Bolivia

Bolivia is a landlocked republic in central South America with an area of 424,165 square miles (1,098,581 square kilometres) and a population that in the early 1970s numbered about 5,000,000. The country has been landlocked since it lost its Pacific coast territory to Chile toward the end of the 19th century. It is bordered to the north and east by Brazil, to the southeast by Paraguay, to the south by Argentina, and to the southwest and west by Chile and Peru. Its constitutional capital is the city of Sucre (population about 70,000), where the Supreme Court is established, but the de facto capital is the city of La Paz (population more than 850,000), where the executive and legislative branches function.

Bolivia is also widely known by the name of República del Altiplano (Republic of the High Plateau) because the most developed and densely populated part of its territory is situated on a plateau between the two branches of the Andes mountain range. The country itself was once a part of the ancient Inca empire and later formed part of the Spanish viceroyalty of Peru. Spanish, though spoken by less than half of the population, remains the official language; in religion, the overwhelming majority of the people are Roman Catholic. Bolivia is still an underdeveloped country whose economic life is based principally upon the production of raw materials, notably tin. (For associated physical features see ANDES MOUNTAIN RANGES; GRAN CHACO; and TITICACA, LAKE; for historical aspects, see BOLIVIA, HISTORY OF.) (V.A.U.)

THE LANDSCAPE

Relief. Although three-fifths of Bolivia's area consists of vast low plains, the western part is one of the highest inhabited areas in the world and constitutes Bolivia's heartland. The Andes there attain the greatest breadth and are divided into two great parallel ranges—the Cordillera Oriental to the east and the Cordillera Real to the west—enclosing a plateau the surface of which lies only a few thousand feet below the summits of the mountains themselves. Between these ranges lies the monotonous, bleak Altiplano (High Plateau), bordered to the west by the Cordillera Occidental. The plateau is a relatively flat-floored depression about 500 miles long and 80 miles wide, lying at elevations of between 12,000 and 12,500 feet. The floor of this great depression, mostly composed of water-laid deposits from the bordering mountains and appearing quite level, slopes gently southward. Its evenness is broken by occasional hills and ridges. The margins of the basin are marked by numerous interlocking alluvial fans (accumulations of debris that have spread out in the shape of a fan), which have built up an almost continuous plain of fairly gentle grade lying at the foot of the mountains.

The Altiplano

The northern and eastern sections of the country, called the Oriente (meaning east), cover three-fifths of Bolivia. They are composed of low alluvial plains, great swamps, flooded bottomlands, and gently undulating forest regions. In the extreme south is the Bolivian Chaco, which forms part of the Gran Chaco; it is a fairly level and low area that varies strikingly with the seasons of rain. It is a veritable swamp during the rainy season and a hot semidesert during the remaining eight or nine months of the year. Northward from the Chaco, but still a portion of the Oriente, is the Santa Cruz area. It is generally level, with a downward slope to the north. Drainage is not the problem there that it is in the Chaco, because several small north-flowing streams interlace the area. The northernmost segment of the Oriente is the Upper Beni, a low, wet plain covered in large part by heavy tropical rain forest. Much of it is subject to heavy inundation during the rainy season—November to May inclusive.

Extremely high mountains (some exceeding 21,000 feet) rise northeast of the Titicaca Basin, which lies in the northwest and also extends into Peru; the descent from these mountains to the eastern plains is extremely precipitous. This rainy and heavily forested belt of rugged terrain (deep valleys and gorges separated by high ridges), known as the Yungas, is situated on the northeast slope of the Cordillera Oriental and extends southward as far as a line drawn from Santa Cruz to Cochabamba. The Yungas, a distinct natural division, is the southern part of an unbroken region that extends along the eastern Andes of Colombia, Ecuador, Peru, and Bolivia as far south as Santa Cruz.

Drainage. The rivers belong to three distinct systems —the Amazon system in the northeast, the Río de la Plata system in the extreme southeast, and the Lake Titicaca system in the west. The eastern lowlands of Bolivia have many lakes, most of them little known.

The great swampy plains along the Beni and Mamoré rivers, which are headwaters of the Amazon, contain several lakes and lagoons, some of them large, such as Lago Rogoaguado.

In the vicinity of the Río Paraguay, which is connected to the La Plata Basin and runs parallel to part of Bolivia's eastern border without entering national territory (though touching a small segment of the frontier in the extreme southeast), there are several lakes, partly produced by obstructed outlets, such as Bahía Negra, Laguna Cáceres, Laguna Mandioré, Laguna Gaiba, and Laguna Uberaba. North of these are the great Zarayes swamps. This region, like that in the northeast, is subject to inundations during the summer.

The third drainage system is that of the great central plateau. One of the most elevated of all inland basins, it consists of Lake Titicaca near the north end; the Río Desaguadero to the southeast, its outlet; Lago de Poopó, into which the Río Desaguadero flows; the Salar de Coipasa (Salt Lake or Marsh of Coipasa) to the southwest of Lago de Poopó (connected with Poopó by the Río Lacajahuira, the small outlet of the latter); and the great Salar de Uyuni, independent of the rest of the system but receiving the waters of an extensive, though very arid area at the south end. Into this system enter many short streams from the neighbouring heights. Having no outlet to the sea, the water of this extensive basin is wholly absorbed by the dry soil and by excessive evaporation.

Lakes Titicaca and Poopó

Lake Titicaca itself is the highest large navigable lake in the world. Situated on the Bolivian–Peruvian border at an elevation of 12,500 feet (3,810 metres), it is about 120 miles long and 50 miles wide; many islands dot its surface. Lago de Poopó is quite different in character from Lake Titicaca. Occupying a very shallow depression in the plateau, only a few feet below the general level of the surrounding land, it is nowhere more than 15 feet deep at its normal level. When its waters are low, it covers an area of 977 square miles; the surrounding land is so flat, however, that at high water the lake reaches sometimes almost to Oruro to the north, fully 30 miles from the low-water shore. The Río Lacajahuira, the only visible outlet of Lago de Poopó, moves underneath the sand and empties into the Salar de Coipasa, which, at high water, covers about the same area as Lago de

Poopó at low water; it usually consists, however, only of wide, marshy, salt-encrusted wastes, with a small permanent body of water in the lowest part. There is no outlet. The Salar de Uyuni, to the south of the Salar de Coipasa, is similar but much larger. Covering about 3,500 square miles, it consists of a great, totally arid, windswept salt flat.

Climate. Bolivia lies wholly within the tropics but possesses every gradation of temperature from that of the equatorial lowlands to Arctic cold. The Yungas climatic zone comprises all the lowlands and the mountain valleys up to an elevation of approximately 6,000 feet. The atmosphere is humid, and the mean temperature is about 77° F (25° C), with no great departures from this figure; the rainfall, occurring throughout the year, is heavy, amounting to between 30 and 50 inches or more.

The valley zone, which includes the deep valleys lying at heights of from 6,000 to 9,500 feet, has a warm climate with moderate variations in temperature and no cold weather; it is semitropical in character.

The zone that includes the heads of the deep valleys, above the valley zone, with elevations ranging from 9,500 to 11,000 feet, is temperate, though subject to an occasional frost in winter. Both in the valleys and in the heads of the deep valleys there is likely to be a scarcity of rain, though there is usually an abundant supply of water for irrigation.

The Puna (or Altiplano) zone, which lies mostly between 11,000 and 14,000 feet, includes the great central plateau. Always cool, it varies little from summer to winter, except for rainfall; summer brings rain, but occasional snow falls in winter. The mean temperature is estimated at 50° F (10° C) at La Paz.

The Puna Brava zone extends from about 13,000 feet up to the snow line, which is about 18,000 feet, and covers a bleak inhospitable territory, inhabited only by shepherds and miners. Above this is an Arctic zone within the tropics.

Precipitation is as varied as temperature. East of the Cordillera Oriental, rains fall throughout the year. On the west side of this cordillera, the elevated plateaus have a limited rainfall in the north (23 inches at La Paz), which occurs only during the summer months and diminishes toward the south until the surface becomes absolutely barren. Brief and furious thunderstorms sometimes sweep the northern plateau and Lake Titicaca in summer. (G.McC.McB./Ed.)

Vegetation. On the Altiplano, where the amount of rainfall is relatively small, vegetation is scarce. In the higher valleys (at mean altitudes of about 8,500 feet) the typical vegetation consists of small trees and bushes, such as the molle (pepper tree), the chanar (a thorny shrub with sweet edible berries), and the pacae (a leguminous tree used as shade for coffee plants). The heights of the Yunga region are covered with great forests; among the trees represented are green pine, black walnut, aliso (a shrublike tree), laurel, cedar, *tarco* (a shade tree producing masses of yellow-white flowers), *saúco* (which yields fruit used to make medicinal syrups), and quina (an evergreen tree yielding quinine).

The tropical area constituted by the great plains of the east is divided into the Amazon and La Plata River Basins, which are separated by a vast forested area, densely covered with tall trees, many of which are valuable hardwoods. The principal species of commercial value include rubber, Brazil nut, and two types of South American mahogany; there are altogether more than 100 types of trees suited to the wood industry, while there are at least 14 kinds of palm trees, many of which have fruits suited to the extraction of oils, as well as 11 varieties of resinous trees. Tree species

The plains of the La Plata Basin are characterized by low brush consisting of such resinous plants as quebracho (the bark of which is used for tanning and dyeing) and *palo santo* (a shrublike tree with blue or purple flowers, also called the soap bush), while the lower lying areas are covered with *mistol* (a bush that produces a nutritive seed); the algarrobo (carob) tree, which has a beanlike pod, is also found. In some areas there are forests of very tall palm trees. The vegetation of the Amazon Basin within Bolivia is more tropical than that of the La Plata Basin, having taller trees and thicker jungles. (V.A.U.)

Animal life. Animal life closely resembles that in the neighbouring areas of Argentina, Brazil, and Peru. In the rain forest of the northeast there is a wide range of species, all of which are kept in balance by competition. Among the snakes are the anaconda, the water boa, and the bushmaster (a kind of viper); caymans (members of the crocodile family) are common, as are lizards. The forest, with its constantly saturated warm air, provides a favourable habitat for salamanders, frogs, and toads. There are large numbers of birds, among which are fruit pigeons, parakeets, toucans, hornbills, and touracos (brightly coloured birds with helmet-like crests). Seen high in the sky, gliding in search of carrion, are king and black vultures. Conspicuous among mammals are the sloth, monkey, jaguar (largest of the American cats), ocelot, opossum, tapir, capybara (so-called water pig, largest of the rodents), peccary, armadillo, and anteater. Insects are particularly abundant because there is no winter and they can breed throughout the year. Among those of the greatest concern to man are mosquitoes, flies, leaf-cutting ants, and termites.

In the grasslands and scrub forest to the south of the rain forest are found jaguar, puma, and deer (among the mammals), the cayman, and some snakes (including the bushmaster and the fer-de-lance, which is a large kind of viper). Conspicuous among the birds are the rhea (a large flightless South American ostrich), a species of large stork, and the common vulture. Waterfowl are abundant, and there are myriad forms of insect life. Since much of the country is swampy for an extended period, mosquitoes of all kinds are present in enormous numbers. Flies, gnats, and ants are also abundant and are a major source of discomfort to man.

In the flat valley bottoms, where the thick tropical forest occurs, mammals are more abundant on the lower slopes and in the valleys than higher up. Here are found deer, armadillo, various opossums, the spectacled bear, peccary, jaguar, capybara, and the tayra—a huge weasel, described as ugly and vicious.

The animals of the highlands are most distinctive, differing markedly from the animals of the adjacent rain forest. On the Puna the most striking animals are the guanaco (a wild ruminant, of which the llama and the alpaca are believed to be the domesticated varieties) and the vicuña (which is related to the guanaco but smaller, yielding a soft, delicate wool). These animals live at altitudes of between about 8,200 and 18,000 feet. Highland rodents include the chinchilla (a small animal with

soft, silvery-gray fur), viscacha (a burrowing rodent), mara (a long-legged, long-eared rodent), and cavy, or guinea pig; the cavy inhabits the more deserted parts of the Altiplano.

Bird life

Bird life is abundant in the highlands, particularly on Lakes Poopó and Titicaca, and includes geese, ducks, grebes, coots, cormorants, and gulls. In the swamps there are curlews, plovers, and snipes. The condor (a large New World vulture, which is the largest flying bird in the Western Hemisphere) roosts and breeds at heights between 10,000 and 16,000 feet but descends to sea level in search of food on the west side of the Andes, but not to low altitudes on the east side of the mountains. Insect life is largely absent above 10,000 feet.

Among domesticated animals indigenous to Bolivia are the llama, alpaca, cavy, and muscovy duck. The llama is the beast of burden in the bleak and barren wastes of the Puna but is seldom to be seen below heights of 7,500 feet; in addition to being a beast of burden, it also yields meat, wool, leather, tallow, hair, and fuel (dung). The alpaca is best adapted to high altitudes and thrives in the wet, marshy ground at high elevations; it is not a pack animal but is reared for wool. The cavy is raised by almost every Indian family in the highlands as a source of meat and as a pet, from 5 to 15 being kept in the average household. The muscovy duck is raised for food and is the only bird that has been domesticated in the central Andes.

Traditional regions. The three principal regions are the Altiplano, the Valleys (Valles, or Montañas), and the Oriente.

The Altiplano, which comprises about one-seventh of the total land area of Bolivia, is high, windswept, bleak, cold, and barren. Strangely enough, this hostile region, one of the highest inhabited areas on Earth, is Bolivia's most densely populated region; about 55 percent of the total population lives there. In this region are located most of the important cities, including La Paz and Oruro, many of the small towns, and most of the mines. The most important crop is the potato, which is dehydrated and frozen to form *chuño*, which keeps indefinitely. Other crops include barley, *quinoa* (a widely-used grain, grown at very high elevations), broad beans, wheat, alfalfa, and *oca* (an edible tuber). These crops are rotated in a three-year cycle, after which a plot of land is not cultivated but is pastured by llamas, alpaca, and sheep for about 12 years. Unfortunately, the Altiplano does not produce enough food for its population, and much has to be imported.

Farming is still largely of the subsistence type, and most of the farm work is performed by Indians. Until the early 1950s, most of the land was held in the form of large estates, most of which dated back to the days of the Spanish conquistadores; the rest of the land was held communally by the Indians. In 1952 the large estates were broken up and plots of land given to the Indians to be paid for within 25 years. As a result, the number of landowners in Bolivia increased 16 times over. By the mid-1960s, however, there was much confusion, and the land of the once productive large estates had become little more than kitchen gardens for the new owners.

The Altiplano is a difficult land for raising crops and most livestock, and fuel for cooking or for comfort is scarce. Clothing and blankets are made from the wool of sheep and llamas. Most Indians chew coca, primarily because it numbs their senses to the cold and deadens the appetite. A cud of dried coca leaves bulges from the cheek of almost every Altiplano Indian. Life is an endless struggle to wrest from a stubborn nature enough food, fuel, and wool to live by. The Altiplano has been Indian for centuries and promises to remain so. Centuries of bitter experience have taught the Indians to have as little as possible to do with white men if they are to protect their tiny plots of land or their harvests.

The Valles, or Montañas, consists of a complex area of deep valleys and high mountain spurs. The most important part of the region is the Yungas. Because of poor transport facilities, the area must produce such subsistence crops as ají (a widely used chili pepper), alfalfa, barley, cacao, coffee, corn, rice, yuca (cassava, or manioc), wheat, and fruits. Such cash crops as coca, sugarcane, and coffee, which have high value per unit of weight or bulk and thus can pay the costly transportation to the Altiplano, are raised wherever climatic conditions permit. Only by exploiting the Indian, however, is it possible to make a profit on these crops. Most important of the three is coca, which is restricted to the lower Yungas, north and east of La Paz, where it is grown by Indians on terraces of steep slopes of valley walls. Since coca is one of the principal items of family expenditure in the highlands, coca production provides the principal source of cash income in the Yungas, which has become Bolivia's richest subregion. The Yungas is one of the most densely populated areas in the country; it is reported to have 30 percent of the total population and about 40 percent of all the country's cultivated land.

The Oriente

The Oriente is the largest, least productive, and most sparsely populated region; it contains probably less than 15 percent of Bolivia's population. Comprising the vast semicircular territory to the north and east of the Valles, it is also probably the least known area. There is sufficient diversity to justify division into subregions: the northern rain forest; the humid subtropical central zone (comprising the northern and southern parts, respectively, of the departments of Santa Cruz and El Beni); and the semi-arid Chaco. Through the centuries this region has been effectively separated from the Yungas and the Altiplano by poor communications.

The Oriente is thus an enormous region, the central portion of which is believed to have promising possibilities for crops and cattle. It is handicapped by poor transport facilities, though they have improved with the completion of the Cochabamba to Santa Cruz highway; arteries connecting with this highway were completed by 1956. Cut off by the mountain barrier, except for this highway, the low-lying Oriente has had little to do with the rest of Bolivia. Its few agricultural and livestock products have trickled into Brazil and Argentina rather than to the Altiplano.

Urban settlements. The city of La Paz including metropolitan area (population estimated at 850,000 in 1971) is the largest and most important of Bolivia. It can be considered a highland city, though a great part of it is in a large canyon, 3,000 feet deep, produced by glacier erosion. The canyon is now drained by the Río Choqueyapu, one of the sources of the Río Beni, which is in turn one of the great tributaries of the Amazonic system. This city has spectacular mountain scenery. It is unique in that one part of it is at an altitude of 13,500 feet and the other at 10,500 feet. This difference of about 3,000 feet between the areas of the city results in peculiar differences in temperature, vegetation, and economic and social activities. The industrial and lower income areas of the city are in the heights, while the residential areas are at the lower levels.

The other cities of the Altiplano—Oruro (with a population of about 95,000), Potosí (64,000), Uyuni (15,000), Tupiza (17,000), and others of lesser importance—are generally connected with the mining industry. The aspect they present is influenced by the scenery of the steppes (extensive treeless plains) and the activities of the mines. Potosí merits special attention as the oldest large city of Bolivia. It was established in 1545 on the slopes of the mountain of Potosí, which was the richest silver mine found by the Spaniards. Potosí had nearly 200,000 inhabitants at the beginning of the 17th century, when it was the largest city in the Americas. It is one of the few cities of America to retain its architectural personality through the years: the large government and religious buildings of the silver mining era remain almost intact.

The most important cities in the valleys are: Cochabamba (180,000), Sucre (70,000), and Tarija (28,000). All of these cities are surrounded by fruit orchards and dairying country. Life is pleasant because of the mildness of the climate, and the inhabitants are inclined to the pursuit of literature; the most important writers and men of politics in the history of Bolivia have been born in these regions.

The most important of the cities of the eastern plains is Santa Cruz. In 1950 this city had a population of 40,000; by the early 1970s, with the growth of several industries and the opening of the road to the west, its population had risen to 135,000 inhabitants.

PEOPLE AND POPULATION

The three ethnic groups

Ethnic and linguistic groups. The population of Bolivia consists of three groups—the Indians, the mestizos (of mixed Indian and Spanish descent), and the descendants of the Spaniards. After four centuries of intermixing it is, however, virtually impossible to measure accurately the percentage of each.

The Indians are the descendants of the Aymaras, Quechua, and forest tribes, the great majority being farmers, mine workers, or factory and construction workers. About 90 percent of this group speak Spanish, but for traditional and cultural reasons the Indian languages, especially Aymara and Quechua, are still widely used.

The mestizos have traditionally devoted themselves to handicrafts, trades, or small business in the cities. Since the initiation of the great social reforms in 1952, a considerable proportion of this group has had access to schools, colleges, and universities; in the early 1970s, about 60 percent of those graduated in the liberal professions in Bolivian universities, a great percentage of whom are women, belong to this group.

Among the descendants of the Spaniards, the Indian element is less apparent, and the outward characteristics of the Spaniards are predominant. Traditionally, this group has formed the local aristocracy. Since the 1940s this group has increasingly intermarried with the mestizos. The division between these groups is rapidly becoming less defined, and total integration is foreseeable. Attached to this group are recent European immigrants, who occupy a lesser position; families and last names are of particular importance, as in Spanish tradition.

Religious groups. The Roman Catholic religion has the adherence of more than 90 percent of the population. Its hierarchy consists of one primate cardinalship, two archbishoprics, and five bishoprics.

The churches and cathedrals, most of which were built during colonial times, constitute a national architectural treasure. They are generally in the extravagantly ornamented baroque style, although some are in Renaissance (*e.g.*, the cathedral of La Paz) or in later styles.

Pre-Columbian religious revivals

In the Indian communities of the Altiplano, some of the characteristics of pantheistic pre-Columbian religion have survived. Its deities were the sun god Pachacama and his spouse Pachamama, the earth goddess. The Catholic religion has been forced through the centuries to accept some of these practices by assimilating them into the cult of these communities.

Protestant denominations that are active include the Methodist Episcopal church, the Baptists, and the Jehovah's Witnesses. The congregations of these denominations, plus Christian non-Catholic immigrants, make up approximately 10 percent of the total population. Other religions, such as Judaism and Islām, claim the adherence of small groups. Freedom of religion is guaranteed by the Constitution. The comparatively few atheists and agnostics are found principally in university circles and among labour leaders.

Since the 1940s the Catholic church, reflecting the new social dynamism of the church, has ventured from an almost exclusively ceremonial role into the fields of social aid and guidance.

Demography. In 1971 the total population of Bolivia was just under 5,000,000. The index of population growth was 2.6 percent; yet, paradoxically, Bolivia remained almost stationary in its population. The primary reason for this was the great volume of emigration, especially of the working population, to the labour markets of neighbouring countries. In Argentina, for example, it is estimated that there are more than 600,000 Bolivian immigrants. Most of them were hired for temporary work in the sugarcane fields, but many later moved to Buenos Aires and its outskirts. Professional unemployment constitutes a serious problem in Bolivia. It is conservatively estimated that there are at least 100,000 Bolivians, more than half of whom are university graduates, in the United States. A factor in this trend is said to be that nationalization and centralization of industry have resulted in an undue emphasis on political influence rather than professional efficiency.

Bolivia, Area and Population

	area		population	
	sq mi	sq km	1950 census*	1971 estimate

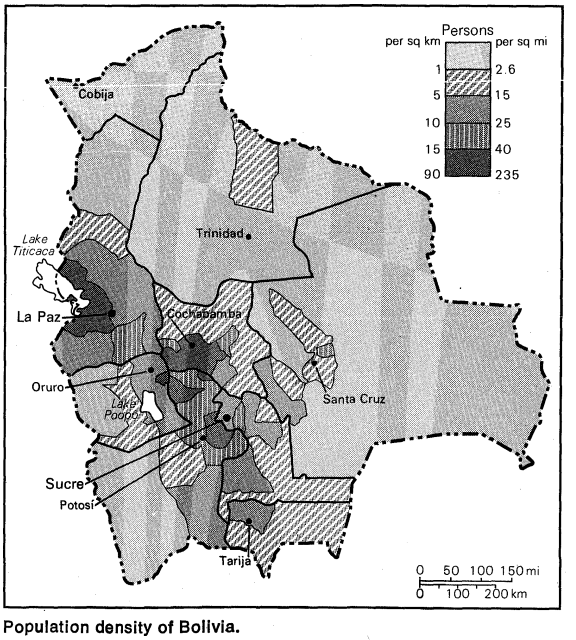
Traditionally, the great majority of the population has been concentrated in the Altiplano and in the high valleys, mainly because of the conjunction of a healthy climate with exploitable natural resources. Health programs, launched in cooperation with the United States, have nearly eradicated diseases such as malaria, yellow fever, bubonic plague, and yaws, that once afflicted the lowlands, and the construction of roads has made access easier. In consequence, these regions, in the 1950s and 1960s, experienced a migratory influx.



Population density of Bolivia.

THE NATIONAL ECONOMY

Economic trends

Until the 1940s, the economy of Bolivia was based mainly upon the production of minerals for export and the meagre consumption of goods by a population that remained separated from the outside world, not only by the high mountains but also by cultural barriers. The rural workers, who made up 80 percent of the population, were both culturally and economically isolated from the rest of the world. They made their own houses with local mud bricks and thatched roofs, their own clothing with sheep or alpaca wool; and they cultivated their own foods, including corn, potatoes, and *quinoa*. Contact with urban centres was negligible, resulting mainly from obligations imposed by landlords.

The export of minerals was used to finance life in the

cities, which required the importation of foodstuffs, furniture, construction materials, textiles, and clothing. Taxes on mineral exports and imports of consumer goods served to pay governmental expenses. Thus, the country lived within its limited horizons, without expectations of economic progress, except from occasional windfalls that might result from exceptionally good market conditions for minerals.

By the early 1970s, this situation had begun to change fundamentally. While minerals still represented over 80 percent of all exports, they no longer represented the decisive economic factor, for the population had become less dependent upon export earnings. An accelerated production of domestic foodstuffs had begun, internal commercial activity had increased tenfold within a quarter of a century, and the consumer indexes for the majority of the population had increased. Rural inhabitants had begun to consume such articles as beef, sugar, shortening, and textiles; to these were also added such totally new articles as transistor radios and bicycles.

Minerals. The strategic importance of Bolivian minerals, especially tin, and of Bolivia's oil and natural-gas reserves, in the very heart of South America, have remained unaltered. Bolivia remains the only secure source of tin in the Western Hemisphere, a factor of immense importance in the event of a worldwide conflict. Such strategic considerations also apply to the oil and natural-gas deposits in the area of Santa Cruz.

In 1971, minerals produced included tin, lead, zinc, copper, antimony, tungsten, bismuth, gold, and silver.

The oil industry

Oil prospecting first began in 1927, when the Standard Oil Company (New Jersey) located some oil fields with relatively low yields in southeastern Bolivia. From 1937 to 1956, oil production was the responsibility of a Bolivian state agency, but, after that, United States companies continued prospecting, and the Gulf Oil Corporation located oil fields near the city of Santa Cruz. In 1969, when the production of Gulf Oil Corporation amounted to 40,000 barrels daily, the Bolivian government cancelled the Gulf Oil Corporation concessions and made the state agency, Yacimientos Petrolíferos Fiscales Bolivianos (YPFB), responsible for production. This action affected the external credit of Bolivia, so that the government experienced temporary difficulty in selling the exportable surplus of oil on the international market. Oil production, which amounted to about 8,800,000 barrels in 1970, rose to 13,200,000 barrels in 1971.

Agricultural resources. Bolivia's most significant agricultural resources consist of its cattle-raising areas and its great forests. Livestock includes cattle, horses, mules, asses, sheep, pigs, goats, llamas, and alpacas.

About 43 percent of the total surface area of the country, amounting to about 180,000 square miles, is covered by natural tropical and subtropical forests, with excellent species of hardwoods. Limited means of access and long distances to the nearest seaports have, however, delayed the development of these riches.

Power resources. There has been a considerable increase in the production of electricity, although consumption is still relatively low. The installed capacity of thermal power, for example, rose from about 17,000 kilowatts (kw) in 1940 to 95,000 kilowatts in 1970, while hydroelectric capacity rose from 31,000 kilowatts in 1940 to 172,000 kilowatts in 1970.

The great differences in altitude between the snow-capped peaks, which rise to 21,000 feet, and the plains, which are nearly at sea level, offer a great potential for the future development of hydroelectric power. Two projects are worthy of notice for the future development not only of Bolivia but also of South America. The first is concerned with the utilization of the waters of Lake Titicaca, which constitutes the highest reservoir in the world with a potential not yet calculated. Because the lake is jointly owned by Peru and Bolivia, the project would have to be jointly financed and implemented. The second project concerns the construction of a dam on the Río Beni, which has a volume of water comparable to that of the Nile. Near the eastern plains, the river passes through a narrow canyon with walls of solid rock, a scant 600 feet apart, rising to about 2,000 feet. The projected dam would form a lake nearly as large as Lake Titicaca, with possibilities for transportation, fishing, and settlement. The power output of this dam would, it is calculated, be similar to that of the Aswān Dam in Egypt. These two projects, if realized, would exert a decisive influence upon the industrialization of Bolivia, Peru, northern Chile, and western Brazil.

Trade and industrial production. More than 80 percent of Bolivia's exports are minerals. In the early 1970s the balance of payments was consistently favourable. The economic situation of the country was not flourishing, however, because of the lack of internal savings and the scarcity of foreign investment. The state agencies, which have taken over most of the means of production, function with permanent deficits because of a mushrooming bureaucracy and poor individual production. Private enterprise has been restricted to small industry and to medium and small-sized mining operations. In manufacturing, the principal private activities are concerned with textiles and drinks; food production is scattered among many small farmers or small primary industries. Sugar production, for the most part, is in the hands of the state.

The state corporations

There are four principal state corporations, all of which were operating at a deficit in the early 1970s. The Corporación Minera de Bolivia (Bolivian Mining Corporation) is responsible for the administration of the large mines nationalized in 1952; Yacimientos Petrolíferos Fiscales Bolivianos (Bolivian National Oilfields) is concerned with the production and exportation of oil and natural gas; the Empresa Nacional de Ferrocarriles (National Railroad Corporation) operates with a government subsidy; Lloyd Aéreo Boliviano, the national airline, is mostly state-controlled.

In general, it appeared that the policy of nationalization and state control of industry resulted in losses.

Transportation. Because of its landlocked situation, Bolivia depends on railroads, highways, and airlines for both internal and external transportation. River navigation is still not developed, partly because the navigable rivers are in the least populated areas, and partly because of geographic problems posed by the other rivers into which they flow.

Bolivia is connected with foreign seaports on the Atlantic and the Pacific by five railways, which have a total length of 2,310 miles. These railways are: La Paz to Arica (Chile); La Paz to Antofagasta (Chile); La Paz to Buenos Aires via La Quiaca (Argentina); Santa Cruz to Buenos Aires via Yacuiba, in southern Bolivia; and Santa Cruz to São Paulo (Brazil) on the Atlantic coast via Corumbá, in southeast Brazil.

The railways to the Atlantic ports are used for the export of agricultural products, and the Pacific railways are used mainly for the export of minerals. Road construction intensified during the late 1960s and early 1970s, with credits being advanced by the United States. In the early 1970s there were about 16,000 miles of roads of which about 600 miles were paved first-class highways; 7,200 miles were crushed stone, 1,600 miles graded earth, and the rest unimproved. The most important paved highways are from La Paz to Oruro, from Cochabamba to Santa Cruz, from Santa Cruz to the north, and from Cochabamba to Chimoré. Studies are being made for the construction of highways toward Chilean and Peruvian seaports.

A permanent bus service runs to Peru over the La Paz–Desaguadero–Puno roads. Throughout Bolivia, bus lines connect the principal cities.

Air transport

Internal air transport is primarily in the hands of a mixed corporation—Lloyd Aéreo Boliviano—of which 74 percent is owned by the state and the rest by private individuals. This airline connects the principal Bolivian cities with international airports in Buenos Aires, Santiago (Chile), Lima (Peru), and São Paulo (Brazil). In its domestic service, it operates regular flights to most Bolivian cities. Airport administration is in the hands of AASANA (the National Council of Aeronautics), a fiscal entity that operates about 30 airports.

The geographic situation of Bolivia poses particularly

difficult transportation problems. The double Andes mountain range, which has only a few mountain passes lower than 15,000 feet, has made road and railway construction particularly expensive. Thus, while mountain roads offer incomparable scenic views for tourists, they also present the difficulties and dangers that attend winding roads, while steep inclines preclude accelerated travel.

ADMINISTRATION AND SOCIAL CONDITIONS

The structure of government. *The constitutional framework.* The executive, legislative, and judicial branches of government are theoretically independent. Since the founding of the Republic in 1825, Bolivia has had a republican and unitary system of government. The central government appoints lesser political authorities, such as the prefects, who govern the nine departments; the subprefects, who govern the provinces into which the departments are divided; and the corregidores, who are the highest authorities in still smaller units called cantons.

According to the constitution, the central government must be elected every four years by popular elections, in which a president and vice president are chosen. The president appoints a 16-member ministerial cabinet; these ministers are heads of the executive branches of government.

The legislative branch consists of a Chamber of Deputies, with approximately 102 members, and a Senate, with a total of 27 (three senators per department). Deputies remain in office four years and senators for six.

The constitution can be changed only by two legislatures, and then only if the second one has been returned after an election in which the issue of the constitutional amendment forms part of the electoral platform. Laws must be sanctioned by the legislative branch and promulgated by the president, who has the power of veto, which can be overridden by a two-thirds majority vote in the legislature. The existing tradition of violent changes of government in Latin America has, however, frequently resulted in these constitutional norms being set aside. Most of the time the country has been governed by de facto regimes headed by members of the armed forces. Between 1900 and 1971 there were 28 presidents, of whom only 14 were elected by popular vote in accordance with the constitution. In addition, during the administration of the de facto regimes, the legislature is not convened, and the central government assumes its functions, promulgating decrees that have the force of law. In the same way, these governments frequently declare judicial offices to be vacant and name new judges to the Supreme Court, which in turn makes appointments to the lesser judicial posts.

The administrative process has generally been inspired by the presidential mode of government in the United States, with certain Anglo-French parliamentary overtones. A vote of no confidence, if approved, can result in the automatic resignation of a Cabinet or of an individual minister.

Constitutionally, municipal governments should be organized through the election of mayors and municipal counsellors. The last municipal elections were, however, held in 1928; since then, centralist tendencies have prevailed, and the central government appoints the mayors.

The electoral system

The political process. Until 1956, only a small minority of the inhabitants of the Republic voted in general elections. Women were not allowed to vote, and literacy requirements disenfranchised more than 70 percent of the men. There were also property and income restrictions, which further diminished the numbers of the electorate. Thus, out of a population of about 5,000,000, a president could be elected with only 80,000 votes. In 1956, however, an electoral reform law eliminated sex and literacy requirements, establishing the voting age at 21 years for men, and 19 for women; as a result, 1,400,000 voters participated in the 1956 elections.

A political party of substantial influence in the early 1970s was the Movimiento Nacionalista Revolucionario, which governed the country from 1952 to 1964. Its program, based on three fundamental points—a universal vote, agrarian reform, and the nationalization of the mines—gained unprecedented popular support. The personal ambitions of its principal leaders, however, resulted in schisms that its adversaries in the armed forces were able to exploit, and the party was ousted from office in 1964.

Another important party has been Falange Socialista Boliviana, a group inspired by the Falangista Party of Spain. The influence of this party reached its peak when totalitarian movements controlled most of central Europe, but—like similar parties throughout South America—it changed direction after the defeat of the Axis forces in World War II. It then took the name Partido Social Cristiano (Christian Social Party).

The parties of the extreme left have become aggressive as a result of the influence of Castroism (the doctrines of Fidel Castro of Cuba) in South America. These parties have had difficulty, however, in following a central authority and are divided into such factions as Moscovite Communists, Maoists, Trotskyites, Castroites, etc. As a result of the opportunities given them by two leftist military governments—that of Alfredo Ovando Candía from 1969 to 1970 and that of Juan José Torres from 1970 to 1971—these groups became active in the Bolivian universities and labour unions. Bolivia seemed capable of becoming one of the first South American countries to have a Communist government until the armed forces ousted the Torres government. A nationalist government was organized in 1971 under the presidency of Col. Hugo Banzer Suárez, with the cooperation of a segment of the Movimiento Nacionalista Revolucionario and the Falange Socialista Boliviana.

The armed forces. The armed forces, in order of importance, consist of the forces of the land army, the air force, and the naval force. There is a commander general for the three combined forces, as well as a commander for each. Since 1904, there has been a one-year military obligation for all male Bolivians who reach the age of 19. The standing army numbers about 20,000 men, and the air force—organized with United States assistance—is a small one. The Bolivian navy is small; it operates on the navigable rivers, as well as on Lake Titicaca, to prevent smuggling and to assist river transport.

Education, health and welfare. Civil education is divided in three categories—elementary, secondary, and university. Most education is state-supported, but private institutions are not forbidden. The Catholic, Protestant, and Jewish churches are active in primary and secondary education. One of the country's eight universities is Catholic. The Bureau of Indian and Rural Education maintains regional schools for teaching trades and crafts. The national illiteracy rate is estimated to be about 60 percent.

Health services

There are three kinds of health services—those supported by the state through the Ministry of Health, those provided by the social security system for its affiliates, and private clinics. In general, the medical services and the hospitals in the cities are adequate. This is not so in rural areas, however; both doctors and nurses are lacking. Nationally, there is approximately one doctor to care for every 2,700 people. The most serious health problems confronting the country are malnutrition, tuberculosis, prenatal and birth attention, and the tropical diseases that break out regularly in the warmer areas.

Cultural life and institutions. Bolivian culture consists of a combination of Indian culture with the Mediterranean cultures brought by the Spaniards. On religious feast days, for example, pagan pre-Columbian rites are still practiced, and the Indians express themselves through dances and songs that blend the two cultures. In such festivities, some symbolic dress presents the Indian interpretation of European attitudes: the dance of the *palla-palla* or *loco palla-palla* caricatures the European invaders; the dance of the *waka-tokoris* satirizes bullfights; and the *morenada* mocks white men, who are represented leading imported African slaves. Indian musical instruments are used to accompany these dances. In the

music itself, the mixture of cultures is also evident, since many of the tunes are based on Spanish dances. The more commonly used instruments are: *el sicu* (pan pipes), and *la tarka*, *la kena*, and *el pinquillo* (vertical flutes). Percussion instruments of various sizes are used. The costumes, highly embroidered and colourful, imitate the dress of the pre-Columbian natives or the dress of 16th-century Spaniards.

Daily dress in the rural regions of Bolivia still reflects the Spanish colonial influence. The men wear short jackets and wide trousers, and the women wear wide pleated skirts and colourful shawls. The hats the women wear vary according to the different regions.

Since the 1940s, Indian culture has experienced a blossoming. Previously, Indians attempted to imitate Europeans, in custom as well as in dress. By the early 1970s, however, Indian values had been re-established; Indian music rose to a higher standard, painters abandoned the imitation of European fashions, and some of the characteristics of Indian culture re-emerged in the general life-style.

Cultural institutions

The National Academy of Fine Arts in La Paz offers courses in music, painting, sculpture, and ceramics. There are two galleries of pictorial arts, and a permanent collection in the National Museum of Art. Jewelry in silver and gold, with pre-Columbian decorations and styles, has been made since colonial times. The local markets offer a profusion of colourful handicrafts and fine woodcarvings.

In the city of Potosí the building of the Mint (Casa de Moneda), erected in the 17th century, has been restored, and its great halls are used to house a collection of fine colonial paintings. Various old temples have been restored, and folk festivals are held periodically. The most important is the one held in Oruro during the carnival holidays; many Indian music and dance groups compete, providing a magnificent display of costumes and decorations. In La Paz there is the National Symphony Orchestra, and at the University of San Andres (also known as the University of La Paz) a choral group specializes in Indian musical themes.

There are five newspapers published daily in La Paz—three in the morning and two in the evening—and there are 17 radio stations and one television channel. In the other large cities there are also local newspapers, and each department capital has at least three radio stations. Some radio stations broadcast in Quechua or Aymara. There is an Academy of the Aymara Language in La Paz; its avowed purpose is the preservation of the purity of this language.

Prospects for the future. Bolivia faces serious problems that hinder its progress. Among them are its lack of access to the ocean and its difficult terrain. It nevertheless constitutes one of the world's reserves: it is capable of supporting a larger population because the extent of its arable lands is great and the density of its population very low. The areas of land without adequate rainfall for human habitation are relatively small, and the energy sources, mineral reserves, and biological possibilities are promising. The fundamental human problem lies in the difficulty of establishing a form of government and social structure stable enough to permit the development of potential resources.

The migratory currents from other continents, which have had so much influence elsewhere in the Americas, have had a minimal influence in Bolivia. The great majority of the population are still either of Indian or of mixed Indian and Spanish blood.

In Bolivia, a great desire to emerge from backwardness can be perceived; in this desire, however, the political tendencies of the modern world play a dramatic role. In the universities, many lean toward the adoption of Socialist methods as a solution to Bolivia's problems, but many of those in the professions and many technicians are inclined toward free enterprise and private initiative. The result of this difference has been a division in a national community that—perhaps more than any other—needs common objectives in order to overcome its enormous problems.

(V.A.U.)

Bolivia, History of

Pre-Columbian civilizations

Bolivian society traces its origins to the advanced pre-Columbian civilizations of South America. The high Bolivian plateau known as the *altiplano* was already densely populated several centuries before the Spanish conquest in the 16th century.

The Bolivia region, to 1825. From the 7th century, the Tiahuanaco empire, the first of the great Andean empires to extend over both the Peruvian coast and highlands, had its centre in the *altiplano* region. By the 11th century it had reached its apogee and was replaced by more simple regional states.

In the centuries that followed the collapse of Tiahuanaco, the Bolivian highland region maintained its dense populations and technological civilizations with irrigation agriculture. By the 15th century the region was mostly controlled by some 12 nations of Aymara-speaking Indians. Competitors to the Quechuan-speaking nation at Cuzco in what is now Peru, these Aymara tribes fought with the latter for control of the central Andean highland region. Though the Aymara nations were eventually dominated by Cuzco, they nevertheless remained the most important non-Quechuan group within the expanding Incan empire; because of their importance they were

the only conquered coastal or highland peoples able to retain their language and cultural identity to such an extent that their Aymara language survived the Spanish conquest. But the Aymara were forced to accept a large body of Quechuan-speaking immigrants within their midst as part of a deliberate Incan policy of colonization. It was this early pattern of colonization and nonassimilation that gave Bolivia its current linguistic and cultural identity (the two major Indian languages in Bolivia today are Quechua, spoken by over a third, and Aymara, spoken by a fourth of the population).

Part of the Spanish Empire

The southern Andean valleys and central plateau of Bolivia, with their dense Indian populations, became a core population area within the Spanish empire after the conquest. To the wealth represented by Indian labour there was added the mineral wealth from newly discovered silver deposits of Potosí (1545)—the largest silver mines then known in the Western world. The arid, high altitude mines of Potosí, along with others discovered near the town of Oruro (founded in 1606), were supplied with food and other basic necessities by such supportive towns as Chuquisaca (founded in 1538), La Paz (1548), and Cochabamba (1571). From the 16th to well into the 18th centuries, this southern Andean area, known then as Charcas, or Upper Peru, was one of the wealthiest and most densely populated centres of Spain's American empire. Its mines were supplied with forced drafts (*mita*) of Indian labourers from all over the Andes; and by the middle of the 17th century, its central mining city of Potosí was the largest city in the Americas, with a population estimated at 150,000. But by the last quarter of the 18th century this famous mining zone was in decay. The exhaustion of the richest and most accessible veins, the poverty of the miners and their ignorance of advanced technology, and the absorption of colonial capital into the thriving international commerce of the late 18th century all contributed to its decline. Though a reduced Potosí continued to be Upper Peru's most important economic centre, the intellectual and political centre of the area was Chuquisaca (also known in the colonial period as Charcas and La Plata and, since independence, as Sucre). With its academies and University, Chuquisaca was the major educational centre for the entire Río de la Plata region, it also served as the seat of Upper Peru's government, which was known from its foundation in 1559 as the Audiencia of Charcas. The Audiencia was first placed under the Viceroyalty of Peru at Lima; but in 1776 it was finally shifted to a new viceroyalty established at Buenos Aires.

In 1809 revolts first at Chuquisaca and then at La Paz gave rise to the Wars of Independence in South America. But, despite several invasions by patriot armies and constant guerilla warfare, Upper Peru was the last major area in South America to be freed from Spanish rule. It was only with Antonio José de Sucre's victory over the Spanish armies in Lower Peru (1824) that Upper Peru's elite groups finally supported a full independence movement.

Independence movement

Though the South American liberator Simón Bolívar was pressing for multiregional confederations, he permitted an Upper Peruvian congress to declare itself an independent republic on Aug. 6, 1825.

Bolivia from 1825 to c. 1930. In recognition of Bolívar's support, the leaders of the congress named the new republic Bolivia after the liberator and invited Sucre, his chief aide, to be the first president.

Foundation and early national history. But the new republic was not as viable as its leaders fervently hoped it would be. It was economically retarded, despite the legendary colonial wealth and prominence of the region. The late-18th-century mining decline had given way to severe depression as a result of the Independence wars. Between 1803 and 1825 silver production at Potosí declined by over 80 percent; and by the time of the first national census in 1846, the republic listed more than 10,000 abandoned mines.

Incapable of exporting its silver at the levels of colonial production, Bolivia rapidly lost its previously advanced economic standing within Spanish America. Already by the end of the colonial period, such marginal areas as the Río de la Plata and Chile were forging ahead on the basis of meat and cereal production. Bolivia, on the other hand, was a net importer of basic foods, even those exclusively consumed by its Indian population. And none of its mineral resources was of sufficient value to overcome the high transportation costs involved in getting the minerals to the coast. The Bolivian republic, with little trade to tax and with few resources to export beyond its very modest precious metals production, was forced to rely on direct taxation of its Indian peasant masses, who made up over two-thirds of the estimated 1,100,000 population in 1825. Until well into the last quarter of the 19th century, this regressive Indian taxation was the largest source of national government revenue. With the more progressive South American states relying almost exclusively on import and export taxes of a constantly expanding international commerce, the Bolivian state rapidly lost its prominent position within the continent and became known as one of the most backward of the new republics.

Economic decline and political stagnation

This economic decline was mirrored by political stagnation. Bolivia emerged initially with a series of military strongmen (caudillos), among whom was Marshal Andrés de Santa Cruz, president from 1829 to 1839. Temporarily reorganizing the war-torn Bolivian economy and state finances, Santa Cruz in the 1830s was able to unite Bolivia with Peru, through the successful overthrow of the Lima regime of Gen. Agustín Gamarra, into a government known as the Confederation (1836–39). But Chilean military intervention destroyed the Confederation attempt; Bolivia quickly turned in upon itself and thenceforth abandoned all attempts at international expansion.

Bolivia's efforts for the next half-century were primarily to integrate its far-flung regions into a coherent relationship between the core of the republic, the *altiplano*, and the eastern Andean valleys. This attempt was doomed to failure, however, because Bolivia lacked the population and resources to exploit either its Amazonian or its Pacific frontiers. Despite the enormous wealth in nitrates and guano available on the Bolivian Pacific coast, the nation was incapable of exploiting them even with the help of foreign capital. What little capital was available within Bolivia's upper class was totally committed to *altiplano* mining. It was Peruvians, Chileans, North Americans, and Englishmen who exploited these resources. Between the Chilean War of the Confederation (1838–39) and the outbreak of the Pacific War (1879), Chile constantly and successfully expanded its claims, both by diplomatic pressure and, finally, by war, against Bolivian sovereignty in the enormous Bolivian Pacific coastal territories.

Loss of the coastal region. The War of the Pacific (1879–84) had its origins in heavy Anglo-Chilean investments in Bolivia, beginning in the 1840s with those in the guano deposits on Bolivia's Atacama coastal province. With the discovery of nitrate deposits in the 1860s, Chilean aggressive expansion along the coast increased even further. By a series of treaties Chile expanded its territorial claims and obtained commercial concessions within Bolivian territory. As a response to this pressure, Bolivia signed an alliance treaty with Peru in 1873; but this did not intimidate the Chileans. When the Bolivian government attempted to increase taxation on Chilean nitrate companies working in Bolivia, Chile unilaterally invaded Bolivian territory in 1879 and forced a war with both Bolivia and Peru. In May 1880, at the Battle of Tacna, Chile defeated a combined Bolivian–Peruvian army, ending effective Bolivian resistance. Rather than attack the Andean core of Bolivia, the Chileans ignored Bolivia for the rest of the war and proceeded on a massive invasion of Peru, which resulted in their eventual capture of Lima.

War with Chile

The fall of the Pacific littoral to Chile may, in many ways, have been a blessing for Bolivia. The War of the Pacific marked a major turning point in national history. From the fall of the Confederation to the War of the Pacific, Bolivia had gone through one of the worst periods of caudillo rule in all Latin America during the 19th century. The decades of the 1860s and 1870s, however, were those in which Andean silver mining had revived under

the impact of new capital inputs from Chile and Great Britain. By the time of the War of the Pacific, international market conditions for silver and the introduction of new technology and capital had greatly revived the national mining industry. The War of the Pacific enabled the new mining entrepreneurs to capture political control of the nation and to break the hold of the by then discredited barracks officers on national political life.

Formation of Liberal and Conservative parties. Starting in 1880, under the presidency (1880–84) of Narciso Campero, Bolivia moved into an era of civilian governments with the national upper class dividing into Liberal and Conservative parties, which then proceeded to share power. This intraclass political party system finally brought Bolivia the stability it needed for economic development. Though the parties split on personality and anticlerical issues, they were identical in their desire to promote economic growth. From 1880 to 1899 the nation was ruled by the Conservatives, whose principal function was to encourage the mining industry through the development of an international rail network.

Era of civilian government

It was thus an economically expanding nation that the Liberals inherited when they seized power from the Conservatives in the so-called Federal Revolution of 1899. Supposedly fought over the permanent placing of national institutions in the cities of Sucre or La Paz, the federal revolt was primarily a power struggle between the Conservative and Liberal parties. Unfortunately for the Conservatives, their strength was too closely tied to the traditional Chuquisaca elite, much of which was coterminous with the silver-mining class. The Liberals, however, had the bulk of their strength in La Paz, which by this period was three times the size of Sucre and had the largest urban concentration (some 72,000 persons) in the national population, which was estimated at 1,700,000 persons in 1900.

Increase in tin mining. The Liberal victory was also closely associated with a basic shift in the mining economy. As the world silver market began to collapse in the 1880s and early 1890s, a major shift to tin mining began on the Bolivian *altiplano*. Found in association with silver, tin did not become an important product until the end of the 19th century, when demand suddenly soared in all the major industrialized countries. Thus by 1900 tin had completely superseded silver as Bolivia's primary export, accounting for over 50 percent of national exports.

The shift to tin mining not only occurred at the same time as the Liberal revolt and was closely associated with the new party but it also brought about a basic change within the capitalist class in Bolivia. Whereas the silver mining elite had been almost exclusively Bolivian, the new tin miners were far more cosmopolitan, including, in the early years, foreigners of all nationalities as well as some new Bolivian entrepreneurs. Tin mining itself absorbed far more capital and produced far more wealth than had the old silver-mining industry, and the new companies that emerged became complex international ventures directed by professional managers.

