New Testament published in 1567. If one considers accuracy of idiom and fidelity to the original, Salesbury's Testament must be called a great pioneer work. Unfortunately it is marred by his philological foibles and the mechanical means which he employed to make the language intelligible in every part of Wales. In the same year was published the Welsh Prayer Book, also translated for the greater part by Salesbury in collaboration with Richard Davies (c. 1501–81), bishop of St. David's. In 1j88 was published the Welsh Bible translated by William Morgan (c. 1541–1604), bishop of St. Xsaph, aided by Edmwnd Prys. This translation, revised and amended by Richard Parry (1560–1623), bishop of St. Xsaph, and John Davies (c. 1567–1644), was republished in 1620—the version which is used to this day. It would be difficult to exaggerate the importance of these three translations, the Testament and Prayer Book of 1567 and the Bible of 1588 and 1620, in the development of Welsh literature. From 1588 onward there was no break in the production of Welsh prose books. The first were translations from English and Latin aimed at grounding the Welsh nation in the principles of the Reformation. The following are the chief among them: *Deffyniad* y Ffydd (1595), a translation of Bishop John Jewel's *Apologia,* by Morys Kyffin (c. 1j55–98); Pevl *Mewn* Adfyd (1595), a translation of Miles Coverdale's A *Spiritual and* Most Precious Pearl, by Huw Lewys (1562–1634); *Homiliau* (1606), a translation of the Homilies, by Edward James (c. 1569–*c.* 1610); Llwybr *Hyfforddd* (1630), a translation of Arthur Dent's Plain *Man's* Pathway, by Robert Llwyd (1565–1655); Yr *Ymarfer* o *Dduwioldeb* (1630), a translation of Lewis Bayly's Practice of Piety, by Rowland Vychan (c. 1590–1667); *Llyfr* y *Resolution* (1632), a translation of Robert Parsons' Christian Directory, by John Davies of Mallwyd (c. 1567–1644). To these must be added the unpublished works of Ellis Gruffydd (b. c. 1500), especially his Chronicle from the creation to 1552. The latter part of it sheds much light on the life of the court and the army.

The Counter-Reformation.—During the years in which the reformed religion was being established in Wales, Welsh society and the Welsh language were at their lowest ebb. Every book during this period bewails the general ignorance. The Catholic writers of the Counter-Reformation regarded the new religion as something imported from England, and they thought that the way to preserve the old religion was to insist on the old Catholic culture. This was why Gruffydd Robert (c. 1522–*c.* 1610), canon of Milan, published his *Dosbarth* Byrr, the first printed grammar of the Welsh tongue. It consists of a series of discussions between teacher and disciple, and in beauty of style it stands among the greatest monuments of Welsh prose. Other works stimulated by the desire to preserve the old religion were: Gruffydd Robert's *Drych Cristianogawl* (158j); Theater *du Mond* (1615), a translation from the French, and two other books in 1609 and 1611 by Rhosier Smyth (1541–1625); Athravaeth *Gristnogawl* (1617) by Morys Clynnog (c. 1525–81); and Eglurhad Helaethlawn (1618), a translation from the Italian. All these and some others were published on the continent.

The Welsh Renaissance.—Just as Italy and other European countries under the Renaissance turned to the Latin and Greek classics, so Wales turned to its own classical tradition of bardism. The result mas the publication during this period of some of the most important Welsh grammars. Gruffydd Robert's Dosbarth Byrr, already mentioned, was followed in 1592 by the *Cambro*-brytannicae . . . *Institutiones* of SiBn Dafydd Rhys (1534–*c.* 1609), which was an attempt to set out before the learned world the rules of bardic poetry and principles of the Welsh language. This work was the foundation of all later grammatical studies, though Rhys was far surpassed in scientific knowledge by John Davies of Mallwyd, who published his Antiquae Linguae . . . *Rudimenta* in 1621 and his great *Dictionarium Duplex* in 1632. The Latin-Welsh portion of this dictionary was based on the work of Thomas Wiliems of Trefriw (c. 1j50–*c.* 1622), still in manuscript.

Puritanism.—So far the writers of Welsh prose had contented themselves with translation. It was left to a Puritan, Morgan Llwyd (1619–59), to make an original contribution to Welsh religious thought. He came under three influences, namely, the Quakers, the Fifth Monarchy men and Jakob Boehme, the German mystic. His chief work, Llyfr y Tri Aderyn (The Book of Three Birds) in 1653, is a disquisition in two parts, on the theory of government and on religious liberty. under the form of a disputation between the eagle (Cromwell or the secular power), the raven (the Anglicans or organized religion) and the dove (the Nonconformists or the followers of the inner light). In this and in many other works, notably *Llythur ir* Cymru (1653), he expounded a mystical gospel which had very little influence, though many editions of his books were published. The most notable prose work between Llyfr y Tri Aderyn and Ellis Wynne's Y *Bardd* Cwsc (1703) was Y Ffydd *Ddi-ffuant* (1667), enlarged in 1671 by Charles Edwards (1628–post 1691).

From the time of Morgan Llwyd until well on in the 19th century translations, mostly of theological works, poured out of the Welsh press and it is almost impossible to thread one's way among these thousands of books. Many were inspired by the Society for Promoting Christian Knonledge (S.P.C.R.). Among the clergy who produced books of this description were Edward Samuel (1674–1748), who published among other works *Holl Ddyledswydd* Dyn (1718), a translation of *The Whole Duty* of *Man* (first published in 1658 and assigned to Richard Allestree); Moses Williams (1685–1742), a most diligent searcher into Welsh manuscripts and a translator; Griffith Jones of Llanddowror (1683–1761), the father of Welsh popular education; Iaco ab Dewi (1648–1722); and Theophilus Evans (1693–1767), the author of *Drych* y *Prif* Oesoedd (1716, 1740). This book, like Llyfr y Tri *Aderyn* and Y Bardd Cwsc, is established in the annals of Welsh literature.

Ellis Wynne o Lasynys (1671–1734) is regarded as the greatest of Welsh prose nriters. His first work was a translation of Jeremy Taylor's Holy Living, under the title of *Rheol Buchedd* Sanctaidd (1710); his second, the immortal *Gweledigaetheu* y Bardd Cwsc (1703), an adaptation of Sir Roger L'Estrange's translation of the *Sueños* of the Spaniard Francisco Gomez de Quevedo y Villegas.

The Rise of Popular Poetry, 1600–1750.—When Henry **VII** ascended the throne the descendants of the old Welsh gentry began to look toward England for recognition and preferment, and their interest in their own country began to wane. It gradually came about that the poets of the older school had no audience. The only poets who still followed the old tradition were the rich gentlemen-farmers who "sang on their own food," as the Welsh phrase goes. A new school. however, was rising. The nation at large had a vast store of folk song and it was this, despised and unrecorded, which, combined with imitation of contemporary English popular poetry and the more sophisticated lyrics, formed the groundwork of the new literature.

The first landmark in this new development was the publication in 1621 of Edmwnd Prys's metrical version of the Psalms and in 1646 of the first poem of The Welshmen's Candle (Canwyll y *Cymry)* of Rhys Prichard (c. 1579–1644), vicar of Llandovery. These works were not written in the old strict metres peculiar to Wales, but in the free metres, like those of English poetry. The *Psalms* is of great importance, as these were about the first metrical hymns in use. Prichard's work, the first complete edition of which was published in 1672, consisted of moral verses in the metres of the old folk songs (Penillion Telyn). Many other poets of the early part of this period wrote in these metres, such as Rowland Fychan, Morgan Llwyd and William Phylip (d. 1669). Poetry in the free metres, however, was generally very crude, until it was given a new dignity by the greatest poet of this period, Huw Morys of Pontymeibion (1622–1709). Most of his earlier compositions are love poems, perfect marvels of felicitous ingenuity and sweetness. Toward the end of the period came Lewys Morys (1701–65), the creator of a new period, the inspirer and patron of Goronwy Owen. As were his brothers Richard and William, he was an accomplished scholar. His poetry, except for a few well-known pieces, will never be popular, because it does not conform to the modern canons of taste.

The Revival, 1750.—The middle of the 18th century was, after the 14th, the most fruitful period of Welsh literature. Up to this time, Wales had lain in a terrible stagnation, both social and literary; a people, who had until now never lacked self-expression in literature, had become inarticulate. It was clear that one of two things was essential if Welsh was to survive as a language of culture—either a recreating literary influence from the outside, or some great spiritual or intellectual revival which would stir the people once more into articulate expression. It was a coincidence that both these events should happen in Wales at the same time.

The first event was the adoption by Goronmy Owen (1723–69), inspired by Lewys Morys, of the literary standards of the English Augustan classicists; the result was the reintroduction into Welsh poetry of the *cywydd* and the awdl in all their traditional correctness of form. but with a new and larger content. Around Goronwy Owen were grouped other poets who thus established a classical school of poetry which is alive to this day. The more important among them were William Wynn of Llangynhafal (1709–60), Edward Richard (1714–77) and Evan Evans (1731–88). Much of the literary activity represented by this school was associated with the Welsh community in London, and with the establishment of the Cymmrodorion society which in turn led to the establishment of local eisteddfods in Wales under the auspices of the learned societies. These eisteddfods. by offering a chair for an *awdl* (this practice it must be noted only dates from the end of the 18th century), perpetuated the classical form *(i.e., cynghanedd* and the strict metres) which would have otherwise certainly disappeared. Thus Goronwy Owen is the fountainhead of modern classicism. His successors, the eisteddfodic bards. though greatly inferior to him in poetic power, did much to reintroduce the knowledge of the classical forms; chief among these was Dafydd Ddu Eryri (1759–1822) who, both as a writer of awdlau and as a grammarian, was the teacher of the 19th century.

His successor. Dewi Wyn o Eifion (1784–1841), was the first to deviate from the strictness of the old tradition, and much of his work is strikingly deficient in quality. Eben Fardd (1802–63) was the last of the 19th-century eisteddfodic bards who made any real contribution to literature; he is the greatest poet of the descriptive school. After him eisteddfodic poetry *(i.e.,* poetry in the classical tradition) suffered eclipse; the last 40 years of the 19th century, though an enormous mass of so-called poetry mas produced, saw what was probably the nadir of popular taste. The end of the 19th century was marked by a reaction toward Goronwy Owen and Dafydd ap Gwilym.

The Free *Metres, 1750–1890.*—The classicists of the 18th century stood aloof from the Methodist revival, but it was the intensity of the religious emotion now set free for the first time that broke the inarticulateness which had befallen Wales. The vast store of experience and expression which had been accumulating out of sight in the Penillion Telyn was at last displayed in the hymns of William Williams Pantycelyn (1717–91), almost the first poet to use the free metres for a serious purpose. He was followed by many hymn writers, the greatest being Ann Griffiths (1776–1805), who alone shows a trace of that mysticism which was lost in Wales after Morgan Llwyd. The literary importance of the hymns lies in the preparation of the Welsh language for secular poetry. All the poetry of the 19th century betrays its religious origin, the later poetry no less than the earlier. John Blackwell (Alun) (1797–1840) may be regarded as the father of the modern secular lyric. Much of his inspiration came from contemporary English songs and in originality he is inferior to Ieuan Glan Geirionydd (1795–1855), who founded the Eryri school of poetry inspired by the natural scenery of Snowdonia; the best-known member of this school is Glasynys (1828–70). These earlier lyric writers were followed by a more Bohemian group consisting of Talhaiarn (1810–70), Mynyddog (1833–77) and Ceiriog (1832–87). Ceiriog was the greatest lyrical writer of the century. Only one poet, Islwyn (1832–78), made a success of the long poem. His *Ystorm* is a series of meditations on life and art, and parts of it are in imitation of Alexander Smith and influenced by Edward Young's *Night* Thoughts.

Prose, 1750–1800.—For a long time after 1750 Welsh prose, though abundant in quantity, had a very narrow range. The end of the 18th century, however, saw much activity in political thought, which was the direct result of the French Revolution. The most important of the early political writers was John Jones Glan-y-gors (1766–1821), who was much influenced by Thomas Paine. Later, when modern liberalism began to emerge, political writing, after the establishment of the periodical press. became an important part of Welsh literature. Two great political thinkers and writers of the century were Samuel Roberts (1800–85) and Gwilym Hiraethog (1802–83).

Literary criticism up to the middle of the 19th century had been confined to the work of eisteddfod adjudicators who were still acting on the old classical theory, *ut pictura* poesis ("poetry is like painting"). The first appearance of a criticism which might be said to follow European standards was in the articles of Lewis Edwards (1809–87), the founder and editor of the *Traethodydd*, though his ideas were dominated by the Edinburgh school. Literary criticism made no progress at all until the great revival in the 20th century. It was in this period that Wales had its national novelist. Daniel Owen (1836–95), who like Dickens "wrote mythology rather than fiction." His novels must always remain an important document for the study of this extraordinary period of theocracy in Wales.

The **Second** Revival. — The most important event for the second revival in Welsh literature was the founding of the university (1872–93). The immediate result was a great widening of the horizons, accompanied by a strong reaction toward the old Welsh classical ideas. The two men who had the most influence on this new movement were Sir Owen Morgan Edwards (1858–1920) and Sir John Morris-Jones (1864–1929). Edwards made the Welsh conscious of their literary identity, and inspired the new movement on its purely literary side. Morris-Jones, by insisting that correctness was the first essential of style and sincerity the first essential of the literary art, revolutionized first the product of the eisteddfod and then literature in general. Another critic whose fearless essays stung the nation into sincerity was Emrys ap Iwan (1851–96).

The extent of the new literary revival is hardly credible to anyone whose study of Welsh ends with 1900. Almost every department of literature is represented. Poetry again became significant. Thomas Gwynn Jones (1871–1949) showed that *cynghanedd* and the old tradition can answer any demand made upon them by the modern interpretation of life; his work is, however, not confined to the strict metres. W. J. Gruffydd (1881–1954) whose medium was the free metres, represented first a rebellion against Victorian standards of morality and literature, and later a nostalgia for the society which formed the background of his youth. Robert Williams Parry (1884–1956) brought back to poetry the gift of poetic observation, expressed in a faultless technique, which had disappeared from Welsh poetry with Dafydd ap Gwilym. Of the other poets whose work has a prominent position in the literary revival, D. Gwenallt Jones and Iorwerth Peate proved outstanding.

In prose there was equal progress. This is clearly seen in the writings of Gruffydd no less than in the standards of Y *Llenor* (1922–51), the literary journal edited by him. A new literary criticism was enriched by the influence of European ideas, which can be seen most clearly in the work of Saunders Lewis. No long novel of great merit was written, though the works of Tegla Davies and T. Rowland Hughes bear many traits of genius. The younger prose writers developed the art of the short story to a high degree; the early promise of Dewi Williams was not fulfilled, but Kate Roberts' work is a striking example of the impact of contemporary Welsh life on a sensitive nature. Starting with no traditions, drama made considerable progress, though it was retarded by material reasons.

One poet, T. H. Parry-Williams, also wrote distinguished essays, which became the model for many others. Dramatists who deserve special mention are D. T. Davies, R. G. Berry, Saunders Lewis and J. Gwilym Jones.

BIBLIOGRAPHY.—(Editions of individual writers are not included, with a few exceptions.) The only modern and authoritative history of Welsh literature: T. Parry, *Hanes Llenyddiaeth Gymraeg* (1944), trans. by H. I. Bell, *A History of Welsh Literature* (1955). Important works in English are: G. Williams, *An Introduction to Welsh Poetry* (1953); H. I. Bell, *The Development of Welsh Poetry* (1936); J. Morris-Jones, "Taliesin," *Cymmrodor*, vol. xxviii (1918) and *Cerdd Dafod* (1925); I. Thomas, *The Life and Work of Bishop Daaies and William Salesbury* (1902); J. H. Davies, *The Morris Letters . . . 1728–65*, 2 vol. (1907–09) and *Letters of Goronwy Owen* (1924); T. Jones, *Brut y Tywysogyon* (1941). (W. J. GRU.; T. Js.)

WELWITSCHIA, a genus of short but remarkably thick-stemmed desert plants of southwestern Africa, belonging to the family Welwitschiaceae of the order Welwitschiales. *See* GYMNOSPERMS.

WELWYN GARDEN CITY, an urban district of Hertfordshire, Eng., 20 mi. N of London by road. Pop. (1951) 18,314. Area 4.1 sq.mi. Founded in 1920 in order to provide a pleasant and well-planned town with an ultimate population of 50,000 who could find work locally and so not have to travel daily elsewhere, Welwyn had about 70 industries in operation in 1952. Under the Town Planning act (1946) Welwyn was bought from the original company by the Welwyn Garden City Development corporation.

WEMBLEY, a municipal borough (1937) of Middlesex, Eng., 7 mi. N.W. of London, which it serves as a residential suburb. Pop. (1961) 124,843. Area 9.8 sq.mi. It returns two members to parliament. Wemba Lea in Saxon times, it remained a village until the 20th century (pop. 4,519 in 1901), when it became involved in the rapid expansion of London. Many buildings erected for the British Empire exhibition (1924–25) became factories and workshops and gave impetus to a limited industrialization. Electrical and mechanical engineering and food preparation are important industries. The exhibition's open-air stadium (accommodating 100,000 spectators) remained and, with the indoor arena (skating, ice hockey, swimming), is a highly popular sports centre.

The borough includes Greenford, where Sir W. H. Perkin (1838–1907) founded the coal-tar dyeing industry, and Kingsbury, a rural retreat of Oliver Goldsmith, which has two strongly contrasting churches, each dedicated to St. Andrew: a small one containing much Saxon work and Roman materials, and a large mid-Victorian one removed stone by stone from Wells street, London, and dedicated in 1934. A farmhouse at Preston is said to have been the birthplace and home of John Lyon, who in 1572 founded Harrow school, about 2 mi. N.

WEMYSS, EARLS OF, heads of a Scottish family who had possessed the lands of Wemyss in Fifeshire since the 12th century. In 1628 Sir John Wemyss, created a baronet in 1625, was raised to the peerage as Baron Wemyss of Elcho; and in 1633 he became earl of Wemyss and Baron Elcho and Methel, in the peerage of Scotland. He took part with the Scottish parliament against Charles I and died in 1649. On the death of David, 2nd earl (1610–79), the estates and titles passed to his daughter Margaret, countess of Wemyss, whose son David, 4th earl, succeeded on her death in 1705, and became lord high admiral of Scotland and a commissioner for concluding the union of England and Scotland in 1707. His son James, 5th earl (1699–1756), married Janet, daughter of Col. Francis Charteris, who had made a large fortune by gambling. His son David, Lord Elcho (1721–87), was attainted for his part in the Jacobite rising of 1745, the estates passing to his younger brother James, while the title remained dormant after his father's death, though it was assumed by Elcho's brother Francis, who took the name of Charteris on inheriting his maternal grandfather's estate. A reversal of the attainder was granted in 1826 to his descendant Francis Charteris Wemyss Douglas (1772–1853), who had been created Baron Wemyss of Wemyss in the peerage of the United Kingdom in 1821 and had assumed the name of Charteris Wemyss Douglas on inheriting some of the Douglas estates.

WEMYSS, a civil parish of Fifeshire, Scot., including the villages of East and West Wemyss and the small burgh of Buckhaven and Methil. Pop. (1951) 28,463. It lies on the northern shore of the Firth of Forth, adjacent to the Fifeshire coal field. Methil is the county's principal port for the export of coal. Industries, apart from coal and shipping, include oilskin manufacture, brickmaking, sawmilling and the preparation of fertilizers and farm supplies.

The district derives its name from the caves (*weems;* Gaelic *uaimh,* "a cave") on the shore between East and West Wemyss. Above the shore is modern Wemyss castle, incorporating part of an earlier work in which Mary, queen of Scots, first met Darnley in 1565. There are also remains of the so-called Macduff's castle.

WEN. The popular name for a sebaceous or fatty cyst (*i.e.,* tumour) formed from a sebaceous gland and therefore occurring in the neighbourhood of hairy parts, particularly the scalp and neck. The fatty or sebaceous material collects in the mass and the normal opening of the duct of the gland is often recognizable on the surface as a minute point. A wen may be as large as a hen's egg. The treatment is surgical removal.

WENCESLAS or WENZEL (1361–1419), German king and. as Wenceslas (Vaclav) IV, king of Bohemia. was the son of the emperor Charles IV. Born at Nuremberg on Feb. 26. 1361. he was crowned king of Bohemia in 1363 In 1370 he married Joanna (d. 1386) daughter of Albert I of lower Bavaria. In 1376. still during his father's lifetime, he was elected and crowned king of the Romans. On his father's death in Nov. 1378, Wenceslas succeeded as sole ruler of Germany and Bohemia. The rest of the Luxemburg lands Charles bequeathed to his younger sons and nephews. From 1378 to 1389 Wenceslas held frequent diets in Germany. seriously endeavouring to keep the peace between town leagues and the nobles. but in spite of some success, ill-health and the endemic anarchy in Germany compelled him to leave that country to its own devices after 1389. He assisted his brother Sigismund to secure the throne of Hungary in 1387, and he himself inherited the duchy of Luxemburg from his uncle Wenceslas in 1383.

In Bohemia Wenceslas' brothers and cousins and the magnates and prelates were greedy for power and jealous of the "new men" and urban patricians to whom the king entrusted the offices of state. In 1394 his cousin Jobst, margrave of Moravia. Jan of Jenštejn, archbishop of Prague, and some of the magnates seized the king and imprisoned him in Austria. He was restored by the efforts of his brother Jan of Görlitz with help from Germany; but the lords continued the struggle for power and in 1396 Wenceslas, compelled to surrender all real power to the aristocratic royal council, made Jobst "governor" of the realm.

Wenceslas' impotence and his neglect of Germany induced the German princes to depose him on Aug. 20, 1400. The next day the three ecclesiastical electors chose Rupert III. count palatine, as king of the Romans. Henceforward Germany was completely lost to Wenceslas. When Rupert died in 1410 he was succeeded by Jobst, and he, in 1411, by Sigismund. who agreed however that Wenceslas should enjoy the title to which he had been elected in Germany until his death.

Meanwhile the struggle between crown and lords continued in Bohemia. In 1402 the lords, led by Sigismund, again made Wenceslas prisoner. He was handed over to the dukes of Austria who held him captive for almost a year. On his release in Nov. 1403 he made peace with the princes and lords. For the rest of his reign Wenceslas was content to leave the government in the hands of the royal council where royal favourites and the magnates shared power. The king grew lethargic and increasingly found solace in wine. After 1403 his only political importance was in connection with the troubles caused by the Schism and the religious reform movement led by John Huss. LVenceslas and his second queen, Sophia of Bavaria (whom he married in 1389), at first gave some support to the reformers; but when after 1411 the Bohemian "heresy" became an international scandal, he withdrew his favour. It was anger at the defenestration of the magistrates whom he had appointed to the New Town of Prague which induced the apoplexy to which Wenceslas succumbed on Aug. 16, 1419. He died childless and the title to the disturbed Bohemian inheritance was left to his brother Sigismund, king of the Romans and king of Hungary. See also GERMANY: *History;* BOHEMIA; SIGISMUND (Holy Roman emperor).

WENCHOW (YUNGKIA), a city in the province of Chekiang, China, and one of the five ports opened by the Chefoo convention (1876) to foreign trade, situated on the Gow river: about 20 mi. from the sea. The population (1953 est.) is 200,000.

The site is said to have been chosen by Kwo P'oh (A.D. 276–324), a celebrated antiquary, and the town became known as Tow, or Great Bear, from a supposed topographical similarity of the neighbouring hills to the constellation. Later, through another legend. it became known as the Deer city, or Luh. During the Ming dynasty (1368–1644) it was named Wenchow. A four-mile wall, built in the 10th century. surrounded it. It fell to Communist forces in 1949 and was made an independent municipality.

WENGEN (4,190 ft.), a health resort and winter sports centre on the slopes of the Jungfrau in the Bernese Oberland, Switz. The place is linked with Interlaken and Lauterbrunnen by a rack railway. From the Little Scheidegg a branch leads to the Jungfraujoch (11,401 ft.) where is the highest station in Europe.

WENLOCK, a market town and municipal borough (1468) in the Ludlow parliamentary division of Shropshire, Eng., 13 mi. S.E. of Shrewsbury by road. on both sides of the Severn. Pop. (1951) 15,095. Area 35.4 sq.mi. To the southwest of Much Wenlock rises the sharp limestone ridge of Wenlock Edge and to its north the isolated hill of the Wrekin (1,385 ft.). The borough includes the townships of Much Wenlock. the civil centre; Broseley; Coalbrookdale. with ironworks; Madeley; Jackfield; Ironbridge, where the first iron bridge in England was built in 1779 at the entrance to the Ironbridge gorge carved by the Severn (the bridge is preserved as an ancient monument); Coalport. once known for its china works, transferred there from Caughley in 1814 and moved to Stoke-on-Trent in 1926; and Little Wenlock, with opencast coal mining. Barge traffic up the Severn was once very important to Broseley, Coalbrookdale and Madeley Wood, all gorge ports. The chief industries are iron founding, limestone quarrying, light engineering and the making of pajamas, at Ironbridge, rubber mats from old tires and metalwork (both in the former Coalport kilns), tiles and bricks, revived at Jackfield and Broseley.

The importance of Much Wenlock in the past depended on the great Cluniac priory of St. Milburge, refounded by Roger de Montgomery in 1017 on the site of a 7th-century foundation. Considerable remains are left of the priory which was dissolved in 1j39; the prior's house, still inhabited, incorporates Norman and 15th-century work. By the 16th century Much Wenlock was a flourishing market town, with a trade in limestone quarrying and burning, and the borough still has many old buildings including the timbered guildhall (1577) and a 12th-century church, a Tudor mansion (1535) at Benthall, the Old hall (16th–17th century) at Little Wenlock and many industrial antiquities at Ironbridge and Coalbrookdale.

WENNERBERG, GUNNAR (1817–1901), Swedish poet, musician, teacher and politician, was born on Oct. 2, the son of a Linkoping clergyman. He studied at Uppsala university from 1837 to 1845 when he was appointed lecturer in aesthetics. He later became a civil servant and politician; a capable and progressive administrator, he was minister of education 1870–7j and 1888–91. In the intervening years he was provincial governor at Vaxjo and member of parliament. In 1866 he was elected to the Swedish academy. He died on Aug. 24, 1901, at Lecko.

Wennerberg is chiefly remembered as a poet and composer, more especially of the trios *De tre* ("The Three"; 1845–47) and of the 30 duets for baritone and bass: *Gluntarne* ("The Lads"; 1849–51), written largely for the Uppsala musical society "The Juvenals." In these lyrics Wennerberg, with ingenious rhyme and singable melody, evoked the joys and troubles of student life in Sweden. Words and music were happily fused as in the work of his great predecessor C. M. Bellman (*q.v.*), and like Bellman, Wennerberg, though a late romantic, merged realism and fantasy.

BIBLIOGRAPHY.—G. Wennerberg, *Samlade skrifter,* 4 vol. (1881–85), *Gluntarne,* de luxe rep. (1949); S. Taube (ed.), *G. Wennerburg: bref och minnen,* 3 vol. (1913–16); S. Almquist, *Om Gunnar Wennerberg* (1917); E. Malm, *Ack, i Arkadien,* (1949). (B. M. E. M.)

WENSLEYDALE, JAMES PARKE, BARON (1782–1868), English judge, perhaps the last of the great "block-letter lawyers." the men to whom technicalities were the breath of life, was born near Liverpool on March 22, 1782. He was educated at Macclesfield Grammar school and Trinity college, Cambridge. Called to the bar at the Inner Temple in 1813. in 1820 he was a junior counsel for the crown in the trial of Queen Caroline. In 1828 he was raised to the king's bench; in 1834 he was transferred to the court of exchequer, where for about 20 years he exercised considerable influence. The changes introduced by the Common Law Procedure acts of 1854 and 1855 proved too much for his legal conservatism and he resigned in Dec. 185j. The government, anxious to have his services as a law lord in the house of lords, proposed to confer on him a life peerage, but this was opposed by the house of lords (*see* PEERAGE), and he was eventually created a peer with the usual remainder (1856). He died at his residence, Ampthill Park. Bedfordshire, on Feb. 25, 1868, and having outlived his three sons, the title became extinct.

Of his devotion to the intricacies of pleading the stories are innumerable; best is perhaps that of his taking one of his special demurrers to read to a dying friend. "It was so exquisitely drawn," he said, "that it must cheer him to read it." In Serjeant Hayes's *Cugate's Case,* printed in Holdsworth's *History* of *English Law,* Parke figures as "Baron Sussebutter."

WENSLEYDALE, part of the upper valley of the river Ure in Yorkshire, Eng. The name Wensleydale is derived from the village of Wensley, about 25 mi. from the source of the river, and is applied to the section of the valley extending about 15 mi upstream from Kilgram bridge, between Jervaulx and Masham, where it opens into the Vale of York, to Hawes Between Masham and Jervaulx are typical morainic hills left by the glacier nhich occupied the valley during the Ice Age. The ivy-clad ruins of Jervaulx abbey, founded in 1156 by Cistercians from Byland, stand on the south side of the river. The remains, mainly transitional Norman and Early English, consist of parts of the chapter house, refectory and cloisters Where Coverdale joins the main valley stands Middleham. overlooked by the massive Norman keep of the 12th-century castle, a stronghold of Warwick the Kingmaker; subsidiary buildings around the toner date down to the 14th century Two miles up the side valley, at Coverham. are the remains of a Premonstratensian abbey, including the gatehouse and other portions of the Decorated period.

Through Leyburn. 1 mi. N. of the Ure, pass the rail and main road connections from Wensleydale to the north–south routes of the Vale of York. The finest part of the dale begins at Wensley, whose 13th-century church with some pre-Norman sculptured stones in its walls suggests its greater importance in early times. A little way upstream and standing high on its northern side are the walls and towers of the 14th-century Bolton castle.

From Leyburn to just above Hawes the valley floor is fertile and carries pastures notable for their dairy produce. though fresh milk is now of much greater importance than the cheese to which the dale long ago gave its name. The valley is bordered by steep slopes with terraces caused by the alternation of thin resistant limestones with softer shale and sandstone beds. Wide moorlands rising to heights of over 2,000 ft. separate Wensleydale from the neighbouring dales. Where the surface rock is limestone many of the moorland streams disappear underground. The Buttertubs pass shows fine examples of such solution drainage. Where the many rapid side streams and the main river cross the limestones in the valley, waterfalls and gorges are formed. At Aysgarth the Ure descends in three main cascades within 1½ mi. and with a total fall of more than 100 ft. Hardraw Force, on a tributary stream near Hawes, has a single leap of 96 ft. from a projecting ledge of limestone. From Hawes to its source the Ure flows in an open moorland valley. (T. HER.)

WENT, FRIEDRICH AUGUST FERDINAND' CHRISTIAN (1863–193j), Dutch botanist, who was responsible for the early knowledge of plant hormones, was born in Amsterdam on June 18, 1863. He contributed greatly to the development of botany in the Netherlands.

From 1891 to 1896 Went was director of a sugar cane experimental station in Java, where he laid the foundation for a physiological analysis of the sugar cane plant and exerted a continuing influence on pure and applied research in the tropics. As professor of botany at the University of Ctrecht (1896–1934), his effective teaching brought him many students. His laboratory became famous for its work on temperature effects, on plant tropisms and on plant growth hormones. particularly auxin. The early acceptance of the plant growth hormone concept in Europe was largely due to his effective lecturing. (*See* PLANTS AND PLANT SCIENCE: *Growth:*) He died at Wassenaar, near The Hague, on July 24,193j.

See G. J. Peirce in *Plant Physiology,* **pp.** 218–223 (April 1936). (F. W. WT.)

WENTWORTH, the name of an English family. various members of which are separately noticed. (*See* FITZWILLIAM, WILLIAM WENTWORTH FITZWILLIAM; ROCKINGHAM. CHARLES WATSON WENTWORTH; STRAFFORD, THOMAS WENTWORTH.) The Wentworths trace their descent to William Wentworth (who died in 1308) of Wentworth Woodhouse, Torkshire. Thomas Wentworth (1501–1551) was summoned to parliament as Baron Wentworth of Nettlestead in 1529. The last baron Wentworth in the male line was Thomas (1613–1665), son of Thomas Wentworth, 1st earl of Cleveland. His daughter Henrietta Maria became Baroness Wentworth in her own right on her grandfather's death. This lady, who was the duke of Monmouth's mistress, died unmarried in 1686. The barony of Wentworth then reverted to Cleveland's daughter Anne. who married the 2nd baron Lovelace, from whom it passed to her granddaughter Martha (d. 1745), wife of Sir Henry Johnson. and then to the great-grandson of Anne's daughter Margaret, Sir Edward Noel. who was created Viscount Wentworth of Wellesborough in 1762. The viscountcy became extinct at his son's death in 1815, when the barony fell into abeyance until 1856. It then passed to Anne Isabella. widow of the poet Lord Byron and daughter of Sir Edward's eldest daughter Judith. Her daughter Augusta Ada, whose husband had been created earl of Lovelace. predeceased her (1852), so that she was succeeded in 1860 by her grandson Byron Noel King-Noel. His brother Ralph Gordon succeeded him as 13th baron in 1862 and became 2nd earl of Lovelace in 1893. but after his death in 1906 the titles were separated, the barony passing successively to his daughter, to his sister and to his niece (1917).

WENTWORTH, WILLIAM CHARLES (1793–1872), an outstanding figure in early Xustralian history. was born Oct. 26, at Norfolk Island, the New South Wales penal settlement, the son of D'Arcy Wentworth. government surgeon of the settlement. He was educated in England, first at Greenwich. after which he went back to Australia to explore the Blue mountains. He returned to England to complete his education at Peterhouse, Cambridge. After he had been called to the bar, he began practising law in Sydney. In 1824 he published *A Statistical Account of the British Settlement in Australasia,* a plea for more powers for colonial governments and a wide franchise. Partly because of his own origin Wentworth became leader of the "emancipists" against the "exclusivists." In the same year, with Robert Wardell, he started a newspaper, the *Australian,* and conducted active opposition to the authoritarian governor Sir Ralph Darling. During the 1830s he continued active work for a constitution giving greater powers of government to New South Wales. In 183j the Xustralian Patriotic association was formed in which Wentworth was a leading figure. But he became wealthy and was no longer in favour of a wide franchise, declaring that "poverty and ignorance went hand in hand." He had much to do with designing the constitution granted to the Australian colonies in 1842. but in the first council he led the exclusivists, or "squatter" party as it had become. Wentworth was also influential in the movement which led to the constitution of 1854. After this he lived abroad for several years, then returned to Australia to become president of the upper house in 1861. In 1862 he settled in Engiand. He died on March 20. 1872, and was buried in Sydney. (J. F. C.)

WERFEL, FRANZ (1890–194j), German writer, was born in Prague on Sept. 10, 1890, and lived successively in Prague, Hamburg, Leipzig, Vienna and Breitenfeld, near Vienna. His early poems, *Der Weltfreund* (1912), *Wir Sind* (1913), *Einander* (191j) and *Der Gerichtstag* (1919), were difficult but beautiful in expression, and were animated by the idea of the community of souls in all living things. World War I and subsequent political troubles gave Werfel's work a strongly revolutionary tinge; his brotherhood seemed best attained by the destruction of obstacles erected by tradition. His novels, *Nicht der Mörder, der Ermordete ist schuldig* (1920) and *Der Abituriententag* (1928) deal with problems and revolt of adolescence, but are less fine than his verse, which ranks with the most powerful in modern German literature. His dramatic works include an adaptation of Euripides' *Troades* (1915); a very brilliant symbolic trilogy, *Der Spiegelmensch* (1920); the more conventional *Juarez und Maximilian* (1924); *Paulus unter den Juden* (1926) and *Der Tod des Kleinburgers* (1926). Werfel died on Aug. 26, 1945, at Hollywood, Calif.

See A. Luther, *Franz Werfel und seine besten Bühnenwerke* (1922).

WERGELAND, HENRIK ARNOLD (1808–1845), Norwegian poet and prose writer, was born at Christiansand on June 17, 1808. He was the eldest son of Professor Nikolai Wergeland (1780–1848), who had been a member of the constitutional assembly which proclaimed the independence of Norway in 1814 at Eidsvold. He established libraries, and tried to alleviate the widespread poverty of the Norwegian peasantry. But his numerous and varied writings were coldly received by the critics, and a monster epic, *Skabelsen, Mennesket* og *Messias* (Creation, Man and Messiah), 1830, showed no improvement in style. It was remodelled in 1845 as *Mennesket*. From 1831 to 1835 Wergeland was submitted to severe satirical attacks from J. S. le Welhaven and others, and his style improved in every respect. His popularity waned as his poetry improved, and in 1840 he found himself a really great lyric poet, but an exile from political influence. In that year he became keeper of the royal archives. He died on July 12, 1845. In 1908 a statue was erected to his memory by his compatriots at Fargo, North Dakota. His *Jan van Huysums Blomsterstykke* (1840), *Svalen* (1841), *Joden* (1842), *Jodinden* (1844) and *Den Engelske Lods* (1844), form a series of interesting narrative poems in short lyrical metres.

Wergeland's *Samlede Skrifter* (9 vols., Christiania, 1852–1857) were edited by H. Lassen, the author of *Henrik Wergeland og hans Samtid* (1866), and the editor of his *Breve* (1867). *See* also H. Schwanenflügel, *Henrik Wergeland* (Copenhagen, 1877); and J. G. Kraft, *Norsk Forfatter-Lexikon* (Christiania, 1857), for a detailed bibliography.

WERMUND, an ancestor of the Mercian royal family, a son of Wihtlaeg and father of Offa. He appears to have reigned in Angel, and his story is preserved by certain Danish historians, especially Saxo Grammaticus. According to these traditions, his reign was long and happy, though its prosperity was eventually marred by the raids of a warlike king named Athislus, who slew Frowinus, the governor of Schleswig, in battle. Frowinus's death was avenged by his two sons, Keto and Wigo, but their conduct in fighting together against a single man was thought to form a national disgrace, which was only obliterated by the subsequent single combat of Offa. It has been suggested that Athislus, though called king of the Swedes by Saxo, was really identical with the Eadgils, lord of the Myrgingas, mentioned in Widsith. As Eadgils was a contemporary of Ermanaric (Eormenric), who died about 370, his date would agree with the indication given by the genealogies which place Wermund nine generations above Penda. Frowinus and Wigo are doubtless to be identified with the Freawine and Wig who figure among the ancestors of the kings of Wessex.

WERNER, ABRAHAM GOTTLOB (1750–1817), father of German geology, was born in Upper Lusatia, Saxony, on Sept. 25, 1750. He was educated at Bunzlau, Silesia, and in 1764 joined his father at Count Solm's iron-works at Wehrau and Lorzendorf, with the idea of ultimately succeeding him as inspector. In 1769, however, he entered the mining school at Freiberg, and in 1771 went to Leipzig, where he studied law and mineralogy. In 1775 he was appointed inspector and teacher in the mining school at Freiberg. He devoted himself for 40 years to the development of the school, which rose to be one of the centres of scientific intelligence in Europe. He died at Freiberg on June 30, 1817.

One of the distinguishing features of Werner's teaching was the care with which he taught lithology and the succession of geological formation; a subject to which he applied the name geognosy. His views on a definite geological succession were inspired by the works of J. G. Lehmann and G. C. Fuchsel (1722–73). He showed that the rocks of the earth follow each other in a certain definite order. He had never travelled, and the sequence of rock-masses which he had recognized in Saxony was believed by him to be of universal application. (*See* his *Kurze Klassifikation und Beschreibung der verschiedenen Gebirgsarten*, 1787.) He taught that the rocks were precipitates of a primaeval ocean, and followed each other in successive deposits of world-wide extent. Volcanoes were regarded by him as abnormal phenomena, probably due to the combustion of subterranean beds of coal. Basalt and similar rocks, already recognized by other observers as of igneous origin, he believed to be water-formed accumulations of the same ancient ocean. Hence arose one of the great historical controversies of geology. Werner's followers preached the doctrine of the aqueous origin of rocks, and were known as Neptunists; their opponents, who recognized the important part taken in the construction of the earth's crust by subterranean heat, were styled Vulcanists.

Though much of Werner's theoretical work was erroneous, science is indebted to him for so clearly demonstrating the chronological succession of rocks.

WERNER, ALFRED (1866–1919), French-Swiss chemist, Nobel laureate in chemistry in 1913 for his work on molecular structure and noted for his co-ordination theory of valency, was born at Mulhouse, in Alsace, on Dec. 12, 1866. In 1886 he went to Zurich to study and later worked at Zurich with George Lunge and in Paris with Marcellin Berthelot, but he returned in 1893 as extraordinary professor of chemistry at Zürich. In 1895 he was made ordinary professor of chemistry, an appointment he held until his death on Nov. 15, 1919. He was awarded the Nobel prize in 1913 "in recognition of his works on the linking up of atoms within the molecule, whereby new light has been thrown upon older fields of research, and new fields have been opened up, especially within the realm of inorganic chemistry."

Werner's earliest work was with Arthur Hantzsch on the stereochemistry of the oximes (*q.v.*), but his greatest contribution to chemistry was the co-ordination theory of valency (*see* VALENCE), which he put forward in 1893. In this he introduced the important ideas of co-ordination number and subsidiary valence. Werner stated that he awoke one morning at 2, as the theory flashed into his consciousness. By 5 in the afternoon the essential features had been worked out. By means of this theory not only was a simple method of classifying complex inorganic compounds made available, but new and unsuspected cases of geometrical and optical isomerism were brought to light, including optically active substances whose activity is due to elements other than carbon. (*See* ISOMERISM.) Although Werner's views met some opposition-and had to be modified slightly, they undoubtedly gave a great stimulus to the development of certain branches of chemistry. His ideas may be said to underlie the modern development of inorganic chemistry, since they departed from the inadequate theories of structure based on the study of carbon compounds, and prepared the way for the electronic theory of valency. Werner deserves to be named with Friedrich Kekulé as an originator of structure theory. More than 200 dissertations were prepared under his direction, and his papers exceed 150 in number. He and his students prepared numerous new series of compounds and fitted them into the new system.

Werner wrote *Neuere Anschauungen auf dem Gebiet der anorganischen Chemie* (1905; 5th ed., 1923), and *Lehrbuch der Stereochemie* (1904).

WERNIGERODE, a town in Magdeburg district, Germany, on the north slopes of the Harz mountains. Pop. (1950) 33,890.

The counts of Wernigerode, who can be traced back to the early 12th century, were successively vassals of the margraves of Brandenburg (1268) and the archbishops of Magdeburg (1381). On the extinction of the family in 1429 the county fell to the counts of Stolberg. The latter surrendered its military and fiscal independence to Prussia in 1714.

WERTHEIMER, MAX (1880–1943), German psychologist and philosopher, founder of the Gestalt theory, was born in Prague, Czech., on April 15, 1880. He studied philosophy and psychology at Prague and Berlin and received his Ph.D. *summa cum laude* from Wurzburg in 1904. He taught at Frankfurt and then at Berlin, returning to Frankfurt in 1929 to accept the chair in psychology. In 1933 he moved to the United States, joining the New School for Social Research in New York city, where he held a professorship until his death on Oct. 12, 1943.

Rertheimer's profound influence on psychology came mainly through his many devoted students. His writings ranged widely, including such fields as the psychology of perception and of thinking, crime detection, musicology and philosophical problems of logic, ethics and truth. His 1912 paper on apparent movement launched the Gestalt school, which he. with Wolfgang Kohler, Kurt Koffka (*qq.v.*) and others, made one of the major approaches of modern psychology. Gestalt theory holds that a whole is something different from the sum of its parts. and therefore analyzing parts does not provide information about the nature of the whole.. Analysis should "proceed from above to below"; in order to understand not only the whole but also its parts, each part must be viewed in its place, role and function within the whole.

See Edwin B. Newman, "Max Wertheimer (1880–1943)," *Am. J. Psychol.*, 57:428–435 (1944). (M. M. WR.)

WERTMÜLLER, ADOLF ULRICH (1751–1811), Swedish-U.S. painter, who is chiefly remembered for his figure composition, was born in Stockholm on Feb. 18, 1751. He was a cousin of the celebrated Swedish artist Alexander Roslin. Trained in Stockholm, Paris and Rome, he had a studio in Paris from 1783 to 1788 and later at Bordeaux. He was also patronized by the French and Swedish courts. He first visited the United States about 1794, remaining in Philadelphia for two years before going back to Sweden in 1796. Four years later Wertmüller returned to Philadelphia, married and settled on a farm in New Castle county, Del., where he lived until his death early in Oct. 1811. The contents of his studio were sold at auction a few months later for $4,500. In the U.S. Wertmüller painted some portraits, including one of George Washington (1795; Metropolitan Museum of Art, New York), but his more notable works are his figure paintings. His "Danae and the Shower of Gold," one of the first nudes exhibited in America, scandalized viewers during the artist's lifetime and long after his death. It is now in the National museum, Stockholm, as are also his diary and other personal papers. (D. H. W.)

WESEL, a town in the North Rhine-Westphalia Land, Ger., siiuated at the confluence of the Rhine and Lippe rivers, 46 mi. S.W. of Münster and 35 mi. N.W. of Duisburg. Pop. (1950) 18,244. Wesel arose from a Frankish court. soon surrounded by a settlement; it was made part of the duchy of Cleve in 1233, was granted municipal status in 1241 and became a flourishing commercial town. A member of the Hanseatic league from 1407, it became the most important trade centre on the lower Rhine next to Cologne. Peter Minuit (*q.v.*), the first director general of New York (New Netherlands). was born in Wesel. From 1680 to 1918 the town was a Brandenburg-Prussian fortress and garrison town. The citadel. Berlin gate and Cleve gate date from this period. In Feb. 1945, Wesel was almost completely destroyed by bombing, but was afterward rebuilt.

WESER (Lat. VISURGIS), one of the chief rivers of Germany, 273 mi. long, formed by the union of the Werra and the Fulda at Münden, flowing generally north and entering the North sea at Bremerhaven, between Jade bay and the estuary of the Elbe. The fairway up to Bremen has a minimum depth of 18 ft. and boats of 350 tons can usually go up to Münden, thanks to locks and weirs which avoid rapids. The Geeste, Wümme and Aller, Weser's right-bank tributaries, and the Hunte, its left-bank tributary, are navigable; so are the Werra and the Fulda. The Weser is connected by canals with the Rhine. Ems and Elbe rivers.

From 1924 to 1947 the urban district formed by the union of the towns of Geestemiinde and Lehe, on the right bank of the Weser estuary, was called Wesermünde. In 1939 Wesermunde had a population of 112,831. In 1947 it was absorbed by the urban district of Bremerhaven.

WESLEY (FAMILY). The Wesley family sprang from Welswe, near Wells in Somerset. Their pedigree has been traced back to Guy, whom Athelstan made a thane about 938. One branch of the family settled in Ireland. Sir Herbert Westley of Westleigh, Devon, married Elizabeth Wellesley of Dangan in Ireland. Their third son. Bartholomew, studied both medicine and theology at Oxford and, in 1619, married the daughter of Sir Henry Colley of Kildare. In 1660 he held the rectories of Catherston and Charmouth in Dorset valued at £35 10*s*. per annum. He was ejected in 1662 and gained his living as a doctor. He was buried at Lyme Regis on Feb. 15, 1670.

His son, JOHN WESTLEY, grandfather of the founder of Methodism, was born in 1636 and studied at New Inn Hall, Oxford, where he became proficient in Oriental languages and won the special regard of John Owen, then vice-chancellor. Cronwell's Triers approved him as minister of Winterborn-Whitchurch, Dorset, in 1658. The following year he married the daughter of John White, the patriarch of Dorchester. In 1661 he was committed to prison for refusing to use the Book of Common Prayer. His candour and zeal made a deep impression on Gilbert Ironside the elder, Bishop of Bristol, with whom he had an interview. He was ejected in 1662 and became a Nonconformist pastor at Poole. He died in 1678; his widow survived him for 32 years. One of his sons, Matthew, became a surgeon in London, where he died in 1737.

Another son, SAMUEL, was trained in London for the Nonconformist ministry, but changed his views, and, in Aug 1683, entered Exeter college, Oxford, as a sizar. He dropped the "t" in his name and returned to what he said was the original spelling, Wesley. In 1689 he was ordained and married Susanna, youngest daughter of Dr. Samuel Annesley, vicar of St. Giles, Cripplegate, and nephew of the 1st earl of Anglesea. Annesley gave up his living in 1662, and formed a congregation in Little St. Helen's, Bishopsgate. Samuel Wesley was appointed rector of South Ormsby in 1691, and moved to Epworth in 1697. He had 19 children, of whom eight died in infancy. His lawless parishioners could not endure his faithful preaching, and in 1705 he was confined in Lincoln castle for a small debt. Two-thirds of his parsonage was destroyed by fire in 1702 and in 1709 it was burnt to the ground. He managed to rebuild the rectory, but his resources were so heavily strained that 13 years later it was only half furnished. Samuel Wesley wrote a *Life of Christ* in verse (1693), *The History of the Old and New Testament in Verse* (1701?), a noble *Letter to a Curate,* full of strong sense and ripe experience, and *Dissertations on the Book of Job* (1735). He died at Epworth in 1735. Susanna Wesley died at the Foundry, London, in 1742 and was buried in Bunhill Fields.

Their eldest son, SAMUEL WESLEY (1690–1739), was born in London, entered Westminster school in 1704, became a Queen's scholar in 1707 and in 1711 went up to Christ Church, Oxford He returned to Westminster as head usher, took orders and enjoyed the intimate friendship of Bishop Atterbury, Harley earl of Oxford, Addison, Swift and Prior. He became headmaster of Blundell's school at Tiverton in 1732 and died there on Nov. 6, 1739. He was a finished classical scholar, a poet and a devout man, but he was never reconciled to the Methodism of his brothers. His poems, published in 1736, reached a second edition in 1743, and were reprinted with new poems and a *Life* by W. Nichols (1862).

CHARLES WESLEY (1707–1788) was the 18th child of the Rector of Epworth, and was saved from the fire of 1709 by his nurse. He entered Westminster school in 1716, became a King's Scholar and was captain of the school in 1725 He was a plucky boy, and won the life-long friendship of the future earl of Mansfield by fighting battles on his behalf. Garret Wesley of Ireland wished to adopt his young kinsman, but this offer was declined and the estates were left to Richard Colley on condition that he assumed the name Wesley. Charles Wesley was elected to Christ Church in 1726. John had become fellow of Lincoln the previous March Charles lost his first 12 months at Oxford in "diversions," but whilst John was acting as their father's curate, his brother "awoke out of his lethargy." He persuaded two or three other students to go with him to the weekly sacrament. This led a young gentleman of Christ Church to exclaim: "Here is a new set of Methodists sprung up." The name quickly spread through the university, and Oxford Methodism began its course. In 1735 Charles Wesley was ordained and went with his brother to Georgia as secretary to Colonel, afterwards General, Oglethorpe, the Governor. The work proved uncongenial, and after enduring many hardships his health failed and he left Frederica for England on July 26, 1736. He hoped to return, but in Feb. 1738 John Wesley came home, and Charles found that his state of health made it necessary to resign his secretaryship. After his evangelical conversion on Whit Sunday (May 21, 1738), he became the poet of the Revival.

He wrote about 6,500 hymns. They vary greatly in merit, but Canon Overton held him, taking quantity and quality into consideration, to be "the great hymn-writer of all ages." Their early volumes of poetry bear the names of both brothers, but it is generally assumed that the original hymns were by Charles and the translations by John Wesley. For some years Charles Wesley took a full share in the hardships and perils of the Methodist itinerancy, and was often a remarkably powerful preacher. After his marriage in 1749 his work was chiefly confined to Bristol, where he then lived, and London. He moved to London in 1771 and died in Marylebone on March 29, 1788. He was strongly opposed to his brother's ordinations, and refused to be buried at City Road, because the ground there was unconsecrated. He was buried in the graveyard of Marylebone Old Church.

Charles Wesley married Sarah Gwynne, daughter of a Welsh magistrate living at Garth, on April 8, 1749. She died in 1822 at the age of ninety-six. Five of their children died as infants and are buried in St. James's churchyard, Bristol. Their surviving daughter Sarah, who was engaged in literary work, died unmarried in 1828. Charles Wesley, Jr. (1759–1834), was organist of St. George's, Hanover Square. He published *Six Concertos for the Organ and Harp* in 1778. He also died unmarried. Samuel, the younger brother (1766–1837) (*q.v.*), was even more gifted than Charles as an organist and composer; he was also a lecturer on musical subjects. Two of his sons were Dr. Wesley, sub-dean of the Chapel Royal, and Dr. Samuel Sebastian Wesley (*q.v.*) (1810–1876), the famous organist of Gloucester cathedral.

BIBLIOGRAPHY.—A volume of Charles Wesley's sermons with memoir appeared in 1816; Lives by Thomas Jackson (1841) and John Telford (1886); Journal and Letters with Notes by Thomas Jackson (1849); *The Early Journal* (1736–39) with additional matter (1910); *Poetical Works of John and Charles Wesley* (13 vols., 1868); *Methodist Hymn Book Illustrated* by J. Telford (1906); Adam Clarke's *Memoirs of the Wesley Family* (1822); Dove's *Biographical History of the Wesley Family* (1832); G. J. Stevenson, *Memorials of the Wesley Family* (1876); Tyerman's *Life and Times of Samuel Wesley, M.A.* (1866).

(J. TE.)

WESLEY, JOHN (1703–1791), English divine, was born at Epworth Rectory on June 17th (O.S.) 1703. He was the 15th child of Samuel and Susanna Wesley. (*See* WESLEY FAMILY.) His mother's training laid the foundation of his character, and under her instruction the children made remarkable progress. On Feb. 9, 1709, the rectory was burnt down, and the children had a narrow escape. On the duke of Buckingham's nomination, Wesley was for six years a pupil at Charterhouse. In June 1720 he went up to Christ Church, Oxford, with an annual allowance of £40 as a Charterhouse scholar. His health was poor and he found it hard to keep out of debt, but he made good use of his opportunities. A scheme of study which he drew up for 1722 with a time-table for each day of the week is still to be seen in his earliest diary.

The standard edition of Wesley's *Journal* (1909) has furnished much new material for this period of Wesley's life, Curnock having unravelled the difficult cipher and shorthand in which Wesley's early diaries were kept. He reached the conclusion that the religious friend who directed Wesley's attention to the writings of Thomas à Kempis and Jeremy Taylor, in 1725, was Miss Betty Kirkham, whose father was rector of Stanton in Gloucestershire. Wesley frankly disclaimed inward holiness.

He was ordained deacon on Sept. 19, 1725, and admitted to priest's orders on Sept. 22. 1728. In 1726 he had been fellow of Lincoln. His private diaries, seven of which are in the hands of Mr. Russell J. Colman of Norwich, contain monthly reviews of Wesley's reading. It covered a wide range. and he made careful notes and abstracts of it. He generally took breakfast or tea with some congenial friend and delighted to discuss the deepest subjects. At the coffee house he saw the *Spectator* and other periodicals. He loved riding and walking and was an expert swimmer.

He preached frequently in the churches near Oxford in the months succeeding his ordination, and in April 1726 he obtained leave from his college to act as his father's curate. The new material in the *Journal* describes the simple manner of his life. He read plays, attended the village fairs, shot plovers in the fenland, and enjoyed a dance with his sisters. In October he returned to Oxford, where he was appointed Greek lecturer and moderator of the classes. He gained considerable reputation in the disputation for his master's degree in February 1727. He was now free to follow his own course of studies and began to lose his love for company, unless it were with those who were drawn like himself to religion. In August he returned to Lincolnshire, where he assisted his father till Nov. 1729. During those two years he paid three visits to the university. In the summer of 1729 he was up for two months. Almost every evening found him with the little society which had gathered round Charles.

The Holy Club.—When he came into residence in November he was recognized as the father of the Holy Club. It met at first on Sunday evenings, then every evening was passed in Wesley's room or that of some other member. They read the Greek Testament and the classics; fasted on Wednesday and Friday; received the Lord's Supper every week; and brought all their life under review. In 1730 William Morgan, an Irish student, visited the gaol and reported that there was a great opening for work among the prisoners. The friends agreed to visit the Castle twice a week and to look after the sick in any parish where the clergyman was willing to accept their help. Wesley's spirit at this time is seen from his sermon on "The Circumcision of the Heart." preached before the university on January 1, 1733. In 1765 he said it "contains all that I now teach concerning salvation from all sin, and loving God with an undivided heart." Wesley rose at four, lived on £28 a year and gave away the remainder of his income. William Law's books impressed him and on his advice the young tutor began to read mystic authors, but he soon laid them aside.

Wesley had not yet found the key to the heart and conscience of his hearers. He says, "From the year 1725 to 1729, I preached much, but saw no fruit to my labour. Indeed it could not be that I should; for I neither laid the foundation of repentance nor of preaching the Gospel, taking it for granted that all to whom I preached were believers, and that many of them needed no repentance. From the year 1729 to 1734, laying a deeper foundation of repentance, I saw a little fruit. But it was only a little; and no wonder; for I did not preach faith in the blood of the covenant. From 1734 to 1738, speaking more of faith in Christ. I saw more fruit of my preaching." Looking back on these days in 1777, Wesley felt "the Methodists at Oxford were all one body, and, as it were, one soul; zealous for the religion of the Bible, of the Primitive Church, and, in consequence, of the Church of England; as they believed it to come nearer the scriptural and primitive plan than any other national church upon earth." The number of Oxford Methodists was small and probably never exceeding twenty-five. John Clayton, James Hervey, Benjamin Ingham and Thomas Broughton, were members of the Holy Club, and George Whitefield joined it on the eve of the Wesley's departure for Georgia.

Mission to Georgia.—Wesley's father died on April 25, 1735, and in the following October John and Charles took ship for Georgia, with Benjamin Ingham and Charles Delamotte. John was sent out by the Society for the Propagation of the Gospel, and hoped to labour as a missionary among the Indians, but though he had many interesting conversations with them the mission was found to be impracticable. The cabin of the "Simmonds" became a study for the four Methodists. The calm confidence of their Moravian fellow-passengers amid the Atlantic storms convinced Wesley that he did not possess the faith which casts out fear. Closer acquaintance with these German friends in Savannah deepened the impression. Wesley needed help, for he was beset by difficulties. Mrs. Hawkins and Mrs. Welch poisoned the mind of Colonel Oglethorpe against the brothers for a time. Wesley's attachment to Miss Hopkey also led to much pain and disappointment. All this is now seen more clearly in the standard edition of the *Journal*. Wesley was a stiff High Churchman, who scrupulously followed every detail of the rubrics. He insisted on baptizing children by trine immersion, and refused the Communion to a pious German because he had not been baptized by a minister who had been episcopally ordained. At the same time he was accused of "introducing into the church and service at the altar compositions of psalms and hymns not inspected or authorized by any proper judicature." The list of grievances presented by Wesley's enemies to the Grand Jury at Savannah gives abundant evidence of his unwearying labours for his flock.

The foundation of his future work as the father of Methodist hymnody was laid in Georgia. His first *Collectzon of Psalms and Hymns* (Charlestown, 1737) contains five of his incomparable translations from the German, and on his return to England he published another *Collection* in 1738, with five more translations from the German and one from the Spanish. In April 1736 Wesley formed a little society of thirty or forty of the serious members of his congregation. He calls this the second rise of Methodism, the first being at Oxford in November 1729. The company in Savannah met every Wednesday evening "in order to a free conversation, begun and ended with singing and prayer." A select company of these met at the parsonage on Sunday afternoons. In 1781 he writes, "I cannot but observe that these were the first rudiments of the Methodist societies."

In the presence of such facts we can understand the significance of the mission to Georgia. Wesley put down many severe things against himself on the return voyage, and he saw afterwards that even then he had the faith of a servant though not that of a son. In London he met Peter Bohler who had been ordained by Zinzendorf for work in Carolina. By Bohler Wesley was convinced that he lacked "that faith whereby alone we are saved." On Wednesday, May 24, 1738, he went to a society meeting in Aldersgate Street where Luther's *Preface to the Epistle to the Romans* was being read. "About a quarter before nine, while he was describing the change which God works in the heart through faith in Christ, I felt my heart strangely warmed. I felt I did trust in Christ, Christ alone, for salvation; and an assurance was given me that he had taken away *my* sins, even *mine,* and saved *me* from the law of sin and death." Mr. Lecky points out the significance of that event. "It is scarcely an exaggeration to say that the scene which took place at that humble meeting in Aldersgate Street forms an epoch in English history. The conviction which then flashed upon one of the most powerful and most active intellects in England is the true source of English Methodism" *(History of England in Eighteenth Century,* ii. 558).

Wesley spent some time during the summer of 1738 in visiting the Moravian settlement at Herrnhut and returned to London on Sept. 16, 1738, with his faith greatly strengthened. He preached in all the churches that were open to him, spoke in many religious societies, visited Newgate and the Oxford prisons. On New Year's Day, 1739, the Wesleys, Whitefield and other friends had a Love Feast at Fetter Lane. In February Whitefield went to Bristol, where his popularity was unbounded. When the churches were closed against him he spoke to the Kingswood colliers in the open air, and after six memorable weeks wrote urging Wesley to come and take up the work. Wesley was in his friend's congregation on April 1, but says, "I could scarcely reconcile myself to this strange way of preaching in the fields . . . having been all my life (till very lately) so tenacious of every point relating to decency and order, that I should have thought the saving of souls almost a sin, if it had not been done in a church." Next day Wesley followed Whitefield's example. His fears and prejudices melted away as he discerned that this was the very method needed for reaching the multitudes.

Foundation **of** the "Society."—On May 1, 1738, he wrote in his journal: "This evening our little society began, which afterwards met in Fetter Lane." Among its "fundamental rules" we find a provision for dividing the society into bands of five or ten persons who spoke freely and plainly to each other as to the "real state" of their hearts. The bands united in a conference every Wednesday evening. The society first met at James Hutton's shop, "The Bible and Sun," Wild Street, west of Temple Bar. About Sept. 25, it moved to Fetter Lane. Wesley describes this as the third beginning of Methodism. After the field preaching began converts multiplied. They found all the world against them, and Wesley advised them to strengthen one another and talk together as often as they could. When he tried to visit them at their homes he found the task beyond him, and therefore invited them to meet him on Thursday evenings. This meeting was held in the end of 1739 at the Foundry in Moorfields which Wesley had just secured as a preaching place. Grave disorders had arisen in the society at Fetter Lane, and on July 23, 1740, Wesley withdrew from it. About 25 men and 48 women also left and cast in their lot with the society at the Foundry. The centenary of Methodism was kept in 1839.

Wesley's headquarters at Bristol were in the Horse Fair, where a room was built in May 1739 for two religious societies which had been accustomed to meet in Nicholas Street and Baldwin Street. To meet the cost of this Captain Foy suggested that each member should give a penny per week. When it was urged that some were too poor to do this, he replied, "Then put eleven of the poorest with me; and if they can give anything, well: I will call on them weekly, and if they can give nothing I will give for them as well as for myself." Others followed his example and were called leaders, a name given as early as Nov. 5, 1738, to those who had charge of the bands in London. Wesley saw that here was the very means he needed to watch over his flock. The leaders thus became a body of lay pastors. Those under their care formed a class. It proved more convenient to meet together and this gave opportunity for religious conversation and prayer. As the society increased Wesley found it needed "still greater care to separate the precious from the vile." He therefore arranged to meet the classes himself every quarter and gave a ticket "under his own hand" to every one "whose seriousness and good conversation" he found no reason to doubt. The ticket furnished an easy means for guarding the meetings of the society against intrusion. "Bands" were formed for those who wished for closer communion. Love-feasts for fellowship and testimony were also introduced, according to the custom of the primitive church. Watch-nights were due to the suggestion of a Kingswood collier in 1740.

Wesley issued the rules of the united societies in February 1743. Those who wished to enter the society must have "a desire to flee from the wrath to come, to be saved from their sins" When admitted they were to give evidence of their desire for salvation "by doing no harm; by doing good of every possible sort; by attending upon all the means of grace." It was expected that all who could do so would contribute the penny a week suggested in Bristol, and give a shilling at the renewal of their quarterly ticket. Wesley had at first to take charge of the contributions, but as they grew larger he appointed stewards to receive the money, to pay debts, and to relieve the needy. The memorable arrangement in Bristol was made a few weeks before Wesley's field of labour was extended to the north of England in May 1742. He found Newcastle ripe for his message. English Christianity seemed to have no power to uplift the people. Dram-drinking was an epidemic. Freethinkers' clubs flourished.

The doctrine of election had led to a temporary separation between Whitefield and the Wesleys in 1741. Wesley believed that the grace of God could transform every life that received it. He preached the doctrine of conscious acceptance with God and daily growth in holiness. Victory over sin was the goal which he set before all his people. He made his appeal to the conscience in the clearest language, with the most cogent argument and with all the weight of personal conviction. Hearers like John Nelson felt as though every word was aimed at themselves. No preacher of the century had this mastery over his audience. His Evangelical Arminianism is shown in his four volumes of sermons and his *Notes on the New Testament.*

Itinerary **Work.**—Up till 1742 Wesley's work was chiefly confined to London and Bristol, with the adjacent towns and villages or the places which lay between them On his way to Newcastle that year Wesley visited Birstal, where John Nelson, the stonemason, had already been working. On his return he held memorable services in the churchyard at Epworth. Methodism this year spread out from Birstal into the West Riding. Societies were also formed in Somerset, Wilts, Gloucestershire, Leicester, Warwickshire, Nottinghamshire and the south of Yorkshire. In the summer Charles Wesley visited Wednesbury, Leeds and Newcastle. Next year he took Cornwall by storm. The work in London was prospering. In 1743 Wesley secured a west-end centre at West

Street, Seven Dials, which for fifty years had a wonderful history. In August 1747 Wesley paid his first visit to Ireland, where he had such success that he gave more than six years of his life to the country and crossed the Irish Channel forty-two times. Ireland has now its own conference presided over by a delegate from the British conference. Wesley's first visit to Scotland was in 1751. In all, he paid 22 visits.

Such extension of nis field would have been impossible had not Wesley been helped by a heroic band of preachers. Wesley says: "Joseph Humphreys was the first lay preacher that assisted me in England, in the year 1738." That was probably help in the Fetter Lane Society, for Wesley then had no preaching place of his own. John Cennick, the hymn-writer and schoolmaster at Kingswood, began to preach there in 1739. Thomas Maxwell, who was left to meet and pray with the members at the Foundry during the absence of the Wesleys, began to preach. Wesley hurried to London to check this irregularity, but his mother urged him to hear Maxwell for himself, and he soon saw that such assistance was of the highest value. The autobiographies of these early Methodist preachers are among the classics of the Evangelical Revival. As the work advanced Wesley held a conference at the Foundry in 1744. Besides himself and his brother, four other clergymen were present and four "lay brethren." It was agreed that "lay assistants" were allowable, but only in cases of necessity. This necessity grew more urgent every year as Methodism extended. One of the preachers in each circuit was the "assistant," who had general oversight of the work, the others were "helpers." The conference became an annual gathering of Wesley's preachers.

In the early conversations doctrine took a prominent place, but as Methodism spread the oversight of its growing organization occupied more time and more attention. In February 1784 Wesley's deed of declaration gave the conference a legal constitution. He named one hundred preachers who after his death were to meet once a year, fill up vacancies in their number, appoint a president and secretary, station the preachers, admit proper persons into the ministry, and take general oversight of the societies. In October 1768, a Methodist chapel was opened in New York. At the conference of 1769 two preachers, Richard Boardman and Joseph Pilmoor, volunteered to go out to take charge of the work. In 1771, Francis Asbury, the Wesley of America, crossed the Atlantic. Methodism grew rapidly, and it became essential to provide its people with the sacraments. In September 1784 Wesley ordained his clerical helper, Dr. Coke, superintendent (or bishop), and instructed him to ordain Asbury as his colleague. Richard Whatcoat and Thomas Vasey were ordained by Wesley, Coke and Creighton to administer the sacraments in America. Wesley had reached the conclusion in 1746 that bishops and presbyters were essentially of one order. *(See* METHODISM: *United States.)*

He told his brother in 1785: "I firmly believe that I am a scriptural ἐπισκοπος as much as any man in England or in Europe; for the uninterrupted succession I know to be a fable, which no man ever did or can prove." Other ordinations for the administration of the sacraments in Scotland, the colonies and England followed. The interests of his work stood first with Wesley. He did everything that strong words against separation could do to bind his societies to the Church of England; he also did everything that legal documents and ordinations could do to secure the permanence of that great work for which God had raised him up. In the words of Canon Overton and Rev. F. H. Relton (*Hist. of Eng. Ch.* 1714–1800): "It is purely a modern notion that the Wesleyan movement ever was, or ever was intended to be, except by Wesley, a church movement." Despite his strong sayings, it was Wesley who broke the links to the church, for, as Lord Mansfield put it, "ordination is separation."

Wesley's account of his itinerancy is given in his famous *Journal*, of which the first part appeared about 1739. Mr. Birrell has called it "the most amazing record of human exertion ever penned by man." The development of his work made a tremendous strain upon Wesley's powers. He generally travelled about 5,000 miles a year and preached fifteen sermons a week. His rule was always to look a mob in the face.

Wesley's writings did much to open the eyes of candid men to his motives and his methods. Besides the incomparable *Journal*, his *Appeals to Men of Reason and Religion* also produced an extraordinary effect in allaying prejudice and winning respect. He constantly sought to educate his own people. No man in the 18th century did so much to create a taste for good reading and to supply it with books at the lowest prices. Sir Leslie Stephen pays high praise to Wesley's writings, which went "straight to the mark without one superfluous flourish." As a social reformer Wesley was far in advance of his time. He provided work for the deserving poor, supplied them with clothes and food in seasons of special distress. The profits on his cheap books enabled him to give away as much as £1,400 a year. He established a lending stock to help struggling business men and did much to relieve debtors who had been thrown into prison. He opened dispensaries in London and Bristol and was keenly interested in medicine.

Wesley's supreme gift was his genius for organization. He was by no means ignorant of this. "I know this is the peculiar talent which God has given me." Wesley's special power lay in his quickness to avail himself of circumstances and of the suggestions made by those about him. The class-meeting, the love-feast, the watch-night, the covenant service, leaders, stewards, lay preachers, all were the fruit of this readiness to avail himself of suggestions made by men or events.

In 1751 Wesley married Mary Vazeille, a widow, but the union was unfortunate and she finally left him. John Fletcher, the vicar of Madeley, to whom Wesley had turned as a possible successor, died in 1785. He had gone to Wesley's help at West Street after his ordination at Whitehall in 1757 and had been one of his chief allies ever since. He was beloved by all the preachers, and his *Checks to Antinomianism* show that he was a courteous controversialist. Charles Wesley died three years after Fletcher. During the last three years of his life John Wesley was welcomed everywhere. His visits were public holidays.

Wesley preached his last sermon in Mr. Belson's house at Leatherhead on Wednesday, Feb. 23, 1791; wrote next day his last letter to Wilberforce, urging him to carry on his crusade against the slave trade; and died in his house at City Road on March 2, 1791, in his eighty-eighth year. He was buried on March 9, in the graveyard behind City Road chapel. (J. TE.)

BIBLIOGRAPHY.—The standard edition of the *Journal*, enlarged from the original mss., with notes from Wesley's unpublished diaries, etc., was edited by N. Curnock (8 vols., 1909–16). The standard life of Wesley is J. S. Simon's *John Wesley, the Master Builder* (1927). Wesley's *Standard Sermons* were edited by E. H. Sugden (1921). See also W. A. Gifford, *John Wesley: Patriot and Statesman* (1922); J. H. Holmes, *John Wesley and the Methodist Revolt* (1923); F. L. Barber, *The Philosophy of John Wesley* (1923); J. Wakinshaw, *John Wesley* (1928). *See* also METHODISM, the articles on the separate Methodist bodies, and WESLEY FAMILY.

WESLEY, SAMUEL (1766–1837), English musical composer, son of Charles Wesley, was born at Bristol, Feb. 24, 1766. Though suffering for many years from an accidental injury to the brain, Wesley was one of the most brilliant organists and most accomplished extemporaneous performers of his time. He may indeed be regarded as the father of modern English organ playing, for he it was who, aided by his friends Benjamin Jacob and C. F. Horn, first introduced the works of J. S. Bach to English organists, not only by his superb playing, but by editing with Horn, in 1813. the first copy of *Das wohltemperirte Clavier* ever printed in England. Wesley died on Oct. 11, 1837, leaving a vast number of manuscripts and printed compositions.

WESLEY, SAMUEL SEBASTIAN (1810–1876), English composer and organist, natural son of Samuel Wesley, the eminent composer. was born in London on Aug. 14. 1810. He was one of the children of the Chapel Royal from 1819, held various unimportant posts as organist from the age of 15 and in 1832 was appointed to Hereford cathedral. He was successively organist at Exeter cathedral. Leeds parish church; Winchester and Gloucester cathedrals. He conducted the Three Choirs festivals of 1834 1865, 1868. 1871 and 1874. A civil list pension of £100 a year was conferred on him in 1873; he died at Gloucester, April 19, 1876, and was buried at Exeter. Wesley was the English organist of his day. As a composer he is still highly esteemed for the dignity and beauty of his anthems, the finest of which are "Blessed Be the God and Father," "The Wilderness," "Ascribe Unto the Lord" and "O Lord, Thou Art My God." His service in E. the most elaborate in design for daily use so far attempted, which was published with a rather trenchant preface in 1845, became widely known.

WESLEYAN METHODIST CHURCH. The Wesleyan Methodist Church was a direct outcome of the evangelical revival of religion in England during the 18th century (see METHODISM; WESLEY, JOHN). The people influenced by the preaching of John and Charles Wesley were its real founders, though. at first, they had no intention of establishing a new church. For some time the societies that they formed remained within the Church of England, and it was only under the compulsion of circumstances that John Wesley took the steps which led. eventually, to separation. When early Rlethodists mere excluded from their local parish churches, meetinghouses were opened and duly licensed for public worship. The services were. at first, outside the regular church hours. The actual separation from the Church of England was gradual and reluctant. It was the result of the indifference rather than the concerted opposition of contemporary Anglicans.

In 1784 two critical events occurred. A legal document, the Deed Poll or Deed of Declaration. regularized and perpetuated the constitution of the Methodist societies. A hundred preachers, carefully selected and duly named. were appointed a body in which was vested authority in matters of discipline, administration and the stationing of ministers. The Legal Hundred elected its own new members to fill up the vacancies caused by death and so remained a continuous entity. This formed the core of the annual conference. a representative body composed of ministers only, until, in 1878, laymen were admitted. The second event in the crisis of 1784 was the ordination of certain preachers to administer the sacraments in Scotland and America. This decisive step was taken by John Wesley, who claimed, as presbyter, the right to ordain. A final severance was now inevitable.

On July 26, 1791, shortly after John Wesley's death, the conference reaffirmed the privileges granted by the Deed Poll to every preacher in full connection. The questions of the sacraments and the relation of Methodists to the Church of England were hotly debated by Alexander Kilham (*q.v.*) and the conclusions were ambiguous. In 1793 it was resolved that the societies should have the privilege of the Lord's Supper where they unanimously desired it. Next year 93 of them were granted the necessary permission.

After prolonged discussions a "plan of pacification" was drawn up and accepted in 1795. This declared that the sacrament of the Lord's Supper, the sacrament of baptism, the burial of the dead and services in church hours were only to be conducted by the preachers when a majority of trustees, stewards and class leaders of the chapel concerned approved. In 1796 Alexander Kilham, refusing to cease his agitation and accusing the ministry of priestcraft, was expelled. He founded the New Connexion.

In 1797 the constitution of the Wesleyan Methodist Church took more definite shape. The nucleus or germ cell had always been the class meeting. Wherever there was a "class" there was a society. These societies or local churches were not independent or unrelated but were grouped into circuits with a senior minister as superintendent and an elected quarterly meeting as the organ of administration. Circuits, in turn. were grouped in districts. comparable to Anglican dioceses. Each district had a ministerial chairman who presided at the synods. held twice each year. The annual conference was composed of the Legal Hundred and representatives from the whole Wesleyan Methodist Church in Great Britain (Ireland had its own conference).

The theology adopted was intended not to "overthrow dogmas but to galvanise them into life." In accepting the .Apostles' Creed and the Nicene Creed the Wesleyan Methodist Church stressed the Arminian doctrine of the Atonement. assurance! conversion and holiness or perfect love. Its appeal was to personal experience of the grace of God in Jesus Christ. Gradually it developed a consciousness of the objective grace in the sacraments and a clearer meaning of the Holy Catholic Church. A modified form of morning prayer was used in many Wesleyan Methodist churches and the offices of holy communion, holy baptism and holy matrimony closely resembled those in use in the established church. The ordination of its ministers by the imposition of hands and a rigid rubric was introduced in 1836 and carefully guarded from any kind of improvisation.

In 1790 there were 294 preachers and 71,668 members in Great Britain and Ireland with 19 missionaries and 5,300 members on the mission stations. In 1848 the membership in Great Britain was 338,861, in Ireland 23,842 and on foreign stations 97.451; the total number of ministers was 1,726. During the first half of the 19th century, known as the middle period of Wesleyan Methodist history, the dominating figure was Jabez Bunting (*q.v.*).

During these years Methodism was growing into a great missionary church. Its work in the West Indies was firmly established in Wesley's lifetime. In 1786 there were 1,100 Negro members of the society in Antigua. The burden of superintending these missions and providing funds for their support rested on Thomas Coke, who took his place as the missionary bishop of Methodism. In 1813 he prevailed on the conference to sanction a mission to Ceylon. He sailed with six missionaries on Dec. 30, but died in the following May in the Indian ocean. To meet the new responsibilities a branch missionary society had been formed in Leeds in Oct. 1813, and others soon sprang up in various parts of the country. Methodist missions really date from 1786 when Coke landed at Antigua. The area of operations gradually extended. Missions were begun in Madras, at the Cape of Good Hope, in Australia and on the west coast of Africa. Two missionaries mere sent to the Friendly Islands in 1826, and in 1835 a mission among the cannibals of Fiji spread and deepened till the whole group of islands was transformed. The work in China began in 1851; the Burma mission was established in 1887. The rapid progress of the Transvaal and Swaziland missions was almost embarrassing.

The missionary jubilee in 1863–68 yielded £179,000 for the work abroad. As the growth of the missions permitted, conferences were formed in various countries. Upper Canada had its conference in 1834, France in 1852, Australia in 1855, South Africa in 1882.

In 1834 Hoxton academy was taken as a training place for ministers. Didsbury college was opened in 1842, Richmond in 1843. Headingley was added in 1868, Handsworth in 1881 and Wesley house, Cambridge, in 1925.

The centenary of Methodism was celebrated in 1839 and £221,-939 was raised as a thank offering: £71,609 was devoted to the colleges at Didsbury and Richmond; £70,000 was given to the missionary society, which spent £30,000 on the site and building of a mission house in Bishopsgate Within; £38,000 was set apart for the removal of chapel debts, etc.

In 1837 Wesleyan Methodism had 9 infant schools and 22 schools for elder children and a grant of £5,000 was made from the centenary fund for the provision of day schools. The conference of 1843 directed that greater attention should be given to this department, and a committee met in the following October which resolved that 700 schools should be established. if possible within the next seven years. In 1849 the Normal Training college for the education of day-school teachers was opened in Westminster, and in 1872 a second college was founded in Battersea for women teachers. The Leys school at Cambridge. Rydal Mount at Colwyn Bay and boarding schools for boys and girls were established.

The Forward movement began about 1878, when a thanksgiving fund was raised. Large mission halls were built in the principal towns of England, Scotland and Ireland. The Forward movement of the 1880s will always be associated with the name of Hugh Price Hughes (*q.v.*). Village Methodism shared in the quickening which the Forward movement brought to the large towns. An aggressive policy of evangelism was combined with a great extension of social ministries.

The Twentieth Century fund was initiated by Sir Robert W.

Perks in 1898. The Royal aquarium at Westminster was purchased and a central hall and church house as the headquarters of Methodism erected. Various secessions from the Wesleyan Methodist Church took place, notably that of the Primitive Methodists (*q.v.*) in 1810–12; but in 1932, the Wesleyan Methodist Church, the Primitive Methodist Church and the United Methodist Church became one under the title of the Methodist Church.

WESSEL, JOHAN HERMAN (1742–1785), Norwegian-born writer who settled in Denmark, famous for his parody of neoclassical tragedy and his light verse. The son of a clergyman, he was born at Jonsrud near Vestby, southeast Norway, on Oct. 6, 1742. In 1761 he matriculated at the University of Copenhagen and he lived in that city until his death on Dec. 29, 1785, supporting a penurious existence by private tuition and the translation of plays for the royal theatre. He was one of the founders (1772) and the outstanding member of the *Norske Selskab,* a literary and convivial society of Norwegian students at Copenhagen, and contributed to its anthologies which began to be published in 1775. The signet of the society bore the inscription *"Vos exemplaria Graeca,"* and it was mainly directed against the extravagances with which it believed contemporary German literature was infecting that of Denmark. Wessel's only important long work *Kierlighed uden Strømper* ("Love Without Stockings," 1772), a "tragedy" in five acts written in alexandrines. by transferring the setting of a heroic tragedy to low life, mocked the rhetorical neoclassical drama then flourishing on the Danish stage. Wessel wrote two more plays, of little account, and a number of graceful epigrams, impromptus, songs and (often indecent) verse tales in the manner of La Fontaine.

Wessel's collected works, *Samtlige Skrivter,* were published in two volumes (1787); his verse, *Digte,* was published with a foreword by P. V. Rubow (1936).

WESSEX, one of the kingdoms of Anglo-Saxon Britain. According to the Saxon Chronicle, it was founded by two princes, Cerdic and his son Cynric, who landed in 494 or 495 and were followed by other settlers in 501 and 514. After several successful battles against the Welsh they became kings in 519 around the southern part of Hampshire. In 530 Cerdic and Cynric are said to have conquered the Isle of Wight, which they gave to two of their relatives, Stuf and Wihtgar. Cerdic died in 534. Cynric defeated the Britons at (Old) Salisbury in 552 and again in conjunction with his son Ceawlin at Beranburh, probably Barbury hill near Swindon, in 556. At his death in 560 he was succeeded by Ceawlin, who is mentioned by Bede as the second of the English kings to hold an imperium in Britain. With him a period of more or less reliable tradition is entered upon. How far the earlier part of the story deserves credence is still much debated. It is worthy of note that the dynasty claimed to be of the same origin as the royal house of Bernicia.

Whatever may be the truth about the origin of the kingdom, its dimensions were largely increased under Ceawlin. In his reign the Chronicle mentions two great victories over the Welsh, one at a place called Bedcanford in 571, by which Aylesbury and the upper part of the Thames valley fell into the hands of the West Saxons, and another at Dyrham in Gloucestershire in 577, which led to the capture of Cirencester, Bath and Gloucester. Ceawlin is also said to have defeated Aethelberht of Kent at a place called Wibbandun in 568. In 592 he was expelled and died in the following year. His obscure successors Ceol and Ceolwulf were followed in 611 by Cynegils. whose son Cwichelm provoked a Northumbrian invasion by the attempted murder of Edwin in 626. These kings are also said to have come into collision with the Mercian king Penda, and it is possible that the province of the Hwicce (*q.v.*) was lost in their time. After the accession of Oswald, who married Cynegils's daughter, to the throne of Northumbria, both Cynegils and Cwichelm were baptized. Cynegils was succeeded in 642 by his son Cenwalh, who married and subsequently divorced Penda's sister and was on that account expelled by that king. After his return he gained a victory over the Welsh near Pen-Selwood, by which most, if not all, of Somerset came into his hands. In 661 he was again attacked by the Mercians under Wulfhere. At his death, probably in 673, the throne is said to have been held for a year by his widow Sexburh, who was succeeded by Aescwine, 674–676, and Centwine, 676–685. According to Bede, however, the kingdom was in a state of disunion from the death of Cenwalh to the accession of Ceadwalla in 685, who greatly increased its prestige and conquered the Isle of Wight, the inhabitants of which he treated with great barbarity. After a brief reign Ceadwalla went to Rome, where he was baptized, and died shortly afterward, leaving the kingdom to Ine. Before the end of the 7th century a considerable part of Devon as well as the whole of Somerset and Dorset had come into the hands of the West Saxons. Ine founded a new bishopric at Sherborne for these western provinces, held synods for the better government of the church and issued an elaborate code of laws. He is the real founder of the organized West Saxon kingdom of later times. On his resignation in 726 he was succeeded by an obscure nobleman named Aethelheard, and he, in 740, by a certain Cuthred, who reigned until 750. Each of these kings was overshadowed by Aethelbald, king of Mercia, though Cuthred revolted, apparently successfully, from Aethelbald's domination in 752. At his death in 756 Sigebert succeeded, but on account of his misgovernment was deserted by most of the leading nobles, and with the exception of Hampshire the whole kingdom came into the hands of Cynewulf. Sigebert, after putting to death the last of the princes who remained faithful to him, was driven into exile and subsequently murdered; but his brother Cyneheard afterward avenged him on Cynewulf. Cynewulf was succeeded in 786 by Berhtric, who married Eadburg, daughter of the Mercian king Offa. Berhtric was succeeded in 802 by Ecgbert, who overthrew the Mercian king Beornwuli in 825. This led to the annexation by Wessex of Sussex, Surrey, Kent and Essex and the temporary recognition of West Saxon supremacy by Mercia.

Aethelwulf (*q.v.*), son of Ecgbert, succeeded to Wessex at his father's death in 839, while the eastern provinces went to his son Aethelstan. A similar division took place on Aethelwulf's death in 858 between his two sons Aethelbald and Aethelberht, but on the death of the former in 860 Aethelberht united the whole in his own hands, his younger brothers Aethelred and Alfred renouncing their claims. Aethelberht was succeeded in 865 by Aethelred, and the latter by Alfred in 871. This was the period of the great Danish invasion which culminated in the submission of Guthrum in 878. Shortly afterward the kingdom of the Mercians came to an end and in 886 Alfred's authority was accepted by all Englishmen who were not under the power of the Danes. From this time onward the history of Wessex is the history of England.

WEST, BENJAMIN (1738–1820), U.S. artist, was history painter to George III, 1772–1801, and a charter member (1768) and president of the Royal Academy (1792–1820). Born on Oct. 10, 1738, near Springfield, Pa., he showed precocious artistic talent and was sent to Philadelphia in 1756 to study painting. In 1759 he sought further commissions in New York and through the assistance of friends sailed for Italy. In 1763 West left Italy for London. He became intimate with Sir Joshua Reynolds and gained widespread popularity. His "Agrippina With the Ashes of Germanicus" was admired by George III. "The Death of Wolfe" (*c.* 1771), one of his best-known works, did not introduce but popularized modern costume in history painting. Though loyal to America he retained the king's friendship and patronage until 1801. In 1802 he visited Paris and exhibited his final sketch for "Death on a Pale Horse," which anticipated developments in French romantic painting. Though he never returned to the United States among his pupils are found all the leading American artists to the foundation of the National Academy (1826). West died in London, March 11, 1820. (WM. O.)

WEST, THE, is a term which in the United States has been applied both to a geographic location and to a social-economic condition. Because settlement began on the eastern rim of the continent and in most cases expanded in a westerly direction, the west was both a place farther out toward the setting sun and a place where men were beginning over again the creation of a new society. Strictly speaking, each eastern physical-social region had its own west where its patterns of life were exposed to a new environment. All wests, therefore. differed to a degree according to the origins of their people. but all partook of the quality of newness and all revealed some similarity in outlook and attitude.

The outer edge of any western advance was known as the frontier. The U.S. census bureau defined it as a place where the population was not more than two persons to the square mile. Its first inhabitants, except in a few unusual cases. were trappers. traders and lone settlers. Always on the move. they left behind them, as they pushed on into the wilderness, a gradually maturing society which the people to its east called the west. In early stages at least, each west was supposed to exhibit certain characteristics --individualism, boastfulness. materialism. hurry, crudeness and a tendency to see things not as they then were but as they might some day become. In time, of course. each west reached some degree of social maturity. political independence and economic complexity, and became eastern in all but geographic location.

Historians, dealing with the growth of the United States, have recognized and given names to at least seven distinct wests that appeared as the population spread from the Atlantic to the Pacific. The first of these, the old west. grew up in the back country of the original colonies. In the years between 1676 and 1763, it constituted a region which contrasted sharply with the older settlements and which was often in conflict with them. It stretched roughly from New England to Georgia and varied in character as the colonies differed from each other. But, as Frederick Jackson Turner says, it formed "a democratic, self-sufficing, primitive agricultural society in which individualism was more pronounced than the community life of the lowlands." It was short on schools and churches, and only gradually acquired a surplus of cattle and grain to exchange for what its people called store goods. Against unjust taxes or the failure to give protection from Indian raids, its people more than once rose in open rebellion against some mother colony.

The thrust of population through the Allegheny mountains after 1763, created a new west in Kentucky and Tennessee. Theodore Roosevelt told its story under the suggestive title *The Winning of the West,* 4 vol. (1889–96). There were settlements whose welfare depended on the use of the Mississippi river and whose citizens did not hesitate to enter into intrigues with the Spanish or French who controlled its waters. They provided much of the drive for expansion in the War of 1812, and caused easterners to tremble at the thought of their growing power in congress.

This, however, was only the beginning. With peace in 1815, what was known as the great migration began and two new wests quickly made their appearance. Between the Ohio river and the Great Lakes and reaching westward to the Mississippi and beyond, the old northwest filled up with peoples irom the south. the east and Europe. On corn and hogs, and then with wheat, they prospered, blended the county system of local government with the township system and, by 1860, had developed such thriving commercial industrial centres as Cleveland, O., Cincinnati. O., Chicago, Ill., and St. Louis, Mo. Expanded a bit to the south and west, the region in later days mas often spoken of as the midwest. (See MIDDLE WEST, THE.)

Meanwhile in the region between Tennessee and the Gulf of Mexico another new west had been developing. Its people came primarily from the old south and that region furnished the patterns on which its social-economic life evolved. With cotton as its major crop, and with the plantation and negro slavery as the basis for large-scale production, this west was soon known as the cotton kingdom. Yet in temper and in attitude toward the public lands, banking and internal improvements. the region was thoroughly western, and in speculation and lawlessness it quite surpassed the old northn-est. Southerners along the Atlantic coast always spoke of it as the west. (See SOUTH. THE.)

In the vast trans-Mississippi territory, the first region to be settled was that lying between the river and the 100th meridian. At this line where the prairies fade out and mood and water grow scarce, commence the Great Plains. extending to the Rocky mountains and their inland basins. followed by the Pacific slopes. Although these units varied greatly in physical features and resources, only two wests distinct enough to acquire names of their own developed within their boundaries. These were the southwest and the Pacific northwest.

At the southern end of the Great Plains. stretching from Texas northward toward Kansas and westward across New Mexico and Arizona, lay a region where the heat and dryness were more extreme and whose Indian tribes had developed a culture quite distinct from that of the tribes to the north. Its early settlement had taken place under Spanish and Mexican auspices and much of the region had come into the possession of the United States after the Mexican War in 1848.

U.S. settlers who came largely from the states directly to the east brought their ways and institutions with them, but Mexican influences remained as a permanent force in the region. The cattle business which became a spectacular feature of its life mas Spanish in most details. Architecture bore the same stamp. Yet the region became the U.S. southwest with a degree of self-consciousness that continued to express itself in titles given to numerous organizations and publications.

The Pacific northwest, because of its great distance from older U.S. settlements and its mixed British and U.S. beginnings, early acquired recognition and a name as a distinct west. The Lewis and Clark expedition in 1803–06, the struggle over the Oregon boundary from 1803 to 1846. and the wide interest in the China trade turned national interest in its direction as a new west.

California never quite became a distinctive American west. It had already progressed beyond early frontier stages before it became a part of the nation. It was always just California. The discovery of gold in 1848 did not greatly alter the situation. It made California a part of the mining frontier and of a great trans-Mississippi west which became the last frontier and the west of song and story.

The discovery of gold and the building of the transcontinental railroads sharply altered the character of the westward movement in the United States. The slow, steady advance suddenly became a series of mad rushes. Where in agricultural areas it had taken a generation to produce a surplus of any great value, localities in this west did so from the first year. Under such conditions, every so-called western characteristic was exaggerated and magnified. Mining camps appeared in a vast area from California to Oregon, from Montana and Idaho to Colorado and the Dakotas. Cattle ranches crowded the buffalo from the plains and the cowboy took his place alongside the miner as a new frontier type. Bad men flourished their six-shooters and brave sheriffs tamed them. The Indian, after a few efforts at resistance, gave way and accepted reservation life until the Dawes act (1887) made possible individual ownership and the Burke act (1896) opened the way to citizenship. Farms grew up about the mines. Supply and shipping towns soon appeared so that by 1890 the census bureau reported that a continuous frontier line could no longer be drawn.

Political organization followed economic developments. Territorial governments were quickly established and by 1890 all but four of these had become states. All had reached statehood by 1912. The constitutions which these states adopted were notable for their democratic provisions. Such advanced ideas as the initiative and referendum and recall were introduced. Women were accorded a larger political place. Even as a territory. Wyoming granted women the vote, and both Wyoming and Utah did so as states. Montana elected the first woman to the U.S. congress, and Texas elected the first woman governor. These states took the lead in passing eight-hour day legislation, in limiting the hours of labour for women and children. in providing for the arbitration of labour disputes and in increasing employer liability. Arizona included the recall of judges in its constitution, removed the provision under pressure, but reinstated it as soon as Arizona became a state.

Thus the term, the west. had by the mid-20th century lost much of its earlier meaning, both as applied to a definite geographic location and as a place where certain attitudes and values existed.

Men still liked to believe that western traits lingered in many parts of the nation, but the forces which once gave them dominance had largely disappeared. Such expressions as the midwest, the far west, the southwest, etc., were still in use, and conveyed to residents and outsiders the idea of a peculiar set of qualities. but they referred more to what once was than to what then existed.

(AY. CN.)

WEST AFRICA is that part of Africa lying between the Sahara and the Gulf of Guinea, west of a line extending along the Cameroons mountains to the desert north of Lake Chad. It comprises about 14° of latitude and 32° of longitude. The political units that roughly coincide with this region total 2,400,000 sq.mi. and in 1960 were estimated to have about 67,200,000 inhabitants.

PHYSIOGRAPHY

From south to north, West Africa can be divided into a number of latitude belts, each of which possesses remarkably uniform characteristics of climate, vegetation and animal life. The natural characteristics of each of these belts are determined principally by the amount and duration of the rainfall received.

Guinea. — From the coast to about 8° N. is the belt of country known as Guinea, where rainfall occurs throughout the year, though mostly during the months from March to November. The amount of rainfall received is in the range from 60 to 170 in. a year, except in an area between about 1" W. and 3° E., where it is between 30 and 60 in. Both diurnally and annually, there is a notably small variation in shade temperatures and in relative humidity. The former are normally in the range 70"–go° F.. and the latter between 80% and 90%. The high and frequent rainfall results in the greater part of this belt being covered with dense tropical forest, whose evergreen trees may reach more than zoo ft. in height. The forest is inhabited by few large mammals but by many birds and reptiles and by myriads of insects and microorganisms, including most of those which infect man and beast with so-called tropical diseases.

The Sudan. — Between about 8° and 16° N. lies the country of the Sudan, where an annual rainfall of between 20 and 60 in. is concentrated almost entirely during the months from June to October. Mean temperatures and relative humidity vary between 65° and 95° F. and 30% and 90% respectively, according to the season and the time of day. The vegetation is of the savanna type, nith coarse grasses and scattered small trees. In the dry season all but the largest rivers run dry, the trees shed their leaves and the dry grass is often subject to bush fires. Wildlife includes elephant, lion. buffalo, antelope and many smaller mammals. In the dry season the country is relatively free of insect-borne diseases.

The **Sahel.**—Between the Sudan and the Sahara desert is the Sahel. where rain falls only between July and October and amounts only to between about 5 and 20 in. a year. Daytime temperatures are high, mean daily maxima lying between 95° and 100° F., but the nights are relatively cool, with temperatures around 65° F. Relative humidity is low except in the rains, and ranges from 25% to 70%. In the dry season. a parching wind from the Sahara, the harmattan (which in December and January penetrates as far south as the coast), creates a constant haze of fine dust. Permanent water is rare and wildlife thin. Grass grows only in small clumps and the typical vegetation is a thorn scrub of bushes and small trees.

Uplands. — There are only three districts where the height of land much exceeds 2,000 ft. and thus serves to modify the characteristic pattern of climatic and vegetation zones. These are the uplands of the Futa Jallon plateau and Nimba mountains in Guinea and the Jos plateau in northern central Nigeria, both of which contain considerable areas of land between 2,000 and 6,000 ft. high. and the Cameroons mountains in the extreme southeast, where the highest peak, Mt. Cameroon. is 13,350 ft. high. Rain falling on the Futa Jallon-Nimba uplands feeds the sources of the Niger and Senegal. the two principal rivers in the drainage pattern of West Africa, while streams rising in the Cameroons and the Jos plateau go to feed the Niger and its principal tributary. the Benue. The Niger can be navigated for most of the 2,500 mi. of its course below Kurussa, about 100 mi. from its source; the Senegal is seasonably navigable below Kayes, about 550 mi. from its mouth.

Coast. — The seacoast is 2,500 mi. long. uncommonly uniform and notoriously difficult of access. A heavy surf beats on most of the coast and has built up a permanent sand bar through nhich only the largest streams can scour a permanent channel, and then rarely more than 10 ft. deep. By exception, the Gambia river has a deep estuary. However, its lower course, and the several outlets of the Niger delta and of other lesser streams, are lined with mangrove swamps, barriers hardly less obstructive than the sand bar. In places the low coast is interrupted by promontories, in the lee of which the surf is reduced. Sporadic examples, generally associated with volcanic action, occur at Cape Verde. the Iles de Los (Conakry). Sierra Leone (Freetown) and Mt. Cameroon. The coast of Ghana (formerly the Gold Coast) east of Cape Three Points presents a score of low headlands, often within sight of each other.

Soils and Minerals. — The soils of Guinea and the Sudan are generally lateritic, contain little plant food and are unproductive except in deltas and areas of high rainfall. The acre yield of crops is thought to be decreasing, especially in the drier grasslands. Some observers believe the Sahara is encroaching on West Africa, but the data are too few to be conclusive. The deterioration may be produced or hastened by improper use of land.

For centuries the natives of West Africa have panned placer gold in the forest region of Ghana and also along the headwaters of the Senegal and Niger. and placer tin on the Nigerian plateau. Europeans have intensified these operations, and have added workings of manganese and bauxite in the Ghana forest region, bauxite in Guinea, iron ore in Sierra Leone and Liberia, columbite on the Nigerian plateau, coal at Enugu in southeastern Nigeria and diamonds in Sierra Leone, Guinea and Ghana. All these minerals except the coal figure in the world market.

SETTLEMENT AND HISTORY

The people of West Africa are for the most part true Negroes, that is Negroes without a significant element of other racial strains. The major unit of social organization is typically the descent group, which among the less advanced peoples does duty as the political unit also. But in general the descent groups have become merged into tribes governed by chiefs and elders, usually elected from among the senior male members of certain prominent families. For about 2.000 years, the West African Negroes, particularly those in the Sudan, have been subjected to economic, social and sometimes political influence from white peoples advancing along the trans-Saharan trade routes from North Africa — Hamitic Berbers and Semitic Arabs and Jews. One of the principal results of this influence has been the emergence of territorial states in West Africa, first in the Sudanic grasslands and then in the Guinea forest. (See AFRICA: *Ethnography [Anthropology.]*)

The Sudan. — Movement across the grasslands is uninterrupted during the dry season, except at a few large rivers. Because both Sahel and Sudan lie open to the desert and stretch without a break across the continent south of the Sahara, a succession of wanderers from the north and east filtered in from very early times. Horses and oxen were the first beasts of burden to be used, but movement appears to have been greatly extended and perhaps also accelerated about A.D. 300, nhen camels appeared in the steppe and desert west of Egypt and camel caravans began to cross the Sahara.

The basis of the trans-Saharan trade was the exchange of salt from rock-salt deposits in the Sahara and manufactures from northern Africa, the Levant and southern Europe for gold, slaves and kola nuts from Guinea. In addition, the nomadic Berbers and Arabs of the desert have for centuries used the Sahel as a grazing ground for their cattle. A specifically Sudanese group of cattle nomads are the Fulani, a people of mixed Negro and white ancestry whose original home was in Tekrur in the extreme west, but who are now widely spread throughout the Sudan to as far east as Lake Chad. Although most of the Fulani have settled down and identified themselves with the life of the various Negro peoples of the Sudan, there are still about 300,000 pastoral nomads—the cow Fulani—who continue to pasture their herds without mixing with the sedentary Negro agriculturalists.

Knowledge of Sudanese conditions before the 19th century comes through Arab chroniclers, who reported on the "land of the blacks" (Bilad-es-Sudan) as a result of their own or others' visits. From a confusion of names emerges a picture of tribal groups consolidated into powerful and extensive states by military rule, the larger and most enduring of which seem to have been associated with the termini of the desert trade routes. West of the great northern bend of the Niger, the white influences reached the Sudan along the trade routes from Morocco; east of the Niger bend, the white influence has come principally from the direction of Egypt.

The earliest of the Sudanese states about which we are tolerably well informed is that of Ghana, created about A.D. 300 by Jewish or Berber settlers in the area to the west of Timbuktu, but which reached its peak under the rule of a Kegro dynasty. The attacks of the Almoravides in the 11th century seriously affected the power of Ghana, and its place as the principal state of the western Sudan was taken by the Mandingo empire of Mali. nhose centre was on the upper Niger. Mali absorbed the territories of Ghana in the 13th century and reached its peak in the early 14th century, when its power extended from Tekrur in the west to the Hausa states in the east, and from the desert in the north to the edge of the forest in the south. In the latter half of the 15th century, Mali was overthrown by the expansion of the Sonrhaï (Songhai) empire of Gao, a state ahich had emerged from Berber settlements on the lower Niger about the 7th century.

All these states of the Niger bend profited not only from the desert caravans but also from easy access to the gold-mining areas of the headwaters of the Niger and Senegal. A military expedition was sent across the desert from Morocco in 1590 to try and secure control of these gold-producing areas. This aim was not achieved, but the Sonrhai empire was destroyed and its chief commercial towns. Gao, Timbuktu and Jenne, occupied. At first these towns owed allegiance to the sultan of Morocco, but after about 1670 political power over most of the western Sudan passed into the hands of the Bambara (Mandingo) states of Segu and Kaarta. Between 1854 and 1863, the Sudan west of Timbuktu was conquered by Moslem Tucolors from Futa Jallon.

Between the Niger and Lake Chad, the states of Hausaland and Bornu were created by Berber invaders of about the 10th century. Bornu became a powerful though not very extensive state. but the Hausa states were always small and divided among themselves. Their strength lay in the industry and commercial ability of their people. The Hausa are noted for the manufacture of cotton cloth, ornamented morocco leatherware and tooled brass- and silverware. They became the leading traders of the Sudan from Lake Chad to Timbuktu, an area in which their language became the lingua franca of commerce. Islam reached the Hausa states from the west about the 14th century and, though never wholly accepted as a religion, greatly influenced their systems of law and administration. Between 1804 and 1810, a group of settled Moslem Fulani in Hausaland organized a crusade against religious dereliction. They made themselves masters of the Hausa states, but failed to conquer Bornu.

In the basin of the upper Volta, south of the Niger bend, the Mossi-Dagomba group of states succeeded in remaining independent of the great Sudanese empires. Although these states were in all probability organized about the 14th century by part-Hamitic refugees from the Berber conquest of Hausaland, their culture is essentially Kegroid, and their political permanence has been ascribed to the success of their rulers in utilizing the animist ancestor worship of their peoples as a tool for the consolidation of nation-states.

Between about 1880 and about 1906, the British and French overthrew the rulers of the Sudanese states and annexed their territories. The French from the first ruled these territories directly, but in northern Nigeria the British, lacking adequate administrators, restored the Fulani rulers, although each was provided with a British resident and a small advisory staff to prevent abuses in his government. This system of indirect rule was afterward widely adopted elsewhere in British tropical Africa.

The strong influence of Levantine civilization is evident throughout the Sudan and Sahel. From about the 11th century onward, Islam was widely disseminated from such Moslem commercial and scholastic centres as Walata, Timbuktu, Jenne and Sokoto. Government and law are commonly based on the precepts of the Koran. Many of the people are Moslems, and most wear the flowing robes and fezzes characteristic of the near east. Although farm villages are generally composed of clusters of circular thatched huts made of sun-baked mud, there are some hamlets and many walled cities built in the Levantine manner, where blind walls of courtyards and rectangular flat-roofed houses, sometimes built of burnt brick, form zigzag alleys that serve as streets. However the Futa Jallon uplands and the Bauchi plateau have remained refuges of animism, and the well-organized Mossi and Dagomba have also kept comparatively aloof from Islam.

Guinea. — Under native conditions, movement through the thick forest was all but impossible except on the streams and lagoons. The formidable surf discourages travel by sea, and seagoing canoes are rare except among the Kru, who live north of Cape Palmas on a coast dotted with offshore islands and reefs, and among the fishermen of the promontory reach of Ghana. Despite a population unusually dense for rain-forest country, most of the tribes have of necessity been small and scattered. Few of the peoples are Moslems; the great majority are animists. practising ancestor worship and, until recently, ritual human sacrifice. There are many professing Christians, particularly in the coast towns where individuals and families are separated from their tribal authority and customs and where Christian missions have been continuously at work since the early 19th century.

The military strength of the great states of the Sudan was based on their possession of cavalry, who could not operate in the forest. Nevertheless powerful states emerged in the forest with political customs and organization remarkably similar to those of the Sudan. The earliest of these states, Oyo and Benin, existed before Europeans began to trade on the coast in the 15th century, but their expansion and that of Ashanti and Dahomey was greatly influenced by the desire to capture slaves for sale to Europeans and by the possession of the firearms received in exchange from European traders. The Yoruba state of Oyo, in the southwest of modern Nigeria. existed before the 11th century, but it reached its peak of extent and prosperity in the 18th century, after which the slave trade engendered chronic warfare and the eventual disintegration of the state. Benin, to the southeast, was founded by Yoruba emigrants in the 14th century, reached its peak about the 16th century and thereafter declined for the same reasons as Oyo. Ashanti and Dahomey were organized as inland states at the beginning of the 17th century and reached their apogee in the early years of the 19th century. Their interest in the slave trade led them to conquer north of the forest in search of slaves, and southward to Ghana and the Slave Coast so as to establish direct contact with the European traders.