Given this new economic complexity and the political stability already achieved by the Conservatives and perpetuated by the Liberals, the tin-mining elite found it profitable to withdraw from direct involvement in national political life. Whereas Bolivian presidents under Conservative rule in the 19th century had either been silver magnates themselves (Gregorio Pacheco, 1884–88; Aniceto Arce, 1888–92), or closely associated with such magnates as partners or representatives (Mariano Baptista, 1892–96; Severo Fernández Alonso, 1896–99), the Liberals and subsequent 20th-century presidents were largely outside the mining elite. No tin magnate actively participated in leadership positions within the political system. Rather, they came to rely on a more effective system of pressure group politics.

Liberal rule (1899–1920). The primary task of the Liberal politicians, who ruled Bolivia from 1899 to 1920 under the leadership of Ismael Montes (twice president: in 1904–08 and 1913–17), was to settle Bolivia's chronic border problems and to continue and expand the communications network initiated by the Conservatives. A definitive peace treaty was signed with Chile (1904), accepting the loss of all Bolivia's former coastal territories. Also, the Acre problem was resolved: this involved an unsuccessful attempt by the central government to crush an autonomist rebellion (1889–1903) in the rubber boom territory of Acre on the Brazilian border. Brazil's covert support of the rebels and the defeat of Bolivian forces finally convinced the Liberals to sell the territory to Brazil in the Treaty of Petrópolis (1903). As a result of the financial indemnities provided by both treaties, Bolivia was able to finance a great railroad construction era—by 1920 most of the major cities were tied together by rails and La Paz was connected to the two Chilean Pacific ports of Antofagasta and Arica; new lines had begun or had been built to Lake Titicaca and thus the Peruvian border, and to Tarija and the Argentine frontier.

Railroad-building era

The period of Liberal rule was also the most calm in Bolivian political history. Dominated by the figure of Montes, the Liberal Party easily destroyed the federalists, who had supported the party during the revolution, and Liberal success led to the total collapse of the Conservative Party. Not until 1914 was an effective two party system again established, when many of the political "outs," along with a large number of new and younger elements, finally organized the Republican Party. Like its predecessors, the Republican Party was a white, upper and middle class grouping, with a fundamental belief in liberal and positivist ideologies.

The Republican Party. The abrasive quality of the strong-willed Montes and the disintegration of the ruling Liberal Party finally permitted the Republicans to stage a successful coup d'etat, in 1920, and become the ruling party. Upon achieving political power, however, the new party immediately split into two warring sections based on a conflict of personalities and led by two Montes-style politicians—Juan Bautista Saavedra, a La Paz lawyer who captured control of the Republican Party and was national president from 1930–34, and Daniel Salamanca, a Cochabamba landowner who took his following into a separate party, the so-called Partido Republicano Genuino (or Genuine Republican Party). The rivalry between these two men became the dominant theme in Bolivian politics for the next decade, until the Salamanca forces captured the presidency.

Below the surface of this political battle of personalities, the national economy in the 1920s was undergoing serious change. The early years of the decade had witnessed a brilliant post-World War I recovery of the Bolivian tin-mining industry, which led to the achievement by 1929 of its highest production figures. This enormous output occurred, however, in a period of steady price decline (a trend that continued long after the Great Depression of the 1930s). By 1930 the international tin market was in a serious crisis, and Bolivian production suffered. The year 1930 marked the end of major new capital investment in tin mining; thereafter the industry in Bolivia would become an ever higher cost producer of lower grade ores for the international market.

Bolivia since 1930. The installation of Salamanca in the presidency after the revolt of 1930 seemingly involved little change in traditional Bolivian government. But the Great Depression cut brutally into national income and forced the closing of a large part of the vital mining industry. Salamanca was thus forced to take new measures. Attempting a policy of inflation and money manipulation, he ran into bitter hostility from the Liberal Party, his key partner in the 1930 overthrow of the regular Republican Party. The opposition of these two forces in the central government led to a tense political climate, the result of which was to force Salamanca to accept a Liberal veto over internal economic decisions. He refused, however, to permit the Liberals to join his cabinet; rather, he sought to overcome Liberal congressional control and to destroy growing strike movements by turning national attention to other themes. Salamanca had the traditional recourse to patriotism and foreign war open to him in a long-standing border conflict with Paraguay.

Already in the mid-1920s, Bolivia and Paraguay both had begun a major program of fort construction in the

largely uninhabited and poorly demarcated Chaco Boreal territory, on the southeastern Bolivian frontier. At the height of the Depression, Salamanca had advocated an even heavier armament and fortification program and had contracted for major European loans. In June 1932 a border incident developed between the two states, and Salamanca deliberately provoked a full-scale Bolivian reprisal, which inevitably led into open war between the two nations.

Conflict with Paraguay

The Chaco War (1932–35). The Chaco War was a long and costly disaster for Bolivia. In the three years of bitter fighting on its southeastern frontiers, Bolivia lost 100,000 men dead, wounded, deserted, or captured; it also lost far more territory than Paraguay had claimed even in its most extreme prewar demands. The fact that Bolivia had entered the war with a better equipped and supposedly far better trained army only aggravated the sense of frustration among the younger literate veterans—the so-called Chaco generation—at the total disaster of Bolivian arms. Charging that the traditional politicians and the international oil companies had led Bolivia into its disastrous war, the returning veterans set up rival Socialist and radical parties and challenged the traditional political system.

Return to military rule. The initial result of this challenge was the overthrow of the civilian government and the first advent of military rule in Bolivia since 1880. In 1936 the younger army officers seized the government, and under two leaders, Col. David Toro in 1936–37 and Maj. Germán Busch in 1937–39, they tried to reform Bolivian society. Little was accomplished during this so-called era of military socialism except for the confiscation of the Standard Oil Company holdings, the creation of an important labour code, and the writing in 1938 of an advanced, socially oriented constitution.

Rise of new political groups. Beginning in the 1940s, civilian dissident groups finally began to organize themselves into powerful national opposition parties. The two most important of these were the middle class and initially fascist-oriented Movimiento Nacionalista Revolucionario (MNR) and the Marxist and largely pro-Russian Partido de la Izquierda Revolucionaria (PIR). Both groups established important factions in the national congress of 1940–44. In 1943 the civilian president Gen. Enrique Peñaranda was overthrown by a secret military group Razón de Patria (Radepa), which allied itself with the MNR and tried to create a new-style government. Under Col. Gualberto Villaroel (1943–46) little was accomplished, except for an initial political mobilization of the Indian peasants by the MNR. Opposed as fascist-oriented by the right and left, the Villaroel government was overthrown in 1946, in a bloody revolution in which Villaroel was hanged before the presidential palace by revolutionary crowds.

Political chaos

During the next six years the PIR tried to rule in alliance with many of the older, traditional parties. But this effort failed, and the PIR was eventually dissolved and replaced in early 1950 by the more radical Bolivian Communist Party. The Conservative parties proved unable to control the situation; and after the MNR won a plurality victory in the presidential elections of 1951, the military intervened directly and formed a military junta government. As for the MNR, its disaster under Villaroel led it to disassociate itself from its fascist wing and to seek an alliance with a small Trotskyite party, which had important mine-union support. The resulting alliance brought the labour leader Juan Lechín into the MNR. After several unsuccessful revolts, each more violent than the preceding one, the MNR, in several days of fighting, finally overthrew the military regime in April 1952. During this struggle, workers, civilians, and peasants were armed and the army was almost totally destroyed.

The Bolivian National Revolution (1952). Thus in April 1952 began the so-called Bolivian National Revolution, which became one of Latin America's most important social revolutions. The MNR and its mine-worker and peasant supporters were pledged to a fundamental attack on the tin-mining industry and its allied political supporters. In October 1952 the three biggest tin-mine companies were nationalized. In August 1953 came one of the most far-reaching land-reform decrees ever enacted in the Western Hemisphere. Universal suffrage was granted with the abolition of literacy requirements. Not only were Indians granted land, freed from servile labour obligations, and given the vote, but they were also given large supplies of arms. From that point on, the Indian peasants of Bolivia became a powerful, if largely passive, political force, upon which all subsequent governments based their strength.

Social reforms

Post-1952 regimes. The most important leader of the MNR, Víctor Paz Estenssoro, was president of Bolivia in 1952–56 and instituted the most revolutionary part of the party's program. In 1956 he was replaced by the more conservative Hernando Siles Zuazo, whose primary concern was to stop an inflation that had followed the 1952 revolution. That inflation had in many ways completed the revolutionary process by virtually destroying the older middle class supporters of the MNR. With massive financial support from the United States, the inflation was stopped; but most of the advanced social programs of the revolution were suspended as well. The government ended worker co-administration of the nationalized mine companies and cut back on expanded social services and other such measures. It also invited U.S. petroleum companies back into Bolivia for the first time since 1937, when Standard Oil of Bolivia had been confiscated by the Toro government.

The return of Paz Estenssoro to the presidency in 1960 did not bring a new movement toward social reform. Rather, the consolidation achieved by Siles Zuazo was further developed, with the power of the army being revived under U.S. support. The attempt of Paz Estenssoro to renew his presidential term for another four years, in 1964, led to the splintering and eventual destruction of the MNR and to the overthrow of his government by the military.

With the support of many conservative elements and the peasant masses, the vice president, Gen. René Barrientos, seized the government and proceeded to dissolve most of the organized labour opposition. From 1964 until his death in 1969, Barrientos continued with the process of conservative economic reform and political retrenchment, with a deliberate attempt to demobilize all the popular groups, except the peasants, that had risen to some power as a result of the National Revolution. It was during Barrientos' period in office that a poorly organized antigovernment campaign, led by the Argentinian-born revolutionary Ernesto (Che) Guevara, was destroyed in 1967, largely because of its failure to mobilize the peasants. The death of Barrientos brought the vice president, Luis Adolfo Siles Salinas, into office temporarily; he was forcibly replaced in mid-1969 by Gen. Alfredo Ovando Candía, who in turn was forced out of office, after he had nationalized Gulf Oil Company holdings, by the more radical Gen. Juan José Torres in October of 1970. The death of Barrientos ended the power of the more conservative elements of the national army. There followed a rapid movement by the more reformist military leaders toward reconciliation with the previously oppressed labour unions and an accommodation with the radical student movement.

The military again emerged as the most powerful element in Bolivian politics, but it was sympathetic to basic elements of social reform. The effective abolition of the *latifundias* (large, poorly cultivated estates) and the arming of the Indian peasants created an entirely new social, economic, and political arrangement in Bolivia's countryside. Thus, despite the conservatism of urban-based governments, the suffering of mine workers and other unionized urban workers at the hands of military regimes, and corruption and economic stagnation, which remained the basic problems in Bolivian society, the post-1952 regimes created a measure of social justice far exceeding that achieved in the majority of Latin American states.

BIBLIOGRAPHY. The standard work on the independence wars in Bolivia is C.W. ARNADE, *The Emergence of the Republic of Bolivia* (1957); for the history of the 19th and 20th cen-

turies, see H.S. KLEIN, *Parties and Political Change in Bolivia, 1880–1952* (1969); and for the developments of the 1952 revolution, the latest and most complete work is J.W. MALLOY, *Bolivia: The Uncompleted Revolution* (1970). All three works have extensive bibliographies in all relevant languages. For a broad survey of the economic, social, and political condition of Bolivia in the last two decades, see J.W. MALLOY and R. THORNE (eds.), *Bolivia Since the Revolution* (1971).

(H.S.K.)

Bombay

Bombay, the capital of Mahārāshtra state, India, is the country's financial and commercial centre and the principal port on the Arabian Sea. It is the seventh largest city in the world, with a population of 5,970,000 (1971 census). It is also one of the most densely populated cities, its inhabitants crowded within an area of 239 square miles (603 square kilometres). Located on a site of ancient settlement, the city took its name from the local goddess Mumba—a form of Pārvatī, the consort of Śiva (Shiva), one of the principal gods of Hinduism—whose temple stood in the southeast of contemporary Bombay.

The cosmopolitan city is inhabited by representatives of every linguistic and religious group in India and has a significant foreign community. Long the centre of India's cotton-textile industry, its manufactures are now well diversified and its commercial and financial institutions strong and vigorous. Bombay suffers, however, from the chronic ills of most large, expanding cities. Its industrial establishment has created problems of air and water pollution, while the promise of employment continually attracts new migrants to the already overcrowded city. Confined by its island location, Bombay seems ready to burst at its seams, and expansion to the mainland may prove to be the only answer to the problem.

History. Paleolithic stone implements found at Kandivli in Greater Bombay indicate human occupation of the area during the Stone Age. The earliest known inhabitants were Kolis, an aboriginal tribe of fishermen that probably arrived at the beginning of the Christian Era. Generally identified as Heptanesia by the ancient Greek astronomer and geographer Ptolemy, the area formed part of the kingdom of Aparānta or north Konkan (2nd century AD) and early came under Buddhist influence. It then passed under the rule of successive Indian dynasties; from the Maurya (*c.* 321–185 BC) to the early Cālukya (6th–8th centuries AD) period, the city of Purī on Elephanta Island (Ghārāpuri) was the chief settlement in Bombay Harbour. The Walkeswar temple at Malabar Point was probably built during the rule of Śilāhāra chiefs from the Konkan Coast (9th–13th centuries). Under the Yadāvas of Devagiri (1187–1312) the settlement of Mahikavati (Māhīm) on Bombay Island was founded in response to raids by the Khālji dynasty of Hindustān in 1294. Descendants of these settlers are found in contemporary Bombay, and most of the place-names on the island date from this era. In 1348 Bombay was conquered by invading Muslim forces and became part of the kingdom of Gujarāt.

In 1507 a Portuguese attempt to conquer Māhīm failed. Twenty-seven years later, Sultan Bahādur Shāh, the ruler of Gujarāt, ceded the islands to the Portuguese who divided them into manors and fiefs and gave them to individuals or religious orders in return for military service or rent.

The British period

The British and Dutch partially sacked the islands and burned portions of the city in 1626, though they failed to establish control. In 1661 the island was ceded to Britain under the terms of the marriage treaty between the English king Charles II and Catherine of Braganza, sister of the King of Portugal; it was not until 1664 that formal possession was taken in the name of the British crown. In 1668 the crown ceded Bombay to the British East India Company, and the company headquarters were shifted to the island four years later. The company settled problems of land revenue, established law courts, strengthened defenses, and secured the freedom of trade and worship to all. The population increased to 50,000, and the modern city was founded.

The city grew steadily during the 18th century, and services and communications to mainland India and Europe were extended. In 1857 the first spinning-and-weaving mill was established, and by 1860 Bombay had become the great cotton market of western and central India. The United States Civil War from 1861 to 1865 and its resultant cutoff of cotton supplies to Britain caused a great trade boom in which financial empires sprouted. When the commercial delirium was at its height, the Civil War ended; the price of cotton fell, and the bubble burst. The city's commercial stability suffered no lasting damage, however, and much construction was carried out in the late 1800s.

Central Bombay and (inset) its metropolitan area.

Urban expansion

With the opening of the Suez Canal in 1869, Bombay prospered, and its population, slums, and insanitary conditions steadily multiplied. Plague broke out in 1896, and a City Improvement Trust was set up to open new localities and erect dwellings for the artisan classes. An ambitious scheme for the construction of a seawall to enclose an area of 1,300 acres was proposed in 1918 but not completed until the completion of Marine Drive from Colāba Point to Malabar Point—the first two-way highway of its kind in India—after World War II. In the postwar years the development of residential quarters in suburban areas was begun, and the administration of Bombay city through a municipal corporation was extended to the suburbs of Greater Bombay. The former capital of Bombay Presidency and Bombay state, it was made the capital of Mahārāshtra state in 1960.

The contemporary city. *The city site.* Bombay occupies a group of isles lying off the Konkan Coast that are united by causeways and breakwaters. Known as Bombay Island, the site is joined on the north with the larger island of Salsette, which is connected with the mainland to the east.

Trapezoid-shaped Bombay Island consists of a low-lying plain, one-fourth of which lies below sea level; the plain is flanked on the east and west by two parallel ridges of low hills. Colāba Point, the headland formed on the extreme south by the longer of these ridges, protects Bombay Harbour on its eastern side from the open sea. The western ridge terminates at Malabar Hill, 180 feet (55 metres) above sea level and the highest point in Bombay. Between the two ridges lies the shallow expanse of Back Bay. On a slightly raised strip of land between the head of Back Bay and the harbour is the Fort, the original nucleus around which the city grew; it is now chiefly occupied by public and commercial offices. From Back Bay, land slopes westward to the central plain. To the north and east, reclamation schemes have shut out the sea and partly redeemed the foreshore for commerce. The extreme north of the island is occupied by a large salt marsh.

The old city covered about 26 square miles from Colāba in the south to Māhīm and Sion in the north. In 1950 Bombay expanded northward with the inclusion of Salsette Island, and by 1957 a number of suburban municipal boroughs—including Bāndra, Kurla, Andheri, Juhu, Ghātkopar, Mālād, and Muland—and some villages of Thāna were incorporated into Greater Bombay, with an area of 169 square miles (434 square kilometres). The metropolitan area has continued to expand and by 1971 had an area of 239 square miles. By the early 1970s, a bridge across Thāna Creek, linking the island with the mainland, had been built, and it was planned to build a "twin city" on the mainland to relieve congestion on the island.

The environment. The natural beauty of Bombay is unsurpassed by that of any city in the region. The entrance into Bombay Harbour from the sea discloses a magnificent panorama framed by the mountains of the Western Ghāts on the mainland. The wide harbour, studded with islands and dotted with the white sails of innumerable native craft, affords secure shelter to ships, particularly when storms lash the coast.

Bombay Harbour

The climate of Bombay is hot and humid. There are roughly four seasons. Cold weather prevails in December and January, and hot weather from March to May. The rainy season, brought by the southwest monsoon winds, lasts from June to September, and the post-monsoon season, when the weather is again hot, lasts through October and November. Mean monthly temperatures vary from 91° F (33° C) in May to 67° F (19° C) in January. Annual rainfall is 71 inches, with an average of 24 inches falling in July alone.

Typical trees include coconut palms, mango trees, and tamarinds, as well as banyan trees. In the past Salsette Island was the haunt of wild animals, including tigers, leopards, jackals, and deer, but these are now extinct. Animal life now consists of cows, oxen, sheep, goats, and other domestic species. Birdlife includes vultures, pigeons, cranes, and ducks.

The older part of the city is much built up, but more affluent areas, such as Malabar Hill, contain some greenery; there are also a few open playgrounds and parks. Burgeoning urbanization has created slums in sections of the city. An alarming rate of air and water pollution has been caused by the smokestacks of the many factories still crowding the city, the growing volume of auto traffic, and the nearby oil refineries.

The financial district is located in the south of the city (around the old Ft. Bombay). Further south (around Colāba) and to the west along Marine Drive and on Malabar Hill are residential areas. To the north of the Fort area is the principal business district, which gradually merges into a commercial–residential area. Most of the older factories are in this area. Still further north are residential areas, and beyond them are the new industrial areas as well as some shantytown districts.

Transport and communications. Bombay is connected by road to the north, east, and south of India. The city itself has a good system of paved roads, and expressways run along the island connecting it to the mainland on the north at Thāna. Bombay is the railhead for the Western and Central railway systems, and trains run from it to all parts of India. The Santa Cruz International Airport on Salsette Island offers extensive domestic services; it is an important point of entry served by many foreign airlines. The city is also India's major western port. Although the ports at Kandla to the north and Goa and Cochin to the south have grown, most of India's international trade still moves through Bombay.

Inside Bombay, the city is literally bursting at its seams. The main public-transportation facility consists of two suburban electric-train systems owned and run by the Western and Central railways (part of the government-owned Indian Railways system), which daily bring in hundreds of thousands of commuters. There is also a municipally owned and run bus fleet and a dwindling number of trams (trolley cars). The growing number of private automobiles and taxis choke the city's streets and create traffic jams during rush hours.

Satellite communications

Bombay is the main international communications outlet. It is linked to the satellite communications system through a ground station at Arvi, near Pune (Poona), to the southeast and through underground cables from Pune to the national headquarters of the Overseas Communications Service. Bombay is also served by domestic and international telex and radio-telephone facilities.

The population. Bombay's growth since the 1940s has been steady if not phenomenal. At the turn of the 20th century, its population was 85,000; by 1941 it had doubled to 1,695,000, and in 1961 it had grown to 4,152,000. The 1971 census showed a decennial growth rate of 43.75, compared to the all-India average of 24.66. The city's birth rate is much lower than that of the nation because of family-planning schemes, and the higher growth rate is entirely attributable to the influx of people in search of employment.

The city has one of the highest population densities in the world, with an average of 35,317 persons per square mile in Greater Bombay. In the older parts of the city, the density is about 116,000 persons per square mile, or 181 persons per acre; there are 1,800 to 2,000 persons per acre (4,400 to 4,900 persons per hectare) in areas such as Girgaum, Bhendi Bazaar, and Bhuleswar.

The city is truly cosmopolitan and has representatives of almost every religion and region of the world. Almost half of the population is Hindu; there are also important communities of Muslims, Christians, Buddhists, Jains, Sikhs, Zoroastrians, and Jews.

Almost every Indian language and many foreign languages are spoken. Marathi is the dominant Indian language, followed by Gujarati and Hindi. Others include Bengali; Afghan, Kabuli, and Pashto; Arabic; Chinese; English; Goanese; Kacchi; Kanarese; Konkani; Marwari; Nepali; Oriya; Parsi; Punjabi; Rajasthani; Sindhi; Tamil; Telugu; Tulu; and Urdu.

Housing. Housing is crowded and scarce and is largely comprised of privately owned apartment buildings. Public housing has been built by the government either

directly or through the municipality and by private co-operatives with public funds. Workers' housing is also financed by employers and the government. The city is so overcrowded that town planners want to stop the further influx of population by prohibiting the addition of industrial and commercial establishments in the city, by creating a twin city across the bay, and even by forcibly removing some of the establishments and their employees.

Bombay's architecture is a mixture of florid Gothic styles, characteristic of the 18th and 19th centuries, and contemporary designs. The older administrative and commercial buildings are intermingled with skyscrapers and four- or five-story concrete block buildings.

The economy. Bombay is the economic hub and commercial and financial centre of India. Its economic composition in some respects demonstrates India's peculiar acceptance of the nuclear and cow-dung ages. The city contains the Indian Atomic Energy Commission's establishment, including nuclear reactors and plutonium separators, while in many areas primitive sources of fuel and energy are still in use.

Manufacturing. The cotton textile industry, on which the city's 19th-century prosperity was founded, is still of importance. Other establishments are concerned with general engineering, printing, and the production of automobiles, chemicals and paints, fertilizers, food products, silk and artificial fibres, oils and soaps, metals, and plastics. In 1968 there were about 4,500 factories that employed about 540,000 workers.

Commerce. Bombay houses the headquarters of the Reserve Bank of India and the nation's leading banking institution, the State Bank of India. The offices of the Life Insurance Corporation of India, the Bombay Mint, Air India (in the Nirmal Building) and a number of private commercial houses are also located in the city.

The Bombay Stock Exchange

The Bombay Stock Exchange is the country's leading stock and share market and is considered the financial barometer of the country. It occupied a pivotal position before and just after independence in 1947, but its importance has been reduced with the growing diversification of India's economic life, the spread of industries and entrepreneurs around the country, and the national government's economic policies, which give the state a primary role.

Administration and social conditions. *Government.* As the capital of Mahārāshtra state, the city is an integral political division of the state government, the headquarters of which are called the Sachivalaya. The state administers the police force and has administrative control over certain of the city's departmental institutions. The central government controls communications such as the post-and-telegraph system, the railways, the port, and the airport. Bombay is also the headquarters of India's western fleet and the base for the Indian flagship.

The Municipal Corporation

The government of the city is vested in the fully autonomous Municipal Corporation of Greater Bombay. Its legislative body has 131 members elected on adult franchise once every four years and functions through its various standing committees. The chief executive, who is appointed every three years by the state government, is the municipal commissioner. The mayor is annually elected by the corporation; he presides over its meetings and enjoys the highest honour in the city, though he has no real power.

Services. The manifold functions of the corporation include the provision or maintenance of medical relief, education, water supply, fire services, markets, gardens, and engineering projects such as drainage development and the improvement of roads and street lighting.

The municipal corporation operates the bus transport system inside the city and the supply of electricity as public utilities. Electric energy is obtained from a grid system supplied by state, government, and privately owned agencies and is then distributed throughout the city. The water supply, also maintained by the municipality, comes from Tulsī and Vehār lakes on Salsette Island. Pawai Lake, originally harnessed for water supply, has proved unsatisfactory because its water is not potable.

Health services

The city has more than 100 hospitals, including those run by the federal, state, or corporation governments and those that are privately run with the aid of state funds. There are also several private clinics and nursing homes, and the state operates an Ayurvedic (an indigenous system of medicine) hospital. A number of institutions specialize in the treatment of tuberculosis and cancer, and the maternity clinics and child-welfare centres run by the state and the corporation are combined with family-planing centres. Bombay is also the site of the Haffkine Institute, a bacteriological-research centre specializing in tropical diseases.

The state-run police force, more than 18,000 strong, is headed by the commissioner of police, who is responsible for the maintenance of law and order in Greater Bombay. He exercises powers and performs functions in matters such as strength, recruitment, promotion, uniforms, and arms. He is assisted by a number of deputy commissioners of police and other officers.

Education. Bombay has a high literacy rate of 64 percent, compared to the national rate of 29 percent. Primary education is free and compulsory; it is the responsibility of the municipal corporation. Secondary education is provided by public and private schools supervised by the state government. There are also public and private polytechnic institutes and institutions offering diploma courses in mechanical and chemical engineering. The central government's Indian Institute of Technology is also located in the city. The University of Bombay, established in 1857, has 70 affiliated colleges and 16 postgraduate departments and in 1970 had almost 96,000 students. Nine colleges in Goa are also affiliated to the university.

Cultural life. Bombay's cultural life reflects its polyglot population. The city has a number of museums, libraries, literary and other cultural institutions, art galleries, and theatres. Perhaps no other city in India can boast of such a high degree of cultural and entertainment facilities. Bombay is the stronghold of the Indian cinema industry and has several open-air theatres. Throughout the year Western and Indian music concerts and festivals and Indian dance shows are performed. The Prince of Wales Museum of Western India, housed in a building of Indo-Saracenic architecture, contains three main sections of art, archaeology, and natural history. Nearby is the Jehangir Art Gallery, Bombay's first permanent art gallery and centre of cultural and educational activities.

Publishing and broadcasting

Bombay is an important centre for the Indian printing industry and has a vigorous press. The city boasts of five morning and two afternoon English dailies and two Hindi, five Gujarati, ten Marathi, one Sindhi, and nine Urdu dailies. There are also several biweeklies and weeklies. The regional stations of All-India Radio are centred in Bombay, and television services for the city were provided in 1972.

Borivli National Park, in the north of Greater Bombay, is a pleasant holiday resort located near the Kanheri Caves, site of an ancient Buddhist university; the more than 100 caves contain gigantic Buddhist sculptures dating from the 2nd to 9th centuries AD. There are several public gardens including the Victoria Gardens, which house Bombay's zoo in the city proper, the Baptista Garden located on a water reservoir in Mazagaon, and the Hanging Gardens, the Kamala Nehru Park, and the Sloping Park—all on Malabar Hill.

Brabourne Stadium has a seating capacity of 35,000 and is the scene of cricket, football (soccer), and hockey matches. Athletic and cycling track events are held at the Vallabhbhai Patel Stadium. Juhu Beach is the most fashionable area for bathing and swimming.

BIBLIOGRAPHY. *The Imperial Gazetteer of India*, vol. 8 (1908); and STEPHEN MEREDYTH EDWARDES, *The Gazetteer of Bombay City and Island*, 3 vol. (1909–10), provide a wealth of detail on Bombay's history up to British times. The *Maharashtra State Gazetteer*, pt. 1–3, published by the Mahārāshtra State Government (1960–68) and its companion volume for Bombay district bring the city's history up to date and give a contemporary, rather than an imperial, view of the city. Bonaventure, Saint

St. Bonaventure, Christian theologian, minister general of the Franciscan Order, and cardinal bishop of Albano, was renowned in his own day as a master of the spiritual life. He is now proclaimed a doctor of the Roman Catholic Church with the special title Seraphic Doctor, denoting the sublimity of his wisdom. For restoring the Franciscans to their original ideal of evangelical perfection, he is honoured as the second founder of their order.

St. Bonaventure, detail of a fresco by Benozzo Gozzoli (1420–1497). In the Church of S. Francesco, Montefalco, Italy.
Alinari

Education and academic career

Named John, he was born about 1217 at Bagnoregio (near Viterbo, Italy), a son of John of Fidanza, a physician, and Maria of Ritella. He fell ill while a boy and, according to his own words, was saved from death by the intercession of St. Francis of Assisi. Entering the University of Paris in 1235, he received the master of arts degree in 1243 and then joined the Franciscan Order, which named him Bonaventure in 1244. He studied theology in the Franciscan school at Paris from 1243 to 1248. His masters, especially Alexander of Hales, recognized in him a student with a keen memory and unusual intelligence; pursuing his studies with a lofty devotion, he reflected with a growing love on every truth he perceived. He was also under the tutelege of John of La Rochelle. After their deaths (1245) he studied further under Eudes Rigauld and William of Meliton. He was later probably influenced by the Dominican Guerric of Saint-Quentin.

By turning the pursuit of truth into a form of divine worship, he integrated his study of theology with the Franciscan mode of the mendicant life. In 1248, he began to teach the Bible; from 1251 to 1253 he lectured on the *Sentences*, a medieval theology textbook by Peter Lombard, an Italian theologian of the 12th century, and became a master of theology in 1254, when he assumed control of the Franciscan school in Paris. He taught there until 1257, producing many works, notably commentaries on the Bible and the *Sentences* and the *Breviloquium* (Summary), which presented a summary of his theology. These works showed his deep understanding of Scripture, the Fathers of the early church, principally St. Augustine, the great Western theologian, and a wide knowledge of the philosophers, particularly Aristotle.

Bonaventure was particularly noted in his day as a man with the rare ability to reconcile diverse traditions in theology and philosophy. He united different doctrines in a synthesis containing his personal conception of truth as a road to the love of God. In 1256, he defended the Franciscan ideal of the Christian life against William of Saint-Amour, a university teacher who accused the mendicants—friars who wandered about and begged for a living—of defaming the Gospel by their practice of poverty and who wanted to prevent the Franciscans and their fellow mendicants, the Dominicans, from attaining teaching positions. Bonaventure's defense of the Franciscans and his personal probity as a member of his religious order led to his election as minister general of the Franciscans on February 2, 1257.

Career as a monastic leader

Founded by St. Francis according to strict views about poverty, the Franciscan Order was at that time undergoing internal discord. One group, the Spirituals, disrupted the order by a rigorous view of poverty; another, the Relaxati, disturbed it by a laxity of life. Bonaventure used his authority so prudently that, placating the first group and reproving the second, he preserved the unity of the order and reformed it in the spirit of St. Francis. The work of restoration and reconciliation owed its success to Bonaventure's tireless visits, despite delicate health, to each province of the order and to his own personal realization of the Franciscan ideal. In his travels, he preached the Gospel constantly and so elegantly that he was recognized everywhere as a most eloquent preacher. As a theologian, he based the revival of the order on his conception of the spiritual life, which he expounded in mystical treatises manifesting his Franciscan experience of contemplation as a perfection of the Christian life. His *Journey of the Mind to God* (1259) was a masterpiece showing the way by which man as a creature ought to love and contemplate God through Christ after the example of St. Francis. Revered by his order, Bonaventure recodified its constitutions (1260), wrote for it a new *Life of St. Francis of Assisi* (1263), and protected it (1269) from an assault by Gerard of Abbeville, a teacher of theology at Paris, who renewed the charge of William of Saint-Amour. He also protected the church during the period 1267–73 by upholding the truth of Christian faith while denouncing the errors of unorthodox masters at Paris who contradicted revelation in their philosophy.

Bonaventure's wisdom and ability to reconcile opposing views moved Pope Gregory X to name him cardinal bishop of Albano, Italy, in May 1273, though Bonaventure earlier had declined to accept appointment to the see of York, England, from Pope Clement IV in 1265. Gregory consecrated him in November at Lyons, where he resigned as minister general in May 1274. At the second Council of Lyons he was the leading figure in the reform of the church, reconciling the secular (parish) clergy with the mendicant orders. He also had a part in restoring the Greek Church to union with Rome. He died at the council on July 15, 1274. His death was viewed as the loss of a wise and holy man, full of compassion and virtue, captivating with love all who knew him. He was buried the same day in a Franciscan church with the Pope in attendance. The respect and love that was held for Bonaventure is exemplified in the formal announcement of the council: "At the funeral there was much sorrow and tears; for the Lord has given him this grace, that all who saw him were filled with an immense love for him." His exemplary life as a Franciscan and the continual influence of his doctrine on the life and devotion of the Western Church won for him a declaration of sanctity by Pope Sixtus IV on April 14, 1482, and the designation Doctor of the Church by Sixtus V on March 14, 1587. Thereafter, St. Bonaventure was regarded as a truly great theologian, a Franciscan of fervent devotion, and a prominent leader of his time.

Modern scholars consider him to have been one of the foremost men of his age, an intrepid defender of human and divine truth, and an outstanding exponent of a mystical and Christian wisdom.

BIBLIOGRAPHY. The critical edition of Bonaventure's works is *Opera omnia*, 10 vol. (Quaracchi; 1882–1902). Translations of his works by JOSE DE VINCK are "The Journey of the Mind to God," in vol. 1 of *The Works of Bonaventure* (1960); and vol. 2, *Breviloquium* (1963). Studies of his doctrine and life (with bibliographies) are J.G. BOUGEROL, *Introduction à l'étude de Saint Bonaventure* (1961; Eng. trans., 1964); and I.C. BRADY, "Bonaventure, St.," in *New Catholic Encyclopedia*, vol. 2, pp. 658–664 (1967).

(J.F.Q.)

Bone

Bone is a rigid body tissue consisting of cells embedded in an abundant, hard intercellular material. The two principal components of this material, collagen and calcium phosphate, distinguish bone from such other hard tissues as chitin, enamel, and shell.

The functions of bone include (1) structural support for the mechanical action of soft tissues, such as contraction of muscles, expansion of lungs; (2) protection of soft parts, as by the brain case; (3) provision of a protective site for specialized tissues such as the blood-forming system (bone marrow); and (4) a mineral reservoir or sink, whereby endocrine systems regulate the level of calcium and phosphate in the circulating body fluids.

EVOLUTIONARY ORIGIN AND SIGNIFICANCE

Bone is found only in vertebrates, and, among modern vertebrates, only in bony fish and higher classes. Although fossil ancestors of the elasmobranchs and cyclostomes had armoured headcases, serving largely a protective function, which appear to have been true bone, modern cyclostomes have only an endoskeleton, or inner skeleton, of noncalcified cartilage, and elasmobranchs, a skeleton of calcified cartilage. Although a rigid endoskeleton performs obvious body supportive functions for land-living vertebrates, it is doubtful that bone offered any such mechanical advantage to the teleost (bony fish) in which it first appeared, for in a supporting aquatic environment, great structural rigidity is not essential for maintaining body configuration. The sharks and rays are superb examples of mechanical engineering efficiency, and their perseverance from the Devonian attests to the suitability of their nonbony endoskeleton.

Bone and homeostasis

In modern vertebrates true bone is found only in animals also capable of controlling the osmotic and ionic composition of their internal fluid environment.

Marine invertebrates exhibit interstitial fluid compositions essentially the same as that of the surrounding sea water. Early signs of regulability are seen in cyclostomes and elasmobranchs, but only at or above the level of true-bone fishes does the composition of the internal body fluids become constant. The mechanisms involved in this regulation are many and complex and include both the kidney and the gills. Fresh and marine waters provide abundant calcium, but only traces of phosphate, and, because relatively high levels of phosphate are characteristic of the body fluids of higher vertebrates, it seems likely that a large, readily available internal phosphate reservoir would confer significant independence of external environment on bony vertebrates. With the emergence of terrestrial forms, the availability of calcium regulation became equally significant. Along with the kidney and the various component glands of the endocrine system, bone has contributed to development of internal fluid homeostasis—the maintenance of an equilibrium with respect to its chemical composition. This was a necessary step for emergence of land-living vertebrates. Moreover, out of the buoyancy of water, structural rigidity of bone afforded the characteristic mechanical advantages of the modern vertebrate skeleton.

THE STRUCTURE OF BONE

Chemical composition. Depending upon species, age, and type of bone, the bone cells represent 1–15 percent of the volume of bone, but in mature bone in most higher animals usually they represent 1–5 percent. The nonliving intercellular material consists of an organic component, collagen (a fibrous protein arranged in long strands or bundles similar in structure and organization to the collagen of ligaments, tendons, and skin), with small amounts of proteinpolysaccharides, mucopolysaccharides chemically bound to protein and dispersed within and around the collagen fibre bundles, and an inorganic mineral component in the form of innumerable rod-shaped crystals with diameters on the order of 50 Å and lengths from 200 to 2,000 Å. These crystals are arranged parallel with the long axes of collagen bundles and many actually lie in voids within the bundles themselves. Organic material comprises 50 percent of the volume and 30 percent of the dry weight of the intercellular composite, and mineral the remainder. The major minerals are calcium and phosphate, present in proportions ranging from 1.4:1 to 2.1:1. When first deposited, mineral is crystallographically amorphous but with maturation becomes typical of the apatite minerals, the major component being hydroxyapatite, $Ca_{10}(PO_4)_6(OH)_2$. Carbonate is also present, in amounts varying from 4 percent of bone ash in fish and 8 percent in most mammals to more than 13 percent in the turtle, and occurs in two distinct phases, calcium carbonate and a carbonate apatite. Except for that associated with its cellular elements, there is little free water in adult mammalian bone (approximately 8 percent of total volume). As a result, diffusion from surfaces into the interior of the intercellular substance occurs at the slow rates more typical of diffusion from surfaces of solids than within liquids.

Physical properties. The structural role of the skeleton depends on the hardness, strength, and rigidity of bone. The mineral crystals are responsible for hardness, rigidity, and the great compressive strength of bone, but they share with other crystalline materials a great weakness in tension, arising from the tendency for stress to concentrate about defects and for these defects to propagate. On the other hand, the collagen fibrils of bone possess high elasticity, little compressive strength, and considerable intrinsic tensile strength. The tensile strength of bone depends, however, not on collagen alone but on the intimate association of mineral with collagen, which confers on bone many of the general properties exhibited by two-phase materials such as fibre glass and bamboo. In such materials the dispersion of a rigid but brittle material in a matrix of quite different elasticity prevents the propagation of stress failure through the brittle material and hence allows a closer approach to the theoretical limiting strength of single crystals.

Hardness, rigidity, and compressive and tensile strength

The fine structure of bone has thus far frustrated attempts to determine the true strength of the mineral-matrix composite at the "unit" structural level. Compact bone specimens have been found to have tensile strength in the range of 10,000–20,000 pounds per square inch (psi), and compressive strengths in the range of 20,000–30,000 psi. These values are of the same general order as for aluminum or mild steel, but bone has an advantage over such materials in that it is considerably lighter. The great strength of bone exists principally along its long axis and hence roughly parallel both to the collagen fibre axis and to the long axis of the mineral crystals.

Elasticity of bone

Although apparently stiff, bones exhibit a considerable degree of elasticity, which is important to the skeleton's ability to withstand impact. Estimates of modulus of elasticity of bone samples are of the order of 6,000 to 10,000 psi, a value very much less than steel, for example, indicating much greater elasticity of bone. Perfect elasticity exists with loads up to 30 to 40 percent of breaking strength; above this, creep occurs, presumably along natural defects within the bony structure. The modulus of elasticity in bone is strikingly dependent upon the rate at which loads are applied, bones being stiffer during rapid deformation than during slow; this behaviour suggests an element of viscous flow during deformation.

As might be anticipated from consideration of the two-phase composition of bone, variation in the mineral-collagen ratio leads to change in physical properties: less mineral tends ultimately to greater flexibility, and more mineral to increased brittleness. Optimal ratios, as reflected in maximal tensile strength, are observed at an ash content of approximately 66 percent, a value that is characteristic of the weight-bearing bones of mammals.

Bone morphology. Grossly, bone tissue is organized into a variety of shapes and configurations adapted to the function of the bone concerned: broad, flat plates, such as scapula, as anchors for large muscle masses, or hollow, thick-walled tubes, such as femur, radius, ulna, for supporting weight or for use as a lever arm (see SKELETAL

SYSTEM, HUMAN). These different types of bone are distinguished more by their external shape than by their basic structure.

In all bones the basic bone has an exterior layer, termed cortex, that is smooth, dense, continuous, and of varying thickness. In its interior, bony tissue is arranged in a network of intersecting plates and spicules, varying in amount in different bones, enclosing spaces filled with blood vessels and marrow. This honeycombed bone is termed cancellous, and the plates and spicules trabeculae. In mature bone, trabeculae are arranged in an orderly pattern that provides continuous units of bony tissue aligned parallel with the lines of major compressive or tensile force. Trabeculae thus provide a complex series of cross-braced interior struts so arranged as to give maximal rigidity with minimal material.

Bones such as vertebrae, subject to primarily compressive or tensile forces, usually have thin cortices and provide necessary structural rigidity through trabeculae; whereas bones such as the femur, subject to prominent bending, shear, or torsional forces, usually have thick cortices, a tubular configuration, and a continuous cavity running through their centres (medullary cavity). The cortical material of tubular bones is termed compact bone and differs in a number of fine structural details from cancellous bone.

Long bones, distinctive of the body's extremities, exhibit a number of gross structural features in common. The central region of the bone (diaphysis) is the most clearly tubular. At one or commonly both ends the diaphysis flares outward and assumes a predominantly cancellous internal structure. This region (metaphysis) functions to transfer loads from weight-bearing joint surfaces to the diaphysis. Finally, at the end of a long bone is a region known as an epiphysis, which exhibits a cancellous internal structure and which comprises the bony substructure of the joint surface. Prior to full skeletal maturity the epiphysis is separated from the metaphysis by a cartilaginous plate, the growth plate or physis; in bones with complex articulations (such as the humerus at its lower end) or bones with multiple protuberances (such as the femur at its upper end) there may be several separate epiphyses, each with its growth plate.

Four types of cells in bone

Microscopically, bone consists of hard, apparently homogeneous intercellular material, within or upon which can be found four characteristic cell types: osteoblast, osteocyte, osteoclast, and undifferentiated bone mesenchymal cells. The osteoblast is responsible for the synthesis and deposition on bone surfaces of the protein matrix of new intercellular material. The osteocyte is an osteoblast that has been trapped within intercellular material, residing in a cavity (lacuna) and communicating with other osteocytes as well as with free bone surfaces by means of extensive filamentous protoplasmic extensions that occupy long, meandering channels (canaliculi) through the bone substance. With the exception of certain higher orders of modern fish, all bone, including primitive vertebrate fossil bone, exhibits an osteocytic structure. Osteoclasts are usually large, multinucleated cells that, working from bone surfaces, resorb bone by direct chemical and enzymatic attack. Undifferentiated mesenchymal cells of the bone reside in the loose connective tissue between trabeculae, along vascular channels, and in the condensed fibrous tissue covering the outside of the bone (periosteum); they give rise under appropriate stimuli to either osteoblasts or osteoclasts.

Depending on how the protein fibrils and osteocytes of bone are arranged, bone is of two major types: woven, in which collagen bundles and the long axes of the osteocytes are randomly oriented, and lamellar, in which both the fibrils and osteocytes are aligned in clear layers. In lamellar bone the layers alternate every few microns, and the primary direction of the fibrils shifts approximately 90°. In compact bone of many mammalian species lamellar bone is further organized into units known as osteons, or haversian systems, which consist of concentric cylindrical lamellar elements several millimetres long and 0.2–0.3 millimetre in diameter. Osteons exhibit a gently spiral course oriented along the axis of the bone. In their centre is a canal (haversian canal) containing one or more small blood vessels, and at their outer margins is a boundary layer known as a "cement line," which serves both as a means of fixation for new bone deposited on an old surface and as a diffusion barrier. Osteocytic processes do not penetrate the cement line, and hence these barriers constitute the outer envelope of a nutritional unit, osteocytes on opposite sides of a cement line deriving their nutrition from different vascular channels. Cement lines are found in all types of bone, as well as in osteons, and in general they indicate lines at which new bone was deposited on an old surface.

Vascular supply and circulation. In a typical long bone, blood is supplied by three separate systems: nutrient artery, periosteal vessels, and epiphyseal vessels. The diaphysis and metaphysis are nourished primarily by the nutrient artery, which passes through the cortex into the medullary cavity and then ramifies outward through haversian and Volkmann's canals to supply the cortex. Extensive vessels in the periosteum, the membrane surrounding the bone, supply the superficial layers of the cortex and connect with the nutrient-artery system. In the event of obstruction of the nutrient artery, periosteal vessels are capable of meeting the needs of both systems. The epiphyses are supplied by a separate system that consists of a ring of arteries entering the bone along a circular band between the growth plate and the joint capsule. In the adult these vessels become connected to the other two systems at the metaphyseal-epiphyseal junction, but while the growth plate is open there is no such connection, and the epiphyseal vessels are the sole source of nutrition for the growing cartilage; hence they are essential for skeletal growth.

Drainage of blood is by a system of veins that runs parallel with the arterial supply and by veins leaving the cortical periosteum through muscle insertions. Muscle contraction milks blood outward, giving rise to a centrifugal pattern of flow from the axial nutrient artery through the cortex and out through muscle attachments.

PHYSIOLOGY AND BIOCHEMISTRY OF BONE

Remodelling, growth, and development. *Bone resorption and renewal.* Whereas renewal in tissues such as muscle occurs largely at a molecular level, renewal of bone occurs at a tissue level and is similar to the remodelling of buildings in that local removal (resorption) of old bone must precede new bone deposition. Remodelling is most vigorous during the years of active growth, when deposition predominates over resorption. Thereafter remodelling gradually declines, in man until about age 35, after which its rate remains unchanged or increases slightly. From the fourth decade on resorption exceeds formation, resulting in a 5–10 percent loss in bone mass per decade, equivalent to a daily loss of 15–30 milligrams of calcium.

Except for the addition of the ossification mechanisms within cartilage, growth and development involve exactly the same type of remodelling as that in the adult skeleton. Both require continuous, probably irreversible differentiation of osteoclasts and osteoblasts from the undifferentiated bone mesenchyme. Life span of osteoclasts is from a few hours to at most a few days, that of osteoblasts a few days to at most a few weeks.

Bone resorption

Resorption is produced by clusters of osteoclasts that either erode free bone surfaces or form "cutting cones" that tunnel through compact bone and create the cylindrical cavities that may be subsequently filled by osteons. Osteoclastic cells secrete enzymes and hydrogen ions onto the bone surface, dissolving the mineral and digesting the matrix at virtually the same moment. The process is associated with locally augmented blood flow and with a greater surface acidity than elsewhere in bone, despite the fact that the process of dissolving apatite consumes hydrogen ions. Resorption is usually a much more rapid process than formation. Osteoclastic cutting cones have been observed to advance at rates up to 500 microns per day.

Bone formation

Bone is formed on previously resorbed surfaces by deposition of a protein matrix material (osteoid) and its subsequent mineralization. Osteoblasts elaborate matrix as a continuous membrane covering the surface on which they are working at a linear rate that varies with both age and species, but which in large adult mammals is on the order of 1.0 micron per day. The unmineralized matrix constitutes an osteoid seam or border, averaging 6 to 10 microns in thickness during active bone formation. The biochemical and physical sequence of events that prepare matrix for mineralization includes intracellular biosynthesis of collagen by osteoblasts, extrusion of collagen extracellularly in soluble form, maturation or polymerization of collagen into an array of fibrils (in random orientation in rapidly deposited bone, in a highly ordered, regular pattern in slowly formed lamellar bone), binding of calcium to collagen fibrils, and formation of protein-mucopolysaccharide complexes. Mineralization itself depends upon establishment of crystal nuclei within the matrix; this process requires five to ten days and is under the control of the osteoblast, but its exact chemistry is obscure. A suitable nucleating configuration is somehow established, and once nuclei reach a critical size further mineralization proceeds spontaneously in the presence of usual body fluid calcium and phosphorus concentrations. Other collagenous tissues, such as dermis, tendon, and ligament, do not normally calcify, even though bathed by the same body fluids as bone. Although extracellular fluid is a highly supersaturated solution with respect to hydroxylapatite, calcium and phosphorus will not spontaneously precipitate in this crystalline form at physiological pH, so that one and the same fluid is indefinitely stable in non-bone-forming regions, yet richly supports mineralization in the presence of suitable crystal nuclei. Mineral movement into new bone is initially rapid and in compact cortical bone is known to reach approximately 70 percent of full mineralization within a few hours after matrix nucleation. This mineral deposition involves replacement of the water that occupied half of the original matrix volume. As water content falls, further mineral diffusion is impeded; and the final mineralization occurs progressively more slowly over a period of many weeks. In normal adult man new bone formation takes up about 400 milligrams of calcium per day, an amount approximately equal to that in the circulating blood.

Osteocyte function

Osteocytes, once thought of as resting cells, are now recognized to be metabolically active and to possess, at least in latent form, the ability to resorb and reform bone on their lacunar walls. Although osteocytes constitute only a small fraction of total bone volume, they are so arranged within bone, and the network of their protoplasmic extensions is so extensive that there is essentially no volume of bony material situated more than a fraction of a micron from a cell or its processes. Of the more than 1,200 square metres of anatomic surface within the skeleton of an adult man, about 99 percent is accounted for by the lacunar and canalicular surfaces. Resorption and deposition on this surface serve both to regulate plasma-calcium concentration and to renew bony material. This renewal may be particularly important because all composite materials change in their physical properties with time. It is not known whether bone properties change sufficiently to have biologic consequence, but to the extent that such change does occur, renewal around osteocytes would provide for the physical maintenance of bone structural material.

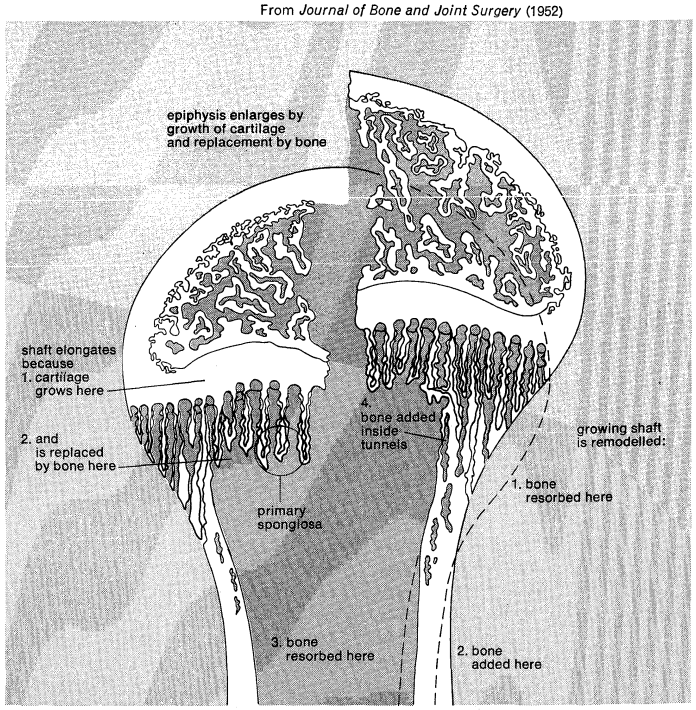
Growth and development of bone

Types of bone formation. Bone is formed in the embryo in two general ways. For most bones the general shape is first laid down as a cartilage model, which is then progressively replaced by bone (endochondral bone formation). A few bones (such as clavicle and calvarium) develop within a condensed region of fibrous tissue without a cartilaginous intermediate (membrane bone formation). In long bones a collar of spongy membrane bone is first laid down in the fibrous tissues surrounding the cartilaginous model of the shaft. At the same time the cartilage deep to this collar begins to degenerate and calcify. The bone is then penetrated by blood vessels, which grow into the degenerating model and remove the calcified cartilage enclosed within the collar. Vascular invasion proceeds toward both ends of the model in parallel with continued extension of the bony collar. This leaves a structure consisting of two cartilaginous epiphyses at the ends of a hollow, bony shaft.

Growth from this point on is accomplished in two ways. Radial growth occurs by deposition of new bone on the periosteal surface and roughly equivalent resorption at the endosteal surface. Longitudinal growth involves replacement of cartilage by bone from the shaft side of the growth plate, at a rate closely matched to the production of new cartilage by the plate itself. The growth plate consists of highly ordered rows of cartilage cells; the row farthest removed from the bony shaft is a basal or germinal layer; it is responsible for cell replication and cartilage growth. The complex sequence of longitudinal growth consists of cartilage cell degeneration farthest from the germinal layer, calcification of cartilage in that area, deposition over it of a thin layer of true bone (primary spongiosa), and, finally, osteoclastic resorption to extend the medullary cavity in parallel with longitudinal growth and to reshape the contour of the shaft.

Cartilage growth, degeneration, calcification, and ultimate replacement by bone is responsible for most growth in length in vertebrates. It first begins in the embryo and continues until full skeletal maturity, when in most species the growth plates fuse and disappear.

From *Journal of Bone and Joint Surgery* (1952)



Principal structures involved in (left) growth and (right) remodelling of a typical long bone.

The appearance of epiphyseal ossification centres and their ultimate fusion, both of which can be detected by ordinary X-rays, normally follows an orderly and predictable sequence that is of great value in the evaluation of disorders of growth and development. Because of the complicated interaction of several tissue elements in the process of endochondral ossification, the metaphyseal region of bones is the seat of, or prominently reflects, many nutritional or metabolic disturbances of growth. Examples of disorders involving this growth mechanism include rickets and achondroplastic dwarfism (see BONE DISEASES AND INJURIES).

Physiology of bone. *Calcium and phosphate equilibrium.* As important as the structural properties of bone is the role bone plays in the maintenance of the ionic com-

Calcium and phosphate homeostasis

position of the blood and interstitial fluids of the body. All vertebrates possessing true bone exhibit body-fluid calcium-ion concentrations of approximately 50 milligrams per litre (1.25 millimoles) and phosphorus concentrations in the range of 30–100 milligrams per litre (1–3 millimoles). These levels, particularly those of calcium, are extremely important for the maintenance of normal neuromuscular function, interneuronal transmission, cell membrane integrity and permeability, and blood coagulation. The rigid constancy with which calcium levels are maintained, both in the individual and throughout all the higher vertebrate classes, attests to the biological importance of such regulation. Approximately 99 percent of total body calcium and 85 percent of total body phosphorus reside in the mineral deposits of bone, and thus bone is quantitatively in a position to mediate adjustments in concentration of these two ions in the circulating body fluids. Such adjustments are provided by two hormonal control loops (control systems with feedbacks) and by at least two locally acting mechanisms. The hormonal loops involve parathyroid hormone (PTH) and calcitonin (CT) and are concerned exclusively with regulation of calcium-ion concentration.

PTH acts to elevate the ionized calcium level in body fluids and CT (from the ultimobranchial body or C cells of the thyroid) to depress it, and the secretion of each hormone is sensitively controlled by the level of calcium ion in the circulating blood, PTH secretion being inversely related and CT secretion being directly related to calcium ion concentration. At normal calcium concentrations there is a low level of secretion of both hormones.

PTH acts on at least two nonbony effector organs (kidney and intestine) as well as on bone, whereas CT appears to act primarily on bone. The skeletal effects of these hormones are exerted predominantly on the resorptive process. PTH stimulates mesenchymal proliferation and osteoclast induction and accelerates the osteolytic activity of osteocytes. The principal long-term effect of the hormone is a considerable increase in the number of osteoclasts with correspondingly increased resorption. Vitamin D is required for the osseous effects of PTH, and in pharmacological quantities stimulates both osteocytic and osteoclastic resorption in the absence of PTH. Finally, PTH produces acute inhibition of osteoblast function, thus decreasing calcium deposition in new bone in periods of total body-calcium need.

With respect to action on organs other than bone, PTH enhances gastrointestinal absorption of calcium from the diet and, by increasing calcium reabsorption from the fluid within the renal (kidney) tubules, reduces renal excretory losses of calcium. The intestinal effect, like that on bone, requires vitamin D for its expression. Finally, PTH, by interfering with renal tubular phosphate reabsorption, also enhances the renal excretion of phosphate. This mechanism, which serves to lower the level of phosphates in the bloodstream, is significant because high phosphate levels inhibit and low levels enhance osteoclastic resorption. Thus phosphate concentration itself directly modulates the calcium-mediated effects of both parathyroid hormone and the many other agencies that influence bone resorption. Calcium ion itself has similar effects on the osteoclastic process, high levels inhibiting and low levels enhancing the effect of systemically acting agents such as PTH. These local effects constitute the only recognizable control of phosphate, but the PTH loop appears to be the more important regulatory process in calcium-ion homeostasis. At extremely low levels both calcium and phosphate become rate-limiting at the mineralization site as well, reducing both deposition of mineral and osteoblast function.

Calcitonin, acting to offset elevations in calcium ion level, works primarily to inhibit bone resorption, whether by osteoclasts or by osteocytes. It does not appear to have significant effects on tissues other than bone. Calcitonin differs further from PTH in its much more rapid action (minutes as opposed to hours) and in its short duration of action. Its primary function seems to be to offset acute elevations in plasma calcium during feeding.

Physiological and mechanical controls. In the language of control mechanics, remodelling depends upon two control loops with negative feedback: a homeostatic loop involving the effects of PTH and CT on resorption and a mechanical loop that brings about changes in skeletal mass and arrangement to meet changing structural needs. The PTH-CT loop is basically a systemic process, and the mechanical loop is local; the two loops do interact significantly at the level of the cells that act as intermediaries in both processes. A large number of other factors, including minerals in the diet, hormonal balance, disease, and aging, have important effects on the skeleton that interact with the control system.

Controls exerted by mechanical forces

The controls exerted by mechanical forces, recognized for over a century, have been formulated as Wolff's law: "Every change in the function of a bone is followed by certain definite changes in its internal architecture and its external conformation." Of the many theories proposed to explain how mechanical forces communicate with the cells responsible for bone formation and resorption, the most appealing has been postulation of induced local electrical fields that mediate this information exchange. Many crystalline or semicrystalline materials, including both bone collagen and its associated mineral, exhibit piezoelectric properties. Deformation of macroscopic units of bone by mechanical force produces a charge in the millivolt range and current flow on the order of 10^{-15} ampere; both voltage and current flow are proportional to the applied force. Regions under tension act as anode and compressed regions as cathode. Currents of this magnitude are capable of aligning collagen fibrils as they aggregate from the solution phase and are known also to alter the cell-based development of regeneration buds in amphibia. The negative-feedback characteristic of this mechanism lies in the fact that bone accumulates about the cathodal region of this system, hence reducing the electrical effects produced by an applied force. The mechanisms by which the bone mesenchyme responds to mechanical stimuli (whether or not mediated by electrical signals) are uncertain. In general, heavy usage leads to heavy bone, and disuse, as in immobilization associated with injury or severe disease, results in decrease in bone mass and increased excretion of calcium, phosphorus, and nitrogen. The cellular response, however, is discouragingly complex. In broad outline it appears that the local expression of decreased stress is an increase in bone resorption coupled variably with a smaller and secondary increase in bone formation, whereas increased stress appears to be accompanied by a decrease in bone resorption coupled also with a smaller and probably secondary increase in bone formation. The decrease in resorption represents a decreased sensitivity to systemic stimuli, such as PTH, and reflects an interaction between hormonal and physical forces at the cellular level. PTH is the major determinant of all remodelling, structural as well as homeostatic; mechanical forces are the major determinant of where that remodelling occurs.

One of the most arresting features of skeletal remodelling is the tendency for rates of bone resorption and bone formation to change in the same direction. Three mechanisms for this coupling can be identified. The first is homeostatic and rises from the mineral demand created by formation of crystal nuclei in the bone matrix. Unless the calcium demands of increased bone formation can be met from some other source (such as increased diet calcium), they will inevitably lead to increased PTH secretion and bone resorption. Since the level of PTH is a principal determinant of bone resorption, it follows that high levels of formation tend to produce high levels of resorption (and vice versa). A second mechanism is the mechanical force-piezoelectric system discussed earlier. Local bone resorption, by reducing structural volume, concentrates applied forces in the remaining bone; this leads to increased strain and presumably increases the stimulus for local bone repair. A third mechanism is inferred from the observation in adult animals that the induction of specialized bony cells from the mesenchyme

proceeds in a predetermined sequence: first osteoclasts and then osteoblasts, so that even on free surfaces resorption usually precedes formation. The ultimate basis of this cellular coupling is not known.

Because of the paramount influences that parathyroid hormone and calcitonin have on bone, their effects have been described in detail in the discussions of calcium and phosphate homeostasis and control of skeletal remodelling.

Estrogens

Hormonal influences. The most striking effects of estrogens are seen in birds, in which during the part of the cycle prior to egg formation a marked increase in osteoblastic activity occurs along the inside surfaces of the long bones, and the medullary cavities become filled with spongy bone. As the egg is formed, this spongy bone is rapidly resorbed, plasma calcium rises dramatically, and calcium is deposited in the shell. In mammals studied prior to skeletal maturity, administration of estrogens produces an accelerated appearance of ossification centres, a slowing in growth of cartilage and bone, and fusion of the epiphyses; the result is an adult skeleton smaller than normal. In older mammals estrogens in certain dosages and schedules of administration may inhibit trabecular bone resorption, and in some species prolonged administration of estrogen may lead to increased bone porosity. In postmenopausal women administration of estrogen suppresses bone resorption and produces a transient decrease in serum calcium and phosphorus and in renal reabsorption of phosphorus, as well as positive calcium balance, effects which help to stabilize the total skeletal bone mass.

The effects described are for estrogens as a general class of steroid hormone, and no attempt has been made to differentiate between the actions of natural estrogenic hormones and the many synthetic varieties now in wide use to suppress ovulation. Extremely few studies have been conducted to determine the effects of the latter on bone.

Effects of progesterone, testosterone, adrenal corticosteroids, thyroid hormone

Very little is known of the effects of progesterone on bone beyond studies in young guinea pigs suggesting slight inhibition of the activity of such hormones as estrogens, which speed skeletal development.

In mammals, including humans, just prior to sexual maturity, the growth spurt occurring in males is attributable principally to the growth-promoting action of the male sex hormone testosterone. When administered, testosterone and related steroids stimulate linear growth for a limited period; ultimately, however, particularly if they are given in large doses, they suppress bone growth as the result of hastened skeletal development and premature epiphyseal closure. Studies have indicated that testosterone derivatives administered to adult mammals suppress the turnover and resorption of bone and increase the retention of nitrogen, phosphorus, and calcium.

The influence of the adrenal corticosteroid hormones on bone is varied, but the principal result is slowing of growth in the young and decrease in bone mass in the adult. In Cushing's syndrome, in which there is abnormally high secretion of corticosteroids, bone loss to the point of fractures often occurs. Cortisol in high concentration suppresses protein and mucopolysaccharide synthesis, with inhibition of bone matrix formation and of incorporation of nucleosides into bone cells.

Lack of the internal secretion of the thyroid gland results in retardation of skeletal growth and development. Action of this hormone to facilitate growth and skeletal maturation is probably indirect, through its general effects on cell metabolism. Thyroid hormone in excess leads in the young to premature appearance of ossification centres and closure of the epiphyses, and in the adult to increased bone-cell metabolism. Commonly in the hyperthyroid adult bone resorption predominates over increased bone formation with resultant loss of bone mass.

The anterior lobe of the pituitary gland secretes a hormone essential for growth and development of the skeleton. This effect of the hormone is indirect and mediated by "sulfation factor," a substance produced in the liver in response to stimulation by the growth hormone. The extent to which growth hormone is involved in skeletal remodelling in the adult is not known, but excessive elaboration of the hormone after maturity leads to distorted enlargement of all bones in the condition known as acromegaly. Excessive elaboration of growth hormone prior to epiphyseal closure leads to gigantism. Studies of the administration of growth hormone to man have indicated marked species specificity; growth in hypopituitary dwarfs is stimulated only by human or primate growth hormone. The principal metabolic effects in man of the hormone are retention of nitrogen and increased turnover of calcium, resulting in increases both in intestinal calcium absorption and in urinary calcium excretion.

Effects of growth hormone and of insulin

Insulin participates in the regulation of bone growth; it may enhance or even be necessary for the effect of growth hormone on bone. Insulin has been found to stimulate growth and epiphyseal widening in rats whose pituitaries have been removed and to promote chondroitin sulfate synthesis in cartilage and bone and the transport of amino acids and nucleosides into bone.

Nutritional influences. The most significant nutritional influence on bone is the availability of calcium. The close relationship between bone and calcium is indicated by the principal processes of calcium metabolism. Bone contains 99 percent of the calcium in the body and can behave as an adequate buffer for maintenance of a constant level of freely moving calcium in soft tissues, extracellular fluid, and blood. The free-calcium concentration in this pool must be kept within fairly narrow limits (50–65 milligrams per litre of extracellular fluid) to maintain the constant internal milieu necessary for neuromuscular irritability, blood clotting, muscle contractility, and cardiac function. Calcium leaves the pool by way of bone formation, by such routes as the urine, feces, and sweat, and periodically by way of lactation and transplacental movement. Calcium enters the pool by the mechanism of bone resorption and by absorption from dietary calcium in the upper intestinal tract.

The significance with respect to bone of adequate availability of calcium to animal or man is that the mechanical strength of bone is proportional to its mineral content. All of the other components of bone, organic and inorganic, are, of course, also essential for bone integrity, but the importance of availability of structural materials is most easily illustrated by consideration of calcium balance (dietary intake versus excretory output). If intake of calcium is limited, maintenance of normal levels of extracellular and soft tissue calcium in the face of mandatory daily losses from this pool by various excretory routes requires that calcium be mined from its storage depot, bone. Abundant mineral intake, then, tends to preserve bone mass, and an increase of positivity of calcium balance has been shown to suppress resorption of bone.

The Recommended Dietary Allowances of the Food and Nutrition Board, National Academy of Sciences–National Research Council (1968) for calcium daily are 800 milligrams for adults and 1.0 to 1.4 grams for adolescents and pregnant and lactating women. The usual daily intake of this element, however, ranges between 500 and 800 milligrams, about 150–250 milligrams from green vegetables and the remainder usually from milk and milk products. Daily urinary excretion of calcium is normally from 50 to 150 or 200 milligrams (the upper limit of normal being uncertain), varying sharply with intake at very low levels but rising only very gradually with increasing intake above 300 to 400 milligrams. Fecal excretion of calcium is much larger than urinary, most of the calcium in the feces being unabsorbed dietary calcium. A man's losses from the skin and in the sweat range from less than 30 milligrams per day to as high as 200 milligrams per day during active sweating. Calcium absorption varies considerably depending on previous and current levels of intake and type of diet. At intakes of 400 milligrams per day, absorption averages 32 percent; at 1,000 milligrams per day, 21 percent.

The other principal mineral constituent of bone, phosphorus, is abundantly available in both milk and in other protein-rich foods, and its daily recommended allowance is the same as for calcium. A prolonged dietary deficiency of phosphate and an extreme deficiency of calcium will result in mineral-poor bone, known as rickets or osteomalacia. The skeleton serves as a storage reservoir for two other cations of considerable physiologic importance, magnesium and sodium. Magnesium ion has a calcium-like effect on parathyroid hormone secretion, and magnesium deficiency has a number of the same effects as calcium deficiency.

Fluoride, an element of proven value and safety in prevention of dental caries when provided in drinking water at concentrations of one part per million, is absorbed into bone lattice structure as well as into enamel and produces a larger crystal more resistant to resorption. Amounts ten or more times that normally taken in fluoridated drinking water have been noted to cause abnormalities of bone collagen synthesis. Extremely large dosages produce in man the more dense but irregularly structured and brittle bone of fluorosis.

Vitamins; proteins

The function of vitamin A remains to be clarified, but it is apparently necessary for proliferation of cartilage and bone growth. Without vitamin A, bone remodelling is also impaired and bones develop in abnormal shapes. Excessive amounts of the vitamin result in thinning of cortical bone and fracture.

Ascorbic acid, or vitamin C, is essential for intracellular formation of collagen and for hydroxylation of proline. In scurvy, a vitamin C deficiency disease, the collagen matrix of bone is either partially or completely unable to calcify (see discussion above on formation of bone).

Vitamin D has several complex physiologic actions that affect the metabolism of bone. The oldest known effect is facilitation of intestinal absorption of calcium and, indirectly, of phosphate. The second target of vitamin D action is the renal tubule. In the child who has rickets administration of the vitamin restores the impaired tubular reabsorption of phosphorus to normal; in the person whose secretion of parathyroid hormone is subnormal, however, the vitamin in large doses has a parathyroid hormone-like effect and reduces the elevated serum phosphorus by suppression of the renal tubular reabsorption of phosphorus. The third site of vitamin D action is the bone cells, in which the vitamin increases citrate production by conversion from pyruvate; the way in which this action is related to the effect of the vitamin on mobilization of bone mineral is at present uncertain. Also at the cellular level both parathyroid hormone and vitamin D stimulate release of calcium from mitochondria, but the hormone cannot do so in the absence of vitamin D, further evidence of the closely coordinated relationship of these important factors. Recent research has shown that to exert its physiologic effects, vitamin D must be converted to 25-hydroxycholecalciferol in the liver and this compound further in the kidney to 1,25-dihydroxycholecalciferol.

Other nutritional factors include protein, which as an essential component of the matrix of bone must be provided by a combination of dietary intake and conversion from other tissues. Changes in acid-base balance also have an influence on the skeleton—acidosis in various clinical disorders and ingestion of acid salts being accompanied by mineral loss.

Bone Diseases and Injuries

Bone diseases and injuries are major causes of disease of the locomotor system, the complex of structures and processes that enable the body to move. Traditionally these conditions belong in the category of orthopedic surgery, but they are often associated with problems of other surgical and medical specialties, notably pediatrics, neurology, and rheumatology.

Physical injury, causing fracture, dominates over other diseases causing locomotor system abnormality. No sharp distinction can be drawn, however, between physical injury and other disease in this respect. Fracture is but one of several common causes of hip disease; and bone disease is a common cause of fracture.

The nature of locomotor disease changes with age. In children, problems related to development and to the nervous system dominate; in young adults, rheumatoid arthritis, back problems, and traffic accident injuries are particularly significant; and, in the aged, metabolic abnormalities of bone, cartilage, and vessels cause fracture, joint disease, and deficient circulation. Moreover, congenital abnormalities frequently do not make their effects known until middle age. Fracture problems also change with age. Fractures in children are usually benign; in young adults they are often associated with severe injury to the soft tissues; and in the aged, fracture is often a symptom of systemic, life-threatening disease.

Bone diseases and injuries were formerly regarded as conditions that were more mechanical than metabolic, more static than dynamic. An improved understanding of the dual mechanical and chemical function of bone has permitted a more integrated biological view of bone disease and injuries.

THE STRUCTURE, FUNCTION, AND METABOLISM OF BONE

The characteristic hardness and elasticity of bones are due to the two-part arrangement of the components of the bone tissue: an organic matrix encrusted with inorganic mineral. The organic fraction is chiefly collagen, a fibrous protein that is also a chief component of cartilage, tendons, and skin. Bone collagen is organized as fibrils—minute fibres—which are also found in attached tendons, fascia (sheaths of connective tissue), and muscles. The main components of bone mineral are calcium, phosphate, and carbonate; a part of it is present in crystal form as hydroxyapatite, closely packed in and between the collagen fibrils. The skeleton contains 1,000–1,500 grams of calcium; *i.e.*, more than 99 percent of the total amount of calcium in the body. Bone cells are of three types that differ in both microscopic appearance and function: osteocytes for maintenance, osteoblasts for formation, and osteoclasts for destruction (resorption) of bone. The cells are interconnected by cellular processes and distributed so that the maximal distance between matrix and the closest cell is one-hundredth of a millimetre, and between a cell and the closest blood capillary, one-fifth of a millimetre.

Functions of bone

The skeleton has two functions, one mechanical and one chemical. The mechanical function of the skeleton is to fight gravity and inertia by providing leverage and support for locomotion and to give protection to sensitive structures such as the brain, spinal cord, heart, lungs, and abdominal organs. The chemical function of the skeleton is associated with the need for the cell membranes of the body to be exposed at all times to a precisely regulated concentration of ionized calcium; the bone tissue provides a store of calcium for deposition or withdrawal as need may be.

The mechanical and the chemical functions of the skeleton are closely interrelated in the sense that they share mechanisms for formation and resorption of bone tissues and yet control these metabolic processes in different

ways. Mechanical demands trigger the formation of bone tissue in areas of stress, and resorption occurs in areas where stress is minimal; an electric signal seems to mediate the response of the bone cells to stress. The chemical function of the bone tissue is regulated by the parathyroid glands, which secrete parathyroid hormone in response to low levels of ionized calcium in the blood and stop secretion when the calcium reaches high levels. The parathyroid hormone in turn raises the blood level of calcium by resorption of bone tissue; in addition to its effect on bone, it promotes absorption of calcium from the gut and restricts loss of calcium through the kidney. The cellular activity of the bone tissue is thus controlled by two partly synergistic and partly antagonistic processes. The two processes are further interrelated by the fact that vitamin D promotes both resorption and formation of bone and that the bone effect of parathyroid hormone is decreased in the absence of vitamin D. The vitamin promotes the mechanical function of bone by resorption of inadequate or superfluous tissue, returning calcium and phosphate to the blood for mineralization at new building sites. The action of vitamin D is clearly important both for remodelling associated with growth and, in the adult, for continued remodelling of the bone tissue that permits adaptation to structural demand and rejuvenation of aged structures.

The average life-span of bone tissue relative to that of other tissues is long; in adult life it is some ten years, in adolescence about two years, and in the newborn infant less than one year. But these average values are misleading inasmuch as the cancellous (spongy) bone in the vertebrae and pelvis and in the long bones close to joints is renewed five to ten times faster than the solid (cortical) bone in the shafts of the long bones. Also, both in cancellous and in cortical bone, only a small part of the tissue is being renewed at any one time.

The demand on the metabolic processes and its regulators described here is illustrated by the fact that new bone mineralization in an adult uses 400–600 milligrams of calcium daily, an amount greater than the total calcium content of the entire blood volume. Furthermore, the rates of formation and resorption are capable of being increased 10- to 100-fold when the mechanical or chemical function of the bone is challenged by disease.

PRINCIPAL TYPES OF DISEASES AND INJURIES

Effects of inactivity and hyperactivity

Abnormal stress on bone. Inactivity has a profound effect on the bone tissue, probably because the mechanical stimulus to bone formation is decreased.

In congenital dislocation of the hip, the socket part of the joint, the acetabulum, has lost the mechanical stimulus to normal growth and development because the ball part of the joint, the head of the femur, does not rest in the joint. The acetabulum and a large part of the pelvis develop poorly or not at all, whereas the femoral head, if it makes contact higher up on the pelvis, may stimulate development of a new joint structure. In the same way, nerve injury during the period of childhood growth results in markedly retarded growth and development. Poliomyelitis affecting the lower extremity in children results in short, thin bones with sometimes severe leg-length discrepancy. In adults, an extremity affected by nerve injury gradually develops osteopenia (a reduced amount of bone tissue), so that it fractures easily. In the elderly, bed rest is regarded as a cause of increased osteopenia with vertebral fractures. The loss of bone tissue and of calcium from the skeleton in space flight has been reported; the resultant high level of calcium in the urine may perhaps make kidney stones a hazard in prolonged weightlessness.

The skeleton is capable of considerable hypertrophy (increased development) when needed. The ballet dancer's big toe, for example, hypertrophies remarkably because of its subjection to abnormal mechanical demands. The bone tissue's capacity for remodelling in response to mechanical demand is retained even in the aged. In osteoarthritis the weight distribution across the knee or hip joints is uneven because of degeneration of the joint cartilage; the bone beneath the cartilage hypertrophies on the compression side of the joint and atrophies on the extension side.

Metabolic bone disease. The normal function of bone requires an adequate supply to the tissue of amino acids (building blocks for proteins) for synthesis of collagen, the chief component for the organic matrix; of calcium and phosphate for mineralization of the organic matrix; and of many more organic compounds and mineral elements. In addition, growth, repair, and remodelling of the bone tissue require a precisely regulated supply of hormones, vitamins, and enzymes. Skeletal disease when it is due to inadequacies in the supply or action of the above essentials, associated with abnormalities outside the skeleton, is termed "metabolic." Examples of such abnormalities are dietary deficiency and gastrointestinal, liver, kidney, and hormonal diseases. In addition, the most important of all bone diseases, osteoporosis (age-related loss of bone with tendency to fractures) is traditionally included among the metabolic conditions even though its cause is not known; it may or may not be associated with one or more of the above abnormalities.

Osteopenia and osteosclerosis

Changes in bone tissue due to metabolic abnormalities are classified with regard to the amount and composition of the bone tissue. When the amount of bone is lower or higher than normal, the conditions are termed, respectively, osteopenia and osteosclerosis. These terms do not imply any specific disease but serve simply to describe the amount of bone. Osteopenia is common both locally and generally throughout the skeleton. Localized osteopenia is evident in X-rays of tumours or infections of bone, in osteonecrosis (death of bony tissue), often in fracture, and in conditions of diminished mechanical demand. Osteopenia may thus be associated both with atrophy from disuse and with active remodelling of bone; it occurs when bone resorption has outstripped formation, regardless of the absolute rates of these processes. Generalized osteopenia occurs in osteomalacia, osteoporosis, and osteogenesis imperfecta. Osteosclerosis occurs locally in osteoarthritis, osteonecrosis, and osteomyelitis; it represents an attempt at structural strengthening by thickening of bony trabeculae, but its X-ray appearance may be confused with that of dead bone (sequestra in osteomyelitis), retaining its density while adjacent normal bone has become osteopenic. Widespread, but hardly ever truly generalized, osteosclerosis occurs in marble bone disease and in Paget's disease. Except in the latter condition, however, osteopenia and osteosclerosis are not associated with detectable biochemical abnormalities. (The diseases mentioned are characterized below.)

When the normal composition of bone tissue is altered by deficient mineralization of the organic matrix, the condition is called rickets if in children and osteomalacia if in adults. The mineralization deficiency is due in part to a lower than normal calcium–phosphate ion product in the body fluids. In rickets the bones become tender, soft, and deformed; X-rays show characteristic abnormalities at the growth zones, especially evident at the wrist, knee, and ankle joints. In osteomalacia, bone tenderness and pain accompany the slow development of spontaneous, often symmetric fractures characteristically present in the pelvis and the thigh bones; these breaks are thus in the category of fatigue fractures rather than traumatic in origin. The X-ray appearance of osteomalacia is rather normal until visible fracture has developed. Biochemical abnormalities, usually present in rickets and osteomalacia, are increased blood concentration of the enzyme alkaline phosphatase, believed to be important for bone formation or resorption, and decreased blood concentrations of calcium, or phosphate, or both; the calcium concentration may occasionally fall to levels so low that muscle and nerve function are impaired (tetany). Examination of the bone tissue in the microscope reveals the deficient mineralization of the organic matrix. The entire skeleton is affected in both rickets and osteomalacia, even though abnormalities are more evident in certain regions; *i.e.*, growth centres in children and areas of maximal mechanical load in adults.

Insufficient protein, caloric, and vitamin intake interferes with bone formation during growth and remodel-

ling, directly because of an inadequate supply for matrix formation and indirectly because of a deficient production of crucial hormones and enzymes. The effect in the young is stunted growth and in adults is osteopenia, the condition seen during World War II in concentration camp inmates (hunger osteopathy).

Effect of dietary abnormalities

Deficient intake of calcium or phosphate or both, unassociated with vitamin D deficiency, causes a compensatory action of parathyroid hormone whereby the mineral is mobilized from the skeleton with eventual development of osteopenia. Deficient calcium intake (milk) and excessive phosphate intake (meat) causes osteopenia, fractures, and loss of teeth in dogs, cats, and other animals by excessive compensatory parathyroid hormone action. Whether this mechanism could at least contribute to osteoporosis and loss of teeth in old age is being debated.

Excessive intake of fluoride, many times higher than that commonly used for the prevention of dental decay, may cause asymptomatic sclerosis of the skeleton (fluorosis); in the Punjab region of India the fluoride intake is extremely high, and bone changes are associated with severe joint and nerve disease.

Insufficient intake of vitamin D is one of many ways in which rickets may develop. The condition, once universally prevalent, is now rare in countries that ensure adequate supply of vitamin D in fortified milk and healthy living habits including adequate exposure to sunshine.

Malabsorption of calcium and vitamin D may be caused by disease of the digestive tract, surgical removal of part of the stomach or intestine, or disease of the pancreas or the liver ducts. The condition causes a mixture of osteopenia and osteomalacia and requires high intake of calcium and vitamin D.

Most hormones have some effect on the bone tissue, but only two play important roles in bone disease: parathyroid and corticosteroid hormones.

Parathyroid hormone is concerned with the maintenance of calcium concentration at the cell membranes. It functions by increasing the passage of calcium through the lining of the intestine, by increasing the resorption of bone tissue, and by increasing the reabsorption of calcium in the renal tubuli. Overactive parathyroid hormone causes osteopenia by excessive resorption of bone; in extreme cases spontaneous fractures may occur. Excessive secretion of parathyroid hormone may be due to a tumour of the parathyroid glands or may be secondary to dietary deficiency or malabsorption of calcium and vitamin D; overactivity of the parathyroid glands is also an integral element in renal osteodystrophy (see below).

Adrenal corticosteroid hormone is associated with skeletal abnormalities, osteopenia, and osteonecrosis. Osteopenia develops because increased levels of corticosteroids, caused by disease (pituitary or adrenal tumour) or by long-term medication (*e.g.*, for asthma), depress the rate of formation of bone tissue. Osteonecrosis is associated with even short-term intake of large doses of high corticosteroid medication; for example, to prevent rejection of a transplanted kidney.

The interrelation between bone and kidney disease is becoming increasingly important as use of the artificial kidney (dialysis) and transplantation have dramatically reduced the incidence of death and illness for chronic kidney failure.

Effects of kidney disease

The effects of kidney disease on bone reflect the role of the kidney in maintaining calcium and phosphate balance, mediated by parathyroid hormone. The two main units of the kidney, the tubules and the glomerulus, are associated with two groups of bone diseases: the former with a low level of phosphate in the blood (hypophosphatemia) and the latter with renal osteodystrophy (see below), both characterized by rickets and osteomalacia. In addition, kidney transplantation is associated with overactivity of the parathyroid glands and osteonecrosis.

Reabsorption of phosphate by the kidney tubules is deficient in a hereditary disorder, familial hypophosphatemia; the phosphate leak causes low concentration of blood phosphate (hypophosphatemia) and, in turn, deficient mineralization of bone tissue, rickets in children and osteomalacia in adults. Since rickets due to vitamin D deficiency has been greatly reduced, familial hypophosphatemia is the most common cause of rickets in Europe and the United States. Until recently this condition was called vitamin-D-resistant rickets, because treatment with the vitamin failed to correct the biochemical and skeletal abnormalities. Better understanding of the basic deficiency has led to more satisfactory treatment with high oral doses of phosphate. Advanced forms of the disease still result in stunted growth and skeletal deformity, often necessitating repeated operative correction. More complex tubular reabsorption defects are the cause of bicarbonate, amino acid, and glucose losses in addition to loss of phosphate; the resulting disease is so severe that the bony abnormalities usually become less important.

Renal glomerular disease with high levels of urea in the blood—uremia—is associated with a complex skeletal abnormality, renal osteodystrophy. The condition leads to severe rickets or osteomalacia associated with compensatory secondary hyperparathyroidism. In children, stunted growth may be the first symptom that leads to detection of the kidney disease; the skeletal abnormality cannot be ascribed solely to an abnormal mineral balance but is probably due also to an adverse effect of uremia on protein metabolism. Growth may resume after successful kidney transplantation, and gross deformity of the extremities may be corrected surgically. Chronic uremia in adults, even when treated by use of the artificial kidney, causes osteoporosis and deposition of calcium apatite in arterial walls and tendon sheaths, probably associated with hyperparathyroidism.

Kidney transplantation is occasionally followed by hyperparathyroidism and osteonecrosis. The overactivity of the parathyroids is ascribed to the fact that prior to correction of the kidney disease, the glands have had to function at an abnormally high level for such a long time that the mechanisms for shutting them off have become deficient. The cause of osteonecrosis after kidney transplantation is at least partly the high doses of corticosteroid treatment used to prevent rejection of the transplant. Osteonecrosis of the hip or knee joints may cause residual disability after succesful kidney transplantation.

Osteoporosis

Generalized osteopenia without evidence of osteomalacia is termed osteoporosis. It may be secondary to metabolic abnormalities discussed above or may be without known cause. Osteoporosis from unknown cause is by far the most common bone disease; it probably occurs in all aged individuals and may sometimes become evident as early as age 30–40. The spine is particularly affected.

Diagnosis of less severe stages of osteoporosis is complicated by the fact that the condition is not associated with measurable chemical abnormalities or with observable tissue abnormality other than a decrease in bone mass. It is generally believed that the common fractures in old age, those of the hip, knee, and wrist, are due to osteoporosis. Unlike the vertebral fractures in osteoporosis, these fractures of the limbs hardly ever occur spontaneously—without a distinct accident—and, unlike fracture in osteomalacia, they are never preceded by bone pain or tenderness. In fact, whereas the diminished quantity of bone tissue, the characteristic feature of osteoporosis, is clearly implicated in the diminished resistance of the bones to fracture, there may also be a change in the quality of the bone tissue.

In women the condition is usually more severe and starts earlier than in men. For this reason osteoporosis is sometimes termed "postmenopausal," to imply that it is caused by a change in the hormonal pattern, and hormonal substitution therapy is sometimes used. So far, hormonal therapy in osteoporosis has not been shown to have any significant effect on the bone disease. Other medical therapy used in osteoporosis includes the administration of fluorides (because of their effect in dental decay and because they are known to cause osteosclerosis in high dosage) and diets high in vitamin D and calcium (because of the possibility that osteoporosis may be due to hyperparathyroidism secondary to nutritional deficiencies or malabsorption in the aged). Except for the occurrence of extremity fractures, the outlook in osteo-

porosis is on the whole good. In the majority of even severe cases the progress of osteopenia eventually ceases, and pain subsides with healing of vertebral fractures. Perhaps the bone structure eventually reaches another biomechanical equilibrium with adequate response to stress; for this reason active muscle exercises are advocated both as prevention and as therapy in osteoporosis.

Paget's disease of bone, increasingly common after middle age, is characterized by widespread areas of osteosclerosis. The sclerotic regions have a high rate of bone metabolism; when the legs are affected deformities gradually develop. Pain in Paget's disease may be due to fatigue fracture or development of a malignant tumour (osteosarcoma). The cause of Paget's disease is unknown.

Deficient blood supply to bone. The cells of the bone tissue die if deprived of arterial blood supply for more than a few hours. The condition is called necrosis of bone or osteonecrosis. Osteonecrosis may be caused by injury to blood vessels, associated with dislocation or fracture of bone; by blood clots or gas bubbles in the blood vessels; by invasion of foreign tissue; and by metabolic disease (as in alcoholism).

Causes and course of osteonecrosis

Osteonecrosis may involve the shaft (diaphysis) or the ends (epiphyses) of the long bones. Sometimes the bone marrow of the diaphysis is primarily involved, and in osteomyelitis it is usually the compact (cortical) bone of the shaft that undergoes necrosis. For mechanical reasons, and because there is a poorer blood supply to cortical bone than to the cancellous bone of the epiphyses, the course of events following osteonecrosis differs in the two types of bone. When cortical bone is involved, the dead bone may prevent healing of osteomyelitis by mechanical irritation. When the cancellous bone of the epiphyses is involved, the lesion is invaded by blood vessels from adjacent bone, and a vigorous repair process ensues, characterized by removal of dead, and the formation of new, bone. The lesion may heal with reconstitution of both structural and mechanical properties, or the process of rebuilding may weaken the bone structure so that it collapses from the mechanical forces across the joint. In these circumstances the joint cartilage is damaged, and osteoarthritis eventually develops. It is for this reason that treatment of osteonecrosis in the early stage consists of protecting the joint from weight bearing; the condition is most often encountered in the hip and the knee.

Whereas it has long been recognized that osteonecrosis may occur in association with fracture or dislocation, it only recently has been recognized that the condition may often develop spontaneously or in association with the use of corticosteroid hormone (*e.g.*, in treatment of hepatitis—liver inflammation—or to prevent rejection of a kidney transplant) and in pancreatic disease. In these conditions the immediate cause of impaired blood supply is not clear; current speculation involves abnormal fat metabolism.

Ionizing radiation injury to bone. Bone tissue and the metaphyseal growth cartilage (the cartilage, between the end of the bone and the shaft, that later becomes bone) may be injured during the course of X-ray treatment of tumours. The risk is well recognized but can not always be avoided. The most common radiation injury to bone is fracture of the neck of the thigh bone (the femur) following radiation treatment of cancer of the uterus or the bladder. There is pain in the bone before this type of fracture can be seen by X-ray; the fracture usually heals without displacement. In children, the X-ray treatment of certain kidney tumours may cause growth abnormalities of the spine with development of lateral curvature (scoliosis); and radium treatment of hemangioma (a tumour made up of blood vessels) of the knee region may cause growth retardation in parts of the metaphyseal cartilages with knock-knee or bowleg deformity. X-ray treatment of certain premalignant bone tumours may make them fully malignant. Intense radiation may cause osteonecrosis, sometimes associated with secondary osteomyelitis. This latter condition was common in dial painters who had ingested radium by licking the brush.

The diagnostic use of radioactive substances or of X-ray techniques is not associated with measurable effects on bone tissue. Higher doses of bone-seeking radioactive substances are currently tried for selective radiation treatment of cancer.

Infectious diseases of bone. Infection of bone tissue by micro-organisms is termed osteomyelitis. Micro-organisms may gain access to bone either by spreading with the bloodstream from an infectious lesion elsewhere in the body (hematogenous osteomyelitis) or through a skin wound, accidental or surgical.

Causes and incidence of osteomyelitis

The incidence of hematogenous osteomyelitis reflects the fact that the body is more susceptible to invasion by micro-organisms when nutrition and hygiene are poor. Thus, hematogenous osteomyelitis is common in South America, Asia, and Africa, but in the developed countries the incidence has declined sharply during the last 50 years. In these latter countries hematogenous osteomyelitis is often associated with slum conditions or systemic disease; for example, infection of the genito-urinary tract in the elderly or blood-clotting abnormalities in children (sickle-cell anemia). On the other hand, high-energy fractures, notably motor or missile accidents, and extensive surgery, associated with the direct introduction of micro-organisms into bone, are increasingly common causes of osteomyelitis all over the world.

Osteomyelitis is commonly caused by pus-forming (pyogenic) micro-organisms, usually *Staphylococcus aureus* or *Mycobacterium tuberculosis*. Pyogenic osteomyelitis occurs both by direct routes and by hematogenous spread from an infection of the skin, urogenital tract, lung, or upper respiratory tract. Tuberculosis of the bone is always hematogenous in origin, usually disseminated from lesions in the lungs or the kidneys.

Goran C.H. Bauer

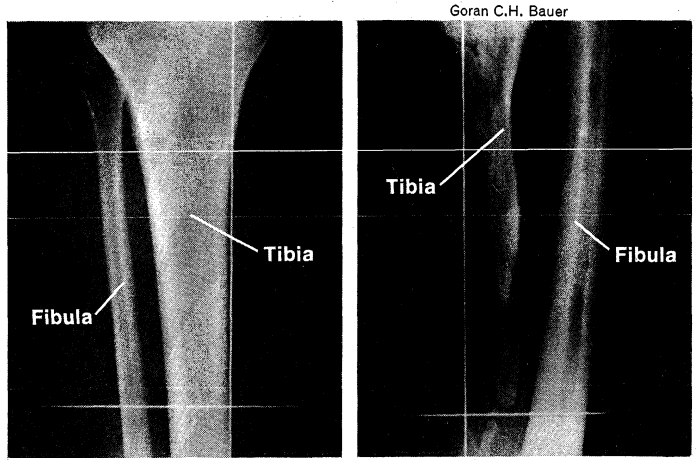

Figure 1: Defect of tibia, caused by septic osteomyelitis in childhood, with compensatory thickening of the fibula (right). The normal bones are shown at left.

Hematogenous osteomyelitis is more common in children than in adults. In children it is usually located in the growing end of the long bones; at the hip, for example, or just above or below the knee. In adults, hematogenous osteomyelitis is commonly located in the vertebrae of the spine (tuberculous or septic spondylitis). Osteomyelitis caused by direct invasion of micro-organisms often complicates open fractures—for example, of the shaft of the tibia—and operations for fracture or for degenerative joint disease—for example, at the hip joint. The risk of introduction of micro-organisms into wounds, either at or after an operation (hospital infections), can be minimized by careful precautions in the operating room and during the dressing of wounds and by the isolation of infected patients.

Osteomyelitis is associated with the cardinal symptoms of inflammation: complaints of illness, fever, local redness, swelling, warmth, pain, and tenderness. In the early stages the X-ray appearance may be normal; later, signs of destruction and repair of bone ensue. Untreated, the condition may cause extensive destruction of bone, blocking of the nutrient blood vessels with death of bone tis-

sue, extension to an adjacent joint with development of arthritis, and eventually a break through the skin with the evacuation of pus. The acute condition has now become chronic. It may heal, but the future course usually is marked by occasional flare-ups, with evacuation of pus and small pieces of dead bone (sequestra) through a persistent communication from skin to bone (a chronic sinus).

The treatment of osteomyelitis is primarily aimed at killing micro-organisms with antibiotics and, in later stages, getting rid of pus and sequestra by surgery.

Contributing factors in fractures

Fractures. A fracture occurs when the bone tissue is subjected to tensile, compressive, or shear forces in excess of its strength. Both the strength of the bone tissue and the nature of the forces acting on bone change from infancy to old age, both normally and as a result of disease. Therefore, the incidence and type of fractures change dramatically with age. The three factors, age, disease, and force, are all involved in the causation of most fractures.

As compared to children and the elderly, the bone tissue in young adults has high resistance to mechanical deformation. Fractures of cortical bone in adults require tremendous forces, such as those encountered in motor accidents, and are therefore often associated with severe skin injuries and other lesions of soft tissue. Bones in children are springy and resilient, like a freshly cut sapling, and the membrane enclosing the bones—the periosteum—is thick. Angular deformation of long bones in children therefore often results in incomplete or "greenstick" fractures. In the elderly the bone tissue becomes more brittle, especially the cancellous bone in vertebrae and in shoulder, wrist, hip, and knee joints; the majority of fractures in the elderly involve these regions.

Children are often exposed to injury because of their lively behaviour and lack of experience. Their bodies are small and light, however, and the forces acting on the skeleton usually are caused by only a fall at ground level. Fractures in children are therefore rarely severely displaced or associated with severe soft tissue injury; the only common exception to this rule is a certain type of elbow fracture. By contrast, in age groups 20–50 years, especially among males, fractures are often caused by direct, high-energy forces sustained in motor vehicles, factories, construction sites, and the like. These forces often have an explosive effect on bone and soft tissues and may cause severely displaced open fractures. Finally, in the aged, fracture is usually caused by mild forces acting on brittle bone. Such fractures are rarely associated with soft tissue injury and often involve cancellous rather than cortical bone.

Many diseases decrease the strength of the bone tissue, either throughout the skeleton or locally, and some expose the body to increased mechanical forces. The most important generalized condition is osteoporosis, which is prevalent in women over 50 and dominates in fractures in old age. Less common causes of decreased bone strength are osteogenesis imperfecta (a hereditary disease in which fragility of bone is associated with deafness and other manifestations), long term corticosteroid treatment, and osteomalacia. Common causes of locally decreased bone strength are injury of peripheral nerves and tumour. Hemiplegia (paralysis of one side of the body) and blindness increase the risk of accidents that may produce fracture in the aged.

Diagnosis and classification of fracture

The existence of a fracture is often deduced from a history of injury and observation of swelling, tenderness, faulty alignment, the sound that the broken ends make, loss of function, and associated injuries. Precise diagnosis is made by X-ray examination.

Most fractures occur without skin injury. These are called closed fractures. The skin wound in open fractures is caused either by severe direct violence or by a sharp bone fragment that pierces the skin from within. Because of the nature of the forces involved, open fracture of the diaphysis is usually transverse, whereas closed fractures, often caused by a twisting injury, are more often spiral-shaped. In fracture through diaphyseal cortical bone, the fragments are usually displaced by muscle action,

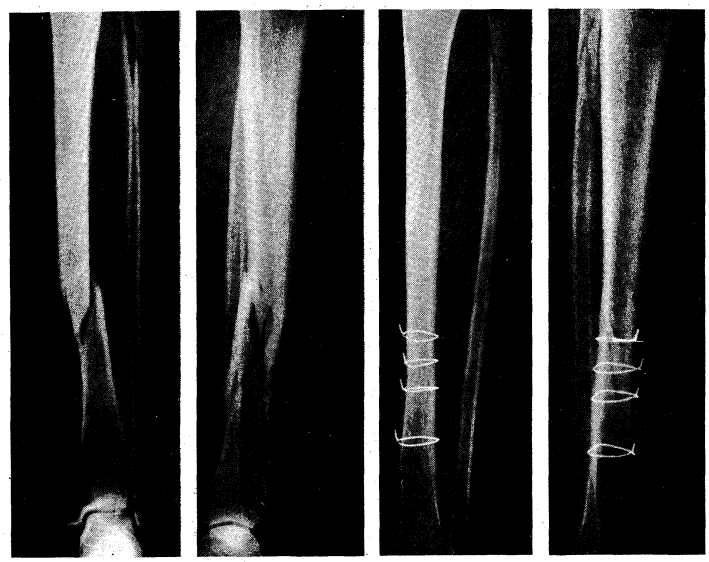

Figure 2: (Left) Front and (centre left) lateral projections of a fractured tibia and fibula. (Centre right and right) Corresponding projections following reduction of the dislocation and immobilization with the aid of four steel wires encircling the tibia. By reducing the fracture of the tibia the less important fracture of the fibula is also reduced and immobilized. Additional immobilization is accomplished with the aid of a groin-to-toe plaster cast.
Goran C.H. Bauer

while fractures of a cancellous bone (as in the vertebrae), more often cause compression. Diaphyseal fractures are therefore usually unstable in contrast to compression fractures, which are stable. Fracture of cancellous bone associated with dislocation of joints may result in severe instability, however. Tear fractures are associated with sudden, violent muscle pull and are usually markedly displaced. Disruption of the growth cartilage in children may cause the epiphysis to slide and form an angle (a condition called epiphyseolysis).

Fracture sometimes develops slowly rather than suddenly. These fatigue, or stress, fractures occur either because the bone tissue is exposed to forces that overwhelm its capacity for structural adaptation or because there is pre-existing disease. Examples of the former are fracture of the thigh bone and fracture of the bones of the foot (march fracture) in soldiers during their initial months of physical training. Bone diseases associated with fatigue fracture are osteomalacia, Paget's disease, and radiation injury to bone. Fatigue fracture usually produces pain even before bony abnormality can be seen in the X-rays.

Except in missile injury, in which the forces act with explosive suddenness, vessels and nerves usually escape injury because of their elasticity and resilience. For anatomic reasons, however, nerve injury may occur in fracture-dislocation of the hip and in fracture of the long bone of the upper arm (the humerus) through the diaphysis in adults and just above the elbow in children; the latter fracture is associated with compression of the accompanying artery. Fracture and dislocation of the vertebrae caused by motor accidents or other severe forces may be associated with spinal cord injury. This injury is particularly common in young adults. Certain fractures injure the nutrient blood vessels of the bone tissue with osteonecrosis as a result.