The Portuguese established trading posts on the Guinea coast in the 15th century and were followed and practically displaced by the Dutch, French, English and Danes in the 17th century. The trading posts built before about 1750 were usuelly fortified and garrisoned to protect them from attacks by rival European trading nations. They served as depots for a trade in gold, ivory. pepper, gum and slaves, but from about 1640 to about 1815 the dominating European interest in West Africa was the trade in slaves to the sugar and other plantations of tropical America. The tribal wars engendered by the slave trade and the jealousy of the African merchants on the coast from whom the Europeans bought their slaves combined with the natural obstacle of the forest to prevent the Europeans extending their power or influence for any great distance inland.

ECONOMICS

During the 19th century both the political and the economic complexion of West Africa changed. The European slave trade was outlaned; the elephants were all but exterminated; the output of the native gold workings declined. The only flourishing trade was in the palm products of the coast east of Ghana. By 1870 Great Britain and France were alone among the European powers in retaining an interest in West Africa. Since 1854 France had begun to penetrate up the Senegal and to develop the export of peanuts from its hinterland. Britain was interested in the suppression of the slave trade and in its replacement by legitimate trade, particularly in Nigeria and Ghana. In 1885 Germany precipitated a political revolution by proclaiming its colonies of Togoland and the Cameroons, forcing France and Britain to convert spheres of influence into definite colonies. While the French advanced from the Senegal eastward across the Sudan and linked up their conquests there with their trading posts in French Guinea and on the Ivory Coast and the Slave Coast of Dahomey, the British struck inland up the Niger and from the coast of Ghana into Ashanti and beyond.

The European penetration and pacification of the interior permitted the use of European capital in developing railways, deepwater ports and inland trade centres. The expanded colonies and the lengthened routes cut across the east-west grain of the country, facilitating internal trade between contrasting areas of production and bringing the interior into direct touch with the overseas world. Principal items of export are palm oil and peanuts, hides and skins, cocoa, cotton, rubber, gold, iron and manganese ores, bauxite and tin. Imports include a wide range of low-priced articles for African consumption, especially textiles and hardware, motor vehicles and machinery. Most goods move through half a dozen harbours constructed after 1910, which are increasingly replacing the primitive landing places previously used.

Tillage and grazing came under African control except for a few plantations in former French and German colonies and in Liberia. Agricultural exports are usually subject to inspection and grading by government authorities. Large-scale mining is organized by Europeans. Trade is shared by European, Asian and African merchants. Big business is largely handled by a few corporations with head offices in Europe and branches in all or several of the colonies. Small shops may be operated by individual Africans, though Levantines from Lebanon and Syria play an important part in the retail trade of the towns. Most shops, large and small, are general stores, each carrying nearly every kind of import and some local products. Perishables and most products of native craftsmen are sold by Africans, principally women, at markets, or by itinerant Hausa traders who traverse the country offering leatherwork, carved ivory and ebony, brassware and cottons and woolens from native looms. The climate prohibits permanent European settlement, and all heavy work is done by Africans.

WEST ALLIS, a city of Wisconsin, U.S., a suburb of Milwaukee (*q.v.*), which surrounds it on three sides. Settlement began with the establishing of a station named North Greenfield by the Chicago and North Western railroad in 1880; the village plat was recorded in 1887.

In 1902 the Allis-Chalmers Manufacturing company (a consolidation of the 40-year-old Edward P. Allis company and three others), manufacturers of heavy machinery, purchased a 100-ac. site near the village and established their plant there. The settlement was renamed West Allis and in 1906 became a city. Thereafter a number of other manufacturing establishments located there. In 1891 grounds in the township were purchased for the Wisconsin State fair, subsequently held there annually.

Pop. (1960) 68,157. For comparative population figures see table in WISCONSIN: Population. (AL. E. SM.)

WEST BENGAL, a state of the republic of India, representing one-third of the former British Indian province of Bengal, partitioned between India and Pakistan in 1947. Area 33,885 sq.mi.; pop. (1951) 26,302,386. State capital, Calcutta (*q.v.*). West Bengal is bounded by the Himalayas on the north, Bihar on the west, Orissa on the southwest, the Bay of Bengal on the south and Assam and East Pakistan (East Bengal) on the east.

The northern districts of Darjeeling, Jalpaiguri and Cooch Behar have no territorial contiguity with the rest of the state. (Cooch Behar, *q.v.*, formerly a princely state, was absorbed into West Bengal on Jan. 1, 1950.) The whole area, apart from some hills in the north, is a deltaic plain watered by the Ganges and its tributaries. Normal annual rainfall is 78.06 in., mostly in the north and southeast. Rice is the most important crop, but some jute is grown and there are large tea plantations in the north. Forests, forming 14% of the total area, are found in the north and in the Sundarbans on the coast of the Bay of Bengal. At Raniganj in the west lies one of the richest coal deposits of India; iron, copper, tungsten and mica are also found. Jute, cotton, tea, oil and sugar are the principal industries, centred mostly in and around Calcutta. The only other important city is Kharagpur (pop., [1951] 129,636). There is a large railway workshop at Chittaranjan.

The state has a ministry and a bicameral legislature: the upper house has 51 members and the lower house or legislative assembly has 238 members. The first stage of the Mayurakshi river irrigation project—a diversion barrage at Tilpara, near Suri—was completed in 1951; the Damodar river valley project (initiated in 1945–46), though in Bihar, will benefit West Bengal, whose government is bearing 57% of the cost. In 1951 a ten-year plan was inaugurated to provide free and compulsory primary education, and in two years one-fifth of the state was covered. The whole state is malarial and intensive antimalarial operations have had to be undertaken. Attempts were being made in the 1950s to introduce legislation abolishing the permanent zamindari revenue settlement of 1793 (see BENGAL). (S. GL.)

WEST BROMWICH, a municipal, county and parliamentary borough in Staffordshire, Eng., 6 mi. N.W. of Birmingham. Pop. (1951) 87,981. Area 11.2 sq.mi. Although of ancient origin, the appearance of the town is modern and industrial. Coal is mined in and around the borough and the industries are mainly metallurgical—heavy and light engineering, springs, weighing machines and many other kinds of hardware. There are also chemical, oil and paint works. Canals connect with the Severn, Mersey, Thames and Humber. The church of All Saints, formerly St. Clement, was rebuilt in 1872. A technical college was built in 1952–53. The picturesque Oak house (16th century) has been modernized as a museum. The borough was incorporated in 1882 and became a county borough in 1888.

WESTBURY, RICHARD BETHELL, 1ST BARON (1800–1873), lord chancellor of Great Britain, whose most important public service was the reform of the then-existing mode of legal education, was born at Bradford, Wiltshire, on June 30, 1800. He was educated at Wadham college, Oxford, and in 1823 was called to the bar at the Middle Temple. He was appointed vice-chancellor of the duchy of Lancaster in 1851. In that year he obtained a seat in the house of commons, where he continued to sit until he was raised to the peerage. Politically a Liberal, he became solicitor general in 1852 and attorney general in 1856 and again in 1859. In 1861, on the death of Lord Campbell, he was created lord chancellor, with the title of Baron Westbury of Westbury. He acted with some laxity, and after parliamentary inquiries he resigned in 1865.

What chiefly distinguished Lord Westbury was the possession of a blistering tongue. He waged a remorseless war on the clergy in general and bishops in particular. He died in London on July 20, 1873, within a day of the death of Bishop Wilberforce, his special antagonist in debate among the clergymen of England.

See T. A. Nash, *Life of Lord Westbury*, 2 vol. (1888).

WESTBURY, an urban district in the Westbury parliamentary division of Wiltshire, Eng., 25 mi. N.W. of Salisbury by road. Pop. (1951) 5,260. Area 5.8 sq.mi. All Saints' church is Norman and later, with a magnificent nave and a chained black-letter copy of Erasmus' Paraphrase of the New Testament.

Westberie figures in Domesday Book as a manor held by the king. The earliest mention of the town as a borough occurs in 1442–43 but in 1886 the borough ceased to exist. Edington priory, now a private house, was owned by the abbess of Romsey in 960, by Augustinian monks in 1352 and by Queen Catherine Parr after the death of Henry VIII. The "White Horse" cut on the side of Bratton down is mentioned in a 1772 edition of William Camden's Britannia and was reshaped in 1873. Principal industries are the manufacture of west of England cloth and of gloves; also there are a tannery and a railway workshop. Westbury is a railway junction.

WEST CHESTER, a borough of southeastern Pennsylvania, U.S., some 18 mi. S.W. of Philadelphia; the seat of Chester county.

In 1762 the Turk's Head inn was established there but the growth of a town awaited the location of the seat of Chester county near the tavern after 1784. Thereafter West Chester history was enlivened for a time by threats of miniature war with Chester over the permanent location of the county seat. Eventually West Chester triumphed and the town came to be graced with the present court house, a Greek Revival structure by Thomas U. Walter. The life of the borough revolves around the adjacent farms, minor industry and the West Chester State Teachers college, established in 1871. West Chester was incorporated as a borough in 1799. Pop. (1950) 15,168. (R. F. WE.)

WESTCOTT, BROOKE FOSS (1825–1901), English theologian and bishop of Durham, was born on Jan. 12, 1825, near Birmingham. Westcott was educated at King Edward VI school, Birmingham, and at Trinity college, Cambridge. He took his degree in Jan. 1848, obtaining double first honours. Westcott remained for four years in residence at Trinity. In 1849 he obtained his fellowship and took holy orders.

In 1852 he became an assistant master at Harrow, where he taught for nearly 20 years. The writings which he produced at this period were: *History of the New Testament Canon* (1855), which, frequently revised and expanded, became the standard English work upon the subject; *Characteristics of the Gospel Miracles* (1859); *Introduction to the Study of the Gospels* (1860), expanded from his Norrisian essay; *The Bible in the Church* (1864); *The Gospel of the Resurrection* (1866); and a *History of the English Bible* (1869).

In 1868 Westcott was appointed examining chaplain by Bishop Connor Magee of Peterborough and in the following year he accepted a canonry at Peterborough, which necessitated his leaving Harrow. But the regius professorship of divinity at Cambridge fell vacant and Westcott was elected to the chair on Nov. 1, 1870. His *Commentaries* on St. John's Gospel (1881), on the Epistle to the Hebrews (1889) and the Epistles of St. John (1883) resulted from his public lectures. One of his most valuable works, *The Gospel of Life* (1892), a study of Christian doctrine, incorporated the materials upon which he was engaged in a series of more private and esoteric lectures delivered on weekday evenings. In 1881 there appeared the famous Westcott and Hort text of the New Testament. *(See* HORT, FENTON JOHN ANTHONY.)

In 1883 Westcott was elected to a professorial fellowship at King's. Shortly afterward he was appointed by the crown to a canonry at Westminster and became examining chaplain to Archbishop Benson. He held his canonry at Westminster in conjunction with the regius professorship. His sermons were generally portions of a series. To this period belong the volumes *Christus Consummator* (1886) and *Social Aspects of Christianity* (1887).

In March 1890 he succeeded his friend J. B. Lightfoot as bishop of Durham. He took an interest in the mining population of Durham and in the great shipping and artisan industries of Sunderland and Gateshead. His last book was *Lessons From Work* (1901). He preached a farewell sermon to the miners in Durham cathedral at their annual festival on July 20, and died on July 27.

See the **Lije** by his son B. F. Westcott (1903), and also that by J. Clayton (1906).

WESTCOTT, EDWARD NOYES (1846–1898), U.S. banker and novelist, author of *David Harum,* which brought him literary fame after his death. Born in Syracuse, N.Y., on Sept. 27, 1846, he attended schools in Syracuse until he was 16, when he became a junior clerk in the Mechanics' Bank of Syracuse. For 30 years his life was devoted to business except for some amateur singing and composing and some writing of pamphlets issued by the Reform club, New York city, of which he was a member. In the summer of 1895 Westcott began *David Harum: a Story of American Life* at Lake Meacham in the Adirondacks, where he had gone to recover from tuberculosis. He continued it in Italy, at a friend's villa near Naples, in the winter of 1895–96, and finished it in late 1896 after returning to the United States. The story of a crusty small-town banker with a hidden heart of gold and an obvious talent for horse trading and homely humour was rejected by six publishers before it was finally accepted late in 1897.

Westcott died on March 31, 1898, six months before publication of the book, which became at once a best seller. Over 1,000,000 copies were sold in the next four decades. A dramatization in 1900 provided William H. Crane (1845–1928) with one of his most successful roles; Crane later appeared in a motion-picture version, and Will Rogers appeared in another motion-picture version in 1934.

In 1901 appeared a short story, "The Teller . . . With the Letters of Edward N. Westcott," in which there was an account of Westcott's life.

WEST COVINA, a suburban residential city of California, U.S., located at the eastern end of the San Gabriel valley, 20 mi. E. of the centre of Los Angeles. Cultivation of the land for citrus fruit and walnuts began in the early 20th century. West Covina was incorporated as a city in 1923, the population then being about 500, and for some time remained primarily an agricultural community. After World War II it experienced rapid growth as part of the urbanization and industrialization of the eastern part of Los Angeles county. Almost entirely made up of moderate-sized single-family dwellings, West Covina had comparatively little commercial and virtually no industrial development in the early 1960s. Its working population mainly commutes by automobile to Los Angeles, Pomona and other neighbouring manufacturing and commercial areas. Its population in 1940 was 1,072 and in 1950 it was 4,499; a special census of 1958 showed an increase to over 47,000. (J. H. K.)

WESTERGAARD, HARALD MALCOLM (1888–1950), U.S. civil engineer and educator, was born in Copenhagen, Den., on Oct. 9, 1888, and received the B.S. degree from the Royal Technical college there in 1911. After further study at the University of Gottingen (1913) and the Technische Hochschule in Munich (1914), he was a fellow of the American-Scandinavian foundation at the University of Illinois (1914–15), receiving the Ph.D. degree in 1916.

He became a U.S. citizen in 1920.

Westergaard taught theoretical and applied mechanics at the University of Illinois from 1916 to 1936, becoming a professor in 1927. In 1936 he was appointed Gordon McKay professor of civil engineering at Harvard university; he also served as dean of the Harvard graduate school of engineering (1937–46).

He became widely known as a specialist in structural mechanics. He served the U.S. bureau of public roads on stresses in pavements, was senior mathematician (1929–30) and consulting engineer (1930–32) for the bureau of reclamation on the Hoover (then Boulder) Dam and was consultant to the bureau of yards and docks (1935–37) and the Panama canal (1946–47). Westergaard rose to captain in the Civil Engineer Corps, U.S. naval reserve (1936–46).

Westergaard died in Cambridge, Mass., on June 22, 1950. (S. C. HR.)

WESTERMARCK, EDWARD ALEXANDER (1862–1939), Finnish sociologist, philosopher and anthropologist, noted chiefly for his studies of the development of marriage and the family, was born at Helsingfors on Nov. 20, 1862. In his philosophical studies he was greatly influenced by the English empiricists. especially Adam Smith and Herbert Spencer, and later opened up for his students in Finland the world of English thought. He was concurrently professor of sociology at the University of London and professor of moral philosophy at the University of Helsingfors. In the course of three decades he also spent about nine years in Morocco, usually devoting the summer months to ethnological research.

Westermarck's major interests were the history of marriage and the comparative, sociological study of the moral ideas and institutions of mankind as well as the culture of the Moors. In his *The History of Human Marriage* (1891; 5th ed., 3 vol., 1921) he maintained that the family lies at the basis of human society and, like Sir Henry Maine earlier, denied the widely held view of J. J. Bachofen, Lewis H. Morgan and Engels that early man had lived in a state of promiscuity. In *The Origin and Development of the Moral Ideas* (2 vol., 1906–08; 2nd ed., 1912–17) he proposed a theory of ethical relativity, according to which moral judgments are ultimately based on emotions of approval and disapproval *(see* ETHICS, HISTORY OF: *Ethical Relativity).* While he appealed to the concept of an ideal society he provided no analysis of the concept of an ideal. for which it is difficult to find a place in his system. In religion, his position was that of an agnostic. He died on Sept. 3, 1939, in Lapinlahti, Fin.

Other works by Westermarck include *Ethical Relativity* (1932); *Christianity and Morals* (1939); *Ritual and Belief in Morocco,* 2 vol. (1926); *Marriage Ceremonies in Morocco* (1914); *A Short History of Marriage* (1926); *Wit and Wisdom in Morocco* (1930); *The Future of Marriage in Western Civilization* (1936); *Early Beliefs and Their Social Influence* (1932); *Memories of My Life* (Eng. trans. by Anna Barwell, 1929). (D. By.)

WESTERN AUSTRALIA, the largest Australian state, covers 975,920 sq.mi. (37.3% lying north of the Tropic of Capricorn) and has a maximum southwest to northeast length of 1,480 mi. Its isolation from the more thickly populated eastern coastal belt of the continent has been diminished by increasingly improved rail, road, sea, air and radio communications with other states in the Australian commonwealth and compensated for by the fact that Fremantle, the port of its capital city. Perth, is the first Australian landfall for most ships from the United Kingdom and Europe. Perth airport is the place of entry for the trans-Indian ocean service from Johannesburg to Sydney and for a weekly service to and from London via Djakarta and Singapore.

Significant changes in the domestic economy of the state around the middle of the 20th century also served to confirm the trend of the preceding 50 years toward increasingly close political integration of the once highly self-conscious western community with the rest of the Australian commonwealth.

PHYSIOGRAPHY

Nearly the whole state lies on the west Australian shield of Archean rocks, chiefly granite and gneiss, overlain in the north by Proterozsic sandstones and other sedimentary rocks, and here and there by younger sediments. The continental shelf is very narrow in the south, very broad, sloping, and deeper than usual in the north (Arafura sea). Evidence of subsidence is given by numerous coral and limestone reefs in the north and west and by granite islands in the south.

The Kimberley block (70,000 sq.mi.) is the northernmost region, bounded by King sound and the King Leopold range (Mt. Broome, 3,040 ft.). It is a plateau of sandstones and some basalts, cut by deep valleys and with a rugged coast line cut by drowned valleys. Tides are extreme (Hanover bay, 38 ft.).

The Canning basin (150,000 sq.mi.) shows Permian sediments covered by Jurassic sediments near the coast, which is low-lying and uniform (Eighty-Mile beach). There is artesian water. Most of the interior is covered with sand dunes.

The Nullagine platform (200,000 sq.mi.) is a plateau (1,000 ft.–1,400 ft.) with residual hills of sandstone, often flat-topped, giving way to dunes in the northeast. Archean granite and greenstone rise in the north to form the Pilbara block, worn down to 1,200 ft., with flat-topped hills. The Hamersley plateau has been uplifted and dissected, residual mountains rising to over 3,000 ft. (Mt. Bruce, 4,024 ft., highest in Western Australia). Metal ores are common. Rocky headlands and coral islets line the shore.

The Carnarvon basin (50,000 sq.mi.) has Permian and other sediments, and artesian water. It rises gradually to 1,000 ft. from the hills near Exmouth gulf and the lowlands around Shark bay.

The Yilgarn block (300,000 sq.mi.) is the main plateau of Archean granites, gneisses, etc., with greenstone intrusions. In the west and south it is covered in patches with a lateritic cap or its residuals (gravel, sand) which form very poor soils. To the southwest are small Permian glacial basins (Collie, Wilga) with coal deposits. To the south is the quartzitic Stirling range (Bluff knoll, 3,640 ft.). The southwestern edge of the plateau is deeply dissected and forms the Darling hills (Mt. Cooke, 1,910 ft.) which rise above the great Darling fault (500 mi. north to south).

The Swan coastal belt covers about 16,000 sq mi. (400 mi. north to south, 30–100 mi. west to east) west of the Darling-fault scarp. The main part is a sunkland covered with Quaternary sands and with calcareous dunes near the shore; it forms an artesian basin. To the west are calcareous reefs and islands (Rottnest, Garden; Abrolhos farther north) which are hazards for navigation. The removal of a bar has opened up Fremantle at the mouth of the Swan and dredging has opened Cockburn sound to oil tankers bound for the Kwinana refinery.

Part of the Eucla basin, which is artesian and underlies the enormous limestone waste of the Nullarbor plain, is in Western Australia; it slopes to the south from about 1,000 ft., ending in cliffs 200–400 ft. high.

Climate. — Weather is affected by any of four types of air masses: equatorial (hot and humid). tropical maritime (warm and humid), tropical continental (hot and dry in summer, cool and dry in winter) and polar maritime (cool and humid), referred to as *Eq*, *Tm*, *Tc* and *Pm* respectively. Migratory anticyclones cross the state regularly from west to east, affecting latitudes 20°–35° S. in summer and 12°–27° S. in winter, at a speed of about 300 mi. a day. Since anticyclonic circulation is anticlockwise in the southern hemisphere, an anticyclone approaches Western Australia from the Indian ocean with a stream of cool humid southwesterly air, usually *Pm* in winter, modified in summer. As the anticyclone proceeds inland, the air becomes drier and the southwesterly is gradually replaced by a northeasterly, with all the characteristics of *Tc* air. Then a new anticyclone arrives and the same sequence is repeated.

In summer (Dec.–Feb.) the anticyclones travel along their southernmost path and bring an alternation of cool southwesterlies (70°–75° F.) and hot dry northeasterlies (80°–100° F.) to the southern parts of the state. Occasional maxima reach 105° F. or 110° F. Humidity is very low and there is no rain except from rare local thunderstorms. The heat over the northwest gives rise to a low pressure which allows Eq air to flow in forming an intertropical front and bringing torrential rains to the north and sultry days to large areas. Temperatures there vary from 75°–80° F. at night to 95°–105° F. in the afternoon. Marble Bar has recorded as many as 160 consecutive days above 100° F. in one year and Wyndham has the highest annual average in Australia (84.4" F.). Summer rains vary from 1–3 in. in the south to 20–30 in. in the north, with large dry areas in the interior.

In February and March disastrous hurricanes ("willy-willies") sometimes hit the coast between Broome and Onslow and proceed toward the southeast, bringing torrential rains, perhaps 2–3 in. in one hour. There are occasional hurricanes in the northwest during autumn (March–May), the last rains in the north with the gradual retreat of *Eq* air and the advance of dry *Tc* air, and the gradual northward migration of the anticyclones. The pressure troughs between anticyclones deepen and cold fronts appear. Humidity varies and the far southwest gets its first frontal rains (6–9 in. for the season). In winter (June–August) the anticyclones are in complete control of northern weather, with cool dry air blowing offshore. There are heavy frontal rains in the south, ranging from 15–20 in. on the coast to 8–10 in. in the interior. Temperatures are 30°–60° F. at night, 60°–75° F. in the afternoon in the south, some 20° warmer in the north. Spring (Sept.–Nov.) brings the last frontal rains to the south (4–8 in.) and the highest temperatures to the parched north, before the first "monsoonal" rains fall, sometime in November.

The rainfall is very reliable in the far south and the far north, but is very variable in the intermediate areas (Onslow 60%) where it is also very scarce, 58% of the state getting under 10 in. a year on the average. Reliable rains of 30 in. a year or more fall over only 5.4% of the state, mostly in the southwest, where the climate is very pleasant.

Rivers and Water Supply. — The Kimberley rivers flow only after the summer rains, but have large permanent pools. The Ord (300 mi.) has a large estuary. The Fitzroy (325 mi.) crosses the King Leopold range. The northwestern rivers flow occasionally, but may be dry for several years.

They include the DeGrey-Oakover (370 mi.), the Fortescue (340 mi.), the Ashburton (220 mi.), the Gascoyne (475 mi.) and the Murchison (440 mi.). A very large inland area has no drainage or sporadic drainage (salt lakes).

The rivers which rise on the Yilgarn block and flow west through the Swan coastal plain are short, like the Swan-Avon (240 mi., dry in summer), the Murray (50 mi., 213,000 ac.-ft. yearly) and the Collie (60 mi.). Farther south the flow is nearly perennial with strong winter-spring maximum. The Blackwood (190 mi.) conveys 445,000 ac.-ft. a year from 6,800 sq.mi. of basin, the Frankland (80 mi.) 135,000 ac.-ft. a year from 1,510 sq.mi.; but these rivers are more or less brackish. The rivers which flow to the south are short and intermittent and run mostly in winter.

Most of the water used in Western Australia comes from reservoirs built in the hills on the western edge of the Yilgarn block. Mundaring (15,100,000,000 gal.) supplies water to agricultural and mining areas east of Perth, as far as Kalgoorlie (348 mi.) and Norseman and is linked with the Canning (20,550,000,000 gal.) which supplies most of Perth's needs. Reservoirs farther south supply irrigation districts on the coastal plain. Many country areas still rely on wells tapping the water table and on rain water, but an increasing number receive water from the Wellington (Collie) reservoir (8,700,000,000 gal., to be increased to 40,800,000,000 gal.).

Flora and Fauna.—Botanically Western Australia may be divided into three provinces each with its own distinctive vegetation. The southwestern province comprises the area inside a line from Shark bay to Israelite bay. Climatically it is characterized by summer drought and winter rain. Nearly 80% of the species are endemic and include the kangaroo-paws (Anigozanthos and Macropidia), the Christmas tree (Nuytsia) and many members of the families Proteaceae and Leguminosae. The richest flora and the most striking flowers occur on the leached sand plains. The northern province experiences summer monsoonal rainfall and the vegetation consists of savanna (grassland), savanna woodland, and harsh Triodia steppe. The Eremean or desert province includes a vast inland area of capricious rainfall, the main types of vegetation being mulga bush (Acacia), eucalyptus woodland and Triodia steppe. In favourable seasons the desert blossoms with annuals.

The isolation of Western Australia is largely responsible for its peculiar flora and fauna. In the evolution of the flora, elements derived from Antarctic and Indo-Melanesian sources are important. (See C. A. Gardner, "The Vegetation of Western Australia, with Special Reference to the Climate and Soils," Proc. Roy. *Soc.* W.A., 1942.)

Fauna in the western state lacks the diversity found in the animals of eastern Australia and is deficient in the large number of endemics characteristic of the plants. Zoogeographically the fauna falls into three regions agreeing in area with the botanical provinces. The southwestern province has a fauna characteristic of the Bassian subregion. Cave deposits indicate that in pleistocene times a much more varied fauna occurred and animals such as the koala (Phascolarctos cinereus), wombat (Phascolomis sp.), Tasmanian devil (Sarcophilus harrisii) and Tasmanian wolf (Thylacinus cynocephalus), now found only in southeastern Australia, were common. Unique forms are the burrowing frog (Myoba trachus gouldii) found associated with termites, and *Metacrinia nichollsi,* often found in the nests of the ant Myrmecia *regularis.* The numbat (*Myrmecobius* fasciatus) formerly had a wider range but is now restricted to the wandoo (Eucalyptus redunca var. elate) forests. The northern province has a fauna related to that of the Torresian subregion of Queensland and northern Australia. In the desert areas between the southwest and northern provinces occurs a fauna characteristic of the Eyrean subregion. The ant-eating mountain devil (Moloch horridus) of the Agamidae is a common and well-known representative of this fauna.

Forests.—Western Australia is a land of vegetation, but not of forests. Species of the genus Eucalyptus are the dominating trees throughout the land. The timber forests in the true sense are confined to a comparatively small area in the extreme southwest of the state in the regions of higher winter rainfalls. Jarrah forest (*Eucalyptus* marginata) occurs on lateritic soil while karri forest (*Eucalyptus* diversicolor) occurs on karri loams in the 40 in. rainfall belt. Important tree growth. however. has occurred on the wheat belt of 34,000,000 ac. About 10,000,000 ac. which carried forest and mallee have been cleared for wheat growing. Farther inland there are 18,000,000 ac. of dry country eucalypt woodlands, with a rainfall of down to 10 in. annually. Of this area about 6,000,000 ac. have been cut over for firewood and timber for gold mining, yielding about 24,000,000 tons of firewood over a period of 60 yr. The mulga belt to the north, covering about 50,000,000 ac., has yielded and is still yielding important supplies of fuel, mining timber, fencing and general pastoral requirements. It has been estimated that 4,000,000 tons of wood have been cut there. In the extreme north of the state river rain-forest is met with along the main streams. This consists of eucalypts with species of other genera. There is a sparse stocking of eucalypts over a large part of the area. In some parts this may amount to three tons of firewood per acre. Native pine (*Callitris* intratropica) is met with rarely and mainly north of the King Leopold range. Mangroves are found near the coast.

A line drawn from York to Walpole marks off what is perhaps the most valuable timber area in Australia. There the distribution of types is markedly dependent upon rainfall and soils. Behind the immediate coastal fringe in the south lie, in the areas of 30–60 in. rainfall, about 250,000 ac. of karri forest composed of handsome giants 200–250 ft. high yielding tough wood valuable for constructional purposes, etc. From near Busselton to north of Fremantle the 5-mi.-wide strip of coastal limestones supports tuart (average height 80 ft.) growing in more open formation. But the greater part of the area (40–25 in. rainfall) north of the karri forests is occupied mainly by jarrah interspersed with marri (about 8,000,000 ac., of which about 6,000,000 ac. are commercially useful). The jarrah prefers lateritic soils and the trees. which in good areas average 100 ft. in height, yield first-class hardwood resistant to weathering and insects, which is in demand for all types of constructional purposes and for interior works.

State forest in the main forest zone of the southwest totalled 3,400,000 ac. in 1953 with 4,000,000 ac. as the ultimate objective.

The sawmilling industry, based chiefly on jarrah and karri, is important to the state and 17,000,000 cu.ft. of sawn timber a year are produced, of which about 24% is exported.

Vigorous measures were taken after the passing of the Forests act in 1918 to control and regenerate the indigenous forests as they were cut over, and to establish pine plantations. Nearly 2,000,000 ac. of indigenous forest over which the sawmilling industry had operated were under intensive management and protection in 1953. Thirty-four fire lookout towers, 13,000 mi. of road and 339 houses in the forest for resident employees indicated the extent of this development in 1953. Plantations of pine then totalled 17,000 ac. and there were 18,000 ac. of mallet plantations, grown chiefly for tanbark. The production of tannin extracts from the wood of the wandoo tree is an important industry using over 65,000 tons of timber a year. Sandalwood, a small tree which grows in the low rainfall inland areas, is exported and also yields oil by distillation of the wood. (See also AUSTRALIA: Forestry.)

HISTORY

The date of the first discovery of the western shores of Australia is uncertain. It has been suggested that both the western and northern coasts of the state may be identified with the "Java le Grande" of maps said to date from around 1550. It is possible that Portuguese navigators sighted the northwest coast on the way to the Spice Islands, as early as 1527. The first landing of which definite record exists is that of the Dutch captain, Dirk Hartog, in Oct. 1616. To commemorate his discovery, Hartog left a pewter dinner plate, with an inscription scratched into it, on the island now bearing his name. Subsequent Dutch navigators, including Abel Janszoon Tasman (*q.v.*), charted the coast as far east as Nuyts Land, between 1618 and 1644. Later comers included William Dampier (*q.v.;* 1688 and 1699), William de Vlamingh (1696–97), George Vancouver (*q.v.;* 1791) and Bruni d'Entrecasteaux (*q.v.,* 1792).

The earliest settlement was made from Sydney, in Dec. 1826, when, due to suspicions that the French might found a base on the west coast of Australia, Maj. Edmund Lockyer was dispatched to take formal possession of King George's sound, with a party of convicts and soldiers. This establishment returned to Sydney in

1831. Meanwhile, in March 1827, Capt. James Stirling had made a survey of the Swan river and Thomas Peel, encouraged by Stirling's report. formed a syndicate, offering to send out and settle 10.000 emigrants to the Swan river.

Because of these prospects of settlement. the British government dispatched Capt. C. H. Fremantle to take possession of the unoccupied part of Australia west of 129° E. In June 1829 Stirling arrived. as lieutenant governor. and shortly after founded the towns of Perth and Fremantle: on the Swan river. Several parties of migrants began to arrive. including those brought out by Peel. They were ill-prepared for pioneering; the coastal land was poor and labour was unobtainable to work the large and scattered land grants. Many left for the eastern colonies, but the discovery of better land beyond the Darling ranges led to the extension and consolidation of settlement by 1835.

Despite Peel's failure, a second syndicate, the Western Australian company, was formed in 1839, to acquire the Lautour estate. 100 mi. S. of Perth. and there to establish a settlement on Wakefieldian lines. Between 1841 and 1843. several parties were sent out to this new settlement. Australind, but loss of confidence among those financing the scheme contributed to its failure. The explorations of George Grey (1838) and the Gregory brothers (1845–46 and 1848) led to the settlement of the Champion bay district, north of Perth. centred around the town of Geraldton. Lead and copper mines were established in this district, although grazing and farming were the principal pursuits.

The continued labour shortage in the colony led to a local demand that convicts should be sent out from the United Kingdom for employment on public works. An order-in-council authorizing the formation of a penal settlement was issued in 1849. The supply of convicts and ticket-of-leave men overcame the labour shortage. which would have become more acute as the result of the gold discoveries in the eastern colonies. The cheap convict labour and the imperial grant-in-aid gave an impetus to expansion before transportation ceased in 1868. The northwest pastoral country was opened in 1863 after further explorations by the Gregory brothers.

After the abolition of transportation. a partly elective legislative council was appointed in 1870, during the administration of Gov. F. A. Weld. Between 1870 and 1890, valuable work in opening up more land for pastoral and agricultural settlement was performed by the officers of the survey department, under Malcolm Fraser and John Forrest. The brothers John and Alexander Forrest crossed the continent between Esperance and Adelaide in 1870 and between Geraldton and the overland telegraph line in 1874. Other transcontinental crossings were made by P. E. Warburton in 1873 and E. Giles in 1875. Such explorations enlarged the area of pastoral settlement but demonstrated the desert nature of much of the interior.

Alexander Forrest opened up the Kimberley district in 1880 and there, in 1884, the government geologist reported indications of auriferous country. A gold rush followed at Hall's Creek (1885–87), but this field was largely abandoned with the proclamation of gold fields in the Pilbara district in the north. in 1888. and in the Yilgarn, 200 mi. to the east of Perth. Within five years, richer finds followed in the Murchison (1891), at Coolgardie (1892) and at Kalgoorlie (1893).

Progress in other directions had included the construction of a railway, begun on the land-grant principle. from Perth to Albany (completed in 1889), and the commencement of another to Geraldton. The improving prospects of the colony induced a demand for complete self-government, A bill enabling Queen Victoria to grant a constitution to Western Australia received the royal assent on Aug. 1 j. 1890. This provided for a governor, a nominee legislative council and an elective legislative assembly. The legislative council mas to become elective when the population reached 60,000 —a change effected in 1893.

Sir (later Lord) John Forrest (*q.v.*), premier from 1890 until his entry into federal politics on the establishment of the Australian commonwealth in 1901, led a parliament at first dominated by primary producing interests. The advent of thousands of gold miners accelerated the progress of the country and led to the provision of such public works as the Fremantle harbour and the Perth-Kalgoorlie railway. Forrest also sponsored the provision of a pipeline through nhich water mas pumped over 300 mi. from Mundaring (near Perth) to the arid Coolgardie gold fields During Forrest's later years of office. however an opposition party arose among the gold-fields men — many of them "t'othersiders" from Victoria and New South Wales—who strongly supported the federation movement.

The agricultural interests hesitated to join the new Australian commonnealth nithout receiving a pledge for the retention of their onn customs dues for five years but after Sir John Forrest had made an unsuccessful attempt early in 1900 to secure this concession from the other colonies. a referendum in July of that year showed a majority of over 25.000 in favour of federation. The Constitution act ultimately provided that Western Australia should have the right to enact its own tariff as against the sister states for the desired five years, decreasing annually at the rate of one-fifth of the amount of the original duty until the whole disappeared.

With the rise of the Labour party in Western Australia, the other two groups in the state parliament sank their differences and coalesced in 1905. With the decline of alluvial mining. a policy of agricultural settlement was pursued and. between 1906 and 1914, the wheat lands were extended within the 10-in. rainfall area. From this region there arose a new Country party. which usually aligned itself against Labour. The latter's strongholds lay in gold fields. inner metropolitan and northern pastoral electorates.

The federal government's policy of protecting secondary industries tended to react unfavourably on Western Australia. a primary producing state, so that. during the depression at the end of the 1920s, a movement arose for secession from the federation. though it included many who were more eager to air grievances than ready to secede. A referendum held in 1933 favoured secession, by 138.653 votes to 70,706, but in 1935 a joint committee of the British houses of parliament declared itself incompetent to consider the state's petition to give effect to this move. With the revival of prosperity and the coming of World War II. during which Western Australia faced a threat of invasion by Japan, the secession movement became moribund. Good wheat and wool prices ensured postwar prosperity and a movement toward industrialization mas highlighted by the decision of the Anglo-Iranian Oil company, in 1952, to begin construction of a refinery at Kwinana, south of Fremantle. as part of an investment of £A40.000,000. Investigations in the Exmouth gulf area. in the northwest, in 1952–53, also aroused hopes of the discovery of oil. In late 1953 oil was discovered at Learmonth and. in some quarters. this was hailed as the most important development in Western Australia since the discovery of the Coolgardie gold field in the 1890s.

Western Australians thus entered the second half of the 20th century with an awareness of impending economic and social changes. The material changes. it was felt. might prove comparable with those following the gold discoveries toward the close of the preceding century, which had revolutionized the economy of the isolated, agricultural western colony and had jolted it into foundation membership of the Australian commonwealth, against the wishes of many of its settled population. Cultural influences were also producing results in the western state whose estimated expenditure in 1953–54 was £A4,902,486 on government primary, secondary and technical education in addition to the expenditure of church (notably Roman Catholic) and other private schools. This was a substantial increase on the amount spent in previous years when Western Australia's expenditure in this field was greater per head of population than that of any other Australian state. In 1953 the University of Western Australia — the first. and. until the establishment of the University of Ceylon, the only "free" university in the British commonwealth — spread its annual expenditure of £A467,1jj over 7 faculties. embracing 16 chairs and 1,741 students. Between 1901 and 1953, non-Labour and Labour ministries each enjoyed 26 years in office. In 1953, the premier (A. R. G. Hawke) headed a Labour ministry; the leader of the opposition was Sir Ross McLarty, who had been premier from 1947 to 1953 in a Liberal-Country party coalition government with the Country party leader (A. F. Watts) as deputy premier.

POPULATION AND ADMINISTRATION

Much of the interior of the state, apart from relatively impermanent mining centres, is sparsely populated by human beings, whatever its pastoral capacities may be. Most of the increase is taking place on and near the coasts. chiefly in the temperate southwest corner. In this zone of settlement, ports naturally play a prominent part. Perth (*q.v.*) with its port Fremantle (*q.v.*; combined population 120,145 in 1954) holds a key position. Commercially if not physically it lies midway between north and south, and a consistent policy of centralization has fostered its importance. The settlements of the southwest are (1955) mainly small agricultural and railway centres, with the beginnings also of some industries processing primary products.

Constitution. — The legislative council of the state parliament consists of 30 members, representing ten provinces and elected on a restricted franchise for six years. The legislative assembly has 50 members elected for three years. Ten senators and eight representatives 'represent the state in the federal parliament at Canberra.

Education. — Two systems of primary and secondary education exist side by side. The state schools are under centralized administration; the private or independent schools, serving between one-quarter and one-fifth of the children, are controlled for the most part by church organizations among which the Roman Catholic teaching orders predominate. Education is compulsory for children between the ages of 6 and 14 years who live within three miles of an established school or within two miles of a school bus route. In rural areas, more than 500 buses cater daily at government expense for 14,000 children attending schools at central points serving a radius of 20 mi. This system, together with correspondence classes for more isolated children, is conducted from Perth and supplemented by itinerant teachers in the extremely remote northwest areas. There are two teachers' colleges, six technical schools and an agricultural college.

The contribution of the private or independent schools is numerically greater at the secondary than at the primary level. All the private schools are dependent on fees and endowments, while both primary and secondary education is free at government schools. There is an increasingly close association between government and nongovernment schools and the secondary school syllabuses are co-ordinated by the requirements of the university's public examinations board.

At the University of Western Australia (founded 1911) there are no tuition fees for bona fide Australian residents in the faculties of arts, law, education, science, engineering and agriculture and relatively low tuition fees are payable in dental science and medicine.

Social Services. — In social services generally, the payment of age. invalid and widows' pensions is regarded as a federal government responsibility. Canberra is also responsible for such income services as unemployment. sickness and certain special payments as well as maternity, child endowment, tuberculosis, repatriation and rehabilitation allowances.

The state's social services additional to the above-mentioned supplementary income services include those of municipalities and state government departments such as public health, police. mental health, child welfare and native welfare as well as education. and those of voluntary associations such as the spastic welfare association, the institute for the blind, the maimed and limbless association and the marriage guidance council. Western Australia played a leading part in executing the federal-state tuberculosis agreement of 1948 and was also a pioneer among the Australian states in making compulsory chest X-ray examinations, which began in Aug. 1952.

The Western Australian Workers' Compensation act, 1912–1954, provides for compulsory insurance by employers to compensate for losses by industrial accident, including industrial diseases. For the year 1954–55 the sum of £41,647,458 was spent on insurance premiums and £A1,248,920 paid out in claims.

ECONOMICS

Agriculture, Pastoral Activities and Land Settlement.

After the foundation of the colony, in 1829, gold, wool and wheat were Western Australia's most important products. In the first 60 years wool was the chief exportable commodity. The colony made very slow progress. the population being 5.886 in 1850 and only 46,290 in 1890. The first ventures into the pastoral lands in the northwest of the state were made in the 1860s and wheat production barely kept pace with the needs of the small community. When the gold rushes of the 1890s led to a rapid population growth — the total reached 179,708 in 1900 and 276.832 in 1910 — agriculture was stimulated by the existence of a profitable home market for nearly everything that could be produced.

The decline of the gold industry between 1900 and 1910 coincided with the opening of the "wheat belt" and the state's emergence as a wheat exporter. This development marked the real beginning of agricultural expansion. The population grew to 331,323 in 1920 and 431,610 in 1930. By 1930 the wheat belt had extended eastward. in some cases into country with less than 11 in. annual rainfall. A record crop of 53,000,000 bu. was harvested in that year. In the next decade low prices and dry seasons forced some retreat from the northeastern section of the wheat-growing country. Fortunately wheat-growing and wool production were complementary activities over most of Western Australia's farming country. When wheat prices became less attractive farmers concentrated more of their attention on carrying sheep and by 1950 nearly every wheat farm had its flock of sheep.

The boom in prices after World War II, particularly in wool, transformed the outlook for thousands of farmers in Western Australia. In 1939 the total value of agricultural and pastoral production had been estimated at £A20,000,000. At that time wool, wheat and other agricultural products accounted for more than 40% of the state's income from exports and were about equal in importance to gold. As a contrast, averages of values for the five-year period 1950–51 to 1954–55 were wool £A40,200,000, wheat £A24,900,000, livestock slaughterings £A10,900,000, milk £A5,300,000, fruit £A3,900,000, vegetables £A3,400,000, poultry £A2,600,000. The total value of agricultural and pastoral production was then more than twice as great as that of manufacturing and nearly five times that from mining, forestry and fisheries combined. Rural industry retained its dominant position in the economic life of the state despite the manufacturing and urban industrial progress referred to below, which helped to raise the state's population to 573,671 in 1950 and 639,771 in 1954.

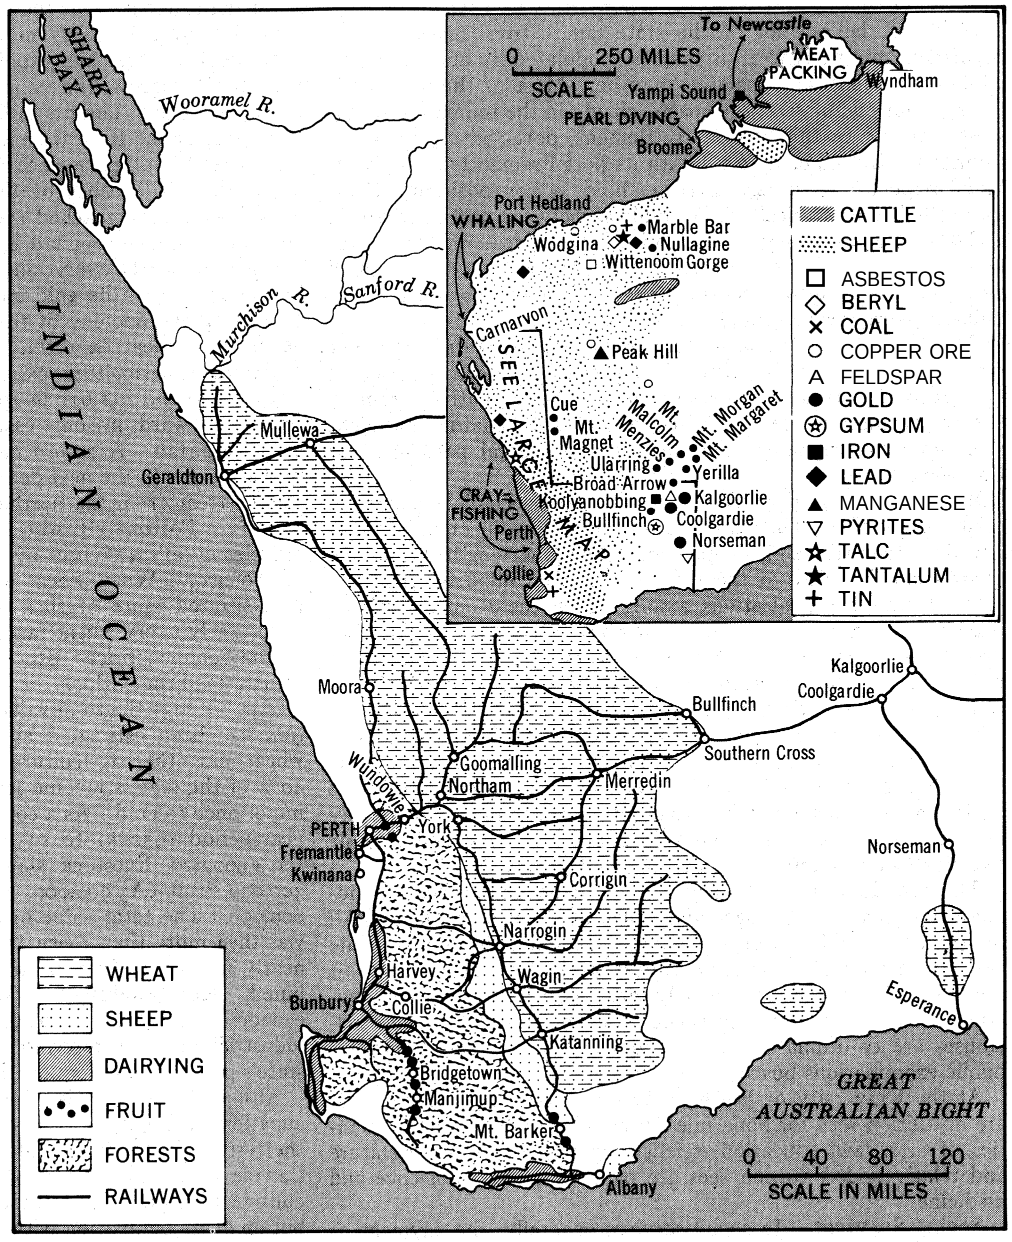
Although there is this strong rural bias in its economy, the occupational grouping of the state's population is similar to that of the rest of Australia and of countries like the United States and Canada where less than 25% of the population is engaged in agricultural pursuits. It resembles these countries, too, in the distribution of its population between town and country. Rather more than half its inhabitants are urban and live in the metropolitan area of Perth. the capital city.

Agriculture is specialized and commercial in character and not of the subsistence or peasant type. The farmer expects to produce sufficient supplies for sale to enable him to enjoy a standard of living comparable with that of the town worker. Farm labour is scarce and expensive and full advantage is taken of mechanization, particularly in cereal growing.

Climate and topography are the chief determinants of the extent to which land can be used for agricultural and grazing purposes and also of the forms of agriculture which can develop. Rainfall has always been the dominant factor governing agricultural and pastoral expansion. On the basis of rainfall distribution the state falls into three well-defined zones, namely (1) the Kimberley division in the extreme ncrth; (2) an area in the southwestern corner where the rainfall ranges from 50 in. on parts of the coastline and the 11 in. isohyet forms the northern and eastern boundaries; and (3) the large area lying between these two. where the annual rainfall is sparse (10 in. and less) and uncertain in its incidence.

The northern region, which lies within the tropics, has a short wet season (December–March) during the hot summer. Average yearly recordings range from 1j in. to over 50 in. in the northern part of the Kimberley division. The rain is often torrential and frequently erratic in its distribution through the season. About half the state's cattle are to be found in this region and sheep raising has penetrated into its southern part. The commonwealth and state governments have co-operated in investigating the potentialities of the valley of the Ord river, one of the region's two large river systems, for an irrigation project. The Rimberley research station, 50 mi. from Wyndham, was established in 1936. Sugar cane and rice have emerged as potential cominercial crops. A dam site on the Ord river has been selected which commands nearly 100,000 ac. of alluvial flats. Private operators have carried out interesting investigations into the air freighting of beef carcasses from a cattle station to coastal meat works and rice growing in the food plain of the Fitzroy river. Pearling and some small-scale mining constitute the only other economic activities of note in this northern region.

The aridity of the vast expanse of country lying between the two well-defined winter and summer rainfall regions of the southnest and the far north imposes severe. limitations on its value for agriculture or grazing purposes. About 200,000,000 ac are occupied as pastoral leasehold and merino wool is produced under conditions of extensive grazing, but, over much of the area, the rainfall is insufficient even for pastoral activities. Nearly half the state. including the central portion and some of the northnest coastal region. has an annual rainfall of less than 10 in. The only agricultural settlement in this region is at Carnarvon, on the coast, where bananas and vegetables are grown under irrigation with water pumped from beneath the sands in the bed of a usually dry river.



WESTERN AUSTRALIA: LAND USE. THE LARGER MAP SHOWS THE SOUTHWESTERN PART. WHERE POPULATION IS CONCENTRATED. PRINCIPAL MINERAL DEPOSITS FOR THE ENTIRE STATE ARE SHOWN ON THE INSET MAP

In the absence of any substantial supplies of water for irrigation, the pastoral country is utilized to nearly its maximum capacity.

Only in the southwestern part of the state, where there is a Mediterranean type of climate, has it been possible for agriculture to develop; it extends. in an irregular pattern, over nearly 100,000 sq.mi. The inland boundary is approximately the 11 in, isohyet. The rainfall, which is concentrated mostly in the April–October period, reaches jo in. along the extreme southwest coast but dwindles rapidly as distance from the coast line increases.

Most of the country in this region has little value for grazing before it is cleared of timber or scrub and fertilized with phosphates. consequently a suitable measure of progress in land development is afforded by statistics of the area of cleared arable land. In 1890 it was only a50,000 ac. compared with 20,500,000 ac. in 1955. A feature of this development was the assumption of the initial risk by governments. It was the government which built railways before the agricultural possibilities of the land were thoroughly examined; it then provided roads, water supplies, schools and even the credit for the potential farmer without capital. After World Wars I and II it concerned itself with settling returned servicemen on the land.

Agriculture was long handicapped by the widespread phosphorous deficiency of Western Australian soils. When the geographical expansion of the wheat belt occurred, between 1905 and 1930, it was associated with the use of superphosphate, the development of new drought-resisting wheats and the adoption of suitable methods and implements for farming in low rainfall areas. After 1920 considerable attention was given to settlement of the wetter, more heavily timbered country nearer the southwest coast. An ambitious government scheme for group settlement of migrants from the United Kingdom encountered technical difficulties, to which the economic depression of the 1930s added a severe setback. However, the practical experience gained in this period was subsequently put to good use. During this phase of land settlement the extraordinary value of subterranean clover as a pioneer pasture plant, when top dressed every year with superphosphate, was first realized.

A third wave of interest in land settlement was assisted by the favourable outlook for agricultural commodities which had developed by 1950. There were then several million acres of country which could be brought into production, and land development, which was mostly being carried out by farmers already established, was progressing at the rate of 500,000 ac. a year. The bulk of this land is the light textured "sand plain" country which is very deficient in plant food.

Subterranean clover (T. *subterraneum*) and heavy dressings of superphosphate, often in association with small applications of trace elements. chiefly copper and zinc, transform this formerly useless land into productive farms. The use of the bulldozer for land clearing and dam sinking constituted another notable technical advance in land development methods in the years following World War II.

Wool production is the most widespread of the state's rural industries. The state's sheep population by the mid-1950s exceeded 12,000,000, mostly merinos; the 1953–54 clip of 126,500,000 lb. was a record. Nearly three-quarters of the sheep are located in the agricultural districts in the southwest where cereal cropping and sheep raising combine well together. Subterranean clover and a variety of introduced grasses and herbage plants constitute the bulk of the grazing available in the farming country. The average yield of wool per head of sheep shorn (including lambs) for the five years 1950–51 to 1954–55 was 8.7 lb. In 1950–51, a year of record prices. wool output was valued at £A59,000,000.

In the northwest. where the rainfall is scanty and uncertain. an "extensive" form of husbandry is practised. The grazing consists of natural grasses, herbage and top feed; *i.e.*, native bushes and low trees. especially acacias. Little or no conservation of fodder or supplementary feeding is possible. thus making the sheep very susceptible to the drought periods which occur with varying frequency throughout the pastoral areas. The pastoral properties are held under leasehold conditions and range in size between 100,000 and 1,000,000 ac. The carrying capacity varies with the district and seasonal conditions; one sheep to 20–30 ac. is regarded as an average for the area.

Wheat is grown on approximately 3,000,000 ac. and on nearly 9,000 holdings each year. Annual production is between 30,000,000 and 50,000,000 bu. Western Australia wheats are white wheats of slightly below "filler" strength. valued mainly for high flour yield and the colour and bloom they impart to flour blends.

Most of the wheat crop is planted with the aid of tractors and the appropriate large machines. Horse teams have almost disappeared from wheat farms. A large modern tractor can comfortably handle from 500 to 1,000 ac. of cereal crop. Planting commences in late April and is usually completed early in June. Superphosphate is always applied in dressings of from 70 to 150 lb. to the acre when the grain is sown. Much of the wheat, particularly in the lower rainfall areas, is sown on bare fallow, but this practice has declined in the higher rainfall districts of the wheat belt. The wheat crop matures in late Oct.–Nov., soon after the warm, dry summer weather begins, and harvesting is carried out in November and December. Locally bred varieties constitute the bulk of the state's crop.

The average yield per acre for the period 1950–54 was 13.2 bu. Although judged by European standards the grain yields of Western Australian farms are low, a favourable combination of circumstances permits high output per man and the large wheat and sheep property is usually a highly mechanized and very efficient concern. Wheat is handled in bulk and a start has been made with the bulk handling of oats and barley. A somewhat unorthodox system has been very successful. The grain is stored at railway sidings in corrugated iron sheds or bins and not in the concrete silos generally used elsewhere. It may be taken to ports in ordinary rail trucks fitted with canvas extensions to the sides and lined with hessian.

About 60% of Western Australian production is exported overseas as grain and another 15% as flour.

Meat *production* ranks third to wool and wheat in value. The only area where it is a single specialized enterprise on a large scale is in the northern part of the state where cattle raising is almost the sole occupation. The cattle carried on large "stations" are utilized solely for beef. Nearly all are shorthorns. There is a pronounced seasonal fluctuation in the quantity and quality of the grazing which constitutes a handicap to the production of high-quality beef. The cattle are treated at meatworks at Wyndham and Broome and shipped abroad in the form of frozen beef Some live cattle are shipped south for slaughter and consumption in the Perth metropolitan area Improvement of the cattle industry on any substantial scale will involve considerable public and private investment for better inland transport facilities, nater supplies and fencing. In the agricultural areas meat production is mainly a sideline to wool production cereal growing and dairying. In the past, appreciable quantities mere exported of frozen lamb and mutton, live sheep (to Singapore) and pork but with a rapidly expanding population a greater percentage of the output is absorbed by the local market.

Dairying has usually been the pioneer occupation in the more heavily timbered country of the extreme southwest. where the annual rainfall ranges from 30 to 50 in. It is associated chiefly with the grazing of annual pasture species, notably subterranean clover. but there is an area near the southern coast where a longer growing season and a light, though useful. summer rainfall makes possible the utilization of certain perennial grasses. Irrigation and drainage schemes on the coastal plain to the south of Perth have considerably increased the productivity of the area. Nearly 20,000 ac., mostly of pasture for dairy cows, are irrigated each year, but lack of suitable water supplies prevents any great expansion of this activity.

By the early 19jos there were about 130,000 dairy cows in Western Xustralia. the chief breeds being milking shorthorns. Jerseys and Guernseys. Less than two-thirds of the state's milk production is used for butter making. About a quarter is consumed as fresh milk and 5% as processed milk.

Miscellaneous Products.—Orchards and vineyards occupy about 30.000 ac. Apples and dried vine fruits form the bulk of the exports. Potatoes, onions. tomatoes and a large variety of other vegetables are grown commercially. Green vegetables of some sort are available throughout the year. Potatoes. tomatoes and green vegetables are exported, the chief markets being the eastern states of Australia and Singapore. The poultry industry produces a surplus of eggs which is exported to the United Kingdom.

Oats are grown extensively for hay. as a grazing crop and for grain. Most of the grain is used as stock feed in the farms where it is produced, though in the postwar period there was some development of an export trade. Barley. of suitable quality. both six-row and two-row, is grown. the latter being used by local malsters. Tobacco and flax are also grown on a small scale.

Mining and Industries.—Of diminished importance since World War II, mining revived somewhat after 1950, output reaching a record value of £A16,920,445 in 1952. Gold, the most important mineral, accounted for £A11,847,917 (729,975 fine oz.. or 73.1% of the commonwealth total); the Coolgardie and Murchison fields being the most valuable. The only coal field being worked in 1953 was at Collie, where 830.461 tons were produced in the preceding year. The coal is consumed within the state. largely by railways. The state is almost entirely self-supporting. only a small quantity of bunkering coal being imported from the eastern states. Iron ore production at Yampi sound was developed after World War II, together with lead and silver-lead mining, asbestos. manganese, tin. wolfram and scheelite. Most of these deposits are in the northwest, Wittenoom and Marble Bar being the centres of activity. Borings for oil in the north. at Learmonth, and in the Kimberleys, attracted increasing attention. (See AUSTRALIA, COMMONWEALTH OF: The Economy: Mining; KALGOORLIE.)

Manufactures are confined mainly to the metropolitan area. particularly Fremantle, Midland Junction. Innaloo and Welshpool, industries favoured there being also those suited to a primary producing country (*e* g., sanmilling, bacon curing, processing dairy produce, ore crushing and concentrating the manufacture of superphosphates and railway engineering).

The limited size of the home market and the strength of established industries in the eastern states retarded manufactures in Western Australia. Following the adverse effect of the depression of 1929–3j on agriculture, a department of industrial development was set up by the state to advance secondary industry. The value of industrial output increased from £A31,740,740 in 1945 to

£A106,377,022 in 1952.

After the 1952 decision to construct a deep-water port at Cockburn sound. south of Fremantle, the site of the Anglo-Iranian Oil company's projected refinery at Kninana was the scene of considerable industrial planning including steel and cement works. (See History, above.)

Trade increased in volume and variety throughout the first half of the century The trade of Fremantle, which took the lion's share, provided an index of this development:

Port of Fremantle	1903–04	1950–51
Shipping tonnage (net!	626,692	5,435,737
Cargo tonnage	560,000	3,097,374
Revenue collected (£A)	79,361	1,574,066
Wheat shipped (bags)	3,132	10,303
" (bulk; tons)	000	500,142
Flour shipped (tons)	000	154,147
Oil fuel bunkered (tons)	000	336,801

A considerable portion of the state's trade is with the other Australian states (1952–53 value of such imports: £A68,606,336; exports: £A24,829,409; 1952–53 value of total imports: £A98,480,531: exports: £A113,132,804).

Communications.—Railways were first developed in the coastal areas behind Geraldton (1879) and Perth (1881). In the following decade. private companies began the construction of lines to join Perth with Albany to the south and Geraldton to the north. After 1894 came the construction of lines to the goldmining centres of the interior—Perth to Kalgoorlie. 380 mi., with extension to Laverton, 591 mi.; Perth to Meekatharra, 600 mi.; and in the northwest an isolated line, Port Hedland to Marble Bar. 114 mi. (closed in 1951).

These lines also proved useful in opening up the pastoral interior. The railway system of the southwest, centralized in Perth, included timber, mineral and agricultural lines. Between 1910 and 1930, an outstanding feature was the construction of developmental wheat-belt spur lines to draw grain and wool into the main trunk systems as in the South Australian Mallee and the Victorian Wimmera. Apart from the Midland railway between Perth and Geraldton. and certain mineral and timber lines, all railways are state-owned. Of narrow gauge (3 ft. 6 in.) the Western Australian railways differ from the commonwealth government's transcontinental line (4 ft. 8½ in.) joining Kalgoorlie with Port Pirie in South Australia. The state railways ran at an increasing deficit after 1945, principally because of increased maintenance costs and the growing competition of privately owned road transport.

Motor transport for road haulage came gradually into use after 192j even in remote pastoral areas where it displaced camel teams and bullock drays, but it was not until after World War II that it presented serious competition to the railways. These responded by developing their own passenger and freighter road services in the southwest.

In the northern pastoral areas the aeroplane provided a pioneering service. As early as 1921, an airline (W.X. Airways) connected Derby with the south. In later years, Airlines (W.A.), MacRobertson-Miller Aviation, and Connellan Airways built up a network of flight schedules connecting outback stations with the larger centres. Of particular importance was the "flying doctor" scheme. begun in 1935, to assure the isolated stations of the northwest of regular medical attention. Air Beef Pty., Ltd.. pioneered the use of air freighters in the Kimberley beef industry in 1949.

In 1953 air services connected I'erth with Adelaide (South Australia) and other state capitals, with Johannesburg (South Africa) and with London (via Djakarta and Singapore, Darwin or Johannesburg). Internal lines provided regular services for all centres of importance.

Shipping services include (1) the main overseas lines which make Fremantle their first port of call and help to make Fremantle the largest oil-bunkering port in Australia; (2) services to other states; (3) Western Australian coastal services. mainly northward, extending also to Java and Singapore. where a trade in fat sheep and fruits has been developed.

From Western Australia submarine cables connect with Africa and Europe.

See J. S. Battye, *History* of *Western Australia (1924)*. (F. A.)

WESTERN EUROPEAN UNION: see PAN-EUROPEAN MOVEMENT.

WESTERN RESERVE UNIVERSITY, a coeducational institution of higher learning. chartered on Feb. 7, 1826. at Hudson. O..and moved to Cleveland in 1882. See CLEVELAND.

WESTFIELD, a city of southwestern Massachusetts, C.S., in Hampden county. is on the Westfield river about 7 mi. W. of Springfield. It is part of the Springfield-Holyoke standard metropolitan statistical area. A central square, a high percentage of privately owned homes on tree-lined residential streets and a predominantly Yankee population give the city a distinctive New England flavour.

Established in 1660 as a trading post within the boundaries of Springfield, it was set off as a town in 1669. Farming gave way to commerce and light industry in the early 19th century. The manufacture of whips and lashes was a leading industry until the advent of the automobile. In 1920. after a steady, slow population growth, Westfield was chartered as a city to meet the needs of the growing community.

The city has a number of small industries. the most important of which produce paper, machinery and bicycles. It is the site of the Westfield State Teachers college. founded by Horace Mann in 1844. For comparative population figures see table in MASSACHUSETTS: *Population.* (GE. G.)

WESTFIELD, a city of Union county. northeastern New Jersey. U.S.. 22 mi. S.W. of New York city. It is almost exclusively residential. industry being restricted to light manufacturing and service enterprises. Most residents commute to nearby metropolitan areas for work. Consequently, it has the character of a suburban town with its network of quiet parks and streets: there are more than 100 different club organizations ranging from national affiliations to local art groups.

Westfield was settled in the 18th century by residents of nearby Elizabeth seeking room in the prairie lands of "West Fields." During the American Revolution it was a strategic outpost for Washington's army, guarding the passes of the nearby Watchung mountains. It was incorporated in 1903. For comparative population figures *see* table in NEW JERSEY: *Population.* (W. L. CA.)

WEST FLANDERS (Flemish WEST-VLAANDEREN; French FLANDRE OCCIDENTALE), the most westerly of the nine provinces of Belgium, is bordered by the North sea, the French and Dutch frontiers. East Flanders and Hainaut. It consists of eight administrative *arrondissements*, 31 judicial cantons and 253 communes. Area 1.249 sq.mi. Pop. (1955 est.) 1,032,169.

Maritime Flanders has a straight. unembayed coast line. 42 mi. long. A broad sandy beach is backed by a rampart of sand dunes, in places a mile wide, many of which exceed 100 ft. in height. Planted marram grass and conifers help to stabilize the sand. This line of dunes is broken only at the mouth of the Yser, at Ostend (Oostende), near Zeebrugge and at the mud-covered inlet marking the former Zwin estuary. Behind the dunes lies a flat plain, the Flemish polders, seamed with drainage channels and extending for 6–10 mi. inland to about 15 ft. above sea level. The surface is interrupted by water-filled depressions and by low sandy hillocks. the remnants of old dunes or patches of Pleistocene marine sands. Soils are variable; yellow sand, black silt and blue or gray clays can be seen within a few yards.

The part of interior Flanders lying within the province includes three elements: the Recent alluvium on the valley floor of the Leie (Lys), the Flanders Clay (Eocene) overlying much of the area, and higher relict patches of Pliocene sands northwest of the Leie valley. The last form a low ridge extending westward from near Passchendaele and reaching 531 ft. in Mt. Kemmel. These hillocks had great tactical importance in World War I.

West Flanders is the most important farming province in Belgium. It has more farmland. cereals, industrial crops, beef cattle and pigs than any other province. Sheep formed the basis of the medieval Flemish textile industry, but few are now kept. Along the edge of the dunes the sandy soils grow potatoes and carrots. and half the polderlands are under permanent or temporary grass. with oats and green crops for fodder. Farther inland. wheat, malting barley, sugar beet, potatoes and tobacco are grown, together with fodder crops for the dairy herds.

Industrial development is found in the coastal towns. at Bruges (Brugge) and in the Leie valley. At Ostend there are fish curing, canning plants, fertilizer factories and a shipyard building trawlers and dredgers. Nieuwpoort (Nieuport) has a chemical works and Zeebrugge a coke-oven plant, glassworks and chemical works. The old part of Bruges still has craft industries (lace, embroidery, glass painting, wood carving), and northwest of the town there is heavy industry (engineering works, barge-building yards, flour mills, timberyards). In the Leie valley is part of the Flanders textile industry, mainly cotton and linen at Courtrai (Kortrijk), Menin (Menen), Roeselare (Roulers) and Ronse (Renaix).

Along the coast line there is an almost continuous line of resorts, the chief being Ostend (also the ferry port for England) and Blankenberge, while Nieuwpoort and Zeebrugge have small commercial harbours. The polders are thinly populated, with isolated farms on sandy hillocks or ridges and only a few small market towns: such as Veurne (Furnes). The largest town is Bruges (*q.v.*), the provincial capital. Interior Flanders is densely populated. The rural dwellers are dispersed widely over the countryside, with individual houses situated within small holdings, but there are many urban centres. the largest being Courtrai, Roeselare and Menin. This area suffered grievously in World War I and many of the towns, such as Tpres. were virtually rebuilt. Most people in the province speak Flemish.

A main line railway runs inland from Ostend to Brussels, joining one from Zeebrugge at Bruges; a line runs from Ostend to Courtrai and another from Veurne to Ghent (Gent). There are numerous tramways, notably linking the coastal resorts. Roads follow embankments among the polders and there are two major trunk roads, Ostend-Brussels and Knokke-Antwerp. The famous Route Royale runs along almost the entire coast from Het Zoute to De Panne. Numerous small canals lie parallel with the coast; the Ghent-Ostend canal runs from the coast via Bruges, and a ship canal links Bruges with Zeebrugge. (For the history of the province see FLANDERS, COUNTY OF.) (F. J. M.)

WEST HAM, a county and parliamentary borough of Essex, Eng., forming an eastward suburb of London. Pop. (1961) 157,-186. Area 7.3 sq.mi. It lies in the angle made by the confluence of the Lea river with the Thames and extends north to Leyton and Wanstead and east to East Ham. The borough. which suffered severely during World War II. includes Stratford. Forest Gate. Plaistow and Canning Town. It is almost entirely a product of 19th-century industrial expansion. 40% of the area being occupied by a variety of factories, railways and docks including the Royal Victoria dock and parts of the Royal Albert and King George V docks. All Saints church has a good Perpendicular tower. The only considerable open spaces are West Ham park (66.19 ac.) and Canning Town recreation ground (20.16 ac.).

After the Conquest the manor of Hamme (approximating to the present East and West Ham) was divided into nine smaller manors. Between the 12th and 14th centuries five of these passed to the abbey of Stratford Langthorne founded in West Ham by William de Montfichet c. 113j. At the dissolution the manor of Westham was retained by the crown and in 1629 became part of the jointure of Henrietta Maria and then of Catherine of Portugal. and was therefore called the Queen's manor. West Ham was incorporated in 1886 and made a county borough in 1888. It returns two members to parliament.

WEST HARTFORD, a residential town in central Connecticut, U.S., is in Hartiord county. A prosperous farming community and Congregational church stronghold during its early history. it became a fashionable residential suburb of Hartford. First laid out in 1672 as West division of Hartford. it was incorporated in 1854, and in 1921 was the first Connecticut town to adopt a manager-council form of government. Rapid growth in population from 8.854 in 1920 to 62.332 in 1960 was accompanied by the application of rigid zoning. which helped to preserve the town's attractive general appearance.

Business zones at intersections of arterial roads provide suburban shopping and service centres for residents of West Hartford and surrounding towns. The per capita income of residents is among the highest in the country. Industry is restricted to a relatively small zone in the southeast corner of town. The American School for the Deaf, founded by Thomas Hopkins Gallaudet in 1817. and St. Joseph's college (1925) are located there. West Hartford was the birthplace of Noah Webster, the American lexicographer. (R. L. GA.)

WEST HARTLEPOOL, a seaport and county borough in the Hartlepools parliamentary division of County Durham. Eng., 18 mi. S.E. of Durham by road. Pop. (1961) 77.073. Area 6.5 sq.mi. In the early 19th century there was only the small village of Stranton near Hartlepool on the site. but intensified coal mining in County Durham led to the building of the railway from Billingham in 1841. West Hartlepool arose from the decision of one man, Ralph Ward Jackson. who, after bringing coal by rail to the old Hartlepool harbour, decided in 1844 to construct his own dock ior coaling about a mile away on wasteland in Stranton parish. Within 20 years this port had become one of the largest on the northeast coast.

By 1882 West Hartlepool and Hartlepool had been joined by docks and building extensions, so that the whole community was often called The Hartlepools. But the towns remained distinct from the point of view of municipal administration. West Hartlepool was incorporated in 1887 and created a county borough in 1902. The port. with two tidal harbours and five docks comprising about 103 ac. of water and 4 mi. of quays, exports mainly coal and basic slag and imports chiefly timber. especially pit props. and iron ore. There are a number of graving docks and extensive areas for storing timber. The principal industries are shipbuilding. iron and steel manufacture. heavy and light engineering and brewing. A trading estate for light industries was opened between the Hartlepools after World War II. The town has a college of art and a technical college.

At the southern end of the borough is the seaside holiday town of Seaton Carew with long sandy beaches. There is a civic airport at Greatham. about 4 mi. S.S.W. of West Hartlepool.

WEST INDIES, sometimes called the Antilles, form an archipelago more than 1.000 mi. in length which lies between North and South America. From the Yucatán and Florida peninsulas in the west. it stretches in the shape of an arc to Venezuela in the south. Except for the Bahamas. which lie farther north. all the islands are between the Tropic of Cancer and latitude 10° N. They enclose the Gulf of Mexico and the Caribbean sea, which they separate from the Atlantic ocean on the east. The land area of the islands is over 91,000 sq.mi., that of the British islands about 12,100 sq.mi.

The West Indies, apart from the Bahamas, are commonly divided into two groups. The Greater Antilles comprise the large islands of Cuba. Jamaica. Hispaniola (Haiti and the Dominican Republic! and Puerto Rico. The Lesser Antilles include the small islands which form the Windward and Leeward groups, Barbados, and Trinidad and Tobago. The largest island is Cuba which, although narrow, covers 44.218 sq.mi., but many of the islands cover only a few square miles. The political allegiance of the different territories is given in the section *Population,* below.

In Jan. 1958 all the British islands (with the exception of the British Virgin Islands and the Bahamas) joined to form the West Indies Federation. The dissolution of the federation was announced in Feb. 1962. (*See* WEST INDIES [FEDERATION], THE.)

Besides its commonwealth of Puerto Rico. the territory of the Virgin Islands, the inhabitants of which are C.S. citizens while the territory is under the jurisdiction of the U.S. department of the interior, and Navassa Island, off the southwest tip of Haiti. the United State.; leases air and naval bases in the British West Indies.

The West Indies are islands of great contrast. The contrasts in population and language reflect their varied history. while they also differ in physical characteristics and economic development. Several steamship services link the West Indies with Europe and America. but interisland communication is chiefly by air.

This article is divided into the following main sections and divisions:

I. Physical Geography

1. Geological History and Geology
2. Physiography
3. Climate
4. Vegetation
5. Animal Life

II. Natural Resources
1. Water Supply
2. Soils
3. Mineral Wealth
4. Land Use

III. Anthropology and Archaeology
IV. History
V. Population

I. PHYSICAL GEOGRAPHY

1. Geological History and Geology.—The West Indian islands are the summits of a partially submerged mountain chain, which is continued westward through Honduras. and in the south through Venezuela. The chain divides into branches which may be traced from Hispaniola through Jamaica, the Sierra Maestra of east Cuba and the Cayman Islands, and the Sierra de los Organos.

A simple distinction may be made between the Greater Antilles and the outer chain of the Lesser Antilles (Antigua, Barbados, east Guadeloupe, Virgins), which are composed largely of sedimentary rocks, and the inner chain of the Lesser Antilles. which is chiefly volcanic. Trinidad is structurally associated more closely with the South American continent. In Cuba and Hispaniola there are schists which are probably older than the Cretaceous period, but the oldest rocks which have been certainly identified in the West Indies, apart from some Jurassic in the northern range of Trinidad, belong to the Cretaceous. Throughout the Greater Antilles, the geological succession begins as a rule with volcanic tuffs and conglomerates of hornblende-andesite. in the midst of which are intercalated occasional beds of limestone with Rudista and other Cretaceous fossils. These are overlaid by sediments of terrigenous origin, and the whole series was folded before the deposition of the next succeeding strata. The nature of these Cretaceous deposits clearly indicates the neighbourhood of an extensive area of land; but during the succeeding Eocene epoch and the early part of the Oligocene, a profound subsidence led to the deposition of the Globigerina chalks and white Radiolarian earths of Jamaica, Cuba and Hispaniola. The Greater Antilles must, at this time, have been almost completely submerged, and the similar deposits of Barbados and Trinidad point to a similar submergence beyond the Windward Islands. In the middle of the Oligocene epoch a mighty upheaval, accompanied.by mountain folding and the intrusion of plutonic rocks, raised the Greater Antilles above their present level and united the islands with one another. and perhaps with Florida. A subsequent depression and a series of minor oscillations finally resulted in the production of the present topography.

Except in Trinidad and Barbados, no deep-sea deposits have yet been found in the Lesser Antilles, and there is no evidence that the area ever sank to abyssal depths. In some of the islands there are old volcanic tuffs which may possibly be the equivalent of the Cretaceous beds of Jamaica, but volcanic activity continued throughout the Tertiary period and persists today in several islands. Both Martinique and St. Vincent have experienced serious eruptions in the 20th century, the worst being that of Mt. Pelée (Martinique) in 1902, when the capital of the island was destroyed. and that of Soufrière (St. Vincent) in the same year. Earthquakes also occur throughout the archipelago. Usually the shocks are slight, but there have been severe shocks in Jamaica and the Windward and Leeward islands.

2. Physiography.—J. A. Froude, writing in 1887, quotes Père Labat as saying of Grenada, one of the Windward Islands; that "In itself it was all that man could desire. To live there was to live in Paradise." The proximity of warm seas, green mountains and fertile valleys give the West Indies this quality which many travelers have noticed.

Generally the islands are of high relief. The highest point is in Hispaniola, where the Pico Trujillo rises to 10,417 ft. In Jamaica, Blue Mountain peak reaches 7,402 ft. and heights of more than 4,000 ft. are reached in Puerto Rico and several of the Windward and Leeward islands. Most islands are dominated by a central range of mountains; long spurs stretch toward the coast and deep valleys lie between them. Rivers are necessarily short and swift-flowing, and plains are chiefly confined to the coasts, although in the larger islands of Hispaniola and Jamaica level valleys lie between the mountain ranges. Passes over the mountains are rare and difficult.

Cuba is the only island with extensive areas of lowland. The high mountains of the Sierra Maestra are restricted to the eastern end and nowhere form a barrier. Barbados and Antigua, composed largely of coral, are also low-lying, while islands such as the Bahamas and Anguilla barely rise above sea level.

Lagoons and mangrove swamps are common features of the island coast lines, which are intricate and fringed by coral reefs. There are many deep natural harbours. such as those of Havana (Cuba) or St. Georges (Grenada), but the approaches are often dangerous.

3. Climate.—In the West Indies, as in most tropical countries. there is little seasonal variation in temperature. Even in the cool months of January and February it rarely falls below 75° F., and the average annual temperature is 80° F. The islands lie in the path of the northeast trade winds which, as they blow from the sea. modify the intensity of the tropical heat, and most of the islands have a pleasant climate. Trinidad, the most southerly of the islands, is slightly hotter, but even there the nights are cool and refreshing.

More significant than the seasonal changes of temperature are those of rainfall, and a wet and dry season are usually distinguished. More rain falls while the sun is north of the equator, until shortly after the autumnal equinox, and the wet season lasts from June to October or November. The average annual rainfall is about 65 in., but there are considerable variations according to position and altitude. Much of Cuba. for example, which is only just within the tropics and is low-lying, receives an average of 55 in., whereas parts of Jamaica, being high, receive 75 in. Altitude also accounts for such different totals as those of Antigua (46 in.) and Dominica (120 in.). In nearly all the islands there is a great difference between the leeward slopes, which are relatively dry, and the windward slopes. which are wet. In eastern Jamaica, for instance, the windward slope receives over 100 in. of rain, whereas the leeward slope receives only 40 in. These local differences can be very important, and show themselves in contrasted vegetation and agriculture.

Hurricanes are the menace of the West Indian climate. These violent wind and rain storms blow in from the Atlantic, generally north of Barbados, and strike one or more of the Lesser Antilles. They then turn northward across the larger islands toward North America. The season for hurricanes, and storms of near-hurricane intensity, is well defined. They are expected between July and October and are a partial cause of the heavier rainfall of these months. Occasionally they strike out of season, The hurricanes are traced and forecast as far as possible, but they often cause great devastation. In Aug. 1951, a hurricane killed many people and did a great deal of damage in Jamaica, and another in Sept. 1955 hit Grenada, Carriacou and Barbados.

4. Vegetation.—The flora of the West Indies is rich and varied. Almost every tropical plant will grow and many temperate plants have been introduced. Much of the mountain land preserves a tropical forest cover! although in places, especially in limestone districts, there is a poor scrub of thorn trees and cacti. Nearly all the lowland has been cleared for cultivation. Economically useful trees include the mahogany, cedar, guaiacum or lignum vitae, greenheart and mora. There are many plants of great brilliance and beauty, such as the flamboyant, frangipani, bougainvillea. hibiscus and poinsettia; there is also a wealth of palm and fruit trees.

5. Animal Life.—The animal life is similar to that of the neighbouring South American continent. Birds, brightly coloured and numerous! include trogons. sugarbirds, chatterers and many parrots and hummingbirds, as well as migrants from Korth America. Mammals, as in most island groups, are rare, but there are agouti, manicou, deer, monkeys and bats. The mongoose, introduced to get rid of snakes and rats, is now abundant, and there

are numerous lizards, iguana, tortoises. scorpions, toads, spiders and centipedes, as well as a few poisonous snakes, such as the fer-de-lance, bushmaster and coral. There is a variety of insects, but much has been done to rid the islands of mosquitoes, so that yellow fever is now almost unknown, although malaria persists in some country districts. The seas abound with fish, the most famous being the flying fish, caught off Barbados, and around the shores are many delicious crustaceans.

Many domestic animals have been introduced and cattle are reared successfully in Cuba and Jamaica, while some sheep are bred for meat. Donkeys are the chief form of transport in the poorer islands. There are also many goats and dogs.

II. NATURAL RESOURCES

1. Water Supply.—The West Indies are on the whole adequately supplied with water, but the marked dry season, which causes rivers to dry up for part of the year, the lack of rainfall on the sheltered leeward slopes and the porosity of much of the land, make drought a very real problem in some areas. Irrigation is used in parts of Jamaica, Cuba and Hispaniola, while in dry islands such as the Virgins and Antigua, deep wells are dug and catchments and cisterns built to conserve water.

2. Soils.—The soils of the islands vary considerably over even small areas. They are sometimes fertile and may give high yields. Limestone, overlain with loam or alluvium, and clay cover large areas in the Greater Antilles, whereas the Lesser Antilles usually have a volcanic soil which is rich and heavy. In Barbados and Puerto Rico, where the land has been worked for a long time, manure must be added to produce good crops. The richest soils are probably the deep red clays of Cuba.

3. Mineral Wealth.—Except in Trinidad, the mineral deposits of the West Indies are neither large nor of great value. There are various deposits in the mountains of Cuba, Hispaniola and Jamaica, and iron, nickel, manganese, chrome and copper are all mined on a small scale. Extensive deposits of bauxite, associated with the Tertiary white limestone, are worked in Jamaica. The petroleum of Trinidad is of far greater importance, and the annual production by 1960 exceeded 40.000.000 bbl. Asphalt is worked in Trinidad's famous Pitch lake. Small quantities of oil have been found in Barbados and Cuba and prospecting has been conducted in Hispaniola and other islands.

4. Land Use.—Much of the land is still forest-clad and in places the cleared hill-slopes are replanted with pine trees, but all the land which is level and fertile enough is cultivated and agriculture is by far the most important occupation of the people. The moist sunny climate and the abundant labour supply ideally suit the West Indies to the production of sugar cane which is still, as it has been since the early days of colonization, the principal crop. However, the islands have suffered from this one-crop economy and although some islands. such as Barbados and St. Kitts, still grow cane almost to the exclusion of anything else, most islands have an important subsidiary crop. Cuba grows tobacco; Jamaica, bananas; St. Vincent, arrowroot; Grenada, spices; Trinidad, cacao; Dominica, limes; Antigua, cotton; Puerto Rico and the Dominican Republic, coffee; and Haiti, sisal. Apart from these and other cash crops, peasant farmers also grow food for their own needs, and of the fruits and vegetables, yams, sweet potatoes, eddoes. mangoes, pineapples, pawpaw, breadfruit and soursop are typical. Some land is always devoted to pasture, as each island produces its own meat. In Cuba, nhere cattle rearing is on a large scale, the animals graze on extensive areas of paraná grass in the eastern half of the island

Most of the manufacturing industries are concerned with the products of the land The processing of sugar cane, which must take place immediately after the cane is cut, is the chief industry By-products of sugar are many and rum is distilled in all the islands. Molasses, molascuit, a cattle feed and alcohol are also produced. Other industries based on agricultural produce include fruit canning, cotton ginning and the manufacture of cigars, cigar boxes and sacking.

The chief extractive industry is the oil drilling of Trinidad. Oil fields underlie the southwestern portion of the island and drilling has been extended to the Gulf of Paria. The ancillary industries are oil refining and the production of gasoline, kerosene and fuel oil. Although bauxite mining began on a large scale in Jamaica only in 1952, by the 1960s bauxite and alumina ranked first in the list of exports. The ores of the Sierra Maestra in Cuba are also mined, although the production has fluctuated with world markets and political upheavals. Limestone quarries and cement works are found in most islands.

Large settlements are usually found on the leeward coasts which, although less pleasant climatically. provide shelter for ports such as Kingston (Jamaica), Port-of-Spain (Trinidad) and Bridgetown (Barbados); Havana (Cuba) and San Juan (Puerto Rico) occupy sheltered sites on the windward coasts. Railways are important only in the large islands although there are small lines to carry cane to the factories. Only Cuba has a network of railways. In most islands there is an effective road system and all but the smallest possess an airport. Tourism and the rapidly increasing facilities for air travel have encouraged public and private enterprise to develop the amenities of the islands. (RD. T.)

III. ANTHROPOLOGY AND ARCHAEOLOGY

According to present estimates, the West Indies were not settled until the first millennium B.C., when primitive Indians. living only by hunting and fishing, arrived from Florida or Venezuela. These Indians are known as Ciboney and the time of their arrival is designated Period I.

During Period II, *i.e.*, shortly after the time of Christ, a new and more advanced group of Indians called Arawak (q.v.), invaded the Antilles from Venezuela, introducing agriculture as well as pottery. The Aramak penetrated as far north as Puerto Rico, while the Ciboney continued to occupy the rest of the islands.

The Arawak seized the remaining islands during Period III, which lasted from about A.D. 350 to 1150 according to the radiocarbon method of dating. They pushed the Ciboney back into the peripheral areas occupied by these Indians in the time of Columbus: the southwestern tip of Haiti, the western end of Cuba and the various islets offshore.

Period IV (A.D. 1150–1500) was marked by the arrival of a third group of Indians, the Carib (q.v.), who appear to have originated in either the Guianas or Venezuela. They seized the small islands of the Lesser Antilles from the Arawak, splitting the latter into tuo groups, one in Trinidad to the south and the other in the Greater Antilles and the Bahamas to the north and west.

Ciboney archaeological remains consist of the refuse of habitation, occurring principally in caves and on islands. The deposits are small and relatively shallow, indicating that the people lived in bands and moved frequently. doubtless as supplies of fish and game became exhausted. Burial was directly in the refuse or in caves, with no grave objects except an occasional series of stone balls.

Archaeologists classify the remains into a series of cultures on the basis of the artifacts they contain. These cannot yet be dated by period, but they indicate a surprising amount of geographical variation from island to island. For example, the Ortoire culture of Trinidad is characterized by tiny, irregular stone chips of unknown function; the Couri culture of Haiti, by large flint blades; and the Cuban cultures, by gouges of shell.

The Ciboney who survived until historic time were so few and so isolated that they never came into effective contact with Europeans. As a result, we know practically nothing about Ciboney ethnology. except that they spoke a language different from that of the Aramak and had a simpler culture.

Arawak archaeological sites contain larger and deeper shell middens. indicating more permanent habitation in villages, and are situated in land more suitable for agriculture. Pottery is abundant, and the changes in its shape and decoration serve as a basis for formulating and dating a large number of cultures.. The earliest cultures, of Period II, are marked by little but pottery Those of Period III also have a few simple amulets and other ceremonial objects carved out of stone, bone and shell. These become more numerous and more elaborate in the sites of Period IV, nith the appearance of such unique and artistic objects as large stone collars and three-pointed, sculptured figures of stone. The latter are associated with ball courts or dance plazas lined with stone slabs. In addition, carved wooden idols and stools are found in caves used as shrines.

These ceremonial developments reached their climax among the Taino and Ciguayo Arawak of the heart of the Antilles, were less in evidence among the sub-Taino of central Cuba and the Lucayo of the Bahamas and were virtually absent among the isolated Igneri of Trinidad. When Columbus established the first Spanish settlement among the Taino, he commissioned a friar, Ramón Pané, to study the Taino religion. Pané's report, which has been termed the first ethnological research in the new world, agrees very well with the archaeological finds. From his and other contemporary accounts. we know that the Arawak were peaceful and had a relatively elaborate social organization headed by hereditary chieftains nho derived their power from personal deities called zemis. Their language belongs to the Arawakan family of tropical South America

Archaeologists are only beginning to identify the remains of the Carib in the Lesser Antilles. The sites of these Indians have relatively crude pottery, characterized by long solid legs not found on Arawak ceramics, and lack the ceremonial structures and cawings of the Arawak.

Much more is known of the ethnology of the Carib, not only from observations made by Columbus and his successors but also from accounts by 17th-century French missionaries and by modern anthropologists who have studied the surviving Indians. These indicate that the Carib had a less elaborate social organization. without hereditary chiefs or classes. Carib life centred about warfare rather than religion; and our term cannibalism is derived from their custom of eating the flesh of captives in order to obtain the latters' personal power.

The Carib have also given their name to the Cariban linguistic stock of South America, although they themselves spoke Arawakan. The explanation for this anomaly is to be found in their tradition that when they conquered the Lesser Antilles they killed the Arawak men but married the women. Apparently, it was the women's language that prevailed.

While Columbus explored all parts of the Antilles, his successors colonized only those parts inhabited by the Ciboney and Arawak, avoiding the Carib islands because they lacked gold and because the Carib were too difficult to subjugate. As the Spaniards conquered each island, they rounded up its Indians and put them to work in mines or on plantations.

Many were worked to death, some starved because the Spaniards failed to provide food; others died from diseases introduced from Europe; and still others lost their lives in unsuccessful efforts to throw off the Spanish yoke. By the time the system of forced labour ended in 1550, the Ciboney had become extinct and appreciable numbers of Arawak survived only on the islands of Cuba and Trinidad. These survivors gradually became assimilated in the European population. A few villages retained their Indian identity well into the 19th century but all are now indistinguishable from the rest of the population.

The Carib fared somewhat better. Their territory was not conquered until the mid-17th century. While most of them perished as pawns in the struggle between the French, English, Dutch and Danes for control of the area, some retained their independence on the smaller islands.

Many runaway Negro slaves took refuge among them They gradually changed in racial composition from Indian to Negro but retained their Indian language and culture because runaway slaves had to "go native" in order to avoid recapture. In 1795 the British moved one group, which had become troublesome, to the coast of Central America, where they multiplied, prospered and are now knonn as the Black Carib. Subsequently. the British rounded up the remnants surviving in the Lesser Antilles and installed them in a reservation on the island of Dominica, which they still inhabit. These island Carib have not retained as much of their aboriginal language and culture.

The Spaniards introduced the first Negro slaves in the middle of the 16th century to replace the dnindling supply of Indian labour. They did not bring in many, for their mines had become exhausted and they specialized in cattle ranches, which did not require much labour. The main influx of Negro slaves took place in the 18th century with the development of sugar plantations by the French, first in the Lesser Antilles and then in Haiti. After the French Revolution the slaves in the latter country revolted, drove out the French plantation owners and set up an independent Negro republic. The owners took refuge in the neighbouring British and Spanish countries, established new plantations there and imported additional slaves from Africa.

The freed slaves of Haiti abandoned the plantations and became subsistence farmers. The same thing happened in the British colonies when slavery was abolished in the middle of the 19th century. To take the place of the slaves the British imported Chinese and East Indians. The latter became particularly common in Trinidad, where they, too, set themselves up as subsistence farmers after their terms on the plantations had expired. They increased in numbers at a greater rate than the Negroes, and by the middle of the 20th century comprised half the population of the island.

Elsewhere, especially in the former Spanish colonies, the Negroes tended to remain on the plantations as paid labourers. There was a greater tendency to intermarry nith whites than in English-speaking countries, and the colour line was weak.

Throughout the Antilles the Negroes and Asians in towns and cities assumed more and more prominence in economic and political affairs, so that in effect they came to dominate the area except in countries with large white populations, such as Cuba and Puerto Rico.

While European languages and customs have been widely adopted, this process has gone further in some places than in others. Everywhere, one finds persistence of many African and Asian traits such as the creole language and voodoo religion of Haiti, and rice cultivation and Islam in Trinidad. The mixture of Amerindian, African, Asian and European peoples and cultures is exceedingly rich and varied, and can scarcely be matched in other parts of the world.

IV. HISTORY

The West Indian islands were revealed to Europeans by the first voyage uhich Christopher Columbus made, in 1492, in search of an Atlantic route to the far east. Columbus touched at various islands in the Bahamas and at points on the north coasts of Cuba and Hispaniola. On his second voyage in 1493 he founded the town of Isabela in Hispaniola, the first permanent European settlement. Santo Domingo (renamed Ciudad Trujillo, 1936–61), for many years the capital of the Spanish Indies, was founded on the southern shore in 1496. The settlement of Puerto Rico was begun in 1508, of Jamaica in 1509 and of Cuba in 1511. The presence of alluvial gold in Hispaniola and Cuba attracted considerable numbers of Spanish settlers. The primitive Arawak natives died off rapidly as the result of European diseases, against which they had no immunity; of starvation, through the destruction of their crops by Spanish domestic animals; and of the severities associated with the forced labour system introduced by the Spaniards. By the end of the 16th century the natives of the greater islands were extinct. From about 1510 the Spaniards began to replace them by purchasing, through Portuguese dealers, small numbers of West African slaves.

Throughout the first three decades of the 16th century the islands were bases from which expeditions sailed to Central Xmerica and Mexico. These territories had the advantage of abundant native labour. and in the 1520s drew many settlers from the islands, especially as the island gold became exhausted. The islands came to be valued chiefly as ports of call. Their inhabitants lived by selling bacon. dried beef and cassava bread for victualing passing ships, and by exporting hides, tallow and sugar to Europe. At the same time, the islands acquired a new strategic importance. The increasing volume of shipping, carrying tropical products and Mexican or Peruvian silver, attracted the attention of pirates, privateers and smugglers. In the second half of the 16th century

the Spanish government was obliged, even in peacetime, to organize shipping through the Caribbean in convoys and to construct ponerful fortifications at the strategic harbours — Cartagena. San Juan de Puerto Rico and, above all. Havana. The leading military engineer of his day, Juan Bautista Antonelli. nas employed on these works.

Spanish dispositions could not prevent all raiding in so large an area. Sir John Han kins' slaving voyages of the 1560s set a new fashion in smuggling. Sir Francis Drake captured a large quantity of silver on the isthmus in 1572, and during his bigger expedition of 1585 took, but could not hold, both Santo Domingo and Cartagena. Another fleet of similar size, however, under the joint command of Drake and Hawkins. in 1595, mas defeated. Despite sporadic raiding despite an extensive, though still risky, smuggling trade, Spain's rivals achieved nothing permanent until the end of the 12 years' truce between Spain and the Netherlands in 1621. In that year the Dutch West India company received its formal charter, incorporating it for conquest and plunder as well as for trade. The heavy attacks which this company delivered against Spanish shipping — even though much of the company's energy was diverted to Brazil — enabled other groups of foreigners to settle in unoccupied islands in the eastern Caribbean nithout fear of Spanish interference. English settlers occupied part of St. Kitts in 1623, Barbados in 1624, St. Croix in 1625, Nevis in 1623, Antigua and Montserrat in 1632. An attempt to settle St. Lucia was defeated by the fierce Carib inhabitants in 1641. The French Compagnie des Isles d'Amérique was formed in 1635. and the settlement of Martinique and Guadeloupe began in the same year. The Dutch themselves, though little interested in settlement. seized betneen 1630 and 1640 Curaçao, Saba, St. Martin and St. Eustatius, all valuable as trading and smuggling depots; all were confirmed to the Dutch in the treaty of Münster in 1648

Before the middle of the 17th century no serious attempt had been made to capture territory in actual Spanish occupation; but in 16jj a large naval and military force sent from England by Oliver Cromwell. after being driven off from Santo Domingo. attacked and eventually conquered Jamaica. Adm. Robert Blake's victory over the Spanish fleet at Santa Cruz in 1657 made the dispatch of a relief expedition impossible; and Jamaica was formally ceded at the treaty of Madrid in 1670. Meanwhile effective control over the western part of Hispaniola passed out of the hands of the Spanish governors into those of buccaneers — cattle hunters turned pirates. many of them of French origin — who received ever increasing support from the French government. This territory, under the name of Saint-Domingue, was eventually ceded to France at the treaty of Rijswijk in 1697. The second half of the 17th century was a period of continuous disorder in the Caribbean, in which bands of buccaneers, either in the nominal employ of French or English governments, or on their own account, plundered Spanish harbours and preyed on the shipping of all nations. It was only after the treaty of Rijswijk that effective steps were taken by all governments to put an end to buccaneering.

The early settlers in the eastern Caribbean relied on tobacco as their main cash crop and employed European labour, recruited either by indenture or by penal sentences. Both proved inadequate; after the middle of the 17th century most island planters turned to sugar as the most profitable crop and to West African slaves as the only form of labour available in sufficient quantity. The techniques of sugar manufacture were introduced from Brazil by Dutch traders, who — having acquired most of the old Portuguese barracoons (enclosures for slaves) in West Africa — also supplied the slaves. In the non-Spanish islands, sugar soon became the main export crop. The peculiarities of sugar production required comparatively large estates. The class of European small holders began to dwindle and disappear, and Negro slaves greatly exceeded in numbers the small groups of planters, overseers, merchants and professional men who remained.

The gronth of trade in sugar, rum and slaves. and the mounting value of the sugar duties, made the possession of West Indian territory a chief aim of European colonial powers Every major European war in the 18th century was reflected in heavy fighting in the Caribbean and every peace treaty included transfers of West Indian islands. The settlements of Utrecht (1713), Aix-la-Chapelle (1738) and Paris (1763) all favoured Great Britain at the expense of France and Spain; and Great Britain also secured most of the slave trade. In the American Revolution major losses of British territory were averted only by Sir George Rodney's last minute victory off the Saintes Islands (Guadeloupe) in 1782. The final settlement of 1815 confirmed to Great Britain: St. Lucia. Grenada, Dominica, St. Vincent. Trinidad. Tobago (all acquired from France) and British Guiana (from the Dutch). France retained Martinique and Guadeloupe; but Saint-Domingue had become in 1804 the independent state of Haiti. Spain retained Cuba, Puerto Rico and Santo Domingo, but lost them in the 19th century. Santo Domingo became the Dominican Republic in 1844; and as a result of the Spanish-American War in 1898, Cuba became independent and Puerto Rico was annexed by the C.S.

West Indian prosperity did not long outlast the 18th century. A steady increase in sugar production in other parts of the world

led to a decline in price. Recurrent war dislocated trade and raised freight and insurance charges. Further blows to the prosperity of planters and sugar factors were the abolition of the British slave trade in 1807; the emancipation of slaves in the British colonies between 1833 and 1838, in the French in 1848; and the abolition of preferential sugar duties by the British government in 1846. For most West Indian territories, the 19th century was a period of impoverishment and neglect. The principal exceptions were Trinidad and British Guiana, where indentured immigrants from India supplied cheap labour, and Cuba, which retained slavery until 1886 and exported vast quantities of sugar to an expanding market in the United States. Only in the 20th century has there been any marked evidence of a change for the better. Oil has brought considerable wealth to Trinidad and great prosperity to Curaçao since the beginning of the 20th century; bananas and bauxite have taken their place beside sugar as the major exports from Jamaica; and the tourist trade has become an important source of revenue.

On the political side, the middle years of the 20th century were marked by a steady trend toward self-government in all the colonial possessions in the West Indies, culminating in the British islands in proposals for independence and plans for federation. In Cuba. Haiti and the Dominican Republic, on the other hand, varying degrees of local dictatorship have been the price of technical independence. Throughout the area, economic dependence upon the United States has steadily increased. *(See* also WEST INDIES [FEDERATION], THE.) (J. H. PY.)

V. POPULATION

Of a total area of over 91.000 sq.mi. the Greater Antilles take up nearly 82,000. Official area and population figures are given in the table; also the political status of territories.

The total population of the West Indies was about 20,000.000 in 1960. In 1957 about 61% were of African and mixed descent and 39% were white — overwhelmingly the Spanish groups of Cuba (73%), Puerto Rico (80%) and the Dominican Republic (20%); Curaçao is about 14% white.

Jamaica and the remaining islands have, with few exceptions, an African and mixed population with a sprinkling of whites; *e.g.,* British territories have a total population of about 3,500,000 people with 1.5% white. Trinidad has the majority of the region's 1,250,000 island East Indians, who form one-third of its population and increase exceptionally fast. The rate of increase of many island populations, *e.g.,* Jamaica and especially Puerto Rico, is notable.

The official language of Cuba and the Dominican Republic is Spanish; of Puerto Rico. Spanish and English jointly; and of Haiti. French. Elsewhere it is that of the associated power Haiti recognizes creole as a language and patois is spoken in French and former French islands. A dialect of mixed origin called Papiamento is spoken in Curaçao.

Education is compulsory in Cuba, Puerto Rico, Martinique, Trinidad and various other islands but cost is a source of acute difficulty in poor communities. There are nine public universities: four in Cuba, two in Puerto Rico and one each in the Dominican Republic, Haiti and Jamaica.

Normally the white and middle-class population adhere to a traditional European culture, ahich may, indeed, penetrate all classes. Large groups of the poorer and more remote African people are, however, incompletely assimilated. especially as regards the basing of family structure upon legal marriage. Possession cults are strong in some parts. East Indians are mainly non-Christian and have retained in some measure their own religions, languages and customs. Puerto Rico and Jamaica show interesting social experiments such as aided self-help and community development.

Until communication by air became possible the islands were much isolated, and differences of situation. size and history, combined with lack of any common indigenous culture, have affected all aspects of social life. Spanish-speaking communities have bonds nith Central and South America, regions little known to others The influence of the U.S. is generally felt, and English-speaking islands have special ties of blood and trade with both the United States and Canada. Artistic and scholarly contacts as well as tourism link the West Indies increasingly with one another and with a wider world, but they still retain an inner diversity.

(D. I.)

WEST INDIES (FEDERATION), THE, islands in the Caribbean sea consisting of 10 territories that voluntarily joined to form a union of free and equal partners. The West Indies federation. a nation within the Commonwealth of Nations, came into existence on Jan. 3. 1958. and its dissolution was announced on Feb. 6. 1962. During the five years of its existence it was subject to certain limitations of authority in matters concerning defense, external relations and finance. The first aim of the government was to fashion the 10 territories into one politically and economically viable union able to act as a sovereign state. Problems common to any new nation are complicated by the unique geographical situation of the federation — it is more than 1,000 mi. from Jamaica to Trinidad — and its intricate historical and cultural background. The site chosen for the capital in Trinidad, Chaguaramas, is leased to the United States, and a Joint commission reported in May 1958 that, for financial and strategic reasons, it could not be made available to the government of The West Indies. Another site, required to be twin-town to a large existing town, remained to be found. (R. To.)

For physical geography, natural resources, anthropology, ***see*** WEST INDIES. This article is divided into the following sections and divisions:

I. HISTORY

The governments which came together to form the federation were Jamaica. Barbados, Trinidad. the Leeward Islands and the Windward Islands; but of these, Jamaica had (and has) dependencies, consisting of the numerous islands of the Cayman, Turks and Caicos groups; the Leeward Islands group was itself a federdtion of presidencies comprising a large number of inhabited islands, including the British Virgin Islands; the Windward Islands was a collection of four fair-sized islands (with various satellites) which had a common governor but othernise had little common machinery of government; and Trinidad had associated with it in government the smaller island of Tobago. When the federation was formed, some of these groupings were disregarded or dissolved The presidencies of the Leeward Islands colony, for instance, and the colonies of the Windward Islands, all entered the federation as separate units. The units of the federation, therefore. were Barbados, Jamaica, Antigua, St. Kitts-Nevis-Anguilla (properly called St. Christopher-Nevis-Anguilla). Montserrat, Trinidad with Tobago, Grenada. Dominica, St. Lucia, and St. Vincent. British Guiana and British Honduras could accede to the federation at any time if they so desired.

Of the islands which made up the federation, Jamaica, uith an area about that of Wales and a population of 1,250,000, was by far the largest; Trinidad with 500.000 people was considerably smaller, and all the others were smaller still, far too small to be workable self-governing units in 20th-century conditions. The island governments were driven to federation by the conviction that only in that way could they achieve dominion status. independence within the British Commonwealth; a status to which the island peoples, or at least their political leaders, all professed to aspire. Only in that way. also, could they exert their maximum bargaining power in international discussions affecting their vital economic interests; in such matters. for example, as the fixing of sugar quotas. The federation came into being in the face of very strong island loyalties and jealousies; jealousies which throughout two and a half centuries had defeated almost all previous attempts at administrative grouping. These jealousies reflect a considerable diversity in social and economic origins and in political development among islands which are superficially much alike.

The first British settlements were made from 1624 onward in the Caribbee Islands, a loosely defined group which included Barbados and the present Leeward Islands. All these settlements developed along similar economic lines, first producing food crops and tobacco for export on small farms with indented European labour. but later turning to sugar produced on relatively large plantations with African slave labour, the European small holders being displaced.

By the late 17th century the Caribbee Islands had become both productive and prosperous and were regarded as valuable possessions. Barbados was the largest and most populous. It retained a bigger proportion of its early white small holders than did the other islands. and its white population was almost entirely English, unlike the Leeward Islands, where many Irish had settled. and where the French held part of St. Kitts. The Caribbee Islands had a common governor in their early days; but friction between St. Kitts and Barbados, and difficult communications. led to a demand for separation. In 1671 Barbados became a separate government. with its own governor, council and assembly. The appointment of a separate governor of the Leeward Islands did not. however, create a united government there. Each island early in its history had developed its own assembly. empowered to vote taxes and make laws not repugnant to the laws of England. A general assembly was created in 1674. but was always unpopular and ineffectual. It met for the last time in 1798. Throughout the 18th century the Leeward Islands were, in effect, four separate colonies under a common governor residing in Antigua.

Jamaica, unlike the Caribbee Islands, was a conquered colony, taken from the Spaniards between 1655 and 1660. and initially governed by the military commander. It came under civil government in 1661, and secured representative institutions similar to those of Barbados and the Leeward Islands. Many dispossessed small holders from those islands moved to Jamaica. which was a base for buccaneering and for illicit trade with Spanish America. as well as a plantation colony. After the treaty of Utrecht (1713) the island was the chief Caribbean depot of the South Sea company, in the company's slave-dealing activities under the Spanish Asiento (*q.v.*). In the 18th century Jamaica became by far the richest of the British Caribbean colonies, and one of the most valuable tropical "plantations" in the world. Being far to leeward of the Caribbee Islands it had feu direct dealings with them, and not until federal government was considered was there any suggestion of associating its government with that of any other colony.