The bone tissue has a rich supply of blood vessels that rupture when there is fracture. The resultant bleeding causes swelling at the site of fracture (fracture hematoma) and later discoloration of the skin. Occasionally the bleeding is so severe (two to three litres in fracture of the thigh) that the circulating blood volume is significantly diminished and shock ensues.

The nerve endings of the periosteum are distended by the bleeding caused by fracture, and motion or pressure at the fracture site is painful.

Healing of fracture

A fracture starts to heal at the very moment that it occurs. The fracture hematoma is invaded by cellular ele-

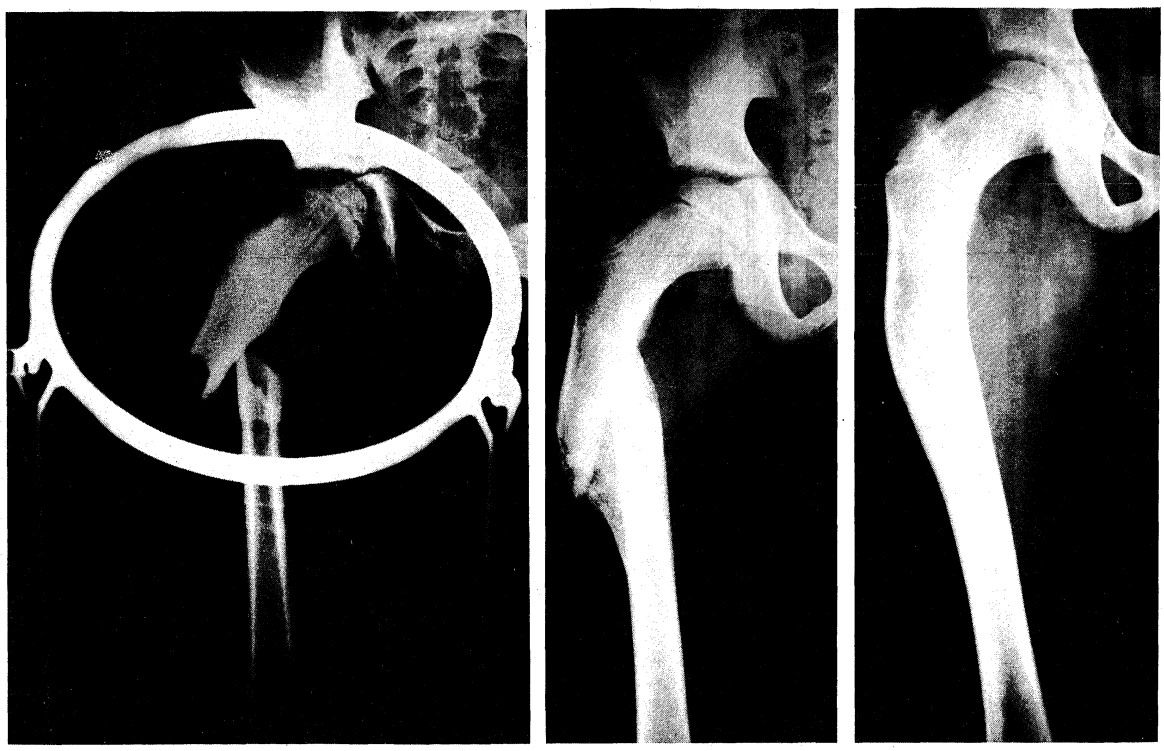

Figure 3: *Fracture of the shaft of the femur sustained by a seven-year-old boy after falling from a tree.*
(Left) Considerable angulation; transport splint visible in radiograph. (Centre) After four months the fracture has healed, with shortening and a reduction in angulation. (Right) By three years the malalignment was disappearing because of the remodelling of the bone tissue. Seven years later both the malalignment and the shortening had disappeared completely.
Goran C.H. Bauer

ments; these form organic matrix and mineral into bone (callus) that bridges the fracture. Formation of callus is faster in children than in adults and in cancellous bone than in cortical bone. Fracture of the thigh, which may heal in four to six weeks in a toddler, may require as many months in an adult. Similarly, fracture of the cancellous bone of the upper end of the humerus usually requires one-third or less of the time required for healing of a fracture of the cortical shaft of the same bone. Bridging of the fracture is hindered by separation and motion of the bone fragments, poor blood supply, and infection. After the fracture has healed, the region is remodelled by resorption and formation of bone so as to accommodate the microstructure of the bone tissue to precise mechanical demands. This remodelling also is most effective in children; a fracture of the humerus sustained during birth may heal in right-angle deformity and yet, in a few months, the normal anatomy will have been restored. In adults, on the other hand, gross deformity may exceed the remodelling capacity.

The most severe and most common cause of deficient healing is infection, osteomyelitis, associated with open fractures, which permit direct access for disease-causing organisms. The condition is prevented by treatment of open fractures with antibiotics and closure of the skin. A fracture may also unite slowly or not at all because of deficient blood supply to one or more of the bone fragments, separation of the fragments by distention or interposition of a tendon or ligament, or excessive motion at the fracture site.

The guiding principle in treatment of fractures is restoration of normal length and alignment when necessary and avoidance of motion between the fracture fragments.

Some fractures, notably compression fractures of cancellous bone (spine, upper end of humerus), are inherently stable (remain in normal alignment) and require temporary immobilization by bed rest or a sling only because of pain. Most fractures are stable in acceptable position only after reduction of dislocation and immobilization by fixation, externally by traction or plaster or internally by introduction of metallic screws, plates, nail, or wire (internal fixation).

Nonunion results in a false joint—pseudarthrosis—characterized by pain and motion at the fracture site. Healing may be achieved by immobilization with or without internal fixation and by transplantation of bone to bridge the defect.

Fracture may cause permanent deformity by residual angulation or by shortening because of overlap of cortical bone fragments, compression of cancellous bone, or, in children, arrest of metaphyseal cartilage growth.

Osteoarthritis is a late complication of fracture at a joint when the joint cartilage surfaces are disturbed and the joint is unstable. Abnormal weight distribution because of an abnormal angle of the diaphysis rarely causes osteoarthritis.

Bone tumour. Bone tumour is either primary or, more commonly, secondary (metastatic) to malignant conditions elsewhere.

Primary tumours, more common in children than in adults, are classified as malignant or benign; intermediary forms exist, however, and benign bone tumour may present therapeutic problems because of its location. Primary bone tumours are characterized by their origin in the skeletal tissue elements; for example, bone tissue tumours (the malignant osteogenic sarcoma and the benign osteoma), cartilage tumours (the malignant chondrosarcoma and the benign chondroma), bone marrow tumours (the malignant myeloma and the benign eosinophilic granuloma). Metastatic tumours are malignant by definition and are characterized by their site of origin, commonly cancer of the breast, prostate, lung, and kidney.

Symptoms of bone tumour

Common symptoms of bone tumour are pain, swelling, and fracture that is spontaneous or is caused by only trivial forces. Most bone tumours cause abnormalities observable in X-rays; defects in the bone tissue can be seen or bone that has formed in reaction to the tumour or, in some types of tumour, the tumours themselves, which consist of bone. Some bone tumours cause biochemical abnormalities detectable by examination of blood sam-

ples: myeloma (production of characteristic protein, a globulin), metastatic cancer of the prostate (production of the enzyme acid phosphatase). The ultimate identification of bone tumour rests on examination of tissue samples.

Benign tumours may be excised and the defect filled with a bone transplant if necessary for structural support. Malignant tumours may be treated by ionizing radiation, by chemical agents, or by surgical operation. Treatment of metastatic bone tumour is aimed at suppression of pain and prevention or repair of imminent or frank fracture by external support or, occasionally, by internal fixation. Treatment of malignant primary bone tumour is aimed at destruction of the tumour either by segmental resection of the involved region or by amputation.

Congenital bone diseases. Many important diseases of the locomotor system are congenital in the sense that they become evident at or soon after birth. This does not imply that they all are genetically determined or heritable. On the contrary, the majority are certainly or probably caused by factors operating during pregnancy, delivery, or early infancy.

Developmental abnormalities

Developmental abnormalities may affect isolated or multiple regions of the skeleton, or they may involve a specific tissue system; the latter are often heritable. Examples of isolated abnormalities are partial or total absence of the collarbone, radius (the long bone on the thumb side of the lower arm), and the thigh bone; congenital false joint in the shin bone (tibia); and absence of a middle segment of a limb (phocomelia; see below). Treatment of these conditions is difficult, often requiring advanced transplantation or orthopedic devices and sometimes necessitating amputation in childhood. Multiple abnormalities are represented by polyostotic fibrous dysplasia, in which affected bone is replaced by connective-tissue matrix of obscure origin. The condition may cause multiple deformities that require surgical correction. Heritable disorders of the skeleton include osteogenesis imperfecta, the Hurler and Marfan syndromes (see below), and several disorders of epiphyseal and metaphyseal growth centres. Osteogenesis imperfecta is characterized by thin bones that fracture spontaneously or from only minimal forces; the tendency to fracture usually decreases with age. The condition also typically involves the skin, which is thin and translucent; the sclerae, which are of slate blue colour; and progressive deafness. Osteogenesis imperfecta is a heritable disease, possibly a deficiency in synthesis of the collagen molecule. The Marfan syndrome is an inherited disorder of the skeleton, the aorta, and the eye. The extremities are long and thin, and the ligaments are lax, producing "loose-jointedness." The basic abnormality may be in the elastic or collagen molecules. The Hurler syndrome was previously thought to be a clinical entity but is now known to be only one of several heritable connective tissue disorders, all characterized by abnormal mucopolysaccharide metabolism. In the prototype condition dwarfism and multiple diaphyseal deformities are conspicuous. Other varieties of this group have primarily epiphyseal abnormalities. Heritable metaphyseal dysplasias, causing bone deformities near the joints, exist in several forms. The primary defect lies in the growth zone of the long bones. One of these conditions (hypophosphatasia) results from a deficiency in the enzyme alkaline phosphatase and is one of the few hereditary generalized disorders of the bony skeleton in which an enzyme defect has been identified. Multiple defects in the growth zones of the skeleton are distinct from familial hypophosphatemia, a condition characterized by low phosphate levels in the blood; it affects the kidney primarily and the skeleton only secondarily. Hemophilia, finally, is a generalized heritable condition that affects the locomotor system only secondarily by bleeding in bones and joints.

Intrauterine and birth injuries

Intrauterine injuries of the locomotor system are dramatically exemplified by the thalidomide catastrophe: children born of some women who received this drug during the initial three months of pregnancy had severe extremity defects (phocomelia). Most intrauterine injuries are probably not caused by drugs, however, but perhaps by viral, hormonal, or mechanical factors. Intrauterine amputations, clubfeet, and congenital dislocation of the hip probably belong to this group.

Birth injuries with fracture of the collarbone or humerus occur because of mechanical difficulties during delivery. These fractures heal extremely fast.

THERAPEUTIC AND CORRECTIVE MEASURES

Diagnosis of locomotor abnormalities is at present generally easier than choice of therapy. Pertinent structures are available for clinical and X-ray examination, and diagnostic categories based on chemical analysis are few in number. By contrast, an individual condition may offer an amazing number of therapeutic alternatives. It is not unusual, for example, that in osteoarthritis a choice has to be made, first, between nonsurgical (conservative) and surgical treatment and, second, between elimination of motion by immobilization of the joint (arthrodesis) and enhancement of motion by creation of an artificial joint (arthroplasty).

Traction counteracts muscle pull on the skeleton and is used to reduce and stabilize fractures and to prevent muscle shortening. Traction is applied by ropes and pulleys fastened to the skin by adhesive tape or directly to the skeleton with the aid of metal pins drilled into bone through the skin.

Internal fixation (osteosynthesis) of bone is aimed at restoration of continuity and stability during healing of a fracture, arthrodesis, or osteotomy (see below). For this purpose a variety of metal screws, pins, plates, and wires have been developed. The metal used is either stainless steel or a chromium–cobalt–molybdenum alloy that resists the corrosive action of the body fluids.

Arthroplasty, aimed at restoration of normal joint motion, is usually performed because of pain and restricted motion—for example, in rheumatoid arthritis of the elbow or the hip—but occasionally to restrict mobility—for example, in recurrent dislocation of the shoulder. Structural support and smooth gliding surfaces can be obtained by insertion of metallic devices; in the hip, for example, both the ball and the socket of the joint can be replaced. Osteotomy is aimed at correction of bony or articular deformity by cutting through bone and letting the fracture heal in the desired position, usually with the aid of internal fixation.

Arthrodesis is aimed at elimination of motion in a joint (fusion) in order to eliminate pain in osteoarthritis and rheumatoid arthritis, stabilize a joint that is either unstable or lacks useful muscle power, and remove an infectious lesion in arthritis. The operation involves removal of joint cartilage and immobilization; a bone transplant is sometimes used for more rapid restoration of continuity.

Bone resection implies surgical removal of bone and is performed either in the course of an arthroplasty or independently. The operation is performed in certain fractures—for example, of the knee cap in crush fracture—and for removal of tumour.

Epiphysiodesis (the fixing of the epiphysis to the bone shaft) is aimed at temporary or permanent cessation of growth in a metaphyseal cartilage. The operation is performed at the knee for compensation of growth in the other leg—for example, because of poliomyelitis—or in one of the other growth cartilages in the same knee—for example, because of injury.

Tendon transfer is aimed at changing the mechanical effect of the corresponding muscle. The operation is performed to restore function lost by paralysis and to correct an abnormality in the motion of a joint.

Transplantation of bone

Transplantation of bone is aimed at stimulation of bone formation and giving structural support until a defect has been bridged by new bone. If the bone cells of the transplant survive, they can continue to form bone and can stimulate adjacent tissue to formation of bone. Without survival, the transplant may function as a scaffold for invasion by tissue from adjacent bone, guided by the microstructure of the dead transplant. Cell-rich cancellous bone stimulates bone formation more effectively

than does cortical bone, which gives better structural support.

The fundamental problems in transplantation of bone, as with other tissues, are cell death because of deficient blood supply and a tendency toward rejection. The smaller the transplant, the better are the possibilities that blood vessels will reach the cells in time; this is why many small chips are used for stimulation of bone formation. Another possibility is to transplant bone in continuity with attached vessels in order to preserve the blood supply of the transplant. The immunologic problem is usually circumvented by use of bone from the individual himself (autotransplantation). In children sufficient bone for autotransplantation is often not available; bone from another individual will then be used. An attempt to modify the immunologic reaction to such a transplant is usually made by radiation and by storage in a deep freeze (bone bank).

Common indications for transplantation of bone are nonunion of a fracture, a bone cyst, arthrodesis, and structural defects in cancellous bone caused by compression fracture—for example, the heel bone.

Amputation is performed for four reasons: arterial disease, gross injury, tumour, and developmental abnormality, all more common in the legs than in the arms. Arterial disease, arteriosclerosis ("hardening of the arteries"), often associated with diabetes, is common in the aged. Gross injury to nerves, vessels, and soft tissues and primary tumours of bone or other connective tissue usually involve relatively young individuals. Developmental abnormalities—for example, congenital false joint in the tibia or abnormal development of the thigh bone—may occasion amputation in childhood.

Bonhoeffer, Dietrich

Dietrich Bonhoeffer, one of the most influential Protestant theologians of the mid-20th century, derives his stature and influence from both his thought and his life. He is important for his cogent and vivid insistence on the role of Christianity in the modern secularized world; for his role in the ecumenical movement, striving not only for the unity of Christians but also for peace among nations; and for his militant resistance to the Nazi rulers of his German homeland (to the point of conspiring to assassinate Hitler), culminating in his own imprisonment and execution. This final dramatic episode not only bore witness to his uncompromising ideals and made his thought far more widely known than it might otherwise have been but it fostered the expression of his most novel and radical theological concepts in the posthumously published *Letters and Papers from Prison.*

Born in Breslau on February 4, 1906, Bonhoeffer grew up amid the academic circles of the University of Berlin, where his father, Karl Bonhoeffer, was professor of psychiatry and neurology. From 1923 to 1927 he studied theology at the universities of Tübingen and Berlin. At Berlin he was influenced by the historical theologians Adolf von Harnack, Reinhold Seeberg, and Karl Holl, but also was strongly attracted by the new "theology of revelation" being propounded elsewhere by Karl Barth. His concern to relate himself critically to Barth is seen in his doctoral thesis, *Sanctorum Communio* (1930; *The Communion of Saints*, 1963), in which he tried to combine a sociological and a theological understanding of the church, and in *Akt und Sein* (1931; *Act and Being*, 1962), in which he traces the influence of transcendental philosophy and ontology, Kantian and post-Kantian theories of knowledge and of being, on Protestant and Catholic theologies.

Bonhoeffer, 1939.
By courtesy of Eberhard Bethge

After serving in 1928–29 as assistant pastor of a German-speaking congregation in Barcelona, he spent a year as an exchange student at Union Theological Seminary in New York. On his return to Germany in 1931 he took up an appointment as lecturer in systematic theology at the University of Berlin. From the first days of the Nazi accession to power in 1933 he was involved in protests against the regime, especially its anti-Semitism, and despite another 18-month absence when he served as pastor of two small German congregations in London (1933–35), Bonhoeffer became a leading spokesman for the Confessing Church, the centre of German Protestant resistance to the Nazi regime. In 1935 he was appointed to organize and head a new seminary for the Confessing Church at Finkenwald (Pomerania), which continued in disguised form until 1940, despite its proscription by the political authorities in 1937. Here he introduced the practices of prayer, private confession, and common discipline described in his book *Gemeinsames Leben* (1939; *Life Together*, 1954). From this period also dates *Nachfolge* (1937; *The Cost of Discipleship*, 1948, rev. ed., 1959), a study of the Sermon on the Mount in which he attacked the "cheap grace" being marketed in Protestant (especially Lutheran) churches—*i.e.*, an unlimited offer of forgiveness, which in fact served as a cover for ethical laxity. It was in this rigorous and even ascetic guise (to which his later theme of "Christian worldliness" provides a contrast if not a contradiction) that Bonhoeffer first became widely known. His views on international affairs at this time were close to pacifism.

Opponent of the Nazis

After attending the ecumenical conference at Cambridge in 1931, Bonhoeffer was appointed a European youth secretary of the World Alliance for Promoting International Friendship through the Churches, and he remained an active participant in ecumenical affairs despite the increasingly nationalistic mood in Germany. In his efforts to interpret to Christians elsewhere the significance of the German Church struggle, he found a sympathetic advocate in G.K.A. Bell, bishop of Chichester, England. Bonhoeffer's own involvement took an increasingly political character after 1938, when his brother-in-law, the jurist Hans von Dohnanyi, introduced him to the group seeking Hitler's overthrow. In 1939 he considered taking refuge in the United States but returned after only two weeks in New York, writing to his sponsor, the theologian Reinhold Niebuhr that "I will have no right to participate in the reconstruction of Christian life in Germany after the war if I do not share the trials

of this time with my people." Despite the restrictions imposed on him, Bonhoeffer was able to continue his work for the resistance movement under cover of employment in the Military Intelligence Department, which in fact was a centre of the resistance. In May 1942, he flew to Sweden to convey to the British government, through Bishop Bell, the conspirators' proposals for a negotiated peace; these hopes were thwarted, however, by the Allies' "unconditional surrender" policy. Bonhoeffer was arrested on April 5, 1943, and imprisoned in Berlin. Following the failure of the attempt on Hitler's life on July 20, 1944, the discovery of documents linking Bonhoeffer directly with the conspiracy led to his further interrogation and eventual execution at Flössenberg (Bavaria) on April 9, 1945. Bonhoeffer never married, his engagement having been announced just before his imprisonment.

Ethical and religious thought

During the years 1940–43 Bonhoeffer worked intermittently on a volume on Christian ethics but completed only fragments, which were published posthumously (*Ethik*, 1949; Eng. trans., *Ethics*, 1955). Abjuring all "thinking in terms of two spheres,"—*i.e.*, any dualistic separation of the church and the world, nature and grace, the sacred and the profane—he called for a unitive, concrete ethic founded on Christology (doctrines about the person and work of Christ), an ethic in which labour, marriage, and government are to be viewed dynamically as divinely imposed tasks or functions ("mandates") rather than orders of creation. Bonhoeffer welcomed the rapprochement of Christianity and humanism in the face of modern tyrannies and urged a recovery of the concept of "the natural" in Protestant thought. The prison writings, published in 1951 (German title *Widerstand und Ergebung*; Eng. trans. *Letters and Papers from Prison*, 1955, rev. ed., 1964), are of interest both for the remarkable richness of cultural and spiritual life that they display and for the theological themes developed especially in the letters to Bonhoeffer's friend and later editor and biographer, Eberhard Bethge. Reviewing the history of secularization in the West since the Renaissance, Bonhoeffer asked whether man's increasing ability to cope with his problems without the hypothesis of God may not indicate the obsolescence of the "religious premise" upon which Christianity has hitherto been based. Rather than looking for gaps in human knowledge or accenting human weaknesses as a basis for apologetics, he asserted that the church ought to affirm man's maturity in a "world come of age." The stripping off of "religion," in the sense of otherworldliness and preoccupation with personal salvation, Bonhoeffer suggested, will in fact free Christianity for its authentic this-worldliness in accordance with its Judaic roots. The church should give up its inherited privileges in order to free Christians to "share in God's sufferings in the world" in imitation of Jesus, "the man for others." These ideas have subsequently been influential in movements for the reform of church and ministry; in the "Honest to God" debate initiated by John A.T. Robinson, the bishop of Woolwich, England; in efforts to propound a "secular Christianity" or "the secular meaning of the Gospel"; in the "death of God" controversy of the 1960s; and, from a different perspective, in the articulation of a "theology of hope."

The chief works by Bonhoeffer in addition to those already mentioned are *Creation and Fall: A Theological Interpretation of Genesis 1–3* (1933; Eng. trans. 1959) and the collected shorter writings, *Gesammelte Schriften* (5 vol., 2nd ed., 1965–69), selections from which have been published in English translation under the titles *No Rusty Swords* (1965), *Christ the Center* (1966; British title *Christology*), and *The Way to Freedom* (1966).

Boniface, Saint

The most important figure in the Christianization of Germany, St. Boniface is often called the Apostle of Germany, because his work there in the 8th century is comparable to that of Peter in Rome and of Paul among the Gentiles. A great organizer, a reformer and leader of men, Boniface set the church in Germany on a firm course of undeviating piety and irreproachable conduct. In his letters and in the writings of his contemporaries, he appears as a man of purpose and dedication, an innovator with a powerful though willful personality.

St. Boniface baptizing converts into the German Church; detail from a manuscript from Fulda Abbey, 10th–11th century. In the Staatsbibliothek Bamberg (MS. Lit. 1).

Boniface, originally called Wynfrid or Wynfrith, was born *c.* 675 of a noble family of Wessex, England. He received an excellent education in the Benedictine abbeys of Adescancastre (Exeter) and Nhutscelle (Nursling, between Winchester and Southampton) and became a Benedictine monk, being ordained priest at about the age of 30. From 716 to 722 he made two attempts to evangelize the Frisian Saxons on the Continent but was balked by their king, Radbod. On his return to England he learned that his abbot had died and that he had been elected in his stead—an honour he declined in favour of a second attempt at a missionary career. In 718 he accompanied a group of Anglo-Saxon pilgrims to Rome, where Pope Gregory II entrusted him with a mission to the pagans east of the Rhine, asking him only to use the Roman formula for Baptism, rather than the Celtic, and to consult with Rome on major problems arising from his work. Gregory II changed Wynfrid's name to Boniface. In the meantime, Radbod had died (719), and Boniface returned to Frisia to assist his countryman Bishop Willibrord in his missionary activities. In 722 he went to Hesse, where he established the first of many Benedictine monasteries as a means of consolidating his work.

So great was his success that he was called to Rome, where Gregory consecrated him a missionary bishop. The Pope also provided him with a collection of canons (ecclesiastical regulations) and letters of recommendation to such important personages as Charles Martel, master of the Frankish kingdom, whose protection was essential to Boniface's success. It was the pagan awe of Martel's name that allowed Boniface to destroy the sacred oak of the Germanic god Thor at Geismar.

For ten years (725–735) Boniface was active in Thuringia, converting pagans and renewing the faith of Christians who had been converted earlier by Irish missionaries, whose haphazard methods of evangelization were

Role as reformer and organizer of the church

henceforth to be the bane of Boniface's life. He met opposition, he said, "from ambitious and free-living clerics" whom he pursued relentlessly, even when they appealed to the popes. On a later occasion, Pope Zachary was forced to moderate the zeal of Boniface, who requested not only excommunication but also solitary confinement for two "heretical" missionaries, Adelbert and Clement the Irishman—sentences that the Pope avoided imposing by deliberate delay. Boniface's handling of missionaries whose methods he deplored sheds light on his personality and temperament; he turned immediately to Rome; he expected prompt and ruthless action; and he seems at times to have been excessively severe in his judgments.

Boniface's career was assisted in a unique and moving way by his brother and sister Benedictines from England. They supported him by gifts and encouraged him by their faithful love, expressed in letters that were delightful in their openness and humanity. Their final expression of love for him was to cast their lots with him in Germany, where they formed the nucleus of four monasteries that served as centres of civilized Christian life.

Ordered by Pope Gregory III (731–741) to organize the church in Bavaria, Boniface initially established four bishoprics there. His work had far-reaching political repercussions, for his Christianization of Bavaria paved the way for the ultimate incorporation of the country into the Carolingian Empire. After 740 he added another see in Bavaria and also created three in central Germany. Aided by his new suffragan bishops—for such they were, in fact, though his appointment as archbishop of Mainz came later (751)—Boniface undertook the reform of the Frankish clergy and, wherever possible, of Irish missionaries. Between 740 and 745, five synods were convened for this purpose. In 747 a reforming council was held for the entire Frankish kingdom with the wholehearted collaboration of Carloman and Pepin, the sons and heirs of Charles Martel. Though Charles had protected Boniface, he had, at the same time, given church land to his magnates and used the discipline of the church as a means of taming recalcitrant Germanic tribes. Carloman and Pepin, on the other hand, made the decisions of the council of 747 binding in Frankish law.

Martyrdom

Boniface's life ended in martyrdom at the hands of a band of pagan Frisians, who killed him as he was reading the Scriptures to Christian neophytes on Pentecost Sunday (June 5, 754). Boniface had asked to be buried at Fulda, the monastery he had entrusted (744) to his Bavarian disciple Sturmi. There his body rests in a magnificent baroque sarcophagus.

Organizer, educator, and reformer, Boniface profoundly influenced the course of intellectual, political, and ecclesiastical history in Germany and France throughout the Middle Ages. He unified the missionary movement by bringing it under the control of Rome. Through his monasteries, which furnished bishops and teachers for many generations, he significantly improved the quality of life in the Frankish kingdom.

Boniface VIII, Pope

Boniface VIII, who was pope from 1294 to 1303, engaged in a fierce struggle over the extent of papal authority with the powerful monarchies of the emerging nations of the West, especially the French monarchy. His stubborn claims to full temporal and spiritual power were certainly no more extravagant than those of his predecessors, but the new forces of nationalism were no longer willing to accept these well-established claims. The conflict culminated in a brutal attack on the person of Boniface VIII, perpetrated by the emissary of King Philip IV of France. Only six years after Boniface's death, the seat of the papacy was moved to Avignon, France, where it remained for 68 years, reaching a low ebb in its international prestige.

Anderson—Alinari

Boniface VIII; fresco by Giotto, *c.* 1300. In the church of S. Giovanni in Laterano, Rome.

Early life and election to the papacy

Benedict Caetani was born in Anagni, near Rome, probably between 1235 and 1240, of an old and influential Roman family. He studied law in Bologna and then for many years held increasingly important functions in the papal government. Martin IV made him cardinal-deacon of St. Nicholas in Carcere Tulliano in 1281; under Nicholas IV he became cardinal-priest of St. Martin in Montibus in 1291. As papal legate to a church council in Paris from 1290 to 1291, he succeeded in delaying the outbreak of renewed war between France and England and in bringing about peace between France and Aragon. It was Cardinal Benedict Caetani who confirmed the unhappy pope Celestine V in his wish to resign and then, after he had succeeded him as Boniface VIII, found it advisable to intern the old man in the castle of Fumone, where he soon died. Although Celestine died of natural causes, the death was open to suspicion and incriminating aspersions by Boniface's enemies. Among those who carried on the propaganda and opposition against Boniface were many of the Franciscan "Spirituals" (members of the order founded by St. Francis of Assisi who followed a literal observance of his rule of poverty), including the poet Iacopone da Todi, some of whose poems were written during his imprisonment by Boniface.

The two principal international conflicts that existed from the beginning of Boniface's pontificate were that between France and England concerning Guyenne and Flanders, and that between the kingdoms of Naples and Aragon concerning the island of Sicily, which, after much provocation, had broken away from the Neapolitan king, disregarding papal feudal overlordship. Boniface finally, though unwillingly, accepted the independence of the island kingdom under Frederick of Aragon. His attempts to stop hostilities between Edward I of England and Philip IV of France, however, became enmeshed with another important problem, the increasing tendency of these warring monarchs to tax the clergy without obtaining papal consent. Although the desire of the late-medieval rulers to tax the wealth of their clergy has been

defended and can perhaps be understood, the practice was unquestionably contrary to the canon law (ecclesiastical law) of the time. That Boniface refused to look on inactively while the struggle between France and England, which he was trying to terminate, was being financed at the cost and to the prejudice of the church and the papacy is not surprising. In 1296 he issued the bull *Clericis Laicos*, which forbade under the sanction of automatic excommunication any imposition of taxes on the clergy without express license by the pope. This bull had some effect in England, chiefly because of its support by the archbishop of Canterbury, Robert Winchelsey; but in France there was no strong defender of papal prerogative against the concerted action of the king and his civil lawyers. Philip IV countered or even forestalled the publication of *Clericis Laicos* with an order forbidding all export of money and valuables from France and with the expulsion of foreign merchants.

Conflicts with Philip IV of France

Although Philip's measures were a serious threat to papal revenues, they alone probably would not have forced Boniface to the far-reaching concessions that he had to grant the French king within the year, concessions that almost amounted to revocation of *Clericis Laicos*. The necessity of coming to terms was primarily the result of an insurrection against Boniface by a section of the Colonna family, a powerful antipapal Roman family that included two cardinals, culminating in the armed robbery of a large amount of papal treasure in May 1297. A year of military action against the Colonna followed, which ended with their unconditional surrender. They were absolved from excommunication but were not reinstated in their offices and possessions; they therefore rebelled again and fled; some of them went to Philip, with whom they had conspired, perhaps, even before the issue of *Clericis Laicos*.

Boniface's first conflict with the French king was followed by an apparent reconciliation, which was emphasized by the Pope's canonization of Philip's holy ancestor Louis IX. A second conflict, which broke out in 1301 around the trumped-up charges against a southern French bishop Bernard Saisset of Pamiers and his summary trial and imprisonment, proved to be irreconcilable. Now the King threatened and meant to destroy one of the most fundamental gains that the papacy had made and maintained in the great struggles of the last two centuries: papal, rather than secular, control of the clergy. The Pope could not compromise here, and in the bull *Ausculta Fili* ("Listen Son") he sharply rebuked Philip and demanded amends, especially the release of the Bishop, who had appealed to Rome. Instead, the King's chancellor, Pierre Flotte, was allowed to circulate a distorted extract of the bull and thus to prepare public opinion for the great assembly of the estates-general (the legislative body of France) in April 1302, in which nobles and burghers enthusiastically, and the clergy reluctantly, supported the King.

Boniface, nevertheless, appears to have had good reason to hope for a favourable termination of the conflict, because Philip's army was shortly afterward disastrously defeated by a league of Flemish townspeople and because the German king and prospective emperor Albert I of Habsburg, was ready to give up his French alliance if the Pope would recognize the contested legitimacy of his rule. This recognition was granted early in 1303 in terms that exalted the ideal and traditional, though rarely realized, harmonious relationship between the papacy and the Holy Roman Empire. This empire now was said by the Pope to possess—under ultimate papal supremacy—an overlordship over all other kingdoms, including France. In November 1302 Boniface had issued an even more fundamental declaration concerning the position of the papacy in the Christian world, the bull *Unam Sanctam* ("One Holy"), which has become the most widely known of all papal documents of the Middle Ages because of its allegedly radical and extreme formulation of the content of the papal office. The bull as a whole is indeed a strong but not a novel invocation of the supremacy of the spiritual over the temporal power. Nevertheless, the old Gelasian doctrine that both powers are distinct and both are from God is clearly stated, and in the final dogmatic sentence the Pope speaks not of the temporal power but of the human creature as the object of the papal plenitude of power, submission to which is said to be necessary for salvation.

Meanwhile in France, Philip IV's councillor Guillaume de Nogaret had taken Flotte's place as the leader of an actively antipapal royal policy. Philip was supported in this policy by other enemies of the Pope, including the legate whom Boniface had dispatched to France in these critical months and who betrayed his master, the French cardinal Jean Lemoine (Johannes Monachus). Many unjustified accusations against Boniface, ranging from unlawful entry into the papal office to heresy, were raised against him at a secret meeting of the King and his advisers held in the Louvre at Paris; these accusations were to be taken up and elaborated upon later during the posthumous trial against the Pope pursued by Philip IV. Shortly after the Louvre meeting, at which Nogaret had demanded the condemnation of the Pope by a general council of the church, Nogaret went to Italy to stir up, if possible, rebellion against the Pope. He was unsuccessful in this attempt, but when he learned that Boniface was about to publish a new bull announcing Philip's excommunication, Nogaret, with the assistance of Sciarra Colonna—a popular member of the powerful family—and with the connivance of some of the cardinals, decided to capture the Pope at Anagni, where the Pope was spending the summer. In this he succeeded through the momentary complicity of the local leaders of the city of Anagni, who, however, after two days changed their minds, rescued the Pope, and thus frustrated whatever further plans Nogaret may have had. During these two days Boniface, whom Sciarra Colonna would have killed but for Nogaret's wish to drag the Pope before a council, was probably physically ill-treated. He bore everything with great courage and patience. Boniface returned to Rome physically and mentally broken and died soon after, on October 11, 1303.

Boniface's capture

Among the lasting achievements of Boniface VIII's turbulent pontificate were the publication of the third part of the *Corpus Juris Canonici* (*Corpus of Canon Law*), the so-called *Liber Sextus* ("Sixth Book"), and the institution of the Jubilee of 1300, the first Holy Year. The event was commemorated in a painting by Giotto, a fragment of which still survives in the basilica of San Giovanni in Laterano. Boniface VIII was a figure of some importance in the revival of the arts in the age of Dante and Giotto. His sepulchre came from the workshop of Arnolfo di Cambio; his tomb with his reclining statue is in the Vatican grottoes. Of the numerous memorial statues erected in his honour by himself or others —and later used by his enemies to brand him as an idolater—several still survive. They are visual evidence for the fact, known also from other sources, that Boniface VIII extended the height of the papal tiara and increased the number of crowns that circle the tiara from one to two and perhaps to three, which is their number in modern times.

Assessment

The violent attack on Boniface VIII marks the first open rejection of papal spiritual dominance by the rising national monarchies of the West and, above all, by France. Boniface's assertions of papal plenitude of power did not go beyond those of his predecessors in the 13th century. They were in fact more moderate than, for instance, those of Innocent IV and were in any case well within the range of the opinions gradually elaborated in the schools of theology and canon law in the period between the age of Gregory VII, the great 11th-century reformer, and that of Boniface. Boniface's failure was not caused by any novelty of his views or claims but by changed circumstances, by his inability or unwillingness to gauge their significance adequately, and, last but not least, by his own character: conscious of his superior intellect and at the same time tormented by illness, he was impulsive to the point of imprudence and short-tempered to the point of uncharitableness. It was his exaggerated harshness against the Colonna—whose hatred for the Caetani Pope was largely the result of con-

flicting interests of the two families—as well as his shortsighted underestimation of the ruthlessness of Philip IV of France and his helpers that led to the coalition of these two disparate forces and to the Pope's downfall. Boniface VIII's personal failings, however, can in no way exculpate Philip IV the Fair and his ministers, who used forgery, defamation, intimidation, and finally violence against the Pope.

BIBLIOGRAPHY. An excellent work and the only full-scale biography in English is T.S.R. BOASE, *Boniface VIII* (1933). The following studies are concerned specifically with Boniface's quarrel with the French king Philip IV: A.F.J.P.M. DE LEVIS-MIREPOIX, *Le Conflit entre la Papauté et le roi de France, 7 Septembre 1303* (1969); J. RIVIERE, *Le Problème de l'église et de l'état au temps de Philippe le Bel* (1926); and C.T. WOOD, *Philip the Fair and Boniface VIII* (1967). Boniface's correspondence and promulgations may be studied in *Les Registres de Boniface VIII*, ed. by G.A.L. DIGARD *et al.*, 4 vol. (1884–1939).

(G.B.L.)

Bonn

Formerly a peaceful cluster of pleasant townships and villages situated on the banks of the Rhine about 15 miles south of Cologne, present-day Bonn was suddenly plunged into a new role of government administration and high politics when it was chosen as the provisional capital of the German Federal Republic in 1949. The home of more than 300,000 people by the early 1970s, Bonn has become the 18th Federal German city in order of size, a position attained in 1969 when the old city of Bonn was amalgamated with the towns of Bad Godesberg and Beuel and several minor parishes. These communities had already been developing into an extensive, built-up urban region during previous decades. The accelerated development of the metropolitan region since 1949 and its integration into the new municipality in 1969 underline the political fact that Bonn is now regarded as the actual capital of the German Federal Republic. As any other capital of a major nation, Bonn has felt the impact of its growing federal administration and its associated institutions. Bonn is also a major and expanding university centre; and as Beethoven's birthplace, it is a town particularly devoted to the promotion of the musical arts.

History. The oldest settlement known by the name of Bonn was a prehistoric river crossing discovered by Roman legionaries in the 1st century BC. The settlement itself probably disappeared soon afterward, but its name was continued in Castra Bonnensia, the fortress the Romans founded about the middle of the 1st century AD and occupied until the 5th. In the centuries that followed the breakup of the Roman Empire, Castra Bonnensia survived as a civilian settlement; and its walls, still intact, enclosed the 9th-century Bonnburg of the Franks.

Roman fortress of Castra Bonnensia

The medieval city, however, did not grow up on the site of the Roman camp but farther away on the Roman burial ground, which, from the 3rd century onward, was a Christian centre and was known later as the Villa Basilica. In the 9th century the Villa Basilica began to take over some of the functions of Bonnburg, until by the 11th century it was firmly established as the leading settlement of the region. As a monastic sanctuary the Villa Basilica was a settlement of clergy served by laymen. Craftsmen, merchants, and other groups, attracted by the expanding town, settled beside it in an emergent Oppidum Bonnense. In the 13th century, both settlements were surrounded by a wall extensive enough to meet the city's spatial needs for centuries to come.

Although Bonn did not expand from the 13th to the 19th century, it did grow in importance, becoming the capital of the Electorate and Archbishopric of Cologne, and then a sovereign state in its own right. This era ended abruptly in 1794, when the French Revolutionary forces occupied the city. Deprived of its function as a capital and reduced to poverty by the Napoleonic Wars, Bonn was annexed to Prussia in 1815. Although the founding of the university in 1818 marked a turning point in the city's history, there was little further development until the second half of the 19th century when the city became fashionable as one of Germany's residential towns. In 1914 the prosperous residential areas to the south and west of the city, enlarged by the incorporation of several villages, accommodated some 200 millionaires. It was their wealth, not industrial or commercial activity, that made the city prosperous. With the disappearance of its wealthy residents after World War I, Bonn again suffered losses from which it had not recovered when it was severely hit by the air raids of World War II. The raids destroyed 19 percent of its buildings and damaged 70 percent. The development of the city since the war is primarily the result of its having been chosen as the provisional capital of West Germany in 1949.

The contemporary city. *Layout and boundaries.* As the city owes its present boundaries and conglomerate makeup to the Bonn Act of 1969, it does not possess a dominant single centre but many centres and subcentres. The heart of the old city of Bonn with its narrow streets and those of the former towns of Bad Godesberg and Beuel form the major centres of the new city, but their influence is very much diminished by the incorporation of some 30 former villages, each with a centre of its own, into Bonn. It is this historical polycentricity that makes Bonn appear to be very much smaller than most cities of its population. The conurbation of Bonn is embedded in a landscape the most important elements of which are the lowlands of the Lower Rhine, Rheinische Schiefergebirge (the Rhine Slate Mountains), and the Rhine River itself. Near the river, the lowlands extend far to the south, while farther from the river the mountains range far to the north. The Rhine flows northwest through both of these regions, which drop toward the river in a series of terraces.

The surrounding landscape

The city has spread along both banks of the river, where multiple railway lines, busy trunk roads, and the intervening built-up areas intersect the city from north to south, causing considerable hindrance to intercity communications.

Population. Since the 1950s both the population increase in Bonn and the mobility of population have exceeded those of any other German city except Munich. In 1969 the number of persons moving out of Bonn (26,803) had risen slightly above that of those moving in (26,496), and the mobility rate (178 migrants per 1,000 inhabitants) is high. These and other demographic facts were in sharp contrast with the national average. Other contrasts include: the high and still-growing proportion of female inhabitants (1,117 per 1,000 male), the high and growing rate of salaried employees (554 per 1,000 persons employed), and the low and declining number of manual workers (320 per 1,000 persons employed). All of those trends reflected the function of Bonn as a capital, whereas the high rate of single-person households (400 per 1,000) was influenced by the fact that Bonn is the seat of a large university. The above figures apply to the city as a whole. Within the city itself, there are differences corresponding to its polycentric structure. The centres of older areas, in contrast with the newer surrounding ones, have a smaller percentage of children, a higher percentage of old people, and a smaller average household. It is the functioning of Bonn as a capital and as a university town that largely determines its demographic structure and particularly its changes.

Economic life. Those responsible for economic development in the late 19th century did their utmost to keep large industries out to preserve the city's attractions as a residential town for the rich. As a result, Bonn has remained a poorly industrialized city. By far the most important employers are the service industries, including the many organizations associated with Bonn's function as a capital, for they employ more than half the working forces. Next are commercial enterprises employing 25,000 persons, or 15.8 percent of the total. Manufacturing employs 23,400 persons in 1,050 plants, or 14.8 percent of the total. A large number and wide range of products supply small and dispersed markets. Typical products are laboratory equipment, switchgear, organs, and flags. The trades are, by West German standards, rather over-

Principal employers

represented, employing some 20,500 persons, or about 13 percent of the total, mainly in the building industry. Produce, supplied mainly by the neighbouring villages, is auctioned in the market in Bonn, which remains a major German centre for the distribution of fruits and vegetables, sold mainly to the Ruhr district.

Bonn has a large civic debt. Politically motivated reluctance to invest in the "provisional" capital ended only in 1970, when the federal government agreed to compensate the city for services rendered; but such payments were thought unlikely to solve the financial problems of a city where economic imbalance prevails and is growing.

Political and governmental institutions. The Bundestag and the Bundesrat (legislative bodies), the *Bundespräsident* (head of state), and the *Bundeskanzler* (head of government) all are found in Bonn. These and other central institutions are located in the south of the old city, in an area that has become the geographical centre. It is here that the government is concentrating the many administrative offices that had previously been dispersed. More than 100 nations are represented in Bonn by embassies or missions, which have put nearly all the former manor houses and 19th-century villas to new use as residences, legations, and consulates. The number of people with diplomatic status exceeds 6,000. Bonn accommodates many regional institutions, such as the offices of the Archaeological Survey, the Geodetic Survey, the Road Survey of North Rhine-Westphalia, the Rhenish Chamber of Agriculture, the Chamber of Industry and Commerce, the Labour Office, and the local and regional courts of justice.

Services and transportation. The city's services are unevenly distributed. Their highest concentration, particularly of the health services, is to be found in old Bonn, which provides 5,099 of the total 5,643 hospital beds. The fact that most of the beds are predominantly occupied by nonresidents emphasizes the function of Bonn as a services centre. There are 27 homes for some 1,500 elderly and disabled, 98 kindergartens for about 6,000 children, and special institutions for the mentally handicapped and 6,000 or so others in need of public assistance.

Water, gas, and electricity are mainly supplied by the municipality, which also provides most local and much regional transport. The number of transit passengers, however, is declining, while private transport is increasing. National and international travel facilities, provided mainly by the Federal Railways and by Cologne Airport, are well developed. The autobahn (expressway) and the four federal roads passing through Bonn attract much of the long-distance traffic, however.

Cultural life. As Beethoven's birthplace, Bonn is particularly devoted to the promotion of the musical arts. It maintains a municipal orchestra and arranges numerous national and international concerts. Many concerts and vocal recitals also are performed by local philharmonic and musical societies. The Beethovenhalle, a modern concert hall, is the centre of Bonn's musical life.

Apart from the spacious municipal theatre (drama, opera, operetta, musicals, and ballet), there are several private theatres renowned for their avant-garde productions. Other important institutions are the Rheinische Landesmuseum (Rhine Provincial Museum; archaeology), the Museum Alexander Koenig (zoology), and well-known city and university art galleries as well as private collections.

Historic churches and palaces

Prominent among surviving historic buildings are the cathedral, a Romanesque basilica (11th–13th century) surmounted by five towers of which the central (315 feet, or 96 metres high) is a landmark in the Rhine Valley, and the old village churches of Muffendorf (10th century), Vilich (11th century), and Schwarz Rheindorf (12th century). The former Kurfürstliche Residenz (Electoral Palace, later university) and the Poppelsdorf Palace, with its botanical gardens, along with the city's beautiful avenues and parks are reminders of the electoral and archiepiscopal capital. The parks, though limited in area, have a high recreational value, since they adjoin some of the densely populated parts of the city. More extensive recreational areas are the forests of Venusberg, Kreuzberg, Kottenforst, and Ennert on the southern and western fringes of the city. Beyond the city, the mountain country of the Westerwald and the Eifel are within easy reach.

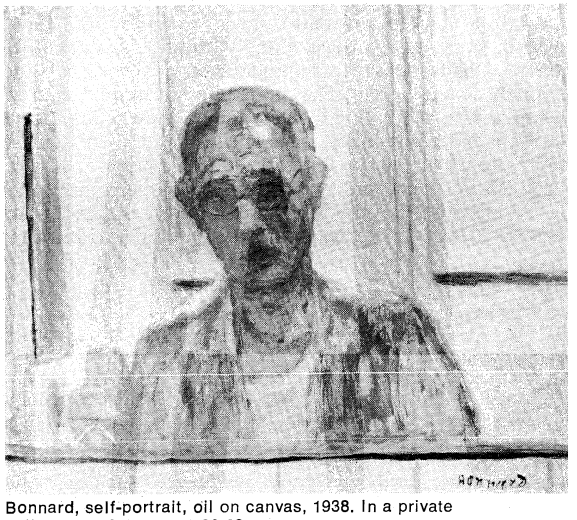
Bonnard, Pierre

Assimilating the lessons of Impressionism, Pierre Bonnard evolved an art style that, though traditional in many aspects, looked ahead to some of the most daring experiments of Modernism. He moved far during his career; his dissolution of form in favour of passages of emotive colour made him a pioneer of abstraction, yet he never forgot that the basis of his art was in nature. His determination to capture the nuances of colour, tone, and light made him one of the most subtle yet brilliant colorists and masters of light of his age.

Private collection, Europe



Bonnard, self-portrait, oil on canvas, 1938. In a private collection. 58.42 cm × 66.68 cm.

Bonnard was born on October 3, 1867, at Fontenay-aux-Roses, near Paris. After taking his baccalaureate, in which he distinguished himself in classics, Bonnard studied law at the insistence of his father, and for a short time in 1888 he worked in a government office. In the meantime he attended the École des Beaux-Arts, but, failing to win the Prix de Rome (a prize to study at the French Academy in Rome), he transferred to the Académie Julian, where he came into contact with some of the major figures of the new artistic generation—Maurice Denis, Ker-Xavier Roussel, Paul Sérusier, Édouard Vuillard, and Félix Vallotton. In 1890, after a year's military service, he shared a studio in Montmartre with Denis and Vuillard. Later they were joined by the theatrical producer Aurélien-Marie Lugné-Poe, with whom Bonnard collaborated on productions for the Théâtre de l'Oeuvre, in Paris. At this time he became influenced by Japanese prints, which had earlier attracted the Impressionists.

Member of the Nabis

During the 1890s Bonnard became one of the leading members of the Nabis, a group of artists who specialized in painting intimate domestic scenes as well as decorative curvilinear compositions akin to those produced by painters of the contemporary Art Nouveau movement. Bonnard's pictures of charming interiors lighted by oil lamps, nudes on voluptuous beds, and Montmartre scenes made him a recorder of France's *Belle Époque*. It was typical of his humour and taste for urban life at the time that he illustrated *Petites scènes familières* and *Petit solfège illustré* (1893), written by his brother-in-law Claude Terrasse, and executed the lithograph series *Quelques aspects de la vie de Paris* ("Aspects of the Life of Paris"), which was issued by the famous art dealer Ambroise Vollard in 1895. He also contributed illustrations to the celebrated avant-garde review *La Revue blanche*. A new phase in book illustration was inaugurated with Bonnard's decoration of the pages in Paul Verlaine's book of Symbolist poetry, *Parallèlement*, published by Vollard in 1900. He undertook the illustration of other books during the 1900s.

His ability as a large-scale decorator is sometimes overlooked, in view of his more quiet, domestic paintings in the Intimist style. But around 1906 he painted "Pleasure, Study, Play, and the Voyage," a series of four decorations made to resemble tapestries, for the salon of Misia Natanson, the wife of one of the editors of *La Revue blanche*. These pictures show that he was an heir to the French grand tradition of pictorial design that may be traced to Charles Le Brun, the director of all artistic activity under Louis XIV, and François Boucher, the most fashionable painter in the mid-18th century.