The treaty of Utrecht. which confirmed all these possessions to Great Britain and added the former French holdings in St. Kitts, set the territorial pattern of the West Indies for more than half a century. Throughout the 18th century the sugar islands were prized objects of war; the purpose of capture, however, was to destroy, rather than to retain, the enemy's possessions. For this reason, conquests were usually restored at each peace treaty. The first major change came in 1763, when as a result of naval operations during the Seven Tears' War, Great Britain temporarily achieved a mastery so complete that. had the government so wished, almost the whole of the West Indies could have been united under one flag. In fact, however, the only territorial cessions in the West Indies eventually agreed at the peace of Paris were those of Grenada, Dominica. St. Vincent and Tobago to Great Britain. This group, then known as the Southern Caribbee Islands, was first organized as a single colony under a governor-in-chief, with lieutenant-governors in the individual islands. The islands had then very few European inhabitants and were still largely occupied by Caribs; but under British government! settlers entered from the Leeward Islands and Barbados and the familiar sugar-plantatisn pattern spread rapidly. The islands developed their own assemblies, as the Leeward Islands had done a century before, and their own insular feelings. Dominica was constituted a separate government in 1771, St. Vincent in 1776. During the American Revolution many of the islands were captured and devastated by the French, but with the exception of Tobago all mere restored at the treaty of Versailles. By the same treaty, the logwood cutters of British Honduras first received a precarious recognition.

During the long period of war between 1793 and 1815 there was much fighting in the West Indies, in the course of which Great Britain seized Trinidad, Tobago and St. Lucia and the three Dutch mainland colonies. Demerara, Essequibo and Berbice. All were retained at the peace in 1815, and the three mainland territories were united in 1831 to form British Guiana.

The 19th century in most of the British islands was a period of economic depression. The steady fall in the price of sugar, due partly to its successful cultivation in other parts of the world, emphasized the costly inefficiency of slave labour (the British slave-labour trade was abolished in 1807). The plantation system was beginning to break down even before the great social revolution of the 1830s, when the slaves were all emancipated and became either labourers or peasant small holders. The equalization of sugar duties in 1846 made fresh difficulties for the West Indian producers. The only exceptions to the general distress were Trinidad and British Guiana. which were largely undeveloped in 181j, and which later in the century imported great numbers of indented labourers. chiefly from India. Increasing poverty led to the decay of the old assemblies. After a dangerous outbreak of rioting in 1865 the Jamaica assembly was abolished and crown colony government instituted there. Most of the other islands followed, Barbados being the only conspicuous exception. Nevertheless, the islands resisted as strongly as ever all attempts to amalgamate their governments.

The Windward Islands were placed in 1833 under the governor of Barbados, as governor-general. but the legislatures remained separate and an attempt to federate them in 1876 was abandoned after rioting in Barbados. In 188; the Windward Islands were again given their own governor. Tobago was separated from the group in 1888 and its government amalgamated with Trinidad. British Honduras. declared a British colony subordinate to Jamaica in 1862, was separated under its own governor in 1884. Only the Leeward Islands agreed, with some reluctance, to federate and to revive their old general legislature; the federal colony of the Leeward Islands was established by act of parliament in 1871.

In the 20th century there has been a revival of the sugar industry in the West Indies, and a development of other export crops, notably bananas. Mineral products—oil and asphalt in Trinidad, bauxite in Jamaica—and the tourist trade increased the islands' prosperity. The authoritarian structure of crown colony government was progressively relaxed, especially after World War II, and Jamaica and Trinidad at least became for all practical purposes internally self-governing. This very progress, however, revealed the limitations of self-government at "unit" level. and led to a demand for federation from the more far-sighted political leaders in the smaller units; a demand which was warmly encouraged by the government of the United Kingdom. both directly by political suggestion and indirectly through the working of the Development and Welfare organization with its headquarters in Barbados.

The first conference on British West India federation was held at Montego Bay in 1947. By a majority vote it accepted the principle of political federation and set up a Standing Closer Association committee to study the possibilities of federation and to draft a federal constitution. The committee produced a report which was notable both for wisdom and for ingenuity. In 1953 the S.C.A.C. report was submitted to a second conference in London and accepted! with modifications, for embodiment in the conference's recommendations. It then went back to the individual governments for acceptance. Jamaica, by a unanimous vote of both houses. accepted the recommendations. British Guiana and British Honduras both announced beforehand that they would not do so, but the other islands followed Jamaica. A period of administrative preparation followed during which a Regional Economic committee, a Regional Labour board and an Air Transport Advisory council were set up. Reports were prepared on a number of important topics. including federal finance, the federal public service and the possibility of a customs union. A third conference on federation met in London in 1956. At this conference the final decision was made to federate the island territories and to leave the way open for the inclusion of British Guiana and British Honduras at a later date. The following year, after long and stubborn argument, it was agreed that the federal capital—to be built with the help of £1,000,000 to be contributed by the government of the United Kingdom—should be in Trinidad.

In 1957 Lord Hailes was appointed the first governor general of the federation. The first federal elections were held in 1958, and Sir Grantley Adams, chief minister of Barbados, became the first federal prime minister.

The difficulties in the way of West Indian federation, apart from insular prejudice, have included the personal jealousies of political leaders; the fear of the larger and stronger territories that they were being asked to support the smaller and weaker ones; and the fear of the politically rnore developed communities that their progress in local self-government might be delayed by association with less "advanced" groups. These fears were. to a great extent, removed by the discussion at the 1953 London conference.

More serious was the resolute refusal of the mainland territories to join in a political federation. It arose from a complicated blend of economic. political, racial, religious and sentimental motives. In both territories the idea of "continental destiny" and similar slogans have considerable emotional force. and in both there is widespread fear of a flood of immigration from the over-populated islands. Their refusal to participate robbed the project of some of its attraction. Dissolution of the federation was announced Feb. 6, 1962. Jamaican independence was announced for Aug. 6, 1962; a proposal was advanced for a federation of the "little eight" islands headed by Barbados; Trinidad offered to accept other territories in its unitary system. (J. H. Py.)

II. POPULATION

The population of the territories comprising the federation was high in relation to the natural resources of the area. and in 1958 the rate of increase was such that the population of nearly 3,000,000 in 1955 would he doubled by 1985. The rate of natural increase (excess of live births over deaths per 1,000) in 1955 over 1954 was 20.5 in Barbados; 26.3 in Jamaica (excluding Cayman Is. and Turks and Caicos Is.); 26.4 in Antigua (including Barbuda); 17.8 in Montserrat; 33.9 in St. Kitts-Nevis-Anguilla; 31.6 in Trinidad and Tobago; 26.9 in Dominica; 31.1 in Grenada with Carriacou; 28.8 in St. Lucia; 33.0 in St. Vincent (including the Grenadine Is.); the average of all being 27.6. In 195j all territories showed birth rates exceeding 30 per 1,000 while the over-all death rate was 12.1. Jamaica recorded for the first time a death rate of under 10, and only St. Vincent stood out as a territory showing little marked decline in its death rate; in 1954 it mas 15.2, and in 19jj it was 14.j—nearly 50% higher than the regional average.

The result of this constant increase is that attempts to provide adequate social services and labour opportunities are apt to come to nothing because the yearly increase in population takes up the margin of improvement and leaves the position unchanged. The population is very young and there are many more women than men, particularly in urban areas. The smaller territories, which have never found adequate employment for their adult populations, claimed that federation gave the right of unrestricted movement within federal territory while the larger islands saw in this claim a threat to their own labour markets. However, it was decided that one of the objects of federation was the greatest possible freedom of movement within the area. and agreement was reached on measures to be taken for facilitating and controlling interisland migration. Emigration, which was common practice during the first 30 years of the 20th century, was later restricted almost entirely to the United Kingdom. The U.S. immigration policy is highly restrictive, and neither Central nor South America wants a large influx of Negro labour. The American and Dutch Caribbean islands gave work to emigrants from British islands in the past, but now have sufficient labour for their own needs. In the United Kingdom there were 80,000 West Indian emigrants in 1958; enough to create a number of welfare problems there, but not enough to make any real difference in the labour markets of the federation.

Birth control would be a solution to the problem of overpopulation, but the social and religious difficulties are great. What is called common-law marriage is the rule in The West Indies, and the rate of illegitimacy is above 65%. The family is a loose structure and family feeling as a restrictive influence unknown. The population problem creates more problems in education and labour employment, and it is difficult to see how production, which is dependent on assistance in some form from outside, can be stepped up to overtake the natural increase in population. At the end of the 1950s the federal and territorial governments were concerned to overcome these difficulties, and if new industries and businesses were to see opportunities for development they would undoubtedly receive every assistance.

For area and population figures of the members of The West Indies federation, see Table in WEST INDIES.

The total area of the federated territories is just over 8,000 sq.mi. In those islands which are mountainous population is concentrated in the valleys and coastal areas, and this must be remembered when considering the figures for the density of population. Even in Antigua, where there are no mountains (Boggy peak, 1,333 ft., is the highest feature), there is a considerable highland region in the southeast which is sparsely inhabited.

The population of the islands is not homogeneous although the majority is of African Negro origin. Of the total shown ,above more than 78% are of Negro origin and about 18% mixed; East Indians form 1.8%; Chinese. 1.0%; Europeans. 0.4%; and Syrians, 0.1%. Jamaica and Trinidad account for nearly four-fifths of the population of the federation; and Trinidad has the largest number of East Indians, 36% of its total.

A conference on demographic problems was held in Trinidad in 1957 under the auspices of the Caribbean commission, and their recommendations included the promotion of vocational guidance and training as a means of economic development; the study of conditions under which emigration can be organized; and the undertaking of fertility surveys as part of the 1960 world census program.

III. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution.—The constitution of The West Indies as agreed in 1956 was approved by the parliament of the United Kingdom in July 1957. The legislature was inaugurated in Port of Spain on April 22, 1958. The constitution provides for a governor general appointed by the crown and assisted by a council of state; a senate of 19 members, nominated by the governor general and serving five years; and a house of representatives of 45 members elected by adult suffrage. In the senate each territory has two representatives, except Montserrat which has one. In the house of representatives. Jamaica has 17 members; Trinidad, 10; Barbados, 5; Antigua. St. Kitts, Dominica, Grenada, St. Lucia and St. Vincent, two members each; and Montserrat, one member. Montserrat also has an "alternate member" who may deputize for the member if he is incapacitated.

The first elections were held in March 1958, with the result'that the Socialists. known as the Federal Labour party. won 25 seats; the anti-Socialists. called the Democratic Labour party, 19 seats; and the Barbados Independent party, one seat. The premier of

Barbados: Sir Grantley Adams, was elected prime minister by secret ballot. Politicians cannot sit in both federal and territorial legislatures. and this accounts for the absence from the federal parliament of the chief ministers of Jamaica and Trinidad.

The executive authority is exercised by the governor general. A council of state, which consists of the prime minister (who is nominated by the house) and 10 ministers, is the chief instrument of policy. Ministers, not less than three of whom are senators, are appointed by the governor general on the prime minister's advice. The governor general is required to act on his council's advice except in certain specified contingencies and he must obtain the secretary of state's approval if he acts against that advice. Provision is also reserved to the United Kingdom government to legislate in respect of defense, external relations and the financial stability of the federation.

The powers of the federation are specifically defined. Certain subjects, including defense, external relations, federal services, migration and borrowing outside the region, are "exclusive" subjects of federal legislation. Emergency powers, criminal law and administration, aviation and trade unions are among the "concurrent" subjects; that is, subjects both of federal and unit legislation. with the understanding that in case of conflict the federal will shall prevail. All subjects not specified—for example, agriculture, housing and the maintenance of public order—are left to the unit legislatures.

Money bills are introduced in the house of representatives only and may be presented for the governor general's assent even if not passed by the senate, which on other bills has delaying powers for one year. The queen in council may amend any of the provisions of the constitution. particularly for the purpose of including other territories in the federation. General elections are held every five years, and the governor general has the power to prorogue or dissolve parliament.

2. Taxation.— Until 1963, the government would obtain revenue chiefly from a mandatory levy on territorial governments, which must not exceed £1,900,000 per annum. It is also entitled to profits from the currency issue and. after five years, will levy its own income tax. The federal government is responsible for the control of territorial governments which receive grants-in-aid. Taxation varies in different territories as do customs and excise.

3. Living Conditions.— The islands are overpopulated in relation to their resources and in the 1950s unemployment and underemployment were severe. Standards of living are low because territorial economies cannot support anything better. and the climate is undemanding. Wages are low, although workers in many industries have received yearly increases since 1946 and tend to regard this as a normal feature of employment.

Housing conditions are poor. The shacks in which the majority live are small and built of timber. with no washing or cooking facilities, and no water or electricity laid on. Overcrowding is the worst defect and if the family is large (the average number of children is five) several members sleep outside. The staple food of the people is fungi or rice and salt fish, fruit and vegetables. Food is cooked on coalpots and eaten outside.

4. Welfare Services.— Public welfare is recognized as an essential part of the administration, and committees representing all social services are working on long-term policies. The Development and Welfare organization, established in 1940, assisted all territories, and its functions and responsibilities have been assumed by the federal government. The organization plans services to agriculture, education, fisheries, forestry. housing. industrial development, health, surveys and water supplies; and during the years 1946–56, £23,140,200 was expended in grants and loans. Voluntary organizations were encouraged to work on modern lines and made great progress. The idea of self-help. based on home, family and village. has been widely adopted and commands the support of administrations, churches and voluntary organizations. The federal government is maintaining the tradition of welfare, and the inclusion of the minister for social affairs in the council of state guarantees the integration of welfare with other services.

5. Justice.— The establishment of the federal supreme court was the first duty of the newly elected federal parliament. The court has original jurisdiction in all federal territories and can hear appeals from courts of colonies not included in the federation. All judges are appointed by the governor general, and the bench consists of a chief justice and three justices. Courts may be established anywhere in the federation. Police forces are organized on a territorial basis. but there is effective co-operation throughout the federation.

6. Education.— Primary education for all children of school age is the declared policy of the government. The system of secondary education, on which the fortunes of the University College of The West Indies depend, is being consolidated; but the problems of education at all levels are (1) the difficulty of providing adequate staff and accommodation; (2) a continuous rise in the costs of education; (3) the need for reform in methods of teacher-training; and (4) the need for a revision of curriculums and for the development of technical education. The university college teaches for honours degrees in English, history, French, Latin and mathematics, and has a well-equipped medical faculty. The extramural department has resident tutors in each territory and peripatetic staff-tutors.

7. Defense.— Defense of The West Indies is essential to the defense of the Americas, and thus closely linked to the over-all defense strategy of the United States. The Caribbean is one of the great seaways and in wartime the federation is peculiarly dependent on its effective defense. The U.S. has established a chain of bases from Newfoundland in the north to Trinidad in the south and it was decided in May 1958 that the existing base at Chaguaramas. which had been considered as a site for the administrative capital of the federation, fulfilled all strategic and military requirements and that an alternate site would cost between £47,000,000 and £88,000,000 and take from $5\frac{1}{2}$ to 10 years to build. The United States has small military bases in other territories, and since the abolition of the Royal Navy's America-West Indies station the defense of the area has been entirely in American hands.

A British army headquarters is situated in Jamaica for liaison purposes. The Jamaica regiment, under its command, was to be incorporated in a re-formed West Indies regiment. The role of these troops is local defense and internal security.

IV. THE ECONOMY

1. Production.— The economy of the islands has in the past been based on a few agricultural products, but the present aim is to diversify production so that each island will be economically independent when grant-aid is withdrawn. Cultivation of the land is the chief occupation in the federation; over 50% of the cultivable land. and over 80% in some islands, is farmed in large plantations on which cash crops are grown, although the number of small holdings is increasing. Much land is also devoted to food crops for home consumption, some of which are traded between the islands. Tree planting is encouraged, not only to promote timber and fruit yields, but also to improve water supply. The largest stands of valuable timber are in Trinidad. Most islands have a small fishing industry, and a variety of fish is caught. In Barbados, famous for flying fish, the fishing fleet is equipped with power units.

In 1957, Trinidad's oil fields were drilled by 12 companies; marine drilling has also achieved favourable results and production

TABLE I.—*Exports, 1955*

Territory	Value of exports	Main exports with percentage of total
Trinidad and Tobago . .	£59,500,000	Oil and oil products, 76%; sugar and rum, 11½%; cocoa, 4%; asphalt. citrus. coffee, copra
Jamaica . . .	£33,627,724	Sugar and rum, 36½%; bauxite and alumina, *2634%;* bananas, 15%; cigars, pimento, coffee, citrus
Barbados	£8,141,085	Sugar, molasses and rum, **93%**
Windward Islands . .	£4,220,000	
Dominica . . .		Lime products, bananas
Grenada		Nutmegs, mace, cocoa
St. Lucia		Sugar, coconut oil, copra, cocoa
St. Vincent		Arrowroot, cotton, copra, bananas
Leeward Islands . . .	£2,640,000	
Antigua		Sugar, cotton
St. Kitts-Nevis-Anguilla .		Sugar, cotton
Montserrat		Cotton, vegetables

Table 11.—Bauxite and Alumina Exports, 1955 and 1957

continues to increase. Asphalt from the pitch lake is mined. The production of bauxite in Jamaica has shown a striking increase since it was first developed on a large scale in 1952. Oil refining and the extraction of alumina are associated industries. However, sugar refining and its by-products are still the chief industries of the area. The territories of the federation produced 815,841 long tons of sugar during 1957. Other industries associated with agriculture are the canning of fruit juices, cotton ginning and the production of copra and coconut oil, while many small manufactures for local consumption include ice! cigarettes, mineral waters and beer.

2. Trade and Finance.—The prosperity of the federation depends on an integrated trade policy and regional co-operation, and in its early days a commission on trades and tariffs sat to examine the fiscal and technical problems involved in the establishment of a customs union. The domestic trade is varied and includes sugar, rum, fruit, vegetables, copra, charcoal, salt and sloops.

The chief importers into the federation are Great Britain, the United States, Canada and Central and South America: the distribution of exports is similar except that the positions of the United States and Canada are exchanged. Imports include flour and meal, rice, salt fish. meat, canned foodstuffs, cotton piece goods, motor vehicles and transport equipment, machinery, fuel oils, lubricants. lumber and fertilizers. Needs vary between islands, and Trinidad—the largest single importer—obtains crude oil from Venezuela which ranks second among its suppliers after Great Britain. The Canada-West Indies trade is traditionally based on the exchange of food and forestry products for sugar, molasses and rum; but the federation lies in the sterling area and trade with North America is less than it used to be. The price for export sugar under the negotiated price quota of the commonwealth sugar agreement was £43 16*s.* 8*d.* a ton for 1958. Potentialities for the entertainment of tourists are great. In all islands, except Trinidad, there is a steady upward trend in the tourist trade. which is one of the largest revenue-producing activities.

The monetary unit in all territories, except Jamaica. is the B.W.I. dollar, and in Jamaica it is the £J. = $4.80 = £1 sterling. Jamaica currency is legal tender in other territories and vice versa. The coinage. introduced in 1955, is that issued by the British Caribbean Currency board with decimal values. A large sum of money is being allowed by the British government to enable the federal government to make grants to territorial governments whose resources are insufficient to enable them to defray their administrative expenses during the first ten years of the federation.

3. Transport and Communications.—&lainhighways in all territories are constantly being improved, but the huge increase in traffic—especially in Trinidad—necessitates a new approach to the problem. Railway systems exist only in Jamaica and Trinidad, but the sugar islands have railways for carrying cane from field to factory. There is an interisland shipping service, two small ships providing a 10-day service from British Guiana to Jamaica calling at islands in between; both carry general and refrigerated cargo and 60 passengers. There are services from Canada and the United States; from the United Kingdom, France. Italy and Sweden. Italian lines have obtained a monopoly of the emigrant trade. Air travel has made the islands accessible, and they are well served by international air lines and there is also an inter-island service. The Leeward Islands Air transport and the St. Vincent Government Air service serve their respective localities. The post office maintains surface and air mail services, and all territories are linked by telecommunications with Europe and America.

WESTINGHOUSE, GEORGE (1846–1914), U.S. inventor and manufacturer, was born at Central Bridge. N.Y., on Oct. 6, 1846. He entered the Union army in the Civil War in 1863, but in 1864 was appointed third assistant engineer in the navy. In 186j he invented a device for replacing derailed cars and also a reversible steel railway frog. In 1869 he patented his air brake and organized the Westinghouse Air Brake company. In 1872 he invented the automatic air brake. This brake was quickly adopted by railways in America and gradually in Europe. He also developed a system of railway signals, operated by compressed air with the assistance of electrical contrivances. In 1893 this system was installed at the Chicago exposition. He built dynamos for the power plants at Niagara falls, for the rapid transit systems of New York city, and for the London Metropolitan railway. He died in New York on March 12. 1914.

WESTLAKE, JOHN (1828–1913), international lawyer and social reiormer, was born at Lostwithiel, Cornwall, on Feb. 4, 1828. and educated privately and at Trinity college. Cambridge. Taking silk in 1874. he became Liberal member of parliament (1885–86) and Whewell professor of international law at Cambridge (1888–1908). Though trained as an equity and conveyancing lawyer, his main interest lay in public and private international law. He virtually laid the foundations of the conflict of laws as a systematic branch of the laws of England, publishing in 1858 his Treatise on Private International Law, which exercised a profound influence on the judicial bench. Westlake was one of the founders of the Institut de Droit International in 1873 and a most active worker in the advancement of international law. His International *Law* (part i. Peace, 1904; part ii. *War,* 1907) and his Collected *Papers* (1914) are representative of his work in this field.

He was active in the movement for the restoration of the constitution of Finland (1899–1900), in the work of the Balkan committee (1905–13) and on behalf of many oppressed peoples. He was one of the founders of the Working Men's college in 1854, and a strong supporter of women's suffrage and many other social movements. He died in London on April 14, 1913.

See *Memories of John Westlake* (1914). (McN.)

WEST LOTHIAN, a county of Scotland, bounded north by the Firth of Forth, east by Midlothian. south and southwest by Lanarkshire and west by Stirlingshire. The area is 120 sq.mi. with a population (1961) of 92.764. The surface rises gradually from the firth to a hilly district in the south. with summits up to 1,000 ft. Traces of the prehistoric inhabitants still exist. Stone cists have been discovered at Carlowrie, Dalmeny, Newliston and elsewhere; the stone burial mound at Cairnpapple hill, excavated in 1946–48, was found to be a "henge" used from Neolithic times (c. 2000 B.C.) and through the Bronze and Iron Ages. At Kipps is a cromlech) that was once surrounded by stones. The eastern end of the wall of Antoninus passed through the shire; and Roman camps can be distinguished. At Carriden evidence has been found of a Roman fort. possibly the Credigone recorded in the 7th-century *Ravenna Cosmography,* and at Bo'ness was a temporary camp. The historical associations mainly cluster round Linlithgow (*q.v.*) and the county was formerly known as Linlithgowshire.

There is arable farming on the coastal lands between the Almond and Avon, fattening cattle, grain and potatoes being the main features. Southward is the grazing area, where dairy farming and stock raising are predominant. The greater part of the county is poor marginal land. There are numerous large shale-oil works and big ironworks; coal is mined, and steel is made at Armadale. Fire clay is extensively worked; limestone, freestone and whinstone are all quarried. Paper is made at Linlithgow and Bathgate, and distilling carried on at Linlithgow. Bathgate and Bo'ness. Bo'ness (Borrowstounness in full) is the principal port. From South Queensferry the Forth railway bridge crosses the firth to North Queensferry in Fife and a ferry perpetuates that used by Queen Margaret. wife of Malcolm Canmore. The Union canal (31 mi. long), connecting Edinburgh with the Forth and Clyde canal, crosses the county. In 1951 Gaelic and English were spoken by 145 persons. The small burghs are Linlithgow (pop. [1961] 4,327), Queensferry (2,929), both royal burghs, Bathgate (12,-686). Bo'ness (10,194), Armadale (6,193) and Whitburn (5,902). There are six county districts. The shire returns one member to parliament and is part of the sheriffdom of the Lothians, Selkirk and Peebles, with a resident sheriff substitute at Linlithgow.

WESTMACOTT, SIR RICHARD (1775–1856), an accomplished and popular English academic sculptor. was born in London on July 1j, 1775. He worked for a time under his father and in 1793 went to Rome to study under A. Canova. He returned to London in 1797, and in the next year set up on his own. soon becoming one of the most popular sculptors, carving statues, busts, chimney pieces and monuments. His principal statues include Lord Duncan in St. Paul's cathedral. Joseph Addison in Westminster abbey. Lord Nelson at Birmingham, Charles James Fox in Bloomsbury square, London, George III at Liverpool and in Windsor Great park, the duke of York in Carlton House terrace, London, and "Achilles" in Hyde park. London. Westmacott also carved reliefs on the Marble arch, London, in 1828 and the bas-relief in the pediment of the British museum in 1847. He was elected royal academician in 1811 He was knighted in 1837 and died Sept 1, 1856, in London. Westmacott, if he never reached the highest point of grandeur or beauty, was a dignified and impressive artist.

(R. Gs.)

WESTMEATH, a county of Ireland in the province of Leinster. Pop. (1961) 52,774; area 680.6 sq.mi. Westmeath is a county of carboniferous limestone and bogs.

The only heights are Knocklayde (797 ft), Hill of Ben (713 ft.) and Knockayon (710 ft). A considerable system of eskers, notably north of Tullamore, diversifies the surface of the limestone plain. In the north, on the borders of Cavan, is Lough Sheelin, 5 mi long and between 2 and 3 mi wide, and adjoining it is the smaller Lough Kinale. In the centre is Lough Derravaragh, 6 mi long by 2 mi broad at its widest part. To the north are Loughs Lene, Glore. Bamn and others; and to the south, Loughs Iron and Owel. Farther south is Lough Ennell or Belvedere, and in the southwest Lough Ree. a great expansion of the river Shannon, forming part of the boundary with Roscommon. The loughs are noted for their trout.

Westmeath was severed from Meath (*q.v.*) in 1543. The insurrection of 1641 was concerted at Multyfarnham abbey, and both in the wars of this period and those of 1688 the majority of the estates in the county were confiscated. There are a considerable number of raths or encampments: one at Rathconrath is of great extent; another at Ballymore was fortified during the Cromwellian wars and those of 1688 and was afterward the headquarters of Gen. Godart van Ginkel, when preparing to besiege Athlone: there is a third near Lough Lene. The soil is generally a deep rich loam well adapted both for tillage and pasturage. The occupations are almost wholly agricultural. The principal crops are oats, potatoes and wheat. Friezes, flannels and coarse linens are produced. The constituency of Longford-Westmeath returns five members to *dnil eireann.* Westmeath includes the towns of Athlone (*q.v.*) and Mullingar (*q.v.*), which is the county town.

WEST MIFFLIN, a borough of Allegheny county, Pa., U S., partially bounded by the Monongahela river, lies 8 mi. S.E of Pittsburgh (*q.v*). It is in the centre of a rich industrial area, producing steel. tin cans. electrical equipment, automobile bodies, oxygen, coal, slag and highway construction materials, and contains Kennywood park, one of the leading recreational centres of the Pittsburgh area. The township of West Mifflin was created in 1788 and incorporated as a borough in 1944. For comparative population figures *see* table in PENNSYLVANIA: *Population.*

(M. R Wo)

WESTMINSTER, MARQUESSES AND DUKES OF. The title of marquess of Westminster was bestowed in 1831 upon Robert Grosvenor, 2nd Earl Grosvenor (1767–1845), whose grandson, Hugh Lupus Grosvenor (1825–99), was created duke of Westminster in 1874. The family of Grosvenor is of great antiquity in Cheshire The ancestors of the dukes of Westminster, the Grosvenors of Eaton, near Chester, were cadets of the knightly house of Le Grosvenur. Their baronetcy dates from 1622.

SIR THOMAS GROSVENOR, the 3rd baronet (1656–1700), in 1676 married Mary (d. 1730), heiress of Alexander Davies (d. 1665), a scrivener, who brought to the Grosvenor family certain lands non covered by some of the most fashionable quarters of the West End. His grandson, SIR RICHARD GROSVENOR (1731–1802), was created Baron Grosvenor in 1761 and Viscount Belgrave and Earl Grosvenor in 1784. The 1st earl, a great breeder of race horses, was succeeded by his only surviving son ROBERT, 2nd earl (1767–1845), who rebuilt Eaton hall and developed his London property. In the house of commons from 1788 to 1802. he mas a follower of Pitt, who made him a lord of the admiralty and a commissioner of the board of control, but after 1806 he left the Tories for the Whigs. He was created a marquess in 1831. HUGH LUPUS (1825–99), grandson of the preceding, was created a duke in 1874, and was a member of parliament for Chester (1847–69) and master of the horse under Gladstone (1880–85), but he left the Liberal party over home rule for Ireland He was succeeded by his grandson Hugh Richard Arthur, 2nd duke (1879–1953).

WESTMINSTER, a part of London, Eng.; strictly a city in the administrative county of London. bounded east by the City, south by the Thames river, west by the boroughs of Chelsea and Kensington and north by Paddington. St Marylebone and Holborn. Westminster was formed into a borough by the London Government act of 1899, and by a royal charter of Oct 29, 1900. it was created a city The cities of London and Westminster comprise one parliamentary constituency and return one member. Pop. (1961) 85,223. Area 3.9 sq.mi. Within its bounds are Hyde park, St. James's and Green parks; Victoria and Charing Cross stations; Piccadilly. Regent street. Park lane. the Strand and Aldwych; Charing Cross and Westminster hospitals; the Royal Albert hall, the Tate gallery, King's college. Covent Garden market and opera house, Drury Lane and many other theatres round Piccadilly circus and Leicester square; the districts of Mayfair, Soho, Belgravia and Pimlico. The City of Westminster, as thus depicted, extends from the western end of Fleet street to Kensington gardens. and from Oxford street to the Thames, which it borders over a distance of 3 mi between Victoria (Chelsea) bridge and a point below Waterloo bridge. It contains a large number of national and imperial public buildings from the Law courts in the east to the Imperial institute in the west, includicg Buckingham and St James's palaces and the National gallery. The name of Westminster is generally associated with a more confined area, namely, the quarter that includes the abbey, the houses of parliament, the government and other buildings in Whitehall, and the Roman Catholic cathedral.

Westminster Abbey.—The abbey, properly the Collegiate Church of St Peter in Westminster, is the most widely celebrated church in the commonwealth The Thames was bordered in early times by a great expanse of fenland from Chelsea and Battersea, while near the point where the abbey stands was a low island perhaps three-quarters of a mile in circumference. known as Thorney or Bramble Isle. There have been stories of a temple of Apollo and of a church founded under "King Lucius"; there is more probability in the statement of Stou that King Sebert founded a church of St. Peter on Thorney Isle, and legend relates the coming of St. Peter himself to hallow his new church.

A charter of Offa, king of Mercia (785), deals with the conveyance of certain land to the monastery of St. Peter, and King Edgar restored the church, defining by a dubious charter dated 951 the boundary of Westminster. extending (in modern terms) from the Marble arch south to the Thames and east to the City boundary, the former Fleet river. Westminster was a Benedictine foundation. In 1050 Edward the Confessor took up the erection of a new church: cruciform, with a central and two western towers. It was consecrated in 1065 before the Confessor died, but building was continued afterward. In 1245 Henry III set about the rebuilding of the church east of the nave.

The present abbey is a cruciform structure consisting of nave with aisles, transepts with aisles (but in the south transept the place of the western aisle is occupied by the eastern cloister walk) and choir of polygonal apsidal form, with six chapels (four polygonal) opening north and south of it, and an eastern Lady chapel, known as Henry VII's chapel. There are two western towers, but in the centre a low square tower hardly rises above the pitch of the roof. The main entrance in common use is through the great west door. The chapter house, cloisters and other conventual buildings and remains lie to the south. The total length of the church (exterior) is 531 ft. and of the transepts 203 ft. in all. The breadth of the nave without the aisles is 38 ft. 7 in. and its height close to 102 ft. These dimensions are very slightly lessened in the choir. The exterior is finely proportioned, but the building has been much altered. Sir Christopher Wren is usually said to have designed the western towers, completed by Nicholas Hawksmoor (1745), and Sir Gilbert Scott and J. L. Pearson rebuilt the north front.

Within, the abbey is a superb example of the Pointed style. The body of the church is remarkably uniform because, although the building of the new nave was continued with intermissions from the 14th century until Tudor times, the Early English design in the eastern part was carried on. The choir, with its radiating chapels, plainly follows French models. Exquisite ornament is seen in the triforium arcade. and beneath the rose windows in the transepts are figures. specially finely carved though much mutilated, known as the censing angels.

Henry VII's chapel replaces an earlier Lady chapel, and is the most remarkable building of its period. It comprises a nave with aisles and an apsidal eastward end formed of five small radiating chapels. A splendid series of carved oak stalls lines each side of the nave. and above them hang the banners of the Knights of the Bath. The fan-traceried roof. with its carved stone pendants. is exquisite. The choir stalls in the body of the church are modern. The reredos is by Scott. with mosaic by Antonio Salviati (1865).

Abbey Ceremonies and Monuments.— From William the Conqueror onward every sovereign has been crowned at Westminster excepting Edward V and Edward VIII. The coronation chair, which stands in the Confessor's chapel. dates from the time of Ednard I and contains beneath its seat the stone of Scone, on which the Scottish kings were crowned. The stone is of Scottish origin, but tradition identifies it with Jacob's pillow at Bethel. (It was stolen by Scottish nationalists on Christmas morning 1950 but was restored to Westminster abbey in April the next year after being left in Arbroath abbey.) In the Confessor's chapel also are kept the sword and shield of Edward III and the second coronation chair that was made for Mary, wife of William III. Subsequent to the Conquest many kings and queens were buried in this chapel. from Henry III to George II. A part of the south transept is famed under the name of the Poets' Corner. The north transept contains many monuments to statesmen, and the abbey is crowded with tombs and memorials of famous British subjects, the custom of burial there being traditionally linked with the presence of the shrine of Edward the Confessor. The burial of the "Unknown Warrior," in the centre of the nave near the west door, after World War I is a notable commemoration of the sacrifice made by the people in that war. A number of undistinguished persons also have their tombs in the abbey.

Conventual and Other Buildings.— The monastery was dissolved in 1539, and Westminster was then erected into a bishopric, but only one prelate, Thomas Thirlby, held the office of bishop. In 1553 Mary I again appointed an abbot. but Elizabeth I reinstated the dean, with 12 prebendaries. Of the conventual buildings, the cloisters are of the 13th and 14th centuries. On the south side of the southern walk remains of a wall of the refectory are seen from without. From the eastern walk a porch gives entry to the chapter house and the Chapel of the Pyx. The first is of the time of Henry III, a fine octagonal building, its vaulted roof supported by a slender clustered column of marble. It was largely restored by Scott. There are mural paintings of the 14th and 15th centuries. The Chapel or Chamber of the Pyx is part of the undercroft of the original dormitory, and is early Norman work of the Confessor's time. It was used as a treasury for the regalia in early times, and there were kept the standard coins of the realm used in the trial of the pyx now carried out at the mint. The undercroft is now the Abbey museum; above it is the chapter library. To the southeast lies the picturesque Little Cloister, with its court and fountain. Near it are slight ruins of the monastic infirmary chapel of St. Catherine. West of the main cloisters is the former abbot's lodging which is now occupied by the Deanery. Jerusalem chamber and College hall. built round a small court and dating mainly from the 14th century. Its most famous portion is the Jerusalem chamber. believed to be named from the former tapestries on its walls, representing the holy city. The College hall, adjoining it, is the dining hall of Westminster school.

During World War II the abbey was seriously damaged at the crossing. but the surrounding buildings suffered more. The Deanery. the Little Cloister. with its residences, the great schoolroom, with its hammer-beam roof. and Dr. Busby's library were completely gutted. The dormitory of Westminster school was also burned out. but its interior was of slight architectural value. It was later rebuilt internally.

Westminster School.— St. Peter's college, commonly called Westminster school, is one of the ancient foundations of England. A school was maintained by the monks from very early times. Henry VIII took interest in it, but the school owes its present standing to Queen Elizabeth I. The school buildings lie east of the conventual buildings. They were remodelled after World War II. Ashburnham house, containing one of the schoolhouses, the library and many classrooms, is named from the family for whom it was built, traditionally, but not certainly. by Inigo Jones. The finest part remaining is the grand staircase. In the college dormitory a Latin play used to be annually presented. but this ancient custom was interrupted during World War II and not resumed afterward. The boys have the privilege of acclaiming the sovereign at the coronation in the abbey. There is a long-standing custom of struggling for the possession of a tossed pancake on Shrove Tuesday. The winner of this Pancake Greaze is rewarded by the dean.

St. Margaret's.— On the north side of the abbey, close beside it, is the parish church of St. Margaret. It was founded in or soon after the time of the Confessor, but the present building is Perpendicular, of greater beauty within than without. St. Margaret's is officially the church of the house of commons.

Westminster Palace: Houses of Parliament.— A royal palace existed at Westminster under Canute. but the building spoken of by Fitzstephen as an "incomparable structure furnished with a breastwork and a bastion" is supposed to have been founded by Edward the Confessor and enlarged by William I. The hall, called Westminster hall. was built by William Rufus and altered by Richard II. In 1512 the palace suffered greatly from fire, and thereafter ceased to be used as a royal residence. St. Stephen's chapel, originally built by King Stephen, was used from 1547 for the meetings of the house of commons, which had been held previously in the chapter house of the abbey; the lords used another apartment of the palace. A fire in 1834 destroyed the whole palace except the historic hall and St. Stephen's chapel. The present buildings were erected on the site in 1840–67, but of these the commons chamber was burned out in the air raids of World War II. The southwestern Victoria tower is 336 ft. high. The Clock tower, 329 ft. high, contains the clock famous for its 13-ton bell, Big Ben, upon which the hours are struck. The bell is named after Sir Benjamin Hall, first commissioner of works at the time it was hung. Of the modern rooms, the house of lords is an ornate chamber, 97 ft. in length; that of the commons, reopened in 1950, is 70 ft. long.

Westminster Hall.— The original hall was finished in 1097. It is recorded that in the year 1099 King William Rufus held his first court in the hall. Little remains of Rufus' hall beyond its walls which have been encased with modern linings. The open timber roofs, described as a "miracle of Gothic carpentry, easily the most remarkable timber structure of its age in any country," was erected by King Richard II (completed 1399), when Richard appointed John Gedeney to supervise the work of repair to the hall. with power to engage any necessary masons, carpenters and labourers. Hugh Herland. a master carpenter in the service of the king, was appointed controller to Gedeney and Herland probably deserves credit for the creation of the magnificent roof.

The span is 67 ft. 6 in. without any intermediate supports, and its construction presented a problem the solving of which had not previously been attempted. The roof was designed with an upper triangulated framed structure consisting of the main collar beam, principal rafters and queen posts. with a crown post centrally supporting the heavy ridge piece. This upper triangular framed structure was supported on two cantilever structures embodying the lower principal rafter, the hammer post, the hammer beam. the wall post and the curved strut between wall post and hammer beam, the whole roof being tied together by a great curved brace or arch springing from the corbel at the foot of the wall post passing the hammer beam, the hammer post with its crown at the centre of the main collar beam.

Evidence is available of repairs being carried out to the structure and the roof on many occasions. but the most drastic restoration work was undertaken in relatively recent years and was not completed until 1922. This restoration became an urgent necessity because of the ravages of the deathwatch beetle (*Xestobium rufovillosum*), whose operations during many years had caused the roof to become entirely unsafe. The ends of many of the principal rafters, the purlins and some of the main collar beams were found to be hollowed out to a thin shell by the attacks of the beetle. In the restoration various expedients were tried to destroy the beetle and its eggs, the most satisfactory result being obtained by spraying the affected timbers after they had been thoroughly cleaned with a solution of orthoparadichlorobenzene. A system of steel reinforcement was adopted for supporting the roof structure, and this was so placed as to be invisible. The roof was damaged. fortunately slightly, during an air raid in World War II.

Westminster hall was the seat of the chief law court of England for centuries and it witnessed the trials of. among others. William Wallace. Richard II. Sir Thomas More. Edmund Campion, Charles I, Titus Oates, Warren Hastings and Queen Caroline. It is thus one of the chief centres of English history.

Whitehall **and** Trafalgar **Square.**—Northward from Parliament square a broad, slightly curving thoroughfare leads to Trafalgar square. This is Whitehall. which replaced the narrow King street. There, between the Thames and St. James's park, formerly stood York house, a residence of the archbishops of York from 1298. Wolsey beautified the mansion and kept high state there, but on his fall Henry VIII acquired and reconstructed it, employed Holbein in its decoration and made it his principal residence. Inigo Jones designed a new palace for James I, but only the banqueting hall was completed (1622) and this survived several fires, one of which (1698) nearly destroyed the whole of the rest of the palace. The hall. converted into a royal chapel by George I and now housing the museum of the Royal United Service institution, is a fine specimen of Palladian architecture, and its ceiling is adorned with allegorical paintings by Rubens.

The principal government offices are situated in Whitehall. Downing street, on the western side and separating the foreign office from the treasury. contains the official residences of the prime minister and first lord of the treasury (No. 10) and the chancellor of the exchequer (No. 11). The official connection of these houses with their occupiers dates from the time of Sir Robert Walpole, the first prime minister, who occupied No. 10 from 1735 to 1742. George II, who owned it. had offered it to Walpole as a gift in 1731. He refused it, but it was soon after arranged that the two houses should accompany the offices with which they are now associated. The Horse Guards was begun by W. Kent and finished in the 1750s after his death. It is on the site of a tiltyard and guardhouse dating from 1631. The portion of the admiralty facing Whitehall dates from 1726, the larger part in St. James's park dates from about 1900. Admiralty arch. between Trafalgar square and the Mall. was built in 1910. On the right of Whitehall, besides the banqueting hall. are the war office and other government office departments. The Cenotaph, erected in memory of those who fell in World War I, stands in Whitehall.

Trafalgar square is an open space sloping sharply up to the north. On the south side, facing the entry of Whitehall. is the Nelson column (1843). 185 ft., a copy in granite from the temple of Mars Ultor in Rome, crowned with a statue of Nelson. Behind the terrace on the north rises the National gallery (1838), with its splendid collection of paintings, and adjoining it is the National Portrait gallery. St. Martin-in-the-Fields (1721–26), with its Corinthian portico, stands at the northeastern corner.

Westminster **Cathedral.**—A short distance from Victoria street. toward its western end. stands Westminster cathedral (Roman Catholic), a remarkable modern building (1895–1905) in early Christian Byzantine style with a stately domed campanile.

WESTMINSTER, STATUTES OF. During the reign of Edward I two statutes were passed bearing this title. The first, in 1275, was, in the words of Stubbs (*Const. Hist.*, ch. xiv), "almost a code by itself; it contains fifty-one clauses, and covers the whole ground of legislation. Its language now recalls that of Canute or Alfred, now anticipates that of our own day; on the one hand common right is to be done to all, as well poor as rich. without respect of persons; on the other, elections are to be free, and no man is by force, malice or menace, to disturb them. The spirit of the Great Charter is not less discernible: excessive amercements, abuses of wardship, irregular demands for feudal aids are forbidden in the same words or by amending enactments."

The second Statute of Westminster was passed in the parliament of 1285. Like the first statute it is a code in itself, and contains the famous clause De *donis conditionalibus*, "one of the fundamental institutes of the mediaeval land law of England." Stubbs says of it: "The law of dower, of advowson, of appeal for felonies. is largely amended; the institution of justices of assize is remodelled. and the abuses of manorial jurisdiction repressed; the statute De *religiosis*, the statutes of Merton and Gloucester, are amended and re-enacted."

The Statute of Westminster, 1931, laid down that "Dominions are autonomous Communities within the British Empire. equal in status, in no way subordinate to one another in their domestic or external affairs though united by a common allegiance to the Crown. and freely associated as members of the British Commonwealth of Nations."

The statute *Quia Emptores* of 1290 is sometimes called the Statute of Westminster III. (See ENGLISH HISTORY: *Edward* I.)

WESTMORLAND, EARLS OF. RALPH NEVILLE. 4th Baron Neville of Raby and 1st earl of Westmorland (1364–1425), eldest son of John, 3rd Baron Neville, and his wife Maud Percy (*see* NEVILLE. family'). was knighted by Thomas of Woodstock, afterward duke of Gloucester. during the French expedition of 1380. and succeeded to his father's barony in 1388.

He was repeatedly engaged in negotiations with the Scots, and his help to the court party against the lords appellant was rewarded in 1397 by the earldom of Westmorland. He had married as his second wife Joan Beaufort, half-sister of Henry of Lancaster, afterward Henry IV, whom he joined on his landing in Yorkshire in 1399. He already held the castles of Brancepeth. Raby, Middleham and Sheriff Hutton when he received from Henry IV the honour and lordship of Richmond for life. The only rivals of the Nevilles in the north were the Percies. whose power was broken at Shrewsbury in 1403; and the wardenship of the west marches was now assigned to Westmorland, whose influence was also paramount in the east. which was under the nominal wardenship of the young Prince John, afterward duke of Bedford. In May 1405 the Percies were in revolt. with Thomas Mowbray, earl marshal. and Archbishop Scrope. Westmorland met them on Shipton moor. near York, on May 29 and suggested a parley between the leaders. By pretending accord with the archbishop. the earl induced him to allow his followers to disperse. Scrope and Mowbray were then seized and handed over to Henry at Pontefract on June 3. The improbabilities of this narrative have led some writers to think, in face of contemporary authorities, that Scrope and Mowbray must have surrendered voluntarily. If Westmorland betrayed them he at least had no share in their execution. Thenceforward he was busily engaged in negotiating with the Scots and keeping the peace on the borders. He did not play the part assigned to him by Shakespeare in *Henry V*, for during Henry's absence he remained in charge of the north: and was a member of Bedford's council. Of his daughters by his second wife, Catherine married in 1412 John Mowbray, 2nd duke of Norfolk, brother and heir of the earl marshal; Anne married Humphrey, 1st duke of Buckingham; Eleanor married first Richard le Despenser, then Henry Percy, 2nd earl of Northumberland; Cicely married Richard! duke of York, and was the mother of Edward IV and Richard III. The earl died on Oct. 21, 1425, and a fine alabaster tomb was erected to his memory in Staindrop church close by Raby castle.

CHARLES, 6th earl (1543–1601), eldest son of Henry, 5th earl, by his first wife Jane, daughter of Thomas Manners, 1st earl of Rutland, was brought up a Roman Catholic and was further attached to the Catholic party by his marriage with Jane, daughter of Henry Howard, earl of Surrey. He was a member of the council of the north in 1569, when he joined Thomas Percy, 7th earl of Northumberland, and his uncle Christopher Neville. in the Catholic rising of the north, which aimed at the liberation of Mary, queen of Scots. On the collapse of the ill-organized insurrection Westmorland fled with his brother earl over the borders and eventually to the Spanish Netherlands, where he died on Nov. 16. 1601. He left no sons, and his honours were forfeited by his formal attainder in 1571. Raby castle remained in the hands of the crown until 1645.

The title was revived in 1624 in favour of SIR FRANCIS FANE (c. 1574–1628), whose mother, Mary Neville, was a descendant of a younger son of the 1st earl. He was created baron of Eurghersh and earl of Westmorland in 1624 and became Lord le Despenser on his mother's death in 1626. His son MILDMAY FANE, 2nd or 8th earl of Westmorland *(c.* 1602–66), at first sided with the king's party, but was afterward reconciled with the parliament. JOHN FANE, 7th or 13th earl of Westmorland (1682?–1762), served with distinction in various campaigns under Marlborough and was made in 1742 lieutenant general of the British armies.

JOHN FAKE, 11th or 17th earl (1784–1859), eldest son of John, 10th earl, was known as Lord Burghersh until he succeeded to the earldom in 1841. He entered the army in 1803, and in 1805 he took part in the Hanoverian campaign as aide-de-camp to Gen. George Don. He was assistant adjutant general in Sicily and Egypt (1806–07), served in the Peninsular War (1808–13), was British military commissioner to the allied armies under Schwarzenberg and marched with the allies to Paris in 1814. He was subsequently promoted major general (1825), lieutenant general (1838) and general (1854), although the latter half of his life was given to the diplomatic service. He was British resident at Florence (1814–30) and ambassador at Berlin (1841–51), after which he was transferred to Vienna. He retired in 18jj and died at Apthorpe house, Northamptonshire, on Oct. 16, 1859. He composed several operas; took a keen interest in the cause of music in England and in 1822 made proposals which led to the foundation in 1823 of the Royal Academy of Music. His wife Priscilla Anne (1793–1879), daughter of William Wellesley-Pole, 3rd earl of Mornington, was a distinguished artist.

His published works include *Memoirs of the Early Campaigns of the Duke of Wellington in Portugal and Spain* (1820) and *Memoir of the Operations of the Allied Armies Under Prince Schwarzenberg and Marshal Blücher* (1822). *See* also *Correspondence of Priscilla, Countess of Westmorland, 1812–1870* (1909).

FRANCIS WILLIAM HENRY, 12th or 18th earl (1825–91), third son of the preceding. served through the Punjab campaign of 1846 and at Gujarat on Feb. 21, 1849. He went to the Crimea as aide-de-camp to Lord Raglan. His great-grandson, DAVID ANTHONY THOMAS; became 15th or 21st earl in 1948.

WESTMORLAND, one of the northwestern counties of England extending from the Pennines on the east to the centre of the Lake district on the west, and from the Eden valley in the north to Arnside, on Morecambe bay, in the south. It is bounded on the north and west by Cumberland (with which it has many affinities), on the west and south by Lancashire, on the southeast by Yorkshire and on the northeast by Durham. The area of the county—including water—is 788.9 sq.mi., of which about one-quarter forms part of the Lake District National park.

Its general character is rural, and there is a large proportion of mountain, fell and moor (hence the name of the county, "the western moorland") but there is also good agricultural land in the Eden valley from Kirkby Stephen to Temple Sowerby and in the Kent valley from Kendal to Milnthorpe. The climate is mild and damp, and the rainfall is heavy in the mountains (about 80 in. per year). Snow frequently lies on the fells in winter and patches sometimes persist until June.

The county town is the tiny borough of Appleby and the most important place is Kendal: the only other borough.

Physical Features.— The outstanding physical features of the county are the mountains and lakes which, with those in Cumberland and Lancashire, together form the Lake district (*q.v.*). Geologically, all this is the "Cumbrian" group of mountains and consists partly of hard volcanic rocks (the Borrowdale series) and partly of an inferior sort (the Silurian), with intrusions of granite, notably near Shap. Three of the highest peaks in Westmorland are on the county boundary and shared with Cumberland: Helvellyn (3,118 ft.), Bow Fell (2,960 ft.) and Crinkle Crags (2,816 ft.). but the following are wholly within the county: Fairfield (2,863 it.), Red Screes (2,541 ft.) and High Street (2.633 ft.). The Cumbrian group is linked to the Pennines by an upland area often between 500 it. and 1,000 ft., largely limestone, which extends eastward across the middle of the county.

The principal lakes are: Windermere (10 mi. long. the largest in England), Ullswater (partly in Cumberland). Hawes Water, Grasmere. Rydal Water, Elterwater and Brothers Water. In 1936 Hawes Water was enlarged to about twice its natural size when it became a reservoir for Manchester. The principal rivers are the Eden, the Lune and the Kent. The Tees rises almost on the boundary between Cumberland and Westmorland (near Cross Fell) and for 8 mi. forms the boundary between Westmorland and County Durham.

History and Antiquities.— Westmorland has no certain remains of the Stone Age but abounds in antiquities of the Bronze Age such as cairns and burial mounds, stone circles and hut settlements—particularly at Crosby Ravensworth—which may still have been occupied in the Early Iron Age. Roman antiquities inside the county consist of a main road from Stainmore to Brougham (Brocavum) with intermediate forts at Brough (Verteraej. Crackenthorpe and Kirkby Thore (Braboniacumj; another main road from Kirkby Lonsdale to Brougham with a fort at Low Borrow Bridge; and a branch road from this, bearing westward to forts at Kendal (Alone) and Ambleside (Galavaj. The latter has been excavated and can be seen (National trust). Between Ambleside and Brougham "the most adventurous Roman road in Britain" went along the ridge of fells aptly named High street—over 1,000 ft. above sea level for more than 10 mi.

In the dark ages the Anglians probably settled in the lower Kent valley and the Eden valley, but did not penetrate into the fells. Very few antiquities of this period have been found and the same is true of the Danes who arrived from Uorkshire in the 9th century and of the Norsemen who came in the 10th century from the Isle of Man. The earliest historical record of Westmorland is in the Anglo-Saxon Chronicle for 996, but at that date the county was not yet in existence and the name refers to what is now the northern part of it, the barony of Appleby (later divided into East and West wards) which until 1092 was part of the earldom of Carlisle and was sometimes claimed by Scotland. It was separated from the earldom in 1131 and, together with the barony of Kendal (later divided into Kendal and Lonsdale wards) took its present administrative form. (Westmorland is not mentioned in Domesday Book but part of the barony of Kendal is included under Yorkshire.) Thus Appleby became the county town, being then a larger and more important place than Kendal. In the Wars of the Roses Westmorland favoured the Lancastrians and in the Civil War the chief local families were royalists. In 174j the Jacobites marched through the county, and a skirmish at Clifton on their return journey was "the last battle fought on English soil."

North Westmorland has been in the diocese of Carlisle since the see was founded in 1133; south Westmorland was in the vast diocese of York until 1543, was then transferred to Chester and was attached to Carlisle only in 1856.

There are fine parish churches at Kendal (with double aisles), Kirkby Lonsdale (Norman), Kirkby Stephen and Appleby. Those at Morland and Crosby Garrett have pre-Conquest features incorporated in them. There was an abbey at Shap. of which the tower still stands. A number of churches have remains of pre-Norman crosses and tombstones, and Windermere has remarkable mediaeval glass.

There are castles at Appleby (12th-century keep; house still occupied), Kendal (ruins). Brough and Brougham. Mediaeval peel towers were built for refuge during Scots raids, and good examples exist in the north. Yanwath and Askham; and in the south, Sizergh and Levens; they are usually combined with later halls. Levens is also remarkable for its topiary garden, and Sizergh (belonging to the National trust since 1950) was the home of the Strickland family from 1239. There are many farmhouses and cottages bearing 17th-century dates, and there is a whole village at Lowther built by the Lowther family about 1700.

The Devil's bridge over the Lune at Kirkby Lonsdale, about 1500, is one of the finest bridges in the north of England.

Agriculture, Industries and **Communications.**—Westmorland has always been a pastoral county, the fells providing enormous areas of grazing for sheep. The two native breeds, the Herdwick and the Rough Fell, have been largely supplanted by the Swaledale and Black-faced. The cattle used to be almost entirely Shorthorn, but dairy breeds (mostly Ayrshire or Friesian) are now found everywhere, and milk is taken daily to a depot at Appleby and a factory at Milnthorpe. The county is noted for its attested herds. There is very little arable land and the climate is more suitable for growing root crops than corn. A breed of fell ponies is native to this county and Cumberland.

Kendal produces shoes, blankets, carpets, laundry machinery, turbines, and tobacco and snuff. and there are paper mills at Burneside. The lead mine at Glenridding is the largest and oldest in the country and in different parts of Westmorland quarries yield slate, granite, limestone and marble. There is a diatomite factory in Kentmere.

Two main railway lines from London to Carlisle pass through the county, one down the Eden valley and the other over Shap Fell, and two trunk roads follow approximately similar routes.

Westmorland has no real coast—barely two miles on Morecambe bay, from which the sea disappears at low tide—but formerly small ships came up the Kent estuary to Milnthorpe. The Kendal and Lancaster canal was opened in 1819 but has been abandoned at the Kendal end.

Population and Administration.—The population in 1801 was 40,805; in 1851, 58,287; in 1901, 64,409; and in 1951, 67.392 (which is less than 100 per square mile). The only large town is Kendal (18.541) which is more than ten times the size of Appleby (1,70j). There are two urban districts. Windermere (6.315) and Lakes (6,096). but the latter is the least "urban" district imaginable, as its area is just short of 50,000 ac. (mostly mountain) and the biggest place in it is Ambleside. The rest of the county is covered by the rural districts of North Westmorland (population 16,959) and South Westmorland (17,776).

The county council functions from Kendal. Assizes are held at the Shire hall. Appleby (Westmorland is in the Northern circuit) and courts of quarter sessions are held at the town hall, Kendal. There are seven petty sessional divisions and nine courts. For many centuries the county returned two members to parliament, and Appleby two until 1832, but the whole county including the two boroughs is now a single constituency and returns only one member.

WEST NEW YORK, a town of Hudson county, in northeastern New Jersey, U.S., is located on the Hudson river adjacent to Weehawken, about 5 mi. N. of Jersey City and due west of Manhattan Island. It is connected with New York city by the Lincoln and Holland auto tunnels and railroads. The area was originally settled by the Dutch in the 17th century and was alternately a part of Guttenberg and North Bergen until 1898, when it was detached from North Bergen as a separate town. It is a part of New York harbour and has over a mile of docks and grain elevators serving ocean-going ships. Local manufactures include a wide variety of textiles, novelties, commercial containers, leather goods, embroideries, silk processing, toys, clothing and rubber products. For comparative population figures *see* table in New Jersey. *Population.* (D. N. A.; M. P. M.)

WESTON-SUPER-MARE, a seaside town and municipal borough (1937) in the Weston-super-Mare parliamentary division of Somerset, Eng., on the Bristol channel, 21 mi. S.W. of Bristol by road. Pop. (1951) 40,396. Area 7.7 sq mi. It lies on a sandy bay between Brean down (south) and Worlebury hill, on which is an Iron Age B hill fort. Weston is a residential and holiday town.

WEST ORANGE, a town of New Jersey, U.S., a suburban industrial and residential community near Newark. was a portion of Orange until 1862 and was incorporated in 1900. The Edison Laboratory National monument there, established in 1956, is composed of the buildings where Thomas A. Edison for 44 years, beginning in 1887, conducted research which brought him 520 patents. It was there that he perfected, among many other things, silent and sound motion pictures; improved methods of recording and reproducing sound; and conducted experiments to extract rubber from plants grown in the United States.

Llewellyn park, established by Llewellyn S. Haskell, is considered the forerunner of the modern garden type of suburban development. The famous inventor resided there at Glenmont. designated as the Edison Home National Historic site in 1955. The Carteret school for boys and the internationally known Kessler Institute for Rehabilitation, a private hospital specializing in physical rehabilitation, are l'ocated in West Orange. For comparative population figures *see* table in New Jersey: *Population.* (E. R. D.)

WEST PALM BEACH: *see* Palm Beach and West Palm Beach.

WESTPHALIA (Ger. Westfalen), formerly a province of Prussia, Ger. The area of the province is 7,806 sq.mi., its length both from north to south and from east to west is about 130 mi. Since 1945 it has been part of the *Land* of North Rhine-Westphalia

Nearly half of Westphalia is an extension of the great north German plain, which is broken by outcrops of the underlying Cretaceous beds, and is not very fertile, except in the Hellweg, a zone between the Haarstrang and the Lippe. There are extensive fens in the north and west, and north of Paderborn is a sandy waste called the Senne. The plain is drained in the north by the Ems and in the south by the Lippe, which rise close together in the Teutoburger Wald. Between their basins are the Vechte and other small rivers flowing into the Zuider Zee. The triangular southern portion of Westphalia, most of which is included in Sauerland ("southland"), is a rugged region of slate hills and wooded valleys drained chiefly by the Ruhr with its affluents, the Lenne. Mohne, etc., and in the south by the Sieg and Eder. The hills rise in the southeast to the Rotlager or Rothaargebirge, culminating in the Winterberg plateau with the Kahler Asten (2.759 ft.), the highest summit in the province. The Rotlagergebirge, Eggegebirge and Teutoburger Wald form the watershed between the Weser and the Rhine and Ems. The Weser divides the U'iehengebirge from the Wesergebirge by the narrow pass called Porta Westfalica.

The climate is temperate except in the south, which is cold in winter and has a heavy rainfall. The crops include grain of all kinds, peas and beans, buckwheat, potatoes, fruit and hemp. The cultivation of flax is very extensive, especially in the northeast.

Swine, which are reared in great numbers in the plains, yield the famous Westphalian hams; horse breeding and the rearing of cattle and goats are also important.

The mineral wealth is very great, especially in coal and iron. The production of coal is greater than that of any other province of Prussia. The great Ruhr coal field extends from the Rhineland into the province as far as Unna, the centre being Dortmund, and there is a smaller coal field in the north at Ibbenbüren. The production of iron ore, chiefly south of the Ruhr, is exceeded in Prussia only by that of the Rhine province. After coal and iron the most valuable minerals are zinc, lead, pyrites and copper. Antimony, quicksilver, stone, marble, slate and potter's clay are also worked, and there are brine springs in the Hellweg and mineral springs at Lippspringe, Öynhausen, etc.

The manufacturing industry of the province, which chiefly depends upon its mineral wealth, is very extensive. Iron and steel goods are produced in the so-called "Enneper Strasse," the valley of the Ennepe, a small tributary of the Ruhr with the town of Hagen, and in the neighbouring towns of Bochum, Dortmund, Iserlohn and Altena, and also in the Siegen district. The brass and bronze industries are carried on at Iserlohn and Altena, those of tin and Britannia metal at Liidenscheid; needles are made at Iserlohn and wire at Altena. The very important linen industry of Bielefeld, Herford, Minden and Warendorf has flourished in this region since the 14th century. Jute is manufactured at Bielefeld and cotton goods in the west. Paper is extensively made on the lower Lenne, and leather around Siegen. Other manufactures are glass, chemicals, sugar, sausages and cigars. An active trade is promoted by several trunk lines of railway which cross the province and by the navigation of the Weser (on which Minden has a port), Ems, Ruhr and Lippe. Beverungen is the chief market for corn and Paderborn for wool.

The population in 1939 was 5,205,705, or about 666 per sq.mi. It is very unevenly distributed, and in the industrial districts has been increasing very rapidly; it includes a considerable element of Polish workpeople. As at the peace of Westphalia, the bishoprics of Munster and Paderborn and the former duchy of Westphalia are Roman Catholic, while the secularized bishopric of Minden and the former counties of Ravensberg and Mark (former possessions of Brandenburg) and Siegen (Nassau) are predominantly Protestant.

The province is divided into the three governmental departments *(Regierungsbezirke)* of Minden, Münster and Arnsberg. Miinster is the seat of government and of the provincial university.

The inhabitants are mainly of the Saxon stock and speak Low German dialects, except in the Upper Frankish district around Siegen where the Hessian dialect is spoken.

History. — Westphalia, "the western plain" (in early records *Westfalani*), was originally the name of the western province of the early duchy of Saxony, including the western portion of the modern province and extending north to the borders of Friesland. When Duke Henry the Lion of Saxony fell under the ban of the empire in 1180, and his duchy was divided, the archbishop of Cologne, Philip of Heinsberg, received from the emperor Frederick I the Sauerland and some other districts which became the duchy of Westphalia. The duchy received a constitution of its own, and was governed for the archbishop, afterwards elector, by a marshal (*Landmarschall,* after 1480 *Landdrost),* who was also stadtholder, and presided over the Westphalian chancellery. This system lasted till 1803. By the settlement of 1803 the Church lands were secularized, and Prussia received the bishopric of Paderborn and the eastern part of Münster, while the electoral duchy of Westphalia was given to Hesse-Darmstadt.

After the peace of Tilsit, the kingdom of Westphalia was created by Napoleon I on Aug. 18, 1807, and given to his brother Jerome (see BONAPARTE). It included the present governmental department of Minden, but by far the larger part of the kingdom lay outside and chiefly to the east of the modern province, and comprised the Hanoverian department of Hildesheim and in part that of Arensberg, Brunswick, the northern part of the province of Saxony as far as the Elbe, Halle, and most of Hesse-Cassel. The area was 14.627 sq mi., and the population nearly 2.000.000. Cassel was the capital. A constitution on the French imperial pattern granted by the king remained practically inoperative, an arbitrary bureaucratic régime was instituted, the finances were from the beginning in a hopeless condition, and the country was drained of men and money for Napoleon's wars. In Jan. 1810 most of Hanover was added, but at the end of the same year half the latter, together with the city of Minden, was annexed to the French empire. At the congress of Vienna (1815) Hesse-Darmstadt surrendered her share of Westphalia to Prussia. The province suffered heavy bombing attacks in World War II.

WESTPHALIA, PEACE OF, the name given to the settlement embodied in two treaties concluded on Oct. 24, 1648, by the Holy Roman Empire with France at Munster and with Sweden and the Protestant estates of the empire at Osnabriick, by which the Thirty Years' War (*q.v.*) was brought to an end.

As early as 1636 negotiations had been opened at Cologne at the instance of Pope Urban VIII, supported by the seigniory of Venice, but failed oning to the disinclination of Richelieu to stop the progress of the French arms, and to the refusal of Sweden to treat with the papal legate. In 1637 the agents of the emperor began to negotiate at Hamburg with Sweden, though the mediation of Christian IV, king of Denmark, was rejected by Sweden, and the discussions dragged on for years without result. In the meantime the new emperor Ferdinand III proposed at the diet of Regensburg in 1640 to extend the peace of Prague to the whole empire, on the basis of an amnesty, from which, however, those Protestant estates[1] who were still leagued with foreign pouers were to be excluded. His aim m-as by settling the internal affairs of the empire to exclude the German princes from participation in negotiations with foreign powers; these efforts failed.

The Comte d'Avaux, French envoy at Hamburg, proposed in 1641 that negotiations should be transferred to Munster and Osnabruck. A preliminary treaty embodying this proposal was concluded betneen the representatives of the emperor, France, and Sweden at Hamburg on Dec. 25, 1641. The two assemblies were to be regarded as a single congress, and neither should conclude peace without the other. The date fixed for the meeting was March 25, 1642, but many months elapsed before all the representatives arrived, and the settlement of many questions of precedence and etiquette caused further delays. England, Poland, Muscovy, and Turkey were the only European powers unrepresented.

The chief representative of the emperor was Count Maximilian von Trautmansdorff, to whose sagacity the conclusion of peace was largely due. The French envoys were nominally under Henry of Orleans, duke of Longueville, but the marquis de Sablé and the comte d'Avaux mere the real agents of France. Sweden was represented by John Oxenstierna, son of the chancellor, and by John Adler Salvius, who had previously acted for Sweden at Hamburg. The papal nuncio was Fabio Chigi, afternards Pope Alexander VII. Brandenburg, represented by Count Johann von Sayn-Wittgenstein, played the foremost part among the Protestant states of the empire. On June 1, 164;. France and Sweden brought forward propositions of peace, which were discussed by the estates of the empire from Oct. 1645 to April 1646. The settlement of religious matters w-as effected between Feb. 1646 and March 1648. The war continued during the deliberations. The treaty was signed at Munster by the members of both conventions on Oct. 24. 1648, and ratifications were exchanged on Feb. 8, 1649. The papal protest of Jan. 3, 1651, was disregarded.

[1]*i.e. Reichsstände,* princes, nobles, and cities holding immediately of the emperor.

Sweden received western Pomerania with the isles of Rügen, Usedom and Wollin, the mouths of the Oder, Wismar, and the lands of the archbishopric of Bremen and the bishopric of Verden, together with an indemnity of 5,000,000 thalers. The privileges of the Free Towns were preserved. Sweden thus obtained control of the Baltic and a footing on the North Sea, and became an estate of the empire with three deliberative voices in the diet.

The elector of Brandenburg received the greater part of eastern Pomerania and Cammin, and, as he had a claim on the whole duchy since the death of the last duke in 1635, he was indemnified by the bishoprics of Halberstadt, Minden and the reversion of the archbishopric of Magdeburg, which came to him on the death of the administrator, Prince Augustus of Saxony, in 1680. The elector of Saxony mas allowed to retain Lusatia. As compensation for Wismar, Mecklenburg-Schwerin obtained the bishoprics of Schwerin and Ratzeburg and some lands of the Knights of St. John. Brunswick-Liineburg restored Hildesheim to the elector of Cologne, and gave Minden to Brandenburg, but obtained the alternate succession to the bishopric of Osnabruck and the church lands of Walkenried and Groningen. Hesse-Cassel received the prince-abbacy of Hersfeld and the county of Schaumburg. The elector of Bavaria was confirmed in his possession of the Upper Palatinate, and in his position as an elector which he had obtained in 1623. Charles Louis, the son and heir of Frederick V., the count palatine of the Rhine, who had been placed under the ban of the Empire, received back the Lower Palatinate, and a new electorate, the eighth, was created for him.

France obtained the recognition of the sovereignty (which she had enjoyed *de facto* since 1552) over the bishoprics and cities of Metz, Toul, and Verdun, Pinerolo in Piedmont, the town of Breisach, the landgraviate of Upper and Lower Alsace, the Sundgau, the advocacy *(Landvogtei)* of the ten imperial cities in Alsace, and the right to garrison Philippsburg. During the Thirty Years' War France had professed to be fighting against the house of Austria, and not against the empire. It was stipulated that the immediate fiefs of the Empire in Alsace should remain in enjoyment of their liberties, but it was added as a condition that the sovereignty of France in the territories ceded to her should not be impaired. The intention of France was to acquire the full rights of Austria in Alsace, but as Austria had never owned the landgraviate af Lower Alsace, and the *Landvogtei* of the ten free cities did not in itself imply possession, the door was left open for disputes. Louis XIV afterwards availed himself of this ambiguous clause in support of his aggressive policy on the Rhine. The independence of Switzerland was at last formally recognized, as was that of the United Netherlands in a separate treaty.

Apart from these territorial changes, a universal and unconditional amnesty to all those who had been deprived of their possessions was declared, and it was decreed that all secular lands should be restored to those who had held them in 1618. Some exceptions were made in the case of the hereditary dominions of the emperor.

Even more important than the territorial redistribution was the ecclesiastical settlement. By the confirmation of the treaty of Passau of 1552 and the religious peace of Augsburg of 1555, and the extension of their provisions to the Reformed (Calvinist) Church, toleration was secured for the three great religious communities of the empire. Within these limits the governments were bound to allow at least private worship, liberty of conscience, and the right of emigration, but these measures of toleration were not extended to the hereditary lands of the house of Habsburg. The Protestant minority in the imperial diet was not to be coerced by the majority, but religious questions were to be decided by amicable agreement. Protestant administrators of church lands obtained seats in the diet. Religious parity was established in the imperial chamber *(Reichskammergericht)*, and in the imperial deputations and commissions.

The difficult question of the ownership of spiritual lands was decided by a compromise. The edict of restitution of 1629 was annulled. By the important provision that a prince should forfeit his lands if he changed his religion an obstacle was placed in the way of a further spread of the Reformation. The declaration that all protests or vetoes by whomsoever pronounced should be null and void dealt a blow at the intervention of the Roman curia in German affairs.

The constitutional changes made by the treaty had far-reaching effects. The territorial sovereignty of the states of the empire was recognized. They were empowered to contract treaties with one another and with foreign powers, provided that the emperor and the empire suffered no prejudice. By this and other changes the princes of the empire became absolute sovereigns in their own dominions. The emperor and the diet were left with a mere shadow of their former power. The emperor could not pronounce the ban of the empire without the consent of the diet. The diet, in which the 61 imperial cities gained the right of voting on all imperial business, and thus'were put on an equality with the princes, retained its legislative and fiscal powers in name, but practically lost them by the requirement of unanimity among the three colleges.

Not only was the central authority replaced almost entirely by the sovereignty of about 300 princes, but the power of the empire was materially weakened in other ways. It lost about 40,000 sq.mi. of territory, and obtained a frontier against France which was incapable of defence. Sweden and France as guarantors of the peace acquired the right of interference in the affairs of the empire, and the former gained a voice in its councils. For many years Germany thus became the principal theatre of European diplomacy and war and the natural development of national unity was delayed. But if the treaty of Westphalia pronounced the dissolution of the old order in the empire, it facilitated the growth of new powers in its component parts, especially Austria, Bavaria, and Brandenburg. The treaty was recognized as a fundamental law of the German constitution, and formed the basis of all subsequent treaties until the dissolution of the empire.

WEST POINT (UNITED STATES MILITARY ACADEMY): see MILITARY, NAVAL AND AIR ACADEMIES.

WEST UNIVERSITY PLACE, a residential city of southeastern Texas, U.S., in Harris county, lies within the Houston standard metropolitan statistical area and is completely surrounded by Houston. Founded in 1917, in what was then a rural area, and incorporated in 1925, the city took its name from its nearness to Rice university, in Houston. West University Place was conceived in 1910 by Ben W. Hooper, governor of Tennessee (1911–15), uho bought a tract of land southwest of Houston and planned to develop a community of country houses. The development was begun seven years later by A. D. Foreman. Managerial, professional and technical workers predominate in the city's population; virtually all the city's 2 sq.mi. of land was occupied by the 1960s. West University Place adopted the council-manager form of government in 1955. For comparative population figures *see* table in TEXAS: *Population.* (G. M. F.)

WEST VIRGINIA, popularly called the "Panhandle state" or the "Mountain state," one of the Ohio valley states of the United States, admitted to the union on June 20, 1863, as the 35th state. Roughly oval in shape except for two extensions or panhandles, West Virginia is bordered on the north by Pennsylvania and Maryland, on the east and southeast by Virginia, on the southwest by Kentucky and on the west by Ohio. Its area is 24,181 sq.mi., of which 102 sq.mi. are water surface; in size it ranks 41st among the states. The state bird is the cardinal, the animal the black bear, the flower the big rhododendron, the tree the sugar maple and the song (unofficial) "West Virginia Hills." The flag has a field of white surrounded by a blue border; in the centre of the field is placed the coat of arms and symbols of the state, and the state motto, *Montani Semper Liberi* ("Mountaineers Are Always Freemen"). The capital is at Charleston.

PHYSICAL GEOGRAPHY

Physical Features. — West Virginia (lying between the extremes of about latitude 37° 12' and 40° 38' N. and longitude 77° 40' and 82° 40' W.) is the most mountainous state east of the Rockies, having an average elevation of 1.500 ft. It may be divided into two distinct physiographic areas: (1) the Allegheny plateau on the west, comprising about two-thirds of the area of the state, and forming a part of the great Appalachian plateau province that extends from New York to Alabama; and (2) the newer Appalachian or Great valley region on the east, being a part of the large province of the same name which extends from Canada to central Alabama.

Allegheny *Plateau.*—The Allegheny plateau consists of nearly horizontal beds of limestone, sandstone and shales, including important seams of coal; it inclines slightly toward the northwest and is intricately dissected by streams into a maze of narrow canyons and steep-sided hills. Along the Ohio river, which forms the western boundary of West Virginia, these hills rise to an elevation of 800 to 1,000 ft. above sea level, while toward the southeast the elevation increases until 3,500 and 4,000 ft. are reached along the eastern margin of the plateau, known as the Allegheny front. The entire plateau area is drained by the Ohio and its tributaries. Starting at the north, the first of these tributaries is the Monongahela, which crosses into Pennsylvania before it joins the Ohio. Its headaater valleys in the east-central part of the state are among the most beautiful and fertile in West Virginia. A system of dams renders the Monongahela navigable as far as Fairmont. Farther south, entering the Ohio at Parkersburg, is the Little Kanawha river, which drains seven or eight central northwestern counties. More than 44 mi. below Parkersburg, at Point Pleasant, the Kanawha river (called New river farther upstream), the principal tributary in West Virginia, enters the Ohio. This river drains more than one-third of the state, and its headwaters reach far back through the long mountain valleys to its source in North Carolina. On its banks the capital of the state, Charleston, is situated, and along its main valley and branch valleys several of the principal railway lines are built. The river itself is navigable to Kanawha falls, about 39 mi, above Charleston, and is used regularly by barge lines. Principal tributaries of the Kanawha-New river are the Elk, Gauley and Greenbrier, entering from. the north; and the Coal and Bluestone, entering from the south.

In the southwest the Guyandot, Big Sandy (forming part of the boundary between West Virginia and Kentucky) and Tug Fork rivers complete the plateau drainage system.

Appalachian Region. — In the Appalachian region, the same beds that lie horizontally in the plateau provinces were long ago thrown into folds and subsequently planed off by erosion, leaving alternate belts of hard and soft rock exposed. Uplift permitted renewed erosion to wear away the soft belts, leaving mountain ridges of hard rock separated by parallel valleys. The mountain ridges vary in height to more than 4,000 ft., the highest point in the state being Spruce Knob (4.860 ft.) in Pendleton county. The parallel valleys are drained by streams flowing northeast and southwest. those in the northeast being tributary to the Potomac, which forms part of the northeastern boundary, and those farther south tributary to the Kanawha. The valleys between the ridges, although not always easy of access, provide broad areas of nearly level agricultural land. The rivers flowing northeast and southwest, after running between parallel ridges for long distances, often turn suddenly through transverse passes formed by erosive cutting of gaps through ridges. One of the best known is Harpers Ferry, where the Potomac has cut through the Blue Ridge mountains; at 247 ft. elevation, this is the lowest point in the state.

All of West Virginia enjoys complete drainage.

Climate. — The climate of West Virginia is determined largely by land elevations and rainfall. The mean annual precipitation varies from about 70 in. at Pickens, Randolph county, to about 25 in. at Upper Tract, Pendleton county. The mean, however, is about 45 in., generally rather evenly distributed, though some seasons, notably that of 1930, are extremely dry, whereas others, notably that of 1950, are extremely wet. These factors combine to give trans-Allegheny West Virginia a decidedly continental climate subject to great and frequent changes in temperature. The range is from −15° to 100° F., but readings as low as −35° and as high as 112° have been recorded. The mean is between 52° and 53°. Because of Atlantic ocean influences, the changes east of the Allegheny front are not so frequent or so extreme.

(C. H. A.; K. K. McC.)

Soil. — The soils of West Virginia were formed under dominantly mixed hardwood forests, with a continental type of climate in which the annual rainfall averages nearly 40 in. The underlying rocks are mainly sandstone and shale, but important areas of limestone occur in some sections. The soils formed under these conditions are mostly in the groups known as gray-brown podzolic and red-yellow podzolic. Due to the downward movement of clays and minerals, most soils are strongly acid in the surface, even though the underlying rock is limestone. Over most of the state, slopes are steep to very steep; consequently, there is much mixing of the soil.

In the Limestone valley, in the eastern part of the state, the soils are mostly deep, well drained and productive. Hagerstown, Fredrick and Duffield are important soil series in this area. These soils also occur in the Greenbrier Limestone valley. In the Ridge and Valley province, the soils are mainly shallow and are formed on strongly folded shales. There the Ashby, Litz and Calvin are important soil series.

On the high Allegheny plateau most of the rocks are sandstone and shales of the coal measures, and the soils are mainly in the Dekalb, Gilpin and Wharton series. In the western part of the state, soils formed on interbedded sandstones and red and gray shales are dominant, and the important soils belong to the Upshur, Muskingum and Westmoreland series.

Where cropland and steep pastures have been mismanaged, erosion has been serious, removing from one-half to nearly all the original topsoil in many places. (B. J. P.)

Vegetation. — Before the white man settled in the region that became West Virginia, it was covered by a practically unbroken forest of hardwood trees, except in the elevated areas where pines were predominant. The area was a part of the Appalachian hardwood forest, early recognized by botanists as richer than any similar area in either Europe or Asia in the variety of its plants and in their economic value. The Appalachian forest then contained, in addition to representatives of all important genera of European forest trees, the following trees unknown to Europe: tulip, locust, gum, hickory, magnolia, persimmon, ash, oak, maple, walnut, beech, chestnut, cherry, buckeye, sycamore, elm, birch, mulberry and willow. The growths just named later made West Virginia one of the chief hardwood-producing states in the United States.

Because of excessive cutting, forest fires, blights and insects, and the long absence of a conservation policy, only small areas of the primeval forest remain. The chestnut trees have disappeared almost entirely. Fortunately, perhaps, the trend to industry led to abandonment of farm lands and subsequent reforestation. Reforestation was aided also by the establishment of a number of national and state forests (see Parks *and* Recreation, below). The timber stands are still predominantly hardwoods, of which oak comprises about 54%.

In addition to trees there are about 1,900 other seed plants or higher forms of vegetable life. The forests are filled with beautiful shrubs, including azaleas (wild honeysuckle), rhododendrons (big laurel), kalmias (laurel) and American wistarias. West Virginia university, Morgantown, catalogued 125 plants that originated in Canada and were brought by glaciers or birds to West Virginia, nhere they thrived; among these are sumac, yew, club moss, hemlock, violet, honeysuckle, raspberry, mountain maple, oxalis and holly. Among rare plants is the box huckleberry.

Animal Life. — White settlers in western Virginia found deer, bears, wolves, pumas (panthers), beaver and elk in large numbers. Except for protected deer the large native animals are almost extinct, but the smaller animals found by the first settlers, such as foxes, skunks, opossums, raccoons and rabbits, remain. This is notably true in those areas left for self-reforestation. Beaver are being rehabilitated and trapped under conservation regulations. About *268* species of birds have been noted, about one-fourth of all the different kinds found in the United States and Canada. Wastes from mines and sawmills have been destructive of fish in many West Virginia streams. Through stocking, restocking and protection, however, enough game fish have been preserved to make good fishing, and there are many varieties of nongame fish. There are also frogs, toads, mud puppies, turtles and snakes. Only two species of native snakes, rattlers and copperheads, are poisonous.

Parks, Monuments and Recreation.—More than *1,100,000* ac. of West Virginia are publicly owned and devoted to conservation or recreation. There are *20* state parks, embracing approximately *41,000* ac.; *11* public hunting areas, embracing *92,000* ac.; and *9* state forests, embracing *80,000* ac. There are *880,000* ac. of national forest lands included in the George Washington and Monongahela National forests, by far the larger part being in the latter.

The forest service has established a'park at Harpers Ferry and is restoring it as of *1865.* At White Sulphur Springs is located the famous Greenbrier hotel.

HISTORY

The first inhabitants of West Virginia were mound builders, whose mounds still may be seen along the Ohio and Kanawha rivers. The largest of these, and the largest in the country, located at Moundsville in the Ohio valley, is *69* ft. high and *927* ft. in circumference. Years before the white man arrived an Indian intertribal war occurred in southern West Virginia, and, by *1700,* Indian towns, villages and camps along New river had been destroyed and the river itself had become a sort of dividing line between the Iroquois (*q.v.*) of the north and the Cherokee (*q.v.*) of the south. White settlers quickly evicted the Indians from the region, but the Shawnee (*q.v.*) from Ohio frequently raided the settlements. Shawnee, Delaware and other Indians occupied the upper Ohio valley as late as *1725.*

A contest between the French and English over control of the Ohio valley began in the early part of the 18th century. French explorers had been to parts of western Virginia as early as *1625.* An English explorer, Abraham Wood, of Petersburg, Va., explored the region in *1671,* and New river was called Wood's river for many years. The activity of Gov. Alexander Spotswood (*q.v.*) of Virginia, was largely responsible for the movement of settlers into the western part of the colony. Spotswood visited the region in *1716* and brought back glowing reports of it. The first settlers of the region may have been Welsh, Scotch-Irish and German pioneers, who as early as *1719* came by way of Pennsylvania or Maryland, crossing the Potomac near Shepherdstown. The first known permanent settler in the state, however, was Morgan ap Morgan, who in *1731* made his home on Mill creek in Berkeley county, in the eastern panhandle. Perhaps the first recorded settlement west of the Alleghenies was made by Jacob Marlin and Stephen Sewell, who settled at Marlinton, in Pocahontas county, in *1749.*

Formation of the Ohio company (*q.v.*) in *1749,* and the subsequent French and Indian War, determined English dominance in the territory now embraced by West Virginia. In *1774,* during Lord Dunmore's war, Gen. Andrew Lewis defeated the allied Indian nations under Chief Cornstalk in a battle at Point Pleasant. Shawnee raids in Mercer and Greenbrier counties and in the bordering counties of Virginia were nonetheless frequent during the American Revolution, and the settlers suffered repeated attacks from British-led Indian armies. By *1800* the settlements were sufficiently strong to fight off raiding parties.

After the American Revolution the older settled parts of the region filled up rapidly. The first federal census of *1790* enumerated *55,873* persons living in what is now West Virginia, and by *1800* the population had increased to *78,592.* Completion of the National, or Cumberland, road, closely paralleling the northern boundary of the state, in *1818* brought in many new settlers.

Statehood.—Many factors played their parts in the ultimate separation of West Virginia from Virginia during the American Civil War. Among these were the differences in background, religion and interests between the settlers north of the Kanawha river and those in east Virginia. Another was the difficulty of transportation to Richmond, the seat of government, from western Virginia; after the opening of the Mississippi and the introduction of steamboats on the Ohio it was easier to get to New Orleans, La. Western Virginians resented their unfair legislative representation; there were few slaves in the area, and since slaves were considered part of the population, and representation was apportioned on the basis of population, the westerners were underrepresented in the legislature.

Several economic factors also existed. Commercial competition between Baltimore and Richmond for control of western Virginia played a part. Building of the Baltimore and Ohio railway, financed by the city of Baltimore, through the region was fought by eastern Virginia interests. In addition, the state of Virginia contracted an enormous debt for improvements in schools, roads, canals and railways, but practically none of the money was spent in the future West Virginia, where schools and roads were desperately needed. A further irritant was the matter of taxation, in which western Virginia suffered as a nonslaveholding region, slaves being taxed at a lower rate than other property.

Talk of separation began as early as the 1820s and continued to gain momentum. Shortly before the American Civil War began, eastern Virginia, realizing that the western part would almost certainly break away if the state seceded from the union, began to grant some concessions to the west, but John Brown's seizure of the arsenal at Harpers Ferry (*q.v.*) in *1859* further widened the breach between the two parts of Virginia. When on April *17, 1861*, Virginia voted to secede, *29* of the *46* legislative members from what is now West Virginia voted against the ordinance (9 voted for it, *7* were absent and *1* was excused).

On April *22, 1,200* citizens met at Clarksburg and called for a general convention to meet at Wheeling in May. The convention, at which *26* counties were represented, voted overwhelmingly against secession. At a second convention held in Wheeling on June *11* the Virginia ordinance of secession was nullified and provision was made for a popular vote on formation of a new state. An election was held Oct. *24, 1861,* resulting in a vote of *18.408* to *781* in favour of separation. At a third convention held at Wheeling (Nov. *1861* to Feb. *1862)* a constitution was drafted. It was ratified by a vote of *18,862* to *514* in April, and on April *20, 1863,* President Lincoln caused a proclamation to be issued under which West Virginia became the 35th state on June *20, 1863.*

Later History.—The state made rapid and peaceful progress for the next several generations, particularly in school and railway construction.

The years *1870, 1872* and *1876* were marked by Democratic election victories, following the enfranchisement of former Confederate soldiers. Confederate veterans had been barred from voting by the Test act of *1865,* which required the voter to swear that he had never borne arms against the United States or aided armed hostile forces, and under it more than *15,000* adult males were disfranchised. When the Democrats elected their first governor in *1870,* the Test act was repealed, and in *1872* a constitutional convention was called. The new constitution, adopted in that year, thoroughly remodeled the state government. In *1896* the state returned to the Republican party, which thereafter controlled the government until *1933,* except during the administration of John Jacob Cornwell, elected governor as a Democrat in *1916;* even during the latter period, however, the legislature remained Republican.

The administration of Gov. Henry D. Hatfield (1913–17) saw the building of the state department of health, adoption of the first workmen's compensation law in the United States, creation of the department of labour and the public service commission and the reorganization of the state department of mines. The administration of Governor Cornwell *(1917–21)* was marked by the creation of the state police, or department of public safety, and the payment of West Virginia's share of the Virginia debt, necessary because bankers declined to purchase $50,000,000 in road bonds until the Virginia debt was satisfied (see VIRGINIA). A new and modern state capitol was built after the burning of the old capitol in Feb, 1921.

The years 1912-21 saw much labour trouble, with a certain amount of violence, calling for the use of the national guard twice and the United States army four times in mining territory. Casualties were few, however, despite two marches by armed miners. The question of the right to organize unions was ended with the passage of the National Recovery act and the Wagner National Labor Relations act.

After 1933 West Virginia remained under Democratic control except for the election of 1956, when Republican Gov. Cecil Underwood was elected (though with a Democratic legislature), the Democrats regaining control of the statehouse in 1960. The principal changes occurring in government under the Democrats were creation of the department of public assistance and of the county unit system of schools, with state aid; and incorporation of the functions of the county systems of roads into the State Road commission. Numbers of new minor departments of state government were created. In national elections the state also voted Democratic after 1932, with the exception of 1956 when the voters supported Republican Dwight D. Eisenhower. In 1960 West Virginia was back on the Democratic side, supporting John F. Kennedy for president and with both senatorial seats and five out of six house seats occupied by Democrats. An increasingly important factor economically as well as politically was prolonged unemployment in the state and the depressed nature of the coal industry after World War II.

GOVERNMENT

At the time of its adoption, in 1872, the West Virginia constitution was described by its critics as reactionary. Revision by a constitutional convention requires the approval of a majority of the members elected to each branch of the state legislature and of a majority of the participating voters in an election held not less than three months after the passage of the legislative authorization. As in the case of constitutional amendments submitted to the voters by a two-thirds majority of the members elected to each house of the legislature, a new constitution would have to be approved by a majority of the participating voters to be effective. All residents of the state who are 21 years old and native or naturalized citizens are entitled to vote, provided they conform to the requirements of a registration law passed in 1902 and amended from time to time thereafter.

Executive. — The executive department of the state government consists of the governor, auditor, treasurer, attorney general, secretary of state, superintendent of free schools and commissioner of agriculture, who jointly constitute the board of public works charged with making the biennial budget and assessing public-service utilities. They are elected by the people at the time of the regular presidential election. The governor is ineligible for re-election to a second consecutive term. With the approval of the senate he appoints all state officers whose selection is not otherwise vested, and practically all of his appointees, except the controlling boards of the institutions of higher learning, are subject to summary removal.

Legislative. — The legislature consists of a senate of 32 members and a house of delegates of 100 members. Two senators are chosen from each of 16 districts for four-year terms; one-half of them retire biennially. The delegates are apportioned among the counties on a population basis, but each county is entitled to one delegate. The legislature meets in odd-numbered years, and its acts are subject to executive veto, which may be overridden by a majority of the total membership of each house. From the mid-1930s most legislatures referred special problems to interim committees instructed to study and report.

Judiciary. — The judicial power of the state is vested in a supreme court of appeals, in circuit courts, in inferior tribunals (domestic, common pleas, criminal, intermediate and juvenile) and in justices of the peace. The highest court, consisting of five judges elected for 12-year terms, holds two regular terms annually. The 28 circuit judges are elected for terms of eight years. Justices of the peace are elected by magisterial districts of the counties.

Local Government. — West Virginia towns and cities choose their own forms of government from a number of models approved by the state legislature. The city-manager form is commonest. County government is of the county-township form.

Finance. — By the second half of the 20th century the state's chief sources of revenue were sales taxes, federal aid, property taxes (on rates of which there is a constitutional limit), goods and services, other taxes, and sale of bonds; there was no state income tax, either corporate or individual. Major items of state expenditure were education, highways, public assistance and unemployment compensation. The state budget had a cash balance. The last road bond issue had been voted $50,000,000 in 1948, but bonds were reissued as other bonds were retired. The state voted $90,000,000 in 1950 for bonuses to the soldiers of World War I and World War II. In Nov. 1956 a bonus for veterans of the Korean war also was voted, being paid out of the unexpended balance of the appropriation of 1950.

POPULATION

The population of West Virginia in 1870 was 442,014; in 1890 it was 762,794; in 1910, 1,221,119; in 1940, 1,901,974; in 1950, 2,005,552; and in 1960, 1,860,421. This last figure represents a decrease of 7.2% from the population in 1950. The population per square mile in 1960 was 76.9, as compared with 83.3 in 1950, with 79.0 in 1940, and with 49.6 for the United States in 1960.

Williamson	6,746	8,624	8,366	6,819	

*Populations are reported as constituted at date of each census.
Note: Dash indicates place did not exist during reported census, or data not available.

Of the 1960 population 476,674, or 25.6%, lived in incorporated places of 2,500 or more, as compared with 32.1% in 1950. The state has four standard metropolitan statistical areas, which are Charleston, Huntington-Ashland, Steubenville-Weirton and Wheeling (three of which include portions of surrounding states). These areas had a total population of 865,803; this included the West Virginia portion, 575,137, or 30.9% of the total population of the state in 1960.

The number of occupied dwelling units (or households) in 1960 was approximately 576,000, as compared with 527,000 in 1950 and 445,000 in 1940. The average population per household had declined from 4.3 in 1940 to 3.8 in 1950 and to 3.2 in 1960.

The population of the state was distributed by colour and nativity in 1950 as follows: 92.5% native white; 1.7% foreign-born white; and 5.8% nonwhite, practically all Negro. There were 100.0 males per 100 females in the native white population, and 101.1 in the Negro population; 6.8% of the population was 65

SCENES IN WEST VIRGINIA

Top left: Zion Episcopal church (1852), Charles Town. In the old church. yard are the graves of many members of the Washington family, and of Revolutionary and Confederate soldiers

Top right: Greenbrier hotel, White Sulphur Springs, a famous resort

Centre left: Coal mines near the West Virginia turnpike. West Virginia ranks first among coal-producing states in the U.S.

Bottom left: Old Stone church, Lewisburg (1796), was the first Presbyterian Church west of the Allegheny mountains

Bottom right: Chemical manufacturing plant at South Charleston. Chemicals and chemical products are the state's leading industries years old or over; and 47.0% of the population 14 years old and over was in the labour force.

Of the total number of employed males, 12.0% was engaged in agriculture, 26.8% in mining, 6.3% in construction, 19.6% in manufacturing and 19.7% in transportation and trade.

West Virginians are 97.5% native-born, and persons of English descent predominate. There are strong German elements in the eastern and northern panhandles, however, and a considerable Scotch-Irish element in southern West Virginia. Northern West Virginia was populated largely by persons from New York, Pennsylvania and Maryland, and southern West Virginia almost wholly by former Virginians, except for Negroes brought in from North Carolina.

Methodists and Baptists predominate in the state, but there is a considerable Roman Catholic population in the northern panhandle, particularly in the city of Wheeling, and a large Presbyterian group in the Kanawha valley.

EDUCATION

Public Schools. — Enactment of a county unit law in 1933 changed the school system from one of magisterial districts to one in which the county unit system prevailed, with consolidation of school districts where improved roads permit and a uniform system of salaries for teachers in grade and high schools; a free textbook system also was adopted. By the second half of the century the state's elementary schools enrolled about 300,000 pupils annually, high schools had about 170,000 students, and teachers numbered 10,500 in the elementary schools and 7,000 in the secondary schools. The total net revenue for public school education was nearly $200,000,000 yearly, of which more than half was state aid.

Racial integration is complete in the schools of West Virginia, and there is no contention. An unusual situation is found in the former Negro colleges, to which many white students have been attracted. Storer college, in Harpers Ferry, a former Negro college, has ceased operation. In some sections Negroes have retained their own secondary schools through agreement.

Higher Education. — There are 11 state-supported institutions of higher learning, chief among which is West Virginia university, at Morgantown. A coeducational land-grant institution, the university was established in 1867 as the Agricultural College of West Virginia. It is governed by a nine-member board of governors, appointed by the governor for nine-year staggered terms. The university's colleges and schools include arts and sciences, agriculture, commerce, dentistry, education, engineering, journalism, law, medicine (a new medical school was opened in 1960), mines, music, pharmacy and physical education. Enrollment approaches 7,000 annually, and the faculty numbers nearly 500. Potomac State College of West Virginia university, at Keyser, is a junior college preparatory to the university.

The other state-controlled institutions of higher education are Bluefield State college (chartered 1895), Bluefield; Concord college (1875), Athens; Fairmont State college (1867), Fairmont; Glenville State college (1872), Glenville; Marshall college (1837), Huntington; Shepherd college (1872), Shepherdstown; West Liberty State college (1837), West Liberty; West Virginia Institute of Technology (1895), Montgomery; West Virginia State college (1891), Institute. These are under the control of a state board of education of nine members.

Private and denominational colleges are Alderson-Broaddus college (Baptist; 1871), Philippi; Bethany college (Disciples of Christ; 1840), Bethany; Davis and Elkins college (Presbyterian; 1904), Elkins; Salem college (Baptist; 1888), Salem; West Virginia Wesleyan college (Methodist; 1890), Buckhannon; Morris Harvey college (nonsectarian; 1888), Charleston; Wheeling college (Roman Catholic; 1954), Wheeling. There are two private junior colleges, Greenbrier college (for women), at Lewisburg, and Beckley college, at Beckley.

HEALTH, WELFARE AND CORRECTIONS

Under the office of public institutions the state maintains a children's home at Elkins for orphaned and neglected boys and girls, and eight hospitals and sanitariums, as well as three correctional institutions (a forestry camp for boys at Davis; an industrial school for boys at Grafton; and an industrial home for girls at Salem) and three penal institutions (a state prison for women at Pence Springs; a penitentiary at Moundsville; and a medium security prison located on a farm near Huttonsville).

Under the department of mental health there are five hospitals for the mentally ill and a training school for mentally defective children at St. Marys.

THE ECONOMY

Agriculture. — West Virginia agriculture is primarily part-time or subsistence in nature, but there were nearly 22,000 commercial farms in the state out of the 68,583 recorded in the 1954 census of agriculture. Early agricultural development was confined to the many small valleys and areas bordering the rivers and the eastern panhandle. Later agricultural development was more or less incidental to the development of the lumber and mineral industries, which brought into cultivation much hill land. Twentieth-century changes in the mineral industries caused some decreases in population in rural areas coupled with a decline in cultivated crops and a shift to livestock farming enterprises. Many agencies assisted in changing interests to horticulture, livestock and livestock products, among them being the Grange (*q.v.*); the West Virginia university college of agriculture working through county and extension agents; the West Virginia Agricultural Experiment station; the state department of agriculture, established in 1911; boys' and girls' clubs, functioning since 1907; 4-H clubs, with headquarters at Jackson's Mill since 1921; the Future Farmers of America; and a number of other societies and associations.

Under the stimulus of these agencies and the demands of a growing population the total state gross farm income reached an all-time high in 1951 of $192,700,000. Four-fifths of the cash total was for livestock and livestock products sold.

After 1953 gross farm income held near the $150,000,000 level because of declining production and lower average prices received. The number of farms declined gradually to about 64,000 in the late 1950s from the peak of 105,000 recorded in 1935. Though the net farm income for the state in 1958 ($904 per farm) was the lowest in the nation, this does not reflect the fact that more than one-half the farm families received more income from other sources than from farming.

The principal agricultural crops are corn, wheat, oats, tobacco, apples (commercial), peaches and potatoes.

Industry. — The value of manufacturing output in West Virginia by the early 1960s was around $2,500,000,000 annually, and about 130,000 West Virginia workers found employment in manufacturing. The durable goods manufacturing industry, with an output valued at around $1,500,000,000, was led by the metals industry (primary metals, machinery and fabricated metals). The glass, clay and stone products industries were only slightly less important; more than 4% of all U.S. workers in such industries were employed in West Virginia.

The nondurable segment of the state's industry produced goods worth more than $1,000,000,000 annually, the chemical manufacturing industry, employing an average of 27,000 workers, leading this division. Food, textile, apparel, printing-publishing and petroleum-coal products industries were also important to the state's economy.

Minerals. — Bituminous coal is the most abundant and the most valuable mineral in West Virginia. The state's 136 coal seams, 62 of which are mineable, contain about 63,000,000,000 tons. There are also thinner (three feet and less) and lower-grade beds containing about 40,000,000,000 tons. The coal area is 17,280 sq.mi., but the total mineable area is equivalent to about 37,550 sq.mi., or about 1½ times the entire area of the state. Of the 55 counties 44 are underlaid by mineable coal. In 1936 West Virginia became first among the soft-coal-producing states. More than 50,000 miners are employed, and total all-time production (to 1960) was about 6,375,000,000 tons.

From 1909 to 1924 West Virginia was first among the states in the production of natural gas, with a peak of 308,617,101,000 cu.ft.

in 1917. In 1924 the state dropped to third place, being passed by both Oklahoma and California, and after the discoveries of gas in the southwest its position was still further lowered. During the decade ending in 1950 the average annual production of the state's 15,800 gas wells was more than 200,000,000,000 cu.ft., but the amount of natural gas imported in 1959 by pipelines from the southwest for redistribution to the east by West Virginia networks was almost as great as the volume produced within the state. After the peak year of 1900, when a total of 16,195,675 bbl. was extracted, West Virginia's production of high-quality crude oil declined rapidly. By the early 1960s it was around 2,000,000 bbl. annually.

Among other widely distributed minerals are rock salt, underlying about 2,400 sq.mi. along the Ohio river and forming the basis of chemical industries that produce pigments, plastics, pharmaceuticals, chlorine, caustic soda and insecticides; the salt brines of the Kanawha valley, which, after World War I, made possible the beginning of the great chemical industry; practically pure glass sand, the use of which for scientific purposes placed West Virginia high among the states in volume output; stone, river sand and gravel, used extensively in construction; and clays, used in the northern panhandle for the fabrication of pottery and china. Other minerals of more or less commercial value include grahamite, once mined extensively in Ritchie county; nitre, in Greenbrier, Monroe and Pocahontas counties; psilomelane and pyrolusite, in Monroe county; sphalerite, in Jefferson county; and limonite, hematite and siderite, found in a number of counties. Minerals of limited occurrence include barite, bromine, celestite, fluorspar, galena and gypsum.

Transportation and Communication. — The major factor in transportation at mid-20th century was the discontinuance of many passenger trains, the increase in air flight, and the replacement of streetcars by buses. Passenger, cargo and air mail service were provided to all the major cities. Martinsburg was the headquarters of the national guard jet transport. Road mileage totaled more than 31,000. In addition, the 88-mi. West Virginia turnpike, constructed by private capital between Charleston and Princeton, one of the most modern mountain roads in the world, had a ½ mi. highway tunnel, all parts of which were under television supervision by an outside watchman. More than 375 mi. of navigable water ays on the Ohio, the Monongahela, the Kanawha and the Big Sandy link the state with Pittsburgh and with the Mississippi and the Gulf of Mexico.

In the early 1960s there were more than 500,000 telephones in the state, more than 50 radio stations, 9 television stations and about 30 daily newspapers.

(C. H. A.; K. K. McC.)

WET, CHRISTIAAN RUDOLF DE (1854–1922), South African soldier, who was commander in chief of the Orange Free State forces in the South African War (*q.v.*) and a leader of the 1914 rebellion, was born in the Smithfield district, Orange Free State, on Oct. 7, 1854. De Wet fought with the Transvaal Boers in their war for independence (1880–81) and then served his political apprenticeship as a member of the Transvaal volksraad (parliament). He later returned to the Free State and became a member of its volksraad. In the first months of the South African War he was with the Free State forces in Natal. He was transferred to the western Free State front in Dec. 1899 and, soon after Piet Cronje's surrender at Paardeberg (Feb. 1900) and the British occupation of Bloemfontein and Pretoria, became commander in chief. He resorted to guerrilla warfare, making numerous hit-and-run raids on British troops, their supplies and lines of communication, and narrowly evaded capture on many occasions. In May 1902 he was still prepared to continue the struggle, in spite of the growing success of British countermeasures, but eventually he yielded and was a signatory of the treaty of Vereeniging (May 31, 1902).

De Wet was minister of agriculture in the Orange River colony under responsible government from 1907 to 1910 and represented that colony in the national convention (1908–09) which drafted the constitution of the Union of South Africa. Although he did not sit in the Union parliament, he threw his great influence on the side of J. B. M. Hertzog when the latter left Louis Botha's cabinet and party and founded the Nationalist party (1913). After the outbreak of World War I he opposed Botha's decision to conquer German South-West Africa and, in conjunction with C. F. Beyers, organized a rebellion. Captured in Dec. 1914, he was found guilty of treason and sentenced to six years' imprisonment but was released in Dec. 1915. He died on Feb. 3, 1922, in the Dewetsdorp district, Orange Free State.

De Wet was an ardent Calvinist. He believed that it was the destiny of Afrikaners to rule South Africa as an independent state, and that African and coloured people were inferior beings. Consequently, he is regarded by Afrikaner nationalists as one of their great heroes. (L. M. T.)

WETTIN, the name of a family from which many European dynasties have sprung. Dietrich, of the tribe of the Buzici, left two sons, Dedo (count of Hassegau, 997; d. 1009) and Frederick (d. 1017), who received lands taken from the Wends, including the county or Gau of Wettin on the right bank of the Saale. Dedo's son Dietrich married Matilda, daughter of Ekkard I, margrave of Meissen. Their son Dedo II obtained the Saxon Eastmark and lower Lusatia in 1046, but in 1069 quarreled with the emperor Henry IV and was compelled to surrender his possessions. He died in 1075, and his lands were granted to his son Henry I, who in 1089 was invested with the mark of Meissen. In 1103 Henry was succeeded by his cousin Thimo (d. 1104), who built a castle at Wettin and was called by this name. Henry II, son of Henry I, followed, but died childless in 1123; his cousin, Conrad I, son of Thimo, claimed Meissen, of which he secured possession in 1130, and in 1136 the emperor Lothair II added lower Lusatia to his possessions. Conrad abdicated in 1156 and his lands were divided between his five sons; Meissen (*q.v.*) fell to Otto and the county of Wettin to the fourth son Henry, whose family died out in 1217. Wettin then passed to the descendants of Conrad's youngest son Frederick. and in 1288 the countv. town and castle of Wettin were sold to the archbishop of Magdeburg, eventually becoming incorporated in the kingdom of Prussia.

Conrad I and his successors had added largely to their possessions, until under Henry III the Illustrious, margrave of Meissen (1221–88), who acquired Thuringia (*q.v.*), the lands of the Wettins stretched from the Oder to the Werra and from the Erzgebirge to the Harz mountains. Frederick the Warlike (1381–1428) became electoral duke of Saxe-Wittenberg in 1423.

From his son Frederick are descended the Ernestine and Albertine branches of the family. To the former belong the dukes of Saxe-Weimar-Eisenach (grand dukes of Saxony), of Saxe-Meiningen, of Saxe-Altenburg and of Saxe-Coburg-Gotha (whence the kings of Belgium from 1831, of Portugal from 1837 to 1910, of Great Britain from 1901 and of Bulgaria from 1908 to 1946); to the latter, the electors (who were also kings of Poland from 1697 to 1763) and the kings of Saxony (*q.v.*).

WEXFORD, a county of Ireland in the province of Leinster, bounded north by Wicklow, east and south by St. George's channel and west by Waterford, Kilkenny and Carlow. The land area is 581,061 ac. or 908 sq.mi. Pop. (1961) 83,259. The number of sandbanks makes navigation dangerous near the shore. The only safe harbour on the east coast is Wexford harbour, which, because of a bar, is not accessible to large vessels at ebb tide. The artificial harbour of Rosslare, outside Wexford harbour to the south, was therefore opened in 1906. On the south coast the great inlet of Waterford harbour separates the county from Waterford and

Kilkenny, and among several inlets Bannow bay is the largest. South from Crossfarnoge point are the Saltee Islands, and Coningmore and Coningbeg, beyond the latter of which is the Saltee lightship. Southeast from Greenore point is the Tuskar rock.

An elevated ridge on the northuestern boundary forms the termination of the granite range in Wicklow, and in Croghan Kinshela, on the borders of Wicklow, rises to a height of 1,993 ft. On the western border another range, situated chiefly in Carlow, extends from the valley of the Slaney at Newtownbarry to the confluence of the Barrow with the Nore at New Ross, and reaches 2,409 ft. in Blackstairs mountain and 2,610 ft, in Mt. Leinster on the border of Countv Carlow. In the southern district a hilly region, reaching in Forth mountain a height of i64 ft., forms with Wexford harbour the northern boundaries of the baronies of Forth and Bargy. a peninsula of flat and fertile land. The Slaney river enters the county in the northwest and flows southeastward to Wexford harbour. Its chief tributary. the Bann, flows southwestward from the borders of Wicklow. The Barrow forms the western boundary of the county from the Blackstairs mountains till its confluence with the Suir at Waterford harbour.

The northern portion of Wexford nas included in Hy Kinselagh, the peculiar territory of the MacMurroughs, overlords of Leinster, who had their chief residence at Ferns. Dermot MacMurrough, having been deposed from the kingdom of Leinster, asked help of Henry II, king of England, secured the aid of the 2nd earl of Pembroke ("Strongbow") and obtained assistance from Robert Fitz Stephen and Maurice Fitz Gerald of Wales. In 1169 Fitz Stephen landed at Bagenbon on the south side of Fethard and captured the town of Wexford. After this Dermot granted the territory of Rexford to Fitz Stephen and Fitz Gerald. MacMurrough having died in 1171, Strongbow became lord of Leinster At first Henry II retained Wexford, but in 1174 he committed it to Strongbow.

Wexford was one of the 12 counties into which the conquered territory in Ireland is generally stated to have been divided by King John, and formed part of the possessions of William Marshal, earl of Pembroke. It ultimately passed to John Talbot. earl of Shrewsbury, who in 1446 was made earl of Waterford and baron of Dungarvan. The district was actively concerned in the rebellion of 1641; and during the Cromwellian campaign the town of Wexford was carried by storm in 1649. Wexford was the chief seat of the rebellion of 1798. in which local priests played a prominent part.

Evidences of the Danish occupation are seen in the numerous raths, or encampments, especially at Dunbrody. Enniscorthy and New Ross. Among the monastic ruins special mention may be made of Dunbrody abbey, of great extent, founded about 1178 for Cistercian monks by Hervey de Montmorency, marshal of Henry II; Tintern abbey. founded in 1200 by William Marshal and peopled by monks from Tintern abbey in Monmouthshire; the abbey of St. Sepulchre. Wexford, founded shortly after the invasion by the Roches, lords of Fermoy: Ferns abbey, founded by Dermot MacMurrough (with other remains including the modernized cathedral of a former see, and ruins of a church); and the abbey of New Ross. founded by St. Alban in the 6th century. Old castles include Ferns dismantled by parliamentary forces in 1641 and occupying the site of the old palace of the MacMurroughs; Enniscorthy. founded by Raymond le Gros: Carrick castle, near Wexford, the first built by the English; and the fort of Duncannon.

The soil of the county of Wexford consists mostly of a cold stiff clay resting on clay slate. Preglacial sands and gravels are used for liming fields, under the name of "manure gravels," on account of the fossil shells which they contain. The interior and western districts are much inferior to those round the coasts. In the southeastern peninsula of Forth and Bargy the soil is a rich alluvial mould mixed with coralline sandstone and limestone. The peninsula of Hookhead, as a result of the limestone formation, is specially fruitful. In the western districts of the county there are large tracts of turf and peat moss. The principal crops are oats. barley, turnips. wheat and potatoes. The numbers of cattle, sheep, pigs and poultry are well maintained. Except in the town of Wexford the manufactures are of small importance. The toun of Wexford is the headquarters of sea and salmon fishing districts, and there are a few fishing villages on the inlets of the south coast.

A railway branch line enters the county from the northeast and serves Wexford by way of Enniscorthy. with a branch westward to New Ross from Macmine Junction. Palace East, on this branch line, is also served by the Kildare line. Wexford has railway connections with Rosslare. and a line across the south of the county connects it also with Waterford (County Waterford). There is water communication for barges by the Slaney to Enniscorthy; by the Barrow for larger vessels to New Ross and by this river and the Grand canal for barges to Dublin. The administrative county of Wexford returns five members to *dail eireann.*

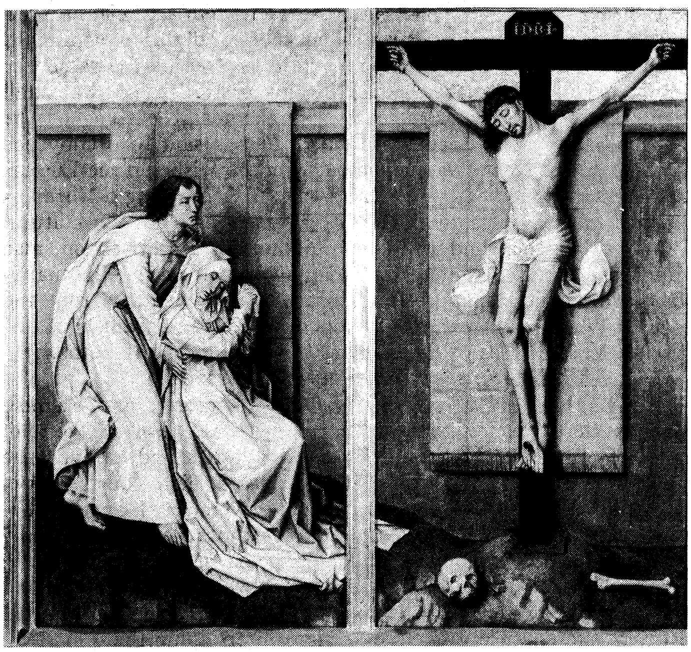
WEXFORD, a seaport and the county town of County Wexford, Ire., 83 mi. S. of Dublin by road. Pop. (1956) 10,838. Wexford was an early colony of the English. having been taken by Robert Fitz Stephen in 1169. In 1318 the town received a charter from Aymer de Valence, which was extended by Henry IV in 1411 and confirmed by Elizabeth I in 1jj8. It was besieged and sacked by Oliver Cromwell in 1649, and in 1690 it was garrisoned for William III. In 1798 it was made the headquarters of the rebels, who, however, surrendered it on June 21.

Wexford harbour, formed by the estuary of the Slaney, is about 5 mi. from north to south and about 4 mi. from east to west. There are quays extending nearly 900 yd. A bar at its mouth prevents the entrance of vessels drawing more than 12 ft. An artificial harbour was therefore opened at Rosslare in 1906, and this is connected with Wexford by a railway ($8\frac{3}{4}$ mi.) and is served by the passenger steamers from Fishguard. Some remains exist of the old walls and flanking towers. The Protestant church, near the ruins of the ancient abbey of St. Sepulchre or Selskar, is said to occupy the spot where the treaty was signed between the Irish and the English invaders in 1169. At Carrick, 2 mi. W., the Anglo-Normans erected their first castle. The principal exports are agricultural produce, livestock and whisky. Shipbuilding is carried on, also tanning, malting, brewing, iron founding, distilling and the manufacture of artificial manure, flour, agricultural implements, rope and twine. Wexford is the headquarters of salmon and sea fishery districts. It is the seat of the Roman Catholic diocese of Ferns.

WEYBRIDGE: *see* WALTON AND WEYBRIDGE.

WEYDEN, ROGIER VAN DER *(c.* 1400–1464), Flemish painter, the most influential artist of his time, born at Tournai, was painter to the town of Brussels (1435–64) and enjoyed the patronage of the Burgundian and various Italian courts (Este, Medici). His early career remains controversial. He was probably the Maistre Rogier de le Pasture who received an honorarium of wine at Tournai in 1426; he is also most generally identified with the Rogelet de le Pasture who was apprenticed to the Tournai painter Robert Campin (*q.v.*) in 1427 and the Maistre Rogier de le Pasture who entered the painters' guild there in 1432, although this namesake is regarded by some as a separate personality. Linked with this problem is that of the attribution of a group of pictures showing a more primitive and virile version of Rogier's style. These, either assigned to the youthful Rogier or to his putative master Campin, include "Entombment" (in private collection), and "Annunciation" (Metropolitan museum, New York), triptychs, altar wings and fragment (Frankfurt), "Nativity" (Dijon), "Marriage of the Virgin" and altar wings dated 1438 (Madrid), "Virgin and Child" (London), "Madonna on a Crescent" (Aix-en-Provence), a diptych with the "Trinity" and the "Madonna at the Chimney" (Leningrad) and a few portraits (Berlin, London).

No painting is authenticated as Rogier's by contemporary documents, but those attributed in early texts provide a reasonably secure basis for the reconstruction of his mature work. The monumental "Deposition" commissioned by the Louvain Archers' guild for their chapel in Notre-Dame-hors-les-Murs, then sent to the Escorial, Madrid, for Philip II of Spain by Mary of Hungary and now in the Prado, Madrid, clasely related to the group just mentioned, is probably of the 1430s, as are probably the "Annunciation" (Louvre, Paris) and "St. Luke Painting the Portrait of the Virgin" (Boston; replicas in Munich, Leningrad, Vienna). The large polyptych of the "Last Judgment" commissioned by the chancellor N. Rolin for his hospital in Beaune and the "Calvary" triptych at Vienna date from the following decade. Of numerous smaller religious pieces, the triptychs of "The Virgin" (Granada, New York, Berlin) and of "John the Baptist" (Berlin) are probably fairly early; of a little later date are the "Seven Sacraments" (Antwerp) painted for the bishop of Tournai, Jean Chevrot, and the large "Christ on the Cross" and "The Virgin and St. John," on two panels (Philadelphia); the "Entombment" (Florence) and "Virgin and Saints" (Frankfurt) show Italian compositional ideas, perhaps assimilated during the reported visit to Rome in the Holy year 1450; the Braque triptych (Paris) is dated 1450–52 by internal evidence; the triptych of the "Nativity" (Berlin) painted for Peter Bladelin, *receveur général* of Philip the Good and founder of Middelburg (Zealand), and of the "Adoration of the Magi," called "Columba Altar" (Munich) from St. Columba in Cologne, are probably late. Rogier's secular works include a lost bathing scene described by B. Facius, and the four large panels exemplifying Justice (Trajan and Herkinbald), which were in the Brussels town hall and were buried in the bombing of 1695. Reflections of them remain in tapestries in Bern. There are some sensitive portraits, most of them being part of a diptych: "Charles the Bold" (Berlin), "Francesco d'Este" (New Tork), "Jean de Gros" (Chicago), "Laurent Froimont" and the "Knight With a Spire" (Brussels), etc.



BY COURTESY OF THE JOHN G JOHNSON COLLECTION, PHILADELPHIA

"THE VIRGIN AND ST. JOHN." AND "CHRIST ON THE CROSS." BY VAN DER WEYDEN

Rogier's style, whether or not derived from Campin's, owes its crystalline vision and colour to Van Eyck, but the profound religious emotion, expressed through Gothic linear rhythms, is his own. In this personal vein of Netherlandish realism, he not only produced unique masterpieces, but also explored a new world of religious art and profoundly affected the whole course of European painting in the second half of the 15th century.

WEYERHAEUSER, FREDERICK (1834–1914), pioneer U.S. lumberman, was born in Neidersaulheim, Ger., on Nov. 21, 1834. He migrated to the United States in 1852 where he soon entered the lumber business in Illinois. In 1899 he led a group of lumbermen to the state of Washington where they purchased 900,000 ac. of Douglas fir from the Northern Pacific railroad. They formed the Weyerhaeuser Timber company in 1900. Weyerhaeuser served as president of this and other lumber companies until his death on April 4. 1914. The Weyerhaeuser firm became the largest lumber company in the United States, in 1957 owning 3,200,000 ac. of timberland. The Weyerhaeuser family is given credit for changing United States lumbering "from a looter's privilege to a responsible business." (J. R. LT.)

WEYGAND, MAXIME (1867–), French army officer, was born at Brussels. Jan. 21, 1867. Having entered the military college of St. Cyr in 1886, he proceeded to the cavalry school at Saumur. He was commissioned second lieutenant in 1888 and in 1914 was made lieutenant colonel in the 5th hussars. In the meantime he graduated from the Centre des Hautes Btudes Militaires. At the beginning of World War I he served as chief of staff of an army under Cen. F. Foch. In Aug. 1916 he was made a general of brigade and the following year was appointed French representative on the Inter-Allied general staff. In April 1918 he resumed his work as chief of the general staff under Marshal Foch, which post he held during the remainder of the war. On July 28, 1920, he arrived in Warsaw as military adviser. After World War I Weygand became a member of the Conseil Supérieur de la Guerre; in 1923–24 he served as French high commissioner in Syria; in Nov. 1924 he took charge of the Centre des Hautes Études hfilitaires; and in 1931–35 was inspector general of the army. He was elected to the French Academy on June 11, 1931.

Recalled to service on the eve of World War II, he left for Beirut on Aug. 29, 1939, as high commissioner for Syria and the Lebanon and commander in chief. On May 20, 1940, he succeeded Gen. Maurice Gamelin as commander in chief in France, and on June 12 advised the French government to capitulate. On July 16, 1940, he was appointed minister of national defense in the Pétain government, but on Oct. 4 was sent to Algiers as the government's delegate and commander in chief for French North Africa. On Nov. 18, 1941, on German orders, he was recalled to France. On Nov. 12, 1942, he was arrested and interned in Germany. Liberated by the Americans on May 2, 1945, in the Tirol, he returned to France and was arrested there a week later. On May 6, 1948, all charges against him were dropped.

Weygand's writings include: *Le Maréchal Foch* (1929), *Turenne* (1930), *Histoire de l'armée française* (1938), *Recalled to Service* (1952).

WEYL, HERMANN (1885–1955), one of the greatest mathematicians of the first half of the 20th century, was born at Elmshorn near Hamburg, Ger., on Nov. 9, 1885. He was professor at the Technische Hochschule, Ziirich (1913), at Gottingen university (1930) and at the Institute for Advanced Study in Princeton, N.J. (1933–51). He died in Zurich on Dec. 8, 1955.

By his original contributions to pure mathematics, mathematical physics and philosophy, Weyl can be compared with his teacher David Hilbert and with Henri Poincaré (*qq.v.*). His interest in philosophical problems influenced his view of science and mathematics; he had a profound belief that the harmony of nature is expressible in mathematically beautiful laws, and the outstanding characteristic of his work nas his ability to unite previously unrelated subjects. In *Die Idee der Riemannschen Fläche* (1913) he created a new branch of mathematics by uniting function theory and geometry, thereby opening up the modern synoptic view of analysis, geometry and topology. He turned his attention to relativity in *Raum-Zeit-Materie* (1918). He produced the first unified field theory in which the Maxwell electromagnetic field, as well as the gravitational field, appeared as a geometrical property of space-time. By freeing T. Levi-Civita's concept of parallel displacement from dependence on a Riemannian metric, he provided the starting point for the researches of O. Veblen and others in projective differential geometry. Weyl created a general theory of matrix representation of continuous groups and discovered that many of the regularities of quantum phenomena could best be understood by means of group theory (*Gruppentheorie und Quantenmechanik,* 1928). Weyl also wrote on the philosophy of mathematics; he inclined to the views of the intuitionist L. E. J.

Brouwer. His *Philosophy of Mathematics and Natural Science* (1949) has been influential. (G. J. Ww)

WEYLER Y NICOLAU, VALERIANO, MARQUESS OF TENERIFE (1838–1930), Spanish soldier of Prussian descent, born at Palma de Mallorca. At 16 he entered the military college of infantry at Toledo, passed into the staff college as lieutenant and came out head of his class. Two years aftenvard he became captain and was sent to Cuba. He distinguished himself in the expedition to Santo Domingo, winning the cross with laurels of San Fernando. From 1868 to 1872 he served brilliantly against the Cuban rebels. He returned to Spain in 1873 as brigadier general, fought the Carlists in the eastern provinces in 1875–76 and was promoted general of division. Then he was elected senator and created marquess of Tenerife. He was captain general in the Canary Isles (1878–83) and afteru-ard in the Balearic Islands and in the Philippines (1888), where he dealt sternly with the native rebels of the Carolines, of Mindanao and other provinces. On his return to Spain in 1892 he commanded the 6th army corps in the Basque provinces and Navarre where he quelled agitations, and then became captain general at Barcelona until Jan. 1896, making himself the terror of anarchists and socialists. On the failure of Arsenio Martinez de Campos to pacify Cuba, Weyler was sent out again by the Conservative Antonio Cánovas del Castillo and pursued a policy of inexorable repression which raised a storm of indignation and led to a demand from the U.S. for his recall. This was granted by the Liberal Práxedes Sagasta. Back in Spain his reputation as a strong and ambitious soldier gave him prominence in times of constitutional disturbance; his appointment in 1900 as captain general of Madrid resulted in more than one ministerial crisis.

Thrice minister of war (1901, 1905 and 1906), he was again captain general at Barcelona (Oct. 1909) and, without bloodshed, quelled the disturbance connected with the execution of Francisco Ferrer. Weyler died Oct. 20, 1930.

WEYMOUTH, a town (township) of Norfolk county, Mass., U.S.. 12 mi. S.E. of Boston, is bordered on the north by Hingham bay and the Weymouth Fore and Back rivers.

The first English colonists arrived in 1622. The plantation (Wessaguscus or Wessagusset), second oldest settlement in the state. became the dispersal point for the earliest adventurers around Massachusetts bay. Incorporated as a town in 1635 and named for Weymouth, Eng., the government came to extend over several villages, which are still identified. The community has become primarily a residential suburb of Quincy and Boston. It is governed by a representative town meeting.

In its first 200 years, Weymouth developed fishing and agriculture. Water pollution ended the herring fishery. Early manufacturing began with iron, discovered in 1771. Modern manufacturing centres on shoes. the oldest plant dating from 1853; fertilizer, lacquers and electric power are other products.

In the township are the Fogg library (1898. in South Weymouth) founded by a bequest of John S. Fogg; and the Tufts library (1879, in Weymouth village) endowed by Quincy Tufts and his sister Susan Tufts. For comparative population figures *see* table in MASSACHUSETTS: *Population.* (CA. M. C.)

WEYMOUTH AND MELCOMBE REGIS, a seaport and municipal borough in the South Dorset parliamentary division of Dorset. Eng., 8 mi. S. of Dorchester. Pop. (1961) 40,962. Area 11.0 sq.mi. The amalgamated towns lie on the western shore of the wide sweep of Weymouth bay, portrayed in a well-known picture by John Constable. The main sandy holiday beach is in Melcombe Regis. Weymouth harbour opens into Radipole lake, a bird sanctuary, which lies behind the esplanade and railway line and into which flows the Wey river.

Bronze weapons and Roman interments have been found there, but the first mention of Waymuth occurs in a Saxon charter of King Aethelstan, dated 938. By Weymouth's first charter, granted in 1252 by the prior and convent of St. Swithin, Weymouth was made a free borough and port for all merchants. As early as 1293 trade was carried on with Bayonne, and six years later a receiver of customs in wool and woolfells is mentioned at Weymouth, which then imported wine from Aquitaine. In 1347 the port supplied Edward III with 15 ships and 264 men, an indication of its importance at this time. Early in the 14th century the town suffered at the hands of the French, though in 1404 the townsmen were victorious over a party which landed in the Isle of Portland. In 1586 sugar is mentioned as an import. Two years later Weymouth sent six ships against the Spanish Armada and at least one Spanish ship, the "San Salvador," was brought into the harbour. Weymouth ships took part in many of the trading ventures with North America during the 17th and early 18th centuries. Commercial disputes with Melcombe Regis had led to amalgamation in 1571 and in 1616 the town received its charter from James I. During the Great Rebellion it was garrisoned by parliamentary troops in 1642, taken by the Earl of Camarvon in 1643 and surrendered in 1644. By 1750 the port was but a simple fishing village.

Weymouth's reputation as a watering place dates from the mid-18th century, and in 1789 George III paid the first of a series of visits which established its growing popularity. During the 19th century the prosperity of the port revived with the expansion of trade with the Channel Islands. Today the principal imports are potatoes, flowers and tomatoes, while the exports are mainly grain, fertilizers and building materials. In 1944 Weymouth was one of the principal embarkation ports for the invasion of Europe by the Allies.

Its various admiralty establishments, and certain light industries (*e.g.*, instrument making) provide additional employment to that of the holiday trade.

WEYPRECHT, KARL (1838–1881), German polar explorer who discovered Franz Josef Land, was born on Sept. 8, 1838, at Konig in Odenwald. In 1856 he became a cadet in the Austrian navy and in 1861 an officer. He made several voyages to the orient and to America and spent two years on a coast survey of Dalmatia. With Julius Payer he took part in two'expeditions to the arctic, sponsored by the Austrian government, with the object of exploring northeast of Novaya Zemlya and discovering a northeast passage. The first, in 1871, was a reconnaissance in the seas between Spitzbergen and Novaya Zemlya and reached latitude 78° 48' N. In the second, 1872–74, his ship, the "Tegetthoff," was beset and drifted north and west for over a year. On Aug. 30, 1873, Franz Josef Land was discovered and the party spent the next year exploring in the area. Eventually the ship was abandoned and the party returned to Novaya Zemlya by sledge and small boat, a journey occupying 96 days. On his return to Austria he advanced a scheme for investigating the polar regions at an international level, proposing that interested governments should establish one or more stations at which scientific work could be done simultaneously according to a previously co-ordinated plan. An International Polar commission was formed and organized the first International Polar year in 1882–83. Eleven countries set up 12 stations in the arctic and 2 in the antarctic. The result of the field work at these stations was published by the commission. The venture was followed by a second International Polar year in 1932–33 and the International Geophysical year in 1957–58.

Weyprecht published *Die Metamorphosen des Polareises* (1879) and *Praktische Anleitung zur Beobachtung der Polarlichter und der magnetischen Erscheinungen in hohen Breiten* (1881). The best account of the Franz Josef Land expedition is the translated account of his lieutenant, J. Payer: *New Lands Within the Arctic Circle,* 2 vol. (1876). He died in Michelstadt on March 29, 1881.

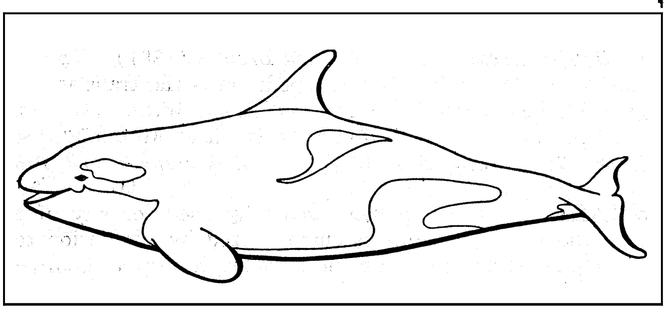
WHALE, the common name generally used for any of the Cetacea, an order of mammals characterized by adaptation to a completely aquatic form of life and divisible into three suborders: Archaeoceti, exclusively fossil, heterodont- (differentiated-) toothed cetaceans; Mysticeti, baleen or whalebone whales; and Odontoceti, homodont- (simplified-) toothed cetaceans comprising the sperm, bottle-nosed, beaked, killer. false killer and pilot whales and the dolphins and porpoises. The term "whale" is more an indication of large size than of zoological classificatory significance. The size range of cetaceans is between 4 and 100 ft., with an adult weight range of about 100 lb. to 150 tons. Cetaceans are extremely ancient as such and probably arose very early from a relatively undifferentiated mammalian ancestral stock. They are warm-blooded, lung-breathing animals with skeletal, vascular, alimentary, respiratory, sensory and reproductive features fundamentally the same as those in other mammals and not as in fishes, despite their superficial general resemblance to the latter. They have exploited all the available aquatic habitats: the oceans and the seas connected with them, estuaries and rivers; one species (Lipotes vexillifer) lives in a lake of the Yangtze river 600 mi. from the sea.

Whales yield several products of commercial value around which has grown the whaling industry (see WHALE FISHERIES). Whale meat, eaten for centuries by the Chinese and Japanese, has become a food specialty in other parts of the world. Whale oil (*q.v.*), whalebone and ambergris (*q.v.*) are other products that find uses in many industries. (F. C. FR.)

Whales in Legend and Literature. — The vast size and inaccessibility of the great whales in the oceans has always aroused men's curiosity and exercised their imaginations. A stranded whale must have been a boon to hungry primitive man. The whale has become the symbol of everything enormously huge, and the term is so used even in modern slang. In addition to mention of the whale among the writers of antiquity and in the Bible, it enters into many traveler's tales of later date, with stories of ships being stranded upon sleeping whales, of sailors landing upon them in mistake for islands and of ships being engulfed by furious whales. Apart from casual mention by many later writers and poets, from Shakespeare on, the whale reached its zenith in fiction with Herman Melville's *Moby-Dick; or,* the Whale (1851). *Moby-Dick,* like several later works of other authors, was based upon real life experiences of the author.

It is however the smaller whales, the dolphins, that have been the subject of the most charming legends. Aristotle, Pliny and other classical writers reiterated the belief that dolphins are the friends of man and that they delight in bearing his ships company and running races with them however fast they sail. Dolphins were supposedly especially attached to boys, and there are many stories of tame dolphins that came to hand when called and even carried their young friends upon their backs daily to and from school. (These legends are probably founded on the truth, for several modern instances are known of dolphins fraternizing with bathers and allowing youngsters to ride upon their backs.) Pliny told how dolphins entered the Nile river and battled with crocodiles. Among the fishermen of the Spanish- and Portuguese-speaking peoples a belief persists that dolphins attack and drive sharks away. The sculptured dolphins so frequently included in the statuary of fountains are a mixture of fish and cetacean (see DOLPHIN), generally with the emphasis on the piscine features. Both the whale and the dolphin have constellations named after them. (L. H. M.)

External Form. — The general body shape is fusiform or spindle-shaped with the head end modified variously into a more or less attenuated beak, rounded, bluff or flattened (fig. 1). The tail



AFTER LUTKEN

FIG. 1.—KILLER (ORCINUS ORCA), THE LARGEST OF THE DOLPHINS

end is always produced into two horizontal fleshy lobes, the flukes, which, by nicely adjusted inclination of their surfaces and the mainly vertical movement of the tail stock. propel the body through the water (fig. 2). The forelimbs (flippers) are paddle-shaped and subserve the functions of equilibrating and steering. A

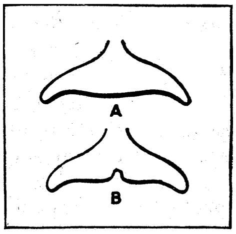


FIG. 2.— TAILS
(A) Tail of Ziphioid
(B) Tail of dolphin

fleshy dorsal fin is generally present, situated about the middle of the body length in smaller cetaceans and about two-thirds of the total length in larger species. Unlike the flippers, which enclose the recognizable elements of the mammalian forelimb skeleton. neither dorsal fin nor flukes have bony support. All three forms of appendages are alike in tapering from a thick, rounded leading edge to a thin trailing edge. No external trace remains of the hind limbs and no ear pinnae are to be distinguished adjacent to the inconspicuous entrance of the external ear tube. The nostrils (blowholes) are remote from the snout tip (except in the sperm whale), being situated near or on the highest part of the head (fig. 3). Eyes are present and usually fully functional, but vision is said to be reduced in some river dolphins. The skin is exceedingly smooth and devoid of hair, except for occasional remnants on the snout and lower jaw (mandible). Near the beginning of the hinder third of the body are found the reproductive opening and the vent. The position of these openings roughly defines the otherwise undeterminable root of the tail. Near the reproductive opening of the female is a pair of evertible teats, each usually concealed in a groove.

AFTER ESCHRICHT AND REINHARDT

FIG. 4.—(A) LOWER JAW OF TOOTHED WHALE (ZIPHIUS, MALE); (B) SKULL OF BALEEN WHALE (MEGAPTERA) FROM ABOVE

Other Characteristic Anatomical Features. — The facial part of the skull is elongated into a rostrum the maxillary bones of which. at their hinder ends, are squamous (wide-spreading) and override the frontal bones in the toothed whales and, to a nearly similar degree, extend under the orbital processes of the frontals in baleen whales (fig. 4[B]). This "telescoping" of the cetacean skull, and the laminated bony structure so produced, together with a high, short, broad brain case result in a skull form that is far removed from the conventional mammalian pattern. To these features must be added the enormous development of the bony processes from the cranium — maxillary, supraorbital and zygomatic—and the unique asymmetry of the rostral and nasal regions of the toothed cetaceans.

The orbit is bounded massively above by the outer limit of the orbital process of the frontal; below, the boundary formed by the zygomatic process of the jugal is contrastingly slender. The nose tubes at first pass nearly vertically downward in front of, and subsequently underneath, the brain box, their extent being emphasized by the backward prolongation of the hard palate, the hinder end of which bounds the air passage ventrally. The shell-like, massive, tympanic bullae are fused by slender bony pillars to the associated periotics (bony casing of the inner ear), but these combined elements are themselves never united with the adjacent cranial bones. Sinuses, distinguishable as maxillary. frontal or ethmoidal, are lacking in all cetaceans.

The neck vertebrae, seven in number, are short and are often blended together to a greater or lesser extent. The thoracic vertebrae vary in number from 8 in Hyperoodon (the bottle-nose whale) to 17 in *Caperea* (the pigmy right whale). In the baleen whales the ribs differ greatly from those of other Mammalia in their extremely loose connection both with the vertebral column above and the sternum below. In the toothed whales the ribs are long and slender. the first four or five are normal in having the head, neck and tubercle; the posterior ribs are articulated solely by the tubercle to the transverse process. The breastbone is greatly reduced in size in the baleen whales and is of variable shape. In the toothed whales the presternum is very broad and is followed by two or three mesosternal segments, all elements fusing into a single bone in the adult. Thoracic vertebrae are followed posteriorly by lumbar vertebrae, generally distinguished by the increased height of the neural spines and the increasing length of the transverse processes, both attaining their maximum development in this region. No part of the backbone is specially modified to form a sacrum. The caudal (tail) vertebrae are characterized by progressively diminishing dimensions of their neural spines and transverse processes and by association of their centre with ventrally situated simple chevron bones. The shoulder blade is fan shaped, with both acromion and coracoid (wanting in *Megaptera*) situated near or on the anterior border.

The forearm, wrist and fingers are incapable of independent movement; the whole limb is hinged at the shoulder. The upper arm bone (humerus) is short, stout and robust; the forearm bones (ulna and radius) are more elongated, but still short by comparison with the combined length of the mosaiclike carpal region, metacarpals and digit bones. In some of the fingers the bones are more numerous than they are in the fingers of other mammals.

The greatly reduced pelvis is represented by a pair of slender, irregularly curved bones, remote from the backbone, embedded in flesh in the vicinity of the reproductive opening. In some of the larger whales bony or cartilaginous remnants of the hind limb skeleton still persist as attachments to the pelvis.

The brain is large and typically mammalian in general structure, but the globular shape, complex convolutions of the cerebral hemispheres and large size of the cerebellum combine to distinguish the cetacean brain from that of any other mammal. The olfactory lobes are greatly reduced or altogether absent.

The system of arteries and veins is much the same as in other mammals, but the retia *mirabilia* (subdivision of parts of the vascular system into plexuses of vessels) are remarkable .in their profusion. The blood supply to the brain is unconventional: the internal carotid arteries are greatly reduced, and their function of carrying blood to the brain is performed by the spinal meningeal arteries, which pass forward into the cranial cavity from the thorax region through the passage formed by the arches of the thoracic vertebrae. The kidneys consist of many small lobes, each renal mass being composed of many smaller kidneys (*reniculi*) numbering up to about 3,000 in the blue whale. The male organ can be retracted into a pouch within the general contour of the body. The testes are within the abdomen. The uterus is bicornuate and the placenta diffuse.

Respiration. — The single nostril (blowhole) of toothed cetaceans and the paired slits of the baleen whales are, with one or two exceptions, situated on the top of the head remote from the snout tip. The blowhole apertures are closed muscularly, more simply in baleen whales, and by a complicated arrangement of plugs. valves and air-filled cavities in the toothed cetaceans. A continuous air passage from blowhole to lungs is effected by the insertion of the spoutlike prolongation of the larynx into the hinder end of the nasal cavity, in which the prolongation is held by powerfully developed palatal muscles. Food going from mouth to esophagus has to pass on either side of this narially inserted, elongated larynx (fig. 5). The system of supporting rings of cartilage in the trachea (windpipe) is continued through the bronchi into the bronchioles, the latter being furnished with muscular sphincters

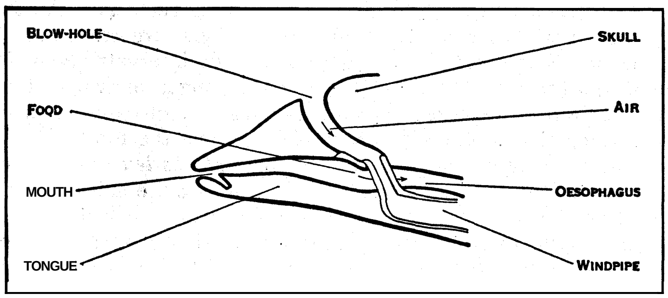

FIG. 5.— MEDIAN SECTION OF THE HEAD OF A PORPOISE. TO SHOW THE COURSE TAKEN BY AIR AND BY THE FOOD

except, according to E. J. Slijper, in the sperm and baleen whales (see Bibliography).

Although whales sometimes idle at the surface, blowhole above water, the normal respiratory pattern is one in which the whale, after a period of submergence, comes to the surface a number of times in quick succession, exhaling (blowing) and inhaling on each occasion. This period of successive respirations alternating with shallow dives is succeeded by a period that commences with the final inspiration of the preceding phase, includes a much deeper dive and more prolonged time of submergence and terminates with the ascent to the surface again.

The blow (spout) of the bigger whales is conspicuous and can be detected at a considerable distance. Its shape is used by experienced whalers to distinguish different kinds of whales: in the rorquals it is single, vertical and plumelike; in the humpbacks, low and bushy; in the right whales, double and directed obliquely forward; and in the sperm whales, single and directed obliquely forward. The blow is made visible by the condensed moisture due to sudden expansion and therefore cooling of the exhaled breath together with a certain amount of waste matter from the respiratory passages and adjacent air spaces. It is not as is popularly believed a fountain of water as such.

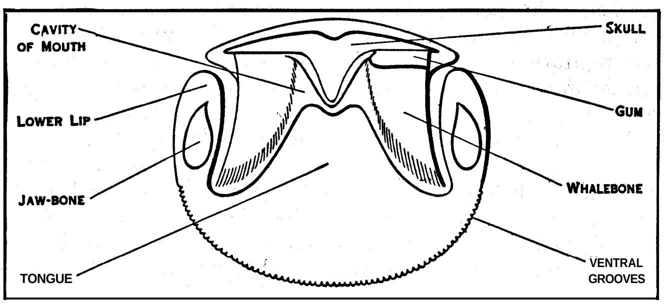
During submergence the whale is subjected to the pressure conditions imposed by the depth attained. The question of the whale's immunity from caisson disease (the bends) was answered by P. F. Scholander, who showed that the essential difference between the cetacean and the human diver is that the former dives with only the air that is in its lungs, while the latter has a constant replenishment of air throughout' the diving period. with all' the implications of increased nitrogen solution in the blood under pressure and the subsequent gasification if relief from pressure is too rapidly achieved. The accommodation of the air contained in the lungs when the whale is submerged is linked with the obliquity of the diaphragm. As the water pressure increases with depth, the air in the lungs is compressed, and the space so created in the thoracic cavity is occupied by the pushing forward of the diaphragm by the pressure of the abdominal viscera and perhaps also by the compression of the rib basket.

It is thought that delicate terminal small cavities (alveoli) of the lungs are evacuated under conditions of pressure and that the lung air is lodged in the more rigid, thick-walled, cartilage-strengthened wind pipe and its branches and in the nasal passages. Since the walls of these cavities have little capacity for absorbing nitrogen, in this way also the whale avoids the potential harmful effect of even that proportion of the gas that is contained in the air in the lungs when the animal submerges.

The myoglobin in cetacean muscles is an important reservoir for the storage of oxygen, in addition to the oxygen accumulated during successive respirations and stored in the blood and in the air contained in the lungs. Even these combined supplies are not believed to be adequate provision for a whale swimming actively and submerged for a period up to half an hour. It is suggested that the muscles may function anaerobically (without replenishment of oxygen) during the dive and that the retia *mirabilia* may act as a shunt. ensuring that while the muscles may be deprived of their oxygen supply, the brain is adequately supplied during the whole period of submergence.

Hair, Baleen and Blubber. — Hair. — Hair in the form of a pelt or protective coat is not found in any existing cetacean. Among the baleen whales hairs, in countable numbers, are restricted to the head. Single hairs are dispersed at wide intervals along the snout; on the chin from 20 to 40 hairs, arranged in two'vertical rows, have been recorded, with further sparsely distributed single hairs along the side of each mandible. Among the toothed cetaceans the beluga or white whale (Delphinapterus leucas) and the narwhal (*Monodon* monoceros) are said to be quite hairless at all stages of development and growth. The white-beaked dolphin (Lagenorhynchus albirostris) carries a few bristles on the sides of the snout during late fetal and early postnatal life but about weaning time these are shed and not replaced. Throughout life the amazon dolphin (*Inia geoffrensis*) bears a few scattered bristle hairs on its slender snout. A tactile function has been suggested for the bristles.

Baleen.—The Mysticeti, or baleen whales, are distinguished from others by the possession, within the mouth, of a double series of triangular horny plates (fig. 6), one set or "side" on each half of the palate. Since these plates do not consist of true bone, the term "baleen" should be used in preference to "whalebone" to



AFTER DELAGE

FIG. 6.— TRANSVERSE SECTION OF A RORQUAL'S HEAD TO SHOW WHALEBONE

avoid confusion. The baleen plates are anchored in the roof of the mouth and are spaced apart by a brief interval from one another, their plane surfaces being at right angles to the long axis of the head The smallest side of the triangular outline is inserted in the jaw, the outer (labial) side is smooth and the inner (lingual) is frayed out into a fringe of bristles. The fringes combine to form a matted sieve or strainer for collecting the planktonic animals on which baleen whales depend for nourishment. The plates are longest (to 12 ft.) in the right whales, and shorter, broader and less flexible in the rorquals A "side" may be composed of upward of 300 plates. Essentially baleen does not differ from hair, and. like the latter, has its origin in the skin. Horn tubes. and compacting horn between these, are enveloped, except at their outer ends (the fringe), in a covering layer. These components combine to form a plate. Between adjacent plates is a pad of softer horn, the intermediate substance. The foregoing description of the plates applies also to the transverse rows of small subsidiary plates situated on the inner aspect of the larger ones.

Blubber.—The body of the whale is enveloped in a layer of subcutaneous fat called blubber. The outermost layer of the skin (stratum *corneum*) is paper-thin and delicate; beneath this is a problematical even thinner layer, the *stratum lucidum.* Still deeper is a thick layer, the *stratum germinativum,* into which penetrate the papillae of the dermis. The dermis merges into the hypodermis, the blubber layer in the restricted sense. The blubber layer is, relative to the other layers, of immense thickness; it is a white. rubbery, tough layer, composed of fat cells and fibrous tissue. It functions as an insulating layer for the retention of body heat in animals whose temperature is always higher than the water in which they live. The internal temperature of a whale (92° F. in a stranded fin whale) is not much different from that of a man. But with the exertion of active swimming. the heat generated beneath the insulating blubber layer tends to increase. In order to maintain its normal body temperature the whale must dissipate the mounting heat. The whale lacks the system of sweat glands common to land mammals and is deprived, by the intermittance of its breathing, of the cooling effect that, for example, a dog obtains from panting. It has been suggested. however. that the flippers, dorsal fin (when present) and flukes, being without blubber, act as radiators and that a system of arteries, each surrounded by a meshwork of veins, acts in combination as a counter-current heat regulating arrangement, conserving the body heat when the whale is inactive and dissipating it from the surface of the appendages when vigorous muscular action tends to make the body temperature increase. In addition to its insulating function the blubber serves also as a food reserve in which fat accumulates when the whales are actively feeding and from which it is withdrawn when food is scarce.

Feeding Adaptations and Food.—The digestive tract and the feeding apparatus show several special features associated with feeding habits. Food enters the large gape and passes unchewed through the esophagus and into a specialized several-chambered stomach. This specialization of the stomach is related to the simplification of dentition, which requires that the food, swallowed whole, undergo prolonged digestion in the various chambers. On analogy with the dentition and food of the crabeater seal the serrate-edged teeth of even the earliest of the archaeocetes may be said to be adapted for dealing with gregariously occurring macroplanktonic species such as the shrimplike crustaceans known as krill, or even smaller fishes, rather than for a carnivorous diet of larger animals. In those cetaceans that are carnivorous (in the generally accepted sense), the teeth are simple, uniform, peglike and single rooted, and frequently exceed the primitive mammalian number, with the top teeth interdigitating, when the mouth is closed, with those of the lower jaw. The teeth are used for seizing prey, which is not chewed before being swallowed.

Generally, dolphins and porpoises eat fishes. but the common dolphin at least also adds cuttlefish to a diet that includes herring and pilchards. Some of the larger delphinids, for example the false killer. the pilot whale and Risso's dolphin, feed either exclusively or predominantly on cuttlefish. The last-named dolphin has teeth reduced to two to six on each side of the lower jaw and none in the upper. This reduction of teeth in association with a cuttlefish diet is even more emphasized in the bottle-nosed and beaked whales whose slender jaws bear a pair (at most two pairs) of functional teeth in the mandible and none in the upper jaw (except in *Tasmacetus*). The sperm whale, in which functional teeth are restricted to the lower jaw, eats large squids almost exclusively, but fishes may also be taken. The killer is exceptional in eating marine mammals (dolphins, porpoises and seals) and aquatic birds such as penguins in addition to salmon, sharks and other large fishes, but squid are also taken. The baleen whales are plankton feeders, including in their diet crustaceans such as krill (euphausians), copepods (*Calanus finmarchicus*) and fishes such as herring, sardines and capelin. The nourishment of these great whales is dependent on the swarming habit of the food animals involved.

Ambergris, a waxlike concretion formed in the intestine or stomach of the sperm whale. is a valuable substance used in the manufacture of perfumes. It is a debated point whether ambergris is a normal or pathological product and whether it is released during life or after death. Some believe that squid beaks cause an inflammation of the intestinal tract and stimulate the formation of ambergris.

Sense Organs.—Smell.—The sense of smell is almost or altogether lacking. The baleen whales still retain a reduced olfactory organ with a nerve supply from the olfactory lobes of the brain passing through a recognizably sievelike cribriform plate; but in the odontocetes the olfactory lobes have atrophied, the cribriform exit from the skull has been shut off by an overgrowth of the ethmoidal bone and the olfactory organ has disappeared.

Sight.—The lens of the eye is modified to accommodate vision to aquatic conditions: the sclerotic capsule is enormously thickened; the optic nerve is ensheathed in thick connective tissue and a network of blood vessels; the conjunctiva is composed of horny epithelium; and the lachrimal glands produce a waxy, not watery, exudation. The anterior chamber of the eye has provision for a rapid inflow and outflow of the liquid it contains, and both aqueous and vitreous humour have a diminished freezing point. The muscles of the eye are functional and of conventional number and disposition.

Hearing.—The sense of hearing is without question the dominant long-range perceptor, cetaceans depending principally on their ears for awareness of their surroundings. The reception of sounds is by a system of hearing comparable with that used by terrestrial mammals, but with modifications of the structural components needed for receiving and transmitting water-borne instead of air-borne sounds. The external aperture of the ear is minute in toothed cetaceans and inconspicuous in even the largest whales. There is no external ear flap (pinna). The cartilages that normally support the pinna are withdrawn under the skin and blubber but still provide insertions for functional "external" ear muscles required for adjustment of tension of the ear tube, which the cartilages partially surround. The ear tube is a duct openly extending to the eardrum in the odontocetes; in the baleen whales it is at first open but deep to the blubber the space is obliterated and it passes some way toward the ear drum as a solid cord. Nearer to the beginning of the middle ear the diameter of the passage increases and the tube is filled internally with a solid laminated mass of desquamated epithelium (flaked skin) and wax. The number of laminations of the ear plug is a guide to the age of the baleen whale. The ear plug fits like a dunce's cap over the grossly enlarged flaccid membrane of the ear drum. In the toothed cetaceans the flaccid membrane is of approximately normal proportions. The fibrous part of the tympanic membrane is ligamentous, not membranous, in structure. It is attached at its inner end to the tip of the "handle" of the malleus. The latter is fused by its channel-girder-shaped *processus* gracilis to the edge of the tympanic bulla. a process to which it gives support along one edge (the sigmoid process). Incus, stapes and cochlea are of conventional mammalian form.

The form of the tympanic ligament. the mode of its attachment to the malleus and the anchoring of the malleus to adjacent bone provide the means for vibrations transmitted along the ligament to be converted into greatly amplified, rotational. molar vibrations of the head of the malleus. The amplification is such that it makes good the difference between the displacement amplitude of sounds in water and in air (1:60). Similarly, by the ratio of the area of the foot of the stapes to that of the distal end of the tympanic ligament and the leverage of the ossicles, there is compensation for the loss in power due to the ossicular leverage, so that the vibrations presented by the foot of the stapes at the oval window are in all ways comparable with those received by the cochlea of a terrestrial mammal. By a system of foam-filled air sacs extending from the middle ear, the hearing mechanism of cetaceans is acoustically isolated from the effects of sound vibrations extraneous to those transmitted along the meatus. The air sacs also perform the function of maintaining a constant balance between external hydrostatic pressure and middle-ear gaseous pressure by a reciprocal adjustment of the amount of blood in the vessels lining the sacs to the varying hydrostatic, pressure-dominated volume of the air-sac spaces. The foam in the middle-ear sacs, while compressible in response to ambient pressure variations. still maintains its gaseous content and. therefore, also the sound-isolating function of the air sacs, at whatsoever depth the cetacean happens to be.

The range of sounds perceived is much greater in cetaceans than in terrestrial mammals. with an upper limit of about 120 kc. (the human upper threshold lies between 15 and 30 kc.).

Sound **Production.**—Cetaceans emit a considerable range of sounds. from low "creaking gate" noises to high-pitched whistles, which can be related to various activities such as feeding, breeding, aggressive display and communication. The dolphin calf starts emitting high-pitched whistles as soon as it is born. That some of the sounds emitted are used in echo-location has been proved, and it has been shown that bottle-nosed dolphins can range in. from a distance, on a comparatively small target in circumstances under which hearing is the only sensory means available for detection. The animal picks up its target by the transmission and reception of an intermittent pulse with a variable recurrence frequency. much as the bat locates its food and avoids obstructions while in flight in' the dark. The dolphin may be said to obtain an assessment of its environment predominantly by auditory impressions, for many of them live in turbid estuaries or river water, while some of the bigger cetaceans descend to depths of extreme light attenuation, conditions in which vision is of, at most, extremely limited use.

Breeding and Reproduction.—Most whales are gregarious during certain times: for example, during migration or at the breeding season schools numbering several hundred individuals may be seen. Smaller groups are referred to as pods or gams. Whales are often found alone as well. The Cetacea are in all respects mammalian in reproduction. The uterus is bicornuate and the placenta of the developing fetus is diffuse. Fetal life generally extends to about a year, but in the humpback whale it is 11 months and in the sperm whale 15 months. The larger cetaceans are usually sexually mature in their fifth to sixth year and produce young in alternate years.

Many of the smaller cetaceans give indication that parturition and pairing are accomplished in the early summer; and although in the bigger whales these activities may occur over a wide period of months, there are nevertheless indications, so far as parturition at any rate is concerned, of a period of maximum frequency. A single calf is normally produced, but twins occur, and there is fetal evidence of occasional larger numbers. The size of the newly born calf is large in relation to that of the parent; for 'example, in the common porpoise the calf is just over 2 ft. long at birth from a parent of about $5\frac{1}{2}$ ft. There is a recorded measurement of $24\frac{1}{2}$ ft. for a full-term fetus of a blue whale from a parent 93 ft. long.

Growth is fairly rapid; a sperm whale calf, for example. may double its length in the first year and may attain adult size in two or three years. The average life span is about half that of a human being.

The calf is delivered in the water and is able to swim as soon as it is born. It is suckled for a period of several months, up to one year in humpbacks. keeping close to the mother until weaning time. Suckling is accomplished as in other mammals. but with the provision for doing so under water. The milk secreted by the mammary gland flows through large channels (galactophorous sinuses) and collects in the lacteal duct. The mammary gland lies between superficial skin muscles and deeper body muscles, which, by their contraction, force the milk out of the lacteal duct and through the nipple. Suckling can thus be accomplished speedily. The tongue of the calf is provided with a strong muscular ridge along each side of its upper surface with an intervening longitudinal depression that widens out into a basin behind the tip of the tongue. When the tongue is applied to the palate a tubular passage is formed so that, when the calf grasps in its mouth the everted nipple of its parent, the milk, free of any surrounding sea water, can be swallowed.

Migrations.—The principal movements of many whales are largely connected with the two functions of feeding and reproduction. For example, the large baleen whales are found in the high latitudes of the Arctic and Antarctic during the summer months, when they become fat from the food they eat. Correspondingly, in the winter time they disperse into the warmer subtropical waters where pairing takes place and where the young are born. Some of the migratory movements of the whales—as, for example, those of the Californian gray whale along the west coast of America and of the humpback along the coast of New Zealand, on their journeys to and from the Antarctic—are predictable within fairly narrow time limits.

CLASSIFICATION

The following taxonomic scheme is one of several in general use:

Suborder Archaeoceti (extinct)
Family Basilosauridae
" Dorudontidae
" Protocetidae
Suborder Mysticeti, baleen or whalebone whales
Family Eschrichtidae, gray whale
" Balaenidae, right whales
" Balaenopteridae, rorquals, etc.

Suborder Odontoceti, toothed whales
Family Ziphiidae, beaked or bottle-nosed whales
" Physeteridae, sperm whales
" Monodontidae, narwhal, etc.
" Platanistidae, river dolphins
Subfamily Platanistinae
" Stenodelphininae
" Iniinae
Family Phocaenidae, porpoises
" Delphinidae, dolphins, etc.
Subfamily Orcinae
" Lissodelphinae
" Cephalorhynchinae
" Delphininae
Family Stenidae

Suborder Archaeoceti.—The Basilosauridae, Dorudontidae and Protocetidae, of the Eocene and Oligocene periods constitute this group. The Archaeoceti are believed by some to be derived from the Creodonta, primitive fossil members of the Carnivora; but W. K. Gregory thinks that they may have descended from Insectivora of the kind represented by *Pantolestes*. G. G. Simpson's opinion, the creodont hypothesis already mentioned, should be borne in mind however, so that the lack of differentiation common to the eutherian ancestral stock is not itself taken as an indication of affinity between one and another existing order. The skull characters of the archaeocetes are intermediate between those of their supposed ancestors and those of recent Cetacea in the position of the nostrils; the relations of the maxillae; and the dentition, which consists of three incisors, one canine, four premolars and two to three molars on either side of each jaw. The first four or five teeth are conical and single rooted; the other teeth are double rooted with serrated crowns. A milk dentition is found.

The teeth of the recent Cetacea are not differentiated into incisors, canines and molars. Whether the dentition of the odontocetes represents the milk or permanent series is debatable. The *Squalodontidae* (Oligocene to Pliocene), included in the Odontoceti, are believed to have descended from the archaeocetes and to hdve given rise to some at least of the recent toothed whales. The origin of the Mysticeti is uncertain but it may be a pointer to an odontocete ancestry that their fetal teeth are. in each tooth row, greatly in excess of the number conventional in primitive mammals.

Suborder Mysticeti.—Baleen or whalebone whales. Baleen present. Teeth lacking in the adult; numerous and vestigial in the embryo. Lower jaw large, the paired mandibles bowed outward and loosely united in front. Blowholes, two posteriorly divergent longitudinal slits. Skull symmetrical; the nasal bones relatively well developed; posterior extension of maxillae below the supraorbital processes of the frontals. First pair of ribs alone joining the sternum, which consists of one piece. The females are slightly larger than the males (some of the whales described below are compared with the size of an elephant in fig. 7).

Family Eschrichtidae.—*Eschrichtius glaucus,* the Californian or Pacific gray whale (45 ft.). Head small. less than one quarter the total length. No dorsal fin; flippers four-fingered. Hairs are scattered over entire head and loner jaw. Baleen blades are short and relatively few (138–174 in a "side"). Neck vertebrae not fused. Pelvis large. Ventral grooving of the skin in the throat region restricted to two or three in number. The gray whale prefers shallow water, swimming even in the surf, and occurs in the North Pacific, from California to the Arctic ocean. and off Japan and Korea.

Family Balaenidae.—Right whales. Skull much arched. Baleen long. narrow and flexible. No ventral grooves. Neck vertebrae fused.

Caperea marginate, pigmy right whale (20 ft.). Zygomatic and supraorbital processes less extended than in other representatives of the family; rostrum less arched: head smaller (one-fifth total length). Contrastingly specialized in relation to its relatives in having dorsal fin and only four digits in each flipper. Baleen typically right whale shape, about 230 plates in each "side." It is known from New Zealand. Austria and South America.

Balaena, Dorsal fin wanting; flippers broad, with five fingers. Head one-quarter to one-third total length.

Balaena mysticetus, Greenland right whale or bowhead whale (60 ft.). Head enormous, nearly one-third total length. Rostrum greatly arched to accommodate baleen plates having an average length of 10–11 ft., about 300 plates in each "side." Body colour predominantly black or dark gray, but the white chin and front portion of lower jaw are diagnostic (sometimes the tip of the upper jaw and associated baleen is white); black may shade into gray in vicinity of eye and of axillary region. Arctic, circumpolar and formerly abundant off Spitzbergen, both sides of Greenland and North Pacific to Beaufort sea.

Balaena glacialis, the Biscayan or North Atlantic right whale (maximum 60 ft.). Head less arched. Baleen shorter than in Greenland right whale and lower lip shape different. No constant white patch at tip of lower jaw; generally black all over but irregularly distributed white patches occasionally on the under surface of the body. Formerly common in the Bay of Biscay. and along the eastern coast of the United States and in Icelandic, Norwegian and British waters, its northern range coinciding nearly with the southern limit of the Greenland whale; but, like other right whales, it avoids the tropics.

Bnlaena australis, the southern right whale, not conclusively distinguishable from *B. glacialis*. Occurs in southern waters off Australia, New Zealand. Kerguelen, South Georgia, South Shetlands, Gough Island, Tristan da Cunha and South Africa. *B. japonica,* frequenting seas off Japan. Like *B. australis,* this is not certainly a distinct species.

Family Balaenopteridae.—Rorquals and the humpback. Rostrum much less arched and broader than in Balaenidae. Baleen blades shorter, broader and less flexible. Dorsal fin present. Skin covering throat has numerous conspicuous longitudinal grooves; flippers narrow. Neck vertebrae free.

Balaenoptera, rorquals. Body relatively slender. Dorsal fin well marked; flippers small, narrow and pointed.

Balaenoptera musculus, blue whale or Sibbald's rorqual (maximum 100 ft.) is the largest of all animals. Dark slate-blue colour predominating over whole body, including both surfaces of the tail flukes, but lighter flecking may be widely distributed. Cosmopolitan. on the assumption that (as in others of the family) the northern and southern races belong to the same species, from polar to temperate seas, occasionally reaching equator. Food, chiefly krill (euphausians).

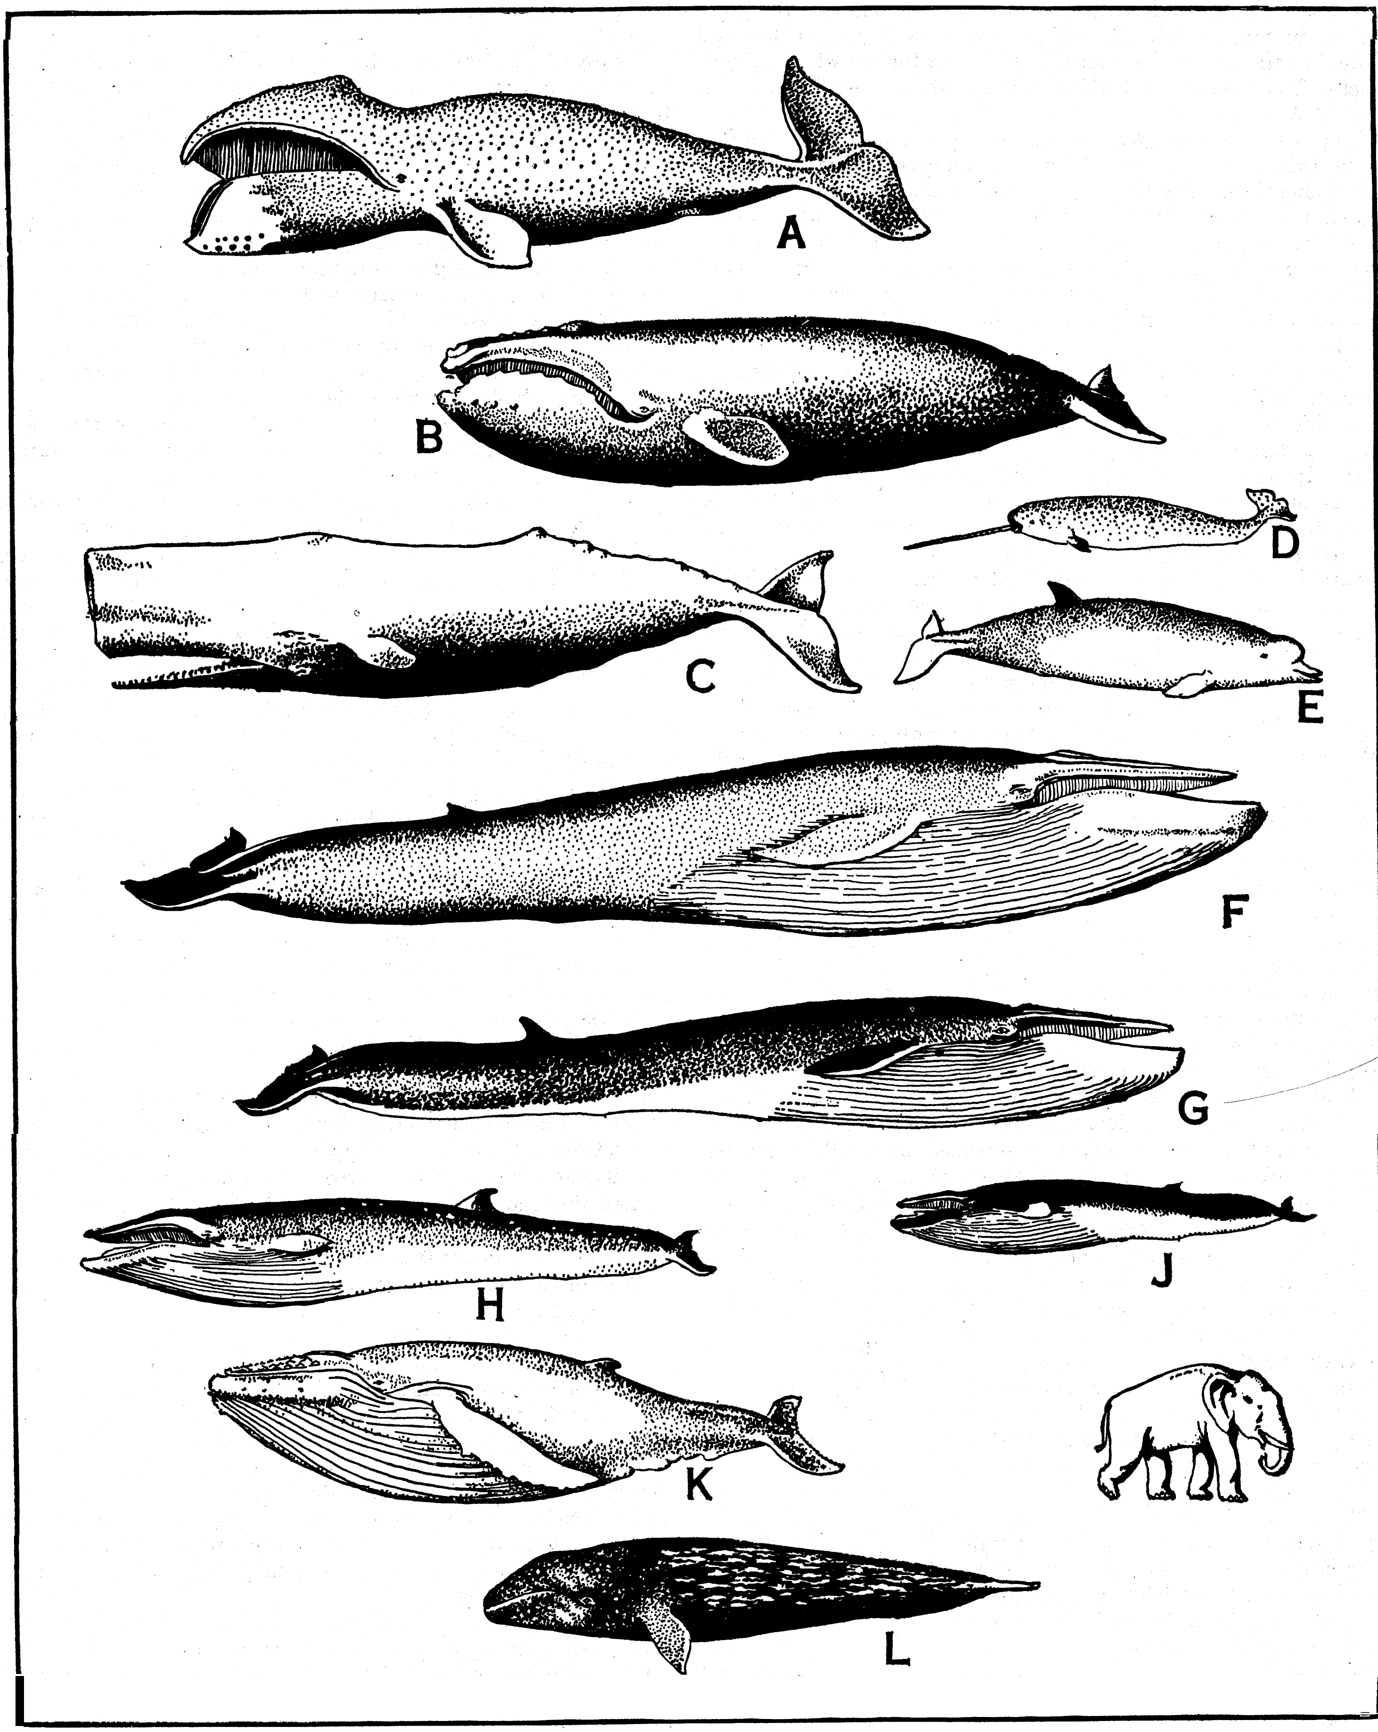
Balaenoptera physalus, fin whale, finner, common rorqual or razorback (maximum about 80 ft. in south). Dark above, pure white below, including the lower surface of the tail flukes and inner side of flippers. Right lower jaw white externally, left pigmented externally, with reverse arrangement inside mouth. Baleen blades anterior third of right side of mouth white, remainder on right and the left sides Blue-gray with streaks of white and yellow; all baleen fringes white. Cosmopolitan in distribution with (as in others of the family) seasonal migrations from lower to higher latitudes and vice versa.

Balaenoptera borealzs, Sei whale or Rudolphi's rorqual (maximum about 60 ft.). Bluish-black back, belly and tail; white area from chin to varying distance along belly but never to tail; lower surface of tail flukes dark. Baleen black. with white, silky. curling fringes, fine in texture. Food, euphausians, sardines and the copepod *Calanus.*

Balaenoptera acutorostrata, lesser rorqual, minke whale or piked whale (maximum 33 ft.). Coloration much as in the fin whale but lacking asymmetrical features. A conspicuous white area on the outer side of the flipper. Baleen and its fringes uniformly yellowish white. Food, largely fishes including herring, cod, capelin and planktonic crustaceans. Temperate and polar latitudes of both hemispheres, including British and North American coasts.

B. bonaerensis and *B. huttoni,* the former from Buenos Aires, the latter from New Zealand. Together with a small number of specimens from the Antarctic, these forms are uncertainly specifically different from *B. acutorostrata,* but flipper colour and baleen colour suggest a distinction.

Balaenoptera brydei, Bryde's uhale. Comparable in size and in many other features with Sei whale. Differing from the latter



FROM (B) ALLEN. 'WHALEBONE WHALES OF NEW ENGLAND,' (C) SCAMMON 'MARINE MAMMALS OF N.W AMERICA ' (E) "NATUURKUNDIGE VERHANDELINGEN " (F, G, J, K) "CHRISTIANIA VIDENSKAPSSELSKAPS FORHANDLINGEN,' (H, L) ANDREWS. "MEMOIRS OF THE AMERICAN MUSEUM OF NATURAL HISTORY

FIG. 7.— VARIOUS TYPES OF WHALES

(A) Greenland whale (after Scoresby); (B) Atlantic right whale; (C) sperm whale; (D) narwhal (after Scoresby); (E) bottle-nosed whale (after Vrolik); (F) blue whale (after Sars); (G) fin whale (after Sars); (H) Sei whale; (J) lesser rorqual (after Sars); (K) humpback whale (after Sars); (L) Pacific gray whale (African Elephant, "Jumbo," 11 feet high, reproduced to same scale) principally in the quality of the baleen, the fringes of which are coarser in texture and the individual bristles larger, thicker and stiffer, average length of blades is less than for Sei whale Food, chiefly fishes including herring and mackerel. South and west Africa, West Indies.

Megaptera novaeangliae, humpback (maximum about 50 ft.). Body thick. Dorsal fin ill-defined: flippers enormously long, nearly one-third body length Colour black and white in variable proportion and distribution. Baleen and its fringes black Flippers sometimes pure white and always characteristically knobby on their anterior edge. Head likewise distinctively knobby Food, krill and small fishes. Cosmopolitan; migratory between higher and lower latitudes, tending to use inshore waters in the neighbourhood of land masses.

Suborder ODONTOCETI.—Toothed whales. Teeth present throughout life, No baleen. Lower jaw more or less triangular in outline (fig. 4[A]), the front part often narrow, the two halves firmly united in the adult. Blowhole single (fig. 3). Skull asymmetrical; nasals reduced; maxillae squamous above the supra-orbital processes of frontals. Several pairs of ribs joining the sternum, which consists of several elements in the young, fusing to form a single bone only in the adult.

Family **Ziphiidae.**—Bottle-nosed or beaked whales. Functional teeth greatly reduced in number. one to two pairs in lower jaw (fig. 8) (except *Tasmacetus, see* belo); vestigial teeth not uncommon in either jaw. A pair of longitudinal grooves in the throat region Dorsal fin at beginning of posterior third of body length; tail not notched at the middle of the posterior margin (fig. 2 [A]); flippers small. Food, cuttlefish. The rostrum becomes consolidated into a dense bony mass in *Ziphius* and *Mesoplodon* and fragments of these have been found in British Late Tertiary deposits, in Western Australia and from the sea bottom off South Africa.

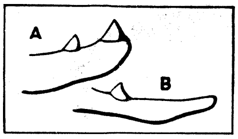


FIG 8 —FRONT ENDS OF LOWER JAWS
(A) Berardius
(B) Mesoplodon bidens

Berardius has two pairs of laterally flattened large teeth at the front end of the lower jaw (fig. 8[A]). *B. bazrdz* (40 ft), occurring in the North Pacific, is the largest existing ziphioid. *B. arnuxi* (about 30 ft.), found off New Zealand and Argentina, is not uncommon in Antarctic waters.

Ziphius cavirostris, Cuvier's whale (26 ft.) has one pair of teeth at the tip of the lower jaw, concealed in the gum in the female and pyriform. or pear-shaped. and prominent in the male. Cosmopolitan and not infrequently stranded on the British coast,

Hyperoodon ampullatus, bottle-nosed whale (male 30 ft., female about 24 ft.). Teeth small. one pair (occasionally a second smaller pair behind the first) at the tip of the lower jaw, alike in both sexes. remaining concealed till a late period. but piercing the gum, at least in old males. A large bony boss. increasing spectacularly in massiveness with age, on each maxilla, producing a progressive alteration of the forehead. which becomes enormous and gibbous (fig 9[B]) Common in the North Atlantic and frequently stranded on the British coasts, but rare in the eastern United States

Hyperoodon planifrons, the southern bottle-nosed whale. found off Australia, New Zealand. Argentina. Falkland Islands and South Shetland Isles, is distinguished from *H. ampullatus* by its lesser development of maxillary crests.

Mesoplodon — Teeth, one pair, smaller in females and usually remaining beneath the gum, according to species variously placed at the jaw tip or near the angle of the mouth

Mesoplodon mirus, True's beaked whale; rarely found Two teeth at the extreme tip of the lower jaw, inserted obliquely forward, robust and characteristically laterally flattened in the male.

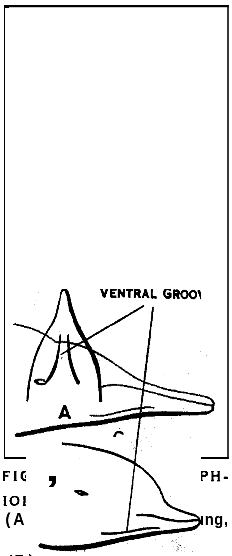

FIG PH-
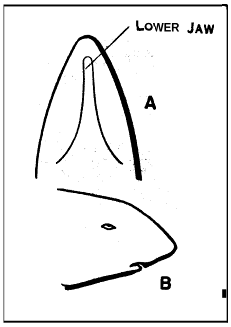
IOI
(A ng,
(B) Hyperoodon, side view
(C) Mesoplodon bidens, adult female

Mesoplodon bidens, Sowerby's whale (fig. 8[B]; 15 ft) has its pair of teeth set at about a third of the length of the lower jaw from the front end: teeth are laterally flattened. hidden in the gum of the female but exposed as short, triangular prominences in the male Those of the males of M. *densirostris, M stegnegeri, M. bowdoini* and *M. ginkgodeus* are similarly situated but greatly enlarged. In *M layardi* of South Africa. Australia and New Zealand. the teeth curve over the beak, nearly meeting and preventing the mouth being opened to more than a small extent. *Mesoplodon* species are oceanic and mostly very inadequately known.

Tasmacetus shepherdz, Oliver's beaked whale, distinguished from all other living ziphioids by having 19 functional teeth in each upper jaw row and 26 similar teeth in lower jaw rows, with a pair of larger bulbous teeth at the tip. New Zealand.

Family **Physeteridae.**—Sperm whales Teeth numerous in lower jaw; vestigial or absent in upper jaw in recent forms. Mandibular symphysis long.



AFTER ESCHRICHT AND REINHARDT
FIG. 10 — WHALE HEADS (A) HEAD OF SPERM WHALE FROM BELOW; (B) HEAD OF A KOGIA WHALE FROM THE SIDE

Physeter catodon, sperm whale, cachalot; male up to 63 ft.. female to 35 ft. Head about one-third the total length; snout massive, truncated and extended beyond the narrow ventrally situated mouth (fig 10[A]). Lower teeth 20–26 on each side, of great size, up to 8 in in length. conical; vestigial upper teeth much smaller, variable in number. The single blowhole on left side of head near the front end. Dorsal fin a low hump succeeded tailward by a further series of diminishing size. Colour dark gray or brownish on back, lightening on sides toward silvery gray, sometimes white belly, variable. The sperm whale occurs in all tropical waters but stragglers, nearly always old males, reach both polar seas Polygamous. The spermaceti organ, occupying much of the snout, consists of a fibrous "case" containing up to a ton or more of clear, colourless oil. The sperm whale can dive to great depths in search of its main food, cuttlefish, although fishes are also eaten. Produces ambergris.

Kogia breviceps, pigmy sperm whale (about 10 ft.) resembles *Physeter* in general characters, but head length only about one-sixth total length (10[B]). Flippers tapering not rounded; dorsal fin well defined and falcate (curved). Blowhole an asymmetrically situated single air passage. Lower teeth 9–14 in each row, long, slender and curved.

Family **Monodontidae.**—No dorsal fin. Neck vertebrae free. Flippers broad and bluntly rounded distally. Partial lateral bony lamina of pterygoid.

Monodon monoceros, narwhal (maximum about 15 ft.). Colour varying with age from bluish gray when young to gray-white with darker mottling when adult. Teeth unlike those of any other animal, reduced. except for concealed vestiges, to a single pair. In the female these are concealed in deep sockets in the rostrum the left one only exceptionally erupting; in the male the right tooth remaining similarly concealed but the left growing out as a straight, spirally marked tusk up to 9 ft. 43 in long (occasionally both teeth equally developed). Long. low ridge in situation of dorsal fin. Food. mainly cuttlefish but also fishes and crustaceans. Arctic. rarely reaching Britain.

Delphinapterus leucas, white whale. beluga (fig 11; 18 ft). Colour dark gray in juvenile, pure white in adult. Teeth 8–10 in each side of upper and lower jaws. Dermis of skin more developed than usual (used as "porpoise hide"). Food, fish of considerable size. cuttlefish and crustaceans. Gregarious Arctic and circumpolar. reaching the St Lawrence river and (rarely) the British coast.

Family **Platanistidae.**—River dolphins Skull less compressed from front to back than in delphinoids. Neck vertebrae all free. Eight pairs of double-headed ribs usual. Breastbone

FIG. 11.— COMMON PORPOISE. WHITE WHALE AND TYPES OF DOLPHINS

(M) Common Porpoise (a'fter Harmer) ; (N) Common Dolphin (after Flower) ; (O) White-beaked Dolphin (after Harmer) ; (P) Steno rostratus; (Q) Commerson's Dolphin (after Harmer) ; (R) Bottle-nosed Dolphin; (S) Risso's Dolphin; (T) Susu (after Anderson) ; (U) White Whale well developed. Flippers short and broad. Sight reduced or lacking. Snout and lower jaw very long and slender; mandibular symphysis extremely long.

Subfamily Platanistinae.—Lateral lamina of pterygoid entire.

Platanista gangetica, gangetic dolphin, susu (maximum 8 ft.). Dorsal fin a very low ridge. Blowhole a longitudinal slit. Large bony, maxillary crests at the base of the rostrum. Teeth 30 on either side of each jaw. Food. mud-frequenting fishes and crustaceans. Rivers Ganges. Indus and Brahmaputra, to far up stream.

Subfamily Stenodelphinae.—Lateral lamina of pterygoid fenestrated. Dorsal fin well developed.

Stenodelphis blainvillei, La Plata dolphin (5 ft.). Beak attenuation extreme. Teeth 50–60 in each row of upper and lower jaws. Blowhole crescentic; only 3–4 pairs of double-headed ribs. La Plata estuary.

Subfamily Iniinae.—Lateral lamina of pterygoid absent. *Inia geoffrensis,* Amazonian dolphin (8 ft.). Teeth 26–30 in each row, hinder ones with distinct internal heel. Beak with numerous scattered hairs. Blowhole crescentic, transverse. Dorsal fin long, low, triangular; flippers broad and cumbersome. Amazon river to 1,500 mi. from the sea.

Lipotes vexillifer, Chinese river dolphin (8 ft.). Grayish or blue-gray on the back, white on the belly. Rostrum curving upward. Teeth 33–36 in each row. Blowhole asymmetrical to the left side. Food, fresh-water fishes. Tung Ting lake, about 600 mi. from the mouth of the Yangtze river.

Family **Phocaenidae.**—Porpoises. Head with rostrum (fig. 12[D]). Dorsal fin, when present, triangular. Teeth with expanded spade-shaped crown. Tail notched posteriorly.

Phocaena phocaena, common porpoise (fig. 11; 6 ft.). Black above, white below. Dorsal fin often with small tubercles on front edge. Male reproductive opening usually far forward. Teeth 22–26. Food, mainly fishes, but also crustaceans and cuttlefishes. Coastal and estuarine. Widely distributed in European waters. and off West Africa to Dakar.

Phocaena spinipinnis, Burmeister's porpoise; and P. *dioptrica,* spectacled porpoise. South American, the range of the latter to South Georgia. P. *spinipinnis* colour entirely black. Teeth 16–17 in each row. *P. dioptrica* back black; belly and both surfaces of tail white: eye encircled by white. Teeth 19–21 in each row.

Phocaenoides, with species in North Pacific *P. truei* and *p. dalli.* Vertebrae numerous, 95–98 as compared with 64–67 in *Phocaena phocaena.*

Neomeris phocaenoides, finless black porpoise or Indian porpoise (maximum 4 ft. 6 in.). Black or dark brown. Without dorsal fin. Narrow longitudinal, depressed, finely tuberculated area mid-dorsally. Food. fishes, prawns and cuttlefish. India and Japan, marine and Yangtze river to beyond the Tung-T'ing lake.

Family Delphinidae.—Dolphins and whale-named dolphins.

Subfamily Orcinae.—No well-defined beak. Forehead globose or gibbous. Dorsal fin present: flippers tapering (except *Orcinus*). Tail notched posteriorly (fig. 2[B]).

Pseudorca crassidens, false killer (19 ft.). Teeth 8–10, massive, round in cross section. Completely black. Sporadic mass strandings in various places from Tasmania to Kiel.

Orcinus orca, killer, grampus (fig. 1; male 30 ft., female 16 ft.). Dorsal fin falcate and large in female and in young of both sexes, prominent and triangular to 5½ ft. in older male. Colour, distinctive black and white, sharply defined: a conspicuous white patch above and behind the eye; a grayish "saddle" behind the dorsal fin, Flippers rounded and, like dorsal fin and tail flukes, increasing disproportionately in the male with age. Teeth massive, pointed, with transversely oval cross section. 10–12 in each row. Food, fishes, marine birds and mammals including even the big whales; extremely voracious. Cosmopolitan; not uncommon in British and American waters.

Orcaella brevirostris, Irawadi dolphin (7½ ft.). Forehead prominent. Dorsal fin low. Teeth 12–19 in each row, small. Colour slate blue. Irrawaddy river. Burma to 900 mi. from the sea, Bay of Bengal, off Singapore and Borneo.

Globicephala, pilot or caa'ing whale, blackfish (maximum 28 ft.). Forehead greatly swollen and prominent (fig. 12[C]).

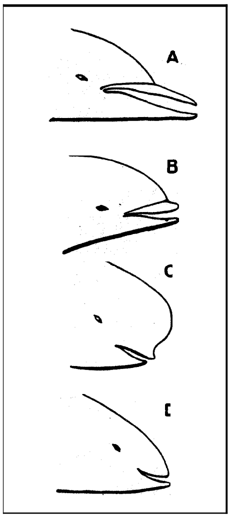

FIG. 12.— DOLPHINHEADS
(A) Delphinus
(B) Lagenorhynchus
(C) Globicephala
(D) Phocoena

Flippers long and narrow. Teeth 7–11, large at front end of the jaws. Highly gregarious to more than 1.000 in a school. *G. melaena,* northern seas. Black except for restricted white throat patch and light belly colour. Commercially hunted in Faeroe Islands and, formerly. Shetland Islands. Southern ocean. G. *edwardii* doubtfully distinct. A tropical species, *G. macrorhyncha,* Atlantic and Indian oceans, with no white patch; flippers shorter: and head more globose than in *G. melaena.*

Feresa, pigmy killer (73 ft.). F. *attenuata.* Rounded forehead, less prominent than in *Globicephala.* Teeth 10–13 in each row. Flippers moderate. falcate. Colour, dark gray except for white lips and vent. Only four specimens known. Japanese seas, Senegal.

Subfamily Lissodelphinae.—Right whale dolphins, No dorsal fin.

Lissodelphis peroni, southern right whale dolphin (6 ft.). Strikingly black and white. black of back not extending to snout, tail or flippers. Teeth small! pointed, 43–44 in each row. Southern seas.

L. borealis, North Pacific. More generally pigmented but with white ventral area.

Subfamily Cephalorhynchinae.—Small porpoiselike dolphins. Beak ill defined. Teeth 25–31 in each row. conspicuously marked.

Cephalorhynchus commersoni, Commerson's dolphin (fig. 11) or piebald porpoise, coloured as latter name. *C. heavisidei, C. hectori, C. albiventris,* like Commerson's; all are southern forms.

Subfamily Delphininae.—*Lagenorhynchus.* Beak short, plowsharelike (fig. 12[B]). Dorsal fin prominent. Vertebrae very numerous, 73–92. Usually oblique light areas on sides. *L, albirostris* (9–10 ft.), white-beaked dolphin (fig. 11); teeth 22–25, diameter 7 mm. *L. acutus,* white-sided dolphin (9 ft.); teeth 30–34, diameter 4 mm., North Atlantic species. coasts of northern Europe and eastern United States. *L. obliquidens,* like *L. albirostris,* North Pacific to California. *L. cruciger,* in general form like *L. acutus,* South Pacific. *L, obscurus,* the dusky dolphin; and *L. australis,* Southern ocean. *L. electra,* probably cosmopolitan.

Lagenodolphis hosei, form intermediate between *Lagenorhynchus* and *Delphinus,* known only from skeleton. Off Borneo.

Grampus griseus, Risso's dolphin (fig. 11; 13 ft.). Grayish, lighter below. Beak lacking. Forehead prominent. Flippers long. Teeth usually absent in upper jaw; lower teeth 2–7 confined to front end of jaw, diameter to 14 mm. Apparently cosmopolitan; not uncommon in British waters. Food, cuttlefish.

Tursiops truncatus, bottle-nosed dolphin (fig. 11). Beak well defined, 2–3 in. long. Teeth 20–22 in each row. in both jaws, diameter 9 mm. Dark brownish on back, belly white. Back fin prominent. falcate. Common in British seas and off the eastern United States. *T. gilli,* a closely related North Pacific form. *T. aduncus,* more heavily pigmented, tropical Indian and South Pacific; smaller, may be distinct. *Stenella,* with many species, often spotted or with distinctive dark narrow flank line. is oceanic. Beak 4–5 in. long, separated from rest of head by a distinct groove. General body shape and size as in *Delphinus,* but palate of skull not grooved.

Delphinus delphis, common dolphin (fig. 11; 8 ft.). Beak, as in *Stenella,* with similar well-defined groove (fig. 12[A]). Mainly black dorsally. white ventrally, but with overlapping. waved, longitudinal streaks of white. brown, yellow or gray on sides. Palate of skull with two deep longitudinal grooves. Teeth 40–50 in each row. Cosmopolitan; common in Atlantic and Mediterranean; one of the commonest British species.

Family Stenidae.—This family includes *Steno* (fig. 11), *Sousa* and *Sotalia,* long snouted dolphins of doubtful affinities inhabiting tropical waters. oceanic. estuarine and fluviatile.

WHALE FISHERIES. Whales provide food and oil. and they have long been hunted for one or both of these. although the emphasis shifted with time. In Europe, in the middle ages and earlier, they provided food, whereas between the 17th and 19th centuries the oil was important for lighting and soapmaking. There was also a demand for whalebone. In the 20th century the emphasis was again on food, for most whale oil is converted into margarine. In the early 1960s the annual world whale-oil production was about 500,000 tons, roughly equal in weight to about one-third of the butter produced. The oil production, together with about 140,000 tons of by-products for food or fertilizers, came from a world catch of nearly 55,000 whales taken by about 360 whalecatchers operating from more than 20 factory ships and nearly jo shore stations. Nearly all the factory ships operated in the antarctic, which became the major field. accounting for about 80% of the world production, but most of the shore stations were outside the antarctic. scattered along the coasts of temperate, tropical and arctic seas, for the highly mechanized industry is also world-wide in operation. Its methods andscale have such potential for destruction of the whale stocks that the industry is regulated by international agreement.

Early **Whaling.**—It is likely that Stone Age man hunted the smaller whales and dolphins. Certainly the Eskimos and North American Indians whaled from ancient times with weapons of bone and horn. flint and slate; one Alaskan whale hunting settlement has been dated back to A.D. 100 or 200. In Europe. the cradle of whaling as it subsequently developed. the earliest records concern Norway and Flanders in the 9th century. but the first important development was the enterprise conducted by French and Spanish Basques from the shores of the Bay of Biscay. Begun about the 10th century. this hunt for the Biscayan or Atlantic right whale flourished in late medieval times! was in decline by the middle of the 17th century and died out in the 18th. Meanwhile. by 1400, some of the Basques were pioneering the whaling voyage. Leaving the harbours and watchtowers of the shore fishery, they built ships which eventually followed the Biscayan whale to Newfoundland, the Gulf of St. Lawrence and, in the 16th century, to Iceland. where they found Icelanders and Norwegians already engaged in the business. By 1joo. however, the Biscayan whale in the eastern North Xtlantic was a much depleted species. But somewhere in their far northern voyages the Basques fell in with the Greenland or arctic right whale, which was more massive than the Biscayan whale, and had thicker blubber and longer whalebone.

The Greenland whale came to support a new enterprise. the northern whale fishery, which continued for three centuries after 1611 when the Muscovy company sent Thomas Edge with the "Mary Margaret" and the "Elizabeth" of London on the first Spitsbergen whaling voyage. The Basque whalemen were mostly engaged in the north under foreign flags, for they were much sought after as harponeers and expert flensers (blubber-strippers) by the British. German, French and especially Dutch vessels which came to exploit the Greenland fishery.

At first whales were killed in the Spitsbergen bays and the blubber flensed from them was boiled out in coppers (large kettles) on the beach; the populous Dutch seasonal settlement called Smeerenburg (Blubbertown) belonged to this period. Bay whaling. however, declined after 1635 and the ships began to whale along the ice between Spitsbergen and Greenland, and in the Davis strait; they flensed the whales at sea and casked the blubber for "trying-out" (melting) at home. After 1840 this ice fishery in turn began to decline. The last phase belonged to the Scottish steam and sail whalers. and these sailed as much for the long whalebone (in great demand for use as stays in corsetsj as for the oil. The last Dundee whaler came home "clean" in 1913. In the Pacific, north of Bering strait and in the Okhotsk sea, the arctic right whale had a last stronghold which was breached by American whalers after 1843; they called this whale the "bowhead." The bowhead fishery was prosecuted so vigorously that it was finished by 1908.

Turning again to the Atlantic right whale. there was a fishery on the western side of the North Atlantic started by New England settlers before 1645. This flourished for a time but was moribund by 1800. Meanwhile it had given rise to one of the greatest maritime ventures in history: this was the Xmerican sperm-whale fishery. begun in 1712 when a shore whaler. blown off the coast in a storm, fastened a sperm whale and got it safely home. Oil from the sperm whale was found to be a much superior illuminant to that from whalebone whales, while the spermaceti from the head made the finest wax candles. More and more vessels sailed from New England ports to "whale out in the deep for sperm whales." The whaleships "cut-in" (removed the blubber fromj their whales alongside. and tried out the blubber at sea. They were at the Azores in 1765, on the coast of Brazil in 1774 and in the Indian ocean by 1789. Although Great Britain (in 1788) was first after sperm whales in the Pacific, the monopoly of this world-wide industry was American; in the peak year of 1846 there were 729 Yankee whaleships at sea. The slow decline which followed (although the last sperm-whaling voyage was not made until 1925) was due to several causes. including the discovery of petroleum in Pennsplvania in 1859. The sperm-whale fishery was the only old-style venture which may not have ended through overfishing.

As a consequence of the sperm whalers' explorations, two further species were exploited. The southern right whale. at first taken in great numbers around the southern continents and subantarctic islands. fared like its congener in the north and was greatly reduced by 1900. The Pacific gray whale. hugging the California coast on its winter migration. suffered great depredations in the breeding lagoons from the boats both of whaleships and shore stations.

Old-style shore whaling, although extinct or moribund on the east and west Xtlantic seaboards. was carried on elsewhere during the 19th century. Excluding Japan (which had stations for gray, right and humpback whaling by a netting method evolved independently of the European tradition) there were settlements in California. South Africa. Australia, New Zealand and Tasmania. By the 1950s these settlements had disappeared except in the Azores. where a shore fishery for sperm whales existed since 1832, and in Madeira where the Xzores whaling spread in 1941. There the Portuguese islanders hunt in open boats with hand harpoon and lance as did their forebears who learned the trade in Yankee whaleships long ago.

Modern **Whaling.**—In the 1860s, when right and gray whaling were already in decline from overfishing. the industry received a new lease of life which it still enjoys. The Norwegian sealing captain. Svend Foyn. developed a method of hunting the great rorquals. including the blue and finback whales. which swim too fast for pursuit in open boats. Svend Foyn' used a cannon, firing a heavy grenade harpoon. mounted in the bow of a steam vessel. His methods revolutionized whaling and have remained unaltered in their essentials.

The new steam whaling,, which by 1900 was conducted from many stations in the North Atlantic and arctic, soon spread to Japan, Korea, British Columbia and, after about 1910, to the coast lines of the southern continents. The varying fortunes of this modern shore whaling (which continues widespread) before World War II were usually associated with periods of local overfishing. In Norway, after 1900, a growing scarcity of whales, and legislation hostile to the steam whalers and designed to protect the Norwegian cod fishermen: caused the industry to look to the antarctic where expeditions between 1892 and 1904 had reported abundant rorquals. In 1904 Capt. C. A. Larsen started whaling at Grytviken in South Georgia. The antarctic industry had begun.

Antarctic Whaling. — Whaling from Grytviken and other stations prospered at South Georgia, and soon spread to the other antarctic islands of South Orkney and South Shetland, where the first factory ships operated. Their heyday was the period from 1906 to 1927. They were really mobile shore stations, for they flensed their whales alongside and therefore could not work on the high seas but had to seek the shelter of some island bay or the calm of the ice-locked Ross sea. Then in 192j the steamship "Lancing" was fitted with a slipway in the stern so that whales could be hauled on deck. Her success opened the great era of pelagic (open sea) whaling. Factory ships could operate wherever their whale-catchers found whales in the Southern ocean. They could also operate outside territorial waters where no governments at that time could control their activities by licences or whaling regulations. Tankers were rapidly converted with stern slipways for pelagic whaling. Other tankers were used as transports, bringing fuel oil to factories in the ice and taking home cargoes of whale oil, so that the factories could work a protracted season. In the season 1930–31, within five years of the "Lancing's" voyage. 41 factory ships operated to produce 3,500,000 bbl. of oil. At mid-20th century this antarctic production, and by consequence world production also, remained the highest in the history of whaling.

Technique. — Except for the introduction of electronic aids and reconnaissance aircraft, the whaling technique developed by 1931 changed little after 1945. A typical pelagic expedition comprised a factory ship of about 16.000 gross tons which operated about 11 or 12 steam whalecatchers each of about 550 tons, although newer catchers attained 900 tons and had diesel engines. They operated within about 100 mi. of the factory ship. Helicopters sometimes helped the search. Experiments with scouting aircraft in the antarctic were first made in 1929, but it was not until 1950 that, in the form of helicopters, they were used effectively. The search from the catcher is still the job of the lookout at the masthead, but he is often helped by the echo-whalefinder, developed from wartime asdic (a sonar device). The whale scarer, another sonar device, frightens whales into flight with ultrasonic vibrations, so that, getting out of breath, they blow more often and are more easily followed. Whales are shot with the grenade harpoon. (Before and after World War II there were experiments with an electric harpoon, which yields an unspoiled carcass and is claimed to be more rapid and more humane than the grenade harpoon.) The dead whale, winched back on the Manila whaleline, is then inflated to prevent sinking and marked with a flag. At the end of the day the flagged whales are collected and towed back to the factory ship or shore station. Flags are sometimes missed due to fog, heavy seas or nightfall and, therefore, radio buoys that transmit a continuous signal to the catchers have been introduced: Flags with radar reflector cones, which can be detected on the catcher's radar screen, are also used.

LANCE (ABOVE) AND HAND HARPOON (BOTTOM) STILL USED IN THE AZORES IN THE 1950S AND AS USED BY AMERICAN WHALEMEN IN THE 19TH CENTURY

A whale delivered to a factory ship is heaved through the stern slipway with a steel clan- attached to hawsers dragged by two 50- or 60-ton winches. The claw, a giant pair of pincers dropped over the whale's tailstock, mas first used in 1932–33. On the afterdeck the blubber is removed in three enormous strips. The flensed carcass is hauled through the midships gantry to the meat-and-bone deck. There, using steam bonesaws and wires strained around winches and capstans, the butchers and bone-sawyers work with anatomists' precision, removing and sectioning the skull, opening the chest and separating the ribs. stripping meat from the backbone and separating the vertebrae. There is no wastage: only the entrails and stomach are turned overboard. Blubber. meat and bone are stuffed into separate cookers. the mouths of which are flush with the deck. A proportion of the lean meat is usually not pressure cooked for oil extraction but is fed into the meat meal plant. Little more than 45 min. is taken to dispose of a blue whale weighing over 100 tons, and 30 min. suffice for a finback n-hale. The work goes on day and night, as long as whales are waiting at the stern.

Products. — Modern whaling! besides producing edible whale oil (*q.v.*) from rorquals. also produces sperm oil which. although inedible and no longer used as an illuminant, has increasing uses in industry. (The largest catches of sperm whales are made in the antarctic and off the coasts of Peru and Chile.) The by-products of whaling became more important after World War II. They include meat meal for cattle cake, bone meal and guano for fertilizers. frozen whalemeat for human and fox food, meat extracts and liver meal, liver oil rich in vitamin A. and a certain amount of ductless gland for hormone extracts. Ambergris. still important in perfumery, is occasionally found in sperm whales. Whalebone, hardly worth saving for brush manufacture between World Wars I and II. began again in the 1950s to find a market in the corset industry. See WHALE; WHALE OIL.

WHALE OIL.

WHALE OIL. Whale oil is used mainly as raw material for margarine and compound cooking fat. Sperm nhale oil. which is really a liquid wax, can be employed only for such purposes as the manufacture of lubricants and fatty alcohols. The two will be considered separately.

Whale Oil and **By-products.**—Two discoveries played important parts in the history of whaling and the use of whale oil The first was in the mid-19th century when petroleum was first discovered. Before that time whale oil had been in demand as a burning oil for lamps and as a lubricant for machinery. Between that date and the discovery of hydrogenation of fatty oils and its commercial application in 1908, nhale oil fought a losing battle since it could not be produced at anything like the low cost of mineral oils and could not, therefore, compete with them as an illuminant or as a lubricant. During that period the whaling industry declined year by year.

Hydrogenation of oils is the addition of molecules of hydrogen to molecules of fatty matter which takes place in the presence of a nickel catalyst. The effect in the case of whale oil is to convert it from a somewhat strong-smelling fishy liquid oil into a bland, odourless. tasteless, stable, solid fat. The discovery of this process came about at a time when soapmakers and margarine manufacturers were searching for solid fats; there were adequate supplies of liquid oils but a great scarcity of solid fats. The soapmaker required solid fats to make a hard soap because the liquid oils were capable of making only soft soaps. while the margarine manufacturer required solid fats to produce a product with the characteristics of butter, which was again impossible from liquid oils.

Whale oil is a true fat oil consisting almost entirely of triglycerides—one molecule of glycerol in combination with three of fatty acids. Such oil can be converted into an excellent edible fat, as well as a high-grade soapmaking material.

Most of the whale oil (or sperm oil) is contained in the blubber. The blubber consists of subcutaneous tissue into which fat is deposited and from which it may be taken back for the process of in-

WHALE FISHERIES

WHALING

Top left: Pelagic whaling. A factory ship on the Antarctic whaling grounds. Flensing (removal of the blubber) takes place on the afterdeck. The stripped carcass is then hauled through the midships gantry to the foredeck where it is completely dismembered into meat, bone and entrails
Top right: View of a pelagic factory ship from the stern showing the slip-way through which whale carcasses are hauled by winches to the flensing deck
Centre left: The flensing deck. A blue whale is being flensed: the blubber is removed in three strips much as a banana is peeled. Note the whale-claw (attached to the tail) used for hauling the whale through the slip-way
Centre right: The meat-and-bone deck. Whalers are shown trimming the shoulder blade from a blue whale's flipper
Bottom left: The factory deck. Blubber, meat and bone, loaded into cookers from the open deck above, are cooked under steam pressure. A Hartmann apparatus for cooking meat is shown
Bottom right: Shore whaling. A female fin whale, 72 ft. long, on the flensing platform at a shore station on the island of South Georgia

ternal metabolism. The thickness of the blubber depends on the size and the state of nutrition of the whale and varies for different species. Normally it increases in proportion to the length of the animal. Seasonally, baleen whales get fatter the longer they stay in their arctic or antarctic plankton areas. Whalers usually estimate an oil yield averaging 50% to 80% of the weight of the blubber. Important as the blubber is as a fat-bearing raw material, it is not the only one—the body also deposits fats in all the meat tissues, and finally in the bones. It has been estimated that whale meat may contain from 2% to 8% oil, with an average of 6% to 7%; and bones from 10% to 70%, with an average of 40% to 60%.

Sperm Oil.—The oil from the sperm whale is not a true fatty oil but is, in fact, one of the liquid waxes, Since it consists mainly of fatty acids in combination with higher monohydric aliphatic alcohols, and only small traces of glycerides. This precludes it from being an edible product because the fatty alcohols are quite indigestible. The number of uses to which sperm oil is put, however, is constantly extending as it has become the basis of an important chemical industry manufacturing derivatives from the separated fatty alcohols.

Crude sperm oil is a very valuable lubricant and is used as such for the cold rolling of steel. Treatment with sulphur gives a sulphurized oil which has exceptional properties for the preparation of extreme pressure lubricants. Sperm oil may be hardened in the same way as other marine oils and in this form is used for its lubricating qualities in the preparation of textile sizes and wax compositions or directly as a metal-drawing lubricant. The crude oil is used directly and in conjunction with other marine oils as a leather dressing. When supplies permit and the price is very low, it can be used as a soapmaking material by a process which involves the conversion of the fatty alcohol portion to fatty acids, but the process is expensive.

Sperm oil is normally refined by a chilling or wintering process followed by filtration so as to remove the solid portion or spermaceti. The spermaceti is pressed and refined to yield a white crystalline solid which finds considerable use in the preparation of textile finishes and thread lubricants, cosmetics and candles.

The saponification of sperm oil under carefully controlled conditions separates the constituent fatty acids and fatty alcohols. The fatty acids so prepared are suitable for soapmaking and for the many other uses to which fatty acids are normally put. The fatty alcohols are used in the manufacture of cosmetics and hair preparations and also in detergents.

As far as antarctic whaling is concerned, sperm oil is largely a by-product, and, compared with whale oil production, sperm oil is only of secondary importance. (J. C. G.)

WHALLEY, EDWARD (*c.* 161j–*c.* 1675), English regicide, risked death by flight rather than trust indemnity after the revolution. He was the second son of Richard Whalley, who had been sheriff of Nottinghamshire in 1595, by his second wife. Frances Cromwell, aunt of Oliver Cromwell. On the outbreak of the Great Rebellion he took up arms for the parliament, became major of Cromwell's regiment of horse and fought with distinction in the campaigns of 1643 to 1647. When the king was seized by the army, he was entrusted to the keeping of Whalley and his regiment at Hampton court. Whalley refused to remove Charles's chaplains at the bidding of the parliamentary commissioners, and treated his captive with due courtesy, receiving from Charles after his flight a friendly letter of thanks. In the second Civil War (1648) Whalley again distinguished himself as a soldier. and when the king was brought to trial he was chosen to be one of the tribunal and signed his death warrant. He took part in Cromwell's Scottish expedition, was wounded at Dunbar, and in the autumn of 1650 was active in dealing with the situation in southwest Scotland. Next year he took part in Cromwell's pursuit of Charles II and was in the fight at Worcester (Sept. 3) which defeated Charles's army. He followed and supported his great kinsman in his political career, presented the army petition to parliament (Xug. 1652), approved of the Protectorate and represented Nottinghamshire in the parliaments of 1654 and 1656, taking an active part in the prosecution of the Quaker James Naylor (*q.v.*). He was one of the administrative major generals, and was responsible for Lincoln, Nottingham, Derby, Warwick and Leicester. He supported the Humble Petition and Advice (March 1657). except as regards the proposed assumption of the royal title by Cromwell, and became a member of the newly constituted house of lords in Dec. 16j7. On the protector's death. at which he was present, he in vain gave his support to Richard; his regiment refused to obey his orders, and the restored Long Parliament dismissed him from his command. In Nov. 1659 he undertook an unsuccessful mission to Scotland to arrange terms with George Monk. At the Restoration, Whalley, with his son-in-law, Maj. Gen. William Goffe, escaped to America, and landed at Boston on July 27, 1660, living successively at New Haven and at Hadley, Mass., the government at home failing to procure his arrest.

See Mark Noble, *Lives of the English Regicides* (London, 1798), *Memoirs of the Protectoral House of Cromwell,* vol ii, 2nd ed (Birmingham, 1787); Ezra Stiles, *History of Three of the Judges of Charles I* (Harttord, Conn, 1794) The article by C H. Firth in the *Dictzonary of National Bzography* is an admirable summary.

WHARTON (FAMILY). The Whartons of Wharton were an old north of England family, and in 1543 THOMAS WHARTON (1495–1568) was created a baron. The 5th baron. THOMAS WHARTON (1648–1715), was created in 1706 earl and in 1714 marquess of Wharton.

The 1st marquess is famous as the author of the political ballad, *Lilliburlero,* which "sang James II out of three kingdoms." Wharton was lord Keutenant of Ireland in Anne's reign, and incurred the wrath of Snift, who attacked him as Verres in the *Examiner* (no. 14), and drew a separate "character" of him, which is one of Swift's masterpieces. Addison dedicated to him the fifth volume of the *Spectator,* giving him a very different "character" from Snift's. His first wife. ANNA WHARTON (1632–85), was an authoress. whose poems, including an *Elegy on Lord Rochester,* were celebrated by Walter and Dryden. His son, PHILIP WHARTON (1698–1731), duke of Wharton, succeeded to his father's marquessate and fortune, and in 1718 was created a duke. But he earned for himself. by his profligacy and reckless playing at politics. Pope's satire of him as "the scorn and wonder of our days" (*Moral Essays,* i, 179). After spending his large estates he went abroad and gave eccentric support to the Old Pretender. He was outlaued in 1729, and at his death the titles became extinct.

For the history of the family *see* E. R. Wharton, *Whartons of Wharton Hall* (1898).

WHARTON, EDITH NEWBOLD (1862–1937), **U.S.** author whose fiction is marked by its concern for form and for the moral significance of subject and treatment and by the irony with which it responds to every symptom of social pretentiousness and stupidity. Born in New York city on Jan. 23. 1862. the daughter of George Frederic Jones, who was independently wealthy, she was educated privately at home and in Europe. In 1885 she married Edward Wharton, a Boston banker, and a few years later resumed the literary career she had begun tentatively as a young girl. The best of her early tales were collected in *The Greater Inclination* (1899). In 1905 the critical and popular success of her second novel, *The House of Mirth,* established her as a leading writer; and in the next two decades, before the quality of her work began to decline under the demands of writing for women's magazines, she wrote such distinguished novels as *The Reef* (1912), *The Custom of the Country* (1913), *Summer* (1917) and the Pulitzer prize-winning *The Age of Innocence* (1920). Her best-known work, however, was the long tale *Ethan Frome* (1911), exploiting the grimmer possibilities of New England farm life. She also wrote many short stories and poems, several books of travel reflecting her interest in architecture and landscape gardening, and a manual, *The Writing of Fzction* (1925). The most ambitious project of her later years was the novel *Hudson River Bracketed* (1929) and its sequel *The Gods Arrive* (1932), but her best writing of that period was in the posthumous *The Buccaneers* (1938). In the beginning an admirer of Henry James's fiction, and always one of his closest friends, she disapproved of his later manner. Her autobiography, *A Backward Glance,* appeared in 1934.

After 1907 Mrs. Wharton lived in France, visiting the United States only at rare intervals. In 1913 she was divorced from her husband. She died on Aug. 11, 1937, and was buried at Versailles. Her literary and personal papers were presented to the Yale university library.

Mrs Wharton was the first woman to be granted an honorary doctor of letters by Yale university (1923) and the gold medal of the National Institute of Arts and Letters (1924), and the second woman to be elected to membership in the American Academy of Arts and Sciences (1934).

See P. Lubbock, *Portrazt of Edith Wharton* (1947); B. Nevius, *Edith Wharton: a Study of Her Fzction* (1953). (B R. N)

WHARTON, HENRY (1664–1695), British writer, descended from Thomas. 2nd Baron Wharton (1520–1572), was born at Worstead on Nov. 9, 1664 and studied at Gonville and Caius college, Cambridge. In 1686 he entered the service of the ecclesiastical historian, William Cave (1637–1713), whom he helped in his literary work. In 1687 he was ordained deacon and in 1688 he met the archbishop of Canterbury. William Sancroft, under whose patronage some of his literary work was done He died on March j. 1695, and was buried in Westminster abbey.

Wharton's most valuable work is his *Anglia sacra,* a collection of the lives of English archbishops and bishops, which was published in two volumes in 1691. Some of these were written by Wharton himself; others were borrowed from early writers His other writings include, in addition to his criticism of the *History of the Reformation, A Treatise of the Celibacy of the Clergy* (1688); *The Enthusiasm of the Church of Rome Demonstrated in Some Observations Upon the Life of Ignatius Loyola* (1688); and *A Defence of Pluralities* (1692). In the Lambeth library there are 16 volumes of Wharton's manuscripts.

A life of Wharton was included in George D'Oyly's *Life of W Sancroft* (1821)

WHATELY, RICHARD (1787–1863), English logician and theological writer, archbishop of Dublin, was born in London on Feb 1. 1787 He was educated at a private school near Bristol, and at Oriel college. Oxford. In 1811 he was elected fellow of Oriel, and in 1814 took orders. During his residence at Oxford he wrote his *Historic Doubts Relative to Napoleon Bonaparte,* a very clever *jeu d'esprit* directed against excessive scepticism as applied to the Gospel history. After his marriage in 1821 he settled in Oxford, and in 1822 was appointed Bampton lecturer The lectures *On the Use and Abuse of Party Spirit in Matters of Religion* were published in the same year. In Aug. 1823 he removed to Halesworth in Suffolk, but in 1825, having been appointed principal of St. Alban hall, he returned to Oxford. In 1825 he published a series of *Essays on Some of the Peculiarities of the Christian Religion,* followed in 1828 by a second series *On Some of the Difficulties in the Writings of St. Paul,* and in 1830 by a third *On the Errors of Romanzsm Traced to Their Origin in Human Nature.* While he was at St Alban hall (1826) the work appeared which is perhaps most closely associated with his name—his treatise on *Logic,* originally contributed to the *Encyclopaedia Metropolitana.* It gave a great impetus to the study of logic throughout Great Britain. A similar treatise on *Rhetoric,* also contributed to the *Encyclopaedia,* appeared in 1828. In 1829 Whately became professor of political economy at Oxford.