By about 1908 Bonnard's Intimist period had concluded. A picture such as "Nude Against the Light" (1908; Musée Royaux des Beaux-Arts de Belgique, Brussels) was painted not only on a bigger scale but also with broader and more coloristic effects. Because of his increasing interest in landscape painting, he had begun painting scenes in northern France. In 1910, however, he discovered the south of France, and from then onward he became the magical painter of this region. The Mediterranean was considered by many of the period to be a source of French civilization. Bonnard was eager to emphasize the connections between his art and France's classical heritage. This was evident in the pose of certain of his figures, which hark back to ancient Hellenistic sculpture. He was also enamoured of the coloristic tradition of the 16th-century Venetian school. "The Abduction of Europa" (1919; Toledo Museum of Art, Ohio), for example, is in a direct line of descent from the work of Titian.

Landscape painting

The subjects of Bonnard's pictures are simple, but the means by which he rendered such familiar themes as a table laden with fruit or a sun-drenched landscape show that he was one of the most subtle masters of his day; he was particularly fascinated with tricks of perspective, as the Postimpressionist painter Paul Cézanne had been. In "The Dining Room," for example, he employed different levels of perspective and varied the transitions of tone, from warm to cool.

By about 1915 Bonnard realized that he had tended to sacrifice form for colour, so from that point until the late 1920s he painted nudes that reflect a new concern for structure without losing their strong colour values. In the 1920s he undertook a series of paintings on one of his most famous themes—a nude in a bath. From the end of the 1920s onward, the subject matter of his pictures hardly varied—still lifes, searching self-portraits, seascapes at Saint-Tropez on the Riviera, and views of his garden at Le Cannet, near Cannes, where he had moved in 1925 after marrying his model and companion of 30 years, Maria Boursin. These are paintings intense with colour.

Subject matter of later works

The chronological order of Bonnard's paintings is difficult to determine, for he would make sketches in pencil or colour and then use them as the basis for several pictures on which he would work simultaneously. When working in the studio, he would rely on his memory of the subject and constantly retouch the surface, building up a mosaic of colours. It is impossible, therefore, to give more than approximate dates for many of his works.

In 1944 Bonnard illustrated a group of early letters, which were published in facsimile under the appropriate title of *Correspondances. Formes et couleurs.* He died on January 23, 1947, at Le Cannet.

MAJOR WORKS

PAINTINGS: "The Croquet Game" (1892; private collection, Paris); "Street Scene with Two Dogs" (1895; private collection, Mexico City); "The Bridge at Chatou" (*c.* 1896; private collection, New York); "Interior" (1898; Norton Simon Collection, Los Angeles); "Place Blanche" (*c.* 1902; private collection, Los Angeles); "Girl in a Straw Hat" (1903; Milwaukee Art Center); "Repas des bêtes" (*c.* 1906; private

collection, New York); "Regatta" (1908–12; Carnegie Institute, Pittsburgh); "The Dining Room" (1913; Minneapolis Institute of Arts, Minnesota); "Woman with Basket of Fruit" (1915–18; Baltimore Museum of Art); "The Brothers Jean and Gaston Bernheim" (1920; Musée d'Art Moderne de la Ville de Paris); "Interior with Woman in Wicker Chair" (1920; Nationalmuseum, Stockholm); "Still Life" (*c.* 1924; Art Gallery of Toronto); "The Table" (1925; Tate Gallery, London); "The Palm" (1926; Phillips Collection, Washington, D.C.); "The Road to Nantes" (*c.* 1930; Cleveland Museum of Art); "The Breakfast Room" (*c.* 1930–31; Museum of Modern Art, New York); "Bowl of Fruit" (*c.* 1933; Philadelphia Museum of Art); "Dining Room on the Garden" (*c.* 1933; Solomon R. Guggenheim Museum, New York); "Nude Before a Mirror" (1933; Galleria Internazionale d'Arte Moderna, Venice); "Table Before Window" (1943; private collection, New York); "Flowering Almond Tree" (1946; Musée d'Art Moderne de la Ville de Paris).

LITHOGRAPHS: "Child with Lamp" (1896); "The Laundry Girl" (1896); "Boating" (*c.* 1897); "Place Clichy" (*c.* 1923); *Quelques aspects de la vie de Paris* (1895); also illustrations for *La Revue blanche* (1891–1903).

BIBLIOGRAPHY. JEAN and HENRI DAUBERVILLE, *Bonnard: Catalogue raisonné de l'oeuvre peint*, vol. 1, 1888–1905 (1966), vol. 2, *1906–1919* (1968), consists of a detailed catalog of the artist's work and is still in progress. CHARLES TERRASSE, *Bonnard* (1927), in French; and THADEE NATANSON, *Le Bonnard que je propose*, 1867–1947 (1951), contain much firsthand information about the artist by writers who knew him. JOHN REWALD, *Pierre Bonnard* (1948), is a valuable account of the artist's development with notes on his technique. ANTOINE TERRASSE, *Bonnard* (1964; Eng. trans., 1964) and *Pierre Bonnard* (1967), in French; and ANDRE FERMIGIER, *Pierre Bonnard* (1969; Eng. trans., 1971), are two modern studies with fresh information and good plates. CLAUDE ROGER-MARX, *Bonnard, lithographe* (1952), is an illustrated catalog of the artist's lithographs. *Bonnard and His Environment*, Museum of Modern Art, New York (1964); and *Pierre Bonnard, 1867–1947*, Royal Academy of Arts, London, 2nd ed. (1966), are two important exhibition catalogs.

(D.Su.)

Bookkeeping

Bookkeeping is the recording branch of accounting (see ACCOUNTING, PRINCIPLES OF). Accounting is the art of recording, classifying, and summarizing transactions of an enterprise and interpreting the results thereof. To make a distinction between bookkeeping and accounting is difficult. Accounting includes bookkeeping but is a broader subject; an accountant, for example, designs the system of records used by the bookkeeper. The bookkeeper accumulates the figures; the accountant summarizes and interprets these figures.

Information provided by bookkeeping

Essentially bookkeeping provides two kinds of information: (1) the current value, or equity, of an enterprise and (2) the change in value—profit or loss—taking place in the enterprise over a given period of time. Management officials, investors, and credit grantors all require such information: management in order to interpret the results of operations, to control costs, to budget for the future, and to make financial policy decisions; investors in order to interpret the results of business operations and make decisions about buying, holding, and selling securities; and credit grantors in order to analyze the financial statements of an enterprise in deciding whether or not to grant a loan.

History. Traces of financial and numerical records can be found for nearly every civilization with a commercial background. Records of commercial contracts have been found in the ruins of Babylon, and accounts for both farms and estates were kept in ancient Greece and Rome. The double-entry method of bookkeeping (see below) began with the development of the commercial republics of Italy. The first double-entry books known to exist date from the year 1340 in Genoa. Because they were in excellent double-entry form, it is assumed that the system must have been in general use long before that time. Double-entry bookkeeping also was used by the members of the Hanseatic League (an association of north German towns and groups of merchants active from the late 13th through the 15th centuries); by the banking houses of the Medici family of Florence in the 15th century and the Fugger family of Germany in the 16th century; and by the great trading companies, such as the East India companies, chartered by the governments of England, France, and Holland in the 17th century; it also was used by the monasteries, the papacy, and individual merchants and adventurers in the early days of capitalism.

Instruction manuals for bookkeeping were developed during the 15th century in various Italian cities, a notable example being *Summa de arithmetica geometria proportioni et proportionalità* (1494), by a monk, Lucas (Luca) Pacioli. The thoroughness of Pacioli's volume, with its extended discussion of debit and credit, establishes him as a pioneer in double-entry bookkeeping. Many books of instruction based on Pacioli's material appeared in Germany, England, and Holland during the 16th and 17th centuries with technical modifications to suit the needs of international trading operations. In 1586 Don Pietra, a Benedictine monk, made a significant contribution by stressing the fact that a business enterprise was a separate economic entity, distinct from its owner or owners.

In the late 18th and early 19th centuries, the Industrial Revolution provided an important stimulus to accounting and bookkeeping. The rise of manufacturing, trading, shipping, and subsidiary services made accurate financial records a necessity. The history of bookkeeping, in fact, closely reflects the history of commerce, industry, and government. In the second half of the 20th century, for example, the vast expansion of industrial and commercial activity required more sophisticated decision-making processes, which in turn required more sophistication in the selection, classification, and presentation of information, increasingly with the aid of computers. Taxation and government regulation became more important and resulted in increased demand for information; business firms had to have available information to support their income tax, payroll tax, sales tax, and other tax reports. Governmental agencies and educational and other nonprofit institutions also grew in size, and the demand for bookkeeping for their own operations increased.

The increasing complexity of bookkeeping

The advent of the computer changed the complexion of the bookkeeping process for many firms, particularly those firms that were able to lease or own computers. But in all firms, large and small, the process of recording transactions continued to benefit through greater mechanization. There was a rapid expansion in the use of electronic tabulating and calculating machines of all sizes. These machines were used for information-processing tasks such as payroll accounting and preparing analyses of sales. They were further used to provide the informational inputs in the decision-making process of modern managers.

Bookkeeping processes. Although bookkeeping procedures can be extremely complex, basically there are two types of books used in the bookkeeping process—journals and ledgers. A journal contains the daily transactions (sales, purchases, and so on), and the ledger contains the record of individual accounts. The daily records from the journals are entered in the ledgers.

Journalizing. Cash slips, check books, stock cards, deposit slips, time cards, sales slips, sales invoices, credit memos, and purchase invoices are some of the original documents with which the bookkeeper is concerned. These transactions are analyzed and entered in a journal. The journal is the book used to make the first record of a transaction. There are many different forms of journals. One journal may be designed to take care of only one kind of transaction—cash receipts or sales on account, for example. In a small business all transactions may be entered in one journal.

Posting in the ledger. The process of transferring journal entries to the accounts in the ledger is known as posting. Entries are made in accounts in terms of debits and credits. A debit signifies an entry in one side of a ledger account. A credit, on the other hand, signifies an entry in the other side of a ledger account. The debits recorded in the ledger for each entry in the journal are always equal in amount to the credits for that entry. Thus, if no errors are made in posting, the total of all debit amounts in the ledger equals the total of all credit

amounts in the ledger. The "trial balance" is a method of testing the accuracy of posting by proving the equality of the debits and the credits in the ledger.

Preparation of the financial statements. The management of a firm is interested in determining whether its operations have resulted in a profit or loss. They are also interested in the financial condition of the firm. Each month, as a general rule, an income statement and a balance sheet are prepared from the trial balance. The purpose of the income statement or profit-and-loss statement is to present an analysis of the changes that have taken place in the ownership equity as a result of the operations of the period. The balance sheet shows the financial condition of a company at a particular date in terms of assets, liabilities, and the ownership equity.

Double-entry recording process. The financial condition of an enterprise at any point in time can therefore be expressed in the form of an equation that expresses the relationship between assets, liabilities, and the ownership equity. This equation is important, for it is the basis for the double-entry recording process. The assets of any enterprise minus its liabilities must equal the ownership equity. That is, if the claims of outsiders other than the owners (liabilities) are subtracted from the things of value owned by the enterprise (assets), the result will be the value of the ownership equity. The basic equation is $A - L = P$, in which A stands for assets, L for liabilities, and P for the proprietorship or ownership equity.

Double-entry equation

No matter how complex the transactions of an enterprise, this equation always stays in balance. The financial condition of a going concern is always changing as cash is collected, bills are paid, and merchandise is purchased. These transactions must be analyzed in terms of their effect on the assets, liabilities, and proprietorship.

Because there are only two ways in which an item (a quantity of merchandise, for instance) can change—increase or decrease—accounts are set up so that increases are placed on one side of the account and decreases are placed on the other side. For example, purchase of merchandise for $2,500 cash would result in an increase in an asset merchandise for $2,500 and a decrease in an asset cash of $2,500. In other words, for every transaction, more than one item is affected; and complete recording of the effects of any transaction means that such a double entry is made in the ledger accounts.

BIBLIOGRAPHY. L.L. VANCE and R. TAUSSIG, *Accounting Principles and Control*, rev. ed. (1966); and H.A. FINNEY and H.E. MILLER, *Principles of Accounting*, 6th ed. (1963), are both introductory accounting texts that contain the best statements of accounting and bookkeeping principles and concepts. L.D. BOYNTON *et al.* (eds.), *Twentieth Century Bookkeeping and Accounting*, 23rd ed. (1967), has long been a standard bookkeeping text. For information on electronic processing and automation, see H. ANTON and W.S. BOUTELL, *Fortran and Business Data Processing* (1968); and G. WOHL and H. JAUCH, *The Computer: An Accounting Tool* (1965).

Boole, George

George Boole, English mathematician and logician, helped to establish modern symbolic logic. As a pioneer of the algebra of logic, now known as Boolean algebra, his ideas have been applied successfully in the design of computer circuits.

Early life

Born on November 2, 1815, at Lincoln, England, the son of a tradesman, he was given his first lessons in mathematics by his father, who also taught him to make optical instruments. Aside from his father's help and a few years at local schools, however, Boole was self-taught in mathematics. When his father's business declined, George had to work to support the family. From the age of 16 he taught in village schools in West Riding, Yorkshire, and opened his own school in Lincoln when he was 20. During scant leisure time he read mathematics journals in the Mechanics Institute, founded about that time for science education. There he wrestled with the *Principia* of the 17th-century English physicist and mathematician Isaac Newton, the *Mécanique céleste* of Pierre-Simon Laplace, and the *Mécanique analytique* of Joseph-Louis Lagrange,

both 18th- and early-19th-century French mathematicians, and began to solve advanced problems in algebra.

Boole submitted a stream of original papers to the new *Cambridge Mathematical Journal*, beginning in 1839 with his "Researches on the Theory of Analytical Transformations." These papers were on differential equations and the algebraic problem of linear transformation, emphasizing the concept of invariance. In 1844 he discussed how methods of algebra and calculus may be combined in an important paper in the *Philosophical Transactions of the Royal Society*. The same year he was awarded a medal by the Royal Society for his contributions to analysis (*i.e.*, using algebra and calculus to deal with the infinitely large and the infinitely small). Boole soon saw that his algebra could also be applied in logic.

Developing novel ideas on logical method, and confident in the symbolic reasoning he had derived from his mathematical investigations, he published in 1847 a pamphlet, "Mathematical Analysis of Logic," in which he argued persuasively that logic should be allied with mathematics, not philosophy. He won the admiration of the English logician, Augustus De Morgan, who published *Formal Logic* the same year. On the basis of his publications, Boole in 1849 was appointed professor of mathematics at Queen's College, County Cork, even though he had no university degree.

In 1854 he published *An Investigation into the Laws of Thought, on Which Are Founded the Mathematical Theories of Logic and Probabilities*, which he regarded as a mature statement of his ideas. The next year he married Mary Everest, niece of Sir George Everest, for whom the mountain is named. The Booles had five daughters.

Boolean algebra

One of the first Englishmen to write on logic, Boole pointed out the analogy between the algebraic symbols and those that can represent logical forms and syllogisms, showing how the symbols of quantity can be separated from those of operation. With Boole in 1847 and 1854 began the algebra of logic, or what is now called Boolean algebra (see ALGEBRAIC STRUCTURES: *Boolean algebra*). It is basically two-valued in that it involves a subdivision of objects into separate classes, each with a given property. Different classes can then be treated as to the presence or absence of the same property.

Boole's original and remarkable general symbolic method of logical inference, fully stated in *Laws of Thought* (1854), enables one, given any propositions involving any number of terms, to draw conclusions, by the symbolic treatment of the premises, that are logically contained in the premises. He also attempted a general method in probabilities, which would make it possible from the given probabilities of any system of events to determine the consequent probability of any other event logically connected with the given events. In 1857 he was elected a Fellow of the Royal Society.

The influential *Treatise on Differential Equations* appeared in 1859 and was followed the next year by its sequel, *Treatise on the Calculus of Finite Differences.*

Used as texts for many years, these works embody an elaboration of Boole's more important discoveries.

Boole's abstruse reasoning led to applications of which he never dreamed: telephone switching and electronic computers use binary digits, which allow a series of dual alternative routines in the mathematical sequence of instructions to these devices. A lung ailment led to his death on December 8, 1864, in Ballintemple, County Cork.

BIBLIOGRAPHY. For details about Boole's life and contributions to logic, see WILLIAM KNEALE, "Boole and the Revival of Logic," *Mind*, 57:149–175 (1948), with bibliography; see also "Boole" by T.A.A. BROADBENT in the *Dictionary of Scientific Biography*, vol. 2 (1970); and E.T. BELL, *Men of Mathematics* (1937, reprinted 1961).

Booth, Edwin

Edwin Booth was a renowned American tragedian of the 19th century, best remembered as one of the greatest of all performers of Shakespeare's *Hamlet*, and as the innocent brother of John Wilkes Booth, assassin of Pres. Abraham Lincoln.

Edwin Thomas Booth was born November 13, 1833, near Belair, Maryland. At 13 he became companion and chaperon to his eccentric father, the actor Junius Brutus Booth (born in London, 1796), who in 1821 moved to the United States, where he achieved popularity second only to that of the American actor Edwin Forrest.

Travelling with his father, whom he endeavoured to keep sane and sober, Edwin absorbed the rudiments of acting in the bombastic style then fashionable. He made his stage debut at the Boston Museum on September 10, 1849, in the part of Tressel to his father's Richard III in an adaptation of Shakespeare's play. Two years later in New York City, when his father refused to act one night, Edwin replaced him as Richard III, giving an imitative but creditable performance.

Early career

In 1852 Edwin accompanied his father to California, and, after his father's death that year, continued acting, barnstorming through the California mining towns, and, in 1854–55, touring Australia and the Sandwich Islands (now Hawaii). His first important appearances as a star were in Boston and New York City in 1857. Younger playgoers flocked to see him, and in 1860, in a series of brilliant performances in New York, he challenged and overcame the dramatic supremacy of the veteran Forrest.

Booth had not yet, however, overcome the unruly temperament inherited from his father. His acting was occasionally fuddled by drink. In 1860 he married the actress Mary Devlin, by whom he had one daughter. It was the double shock of Mary's death in 1863 and his failure to be at her side because he was too drunk to respond to the summons of friends that henceforth made him abstemious.

In 1864 Edwin Booth became comanager of the Winter Garden Theatre in New York. There, he and his brothers, Junius Brutus and John Wilkes, appeared together for the only time on November 25, 1864, playing Brutus, Cassius, and Mark Antony, respectively, in Shakespeare's *Julius Caesar*. From November 26, 1864, to March 22, 1865, Edwin played Hamlet for 100 consecutive nights. Thereafter, he was identified with the part, for which his looks, voice, and bearing suited him. He was slight and dark, with a musical, sympathetic voice and a natural air of reserve. His acting style, quieter than his father's had been, became increasingly sensitive and subdued.

The assassination of President Lincoln by John Wilkes Booth on April 14, 1865, was a blow from which Edwin's spirit never recovered, causing his withdrawal from the stage until January, 1866, when he reappeared at the Winter Garden as Hamlet and received an ovation.

In 1869 Booth married the actress Mary McVicker, whose nervous instability made the marriage unhappy. In the same year he opened his own theatre in New York City. His Shakespearean and other productions were beautifully mounted, but his lack of business acumen ultimately cost him his theatre and left him bankrupt at 40. By hard work he recouped his losses, acting from then on under the management of others.

Booth first acted in London in 1861. When he revisited England in 1880, his appearances at London's Princess Theatre were near failures until Henry Irving, star and manager of the much superior Lyceum Theatre, invited him to costar at the Lyceum in what proved a memorable engagement, the two actors alternating as Othello and Iago. In 1882, the year after his wife's death, Booth again played England and the next year toured Germany, where the acclaim given his Hamlet, Iago, and King Lear (considered, after Hamlet, his finest roles) made the German engagement the peak of his career. At home, his financial affairs improved permanently when, in 1886, he formed a business and acting partnership with the American actor-manager Lawrence Barrett.

European acclaim

In 1888 Booth founded a club, the Players, in New York City, that was intended as a gathering place for actors and eminent men in other professions. He lived at the club in his last years. His farewell stage appearance was as Hamlet, in 1891 at the Academy of Music in Brooklyn.

Booth died on June 7, 1893, long freed from the excesses of his youth and dissociated in the public mind from the dishonour of his brother's crime. To his own and later generations, the nobility of his mature character, his splendid achievement in his art, and his zeal to raise both the moral and social standing of his fellow actors combined to make him one of the great figures of the American stage.

BIBLIOGRAPHY. ELEANOR RUGGLES, *Prince of Players* (1953), is the most recent and comprehensive biography. Earlier biographies are: RICHARD LOCKRIDGE, *Darling of Misfortune* (1932), especially interesting for details of Booth's business misadventures; CHARLES TOWNSEND COPELAND, *Edwin Booth* (1901), an admirably concise profile; and WILLIAM WINTER, *Life and Art of Edwin Booth* (1893), a standard and valuable study by a contemporary. An exhaustive work by STANLEY KIMMEL, *The Mad Booths of Maryland* (1940), examines the entire Booth clan. Family information and reminiscences by Booth's sister and daughter, respectively, are in ASIA BOOTH CLARKE, *The Elder and the Younger Booth* (1882); and EDWINA BOOTH GROSSMAN, *Edwin Booth: Recollections* (1894). KATHERINE GOODALE, *Behind the Scenes with Edwin Booth* (1931), is a touching reminiscence of the aging actor by a young coworker. OTIS SKINNER, *The Last Tragedian* (1939), presents a sensitive selection of Booth's letters, together with Skinner's vivid memories of him.

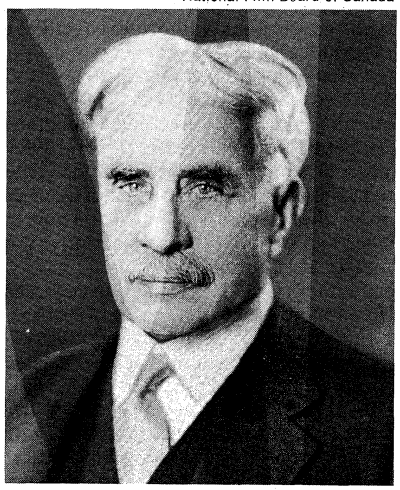
(E.Ru.)

Borden, Sir Robert Laird

The eighth prime minister of Canada (1911–20) and leader of the Conservative Party (1901–20), Robert Laird Borden, by insisting on separate Canadian membership in the League of Nations, played a decisive role in the transformation of Canada's status from colony to nation. His Conservative administration confronted un-

precedented administrative, financial, and political challenges during the years of World War I, and when, despite the voluntary recruitment of half a million Canadians for overseas service, conscription was required to maintain the Canadian forces at full strength, he initiated the formation of a coalition government. The electoral success of the Unionist forces in the election of 1917 ensured a continuation of Borden's policies of total commitment to the war effort and an international role for Canada—but at the price of antagonizing the French-Canadian population, who were unrepresented in the government and opposed to its policies.

National Film Board of Canada



Borden.

Robert Laird Borden was born on June 26, 1854, in Grand Pré, Nova Scotia. He cut short his formal education before his 15th year, when he accepted the post of assistant master of the private school he was attending. His teaching career ended in 1874, when he became articled to a Halifax law firm. Admitted to the bar of Nova Scotia in 1878, he rose to a commanding position in legal circles, and after his marriage to Laura Bond (1889) he founded a law firm that subsequently acquired one of the largest practices in the Maritime Provinces. His friendship with Sir Charles Hibbert Tupper, son of one of the original "Fathers of Confederation," led him to accept the conservative nomination for Halifax in 1896. Borden's entry into politics coincided with the victory of the Liberal Party under the leadership of Sir Wilfrid Laurier. Though he remained an obscure backbench opposition member during his first term, Borden was invited by the caucus upon his re-election in 1900 to assume temporarily the leadership of the party. He accepted the post, and, despite repeated intrigues against his leadership and his own professions of distaste for it, he occupied it until 1911, when the Liberal decision to accept a reciprocal-trade agreement with the United States led to Laurier's defeat.

Anglo-Canadian relations

As prime minister, Borden's major interest was Anglo-Canadian relations. He had long argued for the establishment of a Canadian voice in imperial policy. His prewar naval policy, which involved a grant of $35,000,000 to Britain for the construction of three battleships, was a mixture of opportunism and wishful thinking about the extension of Canada's influence in the councils of empire. During the first two years of war Borden frequently referred to the necessity of Canadian participation in British decisions, but it was not until the British prime minister David Lloyd George created the Imperial War Cabinet (IWC) in 1917 that Borden was given a chance to express Canada's point of view. At the meetings of the IWC in London and its subsequent sessions in Paris during the negotiation of the Treaty of Versailles, Borden supported the Fourteen Points of United States president Woodrow Wilson and argued that Canada's interests demanded the closest possible alliance between the British Empire and the United States. (Borden saw nothing incompatible between insisting on the right to participate in shaping imperial policy and Canada's independent membership of the League of Nations. He seemed to envisage the empire-commonwealth as an alliance in which smaller members might have to defer to the interests of the great power—but after a process of continuous consultation.)

Borden's "imperial" preoccupations may partially account for his first administration's poor performance in domestic affairs. He dealt indecisively with his controversial minister of militia, Sam Hughes, whom he did not remove from office until the end of 1916. As charges of incompetence, patronage, and war profiteering were levelled against Borden's government, public confidence in him decreased. His decision, however, to form a coalition government in order to implement conscription gave him the opportunity of reconstructing his Cabinet and of surrounding himself with a group of able colleagues. With Arthur Meighen, his eventual successor as prime minister, to manage the House of Commons and two liberals, Newton Rowell and Alexander K. Maclean, in charge of key Cabinet committees, Borden was free to concentrate on the larger questions under discussion in London and Paris. He supported the policy of Allied intervention in the Russian Civil War, in which he was anxious to have Canadian troops participate. Public opinion forced the return of a 3,000-man expeditionary force from Vladivostok, which Borden had hoped would establish a Canadian presence leading eventually to trade concessions. His policy of arresting the leaders of the Winnipeg General Strike (1919) and of charging them under a revised definition of sedition that was rushed through Parliament in the form of an amendment to the criminal code won him the enmity of labour. He resigned from office in July 1920.

Formation of coalition government

In retirement he attended the Washington Naval Disarmament Conference (1921) as Canada's delegate and wrote *Canadian Constitutional Studies* (1922) and *Canada in the Commonwealth* (1929). He also published his *Memoirs* (1938) under the editorship of his nephew, Henry Borden. He died on June 10, 1937.

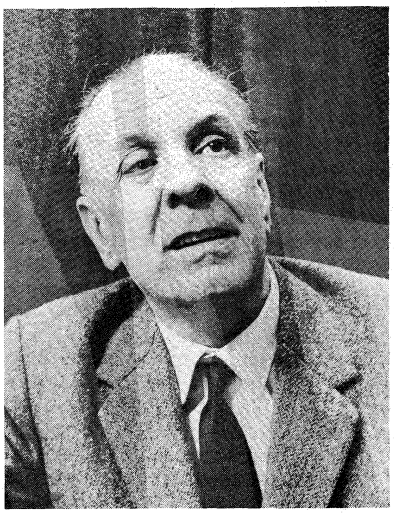
BIBLIOGRAPHY. For a brief biographical sketch, see CRAIG BROWN, "Sir Robert Borden, the Great War and Anglo-Canadian Relations," in JOHN MOIR (ed.), *Character and Circumstance* (1970). An official biography also by Brown, the first volume of which will cover the years to 1914, will be published soon. HAROLD A. WILSON, *The Imperial Policy of Sir Robert Borden* (1966), is a recent examination of Borden's quest for a voice in British foreign and imperial policy.

(J.T.C.)

Borges, Jorge Luis

Since 1961, when he and Samuel Beckett shared the prestigious international award the Formentor Prize, the Argentine writer Jorge Luis Borges has seen his tales and poems increasingly acclaimed as classics of 20th-century world literature. Prior to that time, Borges was little known, even in his native Buenos Aires, except to other writers, many of whom regarded him merely as a craftsman of ingenious techniques and tricks. Now, the nightmare world of his "fictions," which are often compared to the stories of Franz Kafka, are praised for concentrating common language into its most enduring form. Through his work more than that of any other contemporary, Latin-American literature emerges from the academic realm into that of generally educated readers throughout the Western world.

Borges was born on August 24, 1899, in Buenos Aires and was raised in the shabby suburb of Palermo, the setting of some of his works. His family, which had been notable in Argentine history, included British ancestry, and he learned English before Spanish. The first books he read—from the library of his father, a man of wide-ranging intellect who taught at an English school—included *Huckleberry Finn*, the novels of H.G. Wells, *The Thousand and One Nights*, and *Don Quixote*, all in English. Under the constant stimulus and example of his father, the young Borges from his earliest years realized that he was destined for a literary career.



Borges.

In 1914, on the eve of World War I, Borges was taken by his family to Geneva, Switzerland, where he learned French and German and received his B.A. from the Collège de Genève. Leaving there in 1919, the family spent a year in Majorca and a year in Spain, where Borges joined the young writers of the Ultraist movement, a group that rebelled against what it considered the decadence of the established writers of the "generation of '98."

Return to Buenos Aires

Returning to Buenos Aires in 1921, Borges rediscovered his native city and began to sing of its beauty in poems that imaginatively reconstructed its past and present. His first published book was a volume of poems, *Fervor de Buenos Aires* (1923). He is also credited with establishing the Ultraist movement in South America, though he later repudiated it. This period of his career, which included the authorship of several volumes of essays and poems and the founding of three literary journals, ended with a biography, *Evaristo Carriego* (1930).

During his next phase, Borges gradually overcame his shyness in creating pure fiction. At first he preferred to retell the lives of more or less infamous men, as in the sketches of his *Historia universal de la infamia*. To earn his living, in 1938 he took a major post at a Buenos Aires library named for one of his ancestors. He remained there for nine unhappy years.

In 1938, the year his father died, Borges suffered a severe head wound, and subsequent blood poisoning, which left him near death, bereft of speech, and fearing for his sanity. This experience appears to have freed in him the deepest forces of creation. In the next eight years he produced his best fantastic stories, those later collected in the series of *Ficciones* and the volume titled *The Aleph and Other Stories, 1933–69*. During this time, he and another writer, Adolfo Bioy Casares, jointly wrote detective stories under the pseudonym H. Bustos Domecq (combining ancestral names of the two writers' families), which were published in 1942 as *Seis problemas para don Isidro Parodi* ("Six Problems for Don Isidro Parodi"). The works of this period revealed for the first time Borges' entire dreamworld, an ironical or paradoxical version of the real one, with its own language and systems of symbols.

When the dictatorship of Juan Perón came to power in 1946, Borges was dismissed from his library position for having expressed support of the Allies in World War II. With the help of friends, he earned his way by lecturing, editing, and writing. A 1952 collection of essays, *Other Inquisitions, 1937–1952* revealed him at his analytical best.

When Perón was deposed in 1955, Borges became director of the national library, an honorific position, and also professor of English and American literature at the University of Buenos Aires.

Blindness

By this time, Borges suffered from total blindness, a hereditary affliction that had also attacked his father and had progressively diminished his own eyesight from the 1920s onward. It had forced him to abandon the writing of long texts and to begin dictating to his mother or to secretaries or friends.

The works that date from this late period, such as *Dreamtigers* and *The Book of Imaginary Beings*, almost erase the distinctions between the genres of prose and poetry. A later collection of stories, *El informe de Brodie* (1970; "Doctor Brodie's Report"), comprises tales of revenge, murder, and horror—allegories combining the simplicity of a folk storyteller with the complex vision of a man who has explored the labyrinths of his own being to its core.

MAJOR WORKS

POEMS: *Fervor de Buenos Aires* (1923); *Luna de enfrente* (1925); *Cuaderno San Martín* (1929); *Poemas* (1943); *Poemas 1923–1953* (1954); *Poemas* (1958); *Obra poética, 1923–1966* (1966; vol. 6 of Borges' *Obras completas*).

PROSE (ESSAYS): *Inquisiciones* (1925), miscellaneous essays; *El tamaño de mi esperanza* (1926), collected essays; *El idioma de los Argentinos* (1928), essays, one of which was revised and included in *El lenguaje de Buenos Aires* (1963); *Discusión* (1932); *Historia de la eternidad* (1936); *Aspectos de la literatura gauchesca* (1950); *El "Martín Fierro"* (1953), *Otras inquisiciones, 1937–1952* (1952; *Other Inquisitions, 1937–1952*, 1964); *Crónicas de Bustos Domecq* (1967), on aesthetics. (SHORT STORIES AND PARABLES): *Historia universal de la infamia* (1935), translations, adaptations, original stories, and parables; *El jardin de senderos que se bifurcan* (1942), collected stories; *Ficciones 1935–1944* (1944; several later series, 6th enl. ed., 1966), stories; *El Aleph* (1949; *The Aleph and Other Stories, 1933–69*, ed. and trans. by Norman Thomas di Giovanni in collaboration with the author, 1970), collected stories; *La muerte y la brújula* (1951), collected stories; *El hacedor* (1960; *Dreamtigers*, 1964), collected stories, parables, and poems; *El libro de los seres imaginarios* (1967; *The Book of Imaginary Beings*, written by Borges with Margarita Guerrero, rev. and trans. by Norman Thomas di Giovanni in collaboration with the author, 1969). (BIOGRAPHY): *Evaristo Carriego* (1930). (ANTHOLOGIES): Chosen by Borges from his own published and unpublished writings *Antologia personal* (1961), stories, essays, and poems; trans. in *A Personal Anthology*, ed. by A. Kerrigan (1967). Other Eng. trans. in *Labyrinths: Selected Stories and Other Writings of J.L. Borges*, ed. and trans. by D.A. Yates and J.E. Irby (1962; rev. ed. 1970); *Fictions*, selections from the series of *Ficciones*, ed. and trans. by A. Kerrigan (1968).

BIBLIOGRAPHY. ANA MARIA BARRENECHEA, *La expresión de la irrealidad en la obra de Jorge Luis Borges* (1957; Eng. trans., *Borges, the Labyrinth Maker*, 1965), the best critical study, with bibliography; RONALD CHRIST, *The Narrow Act: Borges' Art of Allusion* (1969), a very perceptive analysis of one of Borges' key methods of creation; MARTIN S. STABB, *Jorge Luis Borges* (1970), a superficial over-all presentation; EMIR RODRIGUEZ MONEGAL, *Borgès par lui-même* (1970), a critical introduction, with iconography.

Borgia, Cesare

Cesare Borgia was the son of Alexander VI, the most notorious and controversial of the Renaissance popes. His career was a classic example of how the popes of the 15th century made use of their families in attempting to recover the power and prestige lost by the papacy during the Great Schism (1378–1417, when two or more claimants fought over the papal throne). Cesare helped his father in preserving the independence of the papacy during the French invasions of Italy after 1494 and in re-establishing his control within the Papal States of central Italy. For this purpose he was made duke of the Romagna and captain general of the armies of the church; at the same time he shared with his father that glow of infamous notoriety that was to become associated with the name of Borgia.

Cesare was cited by his contemporary Machiavelli as an example of the new "Prince," and it is perhaps for this characterization by the famous Renaissance political theorist that he is best known.

Youth and education. Born 1475/1476, probably in Rome, he was the son of his father's most famous mistress, Vannozza Catanei. His father, at that time Cardinal

Borgia, oil painting by an unknown artist. In the Uffizi, Florence.
Alinari

Rodrigo Borgia, was vice chancellor of the church and had had three earlier children by other mistresses. Cesare was, however, the oldest of the four children born to Vannozza and Rodrigo (the others being Juan, Lucrezia, and Jofre) and was Rodrigo's second son. As was customary for second sons he was educated for a career in the church and in 1480 was dispensed from the slur of illegitimacy by Pope Sixtus IV so that he might hold ecclesiastical offices.

Although he was born in Italy and spent most of his life there, Cesare's family and cultural background was almost entirely Spanish. His elder half brother, Pedro Luis, was duke of Gandía, and all of his early benefices were in Spain. At the age of seven Cesare was made an apostolic protonotary and canon of the Cathedral of Valencia.

His early tutors were Paolo Pompilio and Giovanni Vera, both Catalans, and he was recognized as being exceptionally brilliant, as well as being, according to at least one observer, "the handsomest man in Italy." In 1489 he went to the University of Perugia to study law and then passed on to the University of Pisa, where he studied under the famous jurist Filippo Decio and gained a degree in canon and civil law. In 1491 he became bishop of Pamplona, and in 1492, after the accession of his father to the papal throne, he was made archbishop of Valencia.

Archbishop

Rise to power. The election of his father as pope in 1492 changed the fortunes of Cesare Borgia. Besides becoming an archbishop, he was also made a cardinal in 1493, with the titular Church of Sta. Maria Nova; he was now one of his father's principal advisers. It was already clear, however, that he did not have a true religious vocation; he was better known at the papal court for his hunting parties, his amorous liaisons, and his magnificent clothes than for the meticulous observance of his ecclesiastical duties.

On the death of Pedro Luis in 1488 the title of duke of Gandía had by-passed him and gone to his younger brother Juan, and it was he who was made commander of the papal army in 1496 for the first of Alexander's campaigns against his rebellious nobility, the Orsini. Cesare was reputed to have been extremely jealous of his brother, and when Juan was mysteriously murdered in 1497 the rumour gradually spread that Cesare was the culprit. There is, however, no evidence that Cesare murdered his brother (who had many other enemies) beyond the fact that he was certainly capable of murder, as he subsequently proved.

After the death of Juan, Cesare's martial and political leanings and his father's need for a trustworthy secular lieutenant coincided, and in 1498 Cesare gave up his cardinalate. Plans were laid for an important dynastic marriage for him, and, after an abortive attempt to win the hand of Carlotta, daughter of the King of Naples, he travelled to France to marry Charlotte d'Albret, sister of the King of Navarre. At the same time he received from Louis XII, the French king, the title of duke of Valentinois, and from this title he derived his nickname—Il Valentino.

The French marriage of Cesare ensured for him and his father French assistance in their plans to re-establish control in the Papal States and, if possible, to carve out a permanent Borgia state in Italy for Cesare. In 1499 Cesare, as captain general of the papal army, assisted by a large contingent of French troops, began a systematic occupation of the cities of Romagna and the Marches, which had largely fallen under the control of semi-independent papal vicars.

Papal campaigns

The campaign of 1499 saw the conquest of Imola and Forlì; that of 1500–01 brought Rimini, Pesaro, and Faenza into Cesare's hands; finally, in 1502, he captured Urbino, Camerino, and Senigallia. It was in this last campaign that Machiavelli, as one of the Florentine ambassadors attached to Cesare's camp, was able to observe at first hand the methods of the man who was to figure so largely in his later writings.

The activities of Alexander and Cesare, although they conformed very much to a pattern established by earlier 15th-century popes, aroused immense opposition within the Papal States and from the other Italian states. The propaganda war waged against them was vitriolic and lastingly effective. Cesare was portrayed as a monster of lust and cruelty who had gained an unnatural ascendancy over his father after having supposedly killed his favourite son, Juan. It seems likely, however, that the two Borgias worked very much in harmony; Alexander was by far the more astute politician, and Cesare the more ruthless man of action. Ambitious and arrogant, he was determined to establish himself as an Italian prince before his father died and left him deprived of the political and financial support of the Papacy. *Aut Caesar, aut nihil* ("Either Caesar or Nothing") was the motto he adopted to indicate the single-mindedness of his purpose. A number of political assassinations have been attributed to him, but the crime of which he was most clearly the author was the murder in August 1500 of his brother-in-law Alfonso, duke of Bisceglie, the second husband of Lucrezia. It seems likely that this was an act of personal vengeance rather than a politically motivated assassination, but it contributed greatly to the fear and loathing in which Cesare was held.

The best example of Cesare's methods was his third Romagna campaign (1502–03). He opened with a lightning march on unsuspecting Urbino, which surrendered without a shot being fired. He then turned on Camerino, which was also quickly subdued. At this stage his leading commanders, fearing his power, turned against him in the so-called Magione conspiracy. Cesare, stripped of most of his troops, was forced to fight defensively in the Romagna. With lavish use of papal funds, however, he managed to rebuild his army while at the same time working on the diplomatic front to break up the league of the conspirators. Having succeeded in breaking it up, he arranged a rendezvous for reconciliation with some of the conspirators at Senigallia and, having isolated them from their troops, he then arrested and executed them (December 1502).

Magione conspiracy

Cesare, with a powerful army he could trust, now seemed to be at the zenith of his fortunes. It is probable that he was planning an attack on Tuscany, which would have provided him with the independent state he craved, when his father died on August 18, 1502. He himself was also ill at the time, and this circumstance, together with the subsequent election of a bitter enemy of the Borgias, Giuliano della Rovere, as Pope Julius II, lessened his already slim chances of survival. Julius refused to confirm Cesare as duke of the Romagna or captain general of the church and demanded the restoration of the Romagna cities. Cesare was arrested, won a brief respite by agreeing to surrender his cities, and fled to Naples only to be arrested once more by Gonsalvo di Córdoba, the Spanish viceroy, who refused to join him in a league against the Pope. Cesare was then taken to Spain and imprisoned,

Arrest and fall from power

first in the castle of Chinchilla near Valencia, and then at Medina del Campo, from whence he escaped in 1506. Unable to see any immediate prospect of returning to Italy, he took service with his brother-in-law, the king of Navarre, and was killed in 1507 in a skirmish with Navarrese rebels outside Viana. He was buried in the Church of Sta. Maria in Viana.

Assessment. Cesare Borgia was a man of extraordinary contrasts. Machiavelli found that he could be at times secretive and taciturn, at others loquacious and boastful. He alternated bursts of demonic activity, when he stayed up all night receiving and dispatching messengers, with moments of unaccountable sloth, when he remained in bed refusing to see anyone. He was quick to take offense and rather remote from his immediate entourage and yet very open with his subjects in the Romagna, loving to join in local sports and to cut a dashing figure.

There can be no doubt of the impact that he made in the Italy of his own day, but this impression was largely because of the backing he received from papal money and French arms. He was undoubtedly a master of politico-military manoeuvre, and it was a combination of daring and duplicity that brought him his striking successes and made him feared all over Italy. His abilities as a soldier and an administrator, however, were never really tested. He fought no major battles in his short military career, but this was perhaps a measure of his success as a planner. He had little time for the organization of the government of his Romagna duchy, but there are indications that he had plans for centralized government and bureaucratic efficiency, which to some extent justify the claims made for him as an administrator by Machiavelli. His interests tended to be scientific and literary rather than artistic, but once again time was too short for him to emerge as an important Renaissance patron. Leonardo da Vinci was for a short time his inspector of fortresses but executed no artistic commissions for him.

Model for Machiavelli's *Prince*

Machiavelli's apparent admiration for a man who was so widely feared and abhorred has led many critics to regard his portrayal of Cesare as an idealization. This interpretation, however, is not really the case. Machiavelli was well aware of the failings and limitations of Cesare Borgia, but he saw in him some of the qualities that he considered essential for the man who aspired to be a prince. The aggressiveness, the speed and ruthlessness of planning and execution, the opportunism of Cesare all delighted Machiavelli, who saw far too little of these qualities in the Italy of his day. Machiavelli was not attempting a rounded portrait of Cesare's character and qualities, which baffled him as much as they did most of his contemporaries.

BIBLIOGRAPHY. The standard biography is still W.H. WOODWARD, *Cesare Borgia* (1913), which may be supplemented by the fuller but less balanced study by E. ALVISI, *Cesare Borgia, duca di Romagna* (1878). More recent but less useful are C.E. YRIARTE, *Cesare Borgia* (Eng. trans. 1947); and C.M.L. BEUF, *Cesare Borgia: The Machiavellian Prince* (1942). On the background of the period and the family, see L. COLLISON-MORLEY, *The Story of the Borgias* (1932); and M.E. MALLETT, *The Borgias* (1969), with the most complete bibliography.

Boris I of Bulgaria

Khan Boris I of Bulgaria was one of the most remarkable rulers of medieval Bulgaria. His long reign (852–889) witnessed the conversion of the Bulgarians to Christianity; the founding of an autocephalous Bulgarian Church; and the advent of Slavonic literature and the establishment of the first centres of Slav-Bulgarian scholarship and education. Boris' active domestic and foreign diplomacy was of great importance in forming a united Bulgarian ethnical community, and it left lasting traces on Bulgaria's later development.

When Boris inherited the throne from his father, Bulgaria's territorial, military, and political potential had made it one of the largest states in Europe. Bulgaria's approximate frontiers were the Dnepr (Dnieper) in the northeast; the Carpathians in the north; the Tisa (Tisza) in the northwest; the Adriatic in the west; and the Tomorr (Tomor), Belasica, Pirin, Rhodope, and Strandzha mountains in the south. Many Slavic tribes lived within the boundaries of the state, together with the proto-Bulgarians, a tribe of Turkic origin that had settled in the Balkan Peninsula at the end of the 7th century. In view of the religious, ethnic, and language difficulties between the Slavs and Bulgars, the introduction of a common and compulsory religion for all subjects was one of the principal preconditions for the formation of a united Bulgaria. Pagan Bulgaria needed to join the "family of Christian states," but the existence of two competing centres of Christianity—Rome and Constantinople—made it difficult for Boris to make his choice. Boris originally intended to accept Roman Christianity, but an unsuccessful war with the Byzantines forced Boris to adopt the Orthodox faith of Constantinople (864). Boris (at his baptism he took the Christian name Michael), his family, and the nobles who supported his policy were baptized one night in secret by a Byzantine bishop and priests who had been sent to Pliska, the Bulgarian capital. There was serious opposition by both the nobility and the common people to Boris' attempt to enforce mass baptism. A pagan rebellion broke out, and Boris retaliated by executing 52 boyars, together with their families.

Conversion of the Bulgars

Negotiations took place between Boris and Photius, patriarch of Constantinople, on the status of the Bulgarian diocese but did not lead to the result expected by the Bulgarians. The Byzantines demanded that the Bulgarian church organization should be entirely subjected to Constantinople. Dissatisfied, Boris renewed his diplomatic contacts with the West. In 866 he sent embassies to Pope Nicholas I (858–867) and to King Ludwig of Germany. The Pope immediately responded by sending a mission to Bulgaria. The Roman clergy's stay (866–870) soon became a sore point in the acute rivalry between Rome and Constantinople. But since Pope Nicholas I and his successor, Adrian II, proved dilatory on the question of church organization in Bulgaria (they hesitated over the creation of an independent Bulgarian archbishopric), Boris again reopened negotiations with Constantinople. The Bulgarian church question was finally solved at the eighth ecumenical council in Constantinople in 869–870. Bulgaria was formally placed under the nominal ecclesiastical jurisdiction of the patriarch of Constantinople but received an independent archbishopric. The attempts of the popes to bring the Bulgarian ruler back into the Roman church by pleas and promises of concessions continued until 882 but produced no results.

Boris was quite active in inculcating the Christian faith among the Bulgarian people, in organizing the Bulgarian Church as an independent institution, and in building churches throughout the country. In 886 he gave asylum to Clement, Nahum, and Angelarius, the disciples of Cyril and Methodius, missionaries to the Slavs, who had been driven out of Moravia. With Boris' active assistance and material support, these disciples founded centres of Slavic learning at Pliska, Preslav, and Okhrid. As a result of the intensive work of the Slav scholars, the Slavic language replaced Greek in church services and in literary life and became the country's official language.

In 889 Boris I abdicated and became a monk, but he retained the right to take an active part in the government of the state. Boris' eldest son and heir, Vladimir (889–893), abandoned his father's policy and became the instrument of a pagan reaction and a leader of the opponents of Slavic letters and literature. Boris then returned to active politics. With the aid of loyal boyars and the army, Boris drove his son from the throne. Vladimir was blinded, unfitting him for rule, and was replaced by Boris' third son, who ruled as Symeon the Great (893–927). Boris afterward retired to his monastery, making generous grants to the Bulgarian Church and patronizing Slav scholarship. He died on May 2, 907, in Preslav. He was canonized by the Orthodox Church, and his feast is celebrated on May 15 (new style; May 2, old style).

Return to politics

BIBLIOGRAPHY. VASIL GJUZELEV, *Knjaz Boris Părvi* (1969), the most recent and complete study in line with the

achievements of modern historiography; FRANTISEK DVORNIK, *Les Slaves, Byzance et Rome au IX^e siècle* (1926), chiefly concerning the diplomacy of Boris I of Bulgaria with a view to relations between the churches of Rome and Constantinople; *The Photian Schism: History and Legend* (1948), a brilliant study in which the author gives an appreciation of the work of Boris I.

(W.T.G.)

Boron Group Elements and Their Compounds

The five elements comprising the so-called boron group are: boron (symbol B, atomic number 5), aluminum (symbol Al, atomic number 13), gallium (symbol Ga, atomic number 31), indium (symbol In, atomic number 49), and thallium (symbol Tl, atomic number 81). Constituting Group IIIa of the periodic table (see Figure 1), they are characterized as a group by having three electrons in the outermost parts of their atomic structure. Boron, the lightest of these elements, is a nonmetal but the other members of the group are silvery-white metals.

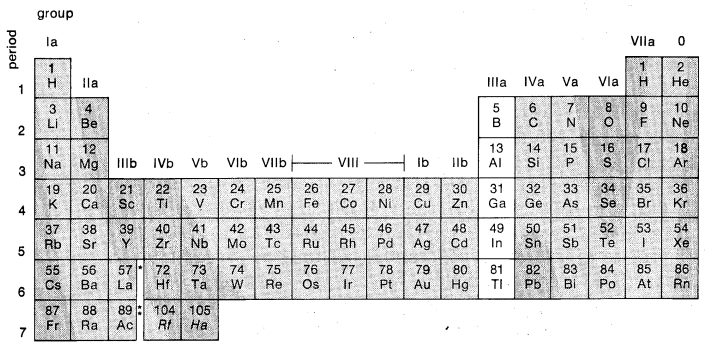

Figure 1: Boron group elements in the periodic table.

None of these elements was known in a pure state before modern chemistry isolated them. Very soon after a method had been found to produce it in commercial quantities, aluminum revolutionized industry. The other members of the group, including boron, still have little commercial value. Some of the compounds of boron and aluminum, however, are indispensable in modern technology and have been widely used in many parts of the world throughout recorded history.

History. The use of a boron compound known as borax (sodium tetraborate, $Na_2B_4O_7 \cdot 10H_2O$) can be traced back to the ancient Egyptians, who used it as a metallurgical flux (a substance that aids the heat joining or soldering of metals), in medicine, and in mummification. During the 13th century, Marco Polo introduced borax into Europe but not until the mid-19th century, when vast deposits of borates were discovered in the Mojave Desert, did borax become relatively common. The ancient Egyptians, Greeks, and Romans used a compound of aluminum known as alum (the compound potassium aluminum sulfate) in dyeing as a mordant; *i.e.*, a substance that fixes dye molecules to the fabric. Lapis lazuli, a rare, dark blue mineral (the compound sodium aluminum silicate containing sulfur), has been widely used as a semiprecious stone throughout history. The metal aluminum was first isolated early in the 19th century but it was not until a modern electrolytic process based on the use of bauxite was developed that commercial production of aluminum became economically feasible. The other elements of the boron group were first detected spectroscopically (*i.e.*, by analysis of the light emitted by or passed through substances containing the element) in the late 19th century. The existence and properties of gallium were predicted by a Russian chemist, Dmitry Ivanovich Mendeleyev, on the basis of the periodic table of the elements that he had developed; the ultimate discovery of gallium and the accuracy of his description of the properties of the then unknown element convinced scientists of the theoretical soundness of the table. Gallium is one of two metals (the other is cesium) whose melting points are low enough for them to turn to liquid when held in the hand.

Historical importance of gallium

GENERAL PROPERTIES OF THE BORON GROUP

Atomic structure. The chemical and physical properties of the elements and their compounds can be understood in terms of their atomic structures. Each of the atoms which make up the various elements in the periodic table has as its core a massive nucleus carrying positive electrical charges. The number of charges is called the atomic number of the element in question. In the periodic table, the elements are arranged in sequence according to their atomic numbers. Since atoms are neutral, every nucleus is surrounded by as many electrons (each carrying a single negative electric charge) as there are positive charges, these electrons being housed in orbitals. The electrons in orbitals closest to the nucleus are held most tightly; those in the outermost orbitals are shielded by intervening electrons and are the most loosely held by the nucleus. Depending on their energy and on rules dictated by quantum mechanics, orbitals are arranged in families, or shells, the more massive atoms having seven such shells. The total energy of each electron varies with its position in the structure, and each position is defined in terms of the number of the shell in which it occurs (the numbers proceeding outward from the nucleus), followed by one of four letters—*s*, *p*, *d*, or *f*—representing different classes of orbitals within the shells. As a result of receiving more energy an electron may move from one orbital to another, as from a 3*s* to a 3*p* orbital. The number of electrons in each orbital is customarily given as a superscript following the orbital designation; thus the notation $4s^24p^1$ means that the atoms of a particular element carry two *s* electrons and one *p* electron in their fourth shell. In boron, the outermost shell is 2, in aluminum it is 3, and so on.

Chemical bonding

There are three main types of chemical bonding. In one called ionic, or electrovalent, electrons are actually donated by one atom to another and the resulting ions, being oppositely charged, then associate in a crystal. In another called covalent, a pair of electrons is shared by two atoms, and the sharing is represented in terms of overlapping orbitals. In a third type of bond called metallic, valence electrons are freed to move about among the bonded atoms. Since some electrons in inner shells also participate in chemical bonds, though to a lesser extent, it is more convenient to use the concept of what is called the oxidation state for bonds in general. (Oxidation is a process of losing electrons.) The oxidation state of an element is the total number of its electrons involved in a chemical bond, without regard to the nature of the bond; most elements have more than one oxidation state; *i.e.*, they can form compounds involving more than one arrangement of their electrons. Oxidation states are depicted as roman numerals following the name of the element: boron(III), thus, is boron in oxidation-state three; B^{III} means the same thing. Another way of examining chemical properties is by measuring the energy required to eliminate an electron from an atom, called the ionization energy. The ionization energy required to remove the first electron from a neutral atom is the lowest; since the rest will then be held more tightly by the nucleus, each successive electron that is removed will require increasingly more energy. (Further explanations of general chemical behaviour may be found in detail in articles such as ATOMIC STRUCTURE; CHEMICAL REACTIONS; PERIODIC LAW.) Molecules of a compound are represented by a formula in which the symbols of the elements comprising the compound are listed with subscripts indicating the number of each atom in the molecule. Thus, $AlCl_3$ means that there are one atom of aluminum and three atoms of chlorine in a molecule of the compound aluminum trichloride.

Ionization behaviour. The Table gives a list of the electronic configurations and several ionization energies

of the boron group elements. Every element in the boron group has three electrons in its outermost shell, and for each element there is a sharp jump in the amount of energy required to remove the fourth electron, reflecting the fact that this electron must be removed from an inner shell. Consequently the elements of the group will have maximum oxidation numbers of three, corresponding to loss of the first three electrons, and will form ions with three positive charges.

The apparently erratic way in which ionization energies vary among the elements of the group is due to the presence of the filled inner *d* orbitals in gallium, indium, and thallium, and the *f* orbital in thallium, which do not shield the outermost electrons from the pull of the nuclear charge as efficiently as do the inner *s* and *p* electrons. In Groups Ia and IIa, in contrast to the boron group, outer shell (always referred to as n) electrons are shielded in every case by a constant inner set of electrons, in the $(n-1)s^2(n-1)p^6$ orbitals, and the ionization energies of these Group-Ia and Group-IIa elements decrease smoothly down the group. The ionization energies of Ga, In, and Tl are thus higher than expected from their Group II counterparts because their outer electrons, being poorly shielded by the inner *d* and *f* electrons, are more strongly bound to the nucleus. This shielding effect also makes the atoms of gallium, indium, and thallium smaller than the atoms of their Group Ia and IIa neighbours by causing the outer electrons to be pulled closer toward the nucleus.

The M^{3+} state for Ga, In, and Tl will be energetically less favourable than Al^{3+} because the high ionization energies of these three elements cannot always be balanced by the crystal energies of possible reaction products. For example, of the simple, anhydrous compounds of trivalent thallium only the trifluoride, TlF_3, is ionic. For the group as a whole, therefore, the M^{3+} ionic state is the exception rather than the rule. More commonly the elements of the group form covalent bonds and achieve an oxidation state of three by promoting one electron from the *s* orbital in the outer shell (designated n*s* orbital) to an n*p* orbital, the shift permitting the formation of hybrid, or combination, orbitals (of the variety designated as sp^2). Increasingly down the group there is a tendency toward the formation of M^+ ions and at thallium the monovalent state is the more stable one. The basicity (a property of metals) of the elements also increases in proceeding down the group as shown by the oxides they form: boric oxide (formula B_2O_3) is acidic, the next three oxides, of aluminum, gallium, and indium (formulas Al_2O_3, Ga_2O_3, and In_2O_3) are either acidic or basic depending on the environment (a property called amphoterism), and thallic oxide (Tl_2O_3) is wholly basic.

Basicity of oxides

The ionization energies listed in the Table suggest that the formation of salts of the M^{2+} ions might be feasible. At first glance, such appears to be the case, since gallium compounds with the formula GaX_2 (X representing chlorine, bromine, or iodine) can be made, and similar cases occur with the other metals of this group. Such compounds, however, are generally found to be of mixed valency—that is, they contain metal atoms in both the one and the three oxidation states, a condition symbolized as $M^+(M^{III}X_4)^-$. The nearest approach to M^{2+} derivatives occurs in gallium sulfide, selenide, and telluride, which are made by heating gallium with stoichiometric amounts of sulfur, selenium, and tellurium, respectively. Studies of the structure of these compounds by X-ray methods show that they contain $(Ga\text{-}Ga)^{4+}$ units arranged in a layer-like lattice; the coupling of the gallium atoms in such a manner pairs the electrons available for the bonds and thereby explains the diamagnetism of the compounds (diamagnetism is a property associated with paired electrons).

The large amount of energy required to remove three electrons from a boron atom makes the formation of salts containing the bare B^{3+} cation impossible; even water of hydration associated with such ions would be too highly deformed to be stable and hence the aquated ion $B^{3+}_{(aq)}$ is unknown. Much less energy is required to promote electrons from 2*s* orbitals into 2*p* orbitals in boron atoms with the result that boron compounds are always covalent. The boron orbitals are hybridized to either the sp^2 (when boron forms bonds with three other atoms) or the sp^3 (when boron forms bonds with four atoms) configuration (see CHEMICAL BONDING).

Some Properties of the Boron Group Elements

	boron	aluminum	gallium	indium	thallium
Atomic number	5	13	31	49	81
Atomic weight	10.811	26.9815	69.72	114.82	204.37

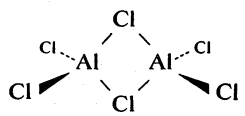
Although simple M^{3+} cations are uncommon in anhydrous compounds of the boron group elements, the hydrated (combined with water) trivalent ions of aluminum, gallium, indium, and thallium are well known in water solution. Nuclear magnetic resonance studies reveal that there are six water molecules held strongly by these positive ions in solution, and their salts often can be crystallized from solution combined with six water molecules. The high charge on the central cation of such hydrates induces the ionization of protons, or hydrogen nuclei, on the coordinated water molecules and thereby leads to the formation of basic salts. This reaction is represented in the following equations:

$$M(H_2O)_n^{3+} \rightleftharpoons (HO)M(H_2O)_{n-1}^{2+} + H_{aq}^{+}$$
$$\rightleftharpoons (HO)_2M(H_2O)_{n-2}^{+} + 2H_{aq}^{+} \rightleftharpoons M(OH)_3 + 3H_{(aq)}^{+}$$

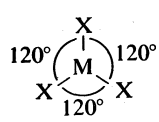
in which, as before, M represents an ion of one of the boron group elements; n is the number of water molecules joined to it; (HO)M represents a hydroxide group joined to the metal ion; and $H(aq)^+$ is a hydrated hydrogen ion. In these and other equations the arrows pointing in two directions indicate that the chemical reactions can proceed both ways depending on the reaction conditions. When acid is added to such aqueous solutions it depresses the hydrolytic processes by reversing the above reactions. At high acid concentrations, however, complex anions (negative ions) are sometimes formed, especially with the aqueous hydrogen halides. The following equation illustrates this: $Ga(aq)^{3+} + HX$ (conc.) $\rightarrow GaX_4^-$, X being chlorine, bromine, or iodine. Intermediate complex ions, MX^{2+} and MX_2^+ can be detected in several cases.

The electrical conductivity of solid aluminum trichloride (formula $AlCl_3$), in which each aluminum ion has three positive charges, increases rapidly as the temperature is elevated toward the melting point, at which the conductivity suddenly falls to zero. This phenomenon occurs because the aluminum and chloride ions form an ionic lattice that partially conducts electricity; but upon melting, the compound changes to the electrically nonconducting, covalent state. The explanation is that the distribution of energy in the liquid state is insufficient to compensate for the ionization energy required to separate the Al^{3+} and Cl^- ions and these then acquire covalent bonds. The liquid consists of double or dimeric molecules with the formula Al_2Cl_6, which may be represented in the following manner that shows a molecule with the position of its atoms in three dimensions; the solid lines are in the plane of the paper, the dotted lines are behind the paper, and the shaded lines indicate that they extend toward the viewer:

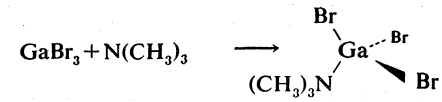


The delicate energy balance between ionic and covalent bonding for aluminum in the trivalent state can be appreciated when it is realized that whereas solid aluminum trifluoride, formula AlF_3, is ionic like the chloride, aluminum tribromide forms molecular crystals containing dimers, with the formula Al_2Br_6.

In contrast with the dimers, the single, or monomeric, trihalides of the boron group elements have trigonal planar structures. If M is the metal and X is any halogen, the arrangement of the atoms can be sketched as follows:

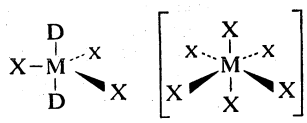


The trihalides of boron have this configuration in all phases whereas the trihalides of Al, Ga, In, and Tl become monomeric only on being heated in the gas phase. In MX_3 molecules, the central atom M has added three electrons to its own making only six electrons in the outer shell, although eight are required to achieve the desired inert-gas configuration. These halides, therefore, readily accept two more electrons from many donor molecules (*e.g.*, ethers, alcohols, amines, and phosphines) that carry unshared pairs of electrons. A typical case, the reaction of gallium tribromide with trimethylamine, is represented in the following equation:



The central gallium atom is coordinated or bonded to three bromine atoms and one nitrogen atom. The electron donor also can be a halide ion, in which case the tetrahedral complex anion, MX_4^- results.

A few compounds are known in which aluminum, gallium, indium, and thallium are coordinated to five or six atoms. These compounds have structures of the following types, M again representing any boron group element, D any donor molecule, and X any halogen (again, the solid lines are bonds in the plane of the paper, the atoms so bonded lying in that plane; the dotted lines lead behind the paper; the shaded lines reach toward the viewer):



In such compounds it is possible, but by no means certain, that the central element makes use of its vacant n*d* orbitals (see above) to increase its valency by way of sp^3d (five-coordination) or sp^3d^2 (six-coordination) hybridization. If the concept of the participation of *d* orbitals in the bonding of these compounds is valid, it would account for the fact that boron, which has no available *d* orbitals, does not form five- and six-coordinate compounds. In many cases, however, spatial requirements also would rule out the possibility of boron increasing its covalency above four because the boron atom is so small no more than four atoms can be arranged around it.

Halides of elements

In the gas phase at high temperature all the boron group elements form diatomic halides MX, either by dissociation of the trihalides or, more commonly, by reduction of the trihalides with the free element as in the following equations for two such reactions:

$$2B + BF_3 \xrightarrow{2{,}000^\circ} 3BF$$

boron — boron trifluoride — boron monofluoride

$$2Al + AlCl_3 \xrightarrow{800^\circ - 1{,}000^\circ} 3AlCl.$$

aluminum — aluminum trichloride — aluminum monochloride

Most of these monohalides, especially those of boron, aluminum, and gallium, are unstable in the solid state under normal conditions; they exist only at high temperatures as gases; all are covalently bonded, except thallium fluoride, which exists as the ion pair, Tl^+F^-.

Thallium is the only element that forms a stable ion having an $(n\text{-}1)d^{10}ns^2$ outer electronic configuration. There is, therefore, no ion to which direct comparisons with the thallium(I) ion, Tl^+, might be made.

COMPOUNDS OF THE INDIVIDUAL BORON GROUP ELEMENTS

Boron. The first three ionization energies of boron, atomic number 5, are much too high to allow the formation of compounds containing the B^{3+} ion; in all its compounds boron is covalently bonded. One of boron's 2*s* electrons is promoted to a 2*p* orbital, giving the outer electron configuration $2s^12p^2$; the *s* and *p* orbitals can then be mixed to give sp^2 and sp^3 hybrids, which allow boron to be three- and four-coordinated, respectively. The three-coordinate derivatives (*e.g.*, halides, alkyls, aryls) are planar molecules that readily form donor-acceptor complexes (called adducts) with compounds containing lone pairs of electrons; in these adducts the boron atom is four coordinated, the four groups being tetrahedrally disposed around it.

Boron is an essential trace element for the healthy growth of many plants, and typical effects of long-term boron deficiency are stunted, misshapen growth and, in root crops, heart rot and dry rot; the deficiency can be alleviated by the application of soluble borates to the soil. Gigantism of several species of plants growing in soil naturally abundant in boron has been reported. It is not yet clear what the precise role of boron in plant life is, but most researchers agree that the element is in some way essential for the normal growth and functioning of apical meristems, the growing tips of plant shoots.

Boron is unique in its group in that it forms a rather large number of compounds with hydrogen, or hydrides, called boranes, many of which have most unusual, three-dimensional structures; it also forms a series of halides with the general formula B_nX_n. These molecules are interesting because they contain closed cages of boron atoms. Examples are the boron chlorides whose formulas are B_4Cl_4, B_8Cl_8, and B_9Cl_9. Unfortunately these interesting halides, most of which are highly coloured in sharp contrast to the more typical boron derivatives, are exceedingly difficult to prepare and to handle. The substance, formula B_4Cl_4, for example, can be prepared only in milligram quantities, and complex electrical-discharge techniques are needed for its production; furthermore, it ignites spontaneously in air and is rapidly decomposed both by water and even by the grease used to lubricate the vacuum equipment employed in its preparation. Closed cages containing 12 boron atoms arranged in the form of an icosahedron (see Figure 2) also occur in the various crystalline forms of elemental boron.

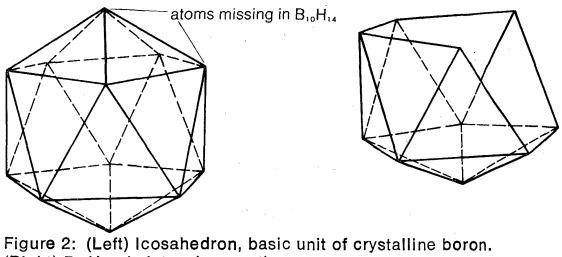


Figure 2: (Left) Icosahedron, basic unit of crystalline boron. (Right) $B_{10}H_{14}$ skeleton (see text).

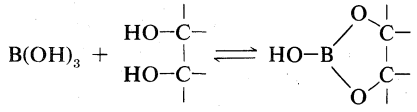
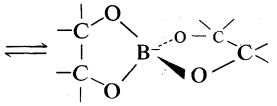
Boric acid, formula H_3BO_3 or $B(OH)_3$, is obtained as a white solid by the action of sulfuric acid on a concentrated solution of borax. It is a weak acid; the addition of a sugar (*e.g.*, mannitol) to its aqueous solution increases the acidity (the tendency to give up a proton, see ACID-BASE REACTIONS AND EQUILIBRIA) and allows it to be neutralized with an alkali. The sugar forms a complex with the acid, and a hydrated proton [symbolized as $H(aq)^+$] is released into solution at the same time. These reactions are written in equations as follows:



boric acid sugar complex



Heating solid boric acid to a red heat produces boric oxide as a hygroscopic (water-absorbing) glassy substance; the glass-forming properties of the oxide lead to its extensive use in the glass industry.

Boron reacts with all halogen elements to give monomeric, highly reactive trihalides, which readily form complexes with amines, phosphines, ethers, and halide ions. Examples of complex formation between boron trichloride and trimethylamine, as well as between boron trifluoride and fluoride ion, are shown in the following equations:

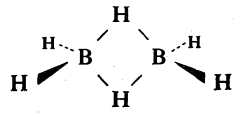
$$BCl_3 + N(CH_3)_3 \longrightarrow (CH_3)_3N \cdot BCl_3$$

$$BF_3 + F^- \longrightarrow BF_4^-$$

in which the heavy dot indicates that a bond is formed between the nitrogen and boron atoms. When boron trichloride is passed at low pressure through devices delivering an electric discharge, diboron tetrachloride, the formula written as $Cl_2B–BCl_2$, and tetraboron tetrachloride, formula B_4Cl_4, are formed. Diboron tetrachloride decomposes at room temperatures to give a series of monochlorides having the general formula $(BCl)_n$, in which n may be 8, 9, 10, or 11; the compounds with formulas B_8Cl_8 and B_9Cl_9 are known to contain closed cages of boron atoms.

Boranes and carboranes

Reduction of the boron trihalides with lithium aluminum hydride gives diborane, formula B_2H_6; the expected hydride, formula BH_3, does not exist under normal conditions, although it has been detected by mass spectroscopy when diborane is heated under low pressure. Diborane has a most unusual bridged structure represented in three dimensions as:



(Again, the bonds shown as solid lines lie in the plane of the paper, those shown as dotted lines extend behind the paper, and the shaded lines represent bonds that extend toward the viewer.) The B–H–B bridges are held together by unique bonds in which electrons normally associated with two atoms are instead associated with three (three-centre bonds). By a variety of techniques, including heating and the application of electrical discharges, diborane can be transformed into a number of higher boranes containing as many as ten boron atoms. (Hydrides containing more than ten boron atoms can be made starting from decaborane-14, formula $B_{10}H_{14}$.) The higher boranes derived from diborane fall into two distinct series one of which has the general formula B_nH_{n+4} and the other the formula B_nH_{n+6}. The unusual molecular structures of certain of these boranes are shown in Figure 3; the bonding in the boranes is complex and involves molecular orbitals extending over several atoms.

The boron skeleton of decaborane-14 (the number indicates the number of hydrogen atoms in the molecular formula $B_{10}H_{14}$) is closely related in shape to an icosahedron, the difference being that it lacks two atoms required to complete the cage (see Figure 2).

The two missing atoms can be added to the decaborane structure by treating the substance either with an amine adduct of BH_3, which completes the icosahedron with boron atoms, or with an acetylene, which completes the cage with carbon atoms. Equations for these reactions are:

$$B_{10}H_{14} + 2(C_2H_5)_3N \cdot BH_3 \longrightarrow [(C_2H_5)_3NH]_2^+(B_{12}H_{12})^{2-}$$

$$B_{10}H_{14} + C_2R_2 \longrightarrow B_{10}C_2H_{10}R_2 + 2H_2.$$

(a carborane)

These cage derivatives are exceptionally stable. Many other carboranes, normally containing two carbon atoms, and cage-borohydrides have been prepared. Isomers (*i.e.*, compounds with identical formulas but a different arrangement of the atoms in the molecules) of the carboranes can be prepared that differ in the relative positions of the two carbon atoms; the most stable isomers are those in which the carbon atoms are farthest apart and are bonded to the lowest possible number of neighbouring atoms. Of the $B_nH_n^{2-}$ ions, by far the most research has been carried out on the $B_{10}H_{10}^{2-}$ salts, which are prepared from decaborane-14 by reaction with amines. Two B_{10} cages can be linked together to give $B_{20}H_{18}$ ions, which are capable of existing in three isomeric forms, differing in the manner in which the cages are joined together.

The bonding in the borane- and carborane-cage compounds is complex; a large number of multicentre molecular orbitals derived from suitable combinations of boron

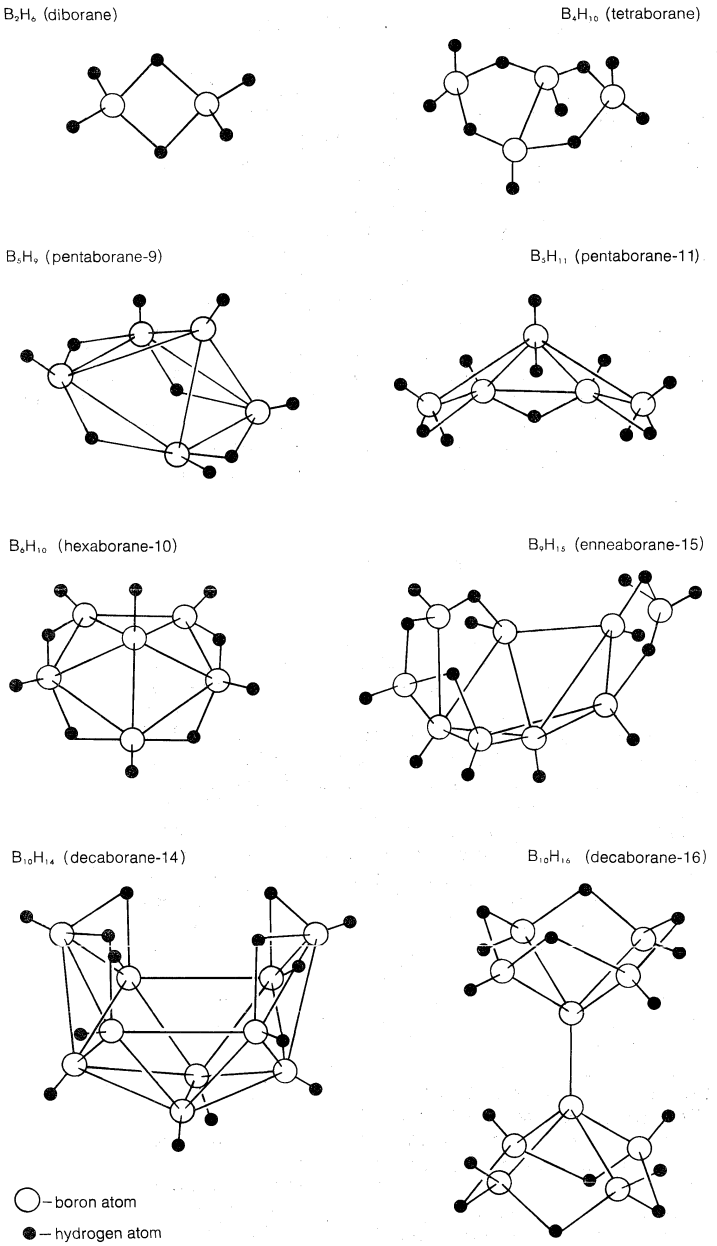


Figure 3: Some typical boranes and their structures.

and carbon atomic orbitals are thought to be involved. Certain of these molecular orbitals are bonding, and others are antibonding (*i.e.*, some help to hold the cage together, and others tend to pull it apart); it is not always easy to determine which orbitals belong to which class. In 1955, however, some years before boron cage compounds had been made, it was shown by calculation that a B_{12}-cage probably would contain 13 bonding molecular orbitals, each of which would have to house two electrons to give the cage stability. Since the molecule $B_{12}H_{12}$ has two electrons too few to fill the 13 bonding orbitals (of the 48 electrons available, 24 are used to form B–H bonds, leaving 24 to fill 12 of the 13 bonding molecular orbitals), it was predicted that $B_{12}H_{12}$ probably would be unstable, while the corresponding ion with two negative charges, $B_{12}H_{12}^{2-}$, might be stable because the two extra electrons could fill the final bonding orbital of the cage. Because of the relative positions of boron and carbon in the periodic table, a $B_{10}C_2$ cage structure would be expected to have the same electronic distribution as would a B_{12}^{2-} cage; thus all 13 bonding orbitals in a $B_{10}C_2$ icosahedral carborane should be filled, and the structure should be stable. Like considerations are thought to account for bonding in smaller-cage compounds.

A B–N bond has the same number of electrons as does a C–C bond and, as might be expected, several boron–nitrogen derivatives are physically similar to their carbon counterparts. This situation is best illustrated by boron nitride itself, which, like carbon, can exist in two allotropic (chemically identical, but physically different) forms—one of which has a layer structure resembling graphite, and the other (borazon) is extremely hard and has a diamond-like structure.

Nuclear properties of boron

Boron exists in nature as two isotopes, one of atomic mass 10 (18.8 percent) and one of atomic mass 11 (81.2 percent). Both nuclei (see NUCLEUS, ATOMIC) possess nuclear spin (rotation of the atomic nuclei); that of boron-10 has a value of 3 and that of boron-11, 3/2, the values being dictated by quantum factors. These isotopes are, therefore, of use in nuclear magnetic resonance spectroscopy; and spectrometers adapted to detecting the boron-11 nucleus are available commercially. The boron-10 and boron-11 nuclei also cause splitting in the resonances (that is, the appearance of new bands in the resonance spectra) of other nuclei (*e.g.*, those of hydrogen atoms bonded to boron). The boron-10 isotope is unique in possessing a very large capture cross section for thermal neutrons (*i.e.*, it readily absorbs neutrons of low energy). The capture of a neutron by a nucleus of this isotope results in the expulsion of an alpha particle (nucleus of a helium atom, symbolized α):

$$^{10}B + {}^{1}n \longrightarrow {}^{7}Li + {}^{4}\alpha.$$

Since the high-energy alpha particle does not travel far in normal matter, boron may be used in the fabrication of neutron shields (materials not penetrable by neutrons). In the Geiger counter, alpha particles trigger a response, whereas neutrons do not; hence if the gas chamber of a Geiger counter is filled with a gaseous boron derivative (*e.g.*, boron trifluoride), the counter will record each alpha particle produced when a neutron that passes into the chamber is captured by a boron-10 nucleus. In this way, the Geiger counter is converted into a device for detecting neutrons, which normally do not affect it. The affinity of boron-10 for neutrons also forms the basis of a technique for treating patients suffering from brain tumours. For a short time after certain boron compounds are injected into a patient with a brain tumour, the compounds collect preferentially in the tumour; irradiation of the tumour area with thermal neutrons, which cause relatively little general injury to tissue, results in the release of a tissue-damaging alpha particle in the tumour each time a boron-10 nucleus captures a neutron. In this way destruction can be limited preferentially to the tumour, leaving the normal brain tissue less affected.

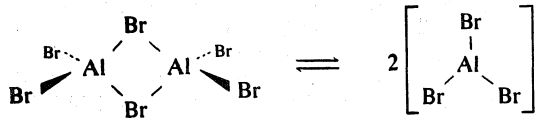
Analytical chemistry of boron

The presence of boron compounds can be detected qualitatively by the green coloration they impart to the flame of an ordinary laboratory, or bunsen, burner. Quantitatively, boron is most easily analyzed by converting the material to be analyzed into boric acid by treatment with acid; the excess mineral acid is then neutralized and the much weaker boric acid is titrated (neutralized on a volume–volume basis) in the presence of a sugar, such as mannitol, to make the acid detectable.

Aluminum. In aluminum, atomic number 13, the configuration of the three outer electrons is such that in a few compounds (*e.g.*, crystalline aluminum fluoride [AlF_3] and aluminum chloride [$AlCl_3$]) the bare ion, Al^{3+}, formed by loss of these electrons, is known to occur. The energy required to form the Al^{3+} ion, however, is very high; and, in the majority of cases, it is energetically more favourable for the aluminum atom to form covalent compounds by way of sp^2 hybridization, as boron does. The Al^{3+} ion can be stabilized by hydration, and the octahedral ion $Al(H_2O)_6^{3+}$ occurs both in aqueous solution and in several salts. The alums, double salts of formula $M^IAl(SO_4)_2 \cdot 12H_2O$, also contain this ion; the univalent ion M can be sodium, potassium, rubidium, cesium, ammonium, or thallium, and the aluminum may be replaced by a variety of other M^{3+} ions; *e.g.*, gallium, indium, titanium, vanadium, chromium, manganese, iron, or cobalt. Although the alums were once thought to be completely isomorphous (*i.e.*, crystallographically iden-

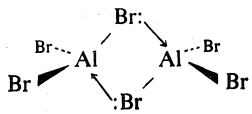
tical), X-ray diffraction techniques show that three slight variations in structure occur, depending on the size of the univalent ion, M^+. These variations occur in such a manner that the ions pack together in the most efficient way and maximize the lattice energy of the crystal. The name aluminum (British usage is aluminium) is derived from the Latin word *alumen* used to describe potassium alum, formula $KAl(SO_4)_2 \cdot 12H_2O$.

Unlike boron, aluminum forms only a few tricoordinate derivatives except at elevated temperatures. For example, the anhydrous tribromide occurs as the dimer, formula Al_2Br_6, both in the solid and liquid states; the vapour at 400° still contains the same molecules, but on stronger heating a breaking up or dissociation of the Al_2Br_6 to the trigonal planar molecule, formula $AlBr_3$, occurs, as shown in the equation:



(tetrahedral) (trigonal planar)

Tricoordinate aluminum compounds are strong Lewis acids—that is, they readily accept electrons from a wide variety of donor molecules such as amines, phosphines, and ethers. In the dimer of aluminum tribromide, one bromine atom in each molecule of $AlBr_3$ acts as an electron donor to the aluminum atom in the other $AlBr_3$ molecule:



Alumina

Crystalline aluminum oxide, also called alumina, occurs naturally as corundum, which is almost as hard as diamond; impure corundum is known as emery. Transparent corundum coloured by traces of the oxides of other metals forms the following gems: sapphires, which have iron, chromium, or titanium as the impurity; rubies, which contain chromium. These gems can now be made artificially. Alumina has a very high melting point (2,050° C) and is used as a refractory (heat-resistant) material for furnaces and crucibles. The addition of alkali hydroxide to an aluminum salt gives a white precipitate of aluminum hydroxide, $Al(OH)_3$, that is soluble in acids, giving aluminum salts, and in alkalies, giving aluminates (substances containing the AlO_2^- ion). Colloidal aluminum hydroxide gives rainproof qualities to fabrics when it is deposited in the pores of the material.

All the trihalides of aluminum are known in the anhydrous state; aluminum trifluoride and aluminum trichloride form ionic crystalline lattices, whereas the bromide and iodide form molecular crystals containing the dimers, formula Al_2X_6 (X being bromine or iodine). When fused (melted), aluminum chloride changes to the covalent dimer, formula Al_2Cl_6, and the coordination number of the aluminum atom alters from six in the crystal to four in the liquid dimer, resulting in a large increase (about 40 percent) in volume when the trichloride melts. The fluoride is only slightly soluble in water, while the other halides react readily with water—for example, the chloride is hydrolyzed in a reaction that is represented by the equation:

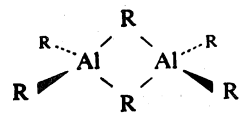
$$AlCl_3 + 3H_2O \rightleftharpoons Al(OH)_3 + 3HCl.$$

Crystalline hydrates of the halides can be obtained from acid solutions (the presence of acid reverses equilibria of the above type and prevents hydrolysis). Complex halide anions, such as AlF_6^{3-} (found naturally in cryolite) and AlX_4^- (X being chlorine, bromine, or iodine), also are known.

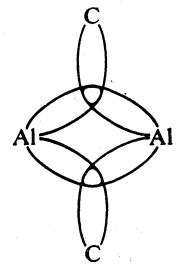
Aluminum chloride reacts with lithium hydride to form lithium aluminum hydride, formula $LiAlH_4$. It is a powerful reducing agent and is widely used in organic chemistry—for example, to reduce aldehydes and ketones to primary and secondary alcohols, respectively. Aluminum hydride is unstable thermally and is readily attacked by water. With Lewis bases it forms complexes, such as $(CH_3)_3NAlH_3$; with diborane it forms a volatile borohydride, formula $Al(BH_4)_3$.

Aluminum alkyls and aryls

Grignard reagents (organomagnesium compounds) react with aluminum chloride to give either aluminum alkyls or aluminum aryls with the general formula AlR_3, the R being either an alkyl or aryl radical. The lowest members of the alkyl series are spontaneously inflammable in air and explosively decomposed by water. Unlike their boron, gallium, indium, and thallium counterparts, many aluminum alkyls and aryls are dimeric, with bridged structures which can be represented in the following manner:



dimer of AlR_3



bonding in bridge

It is possible that bonding in the bridge involves three-centre molecular orbitals formed by overlap of two sp^3 orbitals from aluminum and one from carbon.

It is not clear why aluminum is the only boron group element to form dimeric organoderivatives in the solid, liquid, and gaseous phases. (Very weak associations of a different type are believed to occur in solid organoderivatives of gallium, indium, and thallium.) The aluminum alkyls are important commercially as polymerization and isomerization catalysts for olefins. Titanium tetrachloride and aluminum triethyl, for example, react to produce a catalyst that polymerizes ethylene to polyethylene at room temperature and pressure.

Aluminum can be detected in concentrations as low as one part per million using emission spectroscopy. Aluminum can be quantitatively analyzed as the oxide (formula Al_2O_3) or as a derivative of the organic nitrogen compound 8-hydroxyquinoline. The derivative has the molecular formula $Al(C_9H_6ON)_3$.

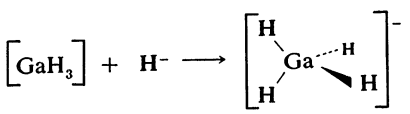
Gallium. Gallium, atomic number 31, is comparable to aluminum in its chemical properties. It does not dissolve in nitric acid because a protective film of gallium oxide is formed over the surface by the action of the acid, but the metal does dissolve in other acids to give gallium salts and it dissolves in alkalies, with evolution of hydrogen, to give gallates (compounds in which gallium appears in the anion). Of the halides, only gallium trifluoride is ionic; the others have molecular lattices containing dimeric molecules, with formula Ga_2X_6. Unlike aluminum, however, gallium forms several derivatives that contain gallium(I) oxidation state; for example, the oxide, formula Ga_2O. The sulfide (GaS), selenide (GaSe), and telluride (GaTe), made directly by combination of the elements at high temperature, are diamagnetic and contain gallium–gallium units with four positive charges, $(Ga–Ga)^{4+}$ in a layer lattice. The metal gallium is stable in dry air. On burning in air or oxygen it forms the white oxide, formula Ga_2O_3. This oxide can be reduced to the metal when heated strongly in hydrogen, and with gallium metal at 700° C it gives the lower oxide Ga_2O. The hydroxide, formula $Ga(OH)_3$, is amphoteric; *i.e.*, it reacts either as an acid or a base depending on the circumstance; it is precipitated from solutions of gallium salts by alkali hydroxides.

Gallium halides

All the anhydrous trihalides of gallium are known; of these only the fluoride is ionic. The other solid trihalides have molecular lattices containing dimer molecules, formula Ga_2X_6, which persist in the liquid and vapour states, although the proportion of dimer to monomer falls in the halogen series as one proceeds from chlorine to iodine. When gallium trichloride is heated with an equivalent

amount of gallium metal, a diamagnetic solid, formula $GaCl_2$, is formed; this, however, is not a gallium(II) derivative but is an ionic, mixed-valency compound whose formula is written $Ga^+ (Ga^{III}Cl_4)^-$. Aluminum can replace the gallium(III) atom, forming $Ga^+ (AlCl_4)^-$, and the other halogens (except fluorine) can replace chlorine. When the trihalides are reduced with an excess of gallium the monohalides, GaX, are produced.

Gallium hydride, formula GaH_3, is polymeric, like aluminum hydride, but the gallium compound is much less stable thermally. Gallium hydride forms two types of adduct with suitable donor molecules: $GaH_3 \cdot D$ and $GaH_3 \cdot 2D$ (in which D stands for an amine or other donor molecule). When the donor is a hydride, a tetrahedral complex ion is formed according to the following equation:



tetrahedral complex ion

Treatment of gallium trichloride with Grignard reagents gives the corresponding alkyls and aryls; unlike their aluminum counterparts, these substances are monomeric under all conditions.

Indium. Indium, atomic number 49, is an amphoteric element; it dissolves in acids to give indium salts and it also dissolves in concentrated alkalies to give indates. All anhydrous indium(III) derivatives, except indium trifluoride, formula InF_3, are covalent. There is a marked tendency for two of the outer electrons of the indium atom (the outer $5s^2$ electrons) not to be used in bonding; this circumstance results in univalent indium compounds.

Indium burns to the yellow oxide, formula In_2O_3, when heated in air or oxygen; a better method of preparation for the oxide is to heat the hydroxide, nitrate, or sulfate. This oxide is easily reduced to the metal, and on strong heating it loses oxygen to give the monoxide In^I_2O. Indium hydroxide dissolves in both acids and alkalies.

Indium halides

Of the anhydrous trihalides, all are known, and only the fluoride (InF_3) is ionic. Although dimers (double molecules) of the chloride, bromide, and iodide exist in the solid state, their vapours are largely dissociated to the monomers, represented by the general formula in which X stands for any halogen: InX_3. Heating indium trichloride with the metal, or treating the metal with an equivalent amount of mercuric chloride, results in the formation of the mixed-valency salt, whose formula is written $In^+(In^{III}Cl_4)^-$. By reducing the indium trihalides, except the fluoride, with an excess of indium metal, solid monohalides can be obtained.

Thallium. Thallium, atomic number 81, is typical of the Group IIIa elements in having an s^2p^1 outer electron configuration. Promoting an electron from an s to a p orbital allows the element to be three or four covalent. With thallium, however, the energy required for $s \rightarrow p$ promotion is high relative to the Tl–X covalent bond energy which is regained on formation of TlX_3; hence, a trivalent derivative is not a very energetically favoured reaction product. Thallium normally forms the more stable thallium(I), or thallous, salts containing the ion Tl^+ (in which the $6s^2$ electrons remain unused); it is the only element to form a stable univalent cation with the outer electron configuration $(n\text{-}1)d^{10}ns^2$, which is, unusually enough, not an inert gas configuration. In its oxidation state three, indicated as thallium(III), or commonly called thallic, thallium resembles aluminum, although the ion Tl^{3+} appears to be too large to form alums. In the monovalent state, thallium(I) displays properties similar to those of both the heavier alkali metals and silver. The very close similarity in size of the thallium(I) ion, Tl^+, and the rubidium ion, Rb^+, makes many thallium(I) salts, such as the chromate, sulfate, nitrate, and halides, isomorphous (*i.e.*, have an identical crystal structure) to the corresponding rubidium salts; also the ion Tl^+ is able to replace the ion Rb^+ in the alums. Thus, thallium does form an alum; but in doing so it replaces the M^I ion, rather than the expected metal atom M^{III}, in the formula $M^IM^{III}(SO_4)_2 \cdot 12H_2O$.

Monovalent thallium

Thallic oxide, formula Tl_2O_3, which is formed when thallium is burned in oxygen, is brown in colour; on strong heating, this substance loses oxygen to form thallous oxide, formula Tl_2O.

Thallous chloride, formula TlCl, prepared by the action of dilute hydrochloric acid on thallium metal, is like silver chloride in that it is light-sensitive and becomes violet on exposure to sunlight. Unlike silver chloride, however, thallous chloride is only slightly soluble in aqueous ammonia. Chlorine oxidizes a suspension of thallous chloride in water to thallic chloride and, from the solution, colourless crystals of the hydrate, formula $TlCl_3 \cdot 4H_2O$, can be obtained. These crystals may be dehydrated, but above about 60° C chlorine is readily lost. Thallic bromide also can be made, but it is even more unstable than the chloride. The compound made by the action of excess iodine on thallium is thallous triiodide, formula $Tl^+I_3^-$, and not thallic iodide, which is unknown. In the presence of iodide ions, however, iodine will oxidize thallium metal to the thallium(III) state, giving the complex anion $(Tl^{III}I_4)^-$. Mixed-valency halides of thallium are known, for example $Tl^+(Tl^{III}Cl_4)^-$ and $Tl_3^+(Tl^{III}Cl_6)^{3-}$. Thallic salts (*e.g.*, the chloride, sulfate, and nitrate) may be made by dissolving thallic oxide in the respective acids, whereas thallous salts result when thallium metal dissolves in dilute acids.

Thallous hydroxide is a strong base, prepared by adding barium hydroxide solution to thallium(I) sulfate, whereupon the insoluble barium sulfate is precipitated, leaving thallous hydroxide in solution. Its aqueous solutions, like those of potassium hydroxide, absorb carbon dioxide from the air, to give thallous carbonate, formula Tl_2CO_3; solutions of thallous carbonate are partially hydrolyzed.

Thallium imparts a brilliant green coloration to a bunsen flame. Thallous chromate, formula Tl_2CrO_4, is best used in the quantitative analysis of thallium, after any thallic ion present in the sample has been reduced to the thallous state.

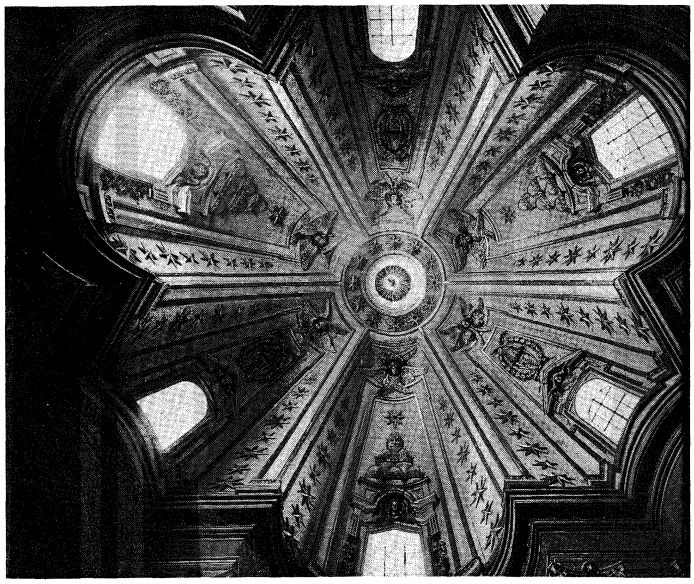
Borromini, Francesco

A difficult person, solitary, compulsive, at times beset by depression, Francesco Borromini offered 17th-century Europe a revolutionary style of architecture. Contemporary Baroque design adhered to the anthropometric architectural theories established during the Renaissance. These held that the human body, created in the image of God, contained the harmonic, divine proportions of the universe; that these proportions could be discovered by arithmetical measure; and that to properly relate a building to this universe, it also must be planned according to arrangements of arithmetical units. Borromini challenged these assumptions by basing his architecture on geometric configurations and subdivisions. In these visually striking plans, he developed the use of space and light as major elements of design. Moreover, his workman's knowledge of building techniques allowed him to introduce structural innovations that other architects would not have dared. Though the catalyst for a century of far-reaching developments, he ended his life in frustration and despair, one of the few known suicides in the history of art prior to the 19th century.

Youth and education. Born to Giovanni Domenico Castelli and Anastasia Garogo on September 25, 1599, in Bissone, on Lake Lugano (Lombardy) in northern



Interior of the dome of the church of S. Ivo della Sapienza, Rome, by Francesco Borromini, 1642–60.
GEKS

Italy, he was christened Francesco Castelli (a name he changed 28 years later). While still a boy, he was introduced to the craft specialities of architecture by his father, who sent him to Milan (1608 or 1614) to learn stonecutting. After several years training in the skills and technology of both architecture and sculpture, he collected a debt owed to his father and, without informing his parents, fled to Rome in 1620. There he became a draftsman and stonemason in the office of his kinsman, Carlo Maderno, who had established himself as the major practicing architect in Italy.

Training under Maderno

Celibate and irascible, Borromini dedicated himself to the discipline of architecture. Maderno quickly recognized Borromini's potential. The aging master and his young pupil worked together closely on various problems at St. Peter's, whose fundamental plan was revised by Maderno. For the Palazzo Barberini, Maderno determined a basic concept, then entrusted Borromini with the realization of specifics. A convergence of both talents produced the facade design of S. Andrea della Valle, and Borromini was permitted to undertake the lantern of the church's dome himself. Borromini's personality is apparent in these projects, though Maderno's style dominates them. This was not always the case. A facade to be attached to the late-16th-century oval church of S. Anna dei Palafrenieri was Borromini's personal project; attempting to integrate a five-bay front and two towers with the existing oval dome, it prefigured his later S. Agnese in Agone (in Piazza Navona) in its placement of plastic volumes in space. Equally significant was his transformation of Maderno's plan for S. Ignazio; through his use of pairs of free-standing columns, he suggested an articulation of space, a major characteristic of his style. Space in his structures is not merely a void but rather something corporeal, an element in itself, molded by the surrounding shell of the building. Later he would develop this concept by replacing the enclosing wall with an extensively penetrated framework, as in the Re Magi chapel.

Collaboration with Bernini

Maderno died in January 1629, three months after construction had begun at the Palazzo Barberini. The famous Gian Lorenzo Bernini was appointed architect in charge, though his architectural abilities were underdeveloped. Borromini continued in a key position, working out the specifics of Maderno's plan and collaborating successfully with Bernini. The patron, however, began to draw heavily on the advice of a third designer, Pietro da Cortona, and eventually abandoned Maderno's project for the east facade of the palace. Unable to work with Cortona and despairing of these changes, Borromini left the project in 1631. With Bernini he now dedicated himself entirely to the task of designing the Baldacchino in St. Peter's, which was conceived as a monumental canopy raised over the tomb of St. Peter, recalling the canopy that is traditionally supported over the pope when he is carried in state through the church. The enormous bronze Baldacchino was realized through the closest coordination between Borromini and Bernini; the huge, S-shaped volutes that crown four corkscrew columns represent their most important common creation. Bernini was in command of all enterprises at St. Peter's, but he paid Borromini a substantial sum from 1631 to 1633 for this work, indicating the great importance of his contribution.

An independent architect. The Baldacchino was completed in 1633. The year before, on the recommendation of Bernini and Cardinal Francesco Barberini, Borromini was awarded the office of university architect. With his new position as support, he began to seek his own patronage as an independent architect. His first independent commission represented an extraordinary challenge to tradition; it was the Roman church and monastery of S. Carlo alle Quattro Fontane, begun in 1638. No larger inside than the dimensions of a single pier at St. Peter's, the small church electrified Rome, and its reputation spread like wildfire through Europe. Borromini began by stacking together three distinct units that normally would have been employed only in separate buildings: a curious, undulating lower zone; a middle one suggesting the standard Greek-cross plan; and an oval dome, a relatively new and still little-used form. This audacious combination of precedent and novelty is integrated by complex, interweaving rhythms. Bold, illusionistic effects, achieved by calculated lighting, intensify the space. The dome appears to be floating above the interior of the church like a hallucinatory vision because its springing point and its light sources are concealed by the zone below.

Borromini established contacts with the eminent Spada family and was sponsored by Pope Innocent X for a decade, but his relations with patrons were frequently estranged and at times reached an impasse because of his intransigent, defiant attitude. Though bitterly resentful of what he felt to be a lack of just recognition, he was indifferent toward wealth and rejected the fashions of normal dress. Intractable and melancholic, his capacity for rage was legend. On one of his building sites he was infuriated to discover a man damaging some materials and had him so violently beaten that he died.

Given Borromini's gloomy disposition, it is not surprising that a conflict developed with the famous and popular Bernini. While they were working together, the relationship between the two artistic giants had been mutually profitable: Borromini's style was injected with a new vitality under Bernini's influence, and Bernini was strongly impressed by Borromini's novel formulations of architectural detail. Later, however, a bitter conflict arose between them. Perhaps Borromini's subordinate position at St. Peter's sufficiently rankled him to provoke his departure. He definitely felt this way later in life, claiming that Bernini had begged him not to abandon him on the work at St. Peter's and had promised to recognize his many labours with a worthy reward. Borromini felt that after he had carried out the work, Bernini drew the remunerations and rewards, never giving him anything except good words and grand promises.