His tenure of office was cut short by his appointment to the archbishopric of Dublin in 1831. One of his first acts was to endow a chair of political economy in Trinity college out of his private purse.

Whately's appointment by Lord Grey to the see of Dublin was a great surprise, for though a decided Liberal, Whately had from the beginning stood aloof from all political parties. The Evangelicals regarded him as a dangerous latitudinarian, while his view of the church was diametrically opposed to that of the High Church party. From the beginning he was the determined opponent of the Tractarian movement. The appointment was challenged in the house of lords. but without success. In Ireland it was immensely unpopular among the Protestants. Whately's blunt outspokenness and his "want of conciliating manners" prevented him from ever completely eradicating these prejudices, while at the same time he met with determined apposition from his own clergy. He opposed them from the first by connecting himself prominently with the attempt to establish a national and nonsectarian system of education. He enforced strict discipline in his diocese, and he published a strong statement of his views on the Sabbath (*Thoughts on the Sabbath,* 1832).

He took a small country place at Redesdale. 4 mi. out of Dublin, where he devoted himself to the questions of tithes, reform of the Irish church and of the Irish poor laws and, in particular, the organization of national education. He was also interested in other public questions, for example. the subject of transportation and the general question of secondary punishments.

In 1837 he wrote his well-known handbook of *Christian Evidences,* which was translated during his lifetime into more than a dozen languages. At a later period he also wrote, in a similar form, *Easy Lessons on Reasoning,* on *Morals,* on *Mind* and on the *British Constitution.* Among his other works may be mentioned *Charges and Tracts* (1836), *Essays on Some of the Dangers to Christian Faith* (1839) and *The Kingdom of Christ* (1841). He edited Bacon's *Essays* and William Paley's *Evidences* and *Moral Philosophy.* His cherished scheme of nonsectarian religious instruction was defeated by the opposition of the new Catholic archbishop of Dublin, and Whately felt himself constrained to withdraw from the education board. From the beginning Whately was a keen-sighted observer of the condition of Ireland question. and gave much offense by openly supporting the state endowment of the Catholic clergy as a measure of justice. He died on Oct. 8, 1863.

Whately often offended people by the extreme unconventionality of his manners. When at Oxford his white hat, rough white coat and huge white dog earned for him the sobriquet of the White Bear. With a remarkably fair and lucid mind, his sympathies were narrow, and by his blunt outspokenness on points of difference he alienated many. With no mystical fibre in his own constitution, the Tractarian movement was incomprehensible to him, and was the object of his bitter dislike and contempt. Whately's qualities are exhibited at their best in his *Logic,* which is as it were, the quintessence of the views which he afterward applied to different subjects.

In 1864 his daughter published *Miscellaneous Remains* from his commonplace book and in 1866 his *Life and Correspondence* in two volumes. *The Anecdotal Memoirs of Archbishop Whately,* by W. J. Fitzpatrick (1864), enliven the picture.

WHATMOUGH, JOSHUA (1897–), U.S linguist, in 1926 was appointed professor of comparative philology at Harvard university, nhere he founded and directed a department of linguist distinguished by its development of statistical and mathematical methods. Born on June 30, 1897, in Rochdale, Eng., he was educated at the University of Manchester and Emmanuel college. Cambridge. He became a U.S. citizen in 1942.

Whatmough originated the theory of selective variation to explain equilibrium in language. He wrote five major works and over 450 articles and critical reviews (complete bibliography in *Studies Presented to Joshua Whatmough on His Sixtieth Birthday,* The Hague, 1957). He served as president of the Linguistic Society of America, became a member of the Comité International Permarlent des Linguistes, and won an outstanding international reputation among linguists (E. Pm.)

WHAUP: *see* CURLEW.

WHEAT. About one-half of the 2,600,000,000 ac. of cultivated land in the world is used in the production of cereals which provide 80% of food calories produced. About two-fifths (450,000,000 ac.) of the cereal acreage is used for wheat production. There are more pounds of wheat produced than of rice, but more people use rice as their chief food. Wheat is used for human food principally as leavened bread, cakes and pastries, and macaroni, spaghetti and other semolina products. Wheat is best adapted to loam or clay soils that are well supplied with organic matter and are in the temperate, drier regions of the world Cultivation and harvest are fairly simple procedures. The grain is easily stored and transported.

This article is divided into 12 sections discussing the relation between wheat and civilization and covering the principal aspects of nheat as an agricultural product. In addition to cross references to related articles given under the various headings of this article, *see* also AGRICULTURE BREAD CEREALS, FLOUR For production and marketing statistics for particular regions *see* also separate articles on individual countries and on the several states of the United States

I. HISTORY

Nearly all important civilizations are considered to have been founded upon the production of cereals. Wheat was probably one of the first cereal crops grown by man. Wheat and other cereals provide a nutritious food containing the important elements needed for an adequate diet, and it is a food product that can be easily stored. Wheat production requires planting and harvesting on an annual basis and consequently. in order to cultivate wheat. man had to settle in permanent locations if he was to depend on cereals as his major source of food. It can be assumed that when certain groups of people stopped their nomadic life and resorted to cereals as the major source of food they had time to use part of their energy for other purposes than securing food. Thus, civilization and the culture of cereals probably began simultaneously. Evidence indicates that cereal culture did not occur during the Paleolithic period (stone age) but began with Neolithic man probably as recent as 6,000 to 7,000 years ago. Wheat is not suitable material for preservation from the archaeological standpoint and evidence from this source is not entirely reliable so that the approximate date of the beginning of wheat culture can only be estimated.

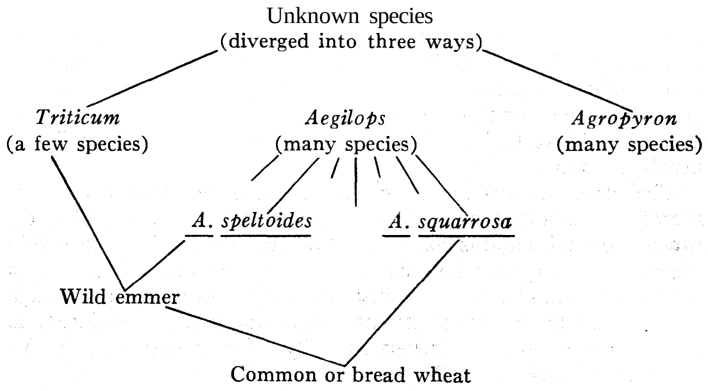
The origin of cereals is still a mystery to 20th century biologists as it was to the Greeks who attributed the cereals to a gift of Demeter. the goddess of agriculture. The Romans gave credit to the goddess Ceres. and some of them identified her with Demeter. A spring wheat variety adapted to the Northern Great Plains of North America mas named Ccres and was a valuable variety for many years, giving protection against the ravages of stem rust The Egyptian goddess. Isis, was supposed to have discovered wheat growing promiscuously in Phoenicia (Lebanon) As early as 2800 B C in China elaborate ceremonies were conducted in the spring honoring the cereals It appears that wheat has been grown prior to or at least since recorded history

The evolution of wheat production occurred very slowly and a farmer of about 4000 B C moved forward to any year prior to A D 1800 probably could have continued wheat production without any appreciable change All that was needed or used was a few seeds, a pointed stick some type of sickle and perhaps a beast of burden. There are still areas in the norld where wheat production remains as primitive as it was 6,000 years ago. After 1800 many remarkable changes occurred Improvement of machinery. relieving man as the source of power resulted in increased nheat production. (*See* TILLAGE MACHINERY; HARVESTING MACHINERY; CROP-PROCESSING MACHINERY; TRACTORS) During the first 50 years of the 20th century much progress in wheat culture was made and a number of countries went from wheat famine to surplus Early settlers in the state of Kansas, which is in the centre of one of the largest nheat producing areas of the world did not produce enough wheat flour to provide for their needs When the proper kind of nheat (Turkey hard red ninter) was introduced into the Great Plains of North America in the 1870s. this nheat became the "gold" of the plains which Coronado so diligently had sought for 230 years earlier Machinery, poner, cultural methods and the proper kind of wheat have made it possible to produce nheat in abundance throughout the world nhen all these factors are properly applied.

II. ORIGIN

Wheat is a grass. of the Gramineae family and of the genus *Triticum.* Two wild species of *Triticum* are still growing in Asia Rlinor and Syria. One of these. wild einkorn. is a simple species, while the other. wild emmer, is more complex in that it originated from two species. The most important group of the genus *Triticum* is made up of three species and contains common bread wheat. No wild bread nheat types have been found.

In addition to the genus *Triticum,* there are two closely related weedy grasses and forage grasses. *Aegilops* and *Agvopyron.* Crosses can be made among all three of these genera. Originally it was thought that common wheat was a combination of all three of these genera. Hitoshi Kihara, a Japanese geneticist, proposed that a single species of *Aegilops* had united with the emmer to produce the common wheat. In 1944 this species was found and its centre of origin appears to be Afghanistan. The species that united with einkorn was thought to be an *Agropyron.* E. R. Sears suggested in 1948 that it might be another *Aegilops.* In 1956 this was partially confirmed by geneticists in the United States and Japan. This information suggests that the *Triticum* species originated some place in the area from Asia Minor to Afghanistan. This also corresponds with the present-day wild species. The ancestry of common wheat can be illustrated as follows:



III. SPECIES

It has been known for a long time that the wheat species were originated by combining several different species. They form three groups. according to the number of chromosomes. The chromosomes are the dark-staining bodies found in the nucleus of young cells. The hereditary traits or genes are carried on these chromosomes and the genera *Trztzcum, Aegilops* and *Agropyron* are built up in units or sets (genomes) of seven chromosomes each. The species names have changed occasionally and the information presented is adapted from systems suggested by James MacKey (1954) and Sears (19j6). There are two main ways in which the seed of wheat is disseminated. In the first. the spike (the ear or head) is brittle and breaks up, leaving the kernels tightly enclosed in the hull or glumes. The other way is for the kernels to thresh free from the hulls.

1. Einkorn (one grain).— Members of this group have seven pairs of chromosomes or two sets and are called the diploids. The heads are bearded, small and flat, and break up so that the kernels remain in the hull. These species are rarely cultivated and. if grown, are used for livestock feed. There are two recognized species.

Triticum boeoticum, the wild form or wild small spelt.

Trztzcum monococcum, the cultivated form, einkorn or small

FIG. 1.—EINKORN (LEFT) AND EMMER WHEATS

spelt.

2. Emmer.—The species included in this group have 14 pairs of chromosomes or four sets and are called tetraploids. All eight species and their varieties, except for a very few, are bearded. Wild emmer *(Triticum dicoccoides)* and Timopheevi wheat *(T. timopheevi)* are the wild forms. The heads are generally flattened, the kernels are narrow and pointed at each end; they remain in the hull when threshed. The wild emmer is still found growing in Syria. *T. dicoccum* is the cultivated emmer, similar to the mild type in that the kernels remain in the hull. Archaeological evidence from the Jarma site in eastern Iraq dated about 5000 B.C. indicates emmer-type wheat was grown at that time. It undoubtedly was used for human food. Little emmer has been grown since 1900 and what is grown usually is used for livestock feed. The other five species are free-threshing and are grown extensively in some areas: durum or macaroni wheat (T. *durum*); poulard, rivet or cone wheat *(T. turgidum)*; Khorason wheat (T. *turanicum*); Polish wheat *(T. polonicum)*; and Persian wheat *(T. carthlicum)*.

Durum wheat is the most important species of this group. The kernels are large, pointed at each end, with a hard and translucent endosperm. It is especially suited for the manufacture of macaroni and spaghetti. Ethiopia and the Mediterranean region were the centres of origin of this species. It is still grown extensively there, especially in Italy, and in the north central United States and nearby Canada.

The other species of this group are of little importance commercially. Poulard type wheat is grown in some of the Mediterranean countries and is common in the mixture of wheats grown in Mexico. This type, which has been known for many years, has a branched spike (fig. 3). Because this spike appears to have a high potential yield, it repeatedly has been fraudulently exploited in the United States and internationally (for example by T. D. Lysenko of the U.S.S.R.) as a wonderful new variety of wheat. Periodically, Polish wheat has also been advertised widely. It has an unusually long, large, lax head, sometimes six or seven inches in length. The kernels are large and hard, the glumes are unusually long, thin and papery in texture.

FIG. 2.—DURUM (LEFT) AND SPELT WHEATS

3. Common.—The members of this group have 21 pairs of chromosomes or six sets and are called the hexaploid wheats. This group contains the most widely grown types. At one time, this group was classified into a number of different species. They have been interbred so profusely that species distinctions are no longer valid, except as subspecies. There are no wild species in this group. Probably there never were any, as the first ancestors of these wheats were presumably not capable of existing in the wild and only could be propagated with the aid of man. Common wheat has been synthesized by crossing wild emmer and the weedy grass *A. squarrosa* and doubling the chromosome number of the hybrid.

BY COURTESY OF KANSAS STATE COLLEGE

FIG. 3.—POULARD (LEFT) AND POLISH WHEATS

The subspecies of the common wheats *(Triticum aestivum)* can be classified as follows:

spelta, spelt or dinkel wheat
macha, a spelt type
vavilovi
vulgare, free threshing bread wheat
compactum. free threshine club wheat
sphaerococcunz, free threshing shot or Indian dwarf wheat

The two subspecies *spelta* and *macha* do not thresh free and are grown only to a limited extent. The subspecies *vavilovi* and *sphaerococcunz*, although they thresh free, are not grown extensively. The common or bread wheat *(vulgare)* and the club wheat *(compactum)* are the two species that are widely grown.

Bread wheat is the most important subspecies and includes all the kinds from which the world bread supply is derived. There are many varieties of bread wheat differing in morphological characters. They are grown extensively in the United States. Canada, the U.S.S R., Argentina, India, Australia and in nearly all other countries where wheats are grown.

Club wheat is similar in most respects to bread wheat except that the heads are very short and compact. This type of wheat is grown only to a limited extent in the Pacific northwest of the United States and in central Asia.

IV. CHARACTERISTICS

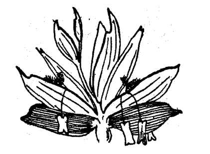
1. The Grain.—This is a single seed or nutlike fruit called a caryopsis. A grain or kernel of wheat is covered by a thin shell. the pericarp, and several other cell layers often referred to as the bran.

The bran coat is generally reddish-brown in colour and varies from light to dark depending on the texture of the interior of the kernel and the intensity of the pigment in the bran. When the colour is absent, the kernel varies from a creamy yellow to white depending on the texture of the interior. Inside the bran coat is the endosperm. the storage organ of food for the embryo or young plant. Sometimes the outside layer of cells of the endosperm may be purple, as found in certain Abyssinian wheats. The endosperm consists largely of thin-walled cells filled with starch, which is imbedded in a protein called gluten, an elastic protein substance present only in wheat and, to a limited extent, in rye. Gluten is essential for making light or leaven breads. The embryo or germ is at the base of the grain under the wrinkled patch of bran. The other end of the kernel generally has hairs. The dorsal or backside is convex and the opposite side is a crease or suture. The embryo is a miniature plant and the rudimentary roots and leaves are present and ready to develop into a plant when proper moisture, light and temperature conditions prevail.

BY COURTESY OF KANSAS STATE COLLEGE

FIG. 4.—COMMON (LEFT) AND CLUB WHEATS

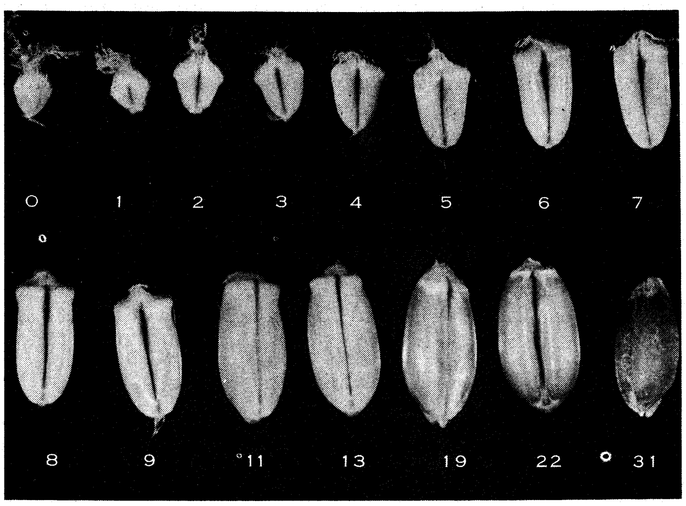
Wheat is largely grown for human food and the wheat grain is an important source of energy. The composition of the kernel varies considerably because of the differences in climate and soil in which it is grown. On the average, the kernel contains about 12% water, 70% carbohydrates, 12% protein, 2% fat, 1.8% minerals and 2.2% crude fibres. A pound of wheat contains about 1,500 cal. (100 g. contains about 330 cal.). Thiamine, riboflavin, niacin and small amounts of vitamin A are present, but the milling processes remove the bran and germ, where these vitamins are found in the greatest abundance.



FROM GROOM, ELEMENTARY BOTANY" (G. BELL & SONS, LTD)
FIG 5 —A SPIKELET OF WHEAT

2. The Plant. — When the kernel is placed in moist soil at 6j° F. or less germination will occur in three to four days The root (radicle) develops first and is soon followed by the shoot (coleoptile). The leaves follow in rapid succession and develop into the main shoot. At the base of this shoot. there are buds that develop into other shoots or tillers. Each tiller terminates in a head or spike. The area where these tillers arise is called the crown and a set of roots also develops from this place The number of tillers that develops depends on the variety of wheat, time of sowing, rate of planting or spacing of plants and other environmental factors. The leaves are long and slender but do vary in length and width. They may be covered profusely with hairs or have none at all. The early growth of leaves is near the ground and they form a rosettelike appearance. When the stems elongate rapidly, these lower leaves die. The stem is made up of sections called internodes mhich are separated by the nodes, or thickened swellings on the stem. The diameter and length vary considerably and the height of the stem (straw) ranges from about 15 in. (40 cm.) to 75 in. (190 cm.) The stems are generally hollow, but some of the durum (tetraploid) wheats have solid stems. At maturity, most of the leaf blades have dropped off. The stems are generally yellow or straw colour. Some varieties may have purple stems; however, this colour generally disappears before harvest.

The head eventually emerges from the last leaf By this time a very important change has taken place in that the plant has changed from vegetative growth to the reproductive phase. There are varying numbers of flowers per head or spike, ranging from 20 to 100. The flowers are grouped together in spikelets and each



BY COURTESY OF KANSAS STATE COLLEGE

FIG. 6.— GROWTH OF A WHEAT KERNEL. NUMBERS INDICATE DAYS AFTER POLLINATION

spikelet has two to six flowers. The spikelets are enclosed in glumes (chaff, hulls). The outer glumes terminate in a tooth or beak that is relatively short. One of the glumes that surround the seed may have an awn (bristlelike extension). Those heads that have awns are called bearded or awned varieties. The awn varies from being nearly imperceptible to several inches in length. The glumes may be coloured white or reddish-brown, and in some cases may have black imposed upon these two colours. In most spikelets. two to three flowers are fertilized and develop a grain. The flower is very simple, consisting of three stamens (the male organs) and a feathery ovary with a branched style (the female organs). The flowers begin to bloom slightly below the middle of the head and proceed both upward and downward. This process is completed in two to four days. The individual flower opens in about three minutes. The glumes are forced apart by the swelling of two scalelike organs called lodicules. The anthers mhich develop and contain the pollen are forced out by elongation of the stalk (filament) bearing the anthers. While this movement is going on, the anthers break open and the pollen is dispersed. The pollen grains fall on the feathery styles and germinate and a tube grows down within the style to the ovary. The pollen grains contain the sperm (male) which eventually unites with the egg (female) and thus starts the development of another kernel. The process of pollination takes less than five minutes and the consequent fertilization of the egg occurs within 24 hours. The newly fertilized egg (zygote) develops into the embryo or new plant, and the surrounding tissue into the endosperm and bran. This growth takes place very rapidly and a kernel is generally fully developed in about 24 to 27 days, when it contains about 35% to 40% water. The kernel then dries at various rates depending on environmental conditions. This ripening period may be 30 days or less in the Great Plains area of North America and up to 60 days or more in areas such as England.

3. Winter Wheat and Spring Wheat are the two major classes of nheat, based on their growth habit. The severity of the winter determines whether the wheat grown is a winter or spring type. Winter wheat is always sown in the fall. Spring wheat is generally sown in the spring, but where the winters are mild, as in Mexico, spring wheat varieties can be sown in the fall. As the area of wheat production progresses either north or south of the equator, the types grown are spring varieties sown either in the fall or spring at the higher altitudes. At about 30° to 45° latitude, the winter types produce best. For example, in northern Texas winter uheat is sown in October and November, in Oklahoma in October, in Kansas in September and October, and in Nebraska, Wyoming and Montana in August and September. Some winter wheat is grown in Canada and generally it is sown in August. As the latitude or altitude increases, the winters become so severe and long that wheat cannot survive. Then the spring wheat varieties are grown. Wherever winter wheat survives the winter, it will generally produce more than spring types.

Temperature, latitude, altitude and length of day all influence the development of the wheat plant. Varieties of winter wheat from North America sown in Colombia (latitude j°) at 13,000 ft. elevation grow slowly and head very poorly in 14 to 15-months. At lower elevations, the same varieties remain as grassy plants and never head. The winter types require a certain amount of cold before they will head, as well as varying day length nhich does not occur in Colombia.

There is a gradual change from one type to another and for this reason each area of wheat production has special selected types adapted to its conditions. A winter wheat satisfactory to the southern Great Plains of North America will be killed by the winter in the northern Great Plains, but both types of winter wheat require cold in order to develop to maturity. Spring wheats grown near the Arctic circle have a shorter growing period under long days and do poorly farther south.

V. PRODUCTION

Wheat is grown under a wide range of climates and soils but is best adapted to the temperate regions where the rainfall is between 12 and 35 in. and between latitudes 30° to 60°. This roughly corresponds to the original large grassland areas of the temperate regions of the world. Although these regions provide the best conditions, wheat can be gronn in areas of less than 12 in. rainfall and up to 70 in., up to the Arctic circle and down to the equator. and from below sea level up to 10,000 ft. The rather heavy, deep, well-drained, dark-coloured soils, well supplied with organic material. of the chernozems and chestnut-bronn groups are the most favourable for wheat production. The prairie soils of the United States, Canada and the U.S.S.R. are excellent examples of good wheat soils. Wheat is not adapted to sandy and peat soils.

During 1945–55 about 400,000,000 to 480,000,000 ac. of wheat were sown annually in the world. with a production of 6,000,000,000 to over 7,000,000,000 bu. or about 200,000,000 short tons. Comparable acreage and production of other important cereals are: rice, 233,000,000 ac. and 176,150,000 tons; corn, 215,000,000 ac. and 146,944,000 tons; oats 128,000,000 ac. and 62,142,000 tons; and barley. 118,000,000 ac. and 45,000,000 tons.

The yield of wheat varies widely throughout the world. In the drier areas, yields are often as low as 8 to 10 bu. per acre while in certain areas in northern Europe and Japan, yields have been as high as 70 to 80 bu. per acre. Yields have been reported as high as 12j bu. per acre under irrigation.

Wheat Acreage and Production by Areas and Major Producing Countries

1. Land Preparation.— Production practices also vary widely throughout the world. In the extensive wheat production areas of North America. Australia, Argentina and the U.S.S.R., a high degree of mechanization is used.

Wheat in the drier areas of these major producing regions generally is grown on the same land without a rotation of crops. A process called summer fallowing is used to store moisture in the soil with as little cultivation as possible, especially where the annual rainfall is less than 15 to 18 in. throughout a growing season. The soil surface is kept rough to absorb rain, prevent wind erosion -and weed growth (see DRY FARMING). Under dry land conditions, enough moisture generally can be stored to grow a good crop every other year. When the soil contains moisture to a depth of 48 in. a crop of wheat is generally assured

Where more than 15 to 18 in. of rainfall occurs, wheat is often brown continuously, and in the more humid areas wheat is grown in rotation with other crops. In semihumid areas, early cultivation (plowing) is an important factor in successful wheat production. Plows or other cultivator tools follow immediately behind the combine harvesters. Early cultivation conserves moisture, controls weeds and increases the amount of nitrates, an important plant food.

In the humid areas, wheat often follows other crops such as soybeans and corn, and the land is often prepared for seeding only by disking. Careful seedbed preparation generally results in higher yields.

Preparation of wheat seedbeds in many parts of the world is still carried on by primitive methods in which the soil surface is merely scratched with inadequate tools. Many more bushels of wheat could be grown in the world if all land was prepared for wheat using modern equipment and procedures.

2. Seeding.— Good seed and equipment for planting are essential to successful crop production. Grain drills are adapted to mechanized farming and large tractor-drawn outfits can sow 100 ac. per day. There are a number of types of drills but the principle is the same in all, in that the seed is distributed uniformly and at an even depth. The depth of seeding varies from $1\frac{1}{2}$ to 3 in. and the amount of seed varies from as little as 20 lb. up to 120 lb. per acre. Broadcast seeding, that is, throwing the seed on the land by hand or with simple equipment, is wasteful of seed because it cannot be covered to uniform depth and uneven stands occur. Machine seeding is highly recommended even on small areas (see PLANTING MACHINERY).

The date of seeding also varies. Wheat is a cool season crop and it is sown as early in the spring as the weather permits. Winter wheat is sown early enough in fall to enable a good root system to develop before cold weather stops growth.

A close sown crop, like wheat, is rarely cultivated except under intensified farming and where hand labour is readily available. If weeds become a problem, they can often be controlled by using chemical sprays that are selective in their action, killing the weeds and not seriously damaging the wheat.

3. Fertilizers.— In the humid areas of wheat cultivation, wheat responds to fertilizers. The most commonly required plant foods are phosphorus (P_2O_5), nitrogen (nitrates and ammonium compounds) and potassium (potash). The amounts required for optimum yields vary with each farm and locality. Commercial fertilizers are widely used where they are available. Other manures are used and the growing of legumes in the rotation will supply nitrogen. Phosphorus is the plant food most commonly needed and it is effective in increasing wheat yields even in the semihumid areas. Proper use of fertilizers increases yield 20% to 200%. Fertilizers generally are not needed in the greater part of the major dry land wheat-producing areas.

Wheat responds to irrigation and the combination of adding fertilizers and water increases the yield three to four times. In the dry land farming areas of the United States, irrigation has expanded rapidly. An entirely new agricultural industry is developing in the Sonora state of Mexico with the use of irrigation and fertilization of wheat. Wheat can be grown as a winter crop and corn or cotton as a summer crop. This double cropping is also common in Japan, where the cool season wheat is grown during the winter months and rice during the summer.

4. Harvesting.— Harvesting of wheat has also become highly mechanized. Combine harvesters are used wherever the area is large enough to handle such machinery. The wheat is cut and threshed by the combine passing through the field only once. In a number of areas, the wheat does not dry rapidly enough, so the wheat is cut and arranged in a windrow to dry and is picked up several days later with a combine. In the large producing areas the wheat is often piled on the ground, as rain does not occur often during harvest. This procedure is followed in order to harvest the standing grain as rapidly as possible to prevent field losses from storms. Most of the grain in these large producing areas is stored in local elevators or moved by railroad to large terminal storage areas. These storage facilities generally are available only in the surplus producing regions.

The production of wheat in the major area of North America had become so mechanized that about three man-hours were needed to handle one acre of wheat in 1957 compared with about fifty hours 100 years previously.

VI. DISEASES

The Romans attributed rust of cereals to the god Robigus, who imposed this damage upon the crops of wicked people. It was about A.D. 1800 before it was understood that rust of cereals was a disease caused by a fungus. There are three rusts that attack wheat: stem rust or black stem rust (Puccinia *graminis* tritici), leaf or brown rust (P. *triticina*) and yellow or stripe rust (P. glumarum). Stem rust is the most destructive, causing severe shriveling of the grain of susceptible varieties, so that in severe cases the crop is not harvested. Stem rust is world-wide in its distribution. It does not occur every year in epidemic proportions but it is the feared rust disease of many wheat growers. The rust organism belongs to the same group of plants as the mushrooms and produces spores of two types: red or uredospores and black or teliospores. The red stage is the one most commonly observed in the field. These spores can be easily blown about and alight on a wheat leaf. If there is high humidity, dew and the proper temperature, the spore germinates and the germ tube enters the breathing pores (stomata) of the leaf and a mass of growth occurs within the leaf. In 8 to 12 days a rupture (pustule) of the leaf epidermis occurs and thousands of new red spores are liberated which are capable of infecting other living wheat plants. This process is repeated as often as there is green wheat to infest and proper climatic conditions prevail. These red spores are also called summer spores. as they cannot live over the ninter. except in mild climate like Mexico's. However, the rust can travel north in the spring and summer in North America from Mexico to Canada, and then travel back south again in the fall on winter wheat or volunteer (self-sonn) wheat. This same pattern is followed in all the major wheat-producing areas of the world. so the rust can live continuously in the red stage. When the wheat begins to ripen the spores formed in the pustules are black or dark bronn. These are the winter spores and they can live over on the wheat straw under very cold conditions. In the spring these black spores germinate and produce small spores (sporidia); these cannot infest wheat but can develop only on the alternate host, the barberry bush (*Berberis* species) and closely related species (*Mahonia* species). This is the part of the life cycle of the rust called the sexual phase. New recombinations occur by crossing on the barberry leaves, and result in many new races (varieties) of stem rust. Control of stem rust is possible by growing resistant varieties and eradicating the barberry bush.

Leaf rust is also world-nide in distribution and has a life cycle similar to stem rust but it has a different alternate host, the meadow rue (Thalictrum species). In Korth America the alternate host is resistant so the leaf rust is entirely dependent upon the summer or red spores. The red spores can uithstand colder temperatures and can overwinter in many areas where winter wheat is gronn This rust is not as spectacular in its damage, but is more prevalent than stem rust and, on the average, does as much or more damage. Control is practical only through the use of resistant varieties of mheat.

Yellow or stripe rust is not as widespread, as it is generally limited to higher altitudes and cooler temperatures. Control of this disease is also only practical by the use of resistant varieties.

Another group of serious diseases is the smuts The important species are bunt or stinking smut (*Tilletia* caries and T. foetida) and loose smut (Cstilago tritici). Stinking smut replaces the kernel with black spores and they are called smut balls. The disease got its name from its fishy odor. The loose smut is evident at blooming time and replaces the head except for the central stem. This smut is not seen at harvest time. Control of stinking smut is possible by seed treatment and the use of resistant varieties. No practical seed treatment has been available to control loose smut, so the use of resistant varieties has been the most practical means of control.

There are many other diseases that cause damage to mheat, such as scab, which is serious in the humid areas. Virus diseases that occur in the soil or are transmitted by insects are often serious. There are other diseases that cause rot of the roots and crown of the plant and damage the leaves. (See also PLANTS AND PLAST SCIENCE)

VII. INSECTS

There are several insects which are injurious to wheat. The Hessian fly (*Phytophaga destructor*) is one of the most serious insect pests, particularly in the eastern half of the United States. The name mas derived from the belief that it was introduced into the United States in the straw used for bedding by the Hessian mercenaries who were brought over from Europe by the British during the Revolutionary War. This insect is a fly which lays its eggs on the leaves of young wheat plants. The hatched larvae (maggots) crawl do n to the base of the plant nhere they extract plant juices and also inject a substance that is toxic to the plant. As a result, winter wheat becomes more subject to winter killing and in the spring the straw breaks over. Control can be obtained on a community basis if all farmers where winter wheat is gronn plant after the main brood of flies has emerged. Sowing of resistant varieties is rnost effective and such varieties were becoming available by 1950.

The wheat-stem sawfly (*Cephus cinctus*) is a serious pest in western Canada and adjacent areas in the United States. The loss occurs by the larvae chewing a ring around the stem from the inside which causes the stem to fall over. Deep plowing and the use of resistant varieties are control measures.

Other insects causing occasional damage are wheat jointworms, wheat strawworms, chinch bugs. green bugs (aphid) and grasshoppers. The last three can be controlled by the use of insecticides.

VIII. STORAGE

Wheat can be stored almost indefinitely without deterioration under conditions whereby it is kept clean, cool, dry (only 12%–13% moisture) and free of insects. Insects that damage stored wheat are not active below 40° F. and multiply rapidly only at temperatures above 70° F. Insects can be controlled readily in proper storage facilities by the use of insecticides that are not detrimental to the quality or use of the wheat. Except in subsistence farming areas. much of the wheat produced moves rather promptly from the farm to the country elevator, then to the great terminal markets from which the demand of the larger mills and the export market are served. Substantial modern storage facilities for wheat and other grains exist not only at the major terminal markets, but at major ports of exit and in importing countries. In addition, the milling industry itself provides a considerable part of its storage facility needs. In the United States and in some other areas the governments have encouraged the erection of additional storage facilities on the farms and at the terminals.

IX. VARIETIES

Extensive programs of wheat improvement have been undertaken in almost all the wheat-groning regions of the world, particularly after 1900 when Mendel's laws of inheritance were recognized. Prior to this time, there were many varieties of wheat available which enterprising farmers had selected from their fields. Some of the first concentrated selections of wheat varieties were begun by the French seed firm of Vilmorins about 1850. The world-recognized Swedish Seed association at Lund was started in 1886. William Farrar in Australia began a planned breeding program as early as 1880. Most of the early breeding work nas selection of pure lines among the variations present in the commonly groan wheats. Seed from individual plants or heads was grown in short rows, the promising lines were studied in successive generations and the best lines increased and distributed to farmers. Such a practice does not create new genetic combinations, so plant breeders have resorted to crossing different varieties.

One of the first and also greatest achievements of breeding wheats by crossing was the development of Marquis spring wheat in Canada. Charles and Arthur Saunders carried on this work. An early variety. Hard Red Calcutta from India, was crossed with Red Fife. a wheat from Poland. In order to cross nheats, the plant breeder removes (emasculates) the anthers (male organs) from the flower before they are mature and protects the head from pollination by covering it with a small paper or plastic bag. Several days later he transfers anthers with live pollen from the selected male parent to the stigma (female organs) in the emasculated floner Plants derived from such matings are first-generation hybrid plants and are uniform. In subsequent generations, especially the second and third, many new recombinations occur. The desired plants are selected and increased. This process requires ro to 15 years. The cross from which Marquis nas selected was made in 1892and not until 1907 was there an appreciable amount of seed (less than one bushel). Once released for general production, if the variety is desirable. it will increase very rapidly. By 1918 there were over 300,000,000bu. of Marquis mheat produced in Canada and the United States. Many similar stories can be told for most parts of the world.

The breeding of rust-resistant spring wheats for winter sowing along nith proper irrigation and fertilizer practices has made wheat production in Mexico profitable where formerly little or no wheat could be grown. In Japan. remarkable achievement was made in breeding wheats that had short stiff straw and responded well to high fertility practices for winter production on the rice paddies. Enrique Klein of Argentina developed many varieties suitable for that country. Nazareno Strampelli in Italy developed durum wheat varieties that have been adapted to much of the Mediterranean area. Pawnee, a winter wheat, was grown on over 7,000,000 ac. ten years after it was released to farmers in Kansas and Nebraska. Thatcher wheat, developed in Minnesota. spread widely over the northern Great Plains and was the leading variety grown in Canada during the late 1940s and early 1950s. The rapidly changing variety pattern and a constant annual release of new varieties make any up-to-date account of all the notable achievements throughout the world impossible.

There are many problems of wheat production that can be partially solved by breeding. Man has created his own problems by growing wheat so extensively and continuously in certain areas. When one variety is widely grown, it offers an immense field for specific diseases to attack the plant. Thus, it is a never-ending battle for the wheat research man to compete with the constantly changing diseases.

There are other objectives in wheat breeding besides disease resistance. The major objectives are stronger straw, insect resistance, good quality for specific uses, cold resistance. heat resistance and higher yields. Achievement of these objectives is often difficult, but along with improved machinery and better cultural practices, breeding better varieties is one of the best ways of increasing wheat production and eventually increasing the world standard of living.

X. USES OF WHEAT

Wheat is not a homogenous commodity but is divided in the United States into various market classes primarily on the basis of use. These classes can be recognized morphologically on examination of the grain. Hard red minter wheat comprises about 60% of the marketed grain in the United States; hard red spring. 20%; soft red ninter, 10%; uhite wheat. 6%; and durum. 4%. Most wheat is grown for use as human food. Houever, about 10% is needed for seed, and small quantities are used for production of starch, paste, malt, dextrose, gluten (a source of monosodium glutamate). alcohol and other products. Inferior and surplus wheat are used for livestock feed. For this purpose, wheat is about equal to corn in nutritive value but it requires grinding for most livestock except poultry. By-products of the milling process are generally used for livestock feeds.

The chief food use is flour in the form of a baked product. The hard red uinter and hard red spring uheats are used primarily for bread flours. Soft wheats are used moatly for cake, crackers, cookies, pastry and family flours. Durum wheat semolina is used mostly for making spaghetti and macaroni and other pasta products. Breakfast foods are also made from wheat and the puffed wheat foods are made from varieties with large white kernels like the Baart variety of the Pacific northwest and certain durum varieties.

Cereal grains are a high energy food source. The grain not only includes the young plant (the embryo) but also the food necessary to nourish this young plant when it begins to grow. Therefore, these grains of wheat are like eggs and milk which also are foodstuffs designed by nature to nourish the young. If the uhole grain is used for food, five important items are supplied: carbohydrates, protein, fats, minerals and some vitamins.

Even though wheat products are a highly nutritious and inexpensive human food, consumption of wheat in a number of countries has declined as the standard of living has increased. largely due to the increased use of other foods that are more expensive but perhaps more tasteful. In the United States in 1910, 482,000,000 bu. of wheat were processed for food and there were 92,000,000 people. Comparable figures for 1956 were 483,000,000 bu and 168,000,000 people. These figures can be further expressed as 216 lb. of wheat per capita consumption in 1910 and 123 lb. in 1956.

XI. PROCESSING

Some wheat is eaten like a porridge or a broth or pudding, prepared by merely soaking the grain and cooking it. Most uses of wheat, however, require some processing before it is used as food. The grain is cleaned at the mill or processing plant to remove chaff, weed seeds and other material, and then it is scoured mechanically to remove the hairs and any dirt. Sometimes it is necessary to mash the wheat. Wheat is tempered or conditioned by adding water to it so that the kernel will break up properly. The dampened bran adheres together in large flakes. In the milling process, the grain is first cracked and then passed through a series of rollers, and each time as the smaller particles are sifted out, the coarser particles are passed on to other rollers for further reduction. About 72% of the milled grain is recovered as white flour. If a higher per cent is extracted, the flour is darker in colour. In Europe and Japan during World War II, the flour extracted was 78% to 85%. The whole wheat flour is called graham flour and includes the whole kernel. As most of the fat in the grain is in the germ, graham flour becomes rancid when stored for any length of time. As white flour does not contain the germ, it is an easily stored product. New processes of milling are being experimented with in the United States in which the flour is separated into various fractions by air separations. Two turbo mills mere in operation in 1957, and by this process it is possible to extract certain fractions from hard wheat flour that are more suitable for soft mheat uses than the soft wheat varieties themselves. This milling process may result in wheat products more competitive with other foods.

Most of the flour produced is used for breadmaking. For this purpose, the protein content should be about 12.5% and of good quality. The quality refers to the ability of the gluten to be elastic and to retain gas in the leaven loaf. The wheats grown in the drier areas, the hard red winter and hard red spring types, generally have a higher protein content (11% to 15%) and also a "stronger" gluten. The wheats grown in the humid areas are soft wheats and the protein content is often 8% to 10% and the gluten is "weak." However, this type of nheat produces flour suitable for special purposes. As the quantity of protein and sometimes the quality vary, the flours of different wheats are blended together to make flours suitable for many purposes. In the United States about 80% of the flour is used by commercial bakeries. New bakeries were being built and some were in operation in the U.S. in the late 1950s in which the breadmaking process was continuous. This automatic procedure produces a slightly different textured bread but of a character that appears to be readily accepted by the public.

XII. MARKETING

Most wheat moves off the farm on which it was produced, except that used for feed or seed. Wheat grain enters the local, national and international trade. The problem of marketing is not the same in all areas, as the use of the wheat is different and the types will reach different markets. Specific grain standards have been established and each lot of wheat that reaches a terminal market is examined and given a grade determined by the weight of a unit measure; condition of the grain; moisture content; presence of insects, stinking smut, other crops and foreign material. The grain may either be bought by grade alone or on sample.

Wheat grown in the semihumid areas, the hard wheats, are the ones produced in surplus. Most of the soft wheats and durum are used in local areas in the countries where they are produced.

Prices are determined in the United States by the price at Chicago, Ill. In the surplus areas, the price is less because of the cost of transportation to Chicago. On the other hand, in those areas to uhich wheat is shipped, the price is higher than at Chicago. There is a variation of pricing where wheat is shipped to seaports for international trade.

In many countries of the world, the production of wheat is under some government control either to increase production in deficient producing countries or to restrict it in surplus producing countries. Some of these activities have been successful in increasing production in countries that are attempting to become self-sufficient in nheat, but acreage and price controls in the surplus producing countries have not decreased production or given the farmers adequate returns for their uheat.

In the U S . Kansas, Nebraska and Oregon have organized wheat commissions financed by a small tax on each bushel of wheat produced in the state. These commissions are attempting to develop new markets as well as to increase exports to areas already using wheat products. Information and demonstrations concerning the use of wheat as human food have been made in areas of the world where the people are not accustomed to this commodity.

The principal export countries after World War II were the United States, Canada, Argentina, Australia and, in some years, France. Prior to World War II, Canada was the leading country. The principal import countries of wheat after World War II were the United Kingdom, the German Federal Republic, Brazil, the Netherlands, Belgium and Luxembourg.

WHEAT BELT: *see* AGRICULTURE: *United States: Type-of-Farming Regions: Wheat Areas.*

WHEATEAR *(Oenanthe oenanthe)*, one of the earliest spring migratory birds in Europe, often reaching England by the end of February. The cock, with his bluish-gray back and light buff breast, set off by black ear coverts, wings and part of the tail, is rendered conspicuous in flight by his white rump, from which comes the name, a corruption of "white rear." Both sexes have a sharp monosyllabic note that sounds like "chat." The nest is placed underground; a large amount of soft material is collected, and on it from five to eight pale-blue eggs are laid. Wheatears were formerly trapped for eating in enormous numbers on the downs. The wheatear ranges throughout the old world. It also breeds in Greenland and arctic North America. About eight species are found in Europe, but the majority are inhabitants of the drier parts of Africa. They are sometimes seen in northern Alaska, the Pribilof Islands and, rarely, in eastern Canada. Wheatears feed on small insects and on seeds and on the small fruits of *Saxifraga*.

ERIC HOSKING

WHEATEAR (OENANTHE OENANTHE), IN FLIGHT, DISPLAYING ITS CONSPICUOUS WHITE REAR

Among allied genera is Saxicola which includes two well-known British birds, the stonechat (*q.v.*) and whinchat (*q.v.*). The wheatear and its allies belong to the family Turdidae, the thrushes (*q.v.*). (HT. FN.)

WHEATON, HENRY (1785–1848), U.S. jurist and diplomat, made significant contributions to international law. Born at Providence, R.I., on Nov. 27, 1785, he graduated from Rhode Island college (now Brown university), Providence, in 1802; was admitted to the bar in 1805; and, after a year of study abroad, practised law at Providence from 1806 to 1812 and, in New York city, edited the Republican *National Advocate* from 1812 to 1815.

A judge advocate of the army in 1814, he published a *Digest of the Law of Maritime Captures and Prizes* (1815). He was a justice of the marine court of New York city from 1815 to 1819. As reporter of the U.S. supreme court in Washington from 1816 to 1827, he was distinguished for the learnedness of his annotations. He was a member of the convention to write a new constitution for the state of New York in 1821; a member of the assembly in 1823; and in 1825, a member of a three-man commission to revise the laws of New York. His diplomatic career began in 1827 with an appointment to Denmark. where he served as chargé d'affaires until 1835. He was also chargé d'affaires and then minister to Prussia from 1835 to 1846. *Elements of International Law* (1836), his most important work, was translated into many languages, including Chinese and Japanese, and became a standard work. *Histoire du progrès du droit des gens en Europe*, written in 1838 for a prize offered by the French Academy of Moral and Political Science, was expanded and translated into English in 1845 as *History of the Law of Nations in Europe and America*. His *History of the Northmen* (1831; expanded in French, 1844) did much to arouse European interest in Scandinavian history.

Wheaton's general theory of international law is that it consists of "those rules of conduct which reason deduces, as consonant to justice, from the nature of the society existing among independent nations, with such definitions and modifications as may be established by general consent." He died at Dorchester, Mass., on March 11, 1848.

See F. C. Hicks, *Men and Books Famous in the Law*, ch. viii and bibliography, p. 245 (1921).

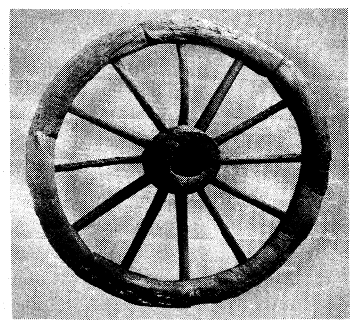
WHEATSTONE BRIDGE: *see* INSTRUMENTS, ELECTRICAL MEASURING: *Indicating Instruments.*

WHEEL. In ancient times the invention of the wheel probably took place in one locality from which its use spread over the ancient world. The saws and other tools of an advanced metal-using community would be necessary for working the wood, and archaeological evidence suggests that it was in ancient Mesopotamia, following the invention of the potter's wheel, that wheeled vehicles first came into use. The earliest wheels found in graves at Kish arid Susa date from the second half of the 4th millennium B.C., and are made of three shaped planks, clamped together with copper clasps across their greater length. The central plank bore a thick hub and the wheels were kept in position by linchpins piercing the extremities of the stationary axle. Rims of these wheels were sometimes bound with metal hoops heavily studded, and fixed to the wheel with long metal clasps which also acted as braces, keeping the planks in position.

The consistency of this tripartite solid wheel form in the ancient near east and in prehistoric Europe constitutes a strong argument for the diffusion of the wheel from a hlesopotamian or other western Asiatic source, and can be followed in the history of the cart. Nowhere is the spoked wheel attested before the 2nd millennium, but shortly after 2000 B.C. spoked wheels occur on clay models in northern Mesopotamia, central Turkey and northeast Persia. By the 15th century B.C. spoked wheels were in use on chariots in Syria, Egypt and the western Mediterranean, and in China they were fitted to chariots used in the first historical Shang dynasty about 1300 B.C. *(See* CART AND WAGON.)

In Europe, miniature four-spoked wheels were used in the Late Bronze Age as mountings for wheeled cauldrons in Bohemia and Denmark, and solid cast bronze wheels of similar broad felly, or peripheral rim, survive from the central European Iron Age. A four-spoked wheel is represented on a chariot carved on a chieftain's grave at Kivik in Sweden about 1000 B.C., from which time spoked wheels were common in northern and western Europe.

Meanwhile the solid wheel was commonly used for agricultural purposes. Tripartite wheels with crescentic openings on both sides of the hub mere in use in the Bronze Age in Denmark, Germany and northern Italy, probably for carts, and are identical with nheels still in use in the Indus valley. Both Etruscan and Roman country carts had solid wheels made either of simple slices of thick tree trunks filled with small, square metal hubs, or of shaped planks nailed onto a square frame behind. Tripartite wheels with circular openings, solid slice wheels and solid plank wheels were in use in modern times in Spain, Sardinia, southern Italy, Wales, Ireland and Orkney, while solid wheels of three arc-shaped pieces uniting at the hub were known in antiquity and can still be seen on modern Anatolian carts.



BY COURTESY OF NATIONAL MUSEUM OF ANTIQUITIES, EDINBURGH

WHEEL FROM ROMAN CAMP AT NEWSTEAD, SCOT., WITH COMPOSITE FELLY

Multiplication of openings in the solid wheel probably did not give rise to the invention of spokes, but a wheel of the crossbar type commonly used in classical Greece and Cyprus, and much earlier in northern Italy, appears to be transitional, or at least to preserve an attempt to provide a spoked wheel with the simpler joinery of the solid wheel.

The fellies of the earliest spoked wheels are made of a single piece of wood bent in a full circle by heat. An Egyptian chariot from Thebes (1435 B.C.) has a felly of a single piece of ash into which the spokes are fitted by a mortice joint after a manner depicted in Egyptian wall paintings. The thick fellies of European Bronze Age wheels were probably made up of several doweled pieces kept in position by a metal tire. Improvement in wheel design was probably the speciality of Celtic wheelwrights of Roman times; not only has Latin several Celtic loanwords for wheeled vehicles, but some of the finest surviving wheels are those found in Roman sites in Celtic areas and southern Gaul. Celtic wheels in Europe have up to 14 spokes and are sometimes fitted with iron tires, shrunk on to the wood while the metal was still hot. Chinese wheels of similar date have up to 40 spokes.

The problem of avoiding the wearing of the hubs in these early wheels was met in Roman times by lining them at both sides with bronze rings, but the hubs of the Celtic wagons preserved in the bog at Dejbjerg, Den., are the earliest with roller bearings, formed by channels inside the hub in which lay rods of wood which turned between hub and axle.

A number of dark age and medieval cart wheels have survived in Denmark. These have broad rims of six or seven fellies with one spoke passing through each to take the strain. Wheels of this type, usually with large hubs, are illustrated in medieval drawings both on carts and plows. Some were fitted with metal tires, banned in most medieval towns for the ruts they made.

The final development in wheel construction was "dishing," an arrangement in use by the 16th century for making the spokes in a flat cone, necessary because of the great increase in size of wheels in medieval times and for the counteraction of swaying loads on rough roads The wheel was one of man's most important inventions and has had a profound effect on cultural diffusion. Insoiar as is known, the Peruvian and Aztec civilizations of America were ignorant of its use until the Spanish conquest. Although a number oi wheeled animal figures are known to have been made in Mexico *c.* A.D. 1000, it is not certain whether wheeled vehicles also were evolved and it is generally thought wheels were not put to practical use in America until the Spanish conquest.

WHEEL, BREAKING ON THE, a form of torture (*q.v.*) or of execution formerly in use in France and Germany, where the victim was placed on a cart wheel and his limbs stretched out along the spokes. The wheel was made to revolve slowly, and the man's bones broken with blows of an iron bar. Sometimes it was mercifully ordered that the executioner should strike the criminal on chest -or abdomen, blows known as *coups de grâce,* ahich at once ended the torture; in France he was usually strangled after the second or third blow. A wheel was not always used. In some countries the victim was stretched upon a frame shaped like St. Andrew's cross. The punishment was abolished in France at the Revolution, but it was employed in Germany as late as 1827. A murderer was broken on the row or wheel at Edinburgh in 1604, and two of the assassins of the regent Lennox thus suffered death. (R. G. CL.)

WHEELER, BENJAMIN IDE (1854–1927), U.S. philologist and university president, was born at Randolph, Mass., on July 15, 1854. and was educated at Brown university, Providence, R.I. (A.B., 1875). After four years as a high-school teacher in Providence and two as an instructor in Greek and Latin at Brown, he spent four more as a student in Germany, graduating with a Ph.D. in comparative philology at Heidelberg in 1885. His doctoral dissertation formulated a law of Attic Greek accentuation of nouns and adjectives that still goes by his name.

After a year (1885–86) at Harvard university he went to Cornell university, Ithaca. N.Y.. as professor and served there until. in 1899. he was elected president of the University of California; he retired 20 years later. His tenure saw not only a natural growth of the university, but a directed growth, over which Wheeler had exercised a guiding and controlling hand. He was the Theodore Roosevelt professor at the University of Berlin in 1909–10 and the liking for Germany and admiration of German scholarship which he had formed in his student days was strengthened and led eventually to difficulty and embarrassment when the United States entered World War I against Germany.

The promise of distinguished scholarship given in his youth was cut short by his duties as university president; otherwise he would be counted as one of the foremost philologists ever produced by the United States. (J. WH.)

WHEELER, WILLIAM ALMON (1819–1887), vice-president of the United States from 1877 to 1881, was born in Malone, N.Y., June 30, 1819. After two years at the University of Vermont. Burlington. he studied law, was admitted to the bar and practised successfully six years. He turned to banking and in 1853, as trustee of mortgage holders, took charge of a railroad.

As a Whig, Wheeler had been elected county attorney in 1846 and New York state assemblyman in 1850. Joining the new Republican party he was elected state senator and president pro tem of the senate in 1858, was a member of congress, 1861–63, and president of his state's constitutional convention, 1867–68. In 1869 he was returned to congress where, in 1875. on a committee investigating a disputed state election in Louisiana, he devised the "Wheeler compromise" which recognized William P. Kellogg as governor and the election of such candidates as gave majorities to the Republicans in the state senate and the Democrats in the louer house. In 1876 he was Rutherford B. Hayes's running mate in the disputed election decided by the electoral commission. (W. E. BY.)

WHEELER, WILLIAM MORTON (1865–1937), U.S. zoologist who was noted for his work on the taxonomy, ecology and behaviour of ants, mas born at Milwaukee, Wis., March 19. 1865. He graduated from the German-American Normal college, Milwaukee, in 1884; received his Ph.D. degree, 1892, from Clark university, Worcester, Mass.; and doctor of science from The University of Chicago, 1916. He was assistant professor of embryology, The University of Chicago, 1896–99; professor of zoology. the University of Texas, .Austin, 1899–1903; curator of invertebrate zoology, American Museum of Natural History, New York city, 1903–08. In 1908 he was made professor of entomology at Harvard and in 1915 became dean of Bussey institution. He was a member of the National Academy of Sciences. His publications include *Ants, Their Structure, Development and Behaviour* (1910); *Social Life Among the Insects* (1923); *Foibles of Insects and Men* (1928); and monographs on numerous species of ants. He was also noted for his humorous and satirical writings, included in *Essays in Philosophical Biology* (1939). (A. E. E.)

WHEELING, a city of West Virginia, U.S., and the county seat of Ohio county, is located on the Ohio river about 40 mi. S.W. of Pittsburgh, Pa.. in an industrial area which includes western Pennsylvania, the West Virginia panhandle and eastern Ohio. More than 400 industries are located within the Wheeling area with metallurgy, glass manufacture. tobacco products, pottery and textile manufacturing heading the list of economic activities. Pop. (1960) city, 53,400; Wheeling standard metropolitan statistical area (Marshall and Ohio counties in West Virginia and Belmont county in Ohio), 190,342. (For comparative population figures *see* table in WEST VIRGINIA: *Population.)*

The city operates under a council-manager type of government. Educational facilities include Linsly Military institute, established in 1814; Mount de Chantal academy, established in 1848; and Wheeling college, a liberal arts institution operated by the Society of Jesus and founded in 1954. Cultural and educational programs are afforded through the operations of Oglebay park, which supports a historical and arts museum and sponsors concert and lecture series. Oglebay institute, another affiliate of Oglebay park, is operated by the college of agriculture of West Virginia university. Wheeling has two daily newspapers, the *Intelligencer* and the *News Register,* three radio stations and one television outlet.

Wheeling was founded in 1769 by Ebenezer Zane of Virginia. who later also helped settle Zanesville, O., and was the site of Ft. Henry, an important outpost of the Virginia frontier. During the Revolutionary War the fort was attacked several times by Indian bands, and was the scene of the last battle of the Revolution in Sept. 1782.

The town, incorporated in 1806, and chartered as a city in 1836, benefited economically from its position as western terminus of the National road for several years after 1818, and was further stimulated by the completion of the Baltimore and Ohio railroad in 1852. During the Civil War Wheeling was a centre for the unionist movement in western Virginia and was the seat of the restored government of Virginia from 1861 to 1863. With the admission of' West Virginia into the union in June 1863. Wheeling became the first capital of the new state and served as such until 1870. From 1875 to 1885 the state capital was again located in Wheeling. (GE. E. M.)

WHEELOCK, ELEAZAR (1711–1779), American educator, founder and first president of Dartmouth college, mas born at Windham. Conn., April 22, 1711. He graduated from Yale in 1733, studied theology and in 1735 became a Congregationalist preacher at Lebanon. Conn. He was a popular preacher throughout the period of the Great Awakening. He also took young men into his house to fit them for college. One of these was a Mohegan Indian. Samson Occom, who made such excellent progress that Wheelock decided to found a free school where both whites and Indians could be educated. With aid from various sources he conducted such a school at Lebanon from 1754 to 1768. but without a large attendance. When the school eventually failed, Wheelock accepted the governor of New Hampshire's offer of a township of land on the Connecticut river. He went there with about 30 students in 1770. and, with other settlers, founded the town of Hanover. The new college was named Dartmouth college in honour of the earl of Dartmouth. For the remaining nine years of his life. which included the turbulent Revolutionary War period. Wheelock worked for the college, supervising building, preaching, teaching and raising money.

Wheelock died at Hanover, April 24, 1779.

His eldest son. JOHN WHEELOCK (1754–1817), succeeded him as president of Dartmouth.

WHEELWRIGHT, WILLIAM (1798–1873), U.S. businessman, promoter and pioneer railroad builder who spent nearly all of his adult life in advancing commerce and technology in South America. He was born in Newburyport, Mass.. Mar. 16, 1798. Wheelwright first went to Chile in 1824 and returned in 1830 to enter business. In 1840 he established a steamship line between Valparaiso and Liverpool, Eng., and subsequently obtained permission to operate a line along the South American west coast. He won numerous concessions from the Chilean government for railroads, telegraphs and public utilities. He built the Caldera-Copiapó railroad (1850–51), often regarded as the first commercial carrier in South America. He also directed the construction of the Valparaiso-Santiago telegraph (1852) as well as the first section of the Valparaíso-Santiago railroad.

His enterprise led to the introduction of modern public utilities in a number of Chilean cities, notably Valparaíso. In 1863 he transferred his interests to Argentina where he directed the construction of the Rosario-Cordoba railroad. Although a U.S. citizen, Wheelwright depended almost entirely upon British financing for his projects. In appreciation of his contributions the Chilean people, in 1877, erected a statue to him in Valparaiso.

He died in England Sept. 26, 1873. (J. J. J.)

WHELK, a common name applied to many species of small to fairly large carnivorous marine snails belonging to several closely related families. They all have a powerful rasping tongue (radula), and have large horny teeth adapted for tearing animal tissue. Whelks commonly feed on clams, worms, barnacles and snails and occasionally on fish, lobsters and crabs caught in commercial traps. These active mollusks crawl about by means of a large muscular foot. A long siphonal tube protrudes from under the edge of the shell and directs water into the mantle cavity for respiratory purposes. The proboscis with the radula at its anterior end can be greatly extended and inserted betneen the valves of a clam, the animal on which whelks most frequently feed. A flattened plate (operculum) attached to the dorsal surface of the foot closes like a lid over the open end of the shell when the animal retires into the shell. The sexes are separate and the male specimens may be readily distinguished by the large external verge or copulatory organ which arises on the right side of the neck but is folded back and lies within the mantle cavity except during copulation. Fertilization is internal and the eggs are deposited in chitinous capsules arranged in clusters or strings and attached to rocks, wood, shells. etc.

The common whelk (*Buccinum undatum*) reaches about 4 in. in length and occurs on the coasts of northwestern Europe and northeastern North America. Used by British fishermen as bait for long lines, common whelks are dredged or are caught in traps baited with crabs. They are food for many bottom-feeding fishes such as cod, and by starfish.

Murex species are sometimes called rock shells or rock whelks. They are distributed throughout tropical and temperate seas: living on or under rocks or on oyster bars, from the intertidal zone to considerable depths. The Tyrian purple of the Phoenicians came from the Mediterranean rock whelks; for example, *Murex brandaris* and *Murex trunculus*. The dog whelks belong to the family Thaisidae; *Thais lapillus* is the common species of the New England and north European coasts. *Thais haemastoma* and various subspecies which occur in southeastern Cnited States and the Caribbean area may be very detrimental to oyster beds. *Busycon* species are also referred to as whelks; they range from southern Massachusetts to Yucatan, living on clam beds and oyster bars usually below the low tide line in shallow water to depths of several fathoms. They are the largest of the whelks, some of them reaching about 16 in. in length.

WHETSTONE, GEORGE (1551?–1587), British author, was a son of Robert Whetstone, prosperous London haberdasher After Robert Whetstone's death (1557) his widow lived near 'Stamford. Thus young Whetstone came to know the Burghleys, to whom several of his works are addressed. Fiction and autobiography are inextricably mingled in his writings (*e.g.*, *The Rock of Regarde*, 1576), but it seems probable that he studied at one of the inns of court and became acquainted with writers and scribblers. His play *Promos and Cassandra* (1578) was one or' the sources of Shakespeare's *Measure for Measure;* the dedication is a venture into dramatic theory. Whetstone joined Sir Humphrey Gilbert's abortive voyage of 1578. In 1580 he visited Italy. His *Heptameron of Civill Discourses* (1582; re-issued as *Aurelia*, 1593) attempts to follow the Italian pattern of interlacing tales and debates. His subsequent works are didactic compilations. His *Mirour for Magestrates of Cyties* and *Touchstone for the Time* (1584; re-issued as *The Enemie* to *Unthryftinesse*, 1586) censures civic corruption; his *Honorable Reputation of a Souldier* (1585) is a conduct book for soldiers in the Low Countries; his *English Myrror* (1586) enjoins civil obedience; his *Censure of a Loyall Subject* (1587) moralizes on the executions following the Rabington conspiracy. In Aug. 1587 Burghley made Whetstone a commissary of niusters in Holland under Sir Thomas Digges. In September, Whetstone was killed by Capt. Edmund Udall in a duel at Bergen-op-Zoom. (T. C. I.; M. M. Ls.)

WHEWELL, WILLIAM (1794–1866), British philosopher, remembered for his work on the theory of induction and for his interest in the physical sciences. was born at Lancaster on May 24, 1794. He secured an exhibition at Trinity college, Cambridge, became second wrangler in 1816 and subsequently a fellow and tutor of his college. He was a fellow of the Royal Society by the age of 26. At Cambridge, Whewell was professor of mineralogy from 1828 to 1832 and professor of moral philosophy (then called moral theology and casuistical divinity) from 1838 to 1855. Master of Trinity college from 1841, he was vice-chancellor of Cambridge university in 1842. He died at Cambridge on March 6, 1866.

From the 1820s on Whewell was a distinguished figure in the academic world. His changing interests were reflected by early works on mechanics and dynamics, followed by studies of the history and philosophy of science, by exhaustive researches on tides and, after 1850, by writings on moral theology. His close study of Kant gave him considerable advantages over other contemporary British philosaphers. Although his work on the theory of induction was overshadowed by that of J. S. Mill, Whewell's lasting reputation rests on his History of the Inductive Sciences, 3 vol. (1837), and his Philosophy of the Inductive Sciences (1840), the latter being eventually expanded into three books, The History of Scientific Ideas, 2 vol. (1858), Novum *Organon* Renovatum (1858) and Philosophy of Discovery (1860).

WHIG AND TORY, names used to denote two opposing political parties in England, were terms of abuse introduced in 1679 during the heated struggle over the bill to exclude James, duke of York, from the succession. "Whig" whatever its origin in Scots Gaelic—was used of cattle and horse thieves and was thence transferred to Scottish Presbyterians. Its connotations were Presbyterianism and rebellion; and it was applied to those who claimed the power of excluding the heir from the throne. "Tory" was an Irish term suggesting a Papist outlaw and was applied to those who supported the hereditary right of James in spite of his Roman Catholic faith. The revolution of 1688–89 greatly modified the division of principle between the two parties, for it was a joint achievement. Thereafter most Tories accepted something of the Whig doctrines of limited constitutional monarchy rather than absolutist divine right monarchy, and under Queen Anne they represented the resistance, mainly by the country gentry, to religious toleration and foreign entanglements. Toryism became identified with Anglicanism and the squirearchy, Whiggism with the aristocratic landowning families and the financial interests of the wealthy middle classes. The death of Anne in 1714, the manner in which George I came to the throne as a nominee of the Whigs, and the flight of the Tory leader Lord Bolingbroke (*q.v.*) to France, conspired to destroy the political power of the Tories as a party (see ENGLISH HISTORY). There followed nearly 50 years of rule by aristocratic groups and connections, regarding themselves as Whigs by sentiment and tradition. The die-hard Tories were discredited as Jacobites, though about 100 country gentlemen, regarding themselves as Tories, remained members of the house of commons throughout the years of the Whig hegemony. As individuals and at the level of local politics, administration and influence, such "Tories" remained of great importance.

The reign of George III brought a new phase in the shift of meanings of the two words. There was no Whig party, only a series of aristocratic groups and family connections operating in parliament through patronage and influence. There was no Tory party, only Tory sentiment, tradition and temperament surviving among certain families and social groups. The so-called "king's friends," from whom George III preferred to draw his ministers (especially under Lord North, 1770–82), came from both traditions and from neither. It was only by 1784, after more profound political issues, which deeply stirred public opinion, had arisen about such controversial matters as the Wilkes case of 1768–69 (see GEORGE III) and the American Revolution, that real party alignments could take shape.

After 1784 the younger Pitt emerged as the leader of a new Tory party. This broadly represented the interests of the country gentry, the merchant classes and official ministerial groups. In opposition a revived Whig party, led by Charles James Fox (*q.v.*), came to represent the interests of dissenters and industrialists, and a desire for electoral, parliamentary and philanthropic reforms. The French Revolution and the wars against France further complicated this division, for a large section of the more moderate Whigs deserted Fox and supported Pitt. After 1815 there followed a further period of party confusion, from which emerged eventually the conservatism of Robert Peel and Benjamin Disraeli, and the liberalism of Lord John Russell and W. E. Gladstone. Although the label Tory continued to be used of the Conservative party, Whiggism ceased to have much political meaning. See CONSERVATIVE PARTY, BRITISH; LIBERAL PARTY. See also Index references under "Whig and Tory" in vol. 24.

See K. G. Feiling, *History of the Tory Party, 1640–1714* (1924) and *The Second Tory Party, 1714–1832* (1938) ; L. B. Namier, *England in the Age of the American Revolution* (1930). (D. TN.)

WHIG PARTY, one of the two major political parties in the United States from about 1834 to 1854. Though its lineage may be traced back through the National Republicans, led by John Quincy Adams and Henry Clay (*qq.v.*), to the Federalists under George Washington and Alexander Hamilton, the party as such was formed in 1834 following the overwhelming victory of the Democrats in electing Pres. Andrew Jackson to a second term in 1832, chiefly on his issue of "killing" the second Bank of the United States by refusing to renew its charter.

Drawing strength and support from three main groups—eastern capitalists, western farmers and southern plantation owners—the Whigs generally espoused the cause of propertied and professional people (without, however, being antilabour) and, above all, the cause of national unity. In the beginning they were united by their bond of opposition to "executive usurpation" under President Jackson and by winning to their ranks the great bulk of the membership of the Anti-Masonic party (*q.v.*). A twofold strategy lay behind the choice of the term Whig: to avoid the handicap of functioning any longer under a name identified with the disastrous defeat of 1832, especially since the loser in that campaign, Clay, was one of their main leaders; and, by implication, to fasten on the Jacksonian Democrats the odious label of Tories.

Senators Clay of Kentucky and Webster of Massachusetts gave the Whigs their best and most sustained leadership; yet Gen. William Henry Harrison (1840) and Gen. Zachary Taylor (1848), neither of whom represented any well-known political views, were their only successful presidential candidates—and both men died in office, with serious consequences for the party. Sen. John C. Calhoun of South Carolina, spokesman of the great slaveowners of the south, supported the Whigs until the close of the 1830s, primarily because of Jackson's ruthless opposition to nullification (*q.v.*); but Calhoun later returned to the Democratic fold.

Not yet fully organized by 1836, the Whigs supported three candidates in that election (Webster in the east, Harrison in the west and Hugh L. White in the south), but in 1840 they nominated the old Indian fighter Harrison and John Tyler, a leading Virginia planter. This was the famous "log cabin and hard cider" campaign of "Tippecanoe and Tyler too." The Whigs won, but Harrison died within a month after his inauguration as president; Tyler, a southern Whig, proved to be so much more concerned about states' rights (*q.v.*) and slavery than about the program of either the Clay or Webster factions, that these factions secured Tyler's formal ejection from the party. In 1844 the Whigs nominated Clay as their standard-bearer and drafted their only real platform, one stressing the need for a well-regulated currency, a tariff for revenue, distribution to the states of the proceeds from the sale of public lands, limitation of the president to a single term, and reform of executive usurpation—all in line with Clay's "American system" of tariff protection and internal improvements proposed in the 1820s. Perhaps, however, because of his indecisive position on the "reannexation of Texas," the key issue of the Democrats, Clay lost and James K. Polk won.

In 1848 the Whigs again offered a military hero, General Taylor of Mexican War fame, as their candidate and succeeded a second time in gaining the White House. only to have their leader die in July 1850. On the accession of Millard Fillmore to the presidency the greatest question before the country was that of the extension or prohibition of slavery in the newly acquired territories. Faithful to the key Whig principle of preserving national unity, Fillmore sided with Clay in the effort of the "great compromise" to forge a final solution to this irrepressible issue. When the Clay-sponsored compromise of 1850 (*see* COMPROMISE MEASURES OF 1850) became law, the Whigs hailed it as a lasting settlement and looked forward with confidence to the next campaign. Their strategy in 1852, based on the assumption that the slavery question had been solved, was to allow the southern states'-rights wing to write the platform while the northern nationalist wing selected the nominee. Passing over Webster and Fillmore, either of whom would have symbolized the party's great achievements, they for a third time nominated a general. \\'infield Scott proved. however, to be so inept a candidate that the Whigs not only went down to defeat but did so in a manner foreshadowing both their own extinction as a party and the dissolution of the union.

The year 1856 witnessed the gathering of a few "silver gray" or "cotton" Whigs to draft a platform calling for "unalterable attachment to the Constitution and the Union" and emphasizing the "absolute necessity of avoiding geographical parties." When it came to nominating a ticket, however. they chose for their candidates the nominees of the "Know-Nothing" or American party (*q.v.*). This was in effect a confession that the bulk of their members had already gone over either to that party or to the new Republican party, which was to win the presidency under Abraham Lincoln. a former Whig. four years later.

WHINCHAT (*Saxicola rubetra*), a European bird related to the wheatear and stonechat (*qq.v.*). A summer migrant, the whinchat is about five inches long and somewhat larger than the stonechat, which it resembles in behaviour and appearance. being distinguished by a prominent eye-stripe, white patches at the base of the tail and a !ess upright pose.

The whinchat ranges over Europe and western Asia, wintering in Africa.

It nests in coarse grass, often at the foot of a small bush or large plant.

WHIP. This article considers first the whip in the English parliament and second. in the U.S. congress.

England. — In English parliamentary usage. whip denotes a party official chosen to assist his leaders in the management of the party. the term being supposedly derived from the "whipper-in" at a hunt. The party whips are expected to secure the attendance of their followers on all necessary occasions, and especially for divisions. If a member finds it difficult or impossible to attend, the whips may arrange a "pair" with a similarly situated member of the opposing party. It is the whips' business to persuade their followers to vote with the party and to speak in accordance with party policy, and they act as a channel of information and complaint between the rank and file and the party chiefs. In the Conservative party the chief whip, deputy chief whip and junior whips are appointed by the leader of the party personally: in the Labour party the chief whip is elected annually by the parliamentary Labour party. and he in turn appoints the other whips. The government and opposition chief whips are the "managers" of their respective parties in the house of commons. They are "the usual channels" through which are negotiated the complicated arrangements for the daily conduct of parliamentary proceedings; these negotiations are said to take place "behind the speaker's chair."

The government chief n-hip is responsible, in collaboration with the leader of the house of commons. for securing the smooth flow of government business. and for ensuring that legislation proceeds in accordance with the plan approved by the cabinet at the beginning of each session. He traditionally holds the office of parliamentary secretary to the treasury. for which he receives a salary of £3,750. He is still popularly known as the "patronage secretary." a reference to the time when public offices were freely bestowed as a reward for parliamentary support, and he is usually consulted by the prime minister when the latter is forming or reconstituting a government. The deputy chief whip and four junior whips are appointed lords commissioners of the treasury; others are paid as officers of the royal household. One or two holders of "household" offices are government whips in the house of lords. There are also, usually. a number of unpaid assistant whips. The opposition whips receive no payment other than their salaries as members of parliament.

The term is also used derivatively to denote the written summons sent out from the whips' office each week (or oftener if required) informing members of the parliamentary program, the importance of the proceedings being indicated by the number of lines underscoring the text. Failure to respond to a "three-line whip" is taken as a serious breach of party loyalty unless an adequate reason is forthcoming. Receipt of the neekly whip is evidence of party membership; hence expulsion (or resignation) from the parliamentary party is commonly referred to as "withdrawal" (or resignation) of the party uhip."

See H. Morrison, *Government and Parliament,* pp. 100 ff. (1954). (JK. W. G.)

United States. — In the 20th century. U.S. congressional party whips, who function much as in the English parliament, came to he used in both houses and both political parties. The first person officially known as a whip in congress was Republican Rep. James E. Watson of Indiana. so designated by his party in 1899. In the senate the first official Democratic whip was Sen. James H. Lewis of Illinois. named in 1913. Two years later the Republicans designated Sen. James W. Wadsworth, Jr.. of New York as their whip.

The Democratic "whip organization" in the house of representatives consisted in the later practice of the 20th century of a chief whip, appointed by the Democratic floor leader, and 15 assistant whips selected on a regional basis by the democratic representatives. The house Republican "whip organization" included a chief whip, chosen by his party's committee on committees; a deputy whip; and 4 regional and 1j area whips, selected by the chief whip. In the senate the whip machinery was smaller, consisting on each side of a single senator, elected by his party conference, and a party secretary. The secretaries to the majority and minority parties performed most of the whip functions in the senate.

The whips send out week-end "whip notices" to party members about the following week's legislative program; conduct polls of party members through a "whip check" to estimate the prospective vote on bills; round up members for the actual votes; arrange voting "pairs" between opposing members: and serve as assistant floor leaders in the absence of their leaders. With the growth of insurgency and factionalism in the congressional parties and the decline of party regularity after 1900, the whips' task steadily increased. (G. B. GY.)

WHIPPING: *set:* FLOGGING.

WHIPPLE, GEORGE HOYT (1878–), U.S. physician, educator and Nobel prize winner, noted for his studies of the liver in its essential relation to blood formation. was born on Xug. 28. 1878, the son of a physician in Ashland, N.H. After graduation from Yale in 1900. he received his M.D. from the Johns Hopkins university. Baltimore. Md., in 1905, where he continued his training in pathology under William H. Welch. He became associate professor of pathology at Johns Hopkins in 1911. From 1914 to 1921 he was professor of research medicine at the University of California. Berkeley, and director of the Hooper Foundation for Medical Research. His discovery during this period that liver is essential for blood formation. together with the demonstration by George Minot and William P. Murphy of Harvard that liver is curative in pernicious anemia. led to the Nobel award, given jointly to these three workers in 1034.

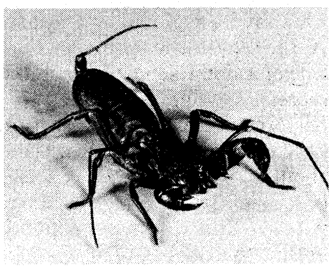
In 1921 Whipple went to the University of Rochester, N.Y., to become the first dean and organizer of its new medical school. He gave basic design to the construction of what has become a world-famous integrated medical centre. combining university hospitals and medical school under one roof. During this period he continued and greatly extended his researches on the liver. (W. S. McC.)

WHIPPOORWILL, common night bird, *Caprimulgus vociferus,* of the hardwood forests of eastern Korth America; the name is taken from its call. It belongs to the world-wide family Caprimulgidae, which also includes nightjars, goatsuckers, poorwills, chuck-mill's-widows and nighthawks. The whippoorwill, about 10 in. long, has a very small bill but a big head, large eyes, a bristle-fringed gape that extends back under its ears, tiny feet and very long wings. In colour the bird is variously patterned in rich browns, tans and black, and the male has a white throat band and white tips to its outer tail feathers.

During the day the whippoorwill sleeps on the ground, where its colour harmonizes with the dead leaves. At night it feeds by watching for insects from some perch or pursuing them swallowlike and snapping them up in its huge maw. Its loud, three-syllable whistled call is heard in the darkness more often than the bird is seen and may be repeated hundreds of times in quick succession, often when the bird is perched on a branch. To some people the call is tiresomely monotonous.

No nest is made; the two plain white or lightly spotted eggs are laid on the ground among the leaves where they are conspicuous if the parent leaves them. The young is down-covered, and though able to walk about some is cared for by the parents in the vicinity of the nest site. In winter the birds go south, some as far as Costa Rica. (A. L Rd)

WHIP SCORPION, a common name applied to any representative of the order Pedipalpida (Thelyphonida) of the class Arachnida (*q.v*). A certain superficial resemblance between true scorpions and whip scorpions is responsible for the name of the latter. But unlike scorpions they are not poisonous and their tail or flagellum is a harmless, tactile appendage. They have powerfully developed pedipalpi, by means of which they grasp beetles and other insects on which they feed, and with which they can inflict a painful prick if picked up carelessly. When irritated they produce a gaseous secretion from glands opening at the base of the tail. The odour of this secretion, resembling vinegar, caused the Mexican people to give the name "vinegaroon" to *Mastigoproctus giganteus,* the common whip scorpion found in Mexico and the southwestern United States. The chemical composition of this secretion is not known, but it is highly irritating to mucous membranes and is quite effective as a means of defense. The first pair of legs is not used in locomotion, but like the tail is a tactile organ.



ROBERT C HERMES FROM NATIONAL AUDUBON SOCIETY

WHIP SCORPION (THELYPHONUS CAUDATUS), FOUND IN JAVA

Whip scorpions are inhabitants of tropical and hot countries. They live under stones, in crevices of rocks, in termite nests, in burrows in the ground and in dark or deserted buildings. The females carry the eggs in a glutinous secretion on the underside of the abdomen until they are hatched. The young climb on the back of their mother and stay there for five or six days when they moult and desert h e parent to lead an independent life. It is not known how long they can live, but it is certain that their life lasts at least several years. Whip scorpions are a comparatively small order. Only ten genera are usually recognized and of these only two belong to the American continent. The rest are found in the eastern hemisphere. The oldest known of these is *Thelyphonus caudatus* from Java, first described by Linnaeus. Its defensive secretion smells of formic acid. A very active creature, half as large as the Mexican whip scorpion, it is, like the latter, occasionally found in dwellings. The courtship and mating of an allied species, *Thelyphonus sepiaris,* of Ceylon and India, has been described by Gravely in the *Records* of the Indian museum of Calcutta. (A. Ph ; X.)

WHIRLPOOL, a rotary flow of ocean currents around a depressed central area, created by the head-on meeting of a rising tidal current with the return-ebb current of the preceding tide. Whirlpools are of common occurrence in the narrow passages between island groups and mainland shores, as in the fiords of Norway, the Hebrides and Orkney Islands off the coast of Scotland. In some cases the rotary flow becomes accentuated and changes to a spiraling flow with downward draft into a deep centre, characteristic of vortex flow (*see* below). This phenomenon is known to occur where tidal inflow through a narrow passage having considerable depth meets ebb-tide outflow, as in the Naruto strait connecting the Inland sea of Japan with the Philippine sea. (*See* "Cruising Japan's Inland Sea," by Willard Price, *National Geographic Magazine,* Nov. 1953, p. 623.) In general, the reversal of tides, which is primarily responsible for the conditions mentioned, is linked with the relative positions of sun and moon, occurring approximately every six hours. The moon, being nearer the earth, exerts by far the stronger force in the formation of the tides and of the resulting tidal currents. Their regularity of occurrence is a material aid to navigators, especially to fishermen in sailing vessels, except when sudden winds of gale force, blowing in a direction contrary to or at an angle with that of tidal flow, create high waves or "choppy" waters that have been responsible for the loss of ships and of life and hence are greatly feared by navigators. Only high-powered steamships and motor-driven boats can withstand their onslaught.

Whirlpools occur in many parts of the world. Among the better known are the whirlpools of Charybdis, along the Calabrian coast, and of Messina, in the Strait of Messina (first described by Homer) between the island of Sicily and the mainland of Italy. The Maelstrom (Dutch for "whirling stream") between the islands of Moskenes and Mosken of the Lofoten Islands, which are off the coast of Norway, is peculiarly subject to "rough water" in windy weather.

Direction of rotary flow in whirlpools is independent of rotation of the earth, as the result of superior control by coast lines and bottom obstructions. However, unhampered strong vortex flows of the type occurring in the Naruto strait, Japan, above described, are controlled by the rotation of the earth turning counterclockwise in the northern hemisphere and clockwise in the southern hemisphere.

The term whirlpool was coined in the early days of small sailing vessels. It is often confused with other rotary forms of flow, notably with vortexes and kolks. A whirlpool in the open ocean is nothing more than a large-scale eddy; *i.e.,* a simple rotary flow, not always truly circular in form because of irregularity of coast lines. Inability on the part of sailors to steer out of whirlpools for lack of favourable wind often resulted in their vessels being either driven against rocky shores or held in a whirlpool's centre. Popular sagas notwithstanding, the centre of a whirlpool in the open ocean is free from suction or downward draft.

Differing distinctly from the steady whirlpool type of rotary flow is vortex flow, which spirals downward into a depressed shaftlike hole at a high rate of speed, entraining floating objects including small vessels.

Different, also, is the river kolk (term borrowed from the Dutch, used also in Germany), which is a short-lived spasmodic upward displacement of bottom water with swiftly whirling vortex motion at stream bed where its strong suction entrains bottom sediment upward. Commonly seen in river bends during high-rising stages, kolks dissipate at the surface in the form of nonrotating "boils" with slightly bulging surfaces. By lifting river-bed materials such as clay and sand and scattering these in the flowing river water, kolks constitute the primary agency that actively deepens streams along the concave shores of bends. (G. H. M.)

WHISKY (**Whiskey**), a potable alcoholic beverage obtained from the distillation of a fermented mash of cereal grains, suitably aged in wood, usually white oak. It is whisky in Scotland and Canada; whiskey (with an "e") in Ireland and the U.S.

The whiskies produced in each country are distinctive in character because of difference in method of production, type and character of the cereal grains and, most important, the quality and character of the water employed. For example, Scotch whisky is inimitable because only in Scotland can be found the spring water that rises through a red granite formation and then passes through peat moss country.

For the same reason the three principal distilling centres in the conterminous United States are located where they are because of the water obtained from springs that rise through limestone rock. The limestone mantel runs along western Pennsylvania, cuts across southern Indiana and over into Kentucky; there is another limestone outcropping in Maryland.

There is no precise record of when whisky was first distilled in either Scotland or Ireland. The earliest direct account is found in the Scottish exchequer rolls of 1494 which lists: "Eight bolls of malt to Friar John Cor wherewith to make aquavitae." There must have been knowledge of the art long before, since Albukassen. the Arabian alchemist had described the distillation process in his writings of the 10th century. The Latin term used to describe distilled spirits was *aquavitae,* "water of life." The Scotsmen and Irish translated this literally into their own Celtic as uisgebeatha, eventually shortened and anglicized into "whisky."

Scotch Whisky. — In the beginning, every Highland laird had his own pot still. The whiskies produced were rough and harsh. with a smoky pungency only Caledonians could appreciate—and they paid no taxes. Commercial distillation dates only from 1814 when excise taxes were levied and stills of less than 500-gal. capacity were prohibited. Even then consumption of Scotch whisky was very much local. A similar situation prevailed in Ireland. The principal contributing factor to the eventual world-wide popularity of Scotch whisky was Robert Stein's invention in 1826 of the column still. a continuous distillation process. In 1832 Aeneas Coffey obtained patents on improvements of this process. The column still is known today as the patent or Coffey still. This improvement made possible the distillation of more refined, lighter-bodied whiskies at higher proofs than was possible with a pot still. Today all Scotch whisky is a blend of pot-still and Coffey-still distillations. Scotch whiskies are fairly light bodied but have a distinctive smoky malt flavour.

Production. — Pot-still or malt whisky is distilled only from a fermented mash of malted barley. Patent-still or grain whisky is distilled from a fermented mash of barley malt and other (unmalted) cereal grains.

Pot-Still Whisky. —The steps in the pot-still process are: (1) cleaning the barley by screening out all foreign matter; (2) malting; (3) drying and grinding; (4) mashing; (5) fermentation; (6) maturation; and (7) blending.

The clean barley is steeped for two or three days in tanks of water, called steeps. It is then spread on the concrete malting floor to germinate under conditions of warmth and moisture for some 8 to 12 days. During this time the grain is constantly sprinkled with water and periodically turned over with wooden shovels. The barley sprouts, the starch in the grain is modified by the enzyme cytase, and the enzyme diastase, which is secreted, converts the starch in grain into maltose and dextrin, fermentable sugars. When the sprouts are some $\frac{3}{4}$ in. long, the water is turned off and the grain is known as green malt.

For drying, the green malt is transferred to a kiln, where it rests on a screen directly above a peat and coke fire. The acrid and oily smoke from the peat swirls around the grain so impregnating it that the aroma is carried over into the distilled spirit. The kilned malt is screened to remove the culm, or dried sprouts, and then ground into a meal, or grist.

In mashing, the grist is thoroughly mixed with hot water in a mash tub. and allowed to soak until the water has liquified all of the starches, and the diastase has converted the starches into maltose and dextrin. When the liquid has absorbed all the goodness from the grain, it is known as the wort which is drawn off the husks or draff (which, being rich in proteins, is dried for cattle feed). It is cooled and pumped into the fermenting vats.

In fermentation, vessels holding from 2,000 to 10,000 gal. are used. Pure cultured yeast is added to the wort and fermentation begins. The yeast causes the sugars in the wort to split into equal parts of alcohol and carbonic acid gas, the latter of which escapes, or is recovered as a by-product, the alcohol remaining in the liquid. The yeast continues to work until all of the sugar has been converted, usually some 48 hours. Simultaneously other subsidiary fermentations take place that are responsible for many of the flavours of the whisky! characteristic of each particular distillery. When fermentation is completed the liquid is known as beer or wash. To this point the process is identical with brewing ale and beer, except for the omission of hops.

For distillation, the beer goes into a pot still (see ALCOHOLIC BEVERAGES. DISTILLED) known as the wash still. The result of the first distillation is a distillate of low alcoholic strength called low wines. The first distillation separates the alcohol from the liquid and eliminates the residue of yeast and unfermentable matter. Also, a further cooking of secondary constituents occurs within the still. The low wines pass into a second pot still, known as the spirit still, where they are redistilled. The first and last part of the distillation, the heads and tails, are called the feints; they are separated from the useful or middle portion and are returned to the wash still for redistillation with the next charge of beer. Pot-still distillation is an intermittent process.

The useful or middle-run spirit that is distilled off at between 140 and 142 proof, now malt whisky, flows into a receiving vat.

Grain Whisky.—The second type of whisky distilled in Scotland, follows the same general production steps outlined above. Grain whisky differs from malt whisky in several respects. A mixture of malted and unmalted cereal grains are mashed, then fermented, and the resultant beer is distilled in a patent or column still in a continuous distillation operation. Grain whiskies are distilled off at slightly over 180 proof. Scotch grain whiskies are very light in body and flavour.

For a discussion of maturation, see ALCOHOLIC BEVERAGES, DISTILLED: *Maturing.* Cask sizes for maturing vary from 33 to 145 gal. capacity. The length of time needed varies with the character of the individual whisky, the size of the cask and the climatic conditions where it is stored. However, the Immature Spirits act of Great Britain establishes that no distilled spirits, such as whisky, rum or brandy, may be sold for public consumption unless they have been matured in wood for at least 3 years.

Blending is a high art, requiring great experience, a very keenly trained nose and palate. No two whiskies are the same. Each has its own particular characteristic, due in part to the geographical location of the distillery and in part to the individual distiller. The four geographical malt distilling divisions of Scotland are the Highlands, Lowlands, Campbeltown and Islay. The grain whisky distilleries are mostly in the Lowlands.

The blender must choose the proper proportion of Highland and Lowland malts for delicacy, lightness and finesse: to which he adds smaller amounts of Campbeltown and Islay malts for body and maltiness, and finally the proper blending of grain whiskies to marry with the blend of malts to produce an identical match to the aroma; flavour and character of the whisky the public has become accustomed to in the brand that is being blended. It is an intricate business, often calling for the use of upward of 40 different malt whiskies and half a dozen grain whiskies. After the blend is made, usually in a large vat, the blended whisky is rebarreled and allowed to marry for a month before bottling. At the time of bottling, the blended whisky is reduced to the proof required by the market for which it is intended. The U.S. market demands Scotch whisky of 86.6 proof, while the United Kingdom, Canada and most of the other markets of the world prefer 80 proof whisky.

Irish Whisky. — Production of whisky began at the same time as in Scotland. The methods used to produce Irish whisky are essentially the same as in Scotland, with several differences. The malted barley is kiln dried, but the kiln has a solid floor so that the smoke from the fuel used has no opportunity to come in contact with the grain. Consequently, Irish whisky does not have a "smoky" aroma or flavour.

Irish pot-still whisky is triple distilled. Irish whisky must be matured a minimum of five years before it can be sold to the public. Irish whiskies are nearly always all pot-still whisky, although patent-still grain whiskies are also used. Irish whiskies are usually bottled as a blend of whiskies of the same distillery, but straight, unblended whisky is also marketed. Irish whiskies vary from medium body and flavour to very full bodies and full malty flavour.

Canadian Whisky. — The first Canadian distilleries at Quebec in 1769 and two at Montreal by 1787 distilled rum (*q.v.*), made from molasses imported from the West Indies. Grain distilling did not develop until the early 19th century, when it resulted from the influx into Canada of United Empire Loyalists after the American Revoiution. Being farmers, they mere soon producing surpluses of grain, which were easier to sell and transport in the form of whisky. Practically every grist mill became a distillery and by 1850 there were 200 distilleries in the province of Ontario alone, whereas in the second half of the 20th century there were only 21 distilleries in all of Canada.

Production Methods.—Canadian whisky distilling techniques and practices are generally similar to those employed in the conterminous United States, described below. There are some differences. Canadian lam establishes that Canadian whisky must be produced from cereal grain only: corn, rye, wheat, barley and malt. The Canadian Excise Tax bureau exercises the customary rigid controls to assure collection of the tax, but allows the distiller complete latitude in detail as to grain formulas, distilling and maturation procedures. Consequently each distiller varies the proportions of the grains mashed, distills off some of his whiskies at low proofs—140 or even lo er—to retain flavouring congeners, and others at over 180 proof, to assure lightness of body, and matures his whisky in either new or reused charred oak or uncharred oak barrels. All Canadian whisky is blended. No straight Canadian whisky is marketed. Legally, no Canadian whisky may be sold until it has been aged in wood for at least two years, but in practice it is usually aged six years. Canadian whisky is bottled at 86 to 90.4 proof. Canadian whisky is always a lightly flavoured, light-bodied, blended whisky.

United States.—The distilling industry in the United States began in the 17th century in the New England colonies, the product being rum, obtained from molasses imported from the West Indies. Distillation of whisky began in colonial times with the settler's grist mills, during the 17th century centred about western Pennsylvania and in Maryland, although some was carried on in Virginia. Gen. George Washington had a commercial distillery at his Dogue farm, near Mount Vernon, Va., and was very proud of the quality of rye whisky he produced there. Thomas Jefferson also distilled whisky. The whiskies produced mere obtained almost entirely from rye grain.

The whisky-distilling industry received its greatest impetus in 1791 during Washington's administration. The newly established federal government, needing revenues with which to conduct its business, imposed an excise tax on whisky. Resented and resisted by the Pennsylvania distillers, President Washington was obliged to order the militia to quell the stormy rioting (see WHISKY INSURRECTION, THE). Many of the disgruntled Dutch, Scottish and Irish farmer distillers decided to move beyond the reach of the tax collectors and so went farther west into Indian territory. They found proper water for distilling in what is today southern Indiana and Kentucky. They also found that maize grew better and more abundantly than rye, and it became the grain the distillers employed.

The first distillery in Kentucky is attributed to Evan Williams in 1783 at Louisville, while the first whisky distilled in Bourbon county is credited to the Rev. Elijah Craig in 1789. Other early distillers of the period were Jacob Spears, John Hamilton and Daniel Stewart. The corn whisky they produced was sweeter to the taste and lighter in body than the rye whisky of Pennsylvania. Soon people were demanding whisky from Bourbon county and bourbon whisky eventually became the most popular type of whisky in the United States.

The United States is the world's largest producer and consumer of whisky. The federal treasury department has regulated and established detailed standards of identity for whiskies, but basically there are only two broad types of U.S. whiskies: straight and blended.

Production **Methods.**—U.S. production methods are basically the same as those employed in Scotland for the making of grain whiskies. Malted and unmalted grain is milled into a fine meal, which is mashed, cooked and fermented. The resultant beer or wash is then distilled in a column still, known as a beer still, but more graphically described as a whisky separating column.

In some distilleries the distillate from the beer still passes into a second column, known as a doubler. In principle, a doubler is like a pot still since the heat employed to vapourize the alcohol is applied externally, from a steam jacket surrounding it, as opposed to the beer still where the rising steam is in direct contact with the beer or wash. In either case, the straight whisky is distilled off at 160 proof or less.

To obtain more highly rectified whiskies or neutral spirits, *i.e.*, distillates of 190 proof or more, multiple column stills are used. These may consist of three or more rectifying columns (sometimes five).

U.S. regulations governing whisky production are the most specific in the world. In addition, to insure the collection of the revenue and until the internal revenue tax is paid, every production step is under close supervision by treasury agents. Thus, the government agents fiscalize the weight of the grain received, the milling, mashing, fermenting, distilling and barreling operations. The agents also hold the keys of the many locks and padlocks on the stills and to the federal bonded store rooms on the distillery property.

Straight Whisky.—Under U.S. regulations, a straight whisky is one that is distilled off at 160 proof or less, barreled at no less than 80 or no more than 110 proof and aged for a minimum of 24 calendar months. If it is distilled from a fermented mash composed of a minimum of 51% rye grain it can be marketed as straight rye whisky; if at least 51% of the grain mash fermented is corn (maize) it can be marketed as straight bourbon whisky. Such whiskies may be reduced in proof by the addition of water only, at the time of bottling to 80 proof, but no lower.

Bottled-in-Bond.—The Bottled in Bond act was passed by congress in 1894 to permit a distiller to bottle his whisky and to hold it in U.S. government bonded storage as bottled whisky, without having to pay the excise tax upon it until it was withdrawn for marketing, provided it was straight whisky, was at least 4 years old and was bottled at 100 proof.

The term "bottled-in-bond" is not a guarantee of quality by the U.S. government, nor does the government assume any responsibility in this respect.

Blended Straight Whisky.—On the whole, quite full-bodied and full-flavoured straight whiskies may be blended together. Such a blend will be labeled "a blend of straight whiskey." If 51% of the blend is bourbon whiskey, it can be labeled "blended bourbon whiskey" or "blended rye whiskey," if 51% is rye whisky.

Blended Whisky.—However, the blended whisky that is most popular is a blend or mixture of a minimum of 20%, 100-proof straight whisky together with neutral spirits (usually grain spirits).

Very light bodied and mildly flavoured, blended whiskies consist of two or more—sometimes in excess of 30—straight whiskies of different flavours and characteristics, which usually make up 27.5% to 35% of the blend, married with 65% to 72.5% of grain neutral spirits.

U.S. grain neutral spirits are essentially highly refined grain whiskies. However, the neutral spirits in a blended whisky need not be aged and generally are not. (I-I. J. GN.)

WHISKY INSURRECTION, THE, an uprising of farmers in western Pennsylvania in the summer of 1794 against the federal government sparked by efforts to enforce an excise tax on distilled liquors enacted March 3, 1791. Alexander Hamilton, secretary of the treasury. had proposed the excise with two purposes in mind: to raise money to help pay the national debt and to assert the power of the federal government. The small farmers of the interior who commonly converted their surplus grain into whisky that they could easily transport and sell, resisted the tax. Leaders such as Albert Gallatin and Hugh Henry Brackenridge protested strongly and under popular agitators such as David Bradford, the farmers resorted to violence. They attacked federal revenue officers, who attempted to collect the tax, and tarred and feathered some.

A law of June 5, 1794, designed to compel noncomplying distillers to pay the tax, touched off what appeared to be organized rebellion.

In July about 500 armed men attacked the home of Gen. John Neville, regional inspector of the excise, and burned it.

Some of Hamilton's followers saw in the insurrection a plot to destroy the federal government. Hamilton himself apparently saw it as the first opportunity to test the strength of the federal government against local defiance. Under authority granted by congress, Pres. George Washington on Aug. 7, 1794, issued a proclamation ordering the rebels to return to their homes and calling for militia from Virginia, Maryland, New Jersey and Pennsylvania.

After negotiations between the federal commissioners and rebel leaders proved fruitless, Washington ordered some 13.000 troops into Pennsylvania's western counties. Opposition melted away and no battle ensued. The troops occupied the region, captured some of the rebels and held them for trial. Two were convicted of treason and pardoned by Washington.

Many Americans, particularly members of the opposition Republican party, were appalled by the overwhelming force used by the government. They considered it unnecessary and feared that Hamilton sought to use the suppression of the insurrection as the first step to absolute power. To Federalists, however, the most important result was that federal authority had triumphed over its first rebellious adversary and had won the support of the state governments in enforcing federal law within the states.

(A. De C.)

WHISPERING BELLS (*Emmenanthe penduliflora*), a North American herb of the waterleaf family (Hydrophyllaceae), known also as yellow bells and golden bells, is native to mountain slopes from central California to Utah and southward to Mexico. It is a low, much-branched, sticky-hairy annual, 10 in. to 20 in. high, with deeply cut leaves and bell-shaped cream-coloured or yellow flowers: one-half inch long, borne on slender, pendulous stalks in loose clusters. This characteristic plant of the chaparral (*q.v.*) is grown in gardens for its showy, persistent flowers. When dry after fruiting these give forth a slight rustling sound.

WHIST, a member of a long line of card games embracing essential common features, much celebrated in history and legend. The essential features of whist family games are: four always play. two against two as partners; a full 52-card pack is dealt out evenly so that each player holds 13 cards; and the object of play is to win tricks, each trick consisting of one card played by each player. The succession of whist family games, from the earliest game to the latest. has included triumph, trump, ruff and honours (or slam). whisk (or whist) and swabbers. whist. bridge, auction bridge and—latest and most popular member—contract bridge (see BRIDGE).

It is generally conceded that whist is of English origin. Unmistakable references to triumph are found in a sermon preached by Hugh Latimer at Cambridge in 1529; in *Gammer* Gzirton's Needle; and in Shakespeare's *Antony and* Cleopatra, iv. 12, 12–20. In a poem (1621) by John Taylor, one line reads, "Ruffe, slam, trump, nody, whisk, hole, sant, new cut." Charles Cotton's Compleat Gamester (1674) says, "*Ruff* and *Honours* (alias *Slamm*) and Whist, are games so commonly known in England in all parts thereof, that every child almost of eight years old hath a competent knowledg (sic) in that recreation."

First a game of the lower classes, whist was taken up in the early 18th century by gentlemen in London's coffeehouses. Primarily because of the publication in 1742 of Edmond Hoyle's Short Treatise on *Whist*, the game became an unprecedented success in fashionable circles, soon spreading to the continent and to America. It developed an extensive literature. This pre-eminence among card games it never surrendered until replaced by its own progeny, bridge.

Procedure of Play.—All four players draw cards to determine partners. who face each other across the table. The player drawing the lowest card deals first; after which the turn to deal passes in rotation (which is always clockwise). The cards are shuffled, cut by the player at the dealer's right and dealt one at a time: face down, in rotation until the last card is reached; this is turned up and every card of its suit becomes a trump. The dealer takes it into his hand when it becomes his turn to play to the first trick.

The player at the dealer's left plays first (leads). He may lead any card. Each player in rotation thereafter must play one card, following suit (playing a card of the suit led) if possible, but playing any card he chooses if he cannot follow suit.

The cards of each suit rank downward: ace, king, queen, knave (jack), 10, 9, 8, 7, 6, 5, 4, 3 (trey), 2 (deuce). Any trick containing a trump is won by the highest trump; any trick not containing a trump is won by the highest card of the suit led. The winner of each trick leads to the next.

Scoring is possible only for the side which wins the odd trick (that is, its 7th trick out of 13). Each trick over 6 counts 1 point for that side.

Laws of Whist.—The first standard laws were those published by Hoyle in 1742; with minor revisions made in 1760, these laws were followed until revised in 1864 by the Arlington and Portland clubs. A different code of laws issued in 1893 by the American Whist league became standard for the United States.

The principal difference was in scoring. Under English laws, 5 points constituted a game (short whist, as distinguished from the long whist, 10 points for the game, of Hoyle). Final settlement was by rubber points: 3 for each game won 5 to 0; 2 for each game won 5 to 3 or less; 1 for any other game won; and 2 for being the first side to win two games.

Skillful Play.—The science of whist was complex but not profound. Its ponderous literature so devoutly embraced the established dogma that even minor changes in tactics were considered radical and any challenge of the prevailing strategy was considered too heretical to treat with gravity.

Hoyle and a group of worthy successors including William Payne (*Maxims*, 1770), Thomas Mathews or Matthews (**Advice** to *the* Young *Whist* Player, 1804), James Clay, Guillaume Deschapelles (according to his contemporaries, the finest of all whist players) and finally "Cavendish" (pseudonym of Henry Jones, best known and most respected authority and most prolific writer that whist produced) all assumed the wisdom of playing a "long-suit game" and leading first from one's longest and strongest suit. Their analysis was therefore devoted to signaling devices wherewith one's partner might be informed of one's holdings.

The principal signaling device was the selection of a conventional card to lead; its nature gave information as to the leader's holding. "American leads," a complex schedule devised by Nicholas B. Trist in 1883, were enthusiastically supported by Cavendish and soon were generally adopted on both sides of the Atlantic because they revealed so many more specific combinations of cards than had the "English leads."

The trump signal, proposed by Lord Henry Bentinck in 1834, was another standard device. By playing an unnecessarily high card, and later a lower card of the same suit, one requested one's partner to shift to the trump suit at his first opportunity.

The "rule of eleven" was formulated by Robert F. Foster in 1889, and mas based on the custom of leading the fourth-highest card of a long suit. By subtracting the number of the card led from 11, one knew the number of higher cards not held by the leader.

Preoccupation with the development of signaling devices prevented adequate analysis of the best methods for winning tricks, so that even the best whist players sacrificed trick after trick without discernible care—usually without even noticing that by better play those tricks might have been won instead of lost. Paradoxically, the greatest improvement in whist play came after the turn of the century when bridge. the successor game, had already arrived and whist was moribund.

(E. Cul.; A. H. Md.; H. St. J. I.)

Solo Whist.—This is a combination of whist, bridge and nap. Four players is the usual number, but five can make up a "school"; the player behind the dealer sitting out for that particular deal. Value and number of cards are as in whist, but the deal is slightly different. Three cards are given to each player in rotation for the first 48 cards, and the last 4 are dealt singly, with the last card again turned up as trumps. As will be seen later, trumps can change.

Starting with the player on dealer's left, each must make a bid (or call). Calls in order of value and rank are: pass, proposal, solo *misère,* abundance, open *misère,* declared abundance. Proposal: here the caller contracts to make eight tricks, with any other player who accepts—whatever the position of the players at the table. Solo: the caller to make five tricks with the other three players against him. *Misère:* the caller must not take a single trick. The other three players are against him. There are no trumps. Abundance: a call when declarer contracts to make nine tricks on his own, naming any suit as trumps. Abundance in the original trump suit has preference over abundance calls in other suits. Open *misère:* the player here declares to make no tricks and exposes his hand on the table as soon as first card is led. Declared abundance: caller contracts to make all 13 tricks, naming the trump suit. The original trump suit has preference.

If a player has made a bid and has been overbid by another player, he can amend his call to any still higher call; *e.g., A* calls solo; *B* calls *misère; A* amends his call to abundance. Any player proposing may amend his call to another if no player accepts him. Stakes are in the following proportions. Proposer and acceptor each receive or pay two points. For all individual calls, the other three players pay or receive: solo, 4 points; *misère,* 6 points; abundance, 8 points; open *misère,* 12 points; and declared abundance, 16 points. By agreement, proposal and acceptance may be omitted from the game, and the individual calls then operate.

(H. St. J. I.)

WHISTLER, JAMES ABBOTT McNEILL (1834–1903), **U.S.** painter, was born at Lowell, Mass., on July 10, 1834. Part of his boyhood was spent in court circles at St. Petersburg, Russia, where his father, a military engineer. was in charge of railway building for the tsar. After a brief and unsuccessful period at the United States Military academy. West Point; S.Y., he spent a year as a draftsman and map engraver in the coast and geodetic survey, Washington. D.C., undoubtedly absorbing traditions of technique and surface layout of value in his later work. In 1855 he went to Paris to study painting in the studio of Charles Gleyre. Through A. Legros and H. Fantin-Latour he became aware of the teaching methods of their master, Horace Lecoq de Boisbaudran, which depended on intensive training of the visual memory; such methods made a permanent impression and seem to have counteracted an enthusiasm for the realism of Gustave Courbet which Whistler shared with the young painters of 1855. He also studied in the Louvre, copying from artists as varied as Rembrandt and François Boucher, and from the Manchester exhibition of 1857 gained more knowledge of Velazquez than could be had in France.