Conflict with Bernini

Divergent characters, disparate backgrounds, and different attitudes toward life presumably provoked the antagonism. Bernini worked easily with the aristocratic and powerful; immensely successful as a sculptor and painter as well as an architect, he was outgoing, charming, and witty. Borromini, on the other hand, was a lonely, withdrawn man; he prided himself on his highly specialized training, and he resented his modest degree of recognition. Conflict between the two became public in 1645 over the decision to eliminate the towers Maderno had designed for the facade of St. Peter's. Maderno left them as substructures, and in 1636 Bernini submitted a proposal for completing them. After one was erected, however, technical deficiences halted further construction in 1641, and four years later a commission decided on its removal. Borromini emerged as Bernini's most effective and destructive critic, accusing him of incompetence.

Bernini seldom indulged in professional envy, however, but, during his Paris visit of 1665, he accused Borromini of abandoning the anthropometric basis of architecture. Because the body of Adam was modeled not only by God but also in his image and likeness, it was argued, the proportions of buildings should be derived from those of the body of man and woman. Borromini, however, based his buildings on geometric configurations in an essentially medieval manner that he probably learned in Lombardy, where medieval building procedures had been handed down from generation to generation. Borromini's approach consisted of establishing a geometric figure for a building or room, then articulating this figure by means of geometric subunits. He thus stood accused of denying the basis of good architecture. He never divorced himself completely from the anthropometric basis of design, however; he insisted, at least once, that his architecture contained human references. The concave facade of St. Philip Neri represented to him the welcoming gesture of outstretched arms: the central unit stood for the chest, the two-part wings for arm and forearm.

Basis of Borromini's design

The bizarre quality of Borromini's designs was as unsettling as his departure from anthropomorphism. Even his supporters felt uneasy with his novel creations. Presumably his license departed too far from orthodox interpretations of antiquity, which were accepted at this time as the fundamental standards of form for architecture. This seems paradoxical because he was an avid student of the ancient world: his drawings of antique fragments demonstrate a critical contact with Roman architecture, and his evocations of classical thought on the project for the Villa Pamphili at San Pancrazio are recorded with philological exactness. Nevertheless, the notion was in the air that it was possible to use and then progress beyond the achievements of antiquity, and Borromini strongly identified with this attitude. He said that he certainly would never have given himself to architecture with the idea of being merely a "copyist," and he invoked the example of Michelangelo, who said that he who follows others never goes ahead. Borromini declared antiquity and nature as his points of departure (though including the work of Michelangelo as well), but he actually spurned the regular and orthodox compositional motifs of the ancient world. Instead he turned to novel, curious, and marvelous interpretations, such as could be found in Hadrian's Villa at Tivoli, and to Roman structural achievements, such as their brickwork and their use of bevelled corners for vault supports.

Just as Borromini's attitude toward antiquity was uncommon, so too were his historical roots in medieval architecture in an era that had rejected medieval culture as corrupt. Yet his tendency toward the annulment of the wall, his use of structural ribwork to strengthen vaults, his designs derived from geometric configurations, his use of decorative motifs, and perhaps even his awareness that light can be given major compositional importance, all represent ideas stimulated by the medieval experience. Closer to his own time, Borromini investigated certain formal qualities found in both Florentine architecture of the 15th century and Mannerist architecture of the 16th century, especially that of Michelangelo, whose architecture was of decisive importance, suggesting Borromini's still more radical experiments. The manner in which space seemed to expand and contract in a number of Michelangelo's designs indicated to Borromini the dynamic potential of this medium. Responding to the past with greater freedom than his contemporaries, Borromini employed those elements that suited his purposes.

His technical virtuosity

This broad selection of pedigree was complemented by his understanding of structures and materials. The artisan tradition of Lombardy stressed technical excellence, providing him with the knowledge to approach a full range of structural problems. It gave him a firm base for his technical virtuosity, which is demonstrated by a long list of achievements, including the careful balancing of his towers for the facade of St. Peter's, the supporting metal cage for a barrel vault in the Palazzo Pamphili in Piazza Navona, the precise brickwork of the Oratory of St. Philip Neri, and his inventive domes and vaults, such as those of S. Ivo della Sapienza or the Re Magi chapel. He used the building yard as an extension of his drafting table and as a place where he could experiment and improvise to generate a fruitful exchange between design and execution. At S. Carlo alle Quattro Fontane, for example, the three-dimensional curve of the arches opening to the chapel vaults, as well as other features, could not have been realized without Borromini's personal guidance of the stonecutters on the site.

Borromini's urban sensibilities were also highly developed, as one of his unexecuted schemes demonstrates. He wished to create a dynamic setting for the facade of S. Giovanni in Laterano by means of a piazza. The street passing through this space was to be seen with 24 uniform building fronts, establishing a large scale, tightly organized arrangement of spaces. Always alert in his commissions to responsible contextual readings, he displayed a deep sensitivity to the relationship of his buildings to the surrounding urban fabric. The bell-tower facade of St. Philip Neri, for example, is composed to conclude and monumentalize the street running up to it.

Later years and influence. Even late in his life, Borromini's innovations continued to be as energetic and radical as ever. For the Re Magi chapel in the Collegio di Propaganda Fide, on which he worked until his death, he designed six pairs of colossal pilasters to define a generally rectangular space with bevelled corners.

Despair and death

In the 1660s, Borromini's fortunes tragically declined. He was increasingly frustrated by the fame and success of his rival, Bernini. His only disciple, Francesco Righi, and his most sympathetic patron, Padre Virgilio Spada, both died early in the decade. His major commission of S. Agnese in Agone, in Piazza Navona, was taken from him; work on another of his projects, S. Andrea delle Fratte, came to a halt; and his facade of St. Philip Neri was disfigured by lateral extensions. Suffering severe melancholia, he travelled to Lombardy, but when he returned to Rome his melancholy returned with him, and he spent whole weeks without ever leaving his house. He burned all of his drawings in his possession. Taken ill, his condition was made worse by hypochondriac hallucinations; when he suffered fits, it was decided that he should be denied all activity so that he might sleep. On a hot summer's night, unable to rest and forbidden to work, he arose in a fury, found a sword, and fell upon it. Though to a Catholic, suicide is a sin, Borromini recovered a lucid mind after mortally wounding himself, repented, received the last sacraments of the church, and wrote his will before he died, on August 2, 1667. At his own request, he was buried anonymously in the grave of his teacher and friend, Maderno. It has been suggested that Borromini's suicide was the result of an increasing schizophrenia and that this pathological process is reflected in his architecture, but this contention is impossible to demonstrate. His career appears to have been successful until the disillusionments of the last years.

In denying the restrictive, enclosing qualities of wall in order to treat space and light as architectonic components, Borromini confronted his architectural inheritance with its most complete and compelling challenge. Scores of designers would capitalize upon this revolutionary legacy. Borromini's works from the first had created an uproar in Rome, and his influence proved highly suggestive for design in northern Italy and in central Europe over the course of the next century. Later, as Neoclassical attitudes gained force, he was increasingly despised. Largely forgotten during most of the 19th century, Borromini's architecture has again been recognized in the 20th century as the creation of genius.

MAJOR WORKS

All works are in Rome—S. Andrea della Valle (with Maderno, *c.* 1622); Palazzo Barberini (with Bernini, 1629–31); St. Peter's (with Bernini, Baldacchino, 1631–33; facade design to 1645); Oratory of St. Philip Neri (begun 1637); S. Carlo alle Quattro Fontane (1638–41); S. Ivo della Sapienza (1642–60); Palazzo Pamphili (vault, 1645–50); Collegio di Propaganda Fide (1646–67, including the Re Magi chapel [1662–64]); S. Giovanni in Laterano (reconstruction, 1647–50); S. Agnese in Agone (continuation, begun 1652; Piazza

Navona); S. Andrea delle Fratte (exterior, 1653–65); Biblioteca Alessandrina in S. Ivo della Sapienza (1659–61).

BIBLIOGRAPHY. *Opera del Borromini . . .* (1720) and *Opus architectonicum* (1725), Borromini's discussion and engravings of S. Ivo della Sapienza and the monastery of St. Philip Neri—both reprinted in the critical edition by PAOLO PORTOGHESI, *Opera and Opus architectonicum* (1964). The Graphische Sammlung Albertina in Vienna holds more than 450 Borromini drawings.

EBERHARD HEMPEL, *Francesco Borromini* (1924), the first complete monograph (in German), still basic to any study of Borromini and his work, though outdated in some respects; PAOLO PORTOGHESI, *Borromini* (1967; Eng. trans., 1968), not distinguished by its scholarship, yet the most exhaustive monograph to date, with a thorough bibliography; HEINRICH THELEN (ed.), Francesco *Borromini: Die Handzeichnungen*, pt. 1 (1967), Borromini's drawings to 1633.

(C.F.O.)

Bose, Subhas Chandra

Described as a "patriot of patriots" by Mahatma Gandhi, Subhas Chandra Bose fought for Indian independence with courage and devotion. But his role in the Indian struggle was different from that of Gandhi himself, for Bose's most spectacular gestures were military ones.

He was born on January 23, 1897, the son of a prominent lawyer in Cuttack, Orissa Province. As a boy Subhas Chandra sought an ideal to which he could devote his life, poring over the letters and speeches of Swami Vivekananda, a Hindu saint and religious leader of the late 19th century, while hardly 15. He later enjoyed a career at the University of Calcutta, proceeding thence to Cambridge. In 1920 he passed the Indian civil service examination, but soon after he resigned to fight for his people and hurried back to India.

Influence of Gandhi and Das

The noncooperation movement had been started by Mahatma Gandhi, who had made the Indian National Congress a powerful, though nonviolent, organization. Bose was advised by Gandhi to work under C.R. Das (Indian politician, founder, and leader of the Swaraj [Self-rule] Party) in Bengal. There he became a youth educator, journalist, and commandant of the Bengal Congress volunteers. His activities led to his imprisonment in December 1921. When the Swaraj Party was formed in 1923, Bose was a devoted adherent. In 1924 he was appointed chief executive officer of the corporation of Calcutta, with Das as mayor. Bose was soon after deported to Burma, suspected of connections with secret revolutionary movements. Released in 1927, he returned to find Bengal Congress affairs in disarray after the death of Das.

Gandhi now resumed his Congress activity, and Bose was elected president of the Bengal Congress. In 1928 he was general officer commanding the Congress volunteers in the Indian National Congress session at Calcutta. His imposing figure, leading a parade of disciplined youth in military formation, gave people visions of a national militia, which accorded ill with Gandhi's philosophy. In the Congress session Bose moved a resolution demanding India's independence. He did not get a majority this time, but in the 1929 session Gandhi himself sponsored the independence resolution. It received overwhelming support. When the civil disobedience movement was started in 1930, Bose was already in detention. Released and then re-arrested, he was finally allowed to proceed to Europe after a year's detention. In enforced exile, he wrote *The Indian Struggle*, 1920–34, made a firsthand study of Europe after the Treaty of Versailles, and pleaded India's cause with European leaders. He returned from Europe in 1936, was again taken into custody, and released after a year. In 1938 he was elected president of the Indian National Congress and formed a national planning committee, as well as a policy of industrialization. This did not harmonize with Gandhian economic thought, which clung to the spinning wheel as a symbol. Bose's vindication came in 1939, when he defeated a Gandhian rival for re-election. Nonetheless, the "rebel president" felt bound to resign because of the lack of Gandhi's support. He founded the Forward Bloc, hoping to rally radical elements, but was again incarcerated in July 1940. His refusal to remain in prison at this critical period of India's history was expressed in a determination to fast to death, which frightened the British government into releasing him. Though closely watched, he escaped from his residence in disguise and reached Germany, hoping to exploit the international situation in favour of India.

Military leadership

In Germany Bose raised a body of Indian volunteers to fight against the Western powers. After the Japanese attack on Pearl Harbor and the fall of Singapore to the Japanese, he thrilled the East by arriving at Penang Island off the west coast of Malaya after about three months' hazardous passage in a German submarine. He then flew to Tokyo, planning to strengthen the independence struggle in India by obtaining Japanese aid against the British. Indian soldiers of the British Indian Army in Japanese captivity were set free to join him, and Indians from Singapore and other places in Southeast Asia also volunteered. He formed a trained army of three active divisions, each consisting of 10,000 soldiers and 20,000 volunteers. In October 1943 he proclaimed the establishment of an independent Indian government, and his Indian National Army, enjoying equal status with the Japanese Army, advanced to Rangoon and thence overland into India, reaching Kohīma and the plains of Imphāl (near the Burmese border, about 200 miles north of the Bay of Bengal). In a stubborn battle the army, lacking Japanese aerial support, was defeated and forced to retreat but for some time succeeded in maintaining its identity as the liberation army of India. Bose was unbroken in defeat and reportedly died in a Japanese hospital on August 19, 1945, after his plane had crashed in Taiwan. By his actions Bose proved that Indians in the British Indian Army could also be inspired by patriotic fervour, and by his work he influenced the conference that led to Indian independence.

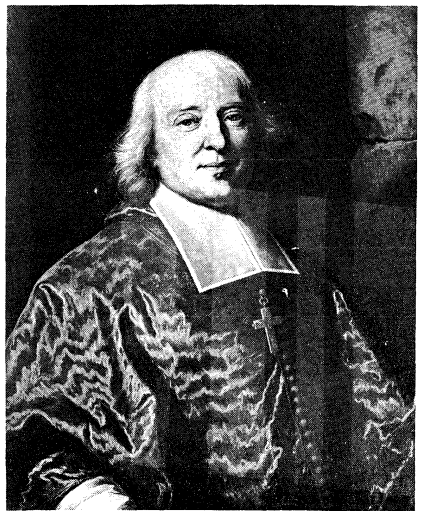
Bossuet, Jacques-Bénigne

Bossuet, a prominent French churchman of the late 17th century, is known as the most celebrated of all French orators; as one of the chief theoreticians supporting the absolute monarchy of Louis XIV; and as the leading opponent of Quietism, a form of mysticism espoused by his contemporary, Archbishop Fénelon.

Jacques-Bénigne Bossuet was born of a family of magistrates on September 25, 1627, in Dijon, Burgundy. There he spent his first 15 years and was educated at the Jesuit college. Intended early for an ecclesiastical career, he was tonsured at the age of ten. In 1642 he went to study in Paris, where he remained for ten years; at the Collège de Navarre, he received a sound theological education. He was deeply impressed by the interest that was then developing among many of the clergy in renewing the ideal of the priesthood; the simple eloquence of St. Vincent de Paul, the founder of hospitals and missionary orders, in particular exerted an influence on him. At the same time, he frequented scientific and intellectual circles and was an eyewitness of the Fronde, an uprising in Paris against the absolutism of the King. In 1652 he was ordained priest and received his doctorate of divinity. Refusing a high appointment offered him at the Collège de



Bossuet, oil painting by Hyacinthe Rigaud, 1698. In the Uffizi, Florence.
Alinari—Mansell

Navarre, he chose instead to settle in Metz, where his father had obtained a canonry for him.

Canon at Metz

Though Bossuet belonged to the Metz clergy until 1669, he divided his time between Metz and Paris from 1656 to 1659, and after 1660 he left Paris hardly at all. When in Metz, he zealously performed his duties as canon. His main concerns, however, were preaching and controversy with the Protestants, and it was at Metz that he began to master these skills. His first book, the *Réfutation du catéchisme du sieur Paul Ferry*, was the result of his discussions with Paul Ferry, the minister of the Protestant reformed church at Metz. Bossuet's reputation as a preacher spread to Paris, where his "Panégyrique de l'apôtre saint Paul" (1657) and his "Sermon sur l'eminente dignité des pauvres dans l'Église" (1659), a sermon on the sublime dignity of the poor in the church, were particularly admired.

Lenten sermons and funeral orations. Bossuet's career as a great popular preacher unfolded during the next ten years in Paris. He preached the Lenten sermons of 1660 and 1661 in two famous convents there—the Minims' and the Carmelites'—and in 1662 was called to preach them before King Louis XIV. The Lenten sermons, abundant with biblical citations and paraphrases, epitomize Baroque eloquence; yet, while they exhibit the majesty and the pathos of the Baroque ideal, the exaggeration and mannerism are conspicuously absent. The content of the sermons included not only religious matters, such as a sermon on death but also political matters, such as the discourse on the duties of kings, a subject that did not endear him to the monarch. Nevertheless, he was summoned in 1669 to deliver the funeral orations that were customary after the death of an important national figure. These first "Oraisons funèbres" include panegyrics on Henrietta Maria of France, queen of England (1669), and on her daughter Henrietta Anne of England, Louis XIV's sister-in-law (1670). Masterpieces of French classical prose, the orations display dignity, balance, and slow thematic development, with emotionally charged passages but organized according to logical argumentation. From the life of the departed subject, Bossuet selected qualities and episodes from which he could draw a moral. Appealing directly to the heart, he convinced his listeners by the passion of his religious feelings, which he expressed in clear, simple rhetoric.

Role in Jansenist quarrel and Protestant controversy

Apart from his work as a preacher, Bossuet, as a doctor of divinity, felt compelled to intervene in the controversy over Jansenism, a movement in the Catholic Church emphasizing a heightened sense of original sin and the role of God's grace in salvation. Bossuet tried to steer a middle course in the quarrel caused by the Jansenist reform movement within the Catholic Church, devoting himself to his controversy with the Protestants. At one point he negotiated with Paul Ferry for a union of the churches, but the project came to nothing. In 1668 he played a decisive part in the conversion to Catholicism of the marshal Henri de Turenne, a former Calvinist, and one of Louis XIV's leading generals. The following year, Bossuet was designated bishop of Condom, a diocese in southwest France, but had to resign the see in 1670 after his appointment as tutor to the Dauphin, the King's eldest son. This post brought about his election to the Académie Française.

Bishop of Condom and tutor to the Dauphin. Thoroughly absorbed in the duties of his new office, Bossuet found time to publish a work against Protestantism, *Exposition de la doctrine de l'église catholique sur les matières de controverse* (1671). He preached only occasionally thereafter. Primarily concerned with religious and moral instruction, he also taught Latin, history, philosophy, and politics. He wrote several treatises for his pupil: the *Discours sur l'histoire universelle* (1681), on the role of divine providence in history, and the *Traité de la connaissance de Dieu et de soi-même*, discussing knowledge of God, oneself, and the concept of divine providence. His major political work, the *Politique tirée des propres paroles de l'Écriture sainte*—which uses the Bible as evidence of divine authority for the power of kings—earned Bossuet his reputation as a great theoretician of absolutism. In the *Politique*, he developed the doctrine of divine right, the theory that any government legally formed expresses the will of God, that its authority is sacred, and that any rebellion against it is criminal. But he also emphasized the dreadful responsibility of the sovereign, who was to behave as God's image, govern his subjects as a good father, and yet remain unaffected by his power. At this time, Bossuet was constantly in the entourage of the King, and he acquired an expertise both in politics and in court life that he had previously lacked. Soon he was engaged to act as Louis XIV's counsellor as well as tutor to the Dauphin. The latter, who was not a very bright pupil, profited little from his tutor's teaching, but Bossuet greatly expanded his own fund of knowledge.

Bishop of Meaux. Bossuet became, in 1681, bishop of Meaux, a post he held until his death. In this period he delivered his second series of great funeral orations, including those of Princess Anne de Gonzague (1685), the chancellor Michel Le Tellier (1686), and the Great Condé (1687). Though he kept in close touch with the Dauphin and the King, he was not primarily a court prelate; he was, rather, a devoted bishop, living mostly among his diocesans, preaching, busying himself with charitable organizations, and directing his clergy. His excursions outside the diocese were in relation to the theological controversies of his time: Gallicanism, Protestantism, and Quietism.

The Gallican controversy

In the Gallican controversy, Louis XIV maintained that the French monarch could limit papal authority in collecting revenues of vacant sees and in certain other matters, while the Ultramontanists held that the pope was supreme. To avert the schism that seemed imminent between the King and the Pope, Bossuet sought to modify the Gallican attitude without totally giving in to the Ultramontane position. An extraordinary general assembly of the French clergy was held to consider this question in 1681–82. Bossuet delivered the inaugural sermon to this body and also drew up its final statement, the *Déclaration des quatre articles* (Declaration of Four Articles), which was delivered, along with his famous inaugural sermon on the unity of the church, to the assembly of the French clergy in 1682. The articles asserted the king's independence from Rome in secular matters and proclaimed that, in matters of faith, the pope's judgment is not to be regarded as infallible without the assent of the total church. They were accepted by all parties of the assembly, and his role in this controversy remained perhaps the most significant of Bossuet's life.

Concurrently, he was engaged in the controversy with the Protestants. The campaign to limit their religious freedom culminated in 1685 in the revocation of the

Edict of Nantes by Louis XIV. The revocation, in effect, forbade French Protestants to practice their religion. Bossuet, who bore no responsibility for this decision, supported the royal policy, though he opposed persecution and endeavoured to convert the Protestants by intellectual argument. In 1688 he published a history of variations in the Protestant churches, *Histoire des variations des églises protestantes*, which was followed by information and advice to Protestants, *Avertissements aux protestants* (1689–91). He maintained an ecumenical correspondence with the great German philosopher Leibniz.

Though Bossuet had displayed moderation in the Gallican quarrel and in the controversy with the Protestants, he showed himself less tolerant in other cases. He violently attacked the theatre as immoral in *Maximes et réflexions sur la comédie* (1694). He had the biblical critic Richard Simon's books, which were modernizing exegesis, condemned, and assailed him in *Défense de la tradition et des saints pères*, a defense of the Church Fathers and of the Catholic tradition.

Quarrel with Quietism

Above all, he led an attack on the form of religious mysticism known as Quietism, which was being practiced by the archbishop of Cambrai, François Fénelon. Although not inaccessible to forms of spirituality other than his own, he was by nature very intellectual and had been nourished on theology. Thus he had been rendered unable to understand a form of mysticism that consisted of passive devotional contemplation and total abandonment to the Divine Presence of God. He wrote such harsh and unfair works against the "new mystics" as his statement on Quietism, *Instruction sur les états d'oraison* (1697) and the *Relation sur le quiétisme* (1698). After a duel of pamphlets and some unpleasant intrigue, he obtained Fénelon's condemnation in Rome in 1699. Bossuet died in Paris on April 12, 1704.

Reputation. In the centuries since his death, Bossuet's reputation has been the subject of much controversy. The only point of agreement is the excellence of his style and eloquence. From a political point of view, he was praised by nationalists and monarchists, but spurned by the liberal tradition, as espoused by Victor Hugo, for example. From a religious point of view, he was often quoted as a master of French Catholic thought, but he had, and has still, against him the Ultramontanists, Catholic progressives and modernists, and many of Fénelon's numerous admirers. His emphasis on immutability of doctrine and the perfection of the Church make him seem old-fashioned in the atmosphere of Catholicism after the second Vatican Council.

BIBLIOGRAPHY. No general or bibliographical work worth mentioning exists in English. The only important study in English is SISTER G. TERSTEGGE, *Providence As idée maîtresse in the Works of Bossuet: Theme and Stylistic Motif* (1948). In French, the most accessible book is J. CALVET, *Bossuet*, 2nd ed. reviewed by J. TRUCHET (1968), with a detailed bibliography. The latest scholarly works are: A.G. MARTIMORT, *Le Gallicanisme de Bossuet* (1953): J. TRUCHET, *La Prédication de Bossuet*, 2 vol. (1960); and T. GOYET, *L'Humanisme de Bossuet*, 2 vol. (1965).

Boston

Boston, the capital of the Commonwealth of Massachusetts, in the United States, lies on Massachusetts Bay, an arm of the Atlantic Ocean. The city proper has an unusually small area for a major city, only 47.8 square miles (123.8 square kilometres), more than one fourth of it water. Early in the 1970s it had over 640,000 inhabitants, ranking 15th among U.S. cities, while its metropolitan area had more than 2,750,000 persons living in 78 communities in five counties of eastern Massachusetts.

The city's symbolic role in America

The area, the people, and the institutions within its political boundaries can only begin, however, to define the essence of Boston. As a city and as a name, Boston is a symbol of much that has gone into the development of the American consciousness. Its presence reaches far beyond its immediate environs: as the spiritual capital of the New England states, as the nation's closest link to its European heritage, as the progenitor of the American Revolution and the nation, and as the earliest centre of American culture, its influence pervaded the country for nearly three centuries. Though Boston, like New England in general, has played a lessening role in national life during much of the 20th century, it remains the focal point of what may be the most diversified and dynamic combination of educational, cultural, and medical-scientific activities in the United States. (For information on related topics, see the articles MASSACHUSETTS; UNITED STATES, HISTORY OF THE.)

THE HISTORY OF BOSTON

Settlement and growth. Boston was settled in 1630 by Puritan Englishmen of the Massachusetts Bay Company, who, for religious reasons, put the Atlantic Ocean between themselves and the Church of England. Ostensibly founded for commercial reasons, the Massachusetts Bay Company, under its governor, John Winthrop (1588–1649), brought its charter—which it regarded as authorization to set up a self-governing settlement in the New England wilderness—along to the New World. The new town was named for Boston in Lincolnshire, the former home of many of the immigrants.

Through necessity rather than choice, New Englanders turned to the sea for a livelihood and, like Norwegians, became shipbuilders, merchants, seamen, and fishermen because there was little else to do. The Shawmut Peninsula, upon which Boston was settled, was an ideal setting for a seaport. It was described in 1634 by William Wood in his *New England Prospects* as "fittest for such as can Trade into England, for such commodities as the Country wants, being the chiefe place for shipping and Merchandize." With the triumph of the Puritan Party in England in 1648, men moved freely between New England and the homeland, and close ties of family and trade linked Boston and London. By the end of the 17th century, Boston's fleet of seagoing vessels was exceeded only by those of London and Bristol in the English-speaking world. Boston held its place as the largest town in British North America until the middle of the 18th century, when it fell behind the faster growing ports of Philadelphia and New York.

Political life and revolutionary activity. During its first 50 years, Boston was a homogeneous, self-governing Puritan community in which the leaders of the Massachusetts Bay Company ruled as they saw fit. The three Puritan churches, established on the congregational principle, accounted for almost all the organized religion in Boston. Religious dissidents were banished, and some Quakers who persisted in returning were hanged for their pains. Although the increasing prosperity of the colonial merchants made London quite aware of Massachusetts Bay, steps to assert royal authority there were taken only near the end of Charles II's reign, in the 1680s. The company's charter was declared null and void in 1684. In 1686, with the arrival of Sir Edmund Andros as the first royal governor of the Province of Massachusetts Bay, the authority of the crown was established in Boston itself. With this change, the Church of England first came to the town, and the Puritan isolation was over. Although the Congregational clergy, particularly the voluble father–son combination of Increase (1639–1723) and Cotton (1663–1728) Mather, still made themselves heard, the lines of authority had altered.

Protests against British rule

Boston never proved wholly docile. When word of the "Glorious Revolution" of 1688 reached them, the citizens on April 18, 1689, dumped Andros out of office and imprisoned him. The memory of the autonomous first half-century lingered. As London endeavoured to enforce navigation laws and gain revenue from the Boston trade at the expense of the colonies, the aggrieved inhabitants indulged in what they felt to be justified resistance against unlawful authority. After passage of the Stamp Act by Parliament in 1765, disaffection grew, and the governor's house was stormed and gutted, an act that destroyed many irreplaceable records of the colony's history. The Boston Massacre of 1770, in which British troops fired on a crowd of civilian hecklers and killed several persons, and the Boston Tea Party of 1773, in

which colonists disguised as Indians dumped three shiploads of tea into Boston Harbor, were key incidents in measuring popular sentiment prior to the Revolution.

With the confrontations and exchange of shots at Lexington and Concord on April 19, 1775, the die was cast. When Washington's army besieged the British in Boston during the following winter, normal life in the town was suspended. On March 17, 1776, impelled by Washington's artillery positioned on Dorchester Heights, British troops and officials left. They were accompanied by loyal supporters of the crown, including a number of the principal merchants. A constitution was framed in 1780, and John Hancock was elected the first governor of the Commonwealth of Massachusetts.

Adjustment to independence. New men risen from obscurity by way of political or military service or ventures at sea during the Revolution quickly filled the places left vacant by departed Loyalists. Independence gravely imperilled Boston's maritime trade, for, at the close of the Revolution, Boston merchants automatically became foreigners in the ports of the British Empire. Thus, survival depended on finding new channels of trade. The crisis was solved by sending ships to distant and hitherto unfamiliar ports. The development of the China trade and other new routes, such as those to India, raised Boston to greater prosperity than ever before.

Throughout the first half of the 19th century, maritime commerce produced substantial fortunes, which were supplemented by others achieved in mercantile and manufacturing pursuits without recourse to the sea. Bostonians from the 1810s established textile mills, first at Waltham in 1813 and then in new towns along the Merrimack River, where water power was plentiful. The advent of railroads in the 1830s brought these once-distant towns suddenly closer. The burgeoning of Boston's population was due not only to maritime commerce and manufacturing but also to the unanticipated arrivals of immigrants from Europe in such numbers that the city grew more than twentyfold during the 19th century. By 1822 the traditional form of government, in which a board of selectmen administered the decisions reached by vote by all citizens at an annual town meeting, had become unmanageable, and a city charter was obtained from the legislature.

The era of culture. The 19th century also saw Boston assume its focal position in the religious and educational life of the new nation. The rapid and large-scale infusion of immigrant groups and the loss of dominance by the Congregational descendants of the Puritan settlers were major factors in the change. When it was built in 1799, the Church of the Holy Cross was the only Catholic church in town. In 1808 its founder, Jean-Louis Lefebvre de Cheverus, a refugee from the French Revolution, was created the first bishop of Boston, and in 1875, when the see was raised to the dignity of an archdiocese, there were 28 Catholic parishes.

Religious diversity

The religious climate of Protestant Boston also changed dramatically. The Anglican King's Chapel, whose Loyalist rector had left with the British in 1776, became Unitarian in 1787, though not until the first quarter of the 19th century did Unitarian doctrine produce permanent cleavage and splinter organizations in many Congregational churches. The creation in 1825 of the American Unitarian Association, in which William Ellery Channing (1780–1842) took the leading part, transformed into a separate denomination what had previously been the liberal wing of Congregationalism. From "Channing Unitarianism" it was only a step to the philosophy of Transcendentalism, which affected a great part of the region's artistic output and thought for much of the century; to the abolitionist movement championed by the outspoken writer and editor William Lloyd Garrison (1805–79) and others; and to liberal high-mindedness in social causes, which preoccupied many 19th-century Bostonians at a time when others were simply making money with great Yankee diligence. In the second half of the century, the city was also the founding place of Christian Science by Mary Baker Eddy (1821–1910). It remains the site of the Mother Church and the headquarters of this faith, which grew into an international Christian denomination.

Educational and cultural institutions had a similarly rapid growth. Across the Charles River in New Towne, later Cambridge, a college had been founded in 1636 to provide the infant colony with religious scholars and ministers. Named for the Charlestown minister John Harvard (1607–1638), who bequeathed his library to the institution in 1638, it was the sole college in the area until the third quarter of the 19th century. Though Harvard retained the most prestigious position throughout the century, a host of other major institutions of higher learning were founded, and Boston became synonymous nationally with scholarship and cultural refinement. It became also the mecca for persons—from abroad or from the "less civilized" parts of the nation outside New England—who sought these qualities amid the bustling commercialism and rambunctious growth that characterized much of 19th-century America.

Financial growth. The Civil War, in which a majority of Bostonians strongly supported the Union, put an end to shipping as a major consideration in the life of Boston. Shipowners and merchants invested thenceforth in manufacturing, in railroads, and in the development of the rapidly expanding frontier. Banking and investment, with the interplay that they implied with various forms of manufacturing and of business, superseded maritime commerce as the principal occupation of Boston in the second half of the century. In the early 20th century, however, the business horizons contracted. Though large sums continued to be invested outside of New England, fewer distant companies were controlled from Boston. The city's financial capital was as strong, but the rising strength of New York and Chicago and of the developing states of the American West gradually reduced the proportion of capital that Boston could muster. Nevertheless, Boston's financial-management firms showed a skill in investment that caused them to be well regarded in other parts of the country. This led eventually to a major growth of those Boston companies that administered mutual investment funds. Thus, the "prudent man," whether in a private trustee's office or an investment company, has survived as a Boston asset, whereas the textile mills and railroads proved less permanent. The textile industry passed into crisis in the 1920s, and the industrial cities on the Merrimack River, created by Boston investment, entered on decades of hardship. In the following years some mills went out of business entirely, while others moved to the South in search of cheaper labour and raw materials.

Problems in the early 20th century

The first half of the 20th century in Boston was a divisive and unhappy period, for, in addition to corruption in local politics, it included two world wars separated by Prohibition and a depression. After World War I, the increase of automobiles led more and more Bostonians to move outside the city limits, with consequent detriment to older central residential districts. Many of the defense industries that sprang up after World War II, based on the imagination of scientists from Harvard, the Massachusetts Institute of Technology, and other centres, were located outside the city limits.

THE CONTEMPORARY CITY

The physical environment. Boston and its sheltered deepwater harbour are ringed by modest hills, from Arlington Heights on the north to the Blue Hills on the south.

The area of the colonial town. The hilly Shawmut Peninsula, upon which Boston was settled, originally was almost completely surrounded by water. It was connected with mainland Roxbury on the south by a narrow neck of land along the line of today's Washington Street. To the west of the neck were great reaches of mudflats and salt marshes, which were covered by tides at high water and known collectively as the Back Bay. Beyond this, the Charles River flowed down to the peninsula, further dividing it from the mainland on the north and east as it approached Boston Harbor. On the east the peninsula fronted on the harbour, and Town Cove, jutting in from

the harbour, divided Boston into the North End and the South End. The centre of the colonial town was at the present Old State House (1711–47), where the only road from the mainland intersected with the principal approach from the harbour.

Although this original centre and the colonial South End have long been given over to banks, offices, and retail and wholesale trade, a few 18th-century buildings survive: Faneuil Hall (1742–1805) and two houses nearby, the Old Corner Book Store (1711), the Old South Meeting House (1729), and King's Chapel (1750). The North End, whose residents are now mainly of Italian descent, is the only part of the early town that has been continuously lived in since the 1630 settlement. Colonial survivals such as the Paul Revere House (*c.* 1680) and Christ Church (1723)—the Old North Church from which lanterns revealed the route of the British march to Lexington in 1775—coexist with the teeming life of a seemingly Mediterranean community.

The considerable extent of shoreline, only a few minutes' walk from any part of the peninsula, provided ample space for wharves and shipyards. From the beginning of the settlement, the shoreline constantly encroached on the harbour as wharves were built and marshy coves were filled. Beyond the original settlement lay Boston Common, a 45-acre tract that has remained public open space since its purchase by the town in 1634. Above the Common rose the Trimountain, a three-peaked hill of which Beacon Hill is the only surviving, though greatly reduced, remnant. The other hills became landfill that added to the city's area in the 19th century.

Bulfinch's designs. In the last years of the 18th century, when space became scarce, a series of major changes began to alter radically the physical lineaments of the place. In this period of expansion, the architect Charles Bulfinch (1763–1844), who for more than a quarter of a century was also the head of the town government, skillfully transformed an 18th-century English town into a 19th-century American city. Although many of Bulfinch's finest works have been destroyed, the central portion of the present State House (1795–98), above the Common on Beacon Hill, is his work. The construction of the State House on this site led to the conversion of the upland pastures of Beacon Hill into a handsome new residential district that has survived with relatively little change. Between the State House and Charles Street are streets, including famous Louisburg Square, filled with many houses by Bulfinch and other leading 19th-century architects. Protected by historic district legislation, the area has been designated as a Registered National Historic Landmark.

Nineteenth-century architecture

As pressures of population in the 19th century caused a demand for more and more land, hills were cut down to fill in the coves. So much new land was created that the once water-ringed peninsula has become an indistinguishable part of the mainland. Fill on both sides of the narrow neck that connected the peninsula with the mainland created a new South End, a region that before the end of the century had lapsed into a slum. The waterfront was greatly extended, and the Back Bay was dammed (1818–21) to create tidal power for new mill sites. A causeway along the dam extended west from the Common to Sewell's Point, the present Kenmore Square in the Back Bay area, thus furnishing more direct communication with the mainland. The filling of Back Bay flats just west of Boston Common created land that in the 1830s was laid out as the Public Garden. This became a splendidly planted area with an artificial pond that is spanned by a miniature suspension bridge and traversed by swan-shaped excursion boats in the summer.

Fashioning of the Back Bay

The Back Bay mill basins never developed as their promoters had envisioned, partly because the introduction of railway lines through them in the 1830s hindered the flow of water. The area became a stinking nuisance, and the Massachusetts legislature in 1857 authorized its filling, thus creating a substantial amount of new land. The plan adopted provided for four new streets parallel to the Mill Dam (Beacon Street), to be intersected by cross streets. Commonwealth Avenue, which ran west from the Public Garden, was 200 feet wide with a park between roadways, creating the atmosphere of a Parisian boulevard. Since there were no hills left to cut down, gravel had to be brought in by train from pits some miles away in Needham. By the end of the 19th century the Back Bay was completely filled and built up with houses that were subject to uniform height limits and setbacks. The region today presents a picture of American architecture that is as consistent for the second half of that century as Beacon Hill is for the first. Although many Back Bay houses have been converted to apartments, offices, schools, or other adaptive uses, the region has retained a good deal of its original character. As on Beacon Hill, changes are subject to architectural control.

Continuous park system. When the Back Bay was nearing completion in the 1880s, the American landscape architect Frederick Law Olmsted (1822–1903) developed an imaginative and large-scale design for city parks. It linked the Common, Public Garden, and Commonwealth Avenue with Franklin Park in West Roxbury by way of an open park known as the Fenway, which followed the Muddy River off to Brookline and Jamaica Plain. Included in this coordinated system was the Arnold Arboretum, a botanical outpost of Harvard University in Jamaica Plain. This led around the turn of the 20th century to a considerable western movement of institutions such as the Boston Symphony Orchestra, the New England Conservatory of Music, the Museum of Fine Arts, and the Harvard Medical School and hospitals. The completion in 1910 of a dam that kept the harbour tides out of the Charles River created an agreeable and handsome body of fresh water north of the Back Bay. The Charles River Basin, inspired by the Alster Basin in Hamburg, Germany, remains one of the most handsome and distinctive features of Boston.

Suburbanization and annexations. The introduction, in the 1850s, of horsecar lines (later electrified) made it possible for many workers to move out of the confines of the city. Suddenly the adjacent towns were inundated. Roxbury, West Roxbury, Dorchester, Brighton, and Charlestown—once pleasant, independent communities—were absorbed into the city between 1855 and 1873. Everywhere, the line of demarcation between city and country was lost in a rapid and chaotic orgy of expansion and building.

Except for Hyde Park in 1912, no other towns have been brought into the city government of Boston in the 20th century. Although the city of Cambridge and the town of Brookline are independently governed, a casual visitor would hardly guess where Boston stops and they begin. The Charles River divides Boston from Cambridge, but both riverbanks appear to be part of one metropolis. Some regional cooperation is assured, however, through the Metropolitan District Commission, created in 1919 through the consolidation of the sewer and water districts and the park commission established earlier by the Massachusetts legislature.

Modern building. Until the middle of the 20th century, the low skyline of Boston was punctuated only by church steeples and by the tower of the Custom House, which as a federal building was not bound by the 125-foot height restriction that prevailed generally in the city. Modification of the building code, coincidental with a construction boom, brought about great changes in the 1960s, of which the first conspicuous example was the Prudential Center, with a 52-story tower on the site of train yards. The first major effort in urban renewal in Boston, initiated early in 1958, led to the wholesale demolition of the West End, the displacement of people, and the disruption of neighbourhoods to make way for the apartment towers of Charles River Park. Unfavourable reaction to such total and large-scale demolition of large areas without regard for the feelings of people led the mayor in 1960 to put an experienced lawyer at the head of the Boston Redevelopment Authority. During the next seven years the Authority emphasized renewal rather than wholesale demolition and rebuilding. It endeavoured to enhance the traditional character of the city by bringing the best contemporary architecture and imag-

Controls on urban renewal

inative civic design to new projects. The Government Center, containing a new city hall completed in 1968, in addition to federal, state, and private office buildings, thereby became a harmonious neighbour to Faneuil Hall and other adjacent historic buildings. The creation of the Government Center stimulated considerable private construction in the vicinity during the 1960s. The John Hancock Mutual Life Insurance Company began construction in 1969 of a tower that would slightly overtop the Prudential Tower, while the Christian Science Church is sponsoring the reconstruction of large blocks of property near the Mother Church. As seen from a distance, the profile of Boston is no longer low but is dominated by a series of towers from the waterfront to well inland.

The narrow and crowded streets of the central city are better suited for walking than driving, for Bostonians are incorrigible jay-walkers. The street markets around Faneuil Hall and in the North End are as essential a part of the city as ever, yet the recently created terraced square of the Government Center provides a handsome setting for the new City Hall that is a welcome great open space. The second-empire exterior of the old City Hall has been preserved by adapting its interior for revenue-producing use by offices, a bank, and a restaurant.

Demography. Between 1800 and 1900, Boston changed from a relatively simple and homogeneous seaport of some 24,000 inhabitants, mainly of English extraction, to a polyglot city of more than 560,000, of whom about one-half were Irish and one-fifth were from the Canadian Maritime Provinces. After counting smaller groups of immigrants from Russia, Italy, Germany, and other European countries, as well as American-born blacks, less than 11 percent of the city's population was of traditional New England origin. The burgeoning of Boston's population in the 19th century was due to seemingly endless waves of immigrants that added not less than 23.6 percent in each decade from 1810 to 1900, while on five occasions the increase was more than 40 percent. The greatest increases were 52.1 percent in the 1830s and 46.6 percent in the 1840s. Many of the new arrivals, who brought with them experience in trades and crafts, though disembarking at Boston, rapidly moved westward to the expanding frontier, where their skills were in demand. Those with only unskilled labour to offer remained in Boston, crowded into urban slums. As earlier arrivals prospered and moved elsewhere, often outside the city limits, their places were taken by more unskilled immigrants. By the middle of the century, Irish immigrants had taken over the North End, but in the last third of the century it became the centre of the first exclusively eastern European Jewish community in Boston. Today its residents are predominantly of Italian descent. Similar changes have occurred in many parts of the city.

Inundation by immigration

In the 20th century the greatly reduced immigration helped to slow population increase from 19.6 percent in 1910 to 4.4 in 1930. The 1940 census showed a decrease of 1.3 percent. Although in 1950 there was a 4 percent increase, the trend since then has been steadily downward. Through migration from the South, the black population of Boston, nearly 43,000 in 1950, reached 105,000 in 1970, the majority of them crowded into the decaying slums of the Roxbury section. After 1965 the outflow of whites diminished and the proportion of nonwhites appeared to have stabilized.

Economic life. Banking, insurance, investment management, and other financial and business-service activities are the chief elements in the economic life of the city. The Federal Reserve Bank of the New England district is located in Boston. The chief industries are food products, clothing, printing and publishing, and fabricated metals. The greater part of the research-and-development activity that burgeoned after World War II is based in the metropolitan area but outside the city limits. Although Boston continues as a centre of retail trade, much wholesale activity has moved outside the city. The great number of universities and hospitals make higher education and health a significant element in the economic life of Boston. Although only a quarter of the people in the metropolitan area live in Boston, the city produces almost half of the metropolitan area's goods. A large share of the 516,000 jobs estimated to exist in Boston in 1970 were filled by commuters from the suburban area.

Political and governmental institutions. Boston is governed by a mayor, who is elected for a four-year term, and by a city council of nine members. The government of the Commonwealth of Massachusetts is centred in the State House at the top of Beacon Hill and in other buildings, some of them constructed in the late 1960s adjacent to the Government Center. Other federal offices occupy an earlier federal building and the Custom House. Boston is the headquarters of the 1st Naval District, whose installations are divided between the Charlestown Navy Yard and South Boston.

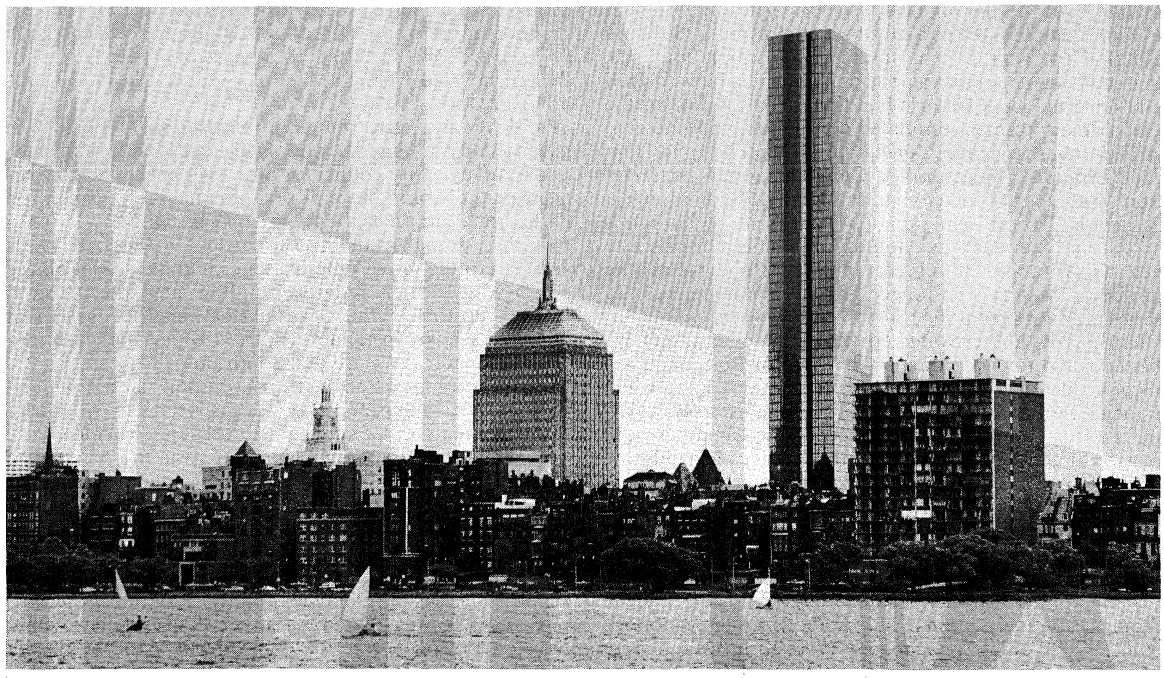
Transportation. Public transportation is maintained by the Massachusetts Bay Transportation Authority through a network of subway, elevated, and surface lines. The subway system, begun in 1897, was the first in the country, and, though it has been designated a Registered National Historic Landmark, it still works to a useful purpose. Railroad passenger service to the metropolitan area, once excellent, has badly deteriorated through competition from private automobiles and buses. Such vehicles increasingly choke the city, especially the narrow and winding downtown streets laid out in colonial times. The Logan International Airport in East Boston is a busy centre for European as well as domestic flights.

Educational and medical facilities. Universities, colleges, and schools of every kind fill more than 15 pages in the classified section of the Boston telephone directory. Boston University (founded 1869), Northeastern University (1898), Suffolk University (1906), and the Boston campus of the University of Massachusetts, as well as Simmons (1899), Emmanuel (1919), and Emerson (1880) colleges, are based within the city, as are the Harvard faculties of medicine, dentistry, public health, and business administration. The rest of Harvard University, Radcliffe College (1879), and the Massachusetts Institute of Technology (1861) are just across the Charles River in Cambridge. Boston College (1863), a Jesuit institution that is a university in everything except name, is in Chestnut Hill, only a step beyond the city limits. Tufts University (1852), although based in Medford, has its medical school in Boston. The Massachusetts General, the oldest of the hospitals, has been joined, among others, by the Beth Israel, Children's, Deaconess, and Peter Bent Brigham hospitals and the New England Medical Center. There are few aspects of higher education or health that are not dealt with somewhere within or close to the city.

Cultural life and recreation. Though Boston has a rich and varied cultural life and the city and its environs offer opportunities for all kinds of participatory or spectator recreation, there are notable gaps as in theatre and dance. In the 19th century, Boston was the home of several full-time professional theatres; but the present-day theatregoer must depend largely on university theatre or on Broadway shows stopping off for tryouts on their way into New York.

The arts. The Boston Symphony Orchestra, which was founded in 1881 and performs in Symphony Hall, is one of the foremost orchestras in the world and the chief musical attraction of Boston. The New England Conservatory of Music is nearby, as are other music schools. Chamber music abounds, as well as an interest in early music encouraged by the presence of several harpsichord and other instrument makers in the region. The summer Esplanade Concerts at the Hatch Memorial Shell by the Charles River Basin are one of the few outdoor events that have thrived consistently over a long period. Most of the concerts are given by the Boston Pops Orchestra. Overall, however, the cultural life of the city depends more upon colleges, museums, libraries, and small private groups than upon a public proliferation of the performing arts.

The Museum of Fine Arts, a major world gallery incorporated in 1870, preserves and exhibits Oriental,



Boston skyline along the Charles River with the old and new Hancock Buildings in the centre.

Museums and galleries

Egyptian, and classical collections of international distinction, as well as important examples of paintings, prints, textiles, and the decorative arts. The Isabella Stewart Gardner Museum in the Fenway is rich in Italian Renaissance painting. Since its arrangement has remained unchanged since the death in 1924 of its creator, Mrs. John Lowell Gardner, in whose home the collection is housed, it is an important monument as well in the history of taste. Across the river at Harvard, there is also a fine-arts museum and several museums devoted to science and natural history. The Museum of Science at Science Park, overlooking the Charles River Basin, and the Children's Museum in Jamaica Plain are aimed at the instruction of the young.

Libraries. Boston is equally rich in libraries. The Boston Public Library (1854) was the first major instance in the United States of a tax-supported free library. It has been housed since 1895 in a building designed by the famous architectural firm of McKim, Mead, and White and is a masterpiece of 19th-century American architecture. Its interior decor, including murals by the Frenchman Pierre Puvis de Chavannes (1824–98) and the American John Singer Sargent (1856–1925), is a striking feature, in addition to its fine library collection. Much of its function is carried out through branches spread throughout the city. The Boston Athenaeum, a proprietary library founded in 1807, the Massachusetts Historical Society, the New England Historic Genealogical Society, the State Library, the Francis A. Countway Library of Medicine, and the libraries of the colleges and universities provide remarkable resources, while, across the Charles, Harvard possesses one of the greatest libraries for scholarship in the world.