The massive forms and sombre tones of Courbet dominate the early works of Whistler, though "At the Piano" (1859; Boston, Mass.) shows that these were combined with a stress on surface arrangement. Works of this period brought Whistler to the notice of Charles Baudelaire, who before 1860 praised his ability to treat fog and darkness on the Thames with something more than a documentary eye. Having settled in London in 1859. he found his work acceptable to the Royal Academy, where "At the Piano" was shown in 1860. Shortly after, Whistler and his now close friend D. G. Rossetti began to introduce into London the taste for Japanese prints and bric-a-brac already current in Paris; and it is not surprising that in such an environment Whistler began to break with the realism of Courbet, with whom he had little fundamentally in common but an unflagging hostility to authority. His "White Girl," shown at the Salon des Refusés of 1863, still showed adherence to Courbet, but was described as "Symphony in White No. 1," the first of the famous series of musical titles indicating a leaning toward abstract harmonies of colour not necessarily dependent on what was to be seen in the model. This consideration militates strongly against attempts to place Whistler with the Impressionists, to whom ocular scrutiny of the subject was vital. By 186j Japanese mannerisms had brought Whistler to the verge of pastiche, as the "Gold Screen" of that year makes clear; but the "Little White Girl," hung at the Royal Academy in the same year, shows that he could extract from Japanese art qualities of composition and line which could be blended with the draftsmanship and tonal interests he had already mastered.

Late in the 1860s his medium became extremely fluid and delicate and his subjects more and more removed from the earlier realism; such works included the "Symphony in White No. 3" (1867; Barber institute, Birmingham), and lie at the roots of the English "aesthetic" movement. By the 1870s, however, a more robust manner emerged, revealing an assimilation of all the various sources discussed; his most famous work, "Mrs. George Washington Whistler" (1872; Louvre, Paris), combines a scrupulous regard for surface harmony with a strong and direct tonality owing much to the art of Velazquez. Whistler called this picture "Arrangement in Grey and Black No. 1," but in view of his known regard for his mother it is hard to support the commonly held view that such titles necessarily indicate a disregard for subject matter. It has also been said that this disregard brought immediate hostility in England; but there is at least one instance of a work of his being refused at the Salon and accepted, as were many others, by the Royal Academy. There is no doubt that Whistler, a close friend of Edgar Degas, was in touch with the Impressionist movement in France, but he did little to foster its success in England and was contemptuous of its brilliance of tone and palette. Following the portrait of his mother and forming his most important group of portraits were the "Thomas Carlyle" (1873; Glasgow) and "Miss Cicely Alexander" (1873; National gallery, London), the former following Velázquez even more clearly than the portrait of his mother, and the latter pointing forward to a phase of English portraiture in which carefully observed tone and agreeable harmonies of line and colour replaced the solemnity and stress on personal character of early Victorian portraiture. Whistler's later portraits. such as the "Yellow Buskin" (1878; Philadelphia Museum of Art) or the "Sarasate" (1884; Carnegie institute Pittsburgh), demonstrate this phase as well as do the works of the younger generation; but it is also noteworthy that W. R Sickert, the dominant figure of that generation in England, was his pupil during the execution of the latter picture, having entered his studio in 1882.

BY COURTESY OF NATIONAL GALLERY. LONDON

"MISS CICELY ALEXANDER" BY JAMES WHISTLER. IN THE NATIONAL GALLERY, LONDON

Meanwhile in landscape Whistler had developed in the 1870s his famous series of "Nocturnes" in which reliance on visual memory rather than on factual observation, and on a preconceived harmony of colour rather than on an imitation of local colour, prevails; his choice of nocturnal urban subjects shows the remoteness of his aims from those of the Impressionists. It was Whistler's artificiality, his dark tones and his supposed unwillingness to scrutinize the matter before him which John Ruskin singled out for attack in his report on the "Nocturne in Black and Gold: the Falling Rocket" (1874; Detroit), shown at the Grosvenor gallery in 1877, which was the cause of the Whistler-Ruskin libel action of 1878. It could thus be argued that Impressionism, which depended on a complex form of naturalism, had more common ground with Ruskin than with Whistler, and that the latter looked forward more to the antinaturalistic reaction of late 19th-century France. It is interesting to find that on his final move to Paris in 1892 he was lauded by J. K. Huysmans and became a friend of Marcel Proust. Whistler was bankrupted after the 1878 trial and from Sept. 1879 to Nov. 1880 lived in Venice. where he reverted to his old craft of etching. On his return to London he was more favourably received by the increasingly hedonistic society of those years; his Venetian etchings were popular and his portraits fashionable.

In 1885 he delivered his famous "Ten O'Clock" lecture which summarized his attitude toward naturalism and the musical analogies suggested by the titles of his works. From 1886 he was president of the Royal Society of British Artists, which during his two years of office was successful in bridging the gap between British and French art, and in setting a new high standard in the display of pictures. In 1891 the portrait of his mother was bought by the city of Paris, and his growing reputation there led to his return in 1892, though he died in Londbn on July 17, 1903.

Whistler's "Ten O'clock" lecture was published in 1880 and his *The Gentle Art of Making Enemies* appeared in 1890.

WHISTON, WILLIAM (1667–17j2), English theologian and mathematician, was born at Norton in Leicester on Dec. 9, 1667. He was educated privately and at Clare college. Cambridge, where he studied mathematics and obtained a fellowship in 1693. He next became chaplain to John Moore, bishop of Norwich, from whom he received the living of Lowestoft in 1698. His *New Theory of the Earth* (1696) received the praise of both Newton and Locke. In 1701 he resigned his living to become deputy at Cambridge to Sir Isaac Newton, whom he succeeded, two years later as Lucasian professor of mathematics. In 1707 he was Boyle lecturer. For several years Whiston continued to write and preach with considerable success. However, his study of the *Apostolical Constitutions* had convinced him that Arianism was the creed of the primitive church and his heterodoxy soon became notorious. In 1710 he was deprived of his professorship and expelled from the university. He vindicated his estimate of the *Apostolical Constitutions* and the Arian views he had derived from them in his *Primitive Christianity Revived* (j vol., 1711–12). In 1713 he produced a reformed liturgy. and'soon afterward founded a society for promoting primitive Christianity.

One of the most valuable of his books, the *Life of Samuel Clarke,* appeared in 1730. His useful and often reprinted translation of Josephus, with valuable notes and dissertations, was printed in 1737, and his *Primitive New Testament* appeared in 1745. His best-known opinion is his advocacy of clerical monogamy, immortalized in the *Vicar of Wakefield.* He died in London on Aug. 22. 1752, leaving a memoir (3 vol., 1749–50) noteworthy for its illustrations of the religious and moral tendencies of the age.

WHITBREAD, SAMUEL (1758–181j), English politician, well-known as a social reformer and as the opponent of abuses of all sorts, was the son of the founder of the famous London brewery, and was born at Cardington, Bedfordshire, in 1758. He was educated at Eton. at Christ Church. Oxford, and at St. John's, Cambridge. After managing the family business for several years, in 1789 he married Elizabeth, daughter of the 1st Earl Grey and sister of his old schoolfellow, afterward prime minister. Taking to politics, he was elected M.P. for Bedford in 1790 as a supporter of Fox; he sat for that borough until his death. His campaign for purity in public life effectively started in 1805 when he led the attack on Lord Melville, who was suspected of malpractices in the naval department; and he was one of the managers of the impeachment. In 1809 he attacked the duke of York, the commander in chief, who was implicated in the Mrs. Clarke scandals; and in 1810 he ruined the reputation of Lord Chatham when he attacked him for mismanaging the Walcheren expedition.

He was an uncompromising pacifist, favouring a negotiated pence with Napoleon. The poor had no greater friend in parliament. He favoured a statutory minimum wage for agricultural labourers, elementary schools for all and a reformed poor law. He continued to advocate parliamentary reform and Catholic emancipation at a time when many Whigs, in view of the unpopularity of these questions, desired to shelve them. He committed suicide in London on July 6, 181j, as a result. it was thought, of ill-health caused by anxiety in connection with his efforts to rebuild Drury Lane theatre, which had burned down in 1809. (A. AL.)

WHITBY, a market town, holiday resort and urban district in the Scarborough and Whitby parliamentary division of the North Riding of Yorkshire, Eng., 46 mi. N.N.E. of York by road. Pop. (1951) 11,674. Area 4 sq.mi. Situated on the cliff-bound northeast coast, backed by some of the most magnificent moorland scenery in the county, Whitby is divided by the mouth of the river Esk, where it flows into the harbour. The old town clusters on the slopes of East Cliff, dominated at its summit by the ruined abbey; the modern, residential quarter, with promenades and the Spa Floral pavilion, etc., is mainly on West Cliff, with nearly 3 mi. of sands below. Whitby is the seat of a bishop suffragan in the diocese of York. Bede mentions that the town called Streanaeshalch, the Saxon name for Whitby, was the seat of a religious house, founded on the site of the abbey in 656. It included establishments for monks and, until the Conquest, for nuns of the Benedictine order. Its abbess, Hilda, opposed the claims of Rome at the synod of Whitby in 664. Caedmon, the cowherd who became a lay brother and the "father of English sacred song," died there in 680, the same year as St. Hilda. The abbey ruins remaining comprise parts of the Early English choir, the north transept of slightly later date and a richly Decorated nave. The south side of the nave fell in 1763 and the tower in 1830. On the south side were the cloisters and domestic buildings. Adjoining the abbey is the Abbey house, built about 1580 from the materials of the monastic building. A little below the abbey is the parish church of St. Mary, originally Norman.

Whitby owes its present name to the Danes. who sacked the town in the 9th century, subsequently refounding it as a Danish colony. William the Conqueror destroyed it again, after it had become the most prosperous town in the district. Henry I made a grant of a burgage to the abbot and convent of Whitby and, toward the end of the 12th century, the abbot granted the town a free burgage to the burgesses. In 1220 King John, bribed by them, confirmed this charter, but afterward, on being bribed by the abbot, quashed it as injurious to the dignity of the church of Whitby. The struggle continued until the 14th century. when a trial resulted in judgment against the burgesses. At the beginning of that century Sir Alexander Percy claimed the hereditary right of buying and selling in Whitby without payment of toll. After the reign of Henry VI the weekly market was held on Saturdays. In 1629 Whitby petitioned for incorporation and received letters patent giving it self-government. In 1674–75, however, the crown restored to the lords of the manor all liberties ever enjoyed by the abbots of Whitby. Having been a port since the 12th century at least. Whitby ranked seventh in England in 1828. Capt. James Cook, R.N., the circumnavigator, lived there, and it was Whitby that constructed the ships for his voyages to Australia in 1769–7j.

Since medieval times, herring fishing has formed the staple industry; although whale fishing began in 1753. The Whitby fleet is joined during the season by Scottish herring boats, and an annual "blessing of the sea" takes place in August. Alum, from the surrounding rocks. was manufactured there between the 17th and 19th centuries. Jet, which was once mined locally, is now only used by a few remaining craftsmen. Deposits of potash near R'hitby are estimated as sufficient to meet Great Britain's need at least until the end of the 20th century. The Chapman wings, added to the Pannett Art gallery and Whitby museum, were opened in 19j3.

WHITCHURCH, a market town and urban district in the Oswestry parliamentary division of Shropshire, Eng.. 20 mi. N.N.E. of Shrewsbury by road. Pop. (1951) 6,856. Area 9.5 sq.mi. It is a residential town for an agricultural community with biweekly cattle markets, a museum and art gallery. a grammar school founded in 1j50 and St. Alkmund parish church in which are commemorated John Talbot, 1st earl of Shrewsbury, Sir Edward German! the composer, and Randolph Caldecott, the humorous artist. Whitchurch has made turret clocks since the mid-17th century. In the middle ages Whitchurch with its fortress Weston castle was a military stronghold guarding the Welsh Marches.

WHITE, ANDREW DICKSON (1832–1918), U.S. educator and diplomat, founder and first president of Cornell university, Ithaca, N.Y., was born in Homer, N.Y., on Nov. 7, 1832. He graduated from Yale (A.B.) in 1853 and studied in Europe for the next three years, serving also as attaché at the U.S. legation at St. Petersburg during 1854–55. He returned to the United States to become professor of history and English literature at the University of Michigan, Ann Arbor. In 1865 White's dream of a state university for New York—based on liberal principles in regard to religion, coeducation, race and science—was realized when Cornell university was chartered, with the aid of a gift of money from Ezra Cornell and a land grant from the state, under the Morrill act. As Cornell's first president, White devoted his best energies and much of his wealth to assure its success and future growth. White served on numerous government commissions and was United States minister to Germany (1879–81) and Russia (1892–94) and ambassador to Germany (1897–1903). In 1899 he was president of the U.S. delegation at the Hague peace conference. The most outstanding of his completed works are *A History of the Warfare of Science With Tlzeology in Christendom* (1896) and *Seven Great Statesmen in the Warfare of Humanity With Unreason* (1910). He died at Ithaca, N.Y., on Nov. 4, 1918. The rich collection of books that he gave Cornell university is housed in a special room in the main library.

WHITE, EDWARD DOUGLASS (1845–1921), US. jurist, first associate justice of the supreme court to become chief justice of the United States. White's career was filled with striking contrasts; a Confederate veteran. a Roman Catholic and a southern Democrat, he mas appointed chief justice by the Republican and Unitarian president, William Howard Taft, nhose family had been loyal to the Union. Essentially a conservative, White, through his major decisions, helped to free the law from outmoded concepts. A vigorous exponent, while senator from Louisiana, of legislation to protect special interests, as chief justice he struck at legal interpretations which would advance the economic good of one section at the expense of another.

White's ancestry was English and Irish; from both his father and mother he inherited a tradition of allegiance to Roman Catholicism. The elder Edward Douglass White was trained as a lawyer and became a judge, a member of congress and seventh governor of the state of Louisiana. The second Edward Douglass White. the youngest of four children, was born Nov. 3, 1845, on the family plantation near Thibodaux, Lafourche parish. La, and attended a Jesuit school in New Orleans and Mount St. Mary's, Emmitsburg. Md., before enrolling at Georgetown college, D C., in 1857. When the American Civil War began, the 15-year-old boy left college unceremoniously and never again attempted to secure a formal education After a short career and capture in the Confederate army, White entered the law officeof Edward Bermudez in New Orleans and was admitted to practise in Louisiana in 1667. His training was in the Roman, or civil, law; White never formally studied philosophy, and later allegations that he was a probabilist undoubtedly derive partially from his style and partially from his civil-law training.

White's legal career was successful; he also joined the Democratic party and participated in turbulent state politics. He was elected state senator in 1874 and again in 1876 and was then named associate justice of the state supreme court in 1878. Two volumes of *Louisiana Annotated Reports* contain White's decisions. From 1881 to 1891 his interest in politics remained active, although he held no office. During this period he associated himself with the formation of Tulane university and with other civic programs.

In 1891 White was elected to the United States senate and served there until his nomination as an associate justice of the supreme court by Pres. Grover Cleveland in 1894. White accepted the nomination but remained in the senate until the Wilson-Gorman tariff safely included a bounty for domestic sugar producers sure to benefit his constituents.

On the supreme court bench, from 1894 to 1910, White's distinction lay in his dissenting opinions in the *Income Tax Cases* and in his concurring and dissenting opinions in the *Insular Cases*, in which he was chiefly responsible for formulating the doctrine of incorporated and unincorporated territories. The White doctrine has remained as the operative principle in congressional and judicial handling of territorial questions. White also wrote opinions or dissents in cases involving interpretation of the Interstate Commerce act. His writing in this field, believed to include his greatest contributions to the law, spanned his entire period of service on the bench and assisted in the formation of American administrative law.

In 1910, upon the death of Chief Justice Melville Weston Fuller, White was appointed his successor by President Taft. As chief justice he aroused comment for his decisions in the *Standard Oil* and *American Tobacco* cases. White declared that the Sherman act's phrase "restraint of trade" had to be interpreted according to the "rule of reason." This rule was the standard applied by reasonable men to the manufacture or distribution of goods. White was castigated for importing from scholastic philosophy into law a dictum so nebulous and was defended on the ground that his use of the phrase was neither novel nor condemnable; his construction has continued to be invoked.

While chief justice, White acted as arbitrator in a boundary dispute between Panamá and Costa Rica; the line fixed by him was not questioned during his lifetime. He handed down decisions in *Knowlton* v. *Moore*, an income-tax case following the adoption of the 16th amendment, and in *Arver* v. *United States* (better known as the *Selective Draft Law Case*). These he regarded as among his best decisions: both of them, like the bulk of the cases in which he wrote—there were nearly a thousand—reflected a conservative and nationalistic attitude, rather than the liberal one then noticeable in other jurists or the states'-rights attitude he might have been expected to adopt.

White died in Washington on May 19, 1921. All his papers had been destroyed during his lifetime, but his law library was given to Loyola university, New Orleans. Outside the Cabildo, in that city, there is a statue of White, and another was Louisiana's choice for one of the state's representatives in the statuary collection in the Capitol in Washington. The University of Chicago named a law lecture hall for him; Louisiana State, Tulane and Georgetown universities have sponsored series of lectures in his honour. Letters scattered through manuscript collections of prominent figures of his time indicate that he numbered among his friends Pres. Theodore Roosevelt and James Cardinal Gibbons; Oliver Wendell Holmes and Charles Evans Hughes spoke of him with respectful affection.

Klinkhamer: *Edward Douglas White, Chief Justice of the United States* (1943); "Chief Justice White and Administrative Law," *Fordham Law Review*, vol. xiii, pp. 194–231 (1944); "The Family Background of Chief Justice White," *Catholic Historical Review*, vol. xxxiii, pp. 191–205 (1947); "The Legal Philosophy of Edward Douglas White," *University of Detroit Law Journal*, vol. xxxv, pp. 174–199 (1957). Incidental mentions of White are to be found in the biographies and memoirs of important American figures of his period.

(M. C. K.)

WHITE, SIR GEORGE STUART (1835–1912), British soldier who commanded the British force which nithstood the siege of Ladysmith (*q.v.*) during the South African War, was born at Whitehall, County Antrim, on July 6, 1835. Educated at Sandhurst, he joined in 1853 the Inniskillings, with whom he served during the Indian mutiny in 1857. In the second Afghan War (1878–80) he was second in command of the Gordon Highlanders, whom he led at the battle of Charasiah, receiving the Victoria cross. After Sir Frederick (afterward Lord) Roberts had left Burma in 1887, White suppressed the dacoits there. Promoted major general in 1889, he succeeded Lord Roberts in 1893 as commander in chief in India, in which office he directed the Chitral expedition in 1895 and the Tirah campaign in 1897. Returning to England in 1898 he became quartermaster general, and on the outbreak of the Boer War in 1899 was given command of the forces in Natal, defeating the Boers at Elandslaagte on Oct. 21, 1899, and at Reitfontein on the 24th; but the superior numbers of the Boers enabled them to invest Ladysmith, which he defended in a siege from Nov. 1, 1899, to Feb. 28, 1900, during which he turned down Sir Redvers Buller's suggestion that he should arrange terms of capitulation with the enemy.

After the relief of Ladysmith, White returned to England and became governor of Gibraltar (1900–04). He was made field marshal in 1903 and received the order of merit in 1905. He died in London on June 24, 1912.

See T. F. G Coates, *Sir George White* (1900).

WHITE, GILBERT (1720–1793), English naturalist, famous as the author of *The Natural History and Antiquities of Selborne,* was born at Selborne, near Alton, Hampshire, on July 18, 1720, and died there on June 26, 1793. The eldest of 11 children, he was educated at Basingstoke grammar school and Oriel college, Oxford (1740–43), of which he became a fellow for half a century, nonresident except for his probationary year and 1752–53, when he served as junior proctor of the university. Unlike his grandfather, who bore the same name, he never became vicar of Selborne, where he served intermittently as curate. He never married, suffered no serious illness except smallpox and, although he traveled often, seems never to have gone beyond the southern and midland regions of England. Although by no means a recluse, he took little part in affairs or in movements of opinion, and was defeated in his most ambitious venture as candidate for the provostship of Oriel in 1757. It was probably a scientific neighbour in Hampshire, Stephen Hales (*q.v.*), who persuaded him to keep a journal in 1751, and this was originally devoted to events in his garden. In 1765 it evolved into a *Calendar of Flora and the Garden* and in 1768 into *The Naturalist's Journal,* in a form of book designed and sent to him by the antiquary and naturalist the Hon. Daines Barrington, whom he first met in London the following year, and who became his friend and correspondent. To him and to Thomas Pennant (*q.v.*) the main substance of what became *The Natural History of Selborne* was addressed in the form of private letters over about 14 years, often answering some query put to White by his two pertinacious correspondents. Both, in letters written by 1771, suggested his publishing something. To one of these White replied on July 19 in that year:

> As to any publication in this way of my own, I look upon it with great diffidence, finding that I ought to have begun it twenty years ago. But if I was to attempt anything it would be somewhat of a Nat: history of my native parish. . .

Encouraged by the Royal society's favourable reception of his papers on swallows and martins in 1774, he actively prepared to go into print, but not until 14 years later, in 1788 (dated 1789), was the *Natural History of Selborne* published. Its simple charm and timeless nierit were instantly recognized, and its consistent appeal is shown by the steady flow of reprints and editions. It consists of 44 letters addressed to Pennant and 66 to Barrington, but reference to the original correspondence shows many suppressions, rewritings, additions, rearrangements, changes of date and use as letters of essays written specially.

White's extensive yet curiously unsystematic editing of his material can be traced in detail but can hardly be explained satisfactorily. As a natural history the work is very incomplete even on the basis of what White himself is known to have had at hand in his journals. In one late addition to Letter XL to Pennant, White states that Selborne parish "has produced more than one hundred and twenty species" of birds, but these are nowhere listed, nor is the status of many made clear. Anecdotes were sought out and included to balance and relieve the more solid observations and analyses. The letter form is disarming and makes *Selborne* an easy and pleasant book to dip into. Controversy and enthusiasm are played down, and the reader is skillfully led to identify himself uith the author's good-tempered and patient but very human endeavours to find out the truth by methods available to all.

It is in this capacity for communicating the pleasures and the simple and enduring means of pursuing natural history studies that the *Natural History of Selborne* excels. While Gilbert White made a number of important discoveries in natural history which are described in his work, these play little part in keeping alive the keen interest of successive generations of readers. He appeals, without rhetoric or artificiality, to man's sense of wonder about nature and to the desire to know how to find out more about it at firsthand. The work's many shortcomings as a comprehensive and accurate account of its ostensible subject matter little; it still achieves what it was meant to achieve.

BIBLIOGRAPHY.—Editions of *The Natural History* include those by E. Blyth, with White's poems and other writings, and a description of Selborne by R. Mudie (1850); by Grant Allen (1900); by E. M. Nicholson, with introductory chapters on White and on Selborne (1929); and by James Fisher (1947). The *Journals* were ed. with introduction by W. Johnson (1931); *see* also his *Gilbert White: Pioaeer, Poet and Stylist* (1928); R. Holt-White, *Life and Letters of Gilbert White,* 2 vol. (1901). (E. M. N.)

WHITE, HENRY (1850–1927), U.S. diplomat, was born in Baltimore, Md., on March 29, 1850. He was educated privately and spent much of his early life in England, Italy, Germany and France. He entered the diplomatic service in 1883 as secretary at the United States legation in Vienna and in the following year was transferred to London, where he served until 1893, and from 1897 to 1905. He was U.S. representative at the International conference in 1887–88, and in 1905 was U.S. delegate to the International Conference on Agriculture. He was appointed ambassador to Italy in March 1905 and from 1907 to 1909 served as ambassador to France. In 1910 President Taft appointed him chairman of the U.S. delegation to the 4th Pan-American conference in Buenos Aires. As a member of the U.S. delegation to the Paris Peace conference in 1918–19 he worked for U.S. entry into the League of Nations. He died on July 15, 1927.

See Allan Nevins, *Henry White: Thirty Years of American Diplomacy* (1930).

WHITE, HENRY KIRKE (1785–1805), English poet, was born at Nottingham, the son of a butcher, on March 21, 1785. He was articled to a lawyer. Capel Lofft encouraged him to publish *Clifton Grove, a Sketch in Verse, with other Poems,* dedicated to Georgiana, duchess of Devonshire. The book was violently attacked in the *Monthly Review* (Feb. 1804), but White was in some degree compensated by a kind letter from Robert Southey. Through the efforts of his friends, he was entered as a sizar at St. John's college. Cambridge. spending a year beforehand with a private tutor. Close application to study induced a serious illness, and fears were entertained for his sanity, but he went into residence at Cambridge, with a view to taking holy orders, in the autumn of 1805. The strain of continuous study proved fatal, and he died on Oct. 19, 1806. He was buried in the church of All Saints, Cambridge. Much of his fame was due to sympathy inspired by his early death, but Byron agreed with Southey in forming a high estimate of the young man's promise.

His *Remains,* with his letters and an account of his life, were edited by Robert Southey, 3 vol. (1807–22). *See* prefatory notices by Sir Harris Nicolas to his *Poetical Works* (new ed., 1866) in the "Aldine Edition" of the British poets; by H. K. Swann in the volume of selections (1897) in the *Canterbury Poets;* and by John Drinkwater to the edition in the "Muses' Library." *See* also J. T. Godfrey and J. Ward, *The Homes and Haunts of Henry Kirke White* (1908).

WHITE, HUGH LAWSON (1773–1840), U.S. statesman, was born in Iredell county (N.C.), Oct. 30. 1773. In 1787 he crossed the mountains into East Tennessee (then a part of North Carolina) with his father, James White (1737–1815). Hugh became in 1790 the secretary to Gov. William Blount, and in 1792–93 served under John Sevier against the Creek and Cherokee Indians, and according to the accepted tradition, killed with his own hand the Cherokee chief, Kingfisher. He studied in Philadelphia, and in 1796 he was admitted to the bar at Knoxville. He was a judge of the superior court of Tennessee (1801–07), a state senator (1807–09), and (1809–15) was judge of the newly organized supreme court of errors and appeals of the state. From 1812 to 1827 he was president of the State Bank of Tennessee, the only western bank that in the trying period during and after the War of 1812 did not suspend specie payments. In 1821–24 he was a member of the Spanish Claims commission and in 1825 succeeded Andrew Jackson in the U.S. senate, serving until 1840 and being president *pro tem.* in 1832–34. In the senate he supported in general the measures of President Jackson, though his opposition to the latter's indiscriminate appointments caused a coolness between himself and Jackson. In 1830, as chairman of the committee on Indian affairs, he secured the passage of a bill looking to the removal of the Indians to land west of the Mississippi. He was opposed to Van Buren, Jackson's candidate for the presidency in *1836,* was himself nominated in several states as an independent candidate, and received the *26* electoral votes of Tennessee and Georgia. About *1838* he became a Whig in politics, and when the Democratic legislature of Tennessee instructed him to vote for Van Buren's subtreasury scheme he objected and resigned (Jan. *1840).* His strict principles and his conservatism won for him the sobriquet of "The Cato of the United States senate." He died at Knoxville, April *10, 1840.*

WHITE, RICHARD GRANT (1821–1885), U.S. scholar, philologist and essayist, best known for his editions and criticisms of Shakespeare, was born in New York city on May *23, 1821.* He graduated from the University of the City of New York in *1839,* studied medicine and then law, and was admitted to the bar in *1845.* He contributed musical criticism to the *New York Courier and Enquirer,* of which he was coeditor from 1851 to 1859, and was briefly on the staff of the *New York World* when that paper was established in *1860.* He then obtained appointment as a chief clerk in the New York customhouse (1861–78). In *1853 Putnam's Magazine* published his destructive, anonymous criticism of the Shakespeare folio manuscript emendations of John Payne Collier (*q.v.*) a criticism which mas republished with other papers in his *Shakespeare's Scholar (1854).* During the Civil War, under the pseudonym "A Yankee," he contributed a series of articles to the *Spectator* (London) which greatly influenced English public opinion in favour of the North; his satire *The New Gospel of Peace According to St. Benjamin (4* vol., *1863–66)* was an influential answer to pro-Southern propaganda. White's Shakespearean scholarship includes a 12-vol. edition of Shakespeare *(1857–66)* containing textual notes, and an *1883* edition in *3* vol. appending a more elaborate historical and critical commentary. In *Memoirs of the Life of William Shakespeare (1865)* he rejected the idea that Shakespeare revealed a central moral philosophy in his plays. White died in New York on April *8, 1885,*

Stanford White (*q.v.*), the architect, was White's son.

WHITE, STANFORD (1853–1906), U.S. architect, *a* member of the most successful and influential architectural firm in American history, was born in New York city on Nov. *9,* 1853, the son of the literary critic Richard Grant White (*q.v.*). His instinct for decoration was inspired, and he was carefully trained as a draftsman by H. H. Richardson while the latter was completing Trinity church, Boston. In *1879* he joined Charles Follen McKim and William Rutherford Mead to found McKim, Mead & White. Until *1887* the firm excelled at informal shingle buildings, and White designed one of the subtlest of these, the Casino *(1881)* at Newport, R.I. In later years the firm championed the formal tradition of the Renaissance. Among the celebrated examples of the formal planning of White are the Villard houses, New York city, completed as early as *1885,* and four other New York landmarks, the Century club, the Herald building, Madison Square Presbyterian church and Madison Square Garden.

On June *25, 1906,* he was murdered at the Garden by Harry Thaw, who was adjudged insane.

See Charles C. Baldwin, *Stanford White* (1931) ; also Wayne Andrews, *Architecture, Ambition & Americans* (1955). (W. As.)

WHITE, SIR THOMAS (1492–1567), founder of St. John's college, Oxford, was a son of William White, a clothier, and was born at Reading. He became a merchant in London and a member, and then master of the Merchant Taylors' company; growing wealthier he became an alderman and sheriff of the city of London. One of the promoters of the Muscovy company, he was knighted in *1553,* and chosen lord mayor. He defended the city against Sir Thomas Wyat and his followers, and took part in the trial of the rebels, as he had done in the case of Lady Jane Grey. In 1555 White received a licence to found a college at Oxford, which, dedicated to the Virgin Mary and St. John Baptist, was opened in *1560.* He died at Oxford on Feb. *12, 1567,* and was buried in the chapel of St. John's College. White had some share in founding the Merchant Taylors' School in London.

WHITE, WILLIAM (1748–1836), American Protestant Episcopal bishop, the first consecrated for the American church by the English bishops and the first presiding bishop of the Protestant Episcopal Church, was born on April *4, 1748,* in Philadelphia. His whole life and ministry was spent in that city during the years that it served as the cradle of American liberty. He was educated at the College and Academy of Philadelphia (later to become the University of Pennsylvania), a school founded by Benjamin Franklin to train men for citizenship at a time when most colleges in America were devoted to the training of men for the ministry.

The influence of White's education was reflected in his pamphlet *The Case of the Episcopal Church in the United States Considered* (1782), in which, referring to the fact that before the Revolution Americans went to England for ordination, he suggested that if the American church could not obtain bishops from England it would have to establish its own episcopate. Overnight White became one of the recognized leaders of the Church of England in America, respected both by those who did and those who did not agree with him. After the war with Britain the scattered remnants of the Church of England in America organized themselves as the Protestant Episcopal Church and sent White and Samuel Provoost (*q.v.*) to England for consecration as their native bishops *(1787).* Because Samuel Seabury (*q.v.*), who had been refused consecration by the English bishops and had gone to the nonjuring bishops of Scotland for ordination (1784), was not recognized by some sections of the American church, a division of the church appeared to be imminent. When a third American, James Madison, of Virginia, had been consecrated by the English bishops, White was able to create unity by bringing the four together in *1792* to consecrate the first bishop on American soil, Thomas Claggett.

White was influential in shaping the new American church and in the revision of the Prayer Book. He was presiding bishop in *1789* and again from *1795* until his death, on July *17, 1836.* His interests were doctrinal as well as practical, and he wrote pamphlets and contributed articles to church periodicals on doctrinal subjects throughout his long life.

BIBLIOGRAPHY.—Complete bibliographies of White's works are available in: Bird Wilson, *Memoir of the Life of the Right Reverend William White* (1839) ; William White, *Life and Letters,* ed. *by W.* H. Stowe (1937) ; S. A. Temple, Jr., *The Common Sense Theology of Bishop White* (1946). *See* also William White, *Memoirs of the Protestant Episcopal Church in the U.S.A.* (1820) ; J. H. Ward, *The Life and Times of Bishop White* (1892) ; *W.* W. Manross, *William White,* Pamphlet (1934). (S. A. T., JR.)

WHITE, WILLIAM ALLEN (1868–1944), U.S. journalist, whose mixture of generous tolerance and provincialism made him the epitome of the small-town American, was born in Emporia, Kan., on Feb. 10, *1868.* He left the University of Kansas to become business manager of the *El Dorado* (Kan.) *Republican.* In *1891* he went to Kansas City as an editorial writer on the *Star;* in *1895* he purchased the *Emporia Daily and Weekly Gazette.* An editorial written in *1896* entitled "What's the Matter With Kansas?", an impassioned plea against Populism, made him and his paper nationally famous. Three books of short stories, *The Real Issue* (1896), *The Court of Boyville (1899)* and *Strategems and Spoils (1901)* and a volume of sketches, In *Our Town* (1906), gave him a wide reputation as an interpreter of rural life in the middle west. In *1909* he published his first novel, *A Certain Rich Man,* which passed through many. editions. Then followed *The Old Order Changeth* (1910), *God's Puppets* (1916), *In the Heart of a Fool (1918)*; *The Life of Woodrow Wilson* (1924), *Calvin Coolidge: the Man Who Is President* (1925), *Masks in a Pageant (1928)* and *A Puritan in Babylon (1938).* In *1937* he published the autobiographical *Forty Years on Main Street,* and in *1939, The Changing West.* His best editorials mere collected by Helen 0. Mahin in *The Editor and His People (1924).* White's *Autobiography* appeared in *1946,* followed a year later by Walter Johnson's *Selected Letters, 1899–1943.* White won the *1923* Pulitzer prize for editorial writing.

White was active for *40* years in the Republican party; he served on many committees and commissions, but refused to run for political office. He died in Emporia on Jan. *29, 1944.*

See Walter Johnson, *William Allen White's Anzerica* (1947).

WHITE, WILLIAM HALE: *see* RUTHERFORD, MARK.

WHITE, SIR WILLIAM HENRY (1845–1913), English naval architect who revolutionized the design of all British warships, was born at Devonport, Devon, on Feb. 2, 1845. In 1881 he became chief constructor at the admiralty and was also instructor at the Royal School of Naval Architecture, London, and later at the Royal Naval college, Greenwich. His lectures were embodied in his *Manual of Naval Architecture* (1877). In 1883 he left the admiralty to organize the shipyards of Armstrong and Co., at Elswick, Northumberland. for the construction of large warships but returned to the admiralty in April 1885 as director of naval construction and, until his retirement in 1902, was responsible for the design and construction of all ships (more than 200) added to the British navy. His ideas were also nidely adopted abroad. He was active in support of W. Froude, nho established ship propulsion on a scientific basis, and also contributed largely to papers read and discussions held before the Institution of Naval Architects. White was elected a fellow of the Royal society in 1888 and made knight commander of the Order of the Bath in 1895. He was president of the Institution of Civil Engineers in 1903 and died in London on Feb. 27, 1913.

(L Wo)

WHITE ANT: *see* TERMITE; SOCIAL INSECTS.

WHITEBAIT (Fr. *Blanchaille*), the name given to the fry of the herring and sprat, and formerly erroneously thought to be a distinct species, *Clupea alba*. These young fish, which are much esteemed for the table, are found in large numbers in estuaries (Firth of Forth, Thames. etc.) and at certain times along the coast, but it appears that the large concentrations which make the fishery a commercial success occur only in estuaries.

In spite of the large numbers of whitebait caught, it is improbable that this has any noticeable effect on the subsequent herring fisheries In America the young of a species of silverside (*Menidia beryllina*) are similarly sold as whitebait.

WHITE FATHERS (SOCIETY OF MISSIONARIES OF AFRICA), a Roman Catholic international missionary society of priests and brothers nhose sole field of activity is Africa, was founded in North Africa in 1868 by the archbishop of Algiers, Cardinal Charles M A Lax-igerie (*q v*). The society's first missions were in northern Algeria. In 1878 its members founded the first Catholic missions in the Great Lakes region of central Africa, and in 1895 the society extended its work to West Africa. Final papal approval was granted the society in 1908, and in 1952 the general headquarters was transferred from Algiers to Rome. The American province was established in 1948.

See Glenn D Kittler, *The White Fathers* (1957). (J. A. RI.)

WHITEFIELD, GEORGE (1714–1770), a great preacher of the Evangelical Revival in both Great Britain and America, who as a young man worked with the Wesley brothers, was born on Dec. 16, 1714. at Gloucester. In 1732 he entered as a servitor at Pembroke college, Oxford, where he came under the influence of the Methodists (*see* WESLEY, JOHN).

Whitefield was made deacon and took his degree in 1736, and then was invited by Wesley to go as a missionary to the colony of Georgia. Before leaving in 1738, he preached to great crowds in some of the principal London churches. After three months at Savannah he returned to England to receive priest's orders and to raise contributions for an orphanage. As the clergy did not welcome him to their pulpits because of his connection with Methodist societies, he began to preach in the open air. His addresses soon attracted crowds, held spellbound by his fervour and dramatic action, while his homely pathos broke down all resistance. He preached in Wales and the west country before embarking in Aug. 1739 for America, where he spent two years preaching in all the larger towns of the English colonies. His journals give a detailed account of these journeys.

On his return to England in 1741, Whitefield found that Wesley was diverging from Calvinist doctrine? so he withdrew from the Wesleyan Connexion. Thereupon his friends in London built for him a wooden church, named the Moorfields tabernacle. A reconciliation was soon effected between the two evangelists, but each henceforth went his own way. Whitefield then paid a visit to Scotland but refused to limit his ministrations to one sect, the Seceders, who had invited him. He broke with them and continued his tour, being received everywhere with enthusiasm. Next he went to Wales, where he married a widow named Elizabeth James. After a second visit to Scotland (1742) and a tour through England and Wales (1742–44) he spent four years in America (1744–48). On returning to England he was appointed one of the chaplains to Selina, countess of Huntingdon (*q.v.*).

The remainder of Whitefield's life was spent chiefly in extensive and exhausting evangelizing tours in Great Britain, Ireland and America. In 1753 he compiled his hymnbook, and in 1756 he opened the Congregational chapel which bears his name in Tottenham Court road, London. In 1769, worn out by his labours, he returned to America and arranged for the conversion of his orphanage into Bethesda college. He died on Sept. 30, 1770, in Nenburyport, Mass.

His influence on religious life in both America and Great Britain was immense. "The Congregational Churches of New England, the Presbyterians and the Baptists of the Middle States, and the mixed colonies of the South, owe their later religious life and energy mostly to the impulses given by his powerful ministrations" (Abel Stevens, *The Centenary of American Methodism*, 1865). His work is said to underlie the founding of some 50 colleges and universities in the United States (including Princeton and Pennsylvania universities). In England he was often criticized and depreciated. but as a preacher he had great influence in awakening the religious conscience of the 18th century. An Anglican priest, he nas a pioneer of all the characteristic forms later adopted by Methodism, and made an important contribution to Calvinistic Methodism in Wales and to Presbyterianism in Scotland. *See* also REVIVALISM.

WHITEFISH, the name of fishes of the genus *Coregonzrs* of the salmon family. These are silvery fishes with rather large scales, and with a small toothless or feebly toothed mouth; they feed on minute crustaceans. Marine species, entering rivers to breed. are chiefly arctic, but fresh-water species inhabit Europe and North America. especially in lakes. Few species of *Coregonus* reach a length of more than 18 in. For the British species *see* GWYNIAD; VENDACE; *see* also SALMON AND SALMONIDAE.

WHITEHALL, a residential city of Franklin county in central Ohio, U.S., immediately east of Columbus. The name is derived from the White Hall tavern, a stagecoach stop on the National road after it was extended to Columbus in 1833. The hamlet that eventually arose in the vicinity became known as Whitehall. Organized as a village in 1947. Whitehall could claim only 4.877 residents in 1950. In 1956, however, it was incorporated as a city after a special census revealed the population to be nearly 20.000. (For comparative population figures *see* table in OHIO: *Population.*) Chiefly responsible for this remarkable increase was the construction of hundreds of small homes and several large multiple-dwelling rental developments within easy reach of the industries, businesses and offices of Columbus. Water coolers and dehumidifiers are the principal manufactures of Whitehall. Several large shopping centres and the Columbus general depot. a U.S. army installation, are also located there. (J. S. ST.)

WHITEHAVEN, a seaport, market town and municipal borough in the Whitehaven parliamentary division of Cumberland, Eng., 39 mi. S.W. of Carlisle by road and on the Solway firth. Pop. (1961) 27,541. Area 6.7 sq.mi. The harbour has a large dock, a tidal harbour and extensive quayage and exports principally coal and detergents.

From early times it was regarded as the port for St. Bees and ultimately passed into the possession of the priory. It was eventually acquired by Sir John Lowther for his son Christopher, who built the first pier there in 1634. Its real expansion began after 1660 under Sir John Lowther who developed the coal mines and the Irish coal trade. Toward the end of the 17th century a tobacco trade was opened with Virginia and Maryland that made Whitehaven a thriving port and thus brought on the famous raid on the town by John Paul Jones on April 23, 1778.

Shipbuilding and pottery industries flourished until the close of the 19th century. Besides the collieries, which extend beneath the sea, there are engineering works, iron foundries, a silk mill and extensive chemical works.

WHITEHEAD, ALFRED NORTH (1861–1947), British-U.S. philosopher and mathematician, was born Feb. 15, 1861, at Ramsgate, Kent. He specialized in mathematics at Cambridge and became a fellow of Trinity college. He taught mathematics and served as dean of science at University college, University of London. In 1924 Whitehead went to Harvard university as professor of philosophy.

He collaborated with Bertrand Russell in writing *Principia Mathematica* (3 vol., 1910–13), a fundamental study of the structure of mathematical and logical thought. *The Concept of Nature* (1920) is an example of his critical examination of the basic concepts of natural science. Other specific problems in which he was interested are indicated by the following titles: *Religion in tlze Making* (1926), *Tlze Aims of Education* (1929). *The Function of Reason* (1929). At Harvard, Whitehead formulated, in tentative fashion, an organic philosophy. It provided a set of general ideas designed to describe and unify adequately all the complex components of the world. He focused his attention not only on the data of mathematics and the natural sciences but also on the data of the social sciences and, as well, on aesthetic, moral and religious experience. Thus he tried to correct a contemporary overemphasis on natural science and hence provide a more effective guide for civilized living.

Whitehead stressed individuality, creative interaction, change, endurance, value and God. The most complete expression of this, his mature philosophy, is found in his stimulating, nontechnical works, *Science and the Modern World* (1925), *Process and Reality* (1929) and *Adventures of Ideas* (1933).

Whitehead's work in mathematics and logic exerted a decisive influence in symbolic logic. His philosophy of education was efficacious in England. The value of Whitehead's comprehensive philosophical system, however, is still debated. His ideas were sometimes expressed in abstruse language, but they were supported by illuminating references to history and everyday life. He died Dec. 30, 1947, at Cambridge, Mass. *See* also references under "Whitehead, Alfred North" in the Index volume.

See A. H. Johnson, *Whitehead's Theory of Reality* (1952), introduction to *The Wit and Wisdom of Whitehead* (1949), *Whitehead's Philosophy of Civilization* (1958). (A. H. J.; X.)

WHITEHEAD, ROBERT (1823–1905), English inventor, was born at Bolton-le-Moors, Lancashire, on Jan. 3, 1823, the son of James Whitehead, owner of a cotton-bleaching business. In 1837 he was apprenticed to a firm of engineers in Manchester, and in 1844 joined his uncle at the works of Philip Taylor and Sons, Marseilles. In 1847 he set up a business of his own in Milan, later joining the staff of the Austrian Lloyd company at Trieste, where he was manager from 1850 to 1856. In 1856 he began to work for the Stabilimento Tecnico Fiumano, building several Austrian warships, and carrying out preliminary experiments for the Whitehead torpedo, completed in 1866. In 1872 Whitehead bought the Stabilimento Tecnico Fiumano, converting the works entirely to the production of torpedoes and their accessories. *(See* TORPEDOES.) In 1876 he improved his torpedoes with the "servo-motor," and gradually increased their speed. His work was perfected in 1896 by Obry's invention, subsequently acquired and improved by Whitehead, of the gyroscope, which guaranteed precision of aim.

See G. E. Armstrong, *Torpedoes and Torpedo Vessels* (1901).

WHITEHEAD, WILLIAM (1715–1785), English poet laureate who "simply lived — and just as simply died." A prosperous baker's son, born at Cambridge early in Feb. 1715, he was educated at Winchester college and Clare hall, Cambridge. His epistle "On the Danger of Writing Verse" appeared in 1741. In 1745 he became tutor to the son of the earl of Jersey, through whose influence he was appointed poet laureate on Colley Cibber's death in 1757. Obliged each year, as he wrote in his "Pathetic Apology for All Laureats Past, Present and to Come," to compose two odes "As innocent as a Gazette," he produced, in Horace Walpole's phrase, "no more poetry than is necessary for a laureate." After the success of his best play, *The School for Lovers* (1762), he read plays for David Garrick. He died in Westminster, April 14, 1785. He was a modest man and, unlike many earlier laureates, not a party propagandist.

BIBLIOGRAPHY.—W. Mason's memoir in Whitehead's *Poems,* 3 vol. (1788); A. Chalmers (ed.), *English Poets,* vol. xvii (1810); H. K. Hopkins, *The Poets Laureate* (1954).

WHITE HORSE, VALE OF, the name of the valley of the Ock, which joins the Thames from the west at Abingdon, Berkshire, Eng. The vale is flat and well wooded, contrasting with the close-cropped turf covering the chalk of the White Horse hills on the south. On the north a lower ridge separates it from the upper Thames valley; but local usage sometimes extends the vale to cover all the ground between the Cotswolds (on the north) and the White Horse hills. Wantage is the only town in the heart of the vale, but upon the lower hill slopes villages are numerous. Toward the west, above Uffington, the hills reach a culminating point of 856 ft in White Horse hill. In its northern flank, a gigantic figure of a horse is cut, the turf being removed to show the white chalky subsoil beneath. This figure gives name to the hill, the range and the vale. It is 374 ft. long and of the rudest outline, the neck, body and tail varying little in width. Its origin is unknown. The figure, with others of a similar character elsewhere in England, is considered to be of high antiquity, dating from the late Iron Age. Many ancient remains occur in the vicinity of the Horse. On the summit of the hill there is an extensive and well-preserved circular earthaork known as Uffington castle. Within a short distance are Hardwell castle, a square work, and, near Ashdown park, a small camp traditionally called Alfred's. A smooth, steep gully on the north flank of White Horse hill is called the Manger, and to the west of it rises a bald mound named Dragon's hill. The name, properly Pendragon, is a Celtic form signifying "chief of kings," and may point to an early place of burial. To the west of White Horse hill lies a megalith called Wayland Smith's cave. The White Horse itself has been carefully cleared of vegetation from time to time, and the process, known as the "Scouring of the White Horse," was formerly made the occasion of a festival. A grassy track represents the Ridgeway, an ancient road along the crest of the hills. Other earthworks in addition to those near the White Horse overlook the vale, such as Letcombe castle above Wantage. Among interesting village churches in the vale is the fine Early English one at Uffington. The length of the vale, from Shrivenham to Abingdon, is about 17 mi.

WHITE HOUSE, the official residence of the president of the United States. Located at 1600 Pennsylvania avenue in Washington, D.C., it looks. out over landscaped lawns to Lafayette square on the north and, on the south, across the fenced grounds and the open space known as the Ellipse to the Washington monument beyond.

In 1791, after the first congress under the new constitution had voted to establish a federal capital and had authorized President Washington to select a site for it on the Potomac river, the president engaged Maj. Pierre Charles L'Enfant, a French engineer who had served with him during the Revolution, to map out a plan for the city. L'Enfant chose for the location of the "President's Palace" a ridge of ground rising above a small creek that debouched into the river at the present-day intersection of Constitution avenue and 17th Street. In a public contest to choose the most suitable design for the residence, Thomas Jefferson and others submitted drawings, but James Hoban, an Irish-American resident in Philadelphia, won the competition and the $500 prize. His plan displayed the characteristic features of the late 18th-century English country house, not, as hearsay later declared, a replica of the Duke of Leinster's seat in Ireland. The harmonious proportions of Hoban's design constituted its chief distinction. The principal ornamentation lay in the fenestration — on the first story a series of large windows with alternating arched and triangular pediments, on the second, smaller rectangular nindows, while balustrading concealed from view the windows of the third floor. The floor plan included a spacious entrance hall, a large ceremonial room on the east balanced by a state dining room on the west, and three smaller drawing rooms between. The cornerstone, of pale gray limestone from nearby quarries in Virginia, was laid on Oct. 12, 1792. The residence is thus the oldest federal building in Washington. It is a three-story structure with a total of more than 100 rooms.

In Nov. 1800, when congress convened for the first time in the new capital, President and Mrs. John Adams became the first occupants of the executive mansion. Mrs. Adams ruefully remarked upon the damp plaster, the lack of bell pulls, and the dearth of firewood that left the large rooms cold and drafty. She hung the family washing in the still unfinished East Room. When Thomas Jefferson moved into the residence in March 1801, his hospitality, as generous as it was lacking in pomp, quickly made the house the gathering place of the most intiresting people in the little city; at the New Year's day levees and the 4th of July celebrations people of all sorts came to pay their respects. In a cage on the 16-ac. grounds about the building Jefferson kept the grizzly bears that Capt. Meriwether Lewis brought back from his 4000-mile expedition to the far west. President and Mrs. Madison introduced somewhat greater formality into official entertaining but, thanks to "Dolly's" inimitable skill as hostess, all Washington's social life centred about the president's house. It was coming to be called the White House by 1809, for its whitish limestone contrasted strikingly with the red brick of the other public buildings and private dwellings in the vicinity. Not until Theodore Roosevelt's time would the president's stationery carry the heading The *White House,* but the name was in use well before the fire-blackened walls left standing after the British army burned the house in Aug. 1814 received a coat of white paint.

In Sept. 1817 the White House, rebuilt under the direction of Hoban and completely refurnished, was ready for occupancy by President and Mrs. Monroe. Having extended the original house by adding an east and a west terrace opening out upon the south lawn. Hoban built the semicircular south portico in 1824 and the imposing colonnaded north portico at the beginning of Andrew Jackson's presidency. John Quincy Adams devoted time and his botanical knowledge to planting a garden and obtained an appropriation for fencing the grounds; President Van Buren further embellished them. During the rest of the 19th century changes to the exterior of the house and to the grounds were few. Rater from a spring a mile to the north was piped into the house in 1832, and shortly thereafter a sewer was laid to drain waste into the canal that skirted the foot of the President's Square along the bed of the little tidal creek. James Polk in 1848 was the first president to enjoy the luxury of gas lighting, and Franklin Pierce the first to have central heating. In 1850 Andrew Jackson Downing, the most famous American horticulturist of his day, undertook the landscaping of the grounds in the then popular romantic style.

While congress yearly appropriated small sums for maintenance of house and grounds and allotted each new president some money for redecorating, by Abraham Lincoln's time the residence was badly in need of basic repairs, such as pointing up the masonry foundations to stop the infestation of rats. Other improvements had to wait. Not until 1872 was the problem of adequate sanitation resolved by substituting for the open sewer emptying into the tidal marsh beyond the Washington Monument a bricked-in culvert carried far out into the Potomac, where the current ran strong enough to prevent backwash on incoming tides. A single telephone line was introduced in 1880 and electric lighting a dozen years later.

Despite some physical inconveniences, the White House over the years served its purpose well. The graciously proportioned rooms witnessed weddings, receptions and state dinners attended by the most eminent Americans and the most notable foreign visitors of each generation. By the 20th century, however, the heightened responsibilities of the chief of state of a nation that had become a world power led Pres. Theodore Roosevelt to request additional space for offices and the release for living quarters of the second-floor rooms that presidents from Lincoln onward had had to use for official business. To the architectural firm of McKim, Mead and White fell the task of designing the new executive office building and rebuilding part of the interior of the main house. Uneasiness lest the changes mar the harmonious lines of the original proved unfounded, and for approximately 40 years the remodeled residence sufficed as it was except for rewiring, new plumbing and the installation of air conditioning.

While large additions to the office building were necessary to accommodate the expanding staff of the 1930s and early 1940s, not until after World War II was the residence itself subjected to renovation. In 1948, when President Truman had a balcony built on the south portico and proposed further changes, a board of architects reported that extensive structural repairs were imperative. The cost would be greater than construction of an entirely new house but, as public sentiment opposed the very thought of abandoning the historic executive mansion, the multi-million-dollar rebuilding was undertaken. It was completed before the inauguration of President Eisenhower in 1953. Over the years the White House has become a major American shrine and each year more than 1,000.000 visitors walk through its public rooms. *See* also WASHINGTON, D.C.

WHITELEY, WILLIAM (1831–1907), English merchant, who developed one of the first large department stores in London, was born at Agbrigg, near Wakefield. Torkshire, Sept. 29, 1831. In 1851 he went to London and in 1863 opened a small shop for the sale of fancy drapery. He made a practice of marking the prices of all goods clearly and of dressing his shopwindow attractively, both being unusual features in the retail trade of that time. He was satisfied with small profit margins and was able to expand his operations until he could call himself "The Universal Provider" and boast that there was nothing which his shops could not supply. He died in London. Jan. 23, 1907. (J. R. LT.)

WHITELOCKE, BULSTRODE (1605–1675), English lawyer and parliamentarian, eldest son of Sir James Whitelocke, was born on Aug. 6, 1605, and educated at Merchant Taylors' school and at St. John's college. Oxford, where he matriculated on Dec. 8. 1620. He was called to the bar in 1626 and chosen treasurer of the Middle Temple in 1628. He was M.P. for Stafford in the parliament of 1626 and was appointed recorder of Abingdon (*c.* 1631) and Henley. In 1640 he was chosen member for Great Marlow in the Long parliament. He took a prominent part in the proceedings against the earl of Strafford. He drew up the bill against the dissolution of the Long parliament without its own consent, and supported the Grand Remonstrance and the action taken in the commons against the illegal canons; on the militia question, however, he advocated a joint control by king and parliament. On the outbreak of the Civil War he took the side of the parliament. He was sent to the king at Oxford in 1643 and 1644 to negotiate terms, and the secret communications with Charles on the latter occasion were the foundation of a charge of treason brought against Whitelocke and Denzil Holles (*q.v.*) later. He was again one of the commissioners at Uxbridge in 1615. Nevertheless, he opposed the policy of Holles and the peace party and the proposed disbanding of the army in 1647, repudiated the claims of divine authority put forward by the Presbyterians for their church. and approved of religious tolerance. He thus gravitated toward Oliver Cromwell and the army party. Under the Commonwealth he was nominated councillor of state and became a commissioner of the new Great Seal. In 1653 he went on a mission to Christina, queen of Sweden. to conclude a treaty of alliance and to secure the freedom of the Sound. On his return he again became a commissioner of the Great Seal, and also a commissioner of the treasury. In 1654 and 1656 he sat as M.P. for Buckinghamshire.

As a lawyer: Whitelocke supported a bill introducing the use of English into legal proceedings. drafted a new treason law. and introduced modifications into chancery procedure. His resistance to the ill-considered changes in the court of chancery proposed by Cromwell and the council, however, led to his dismissal from the commissionership of the Great Seal. He still advised Cromwell on foreign affairs, and was chairman of the committee to urge Cromwell to accept the crown. In Dec. 1657 he became a member of the new house of lords. He was again a commissioner of the Great Seal under Richard Cromwell, and was a member (May 14, 1659) and president (Aug. 1659) of the council of state. On the expulsion of the Long parliament, in which he had a seat, he was included in the committee of safety which superseded the council. He again received the Great Seal on Nov. 1.

On the failure of his plan to persuade Charles Fleetwood to forestall George Monk by making terms with Charles II, he retired to the country. He died at Chilton, in Wiltshire, July 28, 1675.

He was the author of: *Memorials of the English Affairs from the Beginning of the Reign of Charles I . . .* (published 1682 and reprinted; a compilation abounding in errors); *Journal of the Swedish Embassy* (1772; re-edited by Henry Reeve in 1855); *Notes on the King's Writ for Choosing Members of Parliament* (1766); *Memorials of English Affairs from the Supposed Expedition of Bruce to this Island to the End of the Reign of James I* (1709); *Essays Ecclesiastical and Civil* (1706); *Quench Not the Spirit . . .* (1711); and some theological treatises which, like his most valuable work, his *Annals,* remain in manuscript. *See* also the article by Sir Charles Firth in the *Dictionary of National Biography,* vol. xxi (1922).

WHITE MOUNTAINS, a mountainous upland located in north-central New Hampshire and extending slightly into Maine. The northeastern end of the region is marked by the Androscoggin and Ammonoosuc valleys. The region is 87 mi. long and 15 to 20 mi. wide and contains the highest elevations in the northeastern United States. The mountains do not constitute a distinct range but form a broad upland region roughly trending northeast-southwest. There is no distinct alignment of ridges and valleys. Noteworthy features are the many rounded passes, locally termed notches, that were excavated by local mountain glaciers during waning stages of Pleistocene glaciation.

The geologic structure of the region is complex. Granites predominate among the igneous rocks that comprise the higher, more rugged terrain. The Paleozoic shales in the region that antedate the Acadian intrusions have been altered into mica schists. phyllites and slates. The highest elevations, mostly between 5.000 and 6,000 ft., occur in a linear series of distinct peaks that are named for U.S. presidents and make up the Presidential range. The highest point is Mt. Washington (6,288 ft.). The region southwest of Crawford notch is termed locally the Franconia mountains.

Predominantly a recreational region, a large part of the wooded White mountains is included in the White Mountain National forest (715,379 ac.). Only the highest summits extend above the timberline. A highway and cog railway provide access to Mt. Washington during the summer. Over 1,000 mi. of nature trails and numerous campsites make the region a favourite summer vacation area. It also has some of the finest ski slopes and facilities for winter sports in eastern North America, including those at Franconia (Cannon mountain), Conway (Mt. Cranmore) and Mt. Washington. (J. E. V. R.)

WHITE PLAINS, a city of eastern New York, U.S., is located on the Bronx and Hutchinson rivers midway between the Hudson river and Long Island sound, 10 mi. N. of the Bronx (New York city); the seat of Westchester county. It is both the hub of Westchester's transportation system and one of the leading suburban residential and shopping centres in the U.S. Known to the Siwanoy Indians, a Mohegan tribe, as "Quarropas" (the white plains) from the white balsam in the area, White Plains was purchased from them first by John Richbell of Mamaroneck in 1661. The Indians then sold the same site to a group from Rye township in 1683. Long litigation upheld the Rye title in 1721. During the American Revolution the provincial congress met there on June 30, 1776, after moving from New York city, and on July 9, having received the Declaration of Independence from Philadelphia, proclaimed the creation of the state of New York and themselves as the state legislature. At the battle of White Plains, fought on Oct. 28, 1776, Gen. William Howe, unable to force or feint Washington's army out of strongly prepared positions to the north, disengaged and retired to Dobbs Ferry. White Plains became the county seat in 1778, an incorporated village in 1866 and a city in 1916. Major manufactures include hearing aids, aircraft instruments, food products, women's clothing, electroplating, engraving, precision machine parts, plastics, artificial flowers and electronic devices. With a population (1960) of 50,485, White Plains is part of the New York standard metropolitan statistical area. (RI. D. HH.)

WHITE RIVER, the name of several rivers in the U.S. The White river in Arkansas and Missouri is a 690-mi. stream that rises in the Boston mountains of Arkansas, flows northeast into south-central Missouri, where it bends southeast and flows into the Mississippi and Arkansas rivers, above Arkansas City, Ark. Most of the river's descent is in the upper course, where it exceeds 25 ft. per mile. Through the Boston mountains and the Ozark plateau of southern Missouri, the White is deeply entrenched with elaborate windings that occupy gorges not much wider than the river. Much of its middle course is a valley over 500 ft. deep. At Newport, Ark., the White emerges from the highlands on to the flood plain of the Mississippi river. There the stream gradient is less than 3 ft. per mile, with numerous meanders, abandoned stream channels, flooded land and swampland. Major tributaries are the King, Black and Little Red rivers.

In Colorado and Utah the White river rises on the White river plateau. 12,000 ft. high, in western Colorado. The river is 250 mi. long, flows toward the west and empties into the Green river at Ouray, Utah. Its annual discharge of 500,000 ac.ft. supplies a substantial quantity of water to the Colorado river system.

The White river of Nebraska and Dakota rises on the Pine Ridge escarpment in northwestern Kebraska. In its 325-mi. course the river flows northeast into South Dakota. turns east and empties into the Missouri, near Chamberlain, S.D. In the upper course. light rainfall, sparse vegetation and geologic conditions have created the Big Bad Lands. There the numerous, small, intermittent tributaries entering the White have carved a labyrinth of pinnacles, valleys, slopes and fantastic features into the soft clay formations. The lower course is a sand filled, braided, meandering channel over a mile wide.

The New Mexico-Texas White river rises in eastern New Mexico, in Quay county. It flows southeast 110 mi. and joins with the Double Mountain river, near Rule, Tex., to form the Brazos river. Most of the course of the White is across the extremely flat Staked plains of eastern New Mexico and northwest Texas, where the stream bed is dry.

See Nevin M. Fenneman, *Physiography of Western United States* (1931), *Physiography of Eastern United States* (1938). (M. J. L.)

WHITE RUSSIA: see BELORUSSIAN SOVIET SOCIALIST REPUBLIC.

WHITE SAPOTE, a fruit produced by the tree *Casimiroa edulis,* of the citrus family (Rutaceae). The ancient Aztecs called this species *cochiztzapotl,* "sleep-producing sapote," which would imply a reputation as a soporific.

The white sapote, originally a tree of the Mexican highlands, where it is commonly seen in dooryards: has been carried to numerous tropical and subtropical regions, especially to southern California, where local seedlings, which produce fruit of superior quality, have been named and propagated by grafting, using the shield-bud method. (*See* PLANT PROPAGATION.) Pike: Suebelle, Wilson and Coleman are among the best varieties offered by nurserymen.

The tree, which is somewhat more frost resistant than the orange and tolerant of poor soils and drought, is characterized by palmately compound leathery leaves and small inconspicuous racemes of yellowish flowers. The round, yellowish-green, thin-skinned fruits are the size of an orange; they contain one to three (occasionally five) large oval seeds, surrounded by soft, yellowish-white, sweet flesh of not very pronounced flavour. They often appear in the markets of the Mexican highlands, but rarely in other parts of the world, and are eaten fresh.

The *matasano* of the Central American highlands is either a geographical form of the white sapote or a closely allied species, *Casimiroa tetrameria.* (W. Po.)

WHITE-SLAVE TRAFFIC. "White-slave traffic." renamed by the League of Nations in 1921 "traffic in women and children" in order to include all races, may be defined as an organized business, national and international, carried on for the purpose of supplying the trade of prostitution (*q.v.*). The term denotes enforced prostitution.

Contagious Diseases Acts; First International Congress.—The international movement to abolish the traffic began in 1864 with the British parliament's passage of the first of the Contagious Diseases Prevention acts, followed by those of 1866 and 1869. This introduction of state regulation of vice in England was caused by the extremely high incidence of venereal disease among soldiers and sailors and was designed primarily for their protection. It permitted the arrest of women by special police on mere suspicion, registration and police supervision of prostitutes, compulsory medical examination and detention in special hospitals for those found infected. It was modeled upon the French system, with the difference that the latter was not based upon law but was merely a police measure. French brothels were chiefly known as *maisons tolérées; i.e.,* houses tolerated or licensed by the police or municipal authorities. Passage of these acts precipitated a powerful movement for their repeal. Two groups developed: one regarded prostitution as a necessary evil to be regulated and controlled by law; the other opposed this view and the acts theinselves on the ground that they inflicted a grave injustice on women of the most helpless class and failed as health measures. Josephine Butler (*q.v.*) rose as the leader of the abolitionists and began the campaign to abolish state regulation of prostitution and the white-slave traffic. She founded the British: Continental and General Federation for the Abolition of Government Regulation of Prostitution (later known as the International Abolitionist federation). At its first world congress, held in Geneva, Switz., in 1877. the federation adopted a series of reports and resolutions which formed the basis of subsequent work for abolition of state regulation of prostitution and of white-slave traffic. The Contagious Diseases acts were suspended in 1883 and repealed in 1886.

Later International Conferences.—An international congress held in 1899 developed the International Bureau for the Suppression of Traffic in Women, of which William A. Coote was head. The French government called a conference in Paris in 1902 which resulted in an international agreement signed in 1904 by 13 states—Belgium, Denmark, France, Germany, Great Britain, Italy, the Netherlands, Norway and Sweden, Portugal, Russia, Spain and Switzerland (Austria adhered in 1905 and the U.S. in 1908). The signatories recommended a central authority in contracting states to co-ordinate and exchange information concerning the traffic. In 1910 France called another conference in I'aris, resulting in a convention which went further than the agreement of 1904. It was signed by 13 nations, including Brazil, and undertook to make procurers of women punishable and extraditable. Other nations adhered later.

National Enactments.—Important national laws were the British Criminal Law Amendment act of 1885, amended in 1912 and 1922. which made procuration or attempted procuration a misdemeanour with severe penalties; the Children (Employment Abroad) act of 1913; and laws passed by the United States. An investigation made in 1908–1909 by the U.S. Immigration commission revealed that a large number of alien women and girls were then being imported and distributed through the states for purposes of prostitution, and that they were purchased by letters or through agents sent to Europe and Asia. This investigation was followed by an amendment of the immigration law for the protection of alien women and girls and the passage of the White-Slave-Traffic act (Mann act) in 1910, which imposed severe penalties for interstate or foreign traffic in women or girls. These national measures were followed by a number of state laws.

League of Nations.—Publication in 1914 of *Prostitution in Europe* by Abraham Flexner shattered the claim of "safe" regulation and segregation. World War I. however, temporarily ended further international work. The war caused a great increase in venereal disease and raised doubts as to the effectiveness of official control of prostitution and white-slave traffic. One of the earliest acts of the League of Nations after its inauguration on Jan. 10. 1920. was to appoint a permanent official to keep in touch with everything connected uith the traffic. A conference convened by the council in Geneva in 1921 was attended by delegates from 34 nations, thereby extending the area of the movement. At the second ordinary session of the assembly on Sept. 30. 1921. a new convention was opened for signature and by July 24, 1926, had been signed by 33 states (including Japan, China and India), most of which had also ratified it. The United States expressed its support but did not sign on the ground that legislation on prostitution was largely left to the states This convention extended and strengthened provisions of the convention of 1910.

Formation of the advisory committee to the council on all matters relating to traffic in women and children was another important outcome of the conference of 1921. At the committee's request in 1923, the council of the League conducted a special investigation nhich indicated a strong movement for the abolition of the system of licensed houses and of regulation.

One of the most far-reaching accomplishments of the advisory committee was the nomination of a body of experts to conduct an investigation of the world's traffic. With the co-operation of the governments. this group investigated 112 cities and 28 countries in Europe, north Africa, North America and Central and South America. Its report (1927) proved the existence of a highly organized and well-financed national and international traffic.

The League's many inquiries and publications on the two problems of prostitution and traffic helped develop national public opinion and a consciousness of the need for international action in attacking the evils. General European conferences were frequent

A diplomatic conference for the protection of women of full age was held in 1933; in October the 1921 convention was extended by a new convention providing penalties for procuring, enticing and leading away women of full age, even with their consent, for purposes of prostitution in another country.

In 1936 the Advisory Committee on Traffic in Women and Children and the Child Welfare committee were merged into the Advisory Committee on Social Questions. This committee's campaign against the traffic included efforts to obtain new ratifications to the conventions. to abolish licensed brothels and to increase employment of women police. The Social Questions committee also drew up the draft convention of 1937 for the suppression of the exploitation of prostitution. This convention was the first to provide protection for persons of full age of either sex against being procured for profit, even with their consent and when they were not taken beyond national boundaries. The onset of World War II prevented its ratification.

The Far **East.**—Following the investigations of the advisory committee, a conference of central authorities of eastern countries to consider repression of the traffic in women and children was held at Bandung, Java, Feb. 2–13, 1937. It aimed to attain swifter exchange of information between the police and other authorities responsible for preventing the heavy traffic in the east. Migrations of Russian women refugees and other displaced persons in the far east in danger of becoming victims of the traffic, and the existence of licensed and tolerated brothels, were other problems considered.

World War 11.—Such was the prospect for suppression of prostitution and control of traffic in women and children as war approached. Despite the waning of its political power. the League continued its educational work during the prenar and war years wherever avenues of communication remained open. Areas of military operation created new problems of traffic in women, prostitution and increase in venereal diseases. A United Nations report of 1947 stated that the Germans took hundreds of French women and girls to Germany and other occupied countries and placed them in brothels. Similar actions, on both sides, had always been an accompaniment of warfare.

In the United States, the May act of 1941 gave the military and naval authorities power to outlaw prostitution in zones around military and naval areas. Its administration, with the co-operation of local civil and health authorities in closing brothels, was successful; the lowest rate of venereal disease infection in the history of the U.S. armed forces was achieved.

Experience in World War II, according to investigators, undoubtedly made clearer to governments that eradication of prostitution must be accompanied by eradication of its causes. It also made clear that the evils of prostitution and traffic in women cannot be removed, even temporarily, by action against prostitutes.

Postwar Trends. — With the war's end, however, public indifference returned. The exploiter of vice and the trafficker in women, forced underground by the wartime drive, again emerged. According to the American Social Hygiene association, the increase in prostitution began in 1945 when the war ended. By 1949. 38% of the U.S. cities surveyed were found tolerating bad conditions while 12% more were rated as poor. Federal authorities estimated that at least one out of every four communities that had padlocked brothels as a war measure allowed them to reopen a few years later.

Mexico and certain Central and South American countries adopted governmental programs to suppress commercialized prostitution and the increasing spread of venereal diseases, following organization of the International Cooperative Health plan of the 21 American nations. The support of the International Association of Chiefs of Police and other influential bodies was pledged to this objective.

In Europe and Asia, prostitution and submission to traffickers became a chief means of support for impoverished women and their families. Cases of international traffic from China of Chinese natives were registered in the Republic of the Philippines from time to time. In Palestine, according to a report of the United Nations (1946–47), there were many convictions of traffickers in women. Extensive air traffic conducted by specially trained pilots was reported.

The United Nations. — By action of its Economic and Social council on Aug. 14, 1947, and further action of its general assembly on Oct. 20, 1947, the United Nations voted to assume "the functions and powers of the League of Nations" under the International convention of Sept. 30, 1921, for the suppression of traffic in women and children; the International convention of Oct. 11, 1933, for the suppression of the traffic in women of full age; and the functions formerly performed by the French government under the International agreement of May 18, 1904, and the International convention of May 4, 1910, for the suppression of the white-slave traffic.

The Economic and Social council's Social commission at its fourth session in May 1949 approved a draft convention embodying the essential features of the international instruments mentioned above, under the title of the "Draft Convention for the Suppression of the Traffic in Persons and Exploitation of the Prostitution of Others." The convention was based as far as possible on abolitionist, as opposed to regulationist, principles, subject to the requirements of domestic law. The draft convention was approved by the UN general assembly on Dec. 2, 1949. As of Sept. 1, 1958, 24 states had deposited an instrument of ratification or accession.

Another aspect of the world organization's activity was the periodic publication in the *International Review of Criminal Policy* of information submitted by member states in their biennial replies to a questionnaire on traffic in persons drawn up by the United Nations. *See* also PROSTITUTION.

WHITETHROAT, a name given to two European birds belonging to the Sylviidae or warblers (*q.v.*). They are about $5\frac{1}{2}$ in. long. The common whitethroat or nettle creeper, *Sylvia cinerea,* is widely spread over Great Britain and is in some places common. It is a restless bird, and in spring the male often gives his song on the wing. The lesser whitethroat, *Sylvia curruca,* is less often seen. The plumage is smoky gray above and white below. Its song is unusual, consisting of a series of repeated notes. the usual warble being reduced to a short preface inaudible at a short distance. The nests of each of these species are built of bents or other plant stalks and usually lined with horsehair; the eggs are spotted with olive brown. (HT. FN.)

WHITGIFT, JOHN (1530?–1604), English archbishop, was the eldest son of Henry Whitgift, merchant of Great Grimsby, Lincolnshire, where he was born. He was educated by his uncle, Robert Whitgift, abbot of the neighbouring monastery of Wellow, then at St. Anthony's school, London, and finally at Cambridge, where he became a fellow of Peterhouse in 1555. Having taken orders in 1560, he became chaplain to the bishop of Ely, who collated him to the rectory of Teversham, Cambridgeshire. In 1563 he was appointed Lady Margaret professor of divinity at Cambridge, and in 1564 regius professor of divinity. He became master first of Pembroke hall and then of Trinity. He had a principal share in compiling the statutes (1570) of the university, and in November of the same year was chosen vice-chancellor. Macaulay's description of Whitgift as "a narrow, mean, tyrannical priest, who gained power by servility and adulation," is unjust, but he was intolerant and arbitrary. Whitgift, with other heads of the university, deprived Thomas Cartwright in 1570 of his professorship, and in Sept. 1571, as master of Trinity, deprived him of his fellowship. In June of the same year Whitgift was nominated dean of Lincoln. In the following year he published *An Answere to a Certain Libel intituled an Admonition to the Parliament,* which led to further controversy with Cartwright. On March 24, 1577. Whitgift was appointed bishop of Worcester, and during the absence of Sir Henry Sidney in Ireland (1577) he acted as vice-president of Wales. In Aug. 1583 he was appointed archbishop of Canterbury. Although he wrote a letter to Queen Elizabeth I remonstrating against the alienation of church property, Whitgift always retained her special confidence. In his policy against the Puritans, and in his vigorous enforcement of the subscription test, he thoroughly carried out the queen's policy of religious uniformity. He drew up articles aimed at nonconforming ministers, and obtained increased powers for the court of high commission. In 1586 he became a privy councilor. His action gave rise to the Marprelate tracts, in which the bishops and clergy were bitterly attacked. Through Whitgift's vigilance the printers of the tracts were discovered and punished; and in order more effectually to check the publication of such opinions he got a law passed in 1593 making Puritanism an offense against the statute law. In the controversy between Walter Travers and Richard Hooker he interposed by prohibiting the preaching of the former and he moreover presented Hooker with the rectory of Boscombe, Wiltshire, in order to afford him more leisure to complete his *Ecclesiastical Polity,* a work which, however, cannot be said to represent either Whitgift's theological or his ecclesiastical standpoint. In 1595 he, in conjunction with the bishop of London and other prelates, drew up the Calvinistic instrument known as the Lambeth articles. which were not accepted by the church. Whitgift attended Elizabeth I on her deathbed, and crowned James I. He was at the Hampton Court conference in Jan. 1604, and died at Lambeth on Feb. 29 of that year. He was buried in the church of Croydon. Whitgift was noted for his hospitality, and was ostentatious in his habits, sometimes visiting Canterbury and other towns attended by a retinue of 800 horsemen.

Whitgift left several unpublished works, which are included among the manuscripts *Angliae.* Many of his letters, articles, injunctions, etc., are calendared in the published volumes of the "State Paper" series of the reign of Elizabeth I. His *Collected Works,* ed. for the Parker society by John Ayre (3 vol., 1851–53), include, besides the controversial tracts already alluded to, two sermons published during his lifetime, a selection from his letters to Cecil and others, and some portions of his unpublished manuscripts.

WHITHORN, a royal and small burgh in the Machers peninsula of Wigtownshire, Scot., 62 mi. S.E. of Dumfries by road and 18 mi S. of Wigtown. Pop. (1961) 986. St. Ninian or

Ringan, the first Christian missionary to Scotland, landed at the Isle of Whithorn, 3 mi. S.E. of the town, where he built (397) a whitewashed stone church, which, out of contrast with the dark mud and wattle huts of the natives, is said to have been called Candida Casa (Hvit-aern), the "white house." Ninian is buried in the church. The Magnum Monasterium, or monastery of Rosnat, was founded at Whithorn 100 years later and in the 8th century became the seat of the bishopric of Galloway. It was succeeded in the 12th century by St. Ninian's priory, built for Premonstratensian monks by Fergus, "king" of Galloway, of which only the chancel (used as the parish church till 1822) and other fragments remain. There is a museum containing many Christian and other monuments.

WHITING, a city of Lake county in northwestern Indiana, U.S., on the shore of Lake Michigan, immediately S.E. of Chicago and part of the Gary-Hammond-East Chicago standard metropolitan statistical area. The city was started in 1889 when the Standard Oil company, unable to find a site in Chicago, constructed a large refinery there. Although the plant was put into production in 1890, incorporation of the community was delayed until 1896. Whiting was the birthplace of the Standard Oil Company of Indiana and was for many years the capital of that oil empire. In addition to petroleum. Whiting manufactures metals, chemicals, soap and food products. Surrounded by Chicago, Hammond, East Chicago and Lake Michigan, Whiting's area remained small and the population, which reached a peak of 10,880 in 1930, gradually declined after that time. For comparative population figures see table in INDIANA: Population. (P. ME.)

WHITING, a name originally applied to a European marine food fish (*Gadus* merlangus) of the cod family (Gadidae); it ranges from Spain to Norway and Iceland. A closely related species, often called blue whiting (*Gadus poutassou*), is common in and about the Mediterranean; it occurs as far north as Norway and Iceland and a few specimens have been taken in the deep water of the New England banks. In North America the name whiting is applied to several other species, perhaps because of some fancied similarity of form to the European species. On the Atlantic coast of North America the silver hake (*Merluccius* bilinearis) is usually called whiting in the fish trade. It occurs on the continental shelf of eastern North America from North Carolina to the Grand Banks off Newfoundland. Over 90,000,000 lb. are caught annually in the trawl fisheries. Several species of the drum or croaker family (Sciaenidae) are sometimes called whiting; for example, the California corbina (California whiting, Menticirrhus *undulatus*), occurring from the Gulf of California to central California; the northern kingfish (king whiting, Menticirrhus saxatilis), occurring from Massachusetts to the Gulf of Mexico; and the southern kingfish (*Menticirrhus americanus*), occurring from New Jersey to Texas.

"Whiting" is sometimes applied to lake whitefish (*Coregonus clupeaformis*), of the Great Lakes region: and in Australia generally to species of Sillaginodes and *Sillago,* which are small! slender shallow water fishes of the Indo-Pacific region belonging to the family Sillaginidae. (L. A. WD.)

WHITLEY COUNCIL: see INDUSTRIAL RELATIONS.

WHITLOCK, BRAND (1869–1934), C.S. diplomat and writer, was born at Crbana. O., March 4, 1869. As a political reporter on the Chicago *Herald* and as assistant in the office of the Illinois secretary of state, Whitlock came in contact with John P. Altgeld, governor of Illinois, who, like "Golden-Rule" Jones, mayor of Toledo, did much to develop his political idealism. He was admitted to the Illinois bar in 1894, and to the bar of Ohio in 1897. From that year until 1905 he practised law in Toledo and then as an Independent became mayor for four terms, in 1911 refusing nomination a fifth time. The record of his labours for the "Free City" of which he dreamed is told in his autobiography, Forty Years of *It* (1914, new edition 1925).

In 1913 he was appointed U.S. minister (later ambassador) to Belgium. Before he had been in Belgium a year World War I broke out and the German invasion took place. Although the other diplomatic bodies followed the Belgian court to Le Havre, Whitlock insisted on remaining in Brussels. It was largely because of his urgent advice that Brussels did not resist, and thus escaped devastation. In the early days of the war he gave protection to many German residents who had been unable to leave the country. By his firm attitude toward the German military officials he saved many innocent Belgians from death; but his activities on behalf of Fd th Cavell nere unavailing as he was misled at the last moment through false promises by the Germans. After the formation of the Commission for Relief in Belgium. its operations were placed wholly under his direction. His ceaseless work on their behalf won the gratitude of all Belgians and was rewarded by many honours. Whitlock resigned Feb. 1. 1922. An account of his experiences is given in *Belgium*, a Personal *Narrative* (1919).

R'hitlock himself spoke of vacillating "between an interest in letters and an interest in politics," and there is no doubt that his early literary work, at least. reflected this duality of tastes. The *13th* District (1902) revealed the insidiously corrupting influence of certain phases of politics; and *The Turn* of *the Balance* (1907), a poignant exposure of social injustices, was written "out of the contemplation of the misery, the pathos, the hopelessness of the condition" of the victims during his police court experiences. A fruit of his administrative work is the monograph On *the* Enforce*ment* of Law in *Cities* (1913). His later novels, such as J. *Hardin and* Son (1923) and Uprooted (1926). are less concerned with ethical problems. His technique at all times, however, revealed his admiration for the ideals and methods of William Dean Howells. In 1929 he published La Fayette, a biography.

He died at Cannes, Fr., May 24, 1934.

WHITMAN, MARCUS (1802–1847), missionary to American Indians and pioneer settler in Oregon, was born at Rushville, N.Y., Sept. 4, 1802. He studied medicine with a local physician and earned a degree from Berkshire Medical college (Pittsfield, Mass). He then practiced medicine for four years in Canada and briefly thereafter in western New York

In 1835 Whitman offered his services to the American Board of Commissioners for Foreign Missions and was immediately sent out nith the Rev Samuel Parker to explore the possibility of founding missions in Oregon. The tno missionaries traveled as far as the Green river rendezvous in western Wyoming. Whitman then returned east for additional recruits while Parker proceeded westward to investigate potential mission sites. In September of the following year Whitman and his bride Narcissa Prentiss, accompanied by Henry H. Spalding and his wife, W. H. Gray (a lay helper) and two Indian boys, arrived at Fort Vancouver, Wash. Acting upon the advice of John McLoughlin of the Hudson's Bay company. Whitman decided to found a mission among the Cayuse Indians at Waiilatpu, 25 mi. west of the present Walla Walla, Wash. Spalding established himself among the Nez Percés at Lapwai, Idaho, on the Clearwater river, 125 mi northnard. Progress at both missions was slow and disappointing. Whitman and Spalding helped the Indians to build houses for themselves and shoned them how to till their fields and irrigate their growing crops. They also taught them how to erect mills to grind their corn and wheat and hon to cultivate gardens and orchards.

In 1842, the American Missionary board decided to abandon the southern Oregon missions and concentrate on those in the Spokane area Alarmed, Whitman determined to go to Boston and urge the board to reverse its decision. He hoped also to acquaint officials at Washington nith conditions in Oregon and to encourage federal support for the rapidly increasing Oregon immigration. This occasioned Whitman's celebrated 3,000-mi. journey on horseback to Boston during the winter of 1842–43. Whitman's mission was entirely successful The board agreed to continue the Waiilatpu and Lapwai missions and President Tyler promised his support of federal aid. Returning to Oregon, Whitman joined up with nhat became knonn as the "great western migration," a caravan of nearly 900 immigrants, and guided them safely across the mountains. Whitman's compelling personality aroused great interest in the Oregon country and this in turn led directly to the rapid advance of American settlement there.

In 1847 a severe epidemic of measles broke out among the Cayuse Indians Many of the sick were being nursed at the Whitman mission. Several of the Indians became terror-stricken, and, believing themselves to have been deliberately poisoned by the whites, attacked the residents of the mission with frenzied fury. The Whitmans and 12 others were murdered on Nov. 29. Some 50 others were taken captive, but were soon rescued thanks to the efforts of Peter Skene Ogden, factor of Hudson's Bay company, who transferred them to Fort Vancouver.

WHITMAN, WALT (WALTER) (1819–1892), U.S. poet, whose *Leaves of Grass* was a landmark in the history of American literature, was born May 31, 1819, at West Hills, a little farming community near Huntington, Long Island, N.Y. Christened Walter, he did not start calling himself Walt until 1855. His ancestry was typical of the region, his mother, Louisa Van Velsor, being Dutch (with a strain of Welsh) and his father, Walter Whitman, of English descent. Both the Whitmans and the Van Velsors were simple farm people, with little formal education. The Whitman family had moved from Connecticut to Long Island in the 17th century, and at one time owned a large tract of land, but it was so diminished by the time Walt was born that his father had taken up carpentering, though still living on a small section of the ancestral estate. In 1823 Walter Whitman, Sr., moved his growing family to Brooklyn. which was enjoying a boom. There he speculated in real estate and built cheap houses for artisans, but he was a poor manager and had difficulty in providing for his family, which increased to nine children, one of whom died in infancy.

Walt, the second child, attended public school in Brooklyn, began working at the age of 12 and learned the printing trade. He was employed as a printer in Brooklyn and New York city. taught in country schools on Long Island and became a journalist. At the age of 23 he edited a daily newspaper in New York, and in 1846 became editor of the *Brooklyn Eagle,* a fairly important newspaper of the time. Discharged from the *Eagle* early in 1848 because of his support of the free-soil faction of the Democratic party, he went to New Orleans. La, where he worked for three months on the *Crrscent*. Some biographers have constructed a fanciful love affair with a Creole woman, but there is no evidence for it. After another abortive attempt at free-soil journalism in Brooklyn, he built houses and dabbled in real estate from about 1850 until 1855. During these years he read extensively at home and in the New York libraries, and began experimenting with a new style of poetry. While schoolteacher, printer and journalist he had published sentimental stories and poems in newspapers and popular magazines, but they showed almost no literary promise.

By the spring of 1855 he had enough poems in his new style for a thin volume. Unable to find a publisher, he sold a house and printed the first edition of *Leaves of Grass* at his own expense. Little appreciated in 1855. it was warmly praised by Ralph Waldo Emerson ("I greet you at the beginning of a great career") in a personal letter to the poet which he used in the following year to advertise the second edition—also a financial failure. Once again Whitman edited a daily newspaper, the *Brooklyn Times,* but was unemployed by the summer of 1859. In 1860 a Boston publisher, Thayer & Eldridge, brought out the third edition of *Leaves of Crass,* greatly enlarged and rearranged, but the outbreak of the Civil War bankrupted the firm. In 1862 Whitman went down to a battlefield in Virginia to find his wounded brother, George, and stayed on in Washington to assist in the care of the wounded. supporting himself by doing secretarial uork and writing articles for Brooklyn and New York newspapers. After the war he secured a clerkship in the U.S. department of the interior, but was discharged on June 30, 1865, for being the author of *Leaves of Grass,* which was considered a notorious book; hou-ever, he was immediately reemployed in the office of the attorney general, where he remained until stricken by paralysis in Jan. 1873. He left Washington to live with his brother George, in Camden, N.J. His mother died a few months later and this uas the darkest year of his life.

Meanwhile he had continued to print new editions of his poems, a collection of war poems called *Drum-Taps* in 1865, and revised editions of *Leaves of Grass* in 1867, 1871 and 1876. Partly recovered from his illness by 1879, he made a trip by train as far west as Denver, and the following year visited Ontario. Canada. The seventh edition of *Leaves of Crass* was published in Boston in 1881 by James R. Osgood, who soon relinquished the book, however, after the attorney general of Massachusetts threatened criminal prosecution because several poems were regarded as obscene. Osgood suggested a new issue with the objectionable poems omitted. but Whitman refused to make a single change. He quickly found a new publisher in nearby Philadelphia. first in Rees Welsh and company, and then David McKay, who reissued the seventh edition. Newspaper publicity had created interest in the book and it sold better than any previous edition. As a result, Whitman was able to buy a modest little cottage in Camden on Mickle street, where he lived until his death on March 26, 1892, from multiple diseases of the lungs, stomach, liver and kidneys.

As a young man Walt Whitman was unusually robust in appearance, being large, tall and florid in complexion. In the early editions of *Leaves of Grass* he gave symbolical values to health, physical stamina and vigorous ancestry in such poems as "Song of Myself," and "I Sing the Body Electric." Despite the fact that he was disease-ridden in old age, he did have natural stamina, but his family mas not a healthy one. His youngest brother was feeble-minded, one brother died in a mental institution, another died of "tuberculosis of the throat" (possibly cancer) and a sister was neurasthenic. He was remarkably loyal to his family and gave generously of his devotion and income to any member who needed help, but especially to his mother, to whom he was strongly attached. and to his feeble-minded brother, whom he supported and for whom he provided in his will. For personal intimates he preferred uneducated workingmen and mas so affectionate toward several that some critics accused him of being homosexual There is no evidence of perversion, but he made no secret of his love for these men. and celebrated it in the "Calamus" section of *Leaves of Grass* and some war poems in *Drum-Taps*. On the basis of his compassion for the weak and needy and affection for simple men, his first biographers, with his encouragement. created the myth of a saintly carpenter-poet, or poet-messiah.

The Poet.—Under the influence of the romantic age in literature and art, Whitman held the theory that the chief function of the poet was to create and express personality. The first edition of *Leaves of Grass* also appeared during the most nationalistic period in American literature, when critics were calling for a literature commensurate with the size, natural resources and potentialities of the North American continent (Whitman himself expected the eventual annexation of Canada and Mexico to the United States). "We want." shouted a character in Longfellow's *Kavanagh* (1849), "a national literature altogether shaggy and unshorn, that shall shake the earth. like a herd of buffaloes thundering over the prairies." With the same fervour. Whitman declared in his 1855 preface. "Here are the roughs and beards and space and ruggedness and nonchalance that the soul loves."

It was partly in response to this nationalistic ideal, and partly in accord with his own personal ambition to cultivate and express his own personality as an example, that the "I" of his poems asserted a mythical strength and vitality and assumed an appearance as shaggy and unshorn as Longfellow's buffalo. For frontispiece to the first edition he used a picture of himself in work clothes, posed nonchalantly with cocked hat and hand in trouser pocket. as if illustrating a line in his leading poem, "Song of Myself" (untitled in 1855): "I cock my hat as I please indoors or out." In this same poem he also characterized himself as, "Walt Whitman. an American, one of the roughs, a kosmos,/Disorderly fleshy and sensual . . . eating drinking and breeding./ . . . Divine am I inside and out, and I make holy whatever I touch or am touched from. . . ." From this time on throughout his life he attempted to dress the part and act the role of the shaggy. untamed poetic spokesman of the proud young nation. For the expression of this symbolical ego he also created a prosodic form without rhyme or metre, but abounding in oratorical rhythms and chanted lists of names and objects. He learned to handle this primitive, enumerative style with great subtlety and was especially successful in creating empathy of space and movement, but to most of his contemporaries it seemed completely "unpoetic." Both the content and the manner of his verse also caused Whitman's first biographers, John Burroughs, R. M. Bucke and even the poet himself, to confuse the symbolical self of the poems with their physical creator. In reality Whitman was quiet, gentle, courteous; neither "rowdy" (a favourite word) nor lawless. In sexual conduct he may have been unconventional, though no one is sure, but it is likely that the six illegitimate children of whom he boasted (and never identified) in extreme old age were begotten by his imagination. He did advocate greater sexual freedom and tolerance ("Spontaneous Me," "A Woman U'aits for Me"), but sex in his poems is also symbolical—of Rousseauistic innocence. "the procreant urge of the world," and the regenerative power of nature. In some of his poems the poet's own erotic emotions may have confused him, but in his greatest, such as parts of "Song of Myself," and all of "Out of the Cradle Endlessly Rocking," sex is spiritualized. His two greatest themes are death and rebirth ("When Lilacs Last at the Dooryard Bloom'd"), and his poems are filled with the "unflagging pregnancy" of nature: sprouting grass, mating birds, phallic vegetation, the maternal ocean and planets in formation ("the journey-mark of stars"). The poetic "I" of *Leaves of Grass* annihilates time and space, binding past and present and intuiting the future, illustrating Whitman's belief that poetry is a form of knowledge, the supreme wisdom of mankind.

The Book.--Whitman is known primarily for one book, *Leaves of Grass,* though he also published several volumes of prose, notably *Specimen Days* (1882), which contains some fine realistic descriptions of Civil War scenes and some vivid reminiscences. But *Leaves of Grass* is actually more than one book. During his lifetime it went through nine editions, between 1855 and 1892, and each had its own distinct virtues and faults. Whitman compared the finished book to a cathedral long abuilding. and on another occasion to a tree, with its cumulative rings of growth. But both metaphors are misleading because he did not construct his'book unit by unit or by successive layers, but constantly altered titles, diction and even motifs and shifted poems—omitting, adding, separating and combining. Beginning with the third edition (1860), he grouped his poems under such titles as "Chants Democratic," "Enfans d'Adam" (later "Children of Adam"), "Calamus." "Poems of Joy" and "Sea-Drift." Some of his later group titles were highly connotative, such as "Birds of Passage." "By the Roadside," "Autumn Rivulets," "From Noon to Starry Night" and "Songs of Parting," suggesting a life allegory. But only the titles were biographical in sequence; chronology (in order of composition) was not followed at all. After 1881 Whitman made no further shifts in groups or revisions of poems within the groups, merely adding the poems of "Sands at Seventy" (first published in *November Boughs,* 1888) and "Good-Bye My Fancy" (from the book by this title, 1889) as first and second annexes in 1892. Whatever else may be said of Whitman's groupings, some of his best imagery is in his group titles and his first lines. The arrangement gave him personal satisfaction and he specified on his deathbed that the 1892 edition was definitive and only it should be reprinted after his death.

Reoutation.— At the time of his death Whitman was more respected in Europe than in his own country. This European reputation began in 1868, when William Rossetti edited a British edition of selected poems. Ferdinand Freiligrath was then in exile in England and through him Whitman became known in Germany. Mrs. Anne Gilchrist, widow of the famous biographer of William Blake, became so enamoured of the personality in the poems that she fell in love with the poet. wrote critical appreciations. promoted the sale of his books and eventually went to America with the intention of marrying him. During the remainder of his life Whitman received much encouragement, financial and psychological. from leading writers in England. In 1872 he began to attract notice in France, and at the same time in Denmark and Norway. In these countries liberals greeted him as "the poet of democracy," while conservatives denounced him as a dangerous influence. Swinburne addressed an ode to the American poet of freedom, but later criticized his poetry for its excessive didacticism.

It was not as a poet, indeed, but as a symbol of American democracy that Whitman first won recognition, even in his own country. When he lost his government position in 1865, William Douglas O'Connor's defense in *The Good Gray Poet* (1866) aroused sympathy for the victim of injustice and contributed to Whitman's reputation as a social prophet. The naturalist John Burroughs, R. M. Bucke, Horace Traubel and William S. Kennedy—the "hot little prophets," Bliss Perry called these American disciples—tried to form a cult around Whitman; and later he was quite literally worshipped in Germany in the late 19th century and after World War I. There is, of course, a kind of oriental mysticism in Whitman's poetry which several Indian scholars and poets, including Sir Rabindranath Tagore, have recognized. But he is still better known abroad as "the poet of democracy" than simply as a poet, though appreciation of his poetry has grown with the improvement in translations. The complete *Leaves of Grass* (1892) was translated into French, German, Italian, Spanish and Japanese, and selected poems appeared in nearly every civilized language. In the U.S.S.R. many editions exist of Whitman's selected poems and prose. His influence on other poets was slight, but he is admired in many countries. However, he is more of a "musicians' poet" than a "poets' poet." Many of his poems were set to music (*e.g.*, by Frederick Delius, Vaughan Williams, Gustav Holst, Percy Grainger, Howard Hanson, Roy Harris and others) and several symphonic compositions were based on his work. perhaps the most famous being Paul Hindemith's "When Lilacs Last in the Dooryard Bloom'd." Twentieth-century scholars and critics find Whitman's social thought less important than his artistry. T. S. Eliot says, "When Whitman speaks of the lilacs or the mockingbird his theories and beliefs drop away like a needless pretext" (in a review of Emory Halloway's *Whitman,* in *The Nation & Athenaeum,* xl, p. 426 [Dec. 1926]; copyright *New Statesman).*

Bibliography.--There is no standard bibliography but checklists may be found in *Canzbridge History of American Literature, 4* vol. (1917–21), supplemented by G. W. Allen, *Twenty-Five Years of Walt Whitman Bibliography, 1918–1924* (1943) and E. A. and G. W. Allen, "Walt Whitman Bibliography: 1944–1954," in *Walt Whitman Foundation Bulletin* (April 1955); also *Walt Whitman: a Catalog Based Upon the Collections of The Library of Congress,* comp. by Arthur Burton *et al.,* with introduction by Charles Feinberg (1955). Selected and annotated bibliographies: G. W. Allen, *Walt Whitman Handbook* (1946); Roger Asselineau, *L'Évolution de Walt Whitman* (1954).

The "authorized" text of *Leaves of Grass* appeared in 1892, but posthumous poems were added in 189;; *Complete Prose Works* (1892) contains all the prose the poet wished to preserve. *The Complete Writings of Walt Whitman* (1902) is far from complete, but is the fullest edition available.

E. H. Eby, *A Concordance of Walt Whitman's Leaves of Grass and Selected Prose Works,* 5 pts. (1949–54). Emory Holloway has edited much of the poet's journalistic prose.

The fullest biographies are: G. W. Allen, *The Solitary Singer: a Critical Biography of Walt Whitman* (1955); Roger Asselineau, *L'Evolution de Walt Whitman* (1954); briefer, H. S. Canby, *Walt Whitman, an Anzerican* (1943).

The notable critical studies are: G W. Allen (ed.), *Walt Whitman Abroad* (195j), foreign criticism in translation; Milton Hindus (ed.), *Leaves of Grass One Hundred Years After* (1955); James E. Miller, Jr., *A Critical Guide to Leaves of Grass* (1957); Frederik Schyberg, *Walt Whitman* (1933), trans from the Danish by E A Allen (1951); Louis Untermeyer's edition of *The Poetrv and Prose ofWalt Whitman* (1949) contains an anthology of criticism. (G. W. A.)

WHITNEY, ELI (1765–1825), U.S. inventor of the cotton gin, was born on a farm in Westboro. Mass., on Dec. 8. 1765. He exhibited unusual mechanical ability at an early age. After attending Yale college, where he graduated in 1792. he went to Savannah, Ga., where through the friendship of Mrs. Nathaniel Green, the widow of the revolutionary general. he was introduced to some men who were discussing the desirability of a machine that would separate the short staple upland cotton from its seeds. In a few weeks Whitney produced a model consisting of a wooden cylinder encircled by rows of slender spikes, set half an inch apart, which extended between the bars of a grid set so closely together that the seeds could not pass although the lint was pulled through by the revolving spikes; a revolving brush cleaned the spikes and the seeds fell into another compartment. The machine was worked by hand and could clean 50 lb. of lint a day. A patent was granted on March 14, 1794.

Meanwhile Whitney had formed a partnership with Phineas Miller, and they built at New Haven, Conn., a factory for the manufacture of the gins. They were unable to supply the demand for gins, and country blacksmiths constructed many machines. A patent, later annulled, was granted May 12, 1796, to Hogden Holmes for a gin that substituted circular saws for the spikes. Whitney spent much time and money prosecuting infringements of his patent and in 1807 its validity was settled. Disgusted with the struggle, Whitney began the manufacture of firearms near New Haven in 1798 and secured profitable government contracts. His introduction of the concept of interchangeable parts and utilization of the principle of division of labour in his musket factory were perhaps his most significant contributions.

See J. Mirsky and Allan Nevins, *The World of Eli Whitney* (1952); Constance Green, *Eli Whitney and the Birth of American Technology* (1956). (W. E. Hd.)

WHITNEY, WILLIAM COLLINS (1841–1904), U.S. financier who served as secretary of the navy under Pres. Grover Cleveland. He was born at Conway, Mass., July 5, 1841. After graduating from Yale in 1863, he studied law at Harvard and began to practise in New York city. He actively allied himself with the anti-Tammany organization which successfully opposed the Tweed ring, and aided in the election of Samuel J. Tilden as governor in 1874. As corporation counsel of New York city (1872–82) he contested some 3,800 suits against the city. inherited from the Tweed regime, and he saved the municipality about $12,000,000. He did much in the way of organization to secure the election of Cleveland in 1884, and under him became secretary of the navy (1885–89). He played an important role in creating a more modern navy, especially in the building of armour-plated ships. After his term of office he reorganized the Manhattan street railways and established the Metropolitan Street Railway company. His work in 1892 overcame the efforts of T. C. Platt and Tammany Hall, through a snap convention to prevent the nomination of Cleveland for a second time. In 1896, disapproving of the free-silver agitation, he refused to support his party's candidate, William J. Bryan (*q.v.*). One of his latest pieces of work was the organization of the New York Electric Light, Heat and Power company. He died in New York city, Feb. 2, 1904.

WHITNEY, WILLIAM DWIGHT (1827–1894), U.S. philologist nhose most notable achievements were in the study of Sanskrit, was born at Northampton, Mass., on Feb. 9. 1827. He graduated at Williams college with highest honours in 1845. Although he was at first interested in natural science. after 1848 he devoted himself with enthusiasm to Sanskrit, at that time a little-explored field. After one brief course at Yale with Edward Elbridge Salisbury, then the only trained orientalist in the United States, Whitney went to Germany (1850) and studied for three years at Berlin and at Tiibingen. In 1854 he was appointed professor of Sanskrit at Yale, and in 1869 professor of comparative philology also. In 1870 he received from the Berlin Academy of Sciences the first Bopp prize for the most important contribution to Sanskrit philology during the preceding three years—his edition of the *Tāittirīya-Prātiçākhya (Journal* of *the American Oriental Society,* vol. ix). He died at New Haven, Conn., on June 7, 1894.

Whitney edited, along with Roth. the *Atharva-Veda-Sanhitā* (1855–56); published, with a translation and notes, the *Atharva-Veda-Prātiçākhya* (1862); made important contributions to the great Petersburg lexicon; issued an index verborum to the published text of the *Atharva-Veda (Journal of the American Oriental Society,* 1881); made a translation of the *Atharva-Veda,* books i–xix, with a critical commentary, which he did not live to publish (edit. by Lanman. 1905); and published a large number of special articles on Sanskrit philology and *Sanskrit Grammar* (1879). Whitney was editor in chief of *The Century Dictionary* (1889–91).

WHITNEY, MOUNT, a California peak 14,495 ft, above sea level, the highest point in conterminous Cnited States It is the culminating summit of the Sierra Nevada, an upturned fault block range extending for more than 400 mi. in east-central California. Viewed from Lone Pine in Owens valley, Mount Whitney rises precipitously almost 11,000 ft. above the valley floor and forms one of the most spectacular mountain views in the world. The summit of Mount Whitney is a gently sloping tablelike surface that has not yet been dissected by erosion. Large angular blocks of granite that litter the surface make travel exceedingly difficult. No permanent snow fields occur on the summit because the light snowfall is largely blown away and the peak lies near the southern limit of glaciation in the Sierras. The steep sides of Mount Whitney are deeply furrowed by avalanche chutes. The deep canyon of the Kern river borders Mount Whitney on the west while short, precipitous streams tumble down the east slope into Owens valley. Mount Whitney may be approached relatively easily from all but its clifflike southeast face. It was first climbed in 1873 and bears the name of Josiah Dwight Whitney, early chief of the California state geological survey. (C. M. Z.)

WHITSTABLE, a seaside resort and urban district in Kent, Eng., in the Canterbury parliamentary division, 7 mi. N.N.W. of Canterbury by road. Pop. (1951) 17,459. Area 11.9 sq.mi. The district includes Whitstable, Tankerton, Swalecliffe and Chestfield. Whitstable has been famous for its oysters since Roman times; Roman coins and potsherds have been found there. Later the town was a port for pilgrims to Canterbury. All Saints' church, the tower of the so-called castle and the Barn house are mainly 15th century. At the time of Domesday Book, Odo of Bayeux held Swalecliffe and also Chestfield manor. The first passenger railway in southern England was opened in May 1830 between Canterbury and Whitstable.

WHITSUNDAY (Pentecost), one of the three major festivals of the Christian church, celebrated on the Sunday that marks the 50th day after Easter, to commemorate the descent of the Holy Spirit on the disciples at the Jewish Pentecost (*q.v.*) following Jesus' passion. resurrection and ascension (Acts ii). The Jewish feast was primarily a thanksgiving for the first fruits of wheat harvest, but the rabbis associated it with remembrance of the giving of the Law at Sinai. The church's transformation of the feast was thus related to belief that the gift of the Spirit was the first fruits of a new dispensation that fulfilled and succeeded the old one of the Law.

Until the 4th century, Christians usually referred the term Pentecost to the whole 50-day period following Easter, and observed the season with undifferentiated commemoration of all the Lord's redeeming acts. Baptism was administered at a vigil service at both the beginning and end of the season. But in northern Europe Pentecost became a more favoured time for baptism than Easter, doubtless because of its milder weather—hence the popular name "White-Sunday," from the special white garments worn by initiates for a week after their baptism.

Bibliography.—W. Smith and S. Cheetham, "Pentecost," *A Dictionary of Christian Antiquities* (1880); K. Kellner, *Heortology* (1908); A. A. McArthur, *The Evolution of the Christian Year* (1953). (M. H. Sh.)

WHITTIER, JOHN GREENLEAF (1807–1892), U.S. poet and abolitionist, is best know-n as the author of *Snow-Bound,* an idyll of farm life in the rigours of a New England winter. Born Dec. 17, 1807, the son of Quaker parents who farmed the family homestead near Haverhill, Mass., he first attended district schools. As a boy he became familiar with nature and with books: the Bible, works on Quaker history and doctrine, travel and biography. His ambition to become a poet was aroused at the age of 15 when his first teacher, Joshua Coffin, lent him a copy of Burns's poems. Whittier's first poem was published June 8, 1826, in the *Newburyport Free Press,* where his sister Mary had sent it unbeknown to him. The editor. William Lloyd Garrison (*q.v.*), published other poems of his and visited him, thus beginning a friendship that led Whittier into the abolitionist movement. His poems appeared in 1827 in the *Haverhill Gazette* (later the *Essex Gazette),* and in that year he entered a newly established school, the Haverhill academy, for nhich he wrote a dedication poem. In 1828 Whittier extended his small audience by publishing poems in the *Boston Statesman.*

In 1829, through Garrison, he became editor of the *American Manufacturer* in Boston, thus beginning an editorial career that continued intermittently for 30 years. There for eight months, as he was to do in later editorial positions, he published his own poems and wrote editorials on literature and on politics, promoting the cause of Henry Clay. Because he was needed at home, he returned to Haverhill, but soon became editor of the *Essex Gazette.*

At the death of his father in June 1830, he again ran the farm, but soon became editor of the *New England Weekly Review* in Hartford, Conn., where he remained until 1832, except for a brief period spent in New York city, helping gather material for George D. Prentice's biography of Clay. As editor of the *Review* he published many of his own sketches, short stories, essays and poems; politically he sought to aid Clay by fomenting anti-Jackson sentiment. His first book, *Legends of New England,* a collection of short stories and poems, appeared in 1831. In the autumn of that year illness forced him to retire to the farm; overexertion at 17 had made him prone to illness all his life.

Whittier never married. The signs of an unhappy love affair had begun to appear in the *Review* with the publication of poems dealing with rejection of a suitor by a girl who had trifled with his affections. These poems reflected Whittier's ill-starred romance with a former classmate at Haverhill academy, Mary Emerson Smith, who Whittier believed had spurned him because she was socially above him. The theme of the possibility of marital happiness despite social barriers often figured in Whittier's poems.

In 1832 he entered politics actively, keeping the Whig candidacy of Caleb Cushing for congress alive during a party deadlock until Whittier himself reached the age required for candidacy. 25; he lost the election. At the behest of Garrison he published a pamphlet, *Justice and Expediency,* in June 1833. It cost him nomination for election to the state senate in the autumn. Whittier was a delegate to the first American Anti-Slavery convention in Philadelphia in Dec. 1833 and was thereafter engaged in propaganda work for the cause of abolition. Two early antislavery poems, "The Hunters of Men" and "Expostulation," were widely read. He persuaded Cushing, who ran successfully for congress in 1834, to support the abolitionist position, though Cushing was not an abolitionist; Cushing credited Whittier's help in his victory. In the same year, Whittier ran successfully for the state senate. He was too ill to serve after his second election.

From May to Dec. 1836 he edited the *Essex Gazette.* In July, having sold the farm, he moved to a new home in Amesbury. His work for abolition aroused his interest in free speech, and he wrote many poems and editorials on the subject. He traveled to Philadelphia, Harrisburg, Boston and New York for the abolitionist movement. In New York city in the spring of 1837, he was for six months one of the corresponding secretaries of the American Anti-Slavery society. A collection of his abolition poems was published in 1837 without his authorization by some of his friends. He served as editor of the *Pennsylvania Freeman* in Philadelphia from March 15, 1838, to Feb. 20, 1840. On May 17, 1838, Pennsylvania hall, the new building where the abolitionists had been meeting and to which the offices of the *Freeman* had been moved, was burned to the ground by a mob. In 1838 another volume, *Poems,* appeared, containing both abolitionist poems and those on other subjects.

In March 1840 Whittier returned to Amesbury in poor health and low in funds. With the split of the American Anti-Slavery society in May 1840, Whittier broke with Garrison and joined the offshoot organization, the American and Foreign Anti-Slavery society. Whittier at first gave only passive adherence to the newly formed Liberty party (*q.v.*), but supported its presidential candidate, James G. Birney, in 1840. A friendship with Lucy Hooper that had begun in 1837 ended with her death in 1841; only after her death did he realize the depths of her feeling for him. In 1841–42 he worked for the new antislavery society, editing their publications. He ran unsuccessfully for congress in 1842 on the Liberty party ticket. His poem, "Massachusetts to Virginia," against the arrest of fugitive slaves, attracted much attention in 1843. He published many other poems in 1843 and a new volume, *Lays of My Home,* his most successful book to that time, containing such notable poems as "Memories," "Lucy Hooper" and "Lines Written in the Book of a Friend" (later titled "Ego").

His antislavery activities increased in 1844. As editor of the *Middlesex* (Lowell, Mass.) *Standard* from July 1844 to March 1845, he again supported Birney's candidacy for president and opposed the annexation of Texas. He republished some of his *Standard* essays in 1845 under the title, *The Stranger in Lowell.* In 1846 Whittier swung the Liberty party votes behind John P. Hale, candidate for U.S. senator in New Hampshire, who, though not an abolitionist, was the first U.S. senator in sympathy with the antislavery cause. Whittier's antislavery poems were collected and published as *Voices of Freedom* (1846).

More and more, however, Whittier was turning to pure literature, though from 1847 to 1859 he was a contributing editor to the *National Era,* an abolitionist magazine. In 1849 the first collected edition of his poems appeared, as well as his only long piece of fiction, *Leaves from Margaret Smith's Journal of the Massachusetts Bay Colony.* Daniel Webster's "Seventh of March" speech in 1850, supporting compromise on slavery issues, inspired Whittier's stinging rebuke in the poem "Ichabod." During 1850–51 he worked hard for the nomination and election of Charles Sumner (*q.v.*) to the U.S. senate from Massachusetts. Whittier early saw the need of a new party to support the abolitionist position, and he was active in founding and promoting the Republican party.

Volumes of prose and poetry poured from his pen: *Old Portraits and Modern Sketches* (1850), *Literary Recreations and Miscellanies* (1854), *Songs of Labor* (1850), *The Chapel of the Hermits* (1853) and *The Panorama* (1856), the last containing two of his most popular poems, "The Barefoot Boy" and "Maud Muller."

In 18j6 he wrote poems for the campaign of the Republican presidential candidate, John C. Frémont, but after this year, his political and antislavery activities dwindled. As his editorial work waned, he contributed more to the *Atlantic Monthly* (founded 1857) and the *Independent* (founded 1848). A two-volume authorized edition of his poems appeared in 1857. His next. *Home Ballads and Poems* (1860), contained some of his finest work: "Telling the Bees," "My Playmate" and "Skipper Ireson's Ride."

In 1859 Whittier's last romance ended. Elizabeth Lloyd, whom he had met in Philadelphia in the '30s and whom he contemplated marrying after she was widowed in 1856, attacked some of his, and her! Quaker tenets, and he reproved her. From then on his friendships with women were purely Platonic so far as he was concerned, though he attracted the attention of many women poets and writers.

The outbreak of the Civil War placed Whittier in a dilemma: he had been a member of the electoral college that elected Lincoln, but he opposed coercing the southern states. He approved of the war but as a Quaker he was still a pacifist in principle. His early war poem, "Ein feste Burg ist unser Gott," became known as the "prohibited song" when the Hutchinson singers were ordered to stop singing it to the soldiers (President Lincoln countermanded the order). Whittier's best-known war poem, "Barbara Frietchie," was among those collected in his *In War Time* (1864). When the 13th amendment, abolishing slavery, was passed by congress in 1865, he commemorated the event with "Laus Deo."

Whittier's greatest literary triumph came in 1866 with the publication of *Snow-Bound.* The picture of winter farm life, the account of the old house, and the portraits of the members of his family and others won the hearts of U.S. readers. Though the poem depicts a life now partly outmoded, it still is of perennial interest. Rhittier became increasingly popular and was even financially successful. His prose works appeared in a collected edition in 1866, and *The Tent on the Beach* (1867) included his best-known religious poem, "Eternal Goodness."

His fame became transformed from that of a martial prophet who had defied church and state in the cause of freedom to that of the innocuous singer on harmless themes that made him the favourite of women and children. The valiant, aggressive bard became a meek and mild saint. He kept on producing volume after volume of poetry during the '70s and '80s, among them *Miriam* (1871), containing his innocent and beloved poem, "In School Days," and *Hazel-Blossoms* (1875), including some of his sister Elizabeth's poems. He also edited several works, among them *The Journal of John Woolman* (1871).

Although not active in politics, he was consulted by members of the Republican party, whose ticket he voted for the rest of his life, even when candidates were not above criticism. He no longer sided with the liberals; he opposed the railroad strike in 1877, and in his poem, "The Problem," called labour leaders "demagogues." In November 1887 he refused to join in any move ior commutation of the death sentences of the Chicago anarchists convicted for their part in the Haymarket riot.

From 1876 he lived near Danvers, Mass. His 70th birthday celebration is remembered today because Mark Twain made a speech in which he treated the New England writers with irreverence.

Whittier died on Sept. 7, 1892, at Hampton Falls. N.H., after suffering a paralytic stroke, and mas buried at Amesbury.

In a complete edition of his poetry and prose (1888–89), he classified the poems according to subject matter. In abandoning the chronological arrangement of the earlier editions, he concealed the traces of his poetical development. His final volume was *At Sundown,* privately printed in 1890 and published in 1892.

As an abolitionist, Whittier held most to his Quaker principles, but he operated well politically within them (Garrison refused to admit political action as the means to abolition).

Ranked among the favourite U.S. poets of the 19th century. Whittier mas at various periods recommended for different aspects of his work. He was adversely criticized by many for the limited resources of his art, for his uniformity of metre and for lack of imaginative vision. Such criticism he accepted gracefully and even agreed n-ith it. He was most popular in the years immediately after the Civil War and after his death. His reputation declined in the 20th century, though there were signs of its revival.

As a poet he was versatile in choice of theme, however limited the variety of his treatment. He was probably the supreme U.S. ballad writer. His poetry is that of the reiormer, the radical, the Quaker, the preacher, the farmer, the moralist, the lover, the elegist, the nature lover, the prophet, the patriot, the democrat, the hymnist, the social philosopher. He deserves still to be regarded as he n-anted to be: his "Proem" (1837), prefised to all collected editions of his works, shows him as intense a hater of tyranny and as deep and strong a lover of freedom as Milton and Marvell. "The Tent on the Beach" shows that he sought also to be considered an artistic poet, for he says that though he

> Had left the Muses' haunts to turn
> The crank of an opinion-mill. . . .
> He heard the fitful music still
> Of winds that out of dream-land blew.

He was really both a dire prophet and a gentle poet. If he suffered, and he did. from provincialism and puritanism, his love of justice and admiration of heroism permeates many poems. He was not so much loved as Longfellow, but he stands with the very man he disliked, Walt Whitman, as one of the leading advocates of U.S. democracy.

Pollard, *John Greenleaf Whittier, Friend of Man* (1949). (A. Ml.)

WHITTIER, a city 13 mi. E. of Los Angeles, in southern California. U.S.. nithin Los Angeles county and the standard metropolitan statistical area. is on the slopes of the Puente hills. Founded in 1887 by Acquilla H. Pickering. Jonathan Bailey. John Painter and other members of the Society of Friends, and incorporated in 1898, Whittier was settled by Quakers principally from Iowa, Illinois and Indiana. Their plans for a Quaker community included a promotional campaign to attract fellow religionists from all parts of the U.S. as well as anybody else who wished to live in a Christian town. Real estate sold rapidly in the 1880s when railroads brought carloads of Quakers westward.

Until World War II Whittier was a small town surrounded by orange groves. walnut orchards and dairies and tied to Los Angeles by an internrhnn rail line and several highways. After 1945 residential and industrial developments (including the manufacture of oil tools. alloy steel products. auto radiators. gas and oil burners. chemicals, plastics, aircraft parts and cutlery) entirely crowded out the farms and made Whittier the centre of a vast resident community of nearly 200.000 persons by 1960, many of whom commute daily to Los Angeles. The incorporated area of Whittier retains many characteristics of a small town and depends heavily upon the larger population surrounding it for the support of its schools. churches, recreational facilities, intellectual life and light industry. Whittier adopted a council-manager form of government in 1949.

Whittier college, founded in 1891 as the Whittier academy and incorporated in 1901 as a college, was established as a nondenominational institution by its Quaker fathers. With about 1,400 students and 100 faculty members, the college offers instruction in the liberal arts, with specialization in teacher training and work for professional degrees. Richard M Nixon graduated from the college in 1934. Rose Hills Memorial park, one of the largest cemeteries in the U S., bounds the northwest part of the city Whittier was named in honour of the New England poet John Greenleaf Whittier.

For comparative population figures see table in California: *Population.* (J. A. Sz.)

WHITTINGTON, RICHARD (d 1423), mayor of London, described himself as son of William and Joan (Dugdale. *Monasticon Anglicanum,* vi, 740) This enables him to be identified as the third son of Sir William Whittington of Pauntley in Glouce~tershireph o married after 1355 Joan. daughter of William Mansel and widow of Thomas' Berkeley of Cubberley Richard was a mercer by trade, and entered on his commercial career under favourable circumstances. He married Alice, daughter of Sir Ivo Fitzwaryn, a Dorset knight of considerable property; his wife predeceased him. Whittington sat in the common council as a representative of Coleman street ward, was elected alderman of Broad street in March 1393, and served as sheriff in 1393–94. When Adam Bamme, the mayor, died in June 1397, Whittington was appointed by the king to succeed him, and in October was elected mayor for 1398. He had acquired great wealth and much commercial importance, and was ma>-or of the staple at London and Calais. He made frequent large loans to both Henry IV and Henry V, and, according to the legend, when he gave a banquet to the latter king and his queen in 1421, completed the entertainment by burning bonds ior f60.000, which he had taken up and discharged. Henry V employed him to superintend the expenses for completing Westminster abbey; But Whittington took no great part in public affairs. He was mayor again in 1406–07, and in 1419–20. He died in March 1423, bequeathing his vast fortune to charitable and public purposes. He joined in procuring Leadenhall for the city, and bore nearly all the cost of building the Greyfriars library. In his last year as mayor he had been shocked by the foul state of Newgate prison, and one oi the first works undertaken by his executors was its rebuilding. His esecutors, chief of whom was John Carpenter, the famous town clerk, also contributed to the cost of glazing and paving the new Guildhall, and paid half the expense of building the library there; they repaired St. Bartholomew's hospital, and provided bosses for water at Billingsgate and Cripplegate. But the chief of Whittington's foundations mas his college at St. Michael, Paternoster church, and the adjoining hospital. The college was dissolved at the Reformation, but the hospital or almshouses are still maintained by the Mercers' Company at Highgate. Stow relates that his tomb in St. Michael's church was spoiled during the reign of Edward VI, hut that under Mary the parishioners were compelled to restore it (*Survey,* i, 243). There is no proof that he mas ever knighted. 4 writer of the next generation bears witness to his commercial success in *A Libell of English Policy* by styling him "the sunne of marchaundy, that lodestarre and chief-chosen flower."

> Pen and paper may not me suffice
> Him to describe, so high he was of price.

Popular legend makes Dick Whittington a poor orphan employ-ed as a scullion by the rich merchant, Sir Hugh Fitzwarren, who ventures the cat, his only possession, on one of his master's ships. Distressed by ill-treatment he runs away, but turns back when he hears from Holloway the prophetic peal of Bow bells. He returns to find that his venture has brought him a fortune, marries his master's daughter, and succeeds to his business. The legend is not referred to by Stow, who would assuredly have noticed it ii it had been well established when he wrote. The first reference to the story comes with the licensing in 1605 oi a play. now lost. *The History of Richard Whittington, of His Lowe Byrth, His Great Fortune.* "The legend of Whittington," probahly meaning the play of 1605, is mentioned by Beaumont and Fletcher in 1611 in *The Knight of the Burning Pestle.* When a little later Robert Elstracke, the engraver, published a supposed portrait of Whittington with his hand resting on a skull, he had in deference to the public fancy to substitute a cat; copies in the first state arc very rare. Thomas Keightley traced the cat story in Persian, Danish and Italian folklore as far back as the 13th century.

Bibliography.—Important early references are in R. R. Sharpe's *Calendar of Letter-book H.* (1907); H. T. Riley's *Memorials of London* (1868); and *Political Songs,* ii, 178 (Rolls series). For his charities *see* Stow's *Survey of London* (ed. C. L. Kingsford, 1908). For documents relating to Whittington College *see* Dugdale, *Monasticon Anglicanum* (1693; 1846), vi, 740 and the *Calendar of Patent Rolls, Henry 1'1* (1900); ii, 214–217. Samuel Lysons collected the facts but accepted the legend in *The Model Merchant of the Middle Ages* (1860). The *Life* (new ed. 1894) by W. Besant and J. Rice does not

improve on Lysons. There arc useful references in J. H. Wylie's *History of England under Henry IV*, 4 vol. (1884–98). For the legend *see* T Kcightley's *Tales and Popular Fictions*, pp. 241–286 (1834), and H. B Wheatley's preface to his edition of *The History of Sir Richard Whittington* (first published 16j6). (C. L. K.)

WHITTLE, SIR FRANK, (1907–) British inventor and aviator who produced the first British jet propulsive unit. *(See* also JET PROPULSION.) He was born at Coventry, Warwickshire, on June 1, 1907. After attending Leamington college he entered the Royal Air Force as a boy apprentice. He was selected for training for a commission at the R.A.F. college, Cranwell, and, on qualifying as a pilot, was posted to no. 111 (fighter) squadron in 1928. Whittle was trained as a flying instructor and from 1931 to 1932 served as a test pilot at the Marine Aircraft Experimental establishment, Felixstowe. Thence he passed successively through the R.A F. engineering school and Cambridge university. He was then attached to Power Jets, Ltd., to carry out development work on gas turbines for jet propulsion of aircraft. The jet engine of his invention was fitted to the specially built Gloster E28/39 air frame and Whittle carried out the first flights in May 1941. Before the end of World War II, squadrons of jet-engined aircraft had been formed He continued to play an important part in the development of jet propulsion. He became technical adviser to the ministry of supply in 1946 and retired from the R.A.F. in 1948 with the rank of air commodore. In the same year he received knighthood of the Order of the British Empire.

See Sir Frank Whittle, *Jet: The Story of a Pioneer (1953).* (D. CR.)

WHITWORTH, SIR JOSEPH, BART. (1803–1887), British mechanical engineer, was born at Stockport on Dec. 21, 1803. On leaving school at 14 he was sent to learn the business of cotton spinning at an uncle's mill. Possibly as a result of his experience with the rudimentary mill machinery he resolved to become a skilled craftsman, and moved to Manchester in 1821 to work as a mechanic with various machine manufacturers. In 1825 he became a mechanic in Maudslap's works in London and followed this with similar posts before returning to Manchester in 1833 to start his own business as a toolmaker.

During his time as a craftsman he not only recognized the importance of exact measurement and accurate workmanship, he devised methods for improving them far beyond the standards of the time, and the development of these ideas in his own business soon made his machine tools world famous. His recognition of the virtues of standardization and reproducibility in the manufacture of machine parts, and the accuracy upon which they depend, gave rise to his greatest contributions to workshop technique.

His works in Manchester, from a modest start, grew rapidly and at the 1851 exhibition his machine tools. including screw-cutting lathes, planing, drilling, slotting and shaping machines and his millionth-part measuring machine were highly commended. At the age of 48 he was recognized as the leading machine toolmaker of the world. In 1866 his factory employed 700 men and was equipped with about 600 machine tools, all of which had been made in the works.

In 1840, at the British association meeting in Glasgow, he described his method, developed while he was at Maudslay's, of making a true plane by the scraping and matching of three plates instead of the unsatisfactory grinding operation current at the time. At the Institution of Civil Engineers in 1841 he introduced his ideas for standard screw threads to make order out of the chaos of heterogeneous shapes and pitches then in existence. Woolwich arsenal adopted his standard in the same year. In his presidential address to the Institution of Mechanical Engineers in 1856 he put forward his views on the economy in time and money resulting from standardization of designs and sizes of engine parts; he stressed the importance of interchangeability which had become practicable as a result of his development of standard gauges and measuring machines.

In 1855 he was asked to advise the government on the re-equipment of the Enfield Royal Small Arms factory. After many experiments he designed a rifle which was proved the most accurate of the time at the trials. However, the bore of 0.45 in. was considered too small and was not adopted until 1869. His interest was then turned to heavy ordnance and to the use of pressure casting of the steel for it. His success in this field enhanced his world-wide reputation.

He was equally concerned with the quality of his craftsmen. In his later years he gave much of his time and considerable fortune to furthering engineering education and to bringing it within reach of the artisan. He contributed to the foundation of the chair of engineering and laboratories at Owen's college, Manchester. In 1868 he founded the Whitworth scholarships, setting aside an annual sum of £3,000 for the purpose. and in the following year he was created a baronet. He died at Monte Carlo on Jan. 22, 1887. In addition to giving £100,000 for the permanent endowment of 30 Whitworth scholarships, his residuary legatees, in pursuance of what they knew to be his intentions, expended more than £500,000 on charitable and educational objects, mainly in Manchester and the neighbourhood. (J. DD.)

WHOOPING COUGH (PERTUSSIS) is an acute, highly communicable respiratory disease characterized in its typical form by paroxysms of coughing, followed by a long-drawn inspiration or "whoop" and ending with expulsion of clear sticky mucus, and often vomiting. The disease was first adequately described by G. de Baillou in 1578 as it then occurred in Paris; undoubtedly it had existed for a long time before that. About 100 years later the name pertussis mas introduced by Sydenham in England; other English names besides whooping cough have included chincough, hooping cough and slime cough.

In 1906 at the Pasteur institute, Jules Bordet and O. Gengou isolated the bacteria that cause the disease. At first they were called Bordet-Gengou bacilli; later, *Haemophilus pertussis;* and more recently, *Bordetella pertussis.* The small coccobacilli may be grown on a suitable culture medium inoculated either by a spasmodic cough or by a nasopharyngeal swab. These causative bacteria are found in practically all patients during the first two weeks after onset, the most infectious period. By the end of the fourth week, cultures are usually negative.

Nature of the **Disease.**—The course of whooping cough is variable, but in the usual attack several stages are recognized. Following an incubation period of approximately one week, catarrhal symptoms develop; they resemble an ordinary upper respiratory infection, with a short dry cough that is worse at night. This catarrhal stage, after one to two weeks, passes into the distinctive paroxysmal stage, which is variable in duration but commonly lasts four to six weeks. Serious complications include bronchopneumonia, usually due to secondary infection with such organisms as pneumococci, streptococci, staphylococci or influenza bacilli; persistent vomiting; suffocative attacks; and occasionally convulsions and indications of brain damage.

Second attacks. usually mild, sometimes occur, particularly in adults who may then unwittingly infect infants. Attacks of whooping cough caused by related bacteria. *Bordetella para-pertussis,* are usually milder than those caused by B. *pertussis.* Occasionally the disease is caused by B. *bronchiseptica*, an organism found sometimes in animals (*e.g.*, the rabbit).

Importance of Whooping Cough. — This disease is world-wide in its distribution and among the most important of the acute infections of children. In spite of a declining death rate, it causes more deaths every year than diphtheria, measles and scarlet fever put together. Approximately 90% of the deaths that occur are in children under age five and more than 60% of them in infants under one year of age. The severity of the disease in terms of damage to health, growth and resistance of young children is not generally realized. Also, no other infectious disease causes so many lost days of school.

The World Health organization recognized the importance of whooping cough in 1952 in its meeting of experts on diphtheria and whooping cough immunization. Continuing committees are concerned with establishment of reference materials and standards for improvement of protective vaccines throughout the world.

Specific Immunization and Treatment. — Attempts to ansner the apparently opposed results of different efforts to prevent whooping cough by vaccination stimulated the organization of carefully controlled field trials. The incidence of whooping cough in a vaccinated group during a particular period of observation was compared with the incidence in a control group as nearly like the test group as possible except for the lack of vaccine. Such methods demonstrated the protective action of certain preparations of whooping cough vaccine. Also, the study pattern suggested by these trials extended beyond the field of mhooping cough; the methods were refined and expanded in investigations of the usefulness of other preventive agents.

Treatment of whooping cough has been made more effective by the use of certain antibiotics, both by modifying the severity of the primary infection and by controlling the secondary invaders.

See W. W. C. Topley and G. S. Wilson, *Principles of Bacteriology and Immunity,* 4th ed. by G. S. Wilson and A. A. Miles (1955). (P. L. Kk.)

WHORF, BENJAMIN LEE (1897–1941), U.S. chemical engineer by profession, linguistic theoretician by avocation, Whorf gave to linguistics a brilliant and penetrating insight that led to new and original research. Born April 24, 1897, in Winthrop, Mass., he received his engineering training at Massachusetts Institute of Technology (B.S., 1918), and worked all his life for an insurance company. Following some ideas first clearly stated by Edward Sapir, he formulated what came to be known as the Sapir-Whorf hypothesis: that every language is a systematic presentation or analysis of reality as seen by its speakers, that this reality differs from every other such system, that human beings necessarily see reality only through their particular linguistic system and that the linguistic system and the reality the system represents mutually affect and interpenetrate each other. For example: in English the verb *pour* applies both to liquids and to particles, as of sand; in Russian, for liquids one uses one verb (lit') and for particles another. Not only vocabulary, but also the grammatical structure is involved: English always classifies nouns as one or more than one *(boy: boys),* but in Japanese the plurality of reference is pointed out by some other element in the sentence ("as for boy, there was a multiplicity"). In addition to his language-and-culture studies, Whorf contributed to the better understanding of the classification of American Indian languages and first determined the real nature of the Mayan hieroglyphs as a true system of writing. J. B. Carroll edited a selection of his writings, *Language, Thought and Reality* (1956).

He died at Wethersfield, Conn., July 26, 1941. (G. L. T.)

WHYMPER, EDWARD (1840–1911), British explorer, mountaineer and artist, the first man to climb the Matterhorn, was born in London on April 27, 1840. He was trained as a wood engraver and in 1860 he visited the western Alps to make a series of sketches. In 1861 he climbed Mont Pelvoux in this district, then believed to be the highest mountain of the Dauphiné. He discovered that the Pointe des Ecrins was higher and in 1864 made the ascent of that peak.

Whymper's name is chiefly associated with the Matterhorn (14,688 ft.) in the Valais. Between 1861 and 1865 he attempted this formidable peak six times, up the southwest or Italian ridge. It was by accident that he saw the Swiss ridge from the side and noted that it was not so steep as it appeared. He saw also that the strata dipped conveniently for climbing.

At the seventh attempt, on July 14, 1865, Whymper made the ascent by the Swiss ridge, while the Italian guide, J. A. Carrel, was attempting the Italian ridge. On the descent one member of the party slipped and pulled off-three more. The rope broke, thus saving Whymper and two guides. This is perhaps the best-known of all mountaineering accidents and is recorded along with many of his climbs in *Scrambles Amongst the Alps* (1871); illustrated with his own engravings.

In 1867 Whymper visited Greenland with a view to crossing the icecap, but a second expedition, in 1872, convinced him that the undertaking would be too costly. He then visited the Andes, partly to study the effects of mountain sickness. In 1880 he twice ascended Chimborazo (20,702 ft.) and spent a night on the summit of Cotopaxi. *Travels Amongst the Great Andes of the Equator* appeared in 1892. His last journeys, in 1901–05, were among the Canadian Rockies.

Whymper died at Chamonix on Sept. 16, 1911.

See T. G. Bonney in Alp. J. (Feb. 1912); G. Winthrop Young in *Alp. J.* (Nov. 1943); Frank Smythe, *Edward Whymper* (1940). (C. W. F. N.)

WICHITA, a city of south-central Kansas, U.S., on the Arkansas river near the mouth of the Little Arkansas, 200 mi. S.W. of Kansas City; the seat of Sedgwick county. Pop. (1960); city 254.698, an increase of 54.6% in the decade; standard metropolitan statistical area (Sedgwick county) 343,231, an increase of 54.4%. (For comparative population figures for the city see table in KANSAS: *Population.*)

Founded in 1864 as a trading post on the site of a village of the Wichita Indians, for whom the city was named, Wichita owed its early development to the Texas cattle trade along the Chisholm trail and to the rapid spread of agricultural settlement along the Atchison, Topeka and Santa Fe railroad, then under construction. The city was platted in 1870 and incorporated in 1871. In its early years Wichita was a stopover on cattle drives to Abilene and other points as the railroad moved west; in 1872 it reached Wichita and the city became a major cattle shipping centre. In that year 4,000 cars of cattle (80,000 head) were shipped eastward; in 1873 the number increased to 400,000 head. By 1875 settlement by farmers had intensified to such an extent that drovers found it difficult to reach the rail yards (because of fences) and thereafter the shipment of cattle diminished. The loss was more than compensated for by grain, however, and Wichita became a trade and milling centre.

The first commercial airplane made in Kansas was constructed in Wichita in 1920. ,After that, the city became the aircraft manufacturing centre of the state, with plants of several major companies. Also located nearby is McConnell air force base. The city continues to be a large grain and livestock market; the Union stockyards have extensive facilities for cattle, hogs and sheep. Grain milling is also a major activity. In addition, chemicals, pharmaceuticals, garments, precision tools, castings, petroleum products, stoves, millwork and printed materials help make up the diverse products of the city.

Wichita is well served by public and parochial schools and there is an estensive city park system. Higher education is served by the University of Wichita, a municipal institution founded in 1895 as Fairmount college and the oldest municipally supported university west of the Mississippi; and the Friends university, a Quaker institution established in 1898. Wichita has a council-manager form of government, in effect since 1917. (D. P. G.)

WICHITA FALLS, a city of north-central Texas, U.S., 105 mi. N.W. of Fort Worth on the Wichita river 16 mi. S. of the Red river; it is the seat of Wichita county. Named for the Wichita Indians who inhabited the area and a small river falls that existed there in its early days, the city was founded in 1876 and incorporated in 1889. With the arrival of the Fort Worth and Denver City railroad in 1882, Wichita Falls became a cattle centre. Oil was discovered in 1900 and in the same year irrigation projects were begun to aid agriculture in the surrounding area. In 1928 the city adopted a council-manager form of government. Wichita Falls is the centre of extensive oil and gas fields and an especially productive agricultural region, devoted to stock raising, dairying and the cultivation of wheat, cotton, alfalfa, feed grains and fruit in the fertile Wichita valley. Manufacturing industries include oil refineries and oil field machinery factories. Sheppard air force base, an important defense installation, with its unit of the strategic air command, is located at Wichita Falls. Midwestern university, Wichita Falls' municipally operated university, was established in 1922. Pop. (1960) 101,724; standard metropolitan statistical area (Archer and Wichita counties) 129,638. (V. M. S.)

WICK, a royal and small burgh, seaport, and the county town of Caithness. Scot. Pop. (1951) 7,161. It is situated on the Wick river at the head of Wick bay. on the North sea. 17 mi. S. of John O'Groats and 21 mi. S.E. of Thurso by road. The airport is an important link in the services between Orkney and Shetland and southern Scotland and England. Wick is a centre of the herring fisheries and there are hosiery and knitwear industries, a creamery, a distillery and a herring oil factory. The harbour was built by Thomas Telford in 1800. Wick *(Vik* or "bay") is mentioned as early as 1140 and became a roral burgh in 1589.

WICKLOW, a county of Ireland in the province of Leinster, bounded east by St. George's channel, north by the county of Dublin, south by Wexford and west by Carlow and Kildare. The land area is 781.6 sq.mi. Pop. (1956) 60.680. The coast is very dangerous to approach because of sandbanks. The harbour at Wicklow has a considerable trade; but that of Arklow is suitable only for small vessels. The central portion of the county is occupied by a granitic mountain range, running from northeast to southwest, the highest summits being Kippure (2,475 ft.), Mullaghcleevaun (2,788), Thonelagee (2,686), Table mountain (2,302) and Lugnaquillia (3.029). The range rises from the north by a succession of ridges intersected by deep glens, and subsides to ard the borders of Wexford and Carlow. To the north its foothills enter County Dublin. and add attraction to the southern outskirts of Dublin. The water supply of Dublin comes partly from an artificial lake on the first plateau of the foothills at Roundwood.

In the valleys there are many instances of old river terraces, especially at the lower end of Glenmalure and the lower end of Glendalough. Among the more famous of the glens are Glendalough, Dargle. Glencree, Glen of the Downs, Devil's glen, Glenmalure and the beautiful vale of Avoca or Ovoca The principal rivers are the Liffey. on the northwestern border: the Vartry. which passes through Devil's glen to the sea north of Wicklow head; the Avonmore and the Avonbeg, which unite at the "meeting of the waters" to form the Avoca, which is afterward joined by the Aughrim and falls into the sea at Arklow; and the Slaney. in the west of the county, passing southward into Carlow. The principal lakes are Loughs Dan. Bray and Tay or Luggelaw. and the loughs of Glendalough. The trout fishing is generally fair.

Wicklow was not made a county until 1606. It was the last Irish ground shired, for in this mountainous district the Irish were long able to preserve independence. Wicklow sided with the royal cause during the Cromwellian wars, but on Oliver Cromwell's advance submitted to him without striking a blow. During the rebellion of 1798 there were skirmishes at Aughrim and at Arklow and some of the insurgent leaders maintained a guerrilla resistance which gave rise to many popular ballads.

Of the ancient cromlechs there are three of some interest, one near Enniskerry, another on the summit of Lugnaquilla and a third at Donaghmore. The ruins in the vale of Glendalough, known as the "seven churches." including a round tower, owe their origin to St. Kevin, who lived in the vale as a hermit, and is reputed to have died in 618. *See* GLENDALOUGH, YALE OF.

The lower land is fertile; and the higher districts. covered with heath and turf, afford good pasturage for sheep. There is a considerable extent of natural timber as well as artificial plantations. The forestry commission has acquired Shelton abbey. Arklow. formerly the seat of the earl of Wicklow. with extensive woods. to be its main centre for training in forestry. The previous centre was at Avondale. on the slopes further inland. The principal crops of oats and potatoes have decreased. but the numbers of sheep. cattle. pigs and poultry have been maintained. A flourishing modern pottery factory exists at Arklow.

A considerable amount of gold has been extracted from the valley gravels north of Croghan Kinshela on the Wexford border. Tinstone has also been found in small quantities. Lead ore is raised west of Laragh. and the mines in the Xvoca valley have been worked for copper. lead and sulfur. the last named being obtained from pyrite. Paving setts are made from the diorite at Arklow. and granite is extensively quarried at Ballyknockan on the west side of the mountain chain. In 195j a Canadian company received a concession to rework the ancient mines of the vale of Xvoca to obtain copper and iron ores by modern methods.

Because of its proximity to Dublin and its accessibility from England. the portions of the county possessing scenic interest have been opened up to great advantage. Bray in the north is a seaside resort. Inland tourist centres are Enniskerry. west of Bray and near the pass of the Scalp: Laragh, near Glendalough, from which a military road runs southwestward across the hills below Lugnaquilla; and. on the railway south of Wicklow. Rathdrum and Woodenbridge in the Vale of Xvoca and Aughrim. A railway skirts the coast by nay of Bray and the town of Wicklow. touching it again at Arklow, with a branch line from Woodenbridge junction to Shillelagh. Another branch from Sallins (County Kildare) skirts the west of the county by Baltinglass. The administrative county of Wicklow returns three members to *dáil eireann.*

WICKLOW, an old seaport and the county town of County Wicklow. Ire., at the mouth of a lagoon which receives the river Vartry and other streams, 32 mi. S.S.E. of Dublin by road. Pop. (1956) 3,070. The harbour can accommodate vessels of 1,500 tons and has two piers, with quayage. The name shows the town to have been a settlement of the Norsemen.

WICKSELL, (JOHAN GUSTAF) KNUT (1851–1926), Swedish economist, the foremost in his generation and internationally renowned for his pioneering work in monetary theory, nas born at Stockholm on Dec. 20. 1851. In *Geldzins und Güterpreise* (1898; Eng. trans., *Interest and Prices,* 1936) and in *Föreläsningar i Nationalekonomi, del II* (1906). he propounded an explanation of price-level movements by an aggregate demand-supply analysis focused on the relations between prospective profit and interest rates. This anticipated the work of J. M. Keynes in *Treatise on Money* (1930). In *Über Wert, Kapital und Rente* (1893: Eng. trans.! *Value, Capital and Kent,* 1954), Wicksell emerged as an originator of the marginal productivity theory. There and in *Föreläsningar i Nationalekonomi, del I* (1901), he also made striking advances in capital theory. A fundamental principle of public finance, that public enterprises should apply the marginal-cost-pricing rule. was first propounded by Wicksell in *Finanztheoretische Untersuchungen* (1896). He was professor at the University of Lund. 1900–16, and died on May 3, 1926. Because of his abiding allegiance to the Swedish social reform movement, Wicksell's academic career was impeded for many years.

See T. Gardlund, *The Life of Knut Wicksell* (1958); C. G. Uhr, "Knut Wicksell: a Centennial Evaluation," *Amer. Econ. Rev.,* vol. xli (1951).
(C. G. U.)

WIDGEON, an abundant species of duck, *Anas penelope,* breeding in Europe and northern Asia and reaching northern Africa and India in winter. Intermediate in size between the teal and the mallard, the widgeon drake is a handsome bird with cream forehead. chestnut head and neck, penciled gray flanks and green and black speculum (wing bar). Its whistling cry has given it the local name of "whew duck." The widgeon collects in huge flocks on tidal waters in winter and is shot for market in large numbers. When on land it often eats grass. Two allied species occur in America. of which *A. americana,* the baldpate. inhabits northern America, reaching Central America and Trinidad in winter; it differs in that the head is green, with the top of the head white. The other species, A. *sibilatrix,* is South American.

WIDMANN, JOSEPH VICTOR (1842–1911), poet, dramatist, novelist and literary critic! was born at Nennowitz (Moravia) on Feb. 20, 1842, and died at Berne on Nov. 6, 1911. In 1880 he became *feuilleton* editor of the *Berner Bund,* and in this capacity he exercised for 30 years an authoritative sway as critic of German and German-Swiss literature. Among the most important of his own works are *Arnold von Brescia* (1867), a tragedy; *Buddha* (1869), a philosophic epic, which might be described as a forerunner of Nietzsche's *Also Sprach Zarathustra* and Spitteler's *Prometheus und Epimetheus; Mose und Zipora* (1874), an idyll: *Oenone* (1880), a drama; *Die Patrizierin* (1888), a novel of life in Berne; *Die Maikäferkomödie,* "Cockchafer Comedy" (1897), a charming allegorical play, which may possibly have furnished Rostand with the idea of *Chantecleu;* and *Der Heilige und die Tiere* (1905), another dramatic poem in which his interest in the animal world and its right to poetic existence are demonstrated. The last is his profoundest poetical utterance. Widmann was one of the first to champion the genius of Carl Spitteler (*q.v.*), with whom his friendship dated from childhood days at Liestal.

See the *Life by* E. and M. Widmann, 2 vol. (1922–24); the studies by Maria Waser (1927), Jonas Fränkel (1918), W. Scheitler (1925); and the *Briefwechsel Keller-Widmann* (1922).

WIDNES, a municipal borough (1892) in the Widnes parliamentary division of Lancashire, Eng., 14 mi. S.S.E. of Liverpool by road. Pop. (1951) 48,785. Area 9 sq.mi. It is on the north bank of the Mersey at the lowest bridgeable point. A plan was approved in 1954 to replace the famous Runcorn transporter bridge (1905) by an arched bridge. The town is wholly of modern growth, for in 1851 the population was less than 2.000. Well-placed between the Cheshire salt fields and the Lancashire coal fields, Widnes is one of the principal centres of the chemical industry and. besides having general engineering works, makes such varied products as asbestos goods, steel alloys, paper, slippers and clothing; it has a large trade in timber. The name. Wydnes in the early 13th century, meant "wide promontory."

WIDUKIND or WITTEKIND (d. after 785), leader of the Saxons. belonged to a noble Westphalian family. He probably fought the Franks before and during 776. In 778 he returned from exile in Denmark to lead a fresh rising. and in 782 the Saxons at his instigation drove out the Frankish priests and plundered the border territories. His movements in 783–784 are uncertain: but in 785 he was reconciled to Charlemagne at Xttigny and baptized, the king acting as his sponsor and loading him with gifts. The details of his later life are unknown. He probably returned to Saxony. Many legends have gathered round his memory; some would make him a devoted Christian, but it was his grandson. Walbert, n-ho first endowed religious houses on the family estates. Royal houses have sought to establish descent from him. but except in the case of Matilda, wife of the German king Henry I the Fowler, without success.

See W. Diekamp, Widukind der Sachsenfiihrer *nach* Geschichte und Sage (Munster, 1877); J. Dettmer, Der Sachsenfiihrer Widukind nach Geschich'te und Sage (Wiirzburg, 1879); H. Wiedemann, Karl der Grosse, *Widukind und* die *Sachsenbekehrung* (Miinster, 1949).

WIDUKIND, Saxon historian, was the author of Res gestae *Saxonicae*. He was a monk at the Benedictine abbey of Corvey, and he died about 1004. His Res gestae Saxonicae, dedicated to Matilda, abbess of Quedlinburg. who was a daughter of Otto the Great. is divided into three books, and the greater part of it was undoubtedly written during the lifetime of the emperor, probably about 968. Starting with the origin of the Saxons, the history comes down to the death of Otto in 997. Many quotations from the Vulgate are found in his writings, and there are traces of a knowledge of Virgil, Ovid and other Roman poets. The earlier part of his work is taken from tradition, but he wrote on contemporary events as one familiar with court life and the events of the day.

The best edition of the Res gestae is that edited by G. Waitz in the *Monumenta Germaniae historica*. Scriptores, vol. iii (Hanover and Berlin, 1826). A good edition published at Hanover and Leipzig in 1904 contains an introduction by K. A. Kehr.

WIELAND, CHRISTOPH MARTIN (1733–1813), German poet and man of letters, was born at Oherholzheim, a village near Biherach in Württemberg, on Sept. 5, 1733. His father, who was pastor in Oberholzheim. and subsequently in Biberach, took great pains with the child's education, and sent him to the *Gymnasium* at Klosterberge, near Magdeburg. Under the influence of a first love affair. with Sophie Gutermann, he planned his first ambitious work. Die *Natur* der Dinge (1752), a didactic poem in six books. In 1750 he went to Tiibingen to study law, but his time was mainly taken up with literary studies. The poems he wrote at the university—*Hermann,* an epic (published by F. Muncker, 1886), *Zwölf moralische* Briefe in Versen (1752), Anti-Ovid (1752)—are pietistic in tone and dominated by the influence of Klopstock. They attracted the attention of J. J. Bodmer. who invited Wieland to visit him in Ziirich in the summer of 1752. After a few months, however, Bodmer felt himself as little in sympathy with Wieland as, two years earlier, he had felt himself with Klopstock. and the friends parted; but Wieland remained in Switzerland until 1760, residing, in the last year, at Berne where he obtained a position as private tutor. There he stood in intimate relations with Rousseau's friend Julie de Bondeli. Meanwhile a change had come over Wieland's tastes; the writings of his early Swiss years—Der *geprüfte Abraham* (1753), *Sympathien* (1756), *Empfindungen eines* Christen (1757)—were still in the manner of his earlier writings, but with the tragedies, Lady *Johanna* Gray (1758) and Clementina von Porretta (1760)—the latter based on Richardson's Sir Charles *Grandison*—the epic fragment *Cyrus* (1759). and the "moral story in dialogues," *Araspes und* Punthea (1760), Wieland, as Lessing said, "forsook the ethereal spheres to wander again among the sons of men."

Wieland's conversion was completed at Biberach, whither he had returned in 1760, as Kanzleidirektor, or town clerk. He had access to the library of Count Stadion at Warthausen. There he met once more Sophie Gutermann, who had become the wife of the *Hofrat* La Roche, then manager of Count Stadion's estates. The former poet of an austere pietism now became the advocate of a lighthearted philosophy, from which frivolity and sensuality were not excluded. In Don. Sylvio von Rosalva (1764), a romance in imitation of Don *Quixote,* he held up to ridicule his earlier faith, and in the *Komische* Erzahlungen (1765) he gave his extravagant imagination only too free a rein. More important is the novel Gesclzichte des Agathon (1766–1767), in which, under the guise of a Greek fiction. Wieland described his own spiritual and intellectual growth. This work, which Lessing recommended as "a novel of classic taste," is a landmark in the development of the modern psychological novel. Of equal importance was Wieland's translation of 22 of Shakespeare's plays into prose (8 vol., 1762–66); it was the first attempt to present the English poet to the German people in something approaching entirety. With the poems *Musarion* oder die Philosophie der *Grazien* (1768), *Idris* (1768), *Kombabus* (1770), Der *neue Amadis* (1771), Wieland opened the series of light and graceful romances in verse which acted as an antidote to the sentimental excesses of the subsequent *Sturm* und Drung movement.

Wieland married in 1765, and between 1769 and 1772 was professor of philosophy at Erfurt. In the last-mentioned year he published Der goldene *Spiegel* oder die Konige *von* Scheschian, a pedagogic work in the form of oriental stories; this attracted the attention of duchess Anna Amalie of Saxe-Weimar, who appointed him tutor to her two sons, Karl August and Konstantin, at Weimar. With the exception of some years spent at Ossmannstedt. where in later life he bought an estate, Weimar remained Wieland's home until his death on Jan. 20. 1813. There, in 1773, he founded Der *Deutsche Merkur,* which under his editorship (1773–89) became the most influential literary review in Germany. Of the writings of his later years the most important are the admirable satire on German provinciality—the most attractive of all his prose writings—Die Abderiten, *eine* sehr *wahrscheinliche* Gesclzichte (1774), and the charming poetic romances, Das *Wintermärchen* (1776), Das *Sommermärchen* (1777). Geron *der Adelige* (1777), Die *Wünsche* oder Pervonte (1778), a series culminating with Wieland's poetic masterpiece, the romantic epic of Oberon (1780). His later work included novels, translations of Horace, Lucian and Cicero, and the editing of the Attisches Museum (1796–1803). Without creating a school in the strict sense of the term, he influenced considerably the German literature of his time. Modern editions of Wieland's Samtliche Werke are those of H. Diintzer, 4 vol. (1879–82), and the critical edition issued by the Prussian academy (1909, etc.). (J. G. R.)

WIELAND, HEINRICH (1877–1957), German chemist, was awarded the Nobel prize in chemistry in 1927 for research on bile acids and their constitution. He was born at Pforzheim, Baden, June 4, 1877. He was educated at the universities of Berlin, Stuttgart and Munich, at the last of which he received his Ph.D. degree in 1901. He made an exhaustive examination of the reaction between double carbon linkages and the oxides of nitrogen and a study of hydrazines which led to the discovery of free radicals containing divalent and tetravalent nitrogen. Subsequent research proved that free radicals of this type and the ions with the same composition could be distinguished by a characteristic band spectrum for the free radicals. This problem is important to structural organic chemistry. Wieland proposed a mechanism by which halogens and the nitro group are introduced into the benzene nucleus and for the action of nitric acid on the hydrocarbon double bond, thus helping to unify the internal relationship between aliphatic and aromatic organic compounds. His studies of natural substances include morphine alkaloids, a yellow butterfly pigment, the bitter principles of hops and a synthesis of inosite. In addition to the clarification of the structure of the bile acids, Wieland also introduced a dehydrogenation theory of oxidation of importance to physiology, biochemistry and medicine. His revision of Ludwig Gattermann's *Die Praxis des Organischen Chemikers (Laboratory Methods* of *Organic Chemistry,* first published, 1894; 34th ed.. 1952) is a classic. Wieland was professor of chemistry at Munich; and when he retired in 1953 was head of the Chemisches Staatsinstitut, Munich. He died Aug. 5, 1957, in Munich. (V. Bw.)

WIELICZKA, a mining town in Poland, 9 mi. S.E. of Cracow. Pop. (1950) 9,000. It is built over the celebrated salt mines which are the richest in Poland and among the most remarkable in the world. Inside the mines are 16 ponds. The salt of Wieliczka is well known ior its purity and solidity, but has generally a gray or blackish colour. The date of the discovery of the mines is unknown, but they were already worked in the 11th century. The mines suffered from inundations in 1868 and 1879, and the soil on which the town is built shows subsidence.

WIEN, WILHELM (1864–1928), German physicist and Nobel prize winner, whose researches covered almost the whole sphere of physics. was born on Jan. 13, 1864, at Gaffken, East Prussia. He studied at the universities of Gottingen, Heidelberg and Berlin, and in 1890 entered the Physicotechnical institute near Berlin as assistant to Hermann von Helmholtz. In 1896 he was appointed professor at the technical high school, Aix-la-Chapelle; in 1899 he went to Giessen, in 1900 to Würzburg, and in 1920 to Munich. He wrote on optical problems; on radiation, especially black-body radiation, for which in 1911 he was awarded the Nobel prize; on water and air currents, on discharge through rarefied gases, cathode rays, X-rays and positive rays. Wien's most important contributions to black-body radiation are contained in the two laws named after him. From his formula for the energy density associated with a definite wave length at a certain temperature, he obtained what is known as Wien's displacement law: the product of the wave length at which the energy density is a maximum and the absolute temperature is a constant. Wien also developed a formula for the energy distribution of black-body radiation; this was found to hold for short wave lengths only but is important as a link in the chain which led to Planck's formula *(see* also THERMOMETRY). His work on positive rays is of great importance; he showed that these rays underwent electrostatic and magnetic deflection as early as 1898 and continued his researches on this subject. In 1913 he lectured at Columbia university on problems of modern theoretical physics. He died on Xug. 30, 1928.

Wien was the editor of the *Annalen der Physik* from vol. 21 (1906). His chief works are *Lehrbuch der Hydrodynanzik* (1900); *Neuere Probleme der theoretischen Physik* (1913); *Die Relativitätstheorie vom Standpunkte der Physik und Erkenntnislehre* (1921).

WIENER-NEUSTADT, a town in Nieder-Österreich (Lower Austria), from 1938 to 1945 the *Reichsgau* Niederdonau, at the divergence of routes from Vienna to the Semmering pass and to Hungary via the Sopron gate. Founded in 1192, it contains a 12th-century castle built by Duke Leopold V, converted by Maria Theresa in 1752 into a military academy and after 1919 a school for boys; the 13th-century Romanesque Liebfrauen church; and the 15th-century Cistercian abbey with its rich library and museum. Wiener-Neustadt became an industrial town with special interests in locomotives and railway stock, machinery, textiles and leather goods, sugar refining, paper-making and the manufacture of pottery. Trade is facilitated by a canal to the capital, chiefly used for the transport of coal and timber. Pop. (1951) 30,559.

WIESBADEN, the capital since 1945 of the *Land* of Hesse, Ger., and one of the oldest spas in Germany, lies in a valley under the southern spurs of the Taunus range. East and west the town is sheltered by chains of hills but to the south the valley runs into the plain of the Rhine. The old city is built at heights varying between 358 and 556 ft. above sea level; the suburbs Biebrich and Schierstein are situated on the river. Since 1945 Kastel, Amöneburg and Kostheim, suburbs of Mainz on the Wiesbaden rather than the Mainz side, have been administered by the city of Wiesbaden. Pop. (1950) 220,741; (1957 est.) 249,900.

The city is famous for its 27 hot springs, among them Kochbrunnen, Adlerquelle and Faulbrunnen. In addition to the Wilhelmstrasse, Langgasse and Kirchgasse are the main shopping streets, and there are many promenades and large parks. Although the city suffered destruction during World War II, some of the older buildings survived: the old town hall (1610), the new town hall (1887), the Kaiser Friedrich baths (1913), the Griechische Kapelle or Greek chapel (1855) and the castle nhich now houses the *Landtag* (administrative offices) of the *Land* Hesse. The state theatre opened as an opera house and playhouse in 1894. The municipal museum houses a picture gallery. The main railway line up the Rhine valley passes through Wiesbaden, and an overland coach service links the town with cities in France. Belgium and the Netherlands. Boats go to Cologne, Mainz and Frankfurt-on-Main.

Its varied industries include iron foundries, metal and concrete works, chemicals, textiles, printing and plastics. A noted wine centre. it is famous for its *Sekt* (German champagne).

History. — The first Roman earth fortifications, erected in 12 B.C., were superseded by stone fortifications in A.D. 83, and the Roman settlement with its important springs was known as Aquae Mattiacorum. The Roman wall Heidenmauer was built about 370. The place was the site of a Franconian palace and of St. Mauritius church, built between 750 and 775. The name Wisibada (meadow spring) appears in 829. In the mid-13th century Wiesbaden became an imperial city, passing toward the end of the century to the counts of Nassau; in 1744 it became the seat of government of the principality Nassau-Usingen; from 1806–66 it was the capital of the duchy of Nassau. when it passed nith that duchy to Prussia. The city then became capital of the Prussian district of Wiesbaden of the province Hesse-Kassau. After World War II it became the capital of the newly created *Land* of Hesse. (H. M.-WH.)

WIESER, FRIEDRICH VON (1851–1926), Austrian economist and sociologist, one of the leaders of the so-called Austrian school, which developed the marginal utility theory of economic value into a full explanation of price phenomena, was born at Vienna on July 10, 1851. He was professor at the universities of Prague and Vienna, and from 1917 to 1918 minister of commerce of Austria. Wieser realized earlier and more clearly than other marginalists (except Léon Walras) that he was formulating the laws of value not only of capitalism but of any rational economy; in this respect he anticipated ideas that came to full fruition only in the 1930s. His tendency to combine a sociological with an economic approach was a useful counterweight to the exclusive devotion to abstract economic reasoning on the part of other marginalists. Wieser's writings include *Der natürliche Wert* (1889); *Theorie der gesellschaftlichen Wirtschaft* (1914; Eng. trans., *Social Economics,* by A. Ford Hinrichs, 1927); and *Das Gesetz der Macht* (1926). He died on July 23, 1926. (C. L.)

WIG, the short form for periwig, derived from the French *perruque,* is an artificial head of hair or hair piece worn as a personal or theatrical cosmetic adornment, disguise or symbol of office.

The wearing of wigs dates from earliest recorded times, and Egyptian mummies have been found so adorned. In ancient Greece wigs were used by men and women. 4 reference in Xenophon and a story in Aristotle suggest that wigs were introduced from Persia and were in use in Asia Minor. The elaborately frizzled hair worn by some of the figures in the frescoes found at Cnossos indicates that wearing artificial hair was known to the Cretans. Lucian, writing in the 2nd century, mentioned wigs of both men and women as a matter of course. The theatrical wig was also in use in Greece, the various comic and tragic masks having hair suited to the character represented. These conventions appear to have been handed on to the Roman theatre.

In Rome wigs came into use in the early days of the empire. They were also known to the Carthaginians; Polybius said that Hannibal used wigs as a means of disguise. Juvenal described Messallina as assuming a yellow wig for her visits to brothels: Later the fashionable ladies of Rome almost universally adopted the use of hair pieces, and references in the writings of Ovid and Martial indicate that the golden hair imported from Germany was most favoured. The chief names for wigs were *galerus, galericulum, corymbium, capillamentum, caliendrum,* etc. *Galerus* meant a skullcap, or coif, fastening under the chin and made of hide or fur. worn by peasants, athletes and flamens. The first men's wigs then would have been tight fur caps simulating hair. Women continued to have wigs of different colours as part of their ordinary wardrobe and Faustina, wife of Marcus Aurelius, is said to have had several hundred. Some portrait busts, *e.g.*, that of Plautilla in the Louvre, Paris, had the hair made removable so that by changing the wig a statue would never be unfashionable.

The periwig of the 16th century merely simulated real hair, either as an adornment or to correct nature's defects. In the 17th century, in France, the peruke (*perruque*) was worn as a distinctive feature of costume. In 1620 the Abbé de la Rivière appeared at the court of Louis XIII in a periwig made to simulate long fair hair. Four years later the king himself, prematurely bald, also adopted one and thus set the fashion.

Louis XIV, who as a youth was proud of his abundant hair, did not wear a wig till after 1670. From Versailles the fashion spread through Europe. After the Restoration in England, under Charles II, the wearing of the peruke became general. Samuel Pepys records that he parted with his own hair and "paid £3 for a periwigg," and on going to church found that "it did not prove so strange as I was afraid it would." Under Queen Anne the wig attained its maximum development, covering the back and shoulders and floating down over the chest. Many varieties were perfected. Smaller, less pretentious wigs, custom-ordered from London, were also worn in the American colonies.

The differentiation of wigs according to class and profession explains why. when early in the reign of George III the general fashion of wearing wigs began to wane and die out, the practice held its own among professional men. It was by slow degrees that doctors, soldiers and clergymen gave up the custom. In the church it survived longest among the bishops. Both the French and American Revolutions saw the sweeping away of many social customs, including class distinctions indicated by hair styles and wigs. Wigs are now worn as part of the official costume only in Great Britain, by judges and barristers. Post-World War II Britain, however, saw the emergence of therapeutic prescription hair pieces or toupees as an integral part of the socialized medical program.

In the United States, with the development of television (calling for close-up cameras j and greater emphasis upon youthfulness and realism in the movies and theatre, the ancient art of wigmaking turned the full cycle. Since the early 1950s the trend toward men's hair pieces continuously gained in social custom and acceptance. The modern hair-piece industry has evolved entirely new styles and techniques of craftsmanship, in which the undetectable—yet 'secure—collegiate crew cut is the counterpart to the peruke of yesteryear.

For the theatrical use of wigs *see* also MAKE-UP (STAGE, MOTION PICTURE AND TELEVISION).

See Pearl Binder; *Muffs and Morals* (1955). (B. Z. K.)

WIGAN, a market town and a municipal, county and parliamentary borough of Lancashire. Eng., 18½ mi. W.N.W. of Manchester by road. Pop. (1951) 84.560 Area 7.9 sq.mi. The town, on the river Douglas, is the centre of the great south Lancashire coal field. A main line to Scotland runs through it as well as lines between Manchester. Liverpool and the west coast; the Leeds and Liverpool canal provides a means of transport by water. The tower of the parish church of All Saints is Iiorman. the remainder having been rebuilt in the 19th century. The beautiful octagonal war memorial was designed by Sir G. G. Scott. The grammar school, founded in 1597, occupies a new building opened in 1937. There are a mining and technical college and the Thomas Linacre Technical school (1953). Mesnes park. close to the town centre, and Haigh hall and the Plantations, purchased by the corporation in 1947, are open spaces.

It is probable that the borough occupies the site of a Roman fort, Coccium, and numerous Roman relics have been found. The name Wigan is Saxon and according to the college of heralds Wigan was made a borough under a royal ordinance of Henry I in 1100 and it is upon this that its claim to he the oldest borough in Lancashire is based. After the Conquest. Wigan became part of the barony of Newton. Before Henry III's reign, a rector secured the manorial privileges and in 1246 Henry III granted a charter to the rector by which Wigan was constituted a free borough and the burgesses were permitted to have a guild merchant. Wigan soon grew to be a medieval town of importance. A weekly market and two annual fairs have been held since 1258. In 1314 Edward II granted another charter which still exists. Wigan is the setting for the famous medieval legend of Mab's Cross used by Sir Walter Scott in *The Betrothed.*

During the Great Rebellion the town, from its vicinity to Lathom house and the influence of Lord Derby, adhered staunchly to the king. On April 1, 1643, the parliamentarians captured Wigan. The following month Lord Derby regained it for the royalists, but Col. Edward Ashton soon retook it. In 1651 Lord Derby marched through Preston to Wigan and at Wigan Lane, on Aug. 25, the royalist forces were defeated and Lord Derby was executed soon afterward. A new charter was given by Charles II in 1662 and Wigan is described in it as the "ancient and loyal" borough. During the rebellion of 1745 the Young Pretender occupied quarters in the town. For a short period during the later 18th century the town became a spa through the discovery of chalybeate waters. Its subsequent history has been one of intense industrial and commercial development. Wigan became a county borough in 1888.

In 1295 Wigan returned two members to parliament and again in 1307; the right then remained in abeyance until 1547, but from that time until 1885, except during the Commonwealth, the borough returned two members, and since 188; one member.

Wigan was famous for cannel coal: and outcrops were mined early in the 14th century. Coal mining has been largely carried on since the 17th century. though many mines in the immediate vicinity have been exhausted. Ancient industries were pewter making. pottery manufacture and bell founding. Cheap coal led to the development of large ironworks from the 18th century onward and the manufacture of blankets and other woolen goods was once of some significance. The principal industries today apart from coal mining are cotton spinning and weaving, clothing manufacture, heavy engineering and the manufacture of preserved foods. Other industries are plastics. coachbuildisig and the manufacture of fertilizers. footwear, furniture and telephones and electrical equipment. There are tar, rubber, oil, grease. vinegar and paint works. (H: H. G. A.)

WIGGIN, KATE DOUGLAS (1856–1923), U.S. novelist, was best known as the author of the "Rebecca" books. Daughter of Robert N. Smith, a lawyer, she was born in Philadelphia. Pa., Sept. 28. 1856, whence her family removed to Hollis. Me. She was educated at home and at various seminaries including Abbot academy (Andover, Mass.), and when 17 years of age joined her family in California. Having been a member of Miss Marwedel's pioneer training class, she was called from her teaching in Santa Barbara to establish in San Francisco the first free kindergarten on the west coast (1878), and organized her own California kindergarten training school in 1880. She married. in 1881. Samuel B. Wiggin, who died in 1889. In 1895 she married George C. Riggs, hut continued to write under the name of Wiggin. She died in England. Aug. 24. 1923. Her interest in children's education was shown in numerous books, but her literary reputation rests on her prose fiction: *The Birds' Christmas Carol* (188j), the Penelope series (j vol.): *Rebecca* of *Sunnybrook Farm* (1903); *New Chronicles of Rebecca* (1907); and *The Story* of *Waitstill Baxter* (1913). Several of these were dramatized with the assistance of collaborators. An autobiographical volume is *My Garden* of *Memory* (1923).

A uniform "Quillcote" edition of her books appeared in ten volumes. *See* also Nora Archibald Smith, *Kate Douglas Wiggin as Her Sister Knew Her* (1925); and a short biography with a bibliography by Helen Frances Benner (Orono, Me., 1956).

WIGGLESWORTH, MICHAEL (1631–1705), American clergyman, physician and poet. was born in England (probably in Yorkshire) Oct. 18, 1631. His father, persecuted for his Puritan faith. emigrated with his family to New England in 1638, and settled in New Haven. In 1651 Michael graduated at Harvard, where he was a tutor (and a fellow) in 1652–54 and again in 1697–1705. Having fitted himself for the ministry, he preached at

Charlestown in 1653–54, and in spite of ill health was pastor at Malden, Mass., from 1656 until his death. June 10, 1705. Wigglesworth is best known as the author of *The Day of Doom; or a Poetical Description of the Great and Last Judgment* (1662), an exposition of Calvinistic theology which children were made to learn like a catechism. It went through various editions and was reissued several times in the 18th and 19th centuries. An edition by K. B. Murdock. with drawings adapted from early New England gravestones by Wanda Gág, was published in 1929.

WIGHT, ISLE OF, lies off the south coast of England and is a part of Hampshire. separated from the mainland by the Solent. It is 22½ mi. from east to west and 13½ mi. from north to south with an area of 147.1 sq.mi. and a population (1951) of 95,62j. The climate is mild and healthy.

Newport, at the head of the Medina estuary. is the chief town; Cowes. at the mouth, the principal port and a great centre of sailing and yachting. Holiday resorts are Cowes, Ryde and Seaview, Bembridge. Sandown, Shanklin, Ventnor. Freshwater Bay. Totland Bay and Yarmouth. There are airports at Bembridge and Sandown. Osborne house, near Cowes. a residence of Queen Victoria and the scene of her death, was presented to the nation by King Edward VII in 1902. Farringford at Freshwater. now a hotel. was the home of Alfred Lord Tennyson. The principal communications with the mainland are between Ryde and Portsmouth, Cowes and Southampton. and Yarmouth and Lymington.

Its unique geological structure gives the island many rock formations within a small compass and a consequent variety of scenery and natural history. The central range of downs from Culver cliff in the east to the Needles in the west is the thickest bed of chalk in the British Isles. Off the western promontory rise the Needles. three detached masses of chalk about 100 ft. high. Northward the chalk dips steeply below the Tertiary rocks. with heavy soils which support many trees. The Forestry commission's woodlands in the island extend to over 4,000 ac.. Parkhurst forest covering 1,312 ac. Southward the beds dip more gently and there is a second range of downs in the extreme south which reach 787 ft. on St. Boniface down. The south coast is mostly cliff bound. and between St. Catherine's point and Dunnose extends the Undercliff. a series of terraces formed by the slipping of the chalk and Upper Greensand over the Gault Clay. The upper cliffs shelter this area. Off the coast near Brook is a now petrified submerged forest. Alum was formerly obtained at Alum bay, now visited for its multicoloured sandstone cliffs.

Three rivers, the eastern Tar. Medina and western Yar, flow northward into the Solent. The Medina almost bisects the island; while the western Yar almost insulates the western Wight. Along the south coast the action of small streams on the soft rocks has hollowed out steep and beautiful gullies known as chines, the most famous being at Shanklin and Blackgang.

The Isle of Wight County council was established in 1890. There are two boroughs. Newport (pop.. 1951, 20,430) and Ryde (20,105) and three urban districts. A separate court of quarter sessions was established in 1951. In 1927 the island was transferred from the diocese of Winchester to the newly founded diocese of Portsmouth. The island returns one member to parliament.

History. — There are traces of human occupation at every period from the Paleolithic onward. but the Early Bronze Age (c. 1900–1joo B.C.) seems to have been the period of most intense prehistoric settlement. A hoard of bronze weapons of this period was found on Arreton down in 1735, another at Moon's hill near Totland in 1942 and in 1954 a fine grooved bronze dagger of "Wessex" type was found in the side of a burial mound on Xrreton don-n. The Romans named the island Vectis and there are many relics of their occupation after Vespasian annexed it in A.D. 43, but no trace of a town or a military site. The Jutes probably settled there and in 661 it was annexed by Wulfhere to Wessex and subsequently bestowed on the king of Sussex. In 998 it was the headquarters of the Danes. From the 14th to the 16th century the island was under fear of invasion by the French, who in 1377 burned Yarmouth and so devastated Piewport that it lay uninhabited for two years. In 1404 a French force landed and demanded tribute which was refused and the French returned home. Another raid was attempted in 1545 when a French fleet of 225 ships drew up off Brading harbour and wrought much destruction. As a result forts were constructed at Cowes. Sandown, Freshwater and Yarmouth. Charles I was imprisoned in Carisbrooke castle in 1647–48 as were, in 1650, his two children, the princess Elizabeth and Henry. duke of Gloucester. the former dying there.

The lordship of the island was granted by William the Conqueror to William Fitz-Osbern, but escheated to the crown. It was bestowed by Henry I on Richard de Redvers, whose descendant Isabella de Fortibus sold it to Edward I in 1293.

The island quarries have been worked from remote times, that of Quarr supplying material for Winchester cathedral. Apart from agriculture and catering for visitors the main industries are shipbuilding and aircraft construction at Cowes.

Antiquities include about 1jo mounds, mostly Bronze Age, including three long barrows on several of the chalk downs; the Long Stone at Mottistone, a monolith (presumably Neolithic) 13 ft. high; Roman villas at Brading, Shide and Carisbrooke; an earthwork on Chillerton down called The Five Barrows; Carisbrooke castle. a beautiful ruin. built chiefly in the 12th century; a ruined 14th-century lighthouse on St. Catherine's down; and the remains of the medieval Cistercian abbey at Quarr, near Ryde.

WIGMAN, MARY (1886–), German dancer who was an outstanding pioneer of the modem expressive dance as developed in central Europe, was born on Nov. 13, 1886 in Hanover. She studied under Émile Jaques-Dalcroze and Rudolf von Laban, the latter of whom is best known for his widely accepted system of dance notation. Wigman gave her first solo concert in Switzerland in 1918 and thenceforth worked independently, formulating her own theories of movement. She often danced without music or with percussion accompaniment. She toured the United States alone in 1930–31 and with her group in 1933. She taught extensively in Germany and Switzerland; her pupils included Harald Kreutzberg and the noted choreographer Hanya Holm. (LN. ME.)

WIGSTON, an urban district in the Harborough parliamentary division of Leicestershire, Eng., 4 mi. S. of Leicester. Pop. (1951) 15,457. Area 5.4 sq.mi. The parish church is dedicated to St. Wulfstan (Wolstan), 11th-century bishop of Worcester, and in Domesday Book the village appears as Wichingestone — the "tun" or settlement of vikings. Since the 17th century Wigston has been known for its hosiery which, in 1956, was made in about 30 factories. Other industries are clothing, boots and shoes and wooden heels, biscuits, drums and other percussion instruments, and salt refining.

WIGTOWNSHIRE (sometimes called WEST GALLOWAY), a southwestern county of Scotland, bounded north by Ayrshire, east by Kirkcudbrightshire and Wigtown bay, south by the Irish sea and west and north by the North channel. Including the island of St. Helena: at the head of Luce bay, its land area is 487.5 sq.mi. Pop. (1951) 31,620. On the eastern boundary the estuary of the Cree expands into Wigtown bay, between which and Luce bay extends the promontory of the Machars or Machers, terminating in Burrow head. By the indentation of Luce bay on the south and Loch Ryan on the north the hammerheaded peninsula of the Rhins (Rinns or Rhinns) is formed, of which the Mull of Galloway, the most southerly point of Scotland, is the southern, and Milleur point the northern extremity. Loch Ryan is a natural harbour of which Stranraer is the port.

A line northeast from the coast about 3 mi. S. of Portpatrick divides the county so that practically all the rocks on the northern side are of Ordovician age, while those on the south are Silurian. This line coincides with the general direction of the strike of the beds throughout the county. Glacial moraines and drumlins are widespread and are well seen between Glenluce and

Newton Stewart and south of Wigtown. On the coasts of Luce bay and Loch Ryan raised beaches are found at levels of 25 ft. and 50 ft. above the sea. Toward the Ayrshire border, hills reach 1,000 ft. in height. The chief rivers are the Cree and the Bladnoch. Most of the numerous lochs are small.

The history of Wigtownshire is hardly distinguishable from that of Galloway (*q.v.*). Evidences of prehistoric occupation are prevalent in the form of hill forts, cairns, standing stones. hut circles and crannogs or lake dwellings. There are so few Roman remains that it has been concluded they effected no permanent settlement there. Ninian, the first Christian missionary to Scotland, is said to have landed at Isle of Whithorn in 396 though some scholars put his foundation as late as 430–440. A monastery was built at Whithorn, and, though the bishopric founded in the 8th century was shortly afterward removed, it was established again in the 12th, when the priory erected by Fergus, "king" of Galloway, became the cathedral church of the see of Galloway; it is now in ruins. Glenluce abbey, a Cistercian house founded in 1190, is also ruined. At Kirkinadrine are three stones with the Christian Chi Rho symbol dating from about the jth–6th century.

Malcolm MacHeth, who had married a sister of Somerled, lord of the Isles, headed about 1150 a Celtic revolt against the intrusion of Anglo-Norman lords! but was routed at Causewayend near the estuary of the Cree. In the disorder of the realm during David II's reign East Galloway had been surrendered to Edward III (1333), but Wigtownshire, which had been constituted a shire in the previous century and afterward called the Shire to distinguish it from the Stewartry of Kirkcudbright, remained Scottish territory. In 1372 the then earl of Wigtown sold his title and estates to the 3rd earl of Douglas, and under that family in 1426, the region came under the general law. Soon after the fall of the Douglases (1455) the Kennedy family obtained a preponderating influence in Wigtownshire. Gilbert, the 4th earl, held the shire for Mary, queen of Scots, when she broke with the Lords of the Congregation, but could do little for her cause.

Among ancient castles are the cliff towers, possibly of Norse origin, of Carghidown and Castle Feather near Burrow head; the ruins of Baldoon (south of Wigtown), and those of Carscreugh, (northeast of Glenluce), both associated with events which suggested to Sir Walter Scott the romance of *The Bride of Lammermoor;* Corsewall near the northern extremity of the Rhins; the Korse stronghold of Cruggleton, south of Garliestown; Dunskey, south of Portpatrick, built in the 16th century, occupying the site of an older fortress; the fragments of Long castle at Dowalton loch, the ancient seat of the MacDonells; Myrton, the seat of the MacCullochs, in Mochrum parish; and the ruined tower of Sorbie, the ancient keep of the Hannays.

The soil is of a light loamy nature, particularly in the Rhins where from 30% to 50% of the arable land is annually under the plow. In the Machars area, where more stony outcrops appear, the percentage under the plow is rather less. Grass is the chief crop. The high land is devoted mainly to the rearing of sheep and store cattle. Over 2,000 ac. of the shore land annually produce the earliest potatoes in Scotland. Farm cheese making, which at one time was the chief dairy product, has almost ceased. Ayrshire cattle are still the favourite dairy breed while Galloways and their crosses are popular as beef breeds. A few pedigree flocks of Border Leicester sheep are kept chiefly to provide rams for crossing purposes. Pigs are increasing in numbers as are hens.

The four small burghs are Newton Stewart (pop., 1951, 1,997), Stranraer (8,618), Whithorn (1,068) and Wigtown (1,376), the last three being royal burghs. In 1951 there were 65 persons speaking Gaelic and English. There is regular communication by mail steamer between Stranraer and Larne in County Antrim, Ire.

WIGWAM, a term loosely adopted as a general name for the houses of North American Indians. It is, however, strictly applied to a particular dome-shaped or conical hut made of poles lashed together at the tops and covered with bark. The skin tents of many of the Plains Indians are called tepees. "Wigwam" is from the Algonkian.

WIHTRED (d. 725), king of Kent, son of Ecgberht, came to the Kentish throne in 690 after the period of anarchy following the death of Eadric. Bede states that Wihtred and Swefheard were both kings in Kent in 692, and this statement would appear to imply a period of East Saxon influence (*see* KENT [kingdom]). while there is also evidence of an attack by Wessex. Wihtred, however, seems to have become sole king in 694. At his death in 725 he left the kingdom to his sons Aethelberht. Eadberht and Alric. A code of laws issued by him in a council at a place called Berghamstyde (probably 695) is still extant.

WILAMOWITZ-MOELLENDORFF, ULRICH VON (1848–1931), great German classical scholar and teacher, who threw new light on almost every aspect of the ancient world, was born at Markowice, near Poznan, on Dec. 22, 1848. After studying at the universities of Bonn and Berlin and traveling in Italy and Greece he became *Privatdozent* at Berlin in 1874. In 1878 he married the daughter of the famous scholar Theodor Mommsen. He was appointed university professor successively at Greifswald (1876), Gottingen (1883) and Berlin (1897).

He died at Berlin on Sept. 25, 1931.

A man of strong personality and vigorous mind, who aimed at revivifying the past by an imagination controlled by strict scholarship Wilamowitz made fundamental advances in metrics, epigraphy, papyrology, topography and textual criticism. as well as in literary and historical studies on ancient authors. His works include editions of various Greek texts, the most important being that of Euripides' *Heracles,* and books on Greek poetry, the Homeric question, Plato and Greek religion. He was also a brilliant translator of Greek verse.

WILBERFORCE, SAMUEL (1805–1873), English bishop, third son of William Wilberforce (*q.v.*), was born at Clapham common, London, on Sept. 7, 1805. He graduated from Oriel college, Oxford. in 1826, and was ordained in 1828. In 1830 he became rector of Brightstone, Isle of Wight. Although a high churchman Wilberforce held aloof from the Oxford movement; in 1838 his divergence from the "Tract" writers became so marked that Newman declined further contributions from him to the *British Critic.* In 1839 he published *Eucharistica* (from the old English divines), to which he wrote an introduction. *Agathos and Other Sunday Stories,* and a volume of *University Sermons,* and in the following year *Rocky Island and Other Parables.* In March 1844 he was made dean of Westminster, and in October bishop of Oxford.

In 1847 the bishop signed the remonstrance of the 13 bishops to Lord John Russell against R. D. Hampden's appointment to the bishopric of Hereford. He endeavoured to obtain assurances from Hampden; but, though unsuccessful, withdrew from the suit against him. The establishment of a Roman hierarchy in England in 18jo brought the high church party, in which Wilberforce was prominent, into temporary disrepute.

His attitude toward *Essays and Reviews* (1861), against which he wrote an article in the *Quarterly,* won him the gratitude of the low church party, and latterly he enjoyed the confidence of all except the extreme men of either side. On the publication of J. W. Colenso's *Commentary on the Romans* in 1861. Wilberforce sought a private conference with the author; but after the publication of the first two parts of the *Pentateuch Critically Examined* he drew up the address of the bishops which called on Colenso to resign his bishopric. Though opposed to the disestablishment of the Irish Church, yet, when the constituencies decided for it, he advised that no opposition should be made to it by the house of lords. After 24 years in the diocese of Oxford. he was translated by Gladstone to Winchester. He was killed on July 19, 1873, by a fall from his horse near Dorking, Surrey.

See Life of Samuel Wilberforce, With Selections From His Diary and Correspondence, vol. i, ed. by Canon A. R. Ashwell, and vol. ii and iii,

ed. by his son R. G. Wilberforce (1879–82); R. G. Wilberforce also wrote a one-volume *Life* (1905).

WILBERFORCE, WILLIAM (1759–1833), English politician and philanthropist, is chiefly associated with the abolition of the slave trade. He was born at Hull on Aug. 24, 1759. He was descended from an old Torkshire landed family. but his father, who died when William was nine! was associated with commerce. Wilberforce was educated at Hull grammar school and St. John's college. Cambridge. He was not an outstanding student, but he was a good companion and friend. Soon after leaving the university, and already possessed of a considerable fortune which he inherited from his grandfather and uncle. he became a member of parliament for Hull in 1780. As a friend and colleague of William Pitt. who was his contemporary at Cambridge, he was elected member of parliament for Yorkshire at the election of 1784, and offered Pitt valuable support in the house of commons. He became renowned for his parliamentary diplomacy and his private influence with men in office.

Although never firmly bound by party ties. Wilberforce throughout his life remained loyal to Pitt's principles. Although an early supporter of parliamentary reform and of Roman Catholic emancipation in the 1780s, the experience of the French Revolution made him increasingly conservative. In 1812 he exchanged the representation of the large constituency of Porkshire for that of Bramber, Sussex. After 1815 he supported the corn laws and the repressive policy of the government in domestic affairs. In 1825 he retired from the house of commons, but a few months before his death on July 29, 1833, he declared that he considered the first Reform bill too radical.

Wilberforce's interest in slavery was prompted by religion and humanitarianism, but Pitt encouraged him in the cause as a worthy subject, suited to his character and outlook. Converted to evangelical Christianity in 1784 largely under the influence of Isaac Milner, one of his schoolmasters and later president of Queen's college. Cambridge, he helped to set up in 1784 the Society for the Reformation of Manners. and three years later the Abolition society. The former organization was designed to raise the moral standards of Englishmen, the latter to strike at the slave trade in the West Indies. On account of their ideals and purposes, Wilberforce and his friends were known as "the Saints," or, after his marriage in 1797 and acquisition of a house at Clapham, as "the Clapham sect." Along with Henry Thornton, Thomas Clarkson. Charles Grant, E. J. Eliot, Zachary Macaulay and James Stephen, he pressed for rigorous conduct and zeal for moral welfare. The program of the sect was canvassed in the periodical, the *Christian Observer,* which first appeared in 1801.

Wilberforce was neither an original thinker nor a man of outstanding energy, but he was a greatly respected leader of the antislavery movement and many other causes. While Clarkson conducted the agitation in the country, Wilberforce took every opportunity in the house of commons. where he was an able and influential speaker, to expose the evils and horrors of the trade. For the history of the various motions introduced by Wilberforce *see* SLAVERY. It was not until 1807, the year following Pitt's death, that the first great step toward the abolition of slavery was taken. When the antislavery society was founded in 1823, Wilberforce became a vice-president, but before his aim was accomplished he had retired from public life. The Emancipation act. which was the culmination of his life's work, was not passed until a month after his death. In later years Wilberforce's name was identified with championship of oppressed slaves and although his general views have subsequently been criticized, his reputation is firmly established.

In 1797 Wilberforce published *A Practical View of the Prevailing Religious System of Psofessed Christians in the Higher and Middle Classes of this Countsy Contvasted with Real Christianity,* which within half a year vent through fire editions and was translated into French. Italian. Dutch and German.

(A. BRI.)

WILBYE, JOHN (1574–1638), English madrigal composer, was born at Diss, Norfolk, in 1574, the date of his baptism being March 9. For many years nothing was known of his life but many facts later came to light. His father was a well-to-do landowner, Matthew Wilbye. Through his early acquaintance with the Cornwallis family at Brome hall John became resident musician at Hengrave hall. the seat of Sir Thomas Kytson. whose wife was Elizabeth Cornwallis. The inventories of Hengrave give the items of furniture in Wilbye's rooms and the Hengrave Letter Book II contains a letter from Rilbye to a friend, which has been reproduced in vol. VI of *The English Madrigal School.* In 1628 Lady Kytson died. and Wilbye retired to Colchester. where he lived in the house of Lady Rivers, a daughter of the Kytsons. Wilbye died there in Sept. 1638. in his 65th year.

Wilbye's madrigals are the most famous of the English school. He had in a supreme degree the quality of style and he obtained wonderful effects of contrast by his skill in grouping the voices. His *First Set of English Madrigals to 3, 4, 5, and 6 Voices* was published in 1598, bearing the date April 12, and was dedicated to Sir Charles Cavendish, son-in-law of Sir Thomas Kytson. It contains 30 numbers, including the famous "Flora Gave Me Fairest Flowers."

The madrigals of the *Second Set,* dedicated to Lady Xrabella Stuart, which appeared in 1609. are even more finished in style. Among them are "Draw on. Sweet Night"; "Stay, Corydon!'; and "Sweet Honey-sucking Bees."

WILD, JONATHAN (*c.* 1682–1725), English criminal, was born about 1682 at Wolverhampton, where his father was a wigmaker. After a term of imprisonment he set up as a receiver of stolen goods. Wild built up an immense business, posing as a recoverer of stolen goods, the thieves receiving a commission on the price paid for recovery. A special act of parliament was passed by which receivers of stolen property were made accessories to the theft, but Wild's professed "lost property office" had little difficulty in evading the new law, and became so prosperous that two branch offices were opened. Wild went on to arrange robberies himself, and he devised and controlled a huge organization, which plundered London and its approaches wholesale. Such thieves as refused to work with him received short shrift. The notorious Jack Sheppard, wearied of Wild's exactions, at last refused to deal with him, whereupon Wild secured his arrest, and himself arrested Sheppard's confederate, "Blueskin." In return for Wild's services in tracking down such thieves as he did not himself control, the authorities for some time tolerated the offenses of his numerous agents. If an arrest were made. Wild had a plentiful supply of false evidence at hand to establish his agents' alibi, and he obtained the conviction, by similar means, of such thieves as refused to recognize his authority. Such stolen property as could not be returned to the owners with profit was taken abroad in a sloop purchased for this work. At last he was arrested, tried at the Old Bailey and, after being acquitted on a charge of stealing lace, found guilty of taking a reward for restoring it to the owner without informing the police. He was hanged at Tyburn on May 24, 1725.

WILD CARROT (*Daucus casota*). a biennial herb of the parsley family (Umbelliferae, *q.v.*), native to Europe, northern Africa and Asia and extensively naturalized in North America as a weed, often exceedingly pernicious in pastures, meadows and fields. It is the parent species of the common root vegetable from which it differs chiefly in the size and quality of the root. The wild carrot springs from a deep, fleshy. conical root, with an erect stem. 1–3 ft. high, bearing much-dissected. hairy leaves and a great many small white flowers crowded in a large globose or flat-topped cluster (compound umbel), often 3–5 in. across, the central flower of each umbel often purple. The ripening seed-vessels, which are small and bristly hairy, often form a concave cluster, suggestive of a bird's nest. Because of this the plant is popularly called crow's-nest or bird's-nest. It is also known as Queen Anne's lace because of the appearance of the flower clusters. Dairy products from cattle grazing on wild carrot are frequently tainted with a "carrot flavour."

WILDE, OSCAR FINGALL O'FLAHERTIE WILLS (1854–1900), English author, son of Sir William Wilde, a famous Irish surgeon. nas born in Dublin on Oct. 16, 1854; his mother, Jane Francisca Elgee, was well known in Dublin as a graceful writer of verse and prose, under the pen-name of "Speranza." Having distinguished himself in classics at Trinity college, Dublin, Oscar Wilde went to Magdalen college, Oxford, in 1874, and won the Newdigate prize in 1878 with his poem "Ravenna," besides taking a first-class in classical Moderations and in Literae Humaniores. At Oxford he adopted what to undergraduates appeared the effeminate pose of casting scorn on manly sports, wearing his hair long, decorating his rooms with peacock's feathers, lilies, sunflowers, blue china and other *objets d'art,* which he declared it his desire to "live up to," affecting a lackadaisical manner, and professing intense emotions on the subject of "art for art's sake"—then a new-fangled doctrine which J. hi. Whistler was bringing into prominence. Wilde made himself the apostle of this new cult. At Oxford his behaviour procured him a ducking in the Cherwell, and a wrecking of his rooms, but the cult spread. Its affectations were burlesqued in Gilbert and Sullivan's travesty *Patience* (1881). As the leading "aesthete." Oscar Wilde became one of the most prominent personalities of the day; his affected paradoxes and his witty sayings were quoted on all sides, and in 1882 he went on a lecturing tour in the United States, where he wrote a drama, *Vera,* which was produced in New York. In 1884 he married Constance Lloyd. He had already published in 1881 a selection of his poems, which, however, only attracted admiration in a limited circle. In 1888 appeared *The Happy Prince and Other Tales,* illustrated by Walter Crane and Jacomb Hood. This charming volume of fairy tales was followed up by *Lord Arthur Savile's Crime, and Other Stories* (1891), and later by a second collection of fairy stories *Tlze House of Pomegranates* (1892), acknowledged by the author to be "intended neither for the British child nor the British public." *The Picture of Dorian Gray* (1891) was the mirror of the new aesthete. In 1891 his tragedy in blank verse. *The Duchess of Padua,* was produced in New Tork. But Wilde's first real success with the larger public as a dramatist was with *Lady Windermere's Fan* (St. James's Theatre, 1892), followed by *A Woman of No Importance* (1893), *An Ideal Husband* (1895) and *The Importance of Being Earnest* (1895). The wit and brilliance of these pieces helped them to keep the stage, and they are still occasionally revived. In 1893 the licenser of plays refused a licence to Wilde's *Salome,* but it was printed in French in 1893, and produced in Paris by Sarah Bernhardt in 1894, and was translated into English in the same year by Lord Alfred Douglas.

His success as a dramatist had by this time gone some way to disabuse hostile critics of the suspicions as regards his personal character which had been excited by the apparent looseness of morals which since his Oxford days it had always pleased him to affect; but to the consternation of his friends, who had ceased to credit the existence of any real moral obliquity, in 1895 came fatal revelations as the result of his bringing a libel action against the marquis of Queensberry; and at the Old Bailey, in May, Wilde was sentenced to two years' imprisonment with hard labour for offences under the Criminal Law Amendment Act. He went bankrupt soon after. It was a melancholy end to a singularly brilliant career. After leaving prison in 1897 he lived mainly on the Continent, at Berneval and later in Paris under the name of "Sebastian Melmoth." He died in Paris on Nov. 30, 1900. In 1898 he published his powerful *Ballad of Reading Gaol.* His *Collected Poems,* containing some beautiful verse, had been issued in 1892. While in prison he wrote an apology for his life which was placed in the hands of his executor and published in 190j.

BIBLIOGRAPHY.—Oscar Wilde's works were edited in 13 vols. (1908) by Robert Ross, and two small collections of letters to Ross, *After Reading* (1921) and *After Berneval* (1922), were published. *See* also A. Gide, *Oscar Wilde* (1905); A. WILDER, THORNTON NNEN (1897–), U.S. author, presented in his writings ordinary people who make the human race seem worth preserving. He was born April 17, 1897. in Madison. Wis.; attended schools in California, China and Ohio; received his A.B. from Yale in 1920 and his M A. from Princeton in 192j. He taught at The University of Chicago (1930–37) and at Harvard (1950–51) and served in the U.S. army air force during World War II.

Wilder's novels, mostly historical, include *The Cabala* (1926), *The Woman of Andros* (1930), *Heaven's My Destination* (1934) and *The Ides of March* (1948). In them he explicitly emphasizes the universality of what he portrays. In his novel *The Bridge of San Luis Rey* (Pulitzer prize, 1928) his use of six characters whose various lives end in the same disaster underscores his assertion that life is much the same for everyone.

At times in his plays, *e.g., The Matchmaker* (1956), characters address the audience directly and stress the similarities between the events in the play and the spectators' own experiences. In *Our Town* (Pulitzer prize, 1938) the lack of scenery helps keep the action from seeming limited to one small New Hampshire town; the stage manager's comments on the action also suggest the parallel to any town anywhere. In *The Skin of Our Teeth* (Pulitzer prize. 1943) deliberate anachronisms and the use of the same set of characters in various geological and historical periods tend to show that human experience is much the same whatever the time or place. (Js. T. N.)

WILDERNESS, a large forest in Spotsylvania county, Va., on the south bank of the Rapidan, extending from Mine Run on the west to Chancellorsville on the east. It is famous in military history for the battles of Chancellorsville (1863) and Wilderness (1864) during the American Civil War.

In the following accounts the names of the Confederate generals are italicized.

Chancellorsville.—In May 1863 a three days' battle was fought at Chancellorsville between the Army of the Potomac, under General Hooker, and General *Lee's* Army of Northern Virginia. Hooker had now at his disposal 12,000 cavalry, 400 guns, and 120,000 infantry and artillery, organized in seven corps. *Lee* counted only j5,000 men of all arms effective Hooker detached 10,000 cavalry, under Stoneman, to sweep round *Lee's* left, destroy the railways in *Lee's* rear and cut his line of retreat, and the 1st and 6th corps under Sedgwick (40,000) to cross below Fredericksburg and pin *Lee* in his entrenched position, while with the remainder he himself turned *Lee's* left by a wide maneuvre. Hooker on April 30 fixed his headquarters at Chancellorsville. *Lee,* judging that Sedgwick's advance was only a feint, called up *"Stonewall" Jackson's* four divisions from below the Massaponax. At Chancellorsville. *Anderson's* division was in position, and *McLaws* was sent to support him. while *Jackson* took three divisions to the same point, leaving *Early's* division (10,000) to observe Sedgwick. At 11 A.M on May 1, Hooker began his advance toward Fredericksburg. But when he encountered the columns of the Confederates, also advancing, he fell back to Chancellorsville. There he was almost impregnable tq attack from the east or south. *Lee,* however, discovered a route by which the Federals might be attacked from the north and west. At 4 A.M. on May 2, *Jackson* marched westward, passed round the Federal right flank, then moved to take the Federals in reverse. *Jackson's* attack at 6 P.M. surprised the Federals, who fled in panic at nightfall, but *Jackson* was mortally wounded, and the attack lost impetus. Next day the attack was resumed under *Stuart,* reinforced by *Anderson,* while *McLaws* now threatened the left flank of the Federals and *Fitz Lee's* cavalry brigade operated against their line of retreat. Hooker finally gained an inner line of works covering the ford by which he must retreat. Meanwhile *Early* had checked Sedgwick, who had already abandoned his attack when *Lee,* on receiving word that *Early* was hard pressed, ceased to press Hooker's retreat and moved to

Early's aid. Thus on May 4, Sedgwick was assailed by *Early, McLaws* and *Anderson,* and driven over the Rappahannock to join the remainder of Hooker's beaten army, which had recrossed the Rapidan on the night of May j and marched back to Falmouth. That day *Lee* had once more countermarched to concentrate afresh against Hooker, but his attack, delayed by rain, found that his quarry had slipped away.

Grant's Campaign of the Wilderness and Cold Harbor.—On the evening of May 3, 1864, after dark, the Army of the Potomac, commanded by Meade, left its winter quarters about Culpepër to maneuvre across the Rapidan with a view to fighting a battle at or near New Hope Church and Craig's Church. The army and the 9th corps (Burnside), an independent command, were directed by Lieutenant General Grant, who accompanied Meade's headquarters. The opposing Army of Northern Virginia under *Lee* lay in quarters around Orange Court House *(A. P. Hill's* corps), Verdiersville *(Ewell's* corps) and Gordonsville *(Longstreet's* corps). The respective numbers were: Army of the Potomac, 98,000; 9th corps, 22,000; Army of Northern Virginia, rather less than 70,000.

The crossing of the Rapidan was made at Germanna and Ely's fords, out of reach of *Lee's* interference, and in a few hours the two leading corps had reached their halting places—the jth (Warren), Wilderness Tavern; and the 2nd (Hancock), Chancellorsville. The 6th (Sedgwick) followed the 5th and halted south of Germanna ford. Burnside's corps reached Germanna ford during May 5. On that day the maneuvre toward Craig's Church was resumed at 5 A.M., covered by Wilson's cavalry division, while Gregg's unit moved toward Fredericksburg.

Confederate infantry appeared on the Orange turnpike east of Mine Run, where Warren had posted a division of the 5th corps, and some cavalry at Parker's Store, became engaged a little later with hostile forces on the Orange Plank road. The first idea of the Union headquarters was that *Lee* was falling back to the North Anna. But the appearance of infantry on the Plank road as well as the Pike had shown that *Lee* intended to fight in the Wilderness, and Hancock (2nd corps) was called in from Todd's Tavern. while one division (Getty's) of the 6th was hurried to the intersection of the Brock and Plank roads to hold that point until Hancock's arrival. The division then formed up to await Hancock's arrival up the Brock road, practically unmolested.

Meanwhile Warren had been slowly forming up his attacking line with great difficulty in the woods. Grant appears to have used bitter words to Meade on the subject of Warren's delays, and Meade passed these on to Warren, who in turn forced his subordinates into premature action. The result of the attack by the 5th and later the 6th corps, delivered piecemeal owing to the difficulties of direction and touch in the woods, on *Ewell* was completely unsatisfactory, and for the rest of the battle these corps were used principally as reservoirs to find supports for the offensive wing under Hancock, who arrived on the Plank road at 2 P.M.

Hancock's divisions, as they came up, entrenched themselves along the Brock road. In the afternoon he was ordered to attack whatever force of the enemy was on the Plank road in front of him, but was unwilling to do so until he had his forces well in hand. Finally Getty was ordered to attack "whether Hancock was ready or not." The disjointed attacks of the 2nd corps on *Hill's* entrenchments, while forcing the Confederates to the verge of ruin, were not so successful as the preponderance of force on the Union side ought to have ensured. For four hours the two lines of battle were fighting 50 yd. apart, until at nightfall the contest was given up through mutual exhaustion.

The battle of the 6th was timed to begin at 5 A.M., and Grant's attack was wholly directed on Parker's Store, with the object of crushing *Hill* before *Longstreet* could assist him. Grant ordered Hancock with six of the eleven divisions of Meade's army to attack toward Parker's Store, and sent the 9th corps to strike *Hill's* left. The cavalry was drawn back for the protection of the trains. Wilson's division, in its movement on Shady Grove Church on the jth, had been cut off by the enemy's advance on the Plank road and attacked by some Confederate cavalry. But it extricated itself and joined Gregg. who had been sent to àssist him, at Todd's Tavern. Warren and Sedgwick were to hold *Ewell* occupied on the Pike by vigorous attacks. At 5 o'clock Hancock advanced, drove back and broke up *Hill's* divisions, and on his right Wadsworth attacked their left rear. But after an hour's wood fighting the Union attack came to a standstill, and at this moment, the critical moment for the action of the 9th corps, Burnside was still more than a mile away. Then *Longstreet's* corps attacked Hancock and forced him back several hundreds of yards. But by 7:30 the battle had become stationary. *Longstreet* attacked again and gained more ground. When Grant realized the situation he broke off one of Burnside's divisions from the 9th corps column and sent it to the crossroads as direct reserve to Hancock. At this moment *Longstreet* sent four brigades of infantry by a detour through the woods south of the Plank road to attack Hancock's left and the Union troops were hustled back to the crossroads. But *Longstreet* was wounded by his own men, and the battle came to a standstill (2:30 P.M.).

Burnside's corps, arriving shortly before 10 A.M. near Chewning's House, the position whence it was to have attacked *Hill's* left, was about to attack, in ignorance of Hancock's repulse, when fortunately an order reached it to make its way through the woods toward Hancock's right. This flank march was completed by 2 P.M., and Burnside began an attack upon the left of *Longstreet's* command. But Hancock being in no condition to support the 9th corps, the whole attack was, at 3 P.M., postponed by Grant's order until 6 P.M. About 4:15–4:30 *Lee* delivered a fierce assault upon Hancock's entrenchments along the Brock road. Confederates seized the first line of works, but a counterstroke dislodged them. Burnside put into the fight such of his troops as were ready, and at approximately j:30 the assaulting line receded into the woods. On the extreme right of the Union army a sudden attack was delivered at sunset upon the 6th corps, by *Gordon,* one of *Ewell's* brigadiers. This carried off two generals and several hundred prisoners, and caused a panic.

Grant's next plan was for the army to march to Spotsylvania on the night of the 7th–8th, to assemble on the 8th, and to undertake a fresh maneuvre against *Lee's* right rear on the 9th. *Lee* promptly discovered that a movement was in progress. He mistook its object, however, and assuming that Grant was falling back on Fredericksburg, he prepared to shift his own forces to the south of that place so as to bar the Richmond road. This led to a race for Spotsylvania. On the Union side Warren was to move to the line Spotsylvania Court House–Todd's Tavern, followed by Hancock; Sedgwick was to take a roundabout route and to come in between the 5th and 2nd corps; Burnside to follow Sedgwick. The cavalry was ordered to watch the approaches toward the right of the army. The movement began promptly after nightfall on the 7th. But before long the head of Warren's column, passing in rear of Hancock's line of battle, was blocked by the headquarters escort of Grant and Meade. Next, the head of the jth corps was again checked at Todd's Tavern by two cavalry divisions which had been sent by Sheridan to regain the ground at Todd's Tavern, given up on the 6th, and after fighting the action of Todd's Tavern had received no further orders from him. Meade, greatly irritated, ordered Gregg's division out toward Corbin's bridge and Merritt's to Spotsylvania. On the latter road the Gnion cavalry found themselves opposed by *Fitz Lee's* cavalry. and after some hours, Merritt asked Warren to send forward infantry to drive the enemy, which Warren did. Robinson's division at the head of the corps deployed and swiftly drove in *Fitz Lee.* A little beyond Alsop's, however, Robinson found his path barred by entrenched infantry. This was part of *Anderson's* (formerly *Longstreet's)* corps. Wilson's cavalry division acted in accordance with Sheridan's plan of occupying the bridges in front of the position that the army intended to occupy at Spotsylvania Court House, and seized that place, inflicting a smart blow upon a brigade of *Stuart's* force.

About 9 A.M. on the 8th, Warren, facing east, and opposed by part of *Anderson's* corps, was seeking to fight his way to Spotsylvania Court House by the Brock road. Wilson facing south, was holding the Court House and driving *Fitz Lee's* cavalry partly westward on to the backs of the infantry opposing Warren, partly toward Block House bridge, whence the rest of *Anderson's* infantry was approaching. Sheridan ordered Wilson to evacuate the Court House and to fall back over the Ny. Warren fruitlessly attacked the Confederate infantry at Spindler's, Robinson being severely wounded and his division disorganized. The other divisions came up by degrees, and another attack was made about 11. It was pressed close up to, and in some places over, the Confederate log works. but it ended in failure like the first. A third attempt in the evening dwindled down to a reconnaissance in force. *Anderson* was no longer isolated. *Early's* division observed Hancock's corps at Todd's Tavern, but the rest of *Ewell's* and all *Hill's* corps went to Spotsylvania and prolonged *Anderson's* line northward toward the Ny. On the 9th Sedgwick was killed by a long-range shot from a Confederate rifle. His place was taken by H. G. Wright. On this day also a violent quarrel between Meade and Sheridan led to the departure of the cavalry corps on an independent mission This was the so-called Richmond raid, in which Sheridan defeated *Stuart* at Yellow Tavern (where *Stuart* was killed) and captured the outworks of Richmond, but had then to make his way down the Chickahominy to the nearest supply depots of the Army of the James, leaving the Confederate cavalry free to rejoin *Lee*.

Grant decided to fight again on the 10th. While Hancock opposed *Early,* and Warren and Wright faced *Hill* and *Anderson,* Burnside was ordered by Grant to work his way to the Fredericksburg-Spotsylvania road, thence to attack the enemy's right rear. The first stage of this movement of the 9th corps was to be made on May 9, but not the attack itself, and Burnside was consequently ordered not to go beyond a place called "Gate" on the maps. This, it turned out, was not the farm of a person called Gate, as headquarters supposed. but a mere gate into a field. Consequently it was missed, and the 9th corps went on to Gale's or Gayle's house, where the enemy's skirmishers were driven in. The news of an enemy opposing Burnside at "Gate," which Grant still supposed to be the position of the 9th corps, at once radically altered the plan of battle. *Lee* was presumed to be moving north toward Fredericksburg. The 9th corps was ordered to hold its position and the others were to follow up the enemy as he concentrated upon Burnside. Hancock was sent down to force the fords on the Poe at and below Tinder's Mill, and directed upon Block House bridge, while Warren and Wright were held ready. But a handful of cavalry delayed the effective deployment of the moving wing, and by the time that the 2nd corps was collected opposite Block House bridge it was night. Hancock was ordered to resume his advance at dawn on the 10th.

Meade, however, had little or no cognizance of Grant's orders to the 9th corps, and his orders, conflicting with Grant's, puzzled Hancock and crippled his advance. At 10 A.M. the whole scheme was given up, and the widely deployed Union army closed for a direct attack on the Spotsylvania position. At 4 P.M., before the new concentration was complete, Warren attacked unsupported and was repulsed. In the woods on the left Wright was more successful, and at 6 P.M. a rush of 12 selected regiments under Col. Emory Upton carried the right of *Lee's* log works. But for want of support this attack too was fruitless. Burnside, receiving Grant's new orders to attack from Gayle's toward Spotsylvania, sent for further orders as to the method of attack, and his advance was thus made too late in the day to be of use. *Lee* had again averted disaster, this time by his magnificent handling of his only reserve, *Hill's* (now *Early's)* corps, which he used first against Hancock and then against Burnside.

Three corps were formed in a connected line (from right to left, the 5th, 6th, 9th) during May 11, and that night Hancock's corps moved silently to a position between Wright and Burnside and formed up in the open field at Brown's. Burnside was to attack from Gayle's toward McCool's. Warren and Wright were to have at least one division each clear of their entrenchments and ready to move.

Up to the 11th *Lee's* line had extended from the woods in front of Block House bridge, through Perry's and Spindler's fields to McCool's house, and its right was diffused and formed a loop round McCool's. All these works faced northwest. In addition, Burnside's advance had caused *Early's* corps to entrench Spotsylvania and the church to the south of it, facing east. Between these two sections were woods. The connection made between them gave the loop round McCool's the appearance from which it derives its historic name of The Salient. Upon the northern face of this salient Hancock's attack was delivered.

On the 11th the abandonment of Burnside's threatening advance on his rear and other indications had disquieted *Lee* as to his left or Block House flank, and he had drawn off practically all *Ewell's* artillery from the McCool works to aid in that quarter. But at 4:35. in the mist, Hancock's mass swept over their works at the first rush and swarmed in the interior of the Salient. While *Early,* swiftly drawing back from Block House, checked Burnside's attack from the east, and *Anderson,* attacked again and again by parts of the 5th corps, was fully occupied in preserving his own front. *Lee,* with *Ewell's* corps and the few thousand men whom the other generals could spare, delivered a series of fierce counterstrokes against Hancock. Grant and Meade well knew that *Lee* was struggling to gain time for the construction of a retrenchment. If the counterattacks failed to gain this respite. the Confederates would have to retreat as best they could, pressed in front and flank. *Lee* succeeded so well that after 20 hours' bitter fighting the new line was ready and the Confederates gave up the barren prize to Hancock. By the 20th the Federals were entrenched facing east, between Gayle and Quisenberry's, *Lee* facing west from the new works south of Harrison's through the Court House to Snell's bridge on the Po. While the Union army was resting for the first time since leaving Culpeper, *Ewell's* corps attacked its baggage train near Harris's House, but were driven off.

Hancock was now (20th) ordered to move off under cover of night to Milford; thence he was to march southwest as far as possible along the Richmond and Fredericksburg railroad and to attack whatever force of the enemy he met. It was hoped that this bold stroke by an isolated corps would draw *Lee's* army upon it, and the rest of the Army of the Potomac would, if this hope were realized, drive down upon *Lee's* rear while Hancock held him up in front. Supposing, however, that *Lee* did not take the bait, the maneuvre would resolve itself into a turning movement with the object of compelling *Lee* to come out of his Spotsylvania lines.

Hancock's corps started on the night of the 20th–21st. At Milford, where he forced the passage of the Mattapony, Hancock found himself in the presence of hostile infantry from Richmond and entrenched. The main army began to move off, after giving *Lee* time to turn against Hancock, at 10 A.M. on the 21st, and marched to Catlett's, a place a few miles southwest of Guinea's bridge. But no news came in from Hancock until late in the evening, and the development of the maneuvre was consequently delayed, so that on the night of the 21st–22nd *Lee's* army slipped across Warren's front en route for Hanover junction. The four Union corps, therefore, could only pursue him to the North Anna, at which river they arrived on the morning of the 23rd, Warren on the right. Hancock on the left, Wright and Burnside being well to the rear in second line. The same afternoon Warren seized Jericho ford, brought over the 5th corps to the south side, and repulsed a very sharp counterstroke made by one of *Lee's* corps. Hancock at the same time stormed a Confederate redoubt which covered the Telegraph Road bridge over the river. Wright and Burnside closed up. It seemed as if a battle was at hand, but in the night reports came in that *Lee* had fallen back to the South Anna. Union generals gave orders, about midday on the 24th, for what was practically a general pursuit. This led to the discovery that *Lee's* army had not fallen back but was posted in a semicircle to which the North Anna formed a tangent. On the 27th Sheridan's cavalry and a light division of infantry passed the Pamunkey at Hanover town, and the two divided wings of the Army of the Potomac were withdrawn over the North Anna without mishap. On the 28th the Army of the Potomac had arrived near Hanover town. *Lee* was now approaching from Hanover junction via Ashland. and the Army of the Potomac swung round somewhat to the right so as to face in the presumed direction of the impending attack. The Confederate general, however, planted himself behind the Totopotomoy. Here he was discovered on the 29th, and skirmishing all along the line, varied at times by more severe fighting, occupied that day and the 30th.

The last episode of the campaign centred in Cold Harbor, a village close to the Chickahominy, which Sheridan's cavalry seized on the 31st. Here, a considerable force of Confederate infantry was met. Grant and Meade ordered Sheridan to hold the village at all costs and directed Wright's (6th) corps, from the extreme right wing. and Smith's (18th), from Old Church, to march there with all possible speed. Wright and Smith successfully assaulted the Confederate front opposite Cold Harbor in the evening of June 1, and parts of the 6th corps penetrated the main line. Grant at once prepared to renew the attack with larger forces, ordering Hancock. Wright and Smith to assault on the next morning. But Lee had by now moved more forces down, and his line extended from the Totopotomoy to the Chickahominy. Hancock's corps did not form up until after midday, and meanwhile Smith refused to consider the idea of renewing the attack. Grant again ordered the attack to be made by Wright, Smith and Hancock at j P.M. A last modification was made when, during the afternoon, Lee's far distant left wing attacked Burnside and Warren. This, showing that Lee had still a considerable force to the northward, and being read to mean that the Confederate entrenchments were thinly guarded at all points. led to the order being given to all five Union corps to attack at 4:30 A.M. on June 3. The assault was made at the time arranged and was repulsed at all points with a loss to the assailants of about 8,000 men. Thereafter the two armies lay for 10 days less than 100 yd. apart. (C. F. A.; X.)

WILD FLOWER. Most wild flowers are colourful species growing without the intentional aid of man. Commonly they are native to the region in which they occur, but they may be introduced from other lands. For example, the bright flowers characteristic of the Hawaiian Islands are nearly all native to other parts of the tropics and subtropics. Most of them were taken purposely to the islands for cultivation, but in the warm, moist climate of Hawaii they spread rapidly into the fertile lowlands and displaced the less colourful native species, leaving only the steep mountainsides to the original flora. In the lowlands of the United States and Europe most species are native, but many are migrants from other areas or other continents. Disturbance of the native flora began in prehistoric times whenever escaping fires burned off the native vegetation and made way for aggressive species from the same or other areas. In all probability one of the best-known buttercups of northern Europe, *Ranunculus acris,* became more abundant and widespread as the forests were burned away. In the lowlands of northern Europe, this colourful and highly variable species probably became modified during the Stone Age into some new forms better adapted to habitats created by man than the original types. Two forms occurring in the northern United States and Canada, both introduced into eastern North America at least by the early part of the 19th century, gradually spread across the continent, one becoming common in the state of Washington only within the 20th century. This species is so abundant and colourful that few would question it as a wild flower characteristic of the northern states and Canada.

Distinction of weeds (*q.v.*) from wild flowers is not consistent because it depends upon the purpose of the classification. A weed is a plant out of place, that is, one growing where it is unwanted. Sunflowers are looked upon as weeds when growing in cultivated fields or on grazing land of the Great Plains of North America but as wild flowers in uncultivated valleys. In other parts of the world the same plant is a crop plant cultivated for its seeds; in some places it is a garden flower. Most cultivated flowers have wild varieties.

Colour and Form.—Wild flowers are appreciated first for colour and second for form. The shades of flower pigmentation are seemingly infinite in number. The anthocyanin pigments, for example, range from almost red to almost blue. These are water soluble, and they occur in solution in the cell sap. They are subject to modification in the same way as litmus paper—toward red in an acid medium and toward blue in a basic medium. Most other pigments are not soluble in water, and they are contained in plastids (solid bodies) suspended in the living substance of the cell. The flowers of many species of iris (flag) may be modified in colour by placing them in an acid or a base, just as the juice of a beet may be made to tend toward red or toward blue by addition of drops of one substance or the other.

Although the colours of flowers vary greatly in nature, they may be modified further by selection and hybridization. The roses first cultivated were red, pink or white types readily accessible as native plants easily brought into cultivation. Many new colour combinations, for example the red and yellow of the Talisman roses, were made possible by relatively recent bringing of yellow roses from remote regions. Camellias in cultivation have approximately the same shades as roses before the introduction of yellow, and horticulturists are searching for a yellow-flowered wild species.

Usually the colour of wild flowers is described in terms of the conspicuous petals, but in some plants (*e.g.,* anemones) there are no petals and the sepals are colourful. The sepals, petals, stamens and pistils may be differently coloured. A single organ may vary in colour from base to tip. may be mottled, as in some fritillarias, or spotted, as in tiger lilies.

Variation in form is as much to be appreciated as colour but requires closer study. In larger flowers it may be examined with the naked eye, but many of the most beautiful structural patterns are those seen with a magnifying glass, a hand lens or a dissecting microscope. Examples of plants having minute flowers with beautiful patterns are species of goosefoot and lamb's quarter, small-flowered members of the mustard family, nettles, plantains, carrots, rushes, sedges and grasses.

Study of the form of flowers soon reveals repetition of basic patterns with many modifications of detail. In the mustard family the flower almost invariably consists of four sepals, four petals, six stamens and one pistil. The six stamens are in an outer series of two and an inner series of four. The pistil is composed basically of four fused specialized leaves (though it appears to be of only two). This pattern is repeated with petals of many shapes and sizes and in colours varying from white to yellow, red or purple and many shades or combinations between. The stamens vary through several colours and forms. The pistil may form an elongated pod like that of a mustard or it may have an almost bead-like or disclike form. At maturity the fruit may split open as in the mustards, divide crosswise as in the radishes or remain intact as in the fringepods. Yet through all this variation the basic mustard pattern is maintained. In every other family a special arrangement prevails.

Observation of repeated structural patterns led Linnaeus to describe (Classes Plantarum, 1738) 68 "natural orders" of plants, most of which were the approximate equivalents of plant families described in modem botanical literature. To Linnaeus each pattern indicated a group of related plants. To Charles Darwin (Origin of Species . . . , 1859) this relationship indicated a common ancestry in some pre-existing basic type. Interpretations of the patterns of flower structure and of the structure of other organisms provided some of the strongest evidence underlying the concept of evolution. Thus, true appreciation of wild flowers begins with colour, continues with the study of form and structure and leads ultimately to interpretation of the recurrence of patterns in the flowers of many plants and to appreciation of other natural phenomena.

Hybridization and Interbreeding.—The wild flowers of a given species are not identical. While the variations among cultivated plants are well known, those among wild flowers are known to few people. Appreciation of this aspect of the subject requires careful inspection of both the flowers and the vegetative parts of many individuals of the same species. The range of variation is within certain limits but some individuals have borderline combinations of characteristics and cannot be classified readily in one species or another.

In a given area, where the natural vegetation has been disturbed relatively little, two closely related species may occur near each other or even together. Usually, however, there are either genetic barriers to their interbreeding or environmental factors restricting the species to differing habitats. One species may require more moisture, richer soil and more shade than another. Even though the two species are compatible genetically and produce fertile hybrids, relatively few of the hybrid individuals persist. This is because the hybrid seedlings usually occur in the habitat suitable to the female parent plant, where they are in competition with better adapted nonhybrid seedlings similar to the female parent. The surviving hybrids are likely to occur in an intermediate habitat to which they are better adapted than either species, but where they may be crowded out by some competing plants better suited to this area. If fire, flood, overgrazing or some other factor upsets the natural balance, conditions more favourable to the hybrids may be produced and the conditions best for the competing parent species may be destroyed. Thus some of the hybrids with special character combinations may become more abundant, and they may even be able to replace both parental types.

Either (1) two species occurring at one place together and unable to interbreed effectively or (2) two species occurring in different habitats in one locality and not producing many surviving hybrids there, may shade off gradually into differing forms occurring in other places. In these forms either the hereditary or the ecological barriers may disappear and the species may pass into each other in some areas. Intergradation of species or varieties may occur in all degrees, and for this reason classification is difficult. Thus wild flowers provide the technical material and problems upon which the classifier of plants works, just as their colour and form provide subject matter for the artist.

Besides providing insight into the dynamics of formation of new varieties, species and higher categories (evolution) and into problems of classification (taxonomy). wild flowers present problems in the relationships of living organisms to the environment (ecology); the relationships of living plants to those of the past. and of existing floras to pre-existing floras (paleobotany); and the mechanisms and laws of heredity (genetics).

Geographical Distribution. — There are at least 175,000 species of flowering plants, thousands of which are wild flowers. Relatively few occurring on one continent may be found on another, and the individual parts of the same continent may have almost wholly different floras, for wild flowers and other plants are affected by many factors, especially moisture and temperature.

Moisture variation may be extreme on the opposite sides of the same mountain range. In the state of Washington the average rainfall at Snoqualmie falls (east of Seattle on the western edge of the Cascade mountains) is about 8½ ft. Beyond the mountains 65 mi. eastward in the vicinity of Wenatchee it is 8½ in. Almost no species (except those near streams) are native to both places.

Temperature changes due to altitude or latitude are marked by corresponding variations in flora. Species occurring at the top of Pikes peak (14,110 ft. elevation) in Colorado are wholly different from those on the high plains just east of the Rocky mountains and from those in the foothills at Colorado Springs (5,900 ft. elevation). Over long distances from north to south, even in such level areas as between Saskatchewan and Texas, there is almost a complete change with latitude in wild flowers as well as other plants. Many tropical and subtropical species are limited in northward distribution by the occurrence of any frost.

The distribution of wild flowers and other plants is segregated roughly into those of the tropics and subtropics; the horse latitudes of both hemispheres; the temperate regions of both the northern and southern hemispheres; and the arctic and antarctic and the summits of mountain chains ranging to the southward. These major distributional areas are correlated with the planetary winds. Except in the belt of tropical calms at the equator, the trade winds predominate through the tropics and subtropics. Islands and other land masses tend to be moist on the windward side and very dry on the leeward. This is notable in the islands of the Caribbean and especially in the Hawaiian Islands. On western Maui. Iao canyon, facing toward the northeasterly trade winds, receives hundreds of inches of rainfall each year, while areas near Lahaina on the west side of the same mountain resemble the deserts of Arizona.

At sea. the horse latitudes (at about latitude 30° N. and S.) are areas of calms; on the larger land masses they are regions of deserts. for example. in the northern hemisphere the Sahara the deserts of the middle east and of central Asia, and those of North America from southeastern California to Texas and northern Mexico. In the southern hemisphere deserts occur in the corresponding belt in Chile, South Africa and Australia. At this latitude the air that arises in the warm tropics, dropping its moisture, descends as a warm, dry mass.

North or south of 30° are temperate regions largely within the zone of the prevailing westerly winds. On the western temperate coasts of continents heavy rainfall is common in the winter when the land cools more rapidly than the ocean and moisture tends to condense. The high rainfall at Snoqualmie falls, Washington (see above), is due to this condensation. The rain- and snowfall on the Cascade mountains just eastward is even higher because as the air mass ascends over the mountain range it expands, cools and loses moisture. Descending on the eastern side of the same range, the air mass becomes warmer and tends to absorb moisture. Thus the wild flowers on the windward slopes are those of a dense rain forest while those on the leeward side are characteristic of the sagebrush desert.

Along the summits of high mountains and in the arctic and antarctic low temperature takes precedence over all other factors.

In North America there are nine major floral regions, each with characteristic wild flowers almost wholly different from those of each of the other eight. The regions (more or less from north to south and west to east) are as follows:

Boreal-Alpine Region. — This occurs above timber line in the mountains and beyond it to the northward. This is a region of sod (tundra) with many characteristic colourful species of perennial wild flowers that develop rapidly during the short growing season, mostly in the month of July but sometimes in August. Most species occurring in this region are found around the world north of the timber line. They have been in contact across the northern Bering sea within geologically recent times. Within the last 1,000,000 years four great ice sheets formed in northern regions but not throughout the arctic. Withdrawal of water from the oceans lowered the level of the Bering sea sufficiently to permit migration of plants as well as animals between northern North America and Eurasia.

Northern Forest Region. — This is an area of coniferous forest in northern latitudes just south of the timber line. It covers a large part of Canada and limited portions of the United States, especially in Alaska, the Appalachian system and northern New England. A similar forest belt occurs in areas of northern Europe, including the higher parts of Scotland and Scandinavia. For the most part the species of wild flowers and other plants occurring in the northern forests of the eastern and western hemispheres are different, but the genera tend to be the same. This is interpreted as indicating a longer period of separation for these areas than for the boreal regions to the north.

Rocky Mountain Forest Region. — This is an area of coniferous forests in the Rocky mountain system of North America. In the southern Rockies warm summer rains produce seed germination and an abundance of wild flowers different from those in California.

Pacific Northwestern Region. — This is the great coniferous forest belt of south coastal Alaska, lowland British Columbia and the Pacific northwest. It occurs west of the Cascade mountains and the Sierra Nevada and other higher mountains of California. Superficially this forest area is similar to that of the Rocky mountains, but nearly all the species are different. Particularly this is so in the southern portions of each mountain system. Species of wild flowers and other plants in the Sierra Nevada require low temperatures for germination and are dependent on winter rainfall.

Western Woodland and Brush *Region.*—This includes the sagebrush desert of the Great Basin and the Columbia river basin, parts of south-central British Columbia, the Juniper-Pinyon woodland of the Great Basin region, the oak woodlands and the chaparrals of California and Arizona, and the Pacific grassland in the Sacramento-San Joaquin valley of California. Numerous characteristic wild flowers are abundant in the region and before agricultural disturbance the most colourful wild-flower fields of North America were in the grasslands of the San Joaquin valley. These were far more extensive than the flowers in the deserts and perhaps rivaled only by flower fields in Texas.

Southwestern Desert Region.—This is the creosote-bush desert, occurring approximately from Palm Springs, Calif., to St. George, Utah, southern New Mexico and Texas west of the Pecos river. The western portion of this desert becomes colourful through the growth of innumerable wild flowers of many species whenever there is a winter with unusually heavy rainfall (as, for example, with eight or ten inches as opposed to the usual three to five). As far east as Tucson, Ariz., winter rain is important. Beyond that area both winter and summer rains may occur, but the summer rain is more effective because of its coincidence with the growing season.

Eastern Forest Region.—This is the enormous area of deciduous forest, chiefly of dicotyledonous trees, from the longitude of Nebraska eastward to the Atlantic ocean. The most extensive single floral region in North America, it includes innumerable characteristic wild flowers and other plants. In the lowlands of Britain and the-northern parts of continental Europe, the flora is similar in many ways but most species and many genera are different.

The temperate floristic regions described above differ even more extensively in genera and species from the corresponding temperate regions of Eurasia than does the northern forest region. Probably this is the result of longer geological separation and of consequent independent evolution.

Subtropical Region.—Elements of subtropical forests of the Caribbean islands occur especially in swampy areas on the Gulf coast of southern Texas and in southern Florida. These include characteristic wild flowers of tropical regions of the western hemisphere, among them species of the orchid and the Bromelia families. The genera and species characteristic of this area are usually different from those occurring in the tropics of the old world. About **32** plant families are restricted to the tropical and subtropical regions of the Americas and 65 to similar regions of the eastern hemisphere. This is correlated with even longer geological separation.

Principal Kinds of Wild Flowers.—The more colourful herbaceous species of flowering plants are considered wild flowers. Those native to North America are associated with one or sometimes t o or more of the nine major floral regions, those of Britain with a European belt equivalent to the border zone between the northern forest region and the eastern forest region in North America. Reference to all species according to the regions in which they occur is not practical because many genera are represented in nearly all the regions, though by different species, all known by the same English name. (The principal orders and families including wild flowers are enumerated under ANGIOSPERMS.)

The following are examples of groups of wild flowers represented through all of Korth America and many through much of Europe and northern Asia:

Arrowheads (*Sagittaria*)
Evening primroses (Oenothera)
Flag or iris (Iris)
Flaxes (Linum)
Mint family (including blue-curls) (Trichostema)
- Dragonhead (Dracocephalum)
- False dragonhead (Physostegia)
- Germander (Teucrium)
- Giant hyssop (Agastache)
- Hedge nettle (Stachys)
- Horsemint (Monarda)
- Mint (*Mentha*)
- Mock pennyroyal (Hedeoma)
- Mountain mint (Pycnanthemum)
- Sage (Salvia)
- Savory (*Satureia*)
- Selfheal (Prunella)
- Skullcap (Scutellaria)
- Water horehound (*Lycopus*)

Mustard family (Lesquerella, Draba)
- Bitter cress (Cardamine)
- False flax (*Camelina*)

Mustard family (continued)
- Peppergrass (Lepidium)
- Rock cress (Arabis)
- Toothwort (Dentaria)
- Treacle mustard (Erysimum)
- Winter cress (Barbarea)
- Yellow cress (Roripa)

Rattleweeds (*Astragalus*)
Sandworts (Arenaria)
Stonecrops (Sedum)
Sunflower family (Helianthus)
- Arnica (Arnica)
- Aster (Aster)
- Bur marigold (*Bidens*)
- Coreopsis (*Coreopsis*)
- Everlasting (Antennaria, Gnaphalium, etc.)
- Fleabane (Erigeron)
- Goldenrod (Solidago)
- Groundsel (Senecio)
- Gumweed (Grindelia)
- Ironweed (Veronica)
- Sunflower (North America only) (Helianthus)
- Thistle (Cirsium, etc.)

Veronicas (Veronica)
Water lilies (Nymphaea, Nuphar)

The following are widely distributed, the Korth American and European species being mostly of northern and north temperate species groups:

Adder's-mouths (*Malaxis*)
Avalanche lilies, dogtooth violets, chamise lilies (*Erythronium*)
Avens (*Dryas*)
Baneberries (Actaea)
Beardflowers (Pogonia, *Cleistes, Isotria, Triphora*)
Bellflowers (Campanula)
Blue-eyed grasses (*Sisyrinchium*)
Brook orchids (*Epipactis*)
Buck beans (*Menyanthes*)
Buttercups (*Ranunculus*)
Calypsos (Calypso)
Camasses (*Camassia*)
Campions (*Lychnis*)
Catchflies (*Silene*)
Cinquefoils (Potentilla)
Clovers (*Trifolium*)
Columbines (Aquilegia)
Coralroots (*Corallorhiza*)
Elodeas (Anacharis)
Fairy lanterns (Disporum)
False Solomon's-seals (*Smilacina*)
Figworts (*Scrophularia*)
Fireweeds and willow herbs (*Epilobium*)
Gentians (Gentiana)
Goldthreads (Coptis)
Grasses-of-Parnassus (Parnassia)
Grass pinks (*Colopogon*)
Hound's-tongues (*Cynoglossum*)
Jacob's-ladders (*Polemonium*)
Lady's-slippers (Cypripedium)
Lady's-tresses (*Spiranthes*)
Larkspurs (Delphinium)
Lilies (Lilium)
Louseworts (Pedicularis)
Marsh marigolds (*Caltha*)
Meadow rues (Thalictrum)
Monkshoods (Aconitum)
Onions (*Allium*)
Primroses (Primula)
Puccoons (Lithospermum)
Puttyroots (*Aplectrum*)
Rattlesnake plantains (Goodyera)
Rein orchises (Habenaria)
Saxifrages (Saxifraga)
Shooting stars (Dodecatheon)
Snapdragons (Antirrhinum)
Spring beauties (Claytonia)
Stickseeds (Hackelia)
Strawberries (Fragaria)
Sweet peas (Lathyrus)
Toadflaxes (Linaria)
Twayblades (Listera, *Liparis*)
Twisted-stalks (*Streptopus*)
Valerians (*Valeriana*)
Vetches (*Vicia*)
Violets and pansies (Viola)
Virgin's-bowers (Clematis)
Wake-robins (Trillium)
Waterleaves (Hydrophyllum)
Water plantains (Alisma)
Wild gingers (*Asarum*)
Windflowers (Anemone)

The following are widely distributed, the North American and European species being mostly of groups of species occurring in tropical and warm regions:

Allionias (*Allionia*)
Amsonias (Amsonia)
Burmannias (*Burmannia*)
Butterfly peas (Centrosema)
Cottons (Gossypium)
Dayflowers (Commelina)
Devil's-claws (Proboscidea)
Dutchman's-pipes (Arzstolochia)
Four-o'clocks (Mirabilis)
Golden-eyed grasses (Hypoxis)
Ground cherries (Physalis)
Hibiscuses (Hibiscus)
Indian mallows (Abutilon)
Jimson weeds (Datura)
Jussiaeas (Jussiaea)
Leadworts (Plumbago)
Milk peas (Galactia)
Milkworts (Polygala)
Miterworts (*Cynoctonum*)
Morning-glories (Ipomoea)
Sightshades (Solanum)
Petunias (Petunia)
Rattleboxes (Crotalaria)
Redroots (Lachnanthes)
Ruellias (*Ruellia*)
Sennas (Cassia)
Sidas (Sida)
Sorrels (Oxalis)
Spiderworts (*Tradescantia*)
Spurges (Euphorbia)
Summer poppies (Kallstroemia)
Talinums (*Talinum*)
Tobaccos (*Nicotiana*)
Verbenas (Verbena)
Water primroses (*Ludwigia*)
Wild beans (Strophostyles)
Worm grasses (Spigelia)
Zephyr lilies (*Zephyranthes*)

The C.S. western woodland and brush region, the southwestern desert region and the eastern forest region include numerous groups of wild flowers not falling clearly into the categories above. Examples are as follows:

Western Woodland and Brush Region

Baby blue-eyes (*Nemophila*)
Brodiaeas (Brodiaea)
Canchalaguas (*Centaurium*)
Chinese houses (*Collinsia*)
Clarkias and podetias (Clarkia)
Creamcups (Platystemon)
Downingias (*Downingia*)
Dudleyas (Echeveria, Dudleya)
Fritillaries (*Fritillaria*)
Hollyhocks (Sidalcea)
Indian paintbrushes (*Castilleja*)
Mariposa lilies (Calochortus)
Meadow-foams (Limnanthes)
Monkey flowers (*Mimulus*)
Morning-glories (California) (Convolvulus)
Navarretias (*Navarretia*)
Pentstemons (Pentstemon)
Popcorn flowers (Plagiobothrys)
Red maids (Calandrtnia)
Wind poppies (Papaver)

Western Woodland and Brush Region
and Southwestern Desert Region

California poppies (Eschscholtzia)
Fiddle-necks (Amsinckia)
Gilias (Gilia)
Globe mallows (Sphaeralcea, *Malvastrum*)
Linanthuses (Linanthus)
Lotuses (*Lotus*)
Lupines (*Lupinus*)
Mentzelias (Mentzelia)
Nievetas (Cryptantha)
Phacelias (Phacelia)
Prickly poppies (Argemone)
Sages (*Salvia*)
Wild buckwheats (Eriogonum)

Southwestern Desert Region

Chorizanthe (*Chorizanthe*)
Desert lilies (Hesperocallis)
Eucnides (Eucnide)
Filaree (Erodium)
Mohaveas (Mohavea)
Namas (*Nama*)

Eastern Forest Region

Arrow arums (*Peltandra*)
Bloodroots (*Sanguinaria*)
Bog mosses (*Mayaca*)
Eastern skunk cabbages (*Symplocarpus*)
False indigoes (*Baptisia*)
Floating hearts (*Nymphoides*)
Forget-me-nots (*Myosotis*)
Gerardias (*Gerardia*)
Glade mallows (*Napaea*)
Jack-in-the-pulpits (*Arisaema*)
Lobelias (*Lobelia*)
Loosestrifes (*Lysimachia*)
Meadow beauties (*Rhexia*)
Mud plantains (*Heteranthera*)
Pennyworts (*Obolaria*)
Pickerelweeds (*Pontederia*)
Pipeworts (*Eriocaulon*)
Pitcher plants (*Sarracenia*)
Poppy mallows (*Callirrhoë*)
Sabatias (*Sabatia*)
St -John's-worts (*Hypericum*)
St.-Peter's-worts (*Ascyrum*)
Shoe buttons (*Syngonanthus*)
Solomon's-seals (*Polygonatum*)
Spurred gentians (*Bartonia*)
Sweet flags (*Acorus*)
Tephrosias (*Tephrosia*)
Touch-me-nots (*Impatiens*)
Water willows (*Decodon*)
Wood poppies (*Stylophorum*)
Yellow-eyed grasses (*Xyris*)
Yellowroots (*Xanthorhiza*)

Conservation. — Since the beginning of agriculture and animal husbandry parts of Europe, Asia and Africa have been burned over, cultivated, overgrazed and invaded by aggressive weeds, some of which originated as hybrids selected naturally according to their adaptations to the conditions of disturbed soil. Many weeds were accidentally introduced to new regions and throve when the natural conditions in those areas were disturbed. The bands of sheep brought to California by the mission fathers not only overgrazed the countryside but also brought in their wool the seeds of numerous Mediterranean weeds and weedy grasses. These tended to crowd out native plants especially in the lowlands until a new balance was reached, one in harmony with the newly established conditions based upon agriculture and grazing. Although most of the native Californian species persist, a high percentage of the individual plants now living consists of introduced species. Most of these are not colourful and are not considered wild flowers, although some, like the introduced mustards and radishes, are among the most colourful plants in the state. Nevertheless, the once great flower fields of California have become but a pitiful remnant of even those that remained as late as the 1930s.

What is true in California and, as pointed out above, in Hawaii, is true everywhere. With the coming of man conditions change. As the cities grow the country becomes restricted and invaded by suburbs, and even the more remote wilderness tends to disappear. Some wilderness and some wild flower areas have been preserved in national, state or provincial, and local parks and monuments, particularly in the U.S. and Canada, but in general the once vast areas of flower fields have not been preserved. These tracts of land were most vulnerable to civilization because they were easily plowed up or converted to grazing land. The few remaining are among the areas most needing preservation.

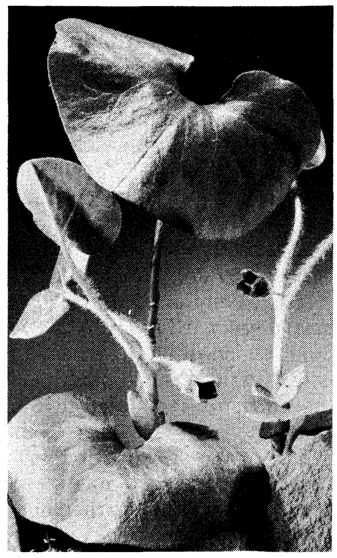
See also FLOWER.

BIBLIOGRAPHY.—Clarence J. Hylander, *The Macmillan Wild Flower Book* (1954), covers most of the U.S. and southern Canada; H. W. Rickett, *Wild Flowers of America* (1953), a large reference book; Edith S. Clements, *Flowers of Prairie and Woodland* (1947). For the British Isles, *see* David McClintock and R. S. R. Fitter, *The Pocket Guide to Wild Flowers (1956)*. Lyman Benson, *Plant Classification* (1957), includes a list of manuals of regional and local floras including the wild flowers of various areas of North America north of Mexico; Earl L. Core, *Plant Taxonomy (1955)*; George H. M. Lawrence, *Taxonomy of Vascular Plants (1951)* and *An Introduction to Plant Taxonomy* (1955). (L. BN.)

WILDGANS, ANTON (1881–1932), Austrian poet and dramatist, was born in Vienna on April 17, 1881, began and completed a course of legal studies in Vienna university and was artistic manager of the celebrated Burgtheater there 1921–24. In 1909 he attracted notice by a book of verses *Herbstfrühling*, and in a series of lyrical volumes he gave expression to erotic passion, to deep sympathy with nature and with human suffering. Wildgans appears to be connected with the Hofmannsthalists, although maintaining his independence.

His plays *Armut* (1914), *Liebe* (1916) and *Dies Irae* (1918) begin in an atmosphere of realism, culminating in that of symbolism or mysticism. As a counterpart to this *bürgerliche* trilogy another of mythological or religious character was planned, the first part of which, *Kain*, was acted in 1921. An epic poem, written in hexameters, *Kirbisch* (1927), depicts Austrian mentality as influenced by World War I.

WILD GINGER (*Asarum canadense*), called also Canada snakeroot and colicroot, a small North American herb of the birthwort family (Aristolochiaceae), native to rich woods from New Brunswick to Manitoba and southward to North Carolina and Kansas.



POCHE
WILD GINGER (ASARUM CANADENSE)

It is a stemless perennial with a creeping aromatic rootstock having the flavour of ginger. From this usually rise two large kidney-shaped or heart-shaped leaves, 4 in. to 7 in. broad, on nearly erect leafstalks 6 in. to 12 in. long. On a short stalk between the bases of the two leafstalks is borne a single somewhat bell-shaped, brownish-purple flower, about an inch broad, with three small more or less pointed lobes on the rim. About nine other species of wild ginger are found in the United States, and three of them native to the Pacific coast. Among these are the halberd-leaved wild ginger (*A. arifolium*), found from Virginia and Tennessee southward, and the western wild ginger (*A. caudatum*), native to the coast redwood belt of California and northuard to British Columbia. The allied European species (*A. europaeum*) is asarabacca (*q.v.*).

WILDLIFE CONSERVATION. Conservation means not only the preservation and protection of natural resources but also their wise use. The term, popularized in the United States by Gifford Pinchot, pioneer of American forestry. stands for the husbandry and use of natural resources by the present and succeeding generations. Aesthetic, sporting, economic and intellectual exploitation of landscapes, game, minerals, animals, plants, soils and water is thus implied in the concept. The term wildlife conservation has been used to include an ever-widening group of animals—mammals, birds, fish, reptiles, amphibians, arthropods (such as the lobster) ,and mollusks (such as the oyster)—and in this article is taken to include plants as well. Certain aesthetically and economically important groups of animals have tended to dominate the list; but it is expanding as values broaden, interest in science grows, and increasingly subtle but important relationships among animals and plants are reported.

This article deals with the development of the conservation movement, its approaches and methods, and with the conservation of game animals, birds, sea mammals, fresh- and salt-water fish, and plants. Other aspects of the wider subject of conservation are discussed in the articles FORESTS AND FORESTRY; LAND RECLAMATION; NATURAL RESOURCES; SOIL EROSION AND CONSERVATION; and HUNTING. For information on the national parks, one of whose chief purposes is conservation of both plant and animal life *see* NATIONAL PARKS AND NATURE RESERVES.

This discussion is outlined as follows:

Animal-conservation problems vary widely depending on the type of animal (whether, for example, it is exploited primarily for commercial or recreational reasons, whether or not it is free to range over national boundaries) and on the social and economic conditions of various countries. In North America, Africa and Europe, game animals are widely hunted by sportsmen, over both private and public lands; thus an outstanding factor in wildlife conservation in these regions is the licensing and supervision of hunters. Birds and marine mammals and fish present the need for international agreement and legislation—birds because they migrate across international boundaries and are shot by sportsmen, marine mammals and fish because they live in waters that know no national boundaries and are exploited commercially by fishermen from many countries. Small mammals that are trapped for their furs must be protected by domestic laws, but seals are the subject of international agreement. Salt-water fish, exploited mainly for commercial reasons, are protected by international agreement; but the exploiters of fresh-water fish, chiefly anglers who fish for recreation (except in such large inland water areas as the Great Lakes), are licensed and controlled domestically. The sections of this article reflect these varying emphases—Game Management deals largely with the production and harvest of animals that are hunted for recreation; Bird Protection and Conservation of *Sea Mammals* and ***Fish*** emphasize international agreements. (X.)

I. THE CONSERVATION MOVEMENT

1. The Problem.—During the past 2,000 years the world has lost, through extinction, about 106 forms (species or subspecies) of mammals, distributed by regions as follows (according to the American Committee for International Wild Life Protection): Australia 11, Malay archipelago 3, Asia 3, Europe 6; Africa 9, Madagascar 1, North America 27, West Indies 41, South America 1, Falkland Islands 1, Galapagos Islands 2, oceans 1. Approximately two-thirds of these losses have occurred since the mid-19th century, most since the beginning of the 20th. In addition to those mammals already extinct, many others are vanishing or threatened.

The primary factor in the depletion of the world's fauna has been civilized man, operating either directly through excessive commercial hunting or, more disastrously, indirectly through invading or destroying natural habitats, placing firearms in the hands of peoples who previously were without them or introducing to the primitive fauna of certain areas (Australia and various islands) more aggressive exotic (nonnative) mammals. Except in the West Indies, comparatively few species seem to have died out within the past 2,000 years from such natural causes as evolutionary senility, disease or climatic change.

Persons interested in the conservation of wildlife realize that much more is required than the mere protection of individual animals from destruction by shooting and other forms of direct action. Animal protection must begin with the conservation of the habitat—the area where animals feed, rest and breed. This naturally involves the preservation of much besides the animal population itself, including conservation of vegetation cover and soil. The comparatively new science of ecology focuses on the association of living things in natural communities and their mutual interdependence, and on the possibility of preserving the conditions under which the variety and abundance of natural living forms may continue to exist (see ECOLOGY, ANIMAL). But unfortunately in all parts of the world, encroaching upon what remains of our natural heritage, are the immense growth of the world's population and its expanding economic needs, including the consequent extension and intensification of industry and agriculture. This has been accompanied by the introduction of new types of cultivation, by the drainage of marshes, by the general lowering of the water table, by the pollution of rivers and lakes, by the destruction of woodlands and by the indiscriminate use of insecticides and herbicides. In many parts of the world there has also been widespread destruction of forests and other great belts of natural vegetation.

Attitudes toward wild animals liable to be killed for food, oil, skins, feathers or sport are undergoing considerable change in many countries of the world An example of earlier attitudes is well illustrated by Great Britain, which passed through two centuries of so-called game protection, the original purpose of which was to create artificially high populations of grouse, partridge, pheasant, mallard and other sporting species and, at the same time, to reduce the populations of such predators as the stoat, weasel, otter, wild cat and badger, as well as birds of prey including owls. This alteration of the natural equilibrium had many other consequences. particularly in agriculture and forestry. The rabbit and wood pigeon increased rapidly and caused widespread damage. In some places in Great Britain the landscape was changed by the planting of woods and the creation of other new areas, including artificial lakes for wildfowl—all with the purpose of creating larger populations of certain species for sport. Sport was the privilege of the well-to-do. There were strictly kept dates for the shooting of game species, and. most significant, there was very strict etiquette in shooting. Poaching was punished by heavy penalties and was kept under control. As a result, the game species did exceptionally well while the total wildlife resources experienced varied fortunes. The modern view is different: total wildlife conservation is rapidly replacing game protection. (G. TL.)

2. General Origins.—The great conservation movements have all been born of fear, after spectacular catastrophes had taken place or were found to be imminent. Thus in North America it was the complete extinction of the passenger pigeon and the near extinction of big game (especially the bison) in the 19th century that led to the development of a wildlife-conservation movement during the presidency of Theodore Roosevelt. Three decades later the Dust Bowl and its great dust storms provoked the soil-conservation movement that was to grow so rapidly in the U.S.

3. Techniques.—Wildlife-conservation techniques have counterparts in forestry and in soil, water and landscape conservation. They include prohibitions, controls, restoration, subsidy, sanctuary and public ownership.

Prohibition.—Hunting of pheasants and partridges without the landowner's permission was prohibited in the time of Henry VII. Closed hunting seasons on deer appeared as early as 1718 in Massachusetts, and by the time of the American Revolution 12 of the 13 colonies had closed seasons on certain species of game. Limitations on hunting were first applied mainly to protect animals during the breeding season. Bag limits have come to be widely enforced in a number of countries, as have total prohibitions against the hunting of many scarce species. Some prohibitions placed on the hunting and transportation of game in the bag are designed to simplify the work of game wardens. Modern limitations on hunting have successfully adjusted available game supplies to mounting human populations in much of North America and western Europe, but they have been less successful in countries where the rural population is poverty-stricken and poorly fed. Laws against pollution of streams have been slow to appear in heavily industrialized countries and are largely ineffective.

Public Controls.—These may be seen in predator- and rodent-control programs and in the public regulation of hunting (including shooting) and fishing, which has become an accepted tradition in most countries. The exploitation of migratory waterfowl, however, has been successfully regulated only in North America, where international treaties are easier to work out than they are elsewhere. Control of the bird-guano industry in Peru and of the harvest of fur-seal herds on the Pribilof Islands (Alaska) has been extremely successful.

Restoration and *Replacement*.—Artificial methods of offsetting resource depletion appear in the introduction of exotic (that is, nonnative) species, in the establishment of game farms and fish hatcheries, and in programs of habitat restoration. While the introduction of exotic species has in several cases been successful (the ring-necked pheasant in North America), it has been disastrous in others (the house sparrow, starling and carp in America, the European rabbit in Australia and the American gray squirrel in England), and the list of introductions that simply failed is long. Experience proves that harmless behaviour of a species on one continent is no guarantee that it will not become a pest on another. Habitat restoration has frequently proved to be expensive, but its results are dramatic in the restoration of marshes, as many of the national wildlife refuges in the U.S. now testify.

Subsidies.—The oldest types of subsidies are bounties on predators and crop-destroying species, which were offered at least as early as the middle ages in England. Some surviving bounties are deplored by scientists but sponsored by politicians as a form of unofficial rural relief. In the U.S. federal subsidies are intended to encourage municipalities to construct sewage works and farmers to retire land in the soil-bank program.

Sanctuaries and Public Ownership.—Sanctuaries—also called preserves. reserves and refuges—have been prominent in wildlife conservation since the mid-19th century. With the large national parks, they have provided the protection and space critically needed in America and Africa by the larger predators and grassland-dwelling big game and the freedom from human interference needed by nesting birds during the breeding season; in the U.S. they also give migratory waterfowl at least partial relief from hunting pressure. In the United States, public ownership, which usually accompanies the establishment of sanctuaries, facilitates the management of wildlife food and cover resources to an extent seldom possible on privately owned lands. The reverse often applies in Britain and much of Europe.

Public ownership finds its soundest manifestations in the development of sanctuaries and in the preservation of wildlife in national parks, though government ownership of forests in Canada and the U.S. is responsible for the maintenance of big-game populations.

4. Education and Research.—Teaching about wildlife conservation varies greatly in different countries. In the United States it is augmented by the work of private conservation groups and by state conservation departments and the federal government. In Europe and Asia the subject is largely neglected by educators. In Africa, however, growing awareness of the part played by wildlife in soil conservation, land use, economics and amenity is being reflected in education programs. Some universities in emergent territories of the British commonwealth are arranging university faculties for game conservation. Research in wildlife conservation holds much the same promise as it does in other fields of science. Inventories of game populations are so standardized in some parts of the world as to be outside the realm of research, but in many regions inventories of threatened species are still relatively uncommon. Birds native to islands and mammals ranging over wide expanses of grassland appear to be particularly endangered.

5. Wildlife and Modern Society.—The social uses of wildlife include nature study, recreational hunting (including shooting in the British sense) and fishing, photography and simple enjoyment of the outdoors. Sanctuaries are therefore being especially developed for nature lovers, game preserves and national parks for tourists, game-management areas for hunters and nature preserves for the scientific study of biotic communities. These differing cultural approaches separate the wildlife-conservation movement into such components as bird protection (the goal being a complete absence of exploitation), game management and fish management. Conflicting interests in such approaches have in the past divided the wildlife-conservation movement. and it is not clear whether this tendency will disappear or increase.

The economics of wildlife conservation, while seemingly opposed to the ethical and aesthetic aspects, are real In general, the commercial hunting of wild birds and mammals has had disastrous effects: this is the lesson of the passenger pigeon, the Eskimo curlew. the American bison and many other species. Commercial fishing also has its risks, but while the ruined California sardine industry and the depleted North sea fisheries are witness to this, the successful restoration of the Pacific halibut fishery demonstrates that, with proper controls, fish can be harvested on a sustained-yield basis. Vast sums are spent yearly for fishing tackle and hunting equipment, camping gear. boats, motors. dogs, licences and travel connected with these sports, in addition to the uncalculable amounts spent by persons whose sole exploitation of wildlife is aesthetic. The capitalization of the wildlife resource involves a figure of staggering magnitude.

Ethical considerations appear to occupy a central position in wildlife-conservation thinking, but their development has been delayed by the fact that man for so many generations had to fight against nature. Although primitive man had a far more important stake in wildlife than modern man has, it is virtually certain that he had little concept of conserving his game. The disappearance of the moa and the mammoth taught no lessons; the disappearance of the passenger pigeon did. Convinced of the enormous destructive power of man, pioneer conservationists of the early 20th century emphasized the ethical responsibility of their own generation to conserve natural resources for posterity. Modern ecologists perceive that nature is a series of complex biotic communities of which man is an interdependent part; a spokesman for conservationists, Aldo Leopold. has argued that the Golden Rule applies to the lands and to its animals as well as to man. Modern man finds himself responsible for the fate of many products of creation and with a conservation tradition and code of conduct less than a century old to guide him. (J. J. Hi.)

II. INTERNATIONAL CO-OPERATION

As the concept of wildlife preservation gradually spread, particularly in the latter part of the 19th century, the necessity for international co-operation became increasingly apparent. Not only does wildlife know no political boundaries, but efforts to protect an animal in one country are futile if a poacher has merely to slip over the border into another country to evade punishment.

1. Conferences on Africa.—This situation became so apparent in Africa—where many territories ruled by European countries adjoined one another and where game reserves and protection laws were simultaneously springing into being—that in 1900 the plenipotentiaries of the United Kingdom, France, Germany, Italy, Spain, Portugal and the Independent State of the Congo signed a convention "for the preservation of wild animals, birds and fish in Africa."

The 1900 convention was never ratified, but it was the forerunner of the International Conference for the Protection of the Fauna and Flora of Africa, called by the British government and held in London in 1933 under the chairmanship of the earl of Onslow, president of the Society for the Preservation of the Fauna of the Empire. Its final act was to sign a convention, which was duly ratified and which came into force on Jan. 14, 1936. This convention was the foundation upon which the preservation of wildlife in Africa was thereafter built. Moreover, it provided a pattern for protection in Asia and served as a guide wherever laws for nature protection were being formulated. Indeed the convention made special provision for other governments to accede to it, even if they had no territory in Africa.,

Before drawing up its convention the conference arrived at four principles by which wildlife could be preserved from extermination: (1) the creation of protected areas; (2) the regulation of the killing and capturing of animals outside these areas; (3) the regulation of traffic in trophies; *(4)* the prohibition of certain methods of killing and capturing animals. The articles of the convention reflected these principles. Protected areas were divided into three categories—national parks, strict nature reserves and reserves. These were defined so as to indicate the purpose of an area and its degree of permanence.

The convention stressed the importance of making protected areas sufficiently large to allow for seasonal migrations of game. Buffer zones were recommended around national parks and strict nature reserves. In these zones controlled hunting would be allowed but the occupier of the land would have no claim to compensation for damage caused by animals from the protected areas. Consultation among governments was insisted upon when protected areas ran along national boundaries.

Animals in need of protection were divided into two classes: class A for those animals whose need was of special urgency and importance—these might be killed or taken only with special permission of the highest authority in the land; class B for animals requiring a lesser degree of protection, which might be killed or taken only under a special—not an ordinary—game licence. An annex gave the names of African animals placed in these classes and provision was made whereby others might be added in the future. The meaning of the term trophy was defined, and rules were given for the control of trade in trophies. (The most important trophy in Africa is, of course, ivory). The use of motor vehicles or aircraft in hunting animals and also the surrounding of animals by ring fires were prohibited. Recommendations were made for the restriction of various other undesirable methods of hunting.

In a protocol to the 1933 convention provision was made for further conferences, and the first of these was held in London in 1938. Besides being a stocktaking conference, at which action taken and contemplated on the 1933 convention was reported and discussed, this conference recommended that a number of new animals should be added to classes A and B and that there should be exchange of information upon animal diseases. A further conference was also agreed upon, to be held in 1939, with the object of extending to tropical Asia and the western Pacific a regime of protection similar to that established for Africa. World War II prevented the meeting of that conference. (C. L. BE.)

2. Western Hemisphere.—In the Americas protection of nature became a matter of recognized hemisphere policy in 1940 with the signing at Washington, D.C., of the Convention on Nature Protection and Wild Life Preservation in the American Republics. This treaty defined nationa! parks, natural reserves and strict wilderness reserves and set forth criteria for their administration. It reinforced the treaties between the United States and Mexico relating to the protection of migratory birds, and its annex listed species that warranted special protection, including the woodland caribou, sea otter, manatee, trumpeter swan, California condor, whooping crane, Eskimo curlew, Hudsonian godwit, Puerto Rican parrot and ivory-billed woodpecker. Although the convention has not been used to full advantage, it was instrumental in stimulating protective conservation practices in the western hemisphere. An important result was the convening of the Inter-American Conference on the Conservation of Renewable Natural Resources at Denver, Colo., in 1948.

International attention was focused effectively on problems of protecting migratory birds and mammals through the work of such organizations as the International Committee for Bird Preservation, founded in 1922, the American Committee for International Wild Life Protection and other private bodies, and organizations whose activities led to conventions regulating harvesting of whales, oil pollution of the sea, protection of the fur seal and the administration of other oceanic resources *(see* below, *Conservation* of *Sea Mammals and Fish).*

3. IUPN.—A major step to ard co-ordination of the efforts of governments, official agencies and international and local conservation and scientific organizations was achieved at Fontainebleau, France, in 1948, when after preliminary meetings in the two previous years an International Union for the Protection of Nature (IUPN) was founded by representatives of 33 countries, with the encouragement of the United Nations Educational, Scientific and Cultural organization (UNESCO). (F. M. PD.)

4. Africa.—An important step in international co-operation for wildlife protection in Africa was taken by the Belgian government, which summoned the third international conference to Bukavu in the Belgian Congo in Oct. 1953. In amending the 1933 convention the conference added a new class C to protect animals which, though not rare everywhere, were locally in need of special protection. The definition of trophy was extended to cover all parts of the animal. Other measures agreed upon were as follows. There should be stringent control of all arms and ammunition and prohibition of the use of standard military arms, of automatic weapons and of rifles of too small a bore to kill an animal outright. Wounded animals must be followed up; dangerous wounded animals must be reported. The sale, exchange or movement of game meat in quantity should be controlled. The control and conservation of wild animals should be vested in a single, adequately staffed authority in each territory. Naines of persons repeatedly convicted under the game laws should be circulated among territories.

The conference ended with a "fundamental recommendation" which was that another convention should be drawn up to lay down the general policy for nature conservation in Africa and to include the vegetation, soil, water and all other natural resources. It was indeed a long step forward from the few simple schedules of the London conference of 1900.

In 1960 the IUCN *(see* below) launched its African special project in co-operation with UNESCO, FAO and CCTA (Commission for Technical Co-operation in Africa South of the Sahara). The purpose of this project was to inform public opinion in Africa, through African leaders, of the need for nature conservation based on ecological knowledge. and to offer help. Stage I of this project was a preliminary visit by the secretary-general of the IUCN to west, central and east Africa. Stage II was an international conference at Arusha. Tanganyika. J. K. Nyerere, prime minister, gave the conference the "Arusha manifesto," pledging his government to do all in its power to make sure that Africans should continue to enjoy their inheritance of wild animals. Stage III, which started in 1962, was a working team sponsored by IUCN and FAO which would visit African countries to advise on wildlife policies and conservation. (C. L. BE.)

5. **IUCN.**—In 1957 IUPN was renamed the International Union for Conservation of Nature and Natural Resources (IUCN). Through the union and its commissions on ecology, national parks, public information and special committees, scientists and conservationists were aided in securing the effective attention and action of governments to the dangers threatening the natural resources of their countries. **A** survival service was founded to investigate and maintain records of wildlife in danger of extermination and to instigate vigorous protective measures to ensure their survival. In *1954* and 1955 the union sent Lee M. Talbot, an American ecologist, to about 30 countries in Africa, the middle east and Asia to ascertain the status of some of the rarest animals on the earth; as a result of his expedition, improved protection was given many of these species. Other missions were sent to study the lemurs of Madagascar and potential park and reserve areas in Indonesia, Thailand, Burma and Vietnam; special projects to determine ways to safeguard African wildlife and the extraordinary wild populations of the Galapagos Islands were undertaken. The union holds frequent international technical meetings and general assemblies, where authorities from many nations can confer together.

A significant program instigated by a resolution adopted by the union at its general assembly in Greece in 1958 was the adoption by the Economic and Social council of the UN. in 1459. of a proposal to publish a register of the national parks and equivalent reserves of the world. More than 50 nations responded to the secretary-general's invitation, and Part I of the list was issued by the United Nations in 1961; an additional 30 nations were represented in Part II issued by the IUCN in 1962. It will be maintained and expanded on a continuing basis. (F. M. PD.)

6. World Wild Life Fund.—In 1961 the World Wild Life fund was inaugurated. It aimed at raising at least £500,000 ($1,300,000) annually to be spent on conservation in any territory where such measures are needed in the interests of species threatened with extinction. Care was taken to avoid national bias in the organization and in the allocation of the funds. Chief executive positions were held by representatives of the smaller and neutral nations, and the first patron was the prince of the Netherlands; a Belgian was elected president and the headquarters were located in Switzerland. National branches were organized independently in all western countries and in several African territories for the purpose of collecting the money eventually to be spent by the international headquarters. A major field in which the fund could help was that of education and technical research, such as the endowment of departments of conservation at certain universities in emergent countries, particularly in Africa. (W. S.)

7. Special Problem of Africa.—An assessment of wildlife conservation problems all over the world led the IUCN to the conclusion that the accelerated rate of destruction of wild fauna, flora and habitat in Africa—without regard to its value as an economic, scientific and cultural resource—was an urgent international conservation problem and that the disappearance of wildlife would be a biological and cultural catastrophe. Wildlife. at the time of transition from colonial to self-government, was Africa's most neglected but potentially most valuable renewable natural asset.

The problem is twofold: first, conservation of the national parks and faunal reserves; and second, the management of wildlife stocks on lands outside the existing parks and reserves, especially on those lands not suited to agriculture. The great national parks and faunal reserves are important; not only do they have national value to their respective countries but also they are part of the cultural heritage of civilized men everywhere. As living museums of natural history the African national parks, in particular, stood to be the most spectacular areas of their kind—priceless examples without comparison on any other continent.

For a million years certain parts of Africa have been producing wild animals at rates that compare favourably with good present-day domestic livestock production, and this without destruction of the pasturage or soil resources. This phenomenon is worthy of continued study. Research on livestock breeding, meat production and even grassland management is accepted and encouraged; comparable research on wildlife populations and their habitats is urgently needed. The economic use of the ungulate fauna (hooved animals) outside the parks has been little considered in Africa. It has apparently been assumed that modern systems of economic production require the disappearance of wildlife or else disregard its presence. Yet, large-mammal populations, scientifically managed and harvested as a renewable resource. may yield protein foods in areas where livestock production has proved to be difficult or hazardous, and over parts of the African continent these populations offer more efficient and productive results than can be achieved with livestock. The management of wild lands for production of natural crops and the economics of such land use have been demonstrated in several parts of the world less well endowed than Africa, and demonstration projects have been put in motion in parts of Africa.

The ecologist especially questions the advisability of disturbing natural plant and animal communities on lands marginal and submarginal for agriculture. Such areas tend to deteriorate rapidly under the grazing of domestic animals or under cultivation. On these lands, where conventional agriculture is uneconomic or impossible on a long-term basis, there is a need to recognize wildlife as an important nutritional resource.

There are indications that in some areas more protein food could be harvested through scientific management of native animals than by ranching cattle or sheep. In still other areas wildlife can contribute to total meat production, supplementing that produced by livestock. The ungulate fauna of Africa is a valuable economic resource, particularly in areas where human populations are short of meat.

For international co-operation in the protection of birds and flora see below, Bird Protection and Plant Conservation.

(G. TL.)

III. GAME MANAGEMENT

Game is any bird or mammal pursued for sport. Game management is the art of making land produce wild game in sufficient abundance to permit harvest for recreational use. With shotgun, rifle or bow and arrow man accomplishes the harvest, much as did his predecessors—then for survival, now for sport. Species that may be taken are defined by law in all developed countries, and periods of closed season are established to provide protection during the reproductive period. The open season may be limited to a few days or few weeks in any one year. Defining these seasons each year is one of the fupctions of game management.

Hunting regulations are based on the findings of game biologists, who are trained in the earth sciences to understand soil fertility and its influence upon nutritive quality of wild animal foods; in botany and forestry and the means for altering the species composition of farm, forest and marsh; in physiology, ecology and animal behaviour, to detect the subtleties of population changes and their influence upon reproduction; and in statistics and public relations in order to interpret their findings for administrators and the public. Game managers are also concerned with species no longer hunted, such as the whooping crane and Hawaiian goose, and many governmental game departments do intensive work with species not remaining in shootable numbers in their areas.

1. Kinds of Game.—Game species are classified arbitrarily in several ways, such as migratory and resident, or, as below, by their habitats.

Upland or Farm Game.—This includes such animals as squirrels, rabbits, quail, partridges and pheasants (also called small game), species that thrive in association with man, feed on waste grains and weed seeds and have small space requirements and low mobility. Effective management consists of providing the right combination of foods, water and cover, or low, dense shrubbery in which protection can be had from sun, wind, snow or pursuit by predators. Wildlife managers effect increases in these species by diagnosing the requirement that is in short supply locally and supplying it through inducements to farmers, by planting shelter belts of trees and shrubs along highways and field borders. by leaving waste grain from the harvest or by digging farm ponds for water in times of drought.

Forest *Game.*—Deer, bear, turkey and grouse live in forested habitats even when these are interspersed with farms and dwellings. They feed heavily upon mast—acorns, nuts and fruits—and search the forest floor for mushrooms, insects and other small animal life. Forest management practices include selective cutting and thinning to make openings in the leaf canopy, which permits more light to penetrate to the forest floor and induces sprouting of shrubs. Deer seek these growing tips because they are high in nutritive value.

Wilderness Game.—Also known as big game, this group includes species that require much space and are highly mobile (elk, caribou, etc). Although they avoid human settlement they seek agricultural crops when natural foods are in short supply, and game managers may be required to help farmers resist their depredations.

Migratory Game.—This term is used for the waterfowl—ducks, geese and swans—as well as the shore birds, most of which breed far north of their wintering grounds and hence are hunted along their migratory paths. Control of the migratory bird harvest through international agreements—on regulation of open seasons hours during which hunting is permitted and numbers allowable in the hunter's daily bag—is of extreme importance. Agreement among Canada, the United States and Mexico, based on the Migratory Bird Treaty act of 1916, provided this control in North America In Europe each country makes its own regulations with little co-ordination among those sharing the waterfowl of one migratory path (See below, *Bird* Protection.)

2. Game Production.—As Charles Darwin observed, animals tend to multiply in geometric proportion; if there were no natural controls limiting their increase, the world would soon be overrun by quail and rabbits. Game managers attempt to discover the factors that limit the increase of a particular species in a given area, usually by diagnosing deficiencies in foods (diversity, nutritive quality and seasonal abundance), cover for nesting, roosting and escape, and availability of water. Frequently deficiencies are very specific and easily remedied; *e.g.*, brush piles alone usually will lead to a great increase in the number of cottontail rabbits in agricultural areas where food is abundant, and rain water caught and stored in underground tanks will enable thousands of quail to live through months of drought in California and Hawaii. Augmenting the wild game crop by release of pen-reared stock is common practice in Europe but has declined in the United States because such stock by its very success in captivity has been selected for tameness; it neither survives well nor reproduces well in the wild.

The human population explosion has led to great competition for space and also to demands for increased agricultural production. The satisfaction of these needs not only causes a reduction in size of the areas where game is produced but also limits the number of such areas available to hunters. Broadcast chemical sprays for insect control are another serious threat to wildlife, causing mortality both directly and indirectly by decreasing the food supplies. Conversely, introductions of game where no effective predators exist have caused great damage through overpopulation. This is illustrated by the case of the red deer introduced into New Zealand; in mountainous areas that are too difficult to reach for adequate harvest by hunters the deer destroy so much vegetation that erosion and vast land slips result. The European rabbit in Australia provides another familiar example; after 70 years of effort to get it established, it finally overran and denuded the countryside, converting immense areas of pasture land into semi-desert. Kot until the 1950s was it brought under control by means of myxomatosis, an insect-borne virus disease that does not spread to other animals.

3. Game Harvest. — In Canada and many regions of the western United States much public land is open to hunting. Elsewhere in the United States, hunting is by permission of the landowner, and exclusive shooting rights are frequently leased for the year by groups of sportsmen. Many ranchers charge a daily fee for deer or pronghorn hunting on their lands.

In Denmark and Finland farms are leased by organized groups of hunters who actually participate in game management practices. In Great Britain most shooting is let by estate owners to sporting tenants, or done by the owners and their guests, free hunting being available only along the foreshore of the sea, for waterfowl.

In the United States there is a growing trend toward purchase or lease of tracts for management by state and federal game departments. These tracts! known as public shooting grounds, are available to hunters either on a first-come, first-served basis or by reservation. Part of each area is used for shooting and part is held as inviolate sanctuary; a large proportion of the geese of North America now stop at a series of managed areas during their autumn migration, and at one such area in southern Illinois as many as 30,000 Canada geese are shot in one season.

4. Research. — Game-management research is necessitated by the rapidity of environmental change as human populations grow. As the proportion of land covered with concrete — because of urban expansion, construction of airports, highways! etc.—continues to rise, management of the remainder increases in importance. Certain principles, such as the territorial requirements of each species, the carrying capacity of the land, the population turnover and age ratios of different species, emerge as research into the habits and needs of game struggles to keep up with environmental change.

Territorial *Requirements*.—These differ greatly among game species. Adult bears tend to be solitary; peccary bands and quail coveys in winter tolerate members of their own group but repel others; most deer, pheasants. grouse and pronghorn gather in great numbers in winter despite local shortages in food supply, but with the onset of the breeding season their expanded space requirements cause unrest and fighting. Spacing out is maintained in most species by means of scent posts, song and other threats without resort to actual conflict. Thus, many game birds and mammals exert automatic control over their own densities. Species lacking these mechanisms of population control and tolerant of crowding (such as deer) may overpopulate their range and destroy their food supply until starvation occurs. With deer this is especially true since man has extirpated the effective predators from most of their range. Man must now assume responsibility for the predator's function by providing adequate hunting harvest.

Polygamous Species. — Such species as pheasants and deer cannot be overharvested by hunting as long as only males are shot. Despite long open seasons, cock pheasants are never too scarce to fertilize all hens. Deer populations cannot be kept within bounds unless does as well as bucks are shot.

Carrying Capacity. — The capacity of any game range is exceeded when a species becomes so numerous as to destroy or reduce in vigour its food plants. Ranges overbrowsed by deer may require 5 to 15 years to recover; lichen ranges overbrowsed in Alaska required 20 years. Game managers are constantly concerned with refinements in measuring carrying capacity and with clues for early detection of overpopulation.

Population Turnover.—The rate at which a species replaces itself annually is controlled by intensity of harvest and by the natural reproductive rate. The higher the percentage of young, the healthier the population. In short-lived species such as quail and rabbits, 85% live through only one reproductive season. If not shot, they will die of other causes before the year is up; hence liberal hunting is allowable and 50% of the autumn population can be harvested each year without hazard to the breeding stock. In long-lived species with slower rates of population turnover, such as deer, about 25% can be safely harvested each year.

Age Ratios — These provide an indication of population density where numbers cannot be readily counted, as among rabbits, ducks and quail. Birds trapped for banding or game examined in hunters' bags provide information on age ratios that makes it possible to measure the season's reproductive success and rate of population recruitment, and to estimate the allowable harvest. These form the basis for many hunting regulations and give insight into causes of breeding failure.

Stress. — Stress, the term for a group of physiological changes induced by crowding, is a common and subtle force limiting populations. In southern Missouri, when a flood during the breeding season of swamp rabbits caused crowding on the areas remaining above water, two of every three females resorbed their litters and gave birth to no young. When snowshoe hares in Minnesota became crowded at the peak of their cyclic abundance, many fell dead in midwinter, seemingly without cause. Game harvest through hunting prevents crowding and stress.

5. Legislation. — In the United States laws regulating hunting of resident game are established by each state. Wildlife management is accomplished largely by the state conservation departments as a result of the Federal Aid to Wild Life Restoration act of congress. 1937, commonly known as the Pittman-Robertson act, under which an 11% excise tax is levied on sporting arms and ammunition. States must provide matching funds equal to 25%. Similar procedures are followed in countries that have fallen under Soviet influence. In parts of Europe game management and research remain privately exercised functions, either by individuals or voluntary organizations deriving no financial aid from the state.

(W. H. E.)

IV. BIRD PROTECTION

Bird protection has taken shape gradually from a variety of motives. These have included anxiety to keep up or increase numbers of birds valued for food or sport and birds believed to be beneficial to agriculture. Sentiment in favour of songbirds, or of birds generally, and dislike of cruel practices in killing or capturing birds have also become important since the middle of the 19th century. Only in modern times has any general written code emerged. Bird protection is best regarded as that part of nature conservation aiming primarily to protect bird life by specific methods, although secondarily providing background protection for many other animals and plants.

A. Legislation and International Agreements

Among early instances of bird protection were St. Cuthbert's successful efforts, about A.D. 680, to establish a tradition of not disturbing birds, especially eider ducks, on the Farne Islands off Northumberland, and Kublai Khan's closed seasons for birds in the 13th century. In 1534, in England under Henry VIII, an act was passed "to avoide destruction of wilde-fowle" which protected the eggs of herons, spoonbills, cranes, bitterns and bustards, but did not protect the birds themselves even in the breeding season.

1. Continental Europe. — In Germany Lippe-Detmold passed a Bird Protection decree in 1777, Saxe-Coburg in 1809 and Hesse in 1837, the latter forbidding the killing of named species useful to agriculture and the taking of their eggs. In 1837 the Netherlands passed a hunting law giving special protection to lapwings and nightingales and prohibiting egg collecting, except of certain eggs for the table. Most continentai European countries developed voluminous but largely ineffective legislation from then on. In Germany the position was chaotic. In 1890, 55 pages of the laws of Austria dealt specifically with bird protection. Swiss laws were advanced and stringent, including prohibitions of birdcatching and sale of importations, and requirements for children to be taught bird protection in schools. Hungary took a leading part in 19th-century bird-protection development and in 1894 a Hungarian central office for ornithology and a body of field police were created.

2. United States. — In the United States Massachusetts led the way in 1818 with a closed season for American robins. In 1846 Rhode Island prohibited spring shooting of waterfowl. In 1870 California established at Lake Merrit, Oakland, the first state wildlife refuge protecting great numbers of wintering ducks. In 1873' Arkansas prohibited killing wild birds for sale as food, and in 1878 Iowa imposed the first bag limit (25 prairie chickens per day). In 1885 the U.S. department of agriculture established a division of economic ornithology and mammalogy which grew into the later biological survey and then into the U.S. fish and wildlife service. In Oct. 1884 the American Ornithologists' union formed a committee "for the protection of North American birds and their eggs against wanton and indiscriminate destruction." The committee's model law of 1886 for the protection of nongame birds was adopted that year by New York and Pennsylvania, and many other states followed.

In 1900 was passed the Lacey act, the first comprehensive federal law for bird protection, followed quickly by both voluntary and federal wildfowl refuges (Pelican Island, Fla., 1903) and by the incorporation in 1905 of the National Association of Audubon Societies (National Audubon society, 1940). In 1916 the Convention for the Protection of Migratory Birds in the United States and Canada provided a firm foundation for bird protection throughout North America, except for Mexico which adhered by separate treaty in 1937.

3. Great Britain. — In Great Britain modern bird-protection legislation dates from the Act for the Preservation of Sea Birds, 1869. This was secured through a movement promoted by the vicar of Bridlington in Yorkshire and was prompted by slaughter of sea birds on Flamborough cliffs, where one man in one year killed 4,000 kittiwakes. The 1869 act was judged a success in saving breeding colonies from extinction and was followed in 1872 by another protecting some 80 additional species during the breeding season. In 1876 a closed season (Jan. 15 to July 10) was imposed for wildfowl. Subsequent acts extended protection to eggs and gave power to create bird sanctuaries (1896). In 1954 all previous legislation was superseded by the Protection of Birds act, giving complete legal protection throughout Great Britain to all wild birds and their nests and eggs with certain exceptions (principally in respect of birds to be shot or taken as game or as pests). Special penalties were made available for offenses on sanctuaries, (which could also be closed to public access) and in respect of rare species. Licences for scientific purposes and for falconry were authorized, and various cruel or destructive aids to killing or taking were prohibited.

4. British Commonwealth. — The first Canadian wildfowl refuge was established in 1887. Most of the Canadian provinces introduced legislation for the protection of wild birds about 1895–98. following several other British territories led by Queensland and British Guiana (1877), New Zealand (1880), Hong Kong (1885) and India (1887). In Canada bird protection since 1917 has been governed by the Migratory Birds Convention act following the convention with the U.S. It is administered by the Canadian Wildlife service, created in 1947, with the help of provincial authorities. In several commonwealth territories bird protection is merged with that of mammals and reptiles (*e.g.,* in the Fauna Protection act of 1950 in Western Australia).

5. International Measures. — Except in North America, repeated efforts toward international bird protection have been only partially successful. These efforts began in 1868 with an appeal from the General Assembly of German Farmers to the Austrian and Hungarian governments to join in a convention for the protection of birds useful to agriculture and forestry. In 1869 the Italian, French and Swiss governments indicated their support, and in 1875 an Austro-Hungarian agreement with Italy was signed.

Eventually, in 1902, an International Convention for the Protection of Birds Useful to Agriculture was concluded by Austria-Hungary. Germany, France, Spain and several smaller European countries (Great Britain and Italy not taking part). Only France, Hungary, Belgium, Sweden and the Netherlands ratified it. A subsequent convention was provisionally adopted in 1950 at Paris and has been ratified by a few countries. The International Council for Bird Preservation (I.C.B.P. or, in French, C.I.P.O.), organized in London in 1922, has promoted much useful action, including the International Convention for the Prevention of the Pollution of the Sea by Oil. concluded in London in May 1954. The committee also. by arrangement with the International Union for Conservation of Nature and Natural Resources, watches over species of birds listed as in danger of extinction. The International Wildfowl Research bureau at Le Sambac in the Camargue, France. under the auspices of the I.C.B.P., serves as a clearing house for information and advice on wildfowl research and conservation.

6. Modern Trends. — In summary, the following trends in the protection of birds may be observed. (1) to codify the law, making it simpler and more easily understandable; (2) to co-ordinate different objectives, utilitarian. sporting, aesthetic and humanitarian, giving increasing weight to conservation and scientific factors; (3) to promote education, especially in schools, and public information about the law and the broad objects of bird protection; (4) to strengthen enforcement, where necessary by means of specialized officers such as rangers or field police; (5) to make specific and flexible exceptions to meet the needs of scientific research, museums, etc., and generally to prohibit disturbance without any valid purpose; (6) to prevent undue shooting pressure by such means as adjustment of closed seasons and by limits; (7) to prohibit killing or taking by cruel or unduly destructive means, and to suppress illegitimate or commercial exploitation of bird life such as plumage hunting or birdcatching for the cage or collecting eggs or stuffed birds as a hobby or for ornaments; (8) to co-ordinate international action, for example by prohibiting import into advanced countries of birds needing protection in their areas of origin; (9) to rely increasingly on scientific investigation and conservation — for example, by provision of refuges and reserves or sanctuaries and by encouragement or provision of suitable food and shelter.

B. Choice and Management of Refuges

Refuges may be selected for many different purposes. Some offer security from persecution or disturbance to scarce, vulnerable or shy species while breeding, while at halting places during migration or in winter quarters. (Breeding colonies of aquatic birds, or areas where waterfowl flock during the open season are prominent instances.) Other reserves are designed to preserve or recreate habitats threatened by reclamation, such as marshes, fens or tall native forest. In some cases such habitats are artificially provided by tree planting or by excavating pools, for example, in areas where they were previously absent. Some are managed experimentally for scientific research or to devise improved conservation techniques. Others are show places where human visitors can watch this wildlife at close quarters (as at the Hawk Mountain sanctuary in Pennsylvania, where thousands of hawks and eagles can be seen on migration'), or where ornithologists, bird photographers, makers of sound recordings and others can satisfy their requirements. Others are kept as free as possible from all intrusion. The underlying principle is, as far as practicable, to combine the conservation of the birds with the enjoyment of sightseers and with meeting the needs of specialists or photographers, but where bird conservation would suffer from even limited disturbance, the birds' welfare must come first. In some cases. for example in rhe royal parks of London, bird sanctuaries are set aside to provide small areas of quiet cover or quiet water for ordinary birds in heavily populated metropolitan districts.

Modern management aims to measure the pressures bearing most heavily on protected birds and to relieve excessive pressures by suitable adjustments. For example, access may be prohibited or limited to conducted parties at certain times (*e.g.*, in the breeding season), or to certain zones. or to observation posts from which the birds can be seen without being disturbed, as at the Wildfowl trust refuge at the New Grounds, Slimbridge, Eng.

The number of sites classed as bird refuges is often large—Switzerland alone has more than 100—but generalizations on the distribution and value of bird refuges in the various countries would be seriously misleading. The great majority are, however, in North America and in northwest Europe. While many are maintained by bird protection societies, others are operated by central and local governments and a wide variety of other agencies.

1. Predators and Pests.—Several early bird sanctuaries allowed pests to multiply. but it has become generally recognized that where this would happen control, especially of crows. rats and foxes, is essential. The need, however, usually arises only where the fauna has already suffered from unwise human interference. The ideal of nonintervention is successfully practised in many refuges, where this is not the case, in the United States and elsewhere. In principle, modern bird protection policies call for protection of all species at all times except insofar as control or "cropping" of certain populations by explicit means and at certain seasons is shown to be justified. The labeling of any species permanently as "harmful" or "beneficial" is not scientifically favoured.

2. Feeding.—Excessive pressure on food is sometimes relieved, especially in the United States, by artificial feeding, by aerial or other planting of suitable mild foods (*e.g.*, wild rice), or by crops (*e.g.*, cereals) deliberately left in the fields to be eaten by waterfowl. Jack Miner's pioneer waterfowl refuge at Kingsville, Ont. (1907), showed how much could be achieved in this way. The C.S. fish and wildlife service and other C.S. organizations developed by experiment various successful means of artificially expanding or supplementing the food resources which determine the carrying capacity of refuges in terms of bird populations. Bird tables and feeding devices are widely used in Europe and North America for similar purposes. In order to ensure that the Hawaiian goose is kept in existence, parts of the stock are being reared in captivity. about one-half of the world population in the early 1960s being so maintained by the Wildfowl trust at Slimbridge and elsewhere in England by arrangement with the Hawaiian authorities.

3. Provision of Breeding Sites.—Shortage of breeding sites is a limiting factor for many species and progress is being made by research and experiments in increasing the numbers and enlarging the range of certain species. In North America the wood duck has taken readily to artificial nest boxes on posts in standing water, where the ducks and eggs are relatively immune to predation by raccoons and other mammals. Experiments with hole-nesting birds have been carried out in Germany, the C.S.S.R.. England and elsewhere on titmice, pied flycatchers and other species. with, in several cases, striking success. At Patuxent Research refuge, Md., the U.S. fish and wildlife service has induced wintering Canada geese to stay to breed far south of the normal breeding range by providing suitable artificial islets and by meeting other habitat requirements. Nesting boxes are among the most generally effective and attractive devices for practical bird protection, but faults in design. siting or construction often cause failures.

4. Other Practical Assistance.—Among other practical methods of bird protection mention must be made of provision of perches on lighthouses and floodlighting of the structure to prevent heavy casualties in poor visibility. First-aid measures are applied where aquatic birds are exposed to oil pollution or at times when onset of cold weather leads to heavy mortality of insectivorous or other delicate species in winter quarters or on passage. Aircraft. including helicopters, are used in such situations for dropping food supplies or even for ferrying numbed and exhausted birds to warmer climates; *e.g.*, swallows have been so carried across the Alps. Icebreaking on frozen waters is also undertaken.

5. Education and Information.— Apart from such practical measures to assist particular bird populations, much can be done rnore generally to educate and inform people of all ages of the importance of bird protection and the means of encouraging bird life or of avoiding actions injurious to it. For example, the Massachusetts Audubon society (founded 1896) conducts special courses in conservation and natural science. reaching regularly about 15,000 boys and girls in the state grade schools, and operates five natural history day camps and one resident camp for boys and girls. The National Audubon society of the U.S. provides extensive and excellent services and literature for schools. giving practical programs and instructions. Bird day is observed in schools in many states. In Hungary a Bird and Tree day was established in 1906, but in most European countries teaching in schools is not general. There are, however, active conservation societies at work, such as the Royal Society for the Protection of Birds in Great Britain (founded 1889). In Great Britain and certain other countries. television and broadcasting services concern themselves with bird-protection matters on a large scale and at a high standard, and nature films also help in educating and informing the public.

6. Control of Undesirable Human Interference.— Success in bird protection calls for effective control of undesirable human interference. For this purpose it is necessary to know what is undesirable, and accordingly to have adequate provision for scientific research and for consultation regarding its practical application among the interests concerned. Experience shows that unless these two needs are satisfactorily met legislatures cannot agree to adopt. nor can governments enforce, reasonable measures of bird protection. In Great Britain they are in principle covered by statutory wild birds advisory committees to advise the secretaries of state (for Scotland, and for England and Wales respectively) and by the official nature conservancy and other agencies, which are represented on these committees and are responsible for providing them with a scientific basis for recommendations, and for advising on repercussions on agriculture, fisheries, sport and so forth. The U.S. fish and wildlife service and the Canadian wildlife service fill similar roles in the United States and Canada. An important problem is to ensure that sectional interests do not pursue conflicting private control policies of their own—for example, regarding predators—often in defiance of the law. The problem, however, is not only one of law enforcement. Both in the United States, at the Aransas refuge for whooping cranes, and in Europe. at the Knechtsand molting area for shelducks, problems arose over threatened destruction of important and vulnerable bird populations by air force bombing ranges. In these instances satisfactory settlements were negotiated, but there is constant danger of major engineering and development projects nullifying bird-protection policies. Protection against cruelty or persecution is part of a wider problem on which public opinion in many countries is still backward. and it is often difficult to enforce the ban on illegal methods of killing or taking in remote places, and especially on private land. (E. M. N.)

V. CONSERVATION OF SEA MAMMALS AND FISH

The seas, apart from narrow coastal zones, are international. and the principle of the freedom of the high seas is well established; hence conservation measures affecting high-seas fisheries are usually subject to international agreement. In general. conservation problems increase in relation to the number of governments involved and are least when the interests of only a single country are at stake, as in many coastal and inland fisheries. The basic principles of conservation are similar in both coastal and pelagic fisheries, and this article therefore deals largely with the more important international conservation measures and organizations.

1. Whales. — Whales are particularly vulnerable to commercial exploitation because of their slow reproductive rates. Historically they have been progressively depleted. species by species, in region after region, and effective conservation measures have proved difficult to apply. When it became apparent that the antarctic stocks of baleen whales were being depleted, restrictions were introduced and a number of international agreements were concluded. The 1931 convention was followed by the agreements of 1937 and 1938, while in 1929 the Bureau of International Whaling Statistics had been established.

After World War II the machinery for regulation was greatly improved by the signing in 1946 of an International Convention for the Regulation of Whaling by 15 contracting governments. The convention set up the International Whaling commission (I.W.C.), which has scientific and technical committees to discuss and report on relevant biological research and advise on conservation measures and procedures. Research is undertaken by some of the member governments. The I.W.C. is empo ered to fix an over-all limit to the antarctic pelagic catch of baleen whales, which in 1959–60 comprised 80% of the total world catch of baleen whales. Competition resulting from increased catching capacity has brought the industry to the limit of economic operations. As a result of associated developments Norway and the Netherlands withdrew from the convention in 1959. Norway rejoined in 1960 but withdrew again late in 1961.

Other important conservation measures applied to whaling have been complete protection of some species, restriction of whaling seasons, minimum length regulations, protection of calves and suckling females, sanctuary areas and provision for utilization of the carcasses and for inspection. In spite of these measures whale stocks have been seriously depleted, but the depletion would certainly have been much more rapid and catastrophic without the restraint imposed by the International Whaling commission.

This convention also regulates pelagic whaling in areas other than the antarctic and shore whaling operations. Chile and Peru, which have whaling industries, are not signatories but, with Ecuador, are member governments of the Permanent Commission for the Exploitation and Conservation of the Maritime Resources of the South Pacific (C.P.E.C.R.M.P.S.), which is concerned with whale conservation among other things.

2. Seals. — Seals breed on land and in this respect are more vulnerable to hunters than whales, but their more rapid reproduction means a quicker build-up of depleted stocks. The history of the northern fur seal, hunted for its fur, provides a classic example of sound conservation practice. The rise of indiscriminate pelagic fur sealing by U.S., Canadian and Japanese nationals in the 1880s caused serious depletion of the fur-seal herds in the North Pacific, but it was not until 1911, after prolonged negotiations, that a convention signed by Great Britain. the United States, Russia and Japan prohibited pelagic sealing and opened the way to rational management. The United States, Japan and Russia each undertook to manage its respective herds and to divide the proceeds of the sale of skins among all four governments. Management on the Pribilof Islands has included the protection of females and the restriction of killing to surplus three- and four-year-old males. The annual kill is determined by population studies, and there is no commercial competition since killing is in the hands of a single contractor. In 1941 Japan withdrew from the convention, claiming that the objectives had been achieved and that the seal herds had become so large that they were damaging Japanese coastal fisheries. In 1952 an interim agreement on co-operative research was negotiated and in 1957 a new Convention on the Conservation of the North Pacific Fur Seals was signed, setting up a commission that co-ordinates research on the seal populations and their effect on other marine resnurces.

The southern fur seals are also recovering under complete or partial protection from the effects of indiscriminate sealing in the 18th and 19th centuries, and there are small industries in South Africa and South America. Conservation of the elephant seal is also of long standing. Exploitation of the herd at South Georgia has been regulated since 1910, and it supports a thriving industry, taking an annual quota of adult. males.

In the north there was for many years a joint Norwegian-Russian sealing commission with consultative status. In 1958 Norway and the U.S.S.R. signed an agreement on measures for conservation of seal stocks in the northeast Atlantic. This covers harp and hooded seals and walrus and may be extended to bearded and ringed seals and polar bears. It includes provision for fixing open seasons and prohibiting certain methods of catching, and a commission was established to recommend measures relating to co-ordination of research and regulation of sealing. In the northwest Atlantic where Canada and Norway exploit the stocks the only control is an informal agreement relating to the starting dates for taking young seals. (See also SEAL FISHERIES.)

3. Other Sea **Mammals.**—In addition to whales and seals, both of which are exploited commercially on a large scale, there are the sea otter of the North Pacific, still increasing in numbers after complete protection since 1911; the polar bear, now partially or completely protected in most parts of its range; and the manatee and dugong. which also receive some protection in most areas they inhabit. The International Union for the Conservation of Nature and Natural Resources watches the status of these and other animals.

4. Salt-Water Fish. — For biological reasons fish stocks are less easily depleted than mammal populations, hence conservation measures rarely include the prohibition of fishing. More usual measures include fixed annual catch quotas, closed seasons. sanctuary areas (frequented by immatures), mesh size regulations (to allow escape of small fish), minimum sizes of fish to be landed, and prohibition of gear considered destructive.

The aim of conservation of exploited stocks. which are usually the only ones needing conservation, is to attain the maximum sustainable yield and at the same time to keep the catch per unit effort (*e.g.*, the catch per hour's tra ling) as high as possible so as to minimize the cost of fishing. It has been shown for a number of fish stocks that by introducing regulatory measures such as the selection of a suitable mesh size; and reducing the over-all fishing effort, it is possible to increase the annual yield. These measures depend on intensive and continuing research on the various stocks of fish, for the solutions to conservation problems vary according to the type of fishery and the resource exploited.

Atlantic Ocean. — It was formerly thought that fish resources were inexhaustible) but with the improvements in fishing techniques and enlargement of markets it became apparent toward the end of the 19th century that certain fish stocks were declining and that conservation measures should be introduced. Following conferences in 1899 and 1901, the International Council for the Exploration of the Sea (I.C.E.S.) was founded in 1902. This organization, an intergovernmental body with the function of co-ordinating and advising on research in the northeast Atlantic, has committees on special topics and on different areas; and the results of investigations are discussed at its meetings. Statistics and scientific results are published.

In the 1930s an intensification of fishing and decreased catches lent urgency to the efforts to reach agreement on conservation measures, and conventions were signed in 1929. 1932 and 1937. The last, the most important and comprehensive, was sigried by ten countries but for various reasons was not ratified by all the signatory governments. An International Fisheries convention, negotiated and signed by 12 countries in 1946, became effective in 1954. It was concerned with mesh sizes and minimum sizes at which a number of species of fish may be legally landed. A permanent commission (P.C.I.F.C.) was set up to advise on extending or altering the provisions of the convention after consultation with I.C.E.S. In 1959 a new agreement, the North-East Atlantic

Fisheries convention. signed by 14 governments, replaced the 1946 convention. It covers a larger area. including the Barents sea, and is more far-reaching in its provisions. The resultant North-East Atlantic International Fisheries commission. which planned to establish three regional committees. may consider any conservation measures for any species of fish, and provision is made for international inspection.

The long-established and productive Rank fisheries of the northwest Atlantic are fished by many European and North American countries. When it was recognized that conservation might be necessary the International Korthwest Atlantic Fisheries convention was signed in 1949 and the 11 member countries set up a commission (I.C.N.A.F.) with a small scientific staff. Subareas roughly corresponding to separate fish stocks mere defined, and panels were formed to co-ordinate research and recommend conservation measures for each area. Research is carried out by member governments and the commission has a co-ordinating role, but can undertake research if necessary.

These two North Atlantic organizations are concerned mainly with groundfish such as cod, haddock, redfish and plaice.

Mediterranean Sea.—A Commission for the Scientific Exploration of the Mediterranean Sea (C.I.E.S.M.M.), set up in 1919, is not directly concerned with fishery problems. The General Fisheries Council for the Mediterranean (GFCM), sponsored by the Food and Agriculture organization of the United Nations (FAO), has 11 member countries and dates from 1949; it functions as an advisory body on research and development.

Pacific Ocean.—In the Pacific ocean there are two international fisheries commissions which, like I.C.E.S., were set up before World War II, and a number of organizations of postwar origin.

The International Pacific Halibut commission (I.P.H.C.), formerly the International Fisheries commission (I.F.C.), and the International Pacific Salmon Fisheries commission (I.P.S.F.C.) were established in 1923 and 1937 respectively. Unlike I.C.E.S. or I.C.N.A.F., they themselves conduct research and regulate the fisheries by fixing quotas and other restrictions. The I.P.H.C. provides a unique and successful example of international regulation and management of a fishery and has set a pattern for several later commissions. It has the advantage, however, that only two countries, Canada and the United States, are involved. Under its supervision the halibut fishery of the northeast Pacific, which had been disastrously depleted by unrestricted fishing, has been successfully restored; by 1954 the annual production was over 50% higher than before regulation by the commission, with only half the previous fishing effort. The management policy adopted in 1932 was preceded by thorough scientific investigation, and included catch quotas, a closed season and protection of nursery grounds. The authority of the commission was broadened by later conventions in 1937 and 1953, and the conservation measures are revised from year to year in the light of improved knowledge of the stocks.

The I.P.S.F.C.. also the result of a bilateral convention and similar to the I.P.H.C., has been markedly successful in restoring stocks of sockeye salmon.

The International Convention for the High Seas Fisheries of the North Pacific Ocean, signed by Canada. Japan and the United States. set up an International North Pacific Fisheries commission (I.K.P.F.C.) similar in scope to I.C.N.A.F. in the northwest Atlantic. This convention employs the principle of abstention. which provides that if it can be shown that a stock of fish is being fully utilized by one or more contracting parties and is under scientific management. then parties that have not historically fished these stocks agree not to engage in fishing them. For the salmon fisheries a provisional boundary was fixed to define salmon stocks of Asian and North American origin. The convention has enforcement provisions which may be reviewed from time to time. Research is to be undertaken by contracting governments, but the commission has a small scientific staff to plan and co-ordinate research.

A convention between Costa Rica and the United States, later joined by Panama, set up in 1950 the Inter-American Tropical Tuna commission (I.-A.T.T.C.) which investigates the biology of tunnies and bait fish. This has its own scientific staff to conduct research. and recommends measures to maintain the stocks at a level that would permit maximum utilization. The 16-nation Indo-Pacific Fisheries council (IPFC), sponsored by FAO and set up in 1948, co-ordinates and reports on research on fisheries and related subjects carried out by member governments (like I.C.E.S. in the North Atlantic). A South Pacific organization with wide terms of reference similar to the FAO councils (GFCM and IPFC) but with regulatory powers, is C.P.E.C.R.M.P.S., referred to above in connection with whale conservation.

For a more detailed discussion of the techniques of fish conservation and fisheries management, see FISHERIES: Scientific Research a d *Fisheries Conservation.* (R. M. Ls.)

5. Fresh-Water Fish.—Fishing (*q.v.*) is one of the most popular outdoor sports. and both recreational and commercial fresh-water fishing are of great economic importance. Since, however, only a small percentage of fresh-water fish have either sport or commercial value, management efforts are mainly limited to these few.

The increasing use of water for individual consumption, industry, irrigation and navigation has created serious problems in fish conservation. Industrial wastes, municipal sewage and silt from eroded farm lands have poisoned many kinds of fish or eliminated them by destroying their food supplies and spawning grounds. Dams have blocked runs of migratory fishes. Increased private ownership of lands and waters has interfered with public use of natural resources. To meet these problems, better methods of waste disposal are being developed, and laws have been enacted to prevent pollution. Where practical, fishways are built so that migrating fish can pass safely around dams. More lands are being purchased by public agencies to provide access to public' waters. Sometimes! where the conservation of fish is incompatible with other uses of the water, the fish are sacrificed. These losses can be offset by creation of new fishing ponds, hydroelectric impoundments or water supply reservoirs. Even in waters where there is no conflict in use, overfishing, slow growth of fish, competition from undesirable species or scarcity of some life requirement such as spawning grounds may be problems.

Number and size of fish harvested, fishing seasons and gear are often restricted by law to preserve sufficient spawning stock or protect fish until they reach a sporting or marketable size. Prolific fishes (such as bass and panfish) need little protection, and liberalization of restrictions on these species has greatly increased fishing opportunity. Where undesirable species are abundant, poisons can be used to kill all the fish in a lake, after which one or a few desirable species are reintroduced. Poisons can also be used to thin out overabundant populations where growth is slow, and chemicals have been developed that kill only a certain type of fish, such as the destructive sea lamprey. Fish are raised in hatcheries for restocking waters after deliberate poisoning, pollution or natural catastrophes. Sometimes only an introductory stocking is necessary. after which the fish perpetuate themselves. Where fish cannot reproduce successfully the waters can be regularly restocked. New fish-management techniques are being evolved continually through scientific research.

(J. T. McF.)

VI. PLANT CONSERVATION

Plant conservation has to do with the preservation of species or communities of plants that are of interest for their beauty, rarity or inherent scientific value. It is distinguished from forest conservation. which is concerned with the proper methods for utilization of forest trees as sources of commercial wood products, but it may include the preservation of individual tree species of particular interest (see FORESTS AND FORESTRY). The goals of the plant-conservation movement (illustrated by the three methods of approach described below) are: to stop, through legislation and education, the needless destruction of interesting or beautiful wild plants over large regions; to ensure the preservation of such plants and the communities in which they occur through the creation of sanctuaries, nature reserves or scientific-study areas; and finally to prevent the complete extermination of as many rare species as possible through cultivation and permanent maintenance in special botanical gardens.

1. Protective Laws.—Several different methods of plant preservation are in general use. One of these is the enactment of protective laws prohibiting the picking, mutilation, destruction or sale of certain enumerated species. usually those in danger of extermination in the region covered by the laws. Many countries provide such protection for cherished wild flowers. and many tropical countries have similar laws regarding the collection and exportation of orchids and other plants of horticultural value. Usually such laws can be effective only for plants growing on government-owned lands, since private ownership of land generally entails the right to dispose of the plants as the owner desires. The method is most valuable in local or national parks, where protection of all plants is comparatively easily enforced.

2. Sanctuaries.— A second approach to plant conservation is based upon the protection of particular tracts of land or pieces of landscape rather than individual species of plants. These tracts are variously called wild-flower sanctuaries, nature reserves, scientific areas, natural areas, etc. Establishment of such reserves is based on recognition that the destruction of the habitat is a far more serious menace to the survival of interesting wild flowers than is any amount of flower picking or other direct utilization of the plants. A further benefit derived from area preservation results from the fact that plants grow in mixed populations, or plant communities, and that protection of a given area thus preserves all plant species in the local community rather than just one or two species. *(See* also PLANTS AND PLANT SCIENCE *Plant Ecology.)* It cannot. however. be too strongly emphasized that effective preservation involves adequate control measures. These may be of communities. as when a particular phase of the natural succession, such as scrub. must be stabilized. or of particular species which become aggressively abundant or need to be artificially encouraged. The acquisition of the requisite techniques to achieve these aims is one of the prime necessities for success. Nothing is further from the truth than the widespread belief that noninterference will achieve preservation.

Many organizations have been concerned with the preservation of wild flowers and with the creation of sanctuaries or other reserved areas. The first such group, the Association pour la Protection des Plantes, was formed at Geneva, Switz.. in 1883 under the leadership of H. Corevon and other prominent botanists. It was devoted largely to the prevention of mass destruction of alpine plants by collectors and dealers in plants for rock gardens. Similar associations with comparable aims were formed in Italy in 1899 and in Germany in 1900.

The Wild Flower Preservation Society of America, organized in 1902 in New York under the sponsorship of the New York Botanical Garden, spent much effort in its early years on educational aids to improve wild-flower appreciation by means of bulletins, posters and motion pictures. After 1930 the society began to urge the creation of wild-flower sanctuaries as the best method for plant conservation and, through the co-operation of local garden clubs, was successful in stimulating a number of them in eastern North America. In the United Kingdom a Society for the Promotion of Nature Reserves was founded by Charles Rothschild with headquarters at the British Museum (Natural History) in London in 1912 and early began the acquisition of nature sanctuaries for the preservation of both fauna and flora. Wild-flower preservation societies were formed about the same time in Australia and South Africa.

In the United States there exist a number of plant-conservation organizations with special objectives. The Save-the-Redwoods league, for example, was formed in California in 1918 to promote the purchase of outstanding groves of sequoia trees and to protect them from destruction by lumbering. Several groups—including the Natural Areas committee of the American Society of Foresters, the Grassland Research foundation and the Nature Conservancy—are organized to urge the preservation of examples of complete plant communities. The members of these groups believe that future research of basic interest in fields dealing with land management, such as forestry, range management and applied ecology, will be dependent on a widespread and complete system of natural area reserves. The first official U.S. governmental organization for the same purpose was created in Wisconsin in 1951 when the legislature of that state formed the Wisconsin State Board for the Preservation of Scientific Areas.

Similar organizations devoted to the preservation of plant communities for scientific-study purposes exist in many other countries. Notable examples are the Nature Conservancy in Great Britain, the All-Russian Society of Nature Protection in the U.S.S.R. and government-sponsored agencies in the Netherlands and other European countries. All of these are affiliated with the International Union for the Conservation of Nature and Natural Resources, with headquarters in Morges, Switz.

3. Botanical Gardens.—The third approach to plant conservation is concerned with the conservation of plant species as living repositories of definite genetic constitution. As such, it seeks to prevent the extinction of rare plant species because of the actual and potential value of the germ plasm they contain. This is most readily accomplished by growing the species in special botanical collections under suitable environmental conditions. Several of the very first efforts at plant conservation employed this method. Anton Kerner established a garden in the Austrian Tirol in 1875 for the cultivation of alpine plants in danger of extermination. Similar gardens were started in Switzerland in 1883 and in Germany in 1900. Other Alpine gardens are maintained by educational institutions of the region, such as that of Grenoble university near Lautaret. France.

A number of botanical gardens and arboreta have expanded this approach by restoring or establishing entire communities so that the rare plants may exist under as nearly natural conditions as possible. The earliest efforts along these lines were conducted by the botanic garden at Bremen, Ger., and by the University of Wisconsin arboretum at Madison, Wis. See also BOTANICAL GARDENS; ARBORETUM. (J. T. Cu.)

WILDMAN, SIR JOHN (1623–1693), English agitator, outlasted political vicissitudes under three kings and two protectors. He was of obscure ancestry and was educated at Cambridge. He first came into prominence in Oct. 1647, when he helped to write

The Case of the Army and the first *Agreement of the People,* expressing the political program of the democratic republican, or Leveller, section of the army, which opposed all compromise with Charles I. (*See* LEVELLERS.) In the debates which took place during 1647 in the general council of the army he defended this program against Henry Ireton and Oliver Cromwell (*q.v.*). Afterward he violently attacked these two in *Putney Projects* and with John Lilburne (*q.v.*) agitated for the abolition of the monarchy and the house of lords. He was thereupon imprisoned (Jan.–Aug. 1648). After his release he helped to draw up the second *Agreement of the People.* He acquiesced in the establishment of the Commonwealth and his name appeared in Aug. 1649 as a major in Sir John Reynolds' regiment: but he devoted most of his time to building up a considerable fortune by land speculation, both on his oun behalf and as agent for others who made use of his wide knowledge of the law. In 1654 he was returned to the first Protectorate parliament. but his election was disallowed. Thereupon he began to conspire with malcontent army officers for a rising against Cromwell and was again imprisoned (Feb 16j5). He was released in July possibly after undertaking to spy upon the royalists. uith uhom he was now in touch. But he occupied himself chiefly in trying to organize a Leveller and royalist rising with Spanish aid and to get Cromwell assassinated. He now came under the influence of the political philosopher James Harrington (*q.v.*) and, after the fall of Richard Cromwell, co-operated with the leaders of the Rump Parliament in the hope of eventually establishing a modified form of democratic republic on the model of Harrington's *Oceana* After the restoration he obtained great influence in the post office, but was again imprisoned (Nov. 1661) for six years on suspicion of using it as a centrè for republican plotting. He owed his release to the duke of Buckingham, with whom he had intrigued before the Restoration. In 1670 he went abroad but was home again by 1675. acting as the duke's solicitor and one of the trustees of his estate. He supported the duke in opposition to the Danby ministry and sided with the earl of Shaftesbury during the "popish plot" agitation. but voted against the Exclusion bill since he preferred a strict limitation of the royal power as being more akin to a republic. He was again imprisoned in 1683 on suspicion of complicity in the Rye House plot. He took no active part in Monmouth's rebellion (1685), but afterward fled to Holland. In 1688 he wrote the influential pamphlet *A Memorial of Protestants* and. returning to England with William of Orange, became a member of the 1689 Convention Parliament. He was appointed postmaster general in Xpril 1689 but fell once more under suspicion and was dismissed in Feb. 1691. Nevertheless he was knighted in 1692. He died on June 4, 1693, leaving an only son, John. who died childless in 1710.

See M. Ashley, *John Wildman, Plotter and Postmaster: a Study of the English Republican Movement in the seventeenth century* (London, New Haven, Conn., 1947). (R B. WM.)

WILD RICE or INDIAN RICE: *see* RICE, WILD.

WILFRID (c. 634–709), English archbishop, born in Northumbria. He attracted the notice of the queen, Eanfled, who placed him in care of an old noble. Cudda, then a monk at Lindisfarne. Later on Eanfled enabled him to visit Rome in the company of Benedict Biscop. On leaving Rome he spent three years with Annemund. archbishop of Lyons. After the murder of his patron he returned to England, where he received a monastery at Ripon, and then took priest's orders.

He was probably already regarded as the leading exponent of the Roman discipline in England when his speech at the council of Whitby determined the overthrow of the Celtic party (664). About a year later he was consecrated to the see of York, not, however, in England, where perhaps he could not find the fitting number of orthodox prelates, but at Compiègne. On his return journey he narrowly escaped the pagan wreckers of Sussex, and reached England to find Ceadda (St. Chad) installed in his see.

The rest of his life is largely a record of wandering and misfortune. For three years (665–668) he ruled his monastery at Ripon in peace, though acting as bishop in Mercia and Kent during vacancies in sees there. On Archbishop Theodore's arrival (668) he was restored to his see, and spent in it nine years of ceaseless activity, especially in building churches, only to be driven out through the anger of King Ecgfrith's queen (677).

After Ecgfrith's death (May 20, 68j) Wilfrid was restored to York (much circumscribed), and Ripon (686–687). He was once more driven out in 691–692, and spent seven years in Mercia. A great council of the English Church held in Northumbria excommunicated him in 702. He again appealed to Rome in person, and obtained another decision in his favour (703–704). He died at Oundle in Northamptonshire as he was going on a visit to Ceolred, king of Mercia (709). He was buried at Ripon.

Wilfrid's is a memorable name in English history, not only because of the large part he played in supplanting the Celtic discipline and in establishing a precedent of appeal to papal authority, but also by reason of his services to architecture and learning. At York he renewed Paulinus's old church, roofing it with lead and furnishing it with glass windows; at Ripon he built an entirely new basilica with columns and porches; at Hexham in honour of St. Andrew he reared a still nobler church, over which Eddius grows eloquent. In the early days of his bishopric he used to travel about his diocese attended by a little troop of skilled masons. He seems to have also reformed the method of conducting the divine services by the aid of his skilled chanters, Aedde and Aeona, and to have established or renewed the rule of St. Benedict in the monasteries. On each visit to Rome it was his delight to collect relics for his native land; and to his favourite basilica at Ripon he gave a bookcase wrought in gold and precious stones, besides a splendid copy of the Gospels.

Wilfrid's life was written shortly after his death by Eddius at the request of Acca, his successor at Hexham, and Tatbert, abbot of Ripon—both intimate friends of the great bishop. Other lives were written by Frithegode in the 10th, by Folcard in the 11th, and by Eadmer early in the 12th century. *See* also Bede's *Hist. Eccl.* v. 19, iii. 25, iv. 13, etc. All the lives are printed in J. Raine's *Historians of the Church of York,* vol. i, "Rolls" series.

WILHELMINA [WILHELMINA HELESA PAULINE MARIA OF ORANGE-NASSAU] (1880–), queen of the Netherlands, was born at The Hague on Aug. 31, 1880 Her father, William III (Willem Paul Alexander Frederik Lodewijk), had by his first wife, Sophia Frederika Mathilde of Württemberg, two sons, both of whom predeceased him. Having been left a widower on June 3, 1877, he married on Jan. 7, 1879, Adelheid Emma Wilhelmina Theresia (1858–1934), second daughter of Prince George Victor of Waldeck-Pyrmont, and Wilhelmina was the only issue of that union. She succeeded to the throne on her father's death, which took place on Nov. 23, 1890, but until her 18th year, when she was "inaugurated" at Amsterdam on Sept. 6, 1898, the business of the state was carried on under the regency of the queen mother. On Feb. 7, 1901, Queen Wilhelmina married Henry Wladimir Albert Ernst, duke of Mecklenburg-Schwerin (1876–1934). The queen's only child, Princess Juliana (b. April 30, 1909), was married on Jan. 7, 1937, to Prince Bernhard zu Lippe-Biesterfeld (1911–) and gave birth to the princess Beatrix (Jan. 31, 1938) and three other daughters. Wilhelmina abdicated Sept. 4, 1948, after a 50-year reign and was succeeded by Juliana.

WILHELMSEN, (MORTEN) WILHELM (1839–1910), the founder of a large Norwegian shipping company, was born in Tonsberg on Dec. 7. 1839. After serving in various shipping offices outside Norway he returned to Tonsberg in 1861 and joined the ship broking firm of I. W. Balchen as a partner, soon becoming the sole proprietor. He specialized in the Baltic timber trades and soon became a shareholder of various shipowning enterprises. In 1887 he gave up the ship broking business and went into partnership as a shipowner with his son Halfdan Wilhelmsen. Much of the credit for the size and prosperity of the Norwegian shipping industry must go to Wilhelmsen. who early realized the benefits of technical developments in ship propulsion. He died at Tonsberg on Nov. 16, 1910. (P. DF.)

WILHELMSHAVEN, a town in Lower Saxony and chief German naval station on the North sea; as such it played an important part in World War I, and in World War II it was very frequently and heavily bombed by British and United States planes. It is situated on the northwest shore of the Jade Busen. Pop. (1959 est.) 99,766. The ground where it stands (19 sq.mi.)

was purchased by Prussia from the grand-duke of Oldenburg in 1853, when the Prussian navy was being formed, but was returned to Oldenburg by Hitler after 1933.

The construction of the harbour and town began in 1855, and the former was opened in 1869. The harbour consists of three large basins and seven smaller ones as well as a basin for shipbuilding.

There are six dry docks. The harbour has three entries and locks are 260 metres long and 40 metres wide, with a depth of from $6\frac{1}{2}$ to 10 metres at the quays. The establishment is defended by strong fortifications. The commercial harbour lies at the east end of the Ems-Jade canal.

WILKES, CHARLES (1798–1877), American naval officer and explorer, born in New York city April 3, 1798. He entered the U.S. Navy as a midshipman in 1818 and became a lieutenant in 1826. In 1830 he was placed in charge of the division of instruments and charts, and in 1838 was appointed to command an exploring and surveying expedition to the South Seas, authorized as the first of its kind by Congress in 1836. The expedition, including naturalists, botanists, mineralogists, taxidermists, a philologist, etc., left Hampton Roads Aug. 1838, stopped at various ports in South America and visited the Paumotu group of the Low Archipelago, the Samoan islands, and New South Wales. From Sydney, Wilkes sailed into the Antarctic ocean and along the Antarctic barrier from 150° to 97° E., reporting land at a number of points in the region which has subsequently been known as Wilkes Land. He visited the Fiji group and the Hawaiian islands in 1840, and in 1841 explored the west coast of the United States. The findings were timely in view of the dispute with Great Britain over the Oregon territory. He visited San Francisco bay, and the Sacramento river, and crossing the Pacific he called at the Philippine islands, Sulu archipelago, Borneo, Singapore, Polynesia and the Cape of Good Hope, reaching New York in June 1842, having sailed around the world. He served on the Coast Survey 1842–43 and in the latter year was advanced to the rank of commander. In 1844–61 he was chiefly engaged in preparing the report of the expedition. Twenty-eight volumes were planned but only 19 were published. Of these Wilkes wrote the *Narrative* (6 vols., 1844); and the volumes *Hydrography* (1851) and *Meteorology* (1851). At the outbreak of the Civil War Wilkes was assigned to the command of the "San Jacinto" to search for the Confederate commerce destroyer "Sumter." On Nov. 8, 1861, he stopped the British mail packet "Trent," and took off the Confederate commissioners to Europe, James M. Mason and John Slidell. Though he was officially thanked by Congress, his action was later disavowed by President Lincolr. Wilkes was commissioned commodore in 1862, and placed in command of a squadron sent to the West Indies to protect the U.S. commerce in that region. On July 25, 1866, he was promoted to the rank of rear-admiral on the retired list. He died at Washington Feb. 8, 1877.

In addition to many shorter articles, reports, etc., he published *Western America, including California and Oregon* (1849); *Voyage Around the World* (1849); and *Theory of the Winds* (1856). "The Diary of Wilkes in the Northwest" (E. S. Meany, ed.) appeared in the *Washington Historical Quarterly,* vol. 16–17 (1925–26).

WILKES, JOHN (1727–1797), English agitator and reformer, was born in St. John's Square, Clerkenwell. His father, Israel Wilkes, a successful malt distiller, came from a yeoman family of Leighton Buzzard. John was the second son; his elder brother, Israel, emigrated to America and became the grandfather of (Admiral) Charles Wilkes (*q.v.*).

John Wilkes was schooled at Hertford and afterwards privately by the Rev. F. Leeson, a dissenting minister of Aylesbury, under whose charge he went to Leyden university in 1744. Here he learnt little—"Jack has great variety of talk, Jack is a scholar, Jack has the manners of a gentleman," said Dr. Johnson. He became close friends with Andrew Baxter and D' Holbach (*qq.v.*).

On his return to England, he married Miss Mary Mead, an Aylesbury heiress. "In my nonage," he says, "to please an indulgent father, I married a woman half as old again as myself; of a large fortune—my own being that of a gentleman. It was a sacrifice to Plutus, not to Venus. I stumbled at the threshold of the temple of Hymen:

"The god of love was not a bidden guest,
Nor present at his own mysterious feast."

Their marriage, uneventful for a time, and even successful while they lived at Aylesbury (they had one child, Mary), was broken up soon after Wilkes entered into politics, and they separated by mutual consent. Mrs. Wilkes had hardly any affection for either her husband or daughter, and she was scandalized by Wilkes' loose life and companions. He had been introduced by Thomas Potter, a finished profligate, to the society of Sir Francis Dashwood, chief of the "Medmenham Monks," of whom he became a member. This was a secret fraternity, which met occasionally in the summer in the ruins of St. Mary's abbey at Medmenham, for obscene orgies, in which it parodied Roman Catholic ritual. Dashwood, Lord Sandwich, Paul Whitehead, Potter, Wilkes and perhaps Charles Churchill the poet were among the ringleaders; the "order," whose reputation for indecency probably exceeded even the reality, was broken up by a practical joke of Wilkes', who unexpectedly released from a box a baboon disguised as a devil during a prayer addressed to Satan by Lord Orford, who nearly went out of his mind in the belief that his supplication was answered.

Partly under the encouragement of these friends, Wilkes had entered politics as a follower of Richard, Lord Temple (*q.v.*). He unsuccessfully fought Berwick in 1754, having bribed a captain to land a shipload of opposition voters from London in Norway instead of Berwick, but in 1757 by a complicated arrangement with Potter and Pitt, which was made to cost him the absurd sum of £7,000, he was elected M.P. for Aylesbury. In 1762, with the aid of Churchill and the countenance of Temple, he began to publish the *North Briton.* The wit and virulence of its attacks on Lord Bute, the Tory favourite of the King, silenced the *Auditor* and *Briton,* the ministerial papers, and were chiefly responsible for the wave of indignation which carried Bute from office on Mar. 8, 1763. Wilkes then held his hand, but when-Pitt and Temple read an advance copy of the King's speech sent to them by George Grenville, the new Premier, they decided that Grenville's ministry was no more than a camouflage of the same autocratic power, and encouraged Wilkes to publish (April 23) the famous "No. 45" of the *North Briton,* which was a devastating attack on the statements in the King's speech, which he described as false. Though he had carefully prefaced his attack by the remark "the King's speech has always been considered by the legislature and by the public at large as the speech of the Minister," George III. chose to consider Wilkes' article as a personal insult, and instigated immediate proceedings. A "general warrant" (one that did not name the persons to be arrested) was issued over the signatures of Lords Halifax and Egremont, secretaries of State, and 48 persons were seized by the authorities before Wilkes was arrested (April 30). He was thrown into the Tower and for a short while kept in the closest confinement. To the public delight, however, Lord Chief Justice Pratt on May 6 released Wilkes on the ground that his arrest was a breach of privilege. Actions against Under-Secretary Woods (who was fined £1,000), against Halifax (who by repeated evasions adjourned the case till 1769 when he was fined £4,000), and against minor agents, established the illegality of general warrants.

A second attack was now more carefully prepared by Wilkes' one-time friend Sandwich, now a member of the Government. By bribery and theft P. Carteret Webb, an under-secretary, secured from Wilkes' private press the proofsheets of an obscene parody written by himself and Potter years before on Pope's *Essay on Man,* called the *Essay on Woman.* Wilkes had commenced, but never completed printing twelve copies of this, probably for the Medmenham monks. This disgusting work, together with notes purporting to be by the Bishop of Gloucester, was read aloud with relish on Nov. 15 by Sandwich to the Lords, who voted it a libel and a breach of privilege. The Commons at the same time declared "No. 45" a seditious libel. To face the forthcoming trial before Lord Mansfield after these pronouncements would have been extremely hazardous. Wilkes, who had been gravely wounded in a duel with Samuel Martin, M.P., one of the vehicles of government bribery, withdrew to Paris, and sent to the Speaker (Jan. 11, 1764), when a motion for his expulsion was brought forward, a certificate of his ill-health. The Speaker declared that this certificate was not sufficiently authenticated, and though triple authentication was forthwith provided, Wilkes was expelled (Jan. 19). In these circumstances, Wilkes, who believed that life sentence would be pronounced against him, decided not to stand his trial and was consequently outlawed (Nov. 1). He spent the next four years on the Continent, chiefly in "amorous delights." The fall of Grenville in 1765 and the accession of the Whigs to power under Rockingham and then Grafton led him to believe that a pardon would be granted to him and his services rewarded by some honourable place. He only slowly realized that none of the Whigs were prepared to risk the King's displeasure for his sake and that the various offers privately made to him were only intended to keep him amused. When he discovered the truth he was extremely bitter against Chatham and Grafton, those chiefly responsible, and pilloried them in a Letter to the *Duke* of *Grafton,* one of his ablest performances.