Sporting and sightseeing. College crews row on the Charles River, and small boats sail on the wide basin between the Back Bay and the Cambridge shore. Little recreational use has been made of the harbour, however, for in the 19th century Boston turned its back on the sea. The Boston Redevelopment Authority hopes to reverse this trend. An aquarium has recently been built on the waterfront, and there are plans for encouraging further recreational use of the harbour. The fine park system designed by Olmsted has suffered from the encroachments of automobiles, save in the Arnold Arboretum in Jamaica Plain, from which they are excluded.

One of the principal forms of recreation in Boston is just looking at the city. Many thousands of visitors come annually to Boston because of its numerous historic sites and the architectural character of the city. Boston has preserved some colonial buildings and an extraordinary number of fine 19th-century structures, yet in the city and its surroundings may be seen a great variety of the works of the principal American and European architects of the second half of the 20th century. As an example, a recent addition to the Boston Public Library, designed with singular respect to the mass and materials of the older building, is as remarkable an example of American architecture of 1972 as the original was in 1895.

Prospects. Though the great majority of the city's citizens may be only a few generations removed from Europe, and though the past few decades have seen great changes in the look of the city, there is a deliberate attempt to preserve the essential elements of Boston's traditional character and life. Public officials attempting to balance budgets often speak despairingly of the very high percentage of Boston's real estate that is tax-exempt because of educational use. Yet, in the second half of the 20th century, learning is the principal industry of Boston, and among the city's major resources in planning for the future are these educational institutions and their faculties, facilities, and student bodies. Since the middle of this century, many observers believe, the level of integrity and intelligence in city government has risen, with a corresponding improvement in civic life. Consequently, there is in most quarters greater hope of solving the problems of Boston than at any time in the memories of those now living.

HERLIHY (ed.), *Fifty Years of Boston* (1932), is a sequel for the years 1880–1930. WALTER MUIR WHITEHILL, *Boston: A Topographical History*, 2nd ed. (1968), describes the extraordinary physical changes in the city from the settlement to the present. HAROLD KIRKER, *The Architecture of Charles Bulfinch* (1969), WALTER H. KILHAM, *Boston after Bulfinch* (1946), and BAINBRIDGE BUNTING, *Houses of Boston's Back Bay: An Architectural History, 1840–1917* (1967), describe characteristic aspects of Boston's buildings. WALTER MUIR WHITEHILL, *Boston Statues* (1970), illustrates all the city's commemmorative statues. SAMUEL ELIOT MORISON, *Maritime History of Massachusetts, 1783–1860* (1921), BERNARD BAILYN, *The New England Merchants in the Seventeenth Century* (1955, reprinted 1964), and with LOTTE BAILYN, *Massachusetts Shipping 1697–1714* (1959), give the essentials about Boston

shipping. OSCAR HANDLIN, *Boston's Immigrants: A Study in Acculturation*, rev. ed. (1959), deals with the changes brought about by 19th-century immigration. WALTER MUIR WHITEHILL, *Boston Public Library: A Centennial History* (1956), and *Museum of Fine Arts, Boston: A Centennial History* (1970), describe two pioneering institutions. WALTER MUIR WHITEHILL, *Boston in the Age of John Fitzgerald Kennedy* (1966), briefly deals with the contemporary institutions that make modern Boston a centre of civilization. DAVID MCCORD, *About Boston* (1948, reprinted 1964) is a poetic evocation of the sights and sounds of the city.

(W.M.Wh.)

Boswell, James

Friend and biographer of Samuel Johnson, James Boswell was revealed by the publication of his journal in the 20th century to be also one of the world's greatest diarists. His *Life of Johnson*, which has made his companionship with Johnson one of the best known in history, is generally regarded as one of the supreme achievements in biography.

LIFE

He was born in Edinburgh on Oct. 29, 1740. His father, Alexander Boswell, advocate and laird of Auchinleck in Ayrshire from 1749, was in 1754 raised to the bench with the judicial title of Lord Auchinleck. The Boswells were an old and well-connected family, and James was subjected to the strong pressure of family ambition. Alexander Boswell was hardheaded and undemonstrative; his wife, retiring and mystical. James, a delicate child, was coddled physically but given severe Calvinistic instruction. He grew up timid, afraid of Hell, with painfully vivid images of predestination fixed in his mind, and at the age of 12 suffered some sort of acute nervous illness.

Education

Boswell hated the select day school to which he was sent at the age of 5, and from 8 to 13 he was taught at home by tutors. From 1753 to 1758 he went through the arts course at the University of Edinburgh. An encounter with metaphysics in the logic class (1756–57) revived the terrors of his childhood and induced a serious depression. On his recovery, he threw off all outward signs of delicacy and attained apparently robust health. He was rather under average height and tended to plumpness, with very swarthy skin, black eyes, and black hair. His expression was alert and masculine and he was conspicuously good humoured. But his nervous limitation persisted, manifesting itself in recurrent periods of depression all the more painful for not being prostrating. And he never outgrew the adolescent faculty of entertaining incompatibles simultaneously.

His conduct began to give his father concern. Returning to the university in 1758 to study law, he became enthralled by the theatre and fell in love with a Roman Catholic actress. Lord Auchinleck thought it prudent to send him to the University of Glasgow, where he attended the lectures of Adam Smith. In the spring of 1760 he ran away to London and made his submission to the Roman Catholic Church. He had hitherto had no sexual experience and entertained notions of becoming a monk. But a disreputable man of letters, Samuel Derrick, introduced him to various ladies of the town, while the Earl of Eglinton, an Ayrshire neighbour, schooled him in deism and brought him into the company of the young Duke of York and of Laurence Sterne. Boswell discovered London and himself simultaneously. He was, he found, passionately fond of metropolitan culture, gregarious, high-spirited, sensual, and attractive to women, and London offered just the combination of gross and refined pleasures that seemed to fulfill him. In order that he might stay permanently in London, he fixed his heart on a commission in the foot guards. When Lord Auchinleck finally went to fetch him (May 1760), he found him suffering from gonorrhea, an affliction that he was to endure many times in the course of his life.

From 1760 to 1763 Boswell was in open though unhappy rebellion. He studied law at home under strict supervision and sought release from boredom in gallantry; in a waggish society called the Soaping Club; and in scribbling, his crony and literary model being a young army officer, the Honourable Andrew Erskine. His publications (mostly in verse) give no indication of conspicuous talent. During these years he deliberately fashioned the personality that he was to show the world, completing the unfinished structure of his good upbringing with a facade of boisterousness, buffoonery, and impudence. His famous vanity consisted simply in avowing what other people think but do not say. He had remarkable gifts as a mimic and at this time exercised them freely.

Boswell came of age still stubborn in his desire to enter the guards. Lord Auchinleck then agreed that if he would pass his trials in civil law, he would supplement his annuity of £100 and allow him to go to London to seek a commission through influence. Boswell passed the examination in July 1762.

Beginning of his journal

It was in anticipation of this great era in his life that he began, in the autumn, the journal that was to be the central expression of his genius. His great zest for life was not fully savoured until life was all written down, and he had a rare faculty for imaginative verbal reconstruction of his past in terms of average human perception. His journal is much more dramatic than most because he wrote up each event as though he were still living through it, with no knowledge of anything that had happened later. People in his journal talk and are given their characteristic gestures. His gifts for the imaginative reporting of conversation have never been paralleled. If he made brief notes on a conversation soon after it occurred, he could at any distance of time recall "the heads and the very words of a great part" of that conversation and construct a miniature having the vividness and economy of fiction while keeping within the bounds of historical circumstance. His power of eliciting memorable conversation was no less remarkable. He had a generousness of mind that enabled him, as he once remarked, so to tune himself to the tone of any bearable man that that man would be as free with him as with another self.

Boswell's second London visit lasted from November 1762 to August 1763. Soon after his arrival, he was informed of the birth in Scotland of a son, Charles, for whom he arranged Anglican Baptism. The mother (Peggy Doig) was probably a servant. He laid siege to a handsome actress, one Mrs. Lewis ("Louisa"), and paid for victory with an infection. He and Erskine roused Lord Auchinleck's fury by publishing a book of their own bantering letters. He met Oliver Goldsmith, the novelist, playwright, and poet, as well as John Wilkes, the politician and polemicist. And on May 16, 1763, in the back parlour of the actor and bookseller Thomas Davies, he secured an unexpected introduction to Samuel Johnson, whose works he admired and whom he had long been trying to meet. Johnson was rough with him, but he kept his temper, went to call a week later, found himself

Meeting with Johnson

liked, and the great friendship was cemented. Johnson was 53 years old when they met, Boswell 22. There was condescension on both sides, Johnson deferring to Boswell's superior birth and Boswell to Johnson's superior wit and wisdom. Having become genuinely convinced that the guards scheme was not practicable, Boswell capitulated to his father and consented to become a lawyer. It was agreed that he should spend a winter studying civil law at Utrecht and should then make a modest foreign tour. Johnson, with touching kindness, made a four-day journey to see him off from Harwich.

Travels abroad

Boswell had been deeply affected by Johnson's piety and goodness and in Holland made a sincere effort to study hard and to keep out of mischief. On Christmas Day, in the ambassador's chapel at The Hague, he received communion for the first time in the Church of England. He engaged in a sparring courtship with the exquisite ironist Belle de Zuylen, who told him that she found him odd and lovable. His strict program proved stimulating for a time but palled when it had lost its novelty. He received word that his little boy had died. In the depression that ensued he had recurring nightmares of being hanged. He was discouraged to find that dissipation brought him more happiness than chastity and hard work and soon lapsed into his former promiscuity.

From Utrecht Boswell travelled to Berlin in the company of the old Jacobite Earl Marischal, friend and counsellor of Frederick the Great, but was never able to meet the King—his greatest and almost his only social defeat. Passing through Switzerland (December 1764), he secured interviews with both Rousseau and Voltaire. His approach to Rousseau was a characteristic piece of bravura. Lord Marischal had provided him with a letter, but he chose to present one of his own describing himself as a man of singular merit.

Boswell stayed nine months in Italy, devoting himself systematically to sightseeing. He established an intimacy with Wilkes (then outlawed) at Naples and travelled with Lord Mountstuart, eldest son of the Earl of Bute, the chief target of Wilkes's scurrilities. His cherished dream of high intrigue—he made blunt proposals to three countesses almost simultaneously on arriving in Turin—finally came true in Siena at the very end of his tour, when Girolama Piccolomini, wife of the chief official of the city, fell deeply and touchingly in love with him.

The most original act of his life followed when he made a six weeks' tour of the island of Corsica (autumn 1765) to interview the heroic Corsican chieftain Pasquale Paoli, then engaged in establishing his country's independence of Genoa. Paoli succumbed to his charm and became his lifelong friend. On his return to the mainland, Boswell sent off paragraphs to the newspapers, mingling facts with fantastic political speculation.

In Paris he was stunned to read in an English newspaper of his mother's death. He was disappointed not to see Rousseau, who had just left for England; but Thérèse Le Levasseur, Rousseau's mistress, accepted his offer to escort her there. During the journey he and Thérèse undoubtedly engaged in an amorous affair, but its details have been lost through family censorship of Boswell's notes.

Edinburgh law practice

Boswell was admitted to the Faculty of Advocates on July 26, 1766, and for 17 years practiced law at Edinburgh with complete regularity and a fair degree of assiduity. His cherished trips to London were by no means annual and until 1784 were always made during the vacations. He had plenty of business, though an uncomfortable amount of it consisted of causes that his father was to try. He was an able courtroom lawyer, especially in criminal cases, but in Scotland neither fortune nor fame could be won in the criminal court and an ambitious lawyer needed to give all and not part of his vacations to study. Also, Boswell hurt his reputation for professional soundness by emotional involvement in his clients' fortunes and by resorting to extralegal tactics in matters before the court.

In February 1768 Boswell published *An Account of Corsica, The Journal of a Tour to That Island; and Memoirs of Pascal Paoli* and stepped into fame. France had unmasked its intention of annexing the island, and people were greedy for information about Corsica and Paoli. Boswell's book (which was promptly translated into French, German, Italian, and Dutch) embarrassed both the French and British ministers, the French because they thought it might force British intervention, the British because they had already written Corsica off. The *Account* is a graceful ad hoc compilation; *The Journal of a Tour to That Island*, Boswell's first work exploiting his journal, is a minor masterpiece. Motives of propaganda caused him to present himself as completely naïve and to cut the tour to a mere frame for the memoirs of Paoli, but the result is still pleasing. Paoli, probably wisely, is presented in a manner reminiscent of that which Plutarch employed in his lives of great men.

Marriage

Between 1766 and 1769 Boswell amused himself with various well-hedged schemes of marriage, maintaining meantime a liaison with a young Mrs. Dodds. Their daughter Sally, like Charles, seems to have died in infancy. He ended by marrying (November 1769) the only woman he had ever wanted to marry, his first cousin, Margaret Montgomerie. Lord Auchinleck, who was deeply disappointed, for the match brought neither lands nor money, took a new wife himself on the very day of his son's wedding.

During the first few years of his marriage, Boswell was on the whole happy, hard-working, faithful to his wife, and confident of getting a seat in Parliament, a good post in the government, or at the very least a Scots judgeship. Paoli visited him in Scotland in 1771; in 1773 he was elected to The Club, the brilliant circle that Sir Joshua Reynolds had formed around Dr. Johnson; and later in the year Johnson made with him the famous tour of the Hebrides. He ultimately had five healthy and promising children. He was made an examinator of the Faculty of Advocates and one of the curators of the Advocates' Library; he served twice as master of the Canongate Kilwinning Lodge of Masons and declined nomination for the grand mastership of Scotland. But by 1776 he began to feel strong intimations of failure. A headlong entry into Ayrshire politics had ranged him in opposition to Henry Dundas, who was then emerging as a political despot in the management of the Scottish elections. His practice was not becoming more notable. He began to drink heavily to replenish his spirits, not, as formerly, to give them vent. He returned to his old traffic with women of the town when separated from his wife by distance, by her pregnancy, or by her frequent complaints. As early as 1778 it was obvious that she was critically ill with tuberculosis.

Between 1777 and 1783 he published in *The London Magazine* a series of 70 essays, significantly entitled *The Hypochondriack*, which deserve to be better known, though they do not engage his full powers. At the end of 1783, in the hope of attracting the attention of Pitt's new government, he published a pamphlet attacking the East India Bill that had been introduced by Charles James Fox, Pitt's great rival. Pitt sent a note of thanks but made no move to employ him. Boswell succeeded to Auchinleck in 1782 and managed his estate with attention and some shrewdness. But he thought he could be happy only in London and encouraged himself in the groundless notion that he could be more successful at the English than at the Scots bar.

Hebridean journal

Johnson died on Dec. 13, 1784. Boswell decided to take his time in writing the *Life* but to publish his journal of the Hebridean tour as a first installment. In the spring of 1785 he went to London to prepare the work for the press but became diverted by dinners and girls and by the writing of a frothy pamphlet against Henry Dundas' bill for diminishing the number of the lords of session. The Irish scholar and editor Edmond Malone, a fellow member of The Club but not previously a close friend, got sight of the work in progress and offered his daily assistance in preparing the remainder of the copy. Boswell's journals show little variation in literary excellence, but in

matter the Hebridean journal tops all the others. It comes from the soundest and happiest period of Boswell's life, the narrative of the tour is interesting in itself, and it provides us with 101 consecutive days with Johnson. The book was a best seller, but it provoked the scornful charge of personal fatuity that has dogged Boswell's name ever since. His intelligence was not really in question. Boswell had a good mind, and his imprudences and sins were of the sort that the world usually tolerates in artists. But he deliberately defied the basic literary rule that no author who wishes respect as a man may publish his own follies without suggesting compensatory strengths of character. Boswell analyzed and recorded his own vanity and weakness with the objectivity of a historian, and in his Johnsonian scenes he ruthlessly subordinated his own personality, reporting the blows that Johnson occasionally gave him without constantly reassuring the reader that he understood the implications of what he had written.

In 1786 Boswell was called to the English bar from the Inner Temple and moved his family to London. Thereafter he had almost no legal practice. His principal business was the writing of the *Life of Johnson*, which he worked at irregularly but with anxious attention. The revision of manuscript and proofs was labyrinthine. Malone again gave him tactful support and sat with him during much of the rewriting.

Though straitened in income, he gave his children expensive educations. He visited Edinburgh only once after his emigration and then almost surreptitiously. Mrs. Boswell pined for Auchinleck and insisted on being taken there when her health grew desperate. Boswell felt that he had to be in London in order to finish the *Life* and to be at the call of the Earl of Lonsdale, who had given him unexpected encouragement and caused him to be elected recorder of Carlisle. When she died (June 4, 1789), he was not at her side; and when he tried to detach himself from Lonsdale, he was treated with shocking brutality.

Publication of the *Life*

The Life of Samuel Johnson, LL.D. was published on May 16, 1791. Contemporary criticism set the pattern of acclaim for the work and derision for its author, which was to receive consummate expression from Macaulay in his well-known essays (1831 and 1856). Boswell took intense pleasure in his literary fame but felt himself to be a failure. His later years were prevailingly unhappy. His eccentricities of manner seemed merely self-indulgent in a man of 50 or over; people were afraid to talk freely in his presence, fearing that their talk would be reported; and his habit of getting drunk and noisy at other people's tables (he was never a solitary drinker) made him a difficult guest in any case. But his five children loved him deeply, and he never lost the solicitous affection of Malone and a few other friends who recognized his worth and his need. He saw the second edition of the *Life* through the press (July 1793) and was at work on the third when he died on May 19, 1795.

ASSESSMENT

For long it was believed that Boswell's private papers had been destroyed shortly after his death, but the bulk of them were recovered in the 1920s at Malahide Castle near Dublin and sold to an American collector, Ralph H. Isham, by Boswell's great-great-grandson, Lord Talbot de Malahide. These papers, as well as others found at Malahide Castle during the 1930s, were united with another portion discovered by Professor Claude Colleer Abbott in Aberdeenshire in the home of descendants of Boswell's executor and sold to Yale University, which began a systematic program of their publication.

The *Life of Johnson* will always be regarded as Boswell's greatest achievement, although, since the publication of his papers, its unique values can be seen to be derivative. It is the stretches of Johnson's conversation that make it superior to all other biographies, and those conversations were lifted bodily from the journal, sometimes with so little change that the journal leaves served as printer's copy. The extended commercial publication of the journal, by proving his ability to compete with 20th-century authors on their own terms, has confirmed and added to Boswell's stature as artist. It also for the first time gives the general reader a properly complex portrait.

MAJOR WORKS

An Account of Corsica, the Journal of a Tour to That Island; and Memoirs of Pascal Paoli (1768); *The Hypochondriack* (1777–83); *The Journal of a Tour to the Hebrides, with Samuel Johnson, LL.D.* (1785); *The Life of Samuel Johnson, LL.D.*, 2 vol.(1791).

BIBLIOGRAPHY. F.A. POTTLE in *The Literary Career of James Boswell* (1929, reprinted 1966) and in the article on Boswell in *The New Cambridge Bibliography of English Literature*, vol. 2 (1971), provides a detailed bio-bibliography and selected list of works about Boswell. The *Private Papers of James Boswell from Malahide Castle*, ed. by GEOFFREY SCOTT and F.A. POTTLE, 18 vol. (1928–34, index 1937), is a virtual autobiography. The commercially published volumes of the Yale editions, beginning with *Boswell's London Journal, 1762–63* (1950, eight subsequent volumes published), present the journal for the general reader. Biographical studies include F.A. POTTLE, *James Boswell: The Earlier Years, 1740–69* (1966), the first biography to draw on all the recovered papers; D.B. WYNDHAM LEWIS, *The Hooded Hawk* (1946; reprinted as *James Boswell: A Short Life*, 1952), warmly pro-Boswellian; C.B. TINKER, *Young Boswell* (1922), a charming portrait; and FRANK BRADY, *Boswell's Political Career* (1965), on a neglected aspect of Boswell's life. For the history of the Boswell papers, see C. COLLEER ABBOTT, *Catalogue of Papers . . . Found at Fettercairn House* (1936); and F.A. POTTLE, "The History of the Boswell Papers," in Heinemann's limited edition of Boswell's *London Journal* (1951). For scholarly reference, L.F. POWELL'S revision of G.B. HILL'S edition of the *Life of Johnson*, 6 vol. (1934–60, 1964); the *Letters of James Boswell*, 2 vol., ed. by C.B. TINKER (1924); and the research series of the Yale editions (2 vol. of correspondence now published) are recommended. Critical studies (chronologically arranged) are: T.B. MACAULAY, "Essay on Boswell's Life of Johnson," *Edinburgh Review*, vol. 54 (1831) and "Samuel Johnson," *Encyclopædia Britannica*, 8th ed. (1856), brilliant but wrongheaded; THOMAS CARLYLE, "Biography" and "Boswell's Life of Johnson," in *Critical and Miscellaneous Essays* (1839), a masterly assessment of Boswell's literary virtues; GEOFFREY SCOTT, introductions to vol. 1–5 of *Private Papers* and vol. 6, *The Making of the Life of Johnson* (1928–29), a modern view of Boswell by a great stylist; SIR HAROLD NICOLSON, "The Boswell Formula, 1791," in *The Development of English Biography* (1927), Boswell shows great literary skill, his character distasteful; F.A. POTTLE, "The Power of Memory in Boswell and Scott," in *Essays on the Eighteenth Century Presented to David Nichol Smith* (1945), Boswell's memory accurate; B.H. BRONSON, "Boswell's Boswell," in his *Johnson Agonistes and Other Essays* (1946), on Boswell's consciousness of himself; F.A. POTTLE, "The Life of Boswell," *Yale Review*, 35:445–460 (1946); and "Boswell Revalued," in CARROLL CAMDEN (ed.), *Literary Views* (1964), Boswell first of all a writer, his style that of the 20th century; W.K. WIMSATT, "Boswell: The Man and the Journal," in his *Hateful Contraries* (1965), Boswell not to be liked or disliked but valued; J.N. MORRIS, *Versions of the Self* (1966), Boswell modern in his anxiety; R.W. RADER, "Literary Form in Factual Narrative: The Example of Boswell's Johnson," in *Essays in Eighteenth-Century Biography*, ed. by P.B. DAGHLIAN (1968), the *Life* organized by a coherent idea of Johnson; and F.A. POTTLE, "The Life of Johnson: Art and Authenticity," in J.L. CLIFFORD (ed.), *Twentieth Century Interpretations of Boswell's Life of Johnson* (1970), the conversations in the *Life*, the quintessence of Boswell's view of Johnson.

(F.A.Po.)

Botanical Garden

A botanical garden, or botanic garden, as it is often called, was originally a collection of living plants designed chiefly to illustrate relationships within plant groups. Today, most botanical gardens are concerned primarily with exhibiting ornamental plants, insofar as possible in a scheme that emphasizes natural relationships. Thus, the two functions are blended: eye appeal and taxonomic order. Plants that were once of medicinal value and extremely important in early botanical gardens are now chiefly of historical interest and are not particularly represented in contemporary collections. A display garden that concentrates on woody plants (shrubs and trees) is often referred to as an arboretum. It may be a collection in its own right or a part of a botanical garden.

This article deals only with public and institutional bo-

tanical gardens and arboretums (see also GARDEN AND LANDSCAPE DESIGN; GARDENING; and HORTICULTURE).

General considerations and history. A major contemporary objective of botanical gardens is to maintain extensive collections of plants, labelled with common and scientific names and regions of origin. Plant collections in such gardens vary in number from a few hundred to several thousand different kinds, depending on the land area available and the financial and scholarly resources of the institution.

As world populations become more urbanized, botanical gardens are increasingly recognized as among the important cultural resources of civilized nations. Botanical gardens offer the city dweller part of the natural environment he no longer has access to; furthermore, they offer a mental escape from population pressure and suggest new interests and hobbies having to do with the natural world.

Early botanical gardens

What can be called the roots of the botanical garden as an institution are traceable to ancient China and many of the countries bordering the Mediterranean. These actually were centres for the raising of fruit trees, vegetables, and herbs used in making the crude medicines of the time. After the discovery of printing, manuscripts on plants, which had been in existence for centuries, became more widely circulated, and these stimulated further publication of descriptive works called herbals. The herbalists and their herbals, in turn, stimulated the founding of botanical gardens. By the end of the 16th century there were five such gardens in Europe, and by the mid-20th century several hundred. The first two were in Italy, at Padua and Pisa (1545). At first, such gardens were associated with the medical schools of universities. Professors of medicine were mainly the botanists of that time, and their "physic gardens" served for the training of students as well as for growing plants to make medicines. But they served in other ways as well. Carolus Clusius, a noted botanist of the 16th century, for example, brought together an extensive collection of flowering bulbs at the botanical garden in Leiden, the Netherlands, which proved to be the beginning of the Dutch bulb industry.

In the early 1800s Jean Gesner, a Swiss physician and botanist, noted that by the end of the 18th century there were 1,600 botanical gardens in Europe. During the 18th and 19th centuries, the science of botany took form, and many of the important botanists of the period were directors of the botanical gardens of their day. Since that time, the classical botanical garden as a teaching and medicinal garden declined, to be replaced by gardens devoted mainly to plant culture and the display of ornamental plants and plant groups of special interest.

Function and purpose. The larger collections of living plants constitute a formidable resource for professional scholars; but, more importantly, they provide a rich opportunity for the general public to learn more about plants and how to grow them. Some gardens offer popular-level short courses on plants and plant cultivation each year, both for adults and for children.

Botanic gardens constitute reservoirs of valuable heritable characteristics, potentially important in the breeding of new varieties of plants. Longwood Gardens, near Kennett Square, Pennsylvania, in collaboration with the U.S. Department of Agriculture, has in recent years sent out several expeditions to collect species that have promise as breeding stock or, in some instances, are already attractive ornamental plants. Historically, England's Royal Botanic Gardens at Kew are most famous for their collecting expeditions and the distribution of economic plants to parts of the world where they could be grown most successfully. Kew is responsible for the wide popularity and spread of such plants as the rubber tree (*Hevea brasiliensis*), pineapple, banana, tea, coffee, cacao, various timbers, and cinchona (yielding quinine) and other drug producers.

Still another function of botanical gardens is the training of gardeners. Canada has long had such a program at the Niagara Falls Parks Commission's School of Horticulture. Such training programs at Kew, Edinburgh, Dublin, and the Royal Horticultural Society's garden at Wisley have produced many able gardeners for supervisory positions in many countries.

Design. Botanical gardens and arboretums differ from parks in that they are generally laid out according to the scientific relationships of their plant collections, rather than exclusively for landscape effect or for playing fields or other essentially recreational endeavours. The traditional practice in laying out a botanical garden is, for example, to gather the trees and shrubs together in an arboretum section of the garden. Oftentimes, though, trees and shrubs are used to enhance landscape effects by interspersing them throughout the garden, in their respective taxonomic groups, with herbaceous collections.

Botanical gardens, or parts of them, are sometimes planned according to the geographic origin of plants. Not infrequently the layout is based on small, special gardens within the greater garden, such as rose, iris, rock, wildflower, and Japanese landscape gardens. As to area, it may be seen in the Table that botanical gardens range in size from a few acres to as many as 2,000.

Selected Botanical Gardens

location	title	number of species and varieties	approximate area (acres)
Australia			
Melbourne	Royal Botanical Gardens and National Arboretum	20,000	88
Belgium			
Meise	National Botanic Garden	15,000	18
Canada			
Montreal, Quebec	Montreal Botanical Garden	20,000	175
Ottawa, Ontario	Dominion Botanic Garden	10,000	100
Denmark			
Copenhagen	Botanic Garden of the Royal Veterinary and Agricultural College	15,000	20
France			
Lyon	Botanic Garden	10,000	15
Germany			
Berlin-Dahlem	Botanic Garden and Museum of the University	18,000	100
Ireland			
Dublin (Glasnevin)	National Botanic Garden	25,000	47
South Africa			
Capetown (Kirstenbosch)	National Botanical Gardens of South Africa	6,200	1,365
Sweden			
Uppsala	Botanical Garden of the University	10,000	46
Switzerland			
Geneva	Botanic Garden	15,000	28
United Kingdom			
Kew, Eng.	Royal Botanic Gardens	25,000	288
Wisley, Eng.	Royal Horticultural Society Garden	10,000	198
Edinburgh, Scot.	Royal Botanic Garden	15,000	60
United States			
Berkeley, Calif.	University of California Botanical Garden	15,000	20
Brooklyn, N.Y.	Brooklyn Botanic Garden and Arboretum	12,000	50
Bronx, N.Y.	New York Botanical Garden	15,000	240
Mentor, O.	Holden Arboretum	5,000	2,200
Kennett Square, Penn.	Longwood Gardens	12,500	1,000
U.S.S.R.			
Moscow	Botanical Garden	16,000	890

Taxonomic groupings

Although the layouts mentioned above often preclude the possibility of arranging plants strictly according to their taxonomic relationships, this is still possible for certain groups. The genus *Rosa*, for example, includes a great many species and hundreds of named man-made hybrids. In addition to the genus *Rosa*, there are many other genera in the rose family (Rosaceae), with their species and innumerable cultivars. The rose family would be a typical taxonomic grouping for a botanical garden, though the tree species would be grown separately from the rose bushes. The same general principle of taxonomic groupings holds for other plant families and genera.

Usually associated with botanical gardens are the service or display greenhouses in which to propagate plants

or to grow those that may not survive seasonal changes. In temperate climates, where the winters are cold, for example, tropical orchids must be greenhouse grown. The same is true of tropical ferns, bromeliads, economic plants of the tropics or near-tropics, many cacti and other succulents, African violets, and begonias. Hotbeds as well as greenhouses serve for starting seedling plants that are to be set outdoors as soon as the weather is warm enough.

A botanical garden that aspires to large plant collections must also have storage areas that provide temperature conditions favourable to certain species at particular seasons. Cold frames may serve this purpose for many kinds of plants and for the wintering over of younger plants that need a cold period but will not tolerate freezing temperatures. Houses built of lathing may also be important for the temporary storage of some species in semishade or even for the growing of certain plants that are intolerant of the hot summer sun.

Herbaria

Many gardens possess herbaria, or collections of a few to many thousands of dried plant specimens mounted on sheets of paper. The species thus mounted have been identified by experts and labelled by their proper scientific names, together with information on where they were collected, how they grew, and so on. They are filed in cases according to families and genera, always available for ready reference. Herbaria, like living plant collections, are the "dictionaries" of the plant kingdom, the reference specimens essential to the proper naming of unknown plants.

Many botanical gardens associated with universities possess extensive libraries, herbaria, and laboratory research facilities. Such gardens offer essential services for the professional plant taxonomist. Some large urban botanical gardens provide classroom and greenhouse workshop facilities for the novice gardener, and the trend for popular-level instruction is growing.

Most large botanical gardens publish technical journals and popular brochures. Books of general appeal and films are produced by some of the larger botanical gardens.

Maintenance. The prime consideration in maintaining plant collections is, of course, good plant-culture practices. Skilled lawn maintenance is particularly important for botanical gardens in cities; the discerning citizen judges a garden more by its general appearance than by the excellence of its plant collections. Tree and shrub collections require systematic pruning, and no important tree should go for more than two years without such attention. Older trees require special pruning attention and care of wounds so that decay does not set in. Spraying for control of pests and diseases is often necessary.

In the early years of botanical gardens, new kinds of plants could be secured only by sending out knowledgeable collectors on expeditions, often to distant places. They would seek out new species growing in the wild and bring back samples of the plants desired. But the nursery industry has now become so great that many smaller firms specialize in particular groups of plants; thus, numerous species and cultivars can be purchased directly from nursery firms, ready for planting. Exchanges of seeds as well as rare plants are often carried out between botanical gardens. Some gardens issue seed-exchange lists annually.

Equipment for the care of plant collections depends upon the size of the operation. Aside from a building adequate to take care of physical needs of the gardening staff and housing space for tools and equipment, attractive and efficient classroom space is essential for gardens with an educational program. A section of a greenhouse arranged for practical work by students (*i.e.*, a greenhouse classroom) is also desirable.

Staff needs

Staff needs depend upon the specific objectives of a botanical garden as well as upon the resources available, the climate, and the area to be cared for. At least one gardener should be a skilled propagator or nursery man. The head gardener, with advanced horticultural training and experience, supervises the entire operation. If the physical plant is of sufficient size, a combination of skilled craftsmen and a superintendent is required to look after all structures and oversee the cleaning, heating, and other routine services.

Professional staff needs also depend upon an institution's objectives as well as financial resources. A general botanist is essential. A taxonomist is basic for the herbarium, as is a librarian, if the book and journal collection is of any size. The taxonomist usually has supervision over the making and placing of plant labels. A plant pathologist, or specialist in plant diseases, is desirable if the plant collections are large. If a teaching program for adults and children is part of the educational pattern of the institution, at least a skeleton force of teachers or part-time instructors who come in and conduct classes is necessary. The total botanical garden program, from gardening through professional staff, is coordinated by a director, who, in turn, is responsible to a board of trustees if the garden is a private corporation. A garden that is part of a university is generally the primary responsibility of a professor of botany or horticulture and is operated as an adjunct of his particular department. Gardens that are government supported usually operate under a director and advisory group.

Some botanical gardens are independently established and financially provided for through endowments set up by wealthy persons. Gardens directly operated by government agencies are usually supported by tax monies. Private colleges and universities with botanical gardens are privately supported and often receive financial assistance by organized, dues-paying-membership groups or by endowment funds established in their behalf.

BIBLIOGRAPHY. H.R. FLETCHER, D.M. HENDERSON, and H.T. PRENTICE, *International Directory of Botanical Gardens*, 2nd ed. (1969), a list of the world's botanical gardens with vital statistics on each; E.S. HYAMS and W. MACQUITTY, *Great Botanical Gardens of the World* (1969); H. REISIGL (ed.), *The World of Flowers* (1965), a collection of articles by international botanists, with a section on botanical gardens, parks, and floral regions. Regional and national handbooks on botanical gardens are published frequently.

Botany

Botany is the study of plants. Plants were of paramount importance to early man; he depended upon them as sources of food, shelter, clothing, medicine, ornament, tools, and magic. Today it is known that, in addition to their practical and economic values, green plants are indispensable to all life on earth: through the process of photosynthesis, plants transform energy from the sun into the chemical energy of food, which makes all life possible. A second unique and important capacity of green plants is the formation and release of oxygen as a by-product of photosynthesis. The oxygen of the atmosphere, so absolutely essential to many forms of life, represents the accumulation of over 3,500,000,000 years of photosynthesis by green plants.

Although the many steps in the process of photosynthesis have become fully understood only in recent years, even in prehistoric times man somehow recognized intuitively that some important relation existed between the sun and plants. Such recognition is suggested by the fact that, in primitive tribes and early civilizations, worship of the sun was often combined with the worship of plants.

Earliest man, like the other anthropoid mammals (*e.g.*, apes, monkeys), depended totally upon the natural resources of his environment, which, until he developed methods for hunting, consisted almost completely of plants. The behaviour of pre-Stone Age man can be inferred by studying the botany of aboriginal peoples in various parts of the world. Isolated tribal groups in South America, Africa, and New Guinea, for example, have extensive knowledge about plants and distinguish hundreds of kinds according to their utility, as edible, poisonous, or otherwise important in their culture. They have developed surprisingly sophisticated systems of nomenclature and classification, which approximate the binomial system (*i.e.*, generic and specific names) found in

modern biology. The urge to recognize different kinds of plants and to give them names thus seems to be as old as the human race.

In time plants were not only collected by primitive man but also grown by him. This domestication resulted not only in the development of agriculture but also in a greater stability of human populations that had previously been nomadic. From the settling down of agricultural peoples in places where they could depend upon adequate food supplies came the first villages and the earliest civilizations.

The basis of botany

Because of the long preoccupation of man with plants, a large body of folklore, general information, and actual scientific data has accumulated, which has become the basis for the science of botany.

HISTORY

Early concepts. Theophrastus, a Greek philosopher who studied first with Plato and then became a disciple of Aristotle, is credited with founding botany. Only two of an estimated 200 botanical treatises written by him are known to science: originally written in Greek about 300 BC, they have survived in the form of Latin manuscripts, *De causis plantarum* and *De historia plantarum*. His basic concepts of morphology, classification, and the natural history of plants, accepted without question for many centuries, are now of interest primarily because of Theophrastus' independent and philosophical viewpoint.

Pedanius Dioscorides, a Greek botanist of the 1st century AD, was the most important botanical writer after Theophrastus. In his major work, an herbal in Greek, he described some 600 kinds of plants, with comments on their habit of growth and form as well as on their medicinal properties. Unlike Theophrastus, who classified plants as trees, shrubs, and herbs, Dioscorides grouped his plants under three headings: as aromatic, culinary, and medicinal. His herbal, unique in that it was the first treatment of medicinal plants to be illustrated, remained for about 15 centuries the last word on medical botany in Europe.

From the 2nd century BC to the 1st century AD, a succession of Roman writers—Cato, Varro, Virgil, and Columella—prepared Latin manuscripts on farming, gardening, and fruit growing but showed little evidence of the spirit of scientific inquiry for its own sake that was so characteristic of Theophrastus. In the 1st century AD, Pliny the Elder, though no more original than his Roman predecessors, seemed more industrious as a compiler. His *Historia naturalis*—an encyclopaedia of 37 volumes, compiled from some 2,000 works representing 146 Roman and 327 Greek authors—has 16 volumes devoted to plants. Although uncritical and containing much misinformation, this work contains much information otherwise unavailable, since most of the volumes to which he referred have been destroyed.

The significance of herbals

The printing press revolutionized the availability of all types of literature, including that of plants. In the 15th and 16th centuries, many herbals were published with the purpose of describing plants useful in medicine. Written by physicians and medically oriented botanists, the earliest herbals were based largely on the work of Dioscorides and to a lesser extent on Theophrastus, but gradually they became the product of original observation. The increasing objectivity and originality of herbals through the decades is clearly reflected in the improved quality of the woodcuts prepared to illustrate these books. Among the herbals most important for their contributions to botany are those by Otto Brunfels (published 1532–37), Hieronymus Bock (1539), Leonhard Fuchs (1542), and Valerius Cordus (published by Conrad von Gesner in 1561 after the death of Fuchs) in Germany; by Rembert Dodoens (1554, 1563), Charles de L'Ecluse (Carolus Clusius; 1601), and Matthias de L'Obel (1570, 1571) in the Netherlands; by Pierandrea Mattioli (1544) in Italy; and by William Turner (1551–62) and John Gerard (1597) in England.

In 1552 an illustrated manuscript on Mexican plants, written in Aztec, was translated into Latin by Badianus; other similar manuscripts known to have existed seem to have disappeared. Whereas herbals in China date back much further than those in Europe, they have become known only recently and so have contributed little to the progress of Western botany.

The invention of the optical lens during the 16th century and the development of the compound microscope about 1590 opened an era of rich discovery about plants; prior to that time, all observations by necessity had been made with the unaided eye. The botanists of the 17th century turned away from the earlier emphasis on medical botany and began to describe all plants, including the many new ones that were being introduced in large numbers from Asia, Africa, and America. Among the most prominent botanists of this era was Gaspard Bauhin, who for the first time developed, in a tentative way, many botanical concepts still held as valid. In 1665 Robert Hooke published, under the title *Micrographia*, the results of his microscopic observations on several plant tissues. He is remembered as the coiner of the word cell, referring to the cavities he observed in thin slices of cork; his observation that living cells contain sap and other materials too often has been forgotten. In the following decade, Nehemiah Grew and Marcello Malpighi founded plant anatomy; in 1671 they communicated the results of microscopic studies simultaneously to the Royal Society of London, and both later published major treatises.

The founding of plant anatomy

Experimental plant physiology began with the brilliant work of Stephen Hales, who published his observations on the movements of water in plants under the title *Vegetable Staticks* (1727). His conclusions on the mechanics of water transpiration in plants are still valid, as is his discovery—at the time a startling one—that air contributes something to the materials produced by plants. In 1774, Joseph Priestley showed that plants exposed to sunlight give off oxygen, and Jan Ingenhousz demonstrated, in 1779, that plants in the dark give off carbon dioxide. In 1804 Nicolas de Saussure demonstrated convincingly that plants in sunlight absorb water and carbon dioxide and increase in weight, as had been reported by Hales nearly a century earlier.

The widespread use of the microscope by plant morphologists provided a turning point in the 18th century—botany became largely a laboratory science. Until the invention of simple lenses and the compound microscope, the recognition and classification of plants were, for the most part, based on such large morphological aspects of the plant as size, shape, and external structure of leaves, roots, and stems. Such information was also supplemented by observations on more subjective qualities of plants, such as edibility and medicinal uses.

Binomial nomenclature

In 1753 Carl Linné (Carolus Linnaeus) published his master work, *Species Plantarum*, which contains careful descriptions of 6,000 species of plants from all of the parts of the world known at the time. In this work, which is still the basic reference work for modern plant taxonomy, Linnaeus established the practice of binomial nomenclature—that is, the denomination of each kind of plant by two words, the genus name and the specific name, as *Rosa canina*, the dog rose. Binomial nomenclature had been introduced much earlier by some of the herbalists, but it was not generally accepted; most botanists continued to use cumbersome formal descriptions, consisting of many words, to name a plant. Linnaeus for the first time put the contemporary knowledge of plants into an orderly system, with full acknowledgment to past authors, and produced a nomenclatural methodology so useful that it has not been greatly improved upon. Linnaeus also introduced a "sexual system" of plants, by which the numbers of flower parts—especially stamens, which produce male sex cells, and styles, which are prolongations of plant ovaries that receive pollen grains—became useful tools for easy identification of plants. This simple system, although effective, had many imperfections. Other classification systems, in which as many characters as possible were considered in order to determine the degree of relationship, were developed by other botanists; indeed, some appeared before the time of Linnaeus. The application of the concepts of Charles Darwin (on evolution) and Gregor Mendel (on genetics)

to plant taxonomy has provided insights into the process of evolution and the production of new species.

Systematic botany now uses information and techniques from all the subdisciplines of botany, incorporating them into one body of knowledge. Phytogeography (the biogeography of plants), plant ecology, population genetics, and various techniques applicable to cells—cytotaxonomy and cytogenetics—have contributed greatly to the current status of systematic botany and have to some degree become part of it. More recently, phytochemistry, computerized statistics, and fine-structure morphology have been added to the activities of systematic botany.

Recent concepts. The 20th century has seen an enormous increase in the rate of growth of research in botany and the results derived therefrom. The combination of more botanists, better facilities, and new technologies, all with the benefit of experience from the past, has resulted in a series of new discoveries, new concepts, and new fields of botanical endeavour. Some important examples are mentioned below.

New and more precise information is being accumulated concerning the process of photosynthesis, especially with reference to energy-transfer mechanisms.

The discovery of phytochrome

The discovery of the pigment phytochrome, which constitutes a previously unknown light-detecting system in plants, has greatly increased knowledge of the influence of both internal and external environment on the germination of seeds and the time of flowering.

Several types of plant hormones (internal regulatory substances) have been discovered—among them auxin, gibberellin, and kinetin—whose interactions provide a new concept of the way in which the plant functions as a unit.

The discovery that plants need certain trace elements usually found in the soil has made it possible to cultivate areas lacking some essential element by adding it to the deficient soil.

The development of genetical methods for the control of plant heredity has made possible the generation of improved and enormously productive crop plants.

The development of radioactive-carbon dating of plant materials as old as 50,000 years is useful to the paleobotanist, the ecologist, the archaeologist, and especially to the climatologist, who now has a better basis on which to predict climates of future centuries.

The discovery of alga-like and bacteria-like fossils in Precambrian rocks has pushed the estimated origin of plants on earth to 3,500,000,000 years ago.

The isolation of antibiotic substances from fungi and bacteria-like organisms has provided control over many bacterial diseases and has contributed biochemical information of basic scientific importance as well.

THE SCOPE OF BOTANY

For convenience, but not on any mutually exclusive basis, several major areas or approaches are recognized commonly as disciplines of botany; these are morphology, physiology, ecology, and systematics.

The major botanical disciplines. *Morphology.* Morphology deals with the structure and form of plants and includes such subdivisions as: cytology, the study of the cell; histology, the study of tissues; anatomy, the study of the organization of tissues into the organs of the plant; reproductive morphology, the study of life cycles; and experimental morphology, or morphogenesis, the study of development.

The close relationship of plant form and function

Physiology. Physiology deals with the functions of plants. Its development as a subdiscipline has been closely interwoven with the development of other aspects of botany, especially morphology. In fact, structure and function are sometimes so closely related that it is impossible to consider one independently of the other. The study of function is indispensable for the interpretation of the incredibly diverse nature of plant structures. In other words, around the functions of the plant, structure and form have evolved. Physiology also blends imperceptibly into the fields of biochemistry and biophysics, as the research methods of these fields are used to solve problems in plant physiology.

Ecology. Ecology deals with the mutual relationships and interactions between organisms and their physical environment. The physical factors of the atmosphere, the climate, and the soil affect the physiological functions of the plant in all its manifestations, so that, to a large degree, plant ecology is a phase of plant physiology under natural and uncontrolled conditions; in fact, it has been called "outdoor physiology." Plants are intensely sensitive to the forces of the environment, and both their association into communities and their geographical distribution are determined largely by the character of climate and soil. Moreover, the pressures of the environment and of organisms upon each other are potent forces, which lead to new species and the continuing evolution of larger groups.

Systematics. Systematics deals with the identification and ranking of all plants; it includes classification and nomenclature (naming) and enables the botanist to comprehend the broad range of plant diversity and evolution.

Specialized botanical disciplines. In addition to the major subdisciplines, several specialized branches of botany have developed as a matter of custom or convenience. Among them are bacteriology, the study of bacteria; mycology, the study of fungi; algology or phycology, the study of algae; bryology, the study of mosses and liverworts; pteridology, the study of ferns and their relatives; and paleobotany, the study of fossil plants. Palynology is the study of modern and fossil pollen and spores, with particular reference to their identification; plant pathology deals with the diseases of plants; economic botany deals with plants of practical use to man; and ethnobotany covers the use of plants by aboriginal peoples, now and in the distant past.

Botany also relates to other scientific disciplines in many ways, especially to zoology, medicine, microbiology, agriculture, chemistry, forestry, and horticulture, and specialized areas of botanical information may relate closely to such humanistic fields as art, literature, history, religion, archaeology, sociology, and psychology.

Fundamentally, botany remains a pure science, including any research into the life of plants and limited only by man's technical means of satisfying his curiosity. It has often been considered an important part of a liberal education, not only because it is necessary for an understanding of agriculture, horticulture, forestry, pharmacology, and other applied arts and sciences, but also because an understanding of plant life is related to life in general.

The aesthetic influence of plants

Because man has always been dependent upon plants and surrounded by them, he has woven them into his designs, into the ornamentation of his life, even into his religious symbolism. A Persian carpet and a bedspread from a New England loom both employ conventional designs derived from the forms of flowers. Medieval painters and great masters of the Renaissance represented various revered figures surrounded by roses, lilies, violets, and other flowers, which symbolized chastity, martyrdom, humility, and other Christian attributes.

METHODOLOGY

Morphological aspects. The invention of the compound microscope provided a valuable and durable instrument for the investigation of the inner structure of plants. Early plant morphologists, especially those studying cell structure, were handicapped as much by the lack of adequate knowledge of how to prepare specimens as they were by the imperfect microscopes of the time. A revolution in the effectiveness of microscopy occurred in the second half of the 19th century with the introduction of techniques for fixing cells and for staining their component parts. Before the development of these techniques, the cell, viewed with the microscope, appeared as a minute container with a dense portion called the nucleus. The discovery that parts of the cell respond to certain stains made observation easier. The development of techniques for preparing tissues of plants for microscopic examination was continued in the 1870s and 1880s and resulted in the gradual refinement of the field of nuclear cytology, or karyology. Chromosomes were recognized

as constant structures in the life cycle of cells, and the nature and meaning of meiosis, a type of cell division in which the daughter cells have half the number of chromosomes of the parent, was discovered; without this discovery, the significance of Mendel's laws of heredity might have gone unrecognized. Vital stains, dyes that can be used on living material, were first used in 1886 and have been greatly refined since then.

Improvement of the methodology of morphology has not been particularly rapid, even though satisfactory techniques for histology, anatomy, and cytology have been developed. The embedding of material in paraffin wax, the development of the rotary microtome for slicing very thin sections of tissue for microscope viewing, and the development of stain techniques are refinements of previously known methods. The invention of the phase microscope made possible the study of unfixed and unstained living material—hopefully nearer its natural state. The development of the electron microscope, however, has provided the plant morphologist with a new dimension of magnification of the structure of plant cells and tissues. The fine structure of the cell and of its components, such as mitochondria and the Golgi apparatus, have come under intensive study. Knowledge of the fine structure of plant cells has enabled investigators to determine the sites of important biochemical activities, especially those involved in the transfer of energy during photosynthesis and respiration. The scanning electron microscope, a relatively recent development, provides a three-dimensional image of surface structures at very great magnifications.

Fine structure a clue to biochemical activities

For experimental research on the morphogenesis of plants, isolated organs in their embryonic stage, clumps of cells, or even individual cells are grown. One of the most interesting techniques developed thus far permits the growing of plant tissue of higher plants as single cells; aeration and continuous agitation keep the cells suspended in the liquid culture medium.

Physiological aspects. Plant physiology and plant biochemistry are the most technical areas of botany; most major advances in physiology also reflect the development of either a new technique or the dramatic refinement of an earlier one to give a new degree of precision. Fortunately, the methodology of measurement has been vastly improved in recent decades, largely through the development of various electronic devices. The phytotron at the California Institute of Technology represents the first serious attempt to control the environment of living plants on a relatively large scale; much important information has been gained concerning the effects on plants of day length and night length and the effects on growth, flowering, and fruiting of varying night temperatures. Critical measurements of other plant functions have also been obtained.

Certain complex biochemical processes, such as photosynthesis and respiration, have been studied stepwise by immobilizing the process through the use of extreme cold or biochemical inhibitors and by analyzing the enzymatic activity of specific cell contents after spinning cells at very high speeds in a centrifuge. The pathways of energy transfer from molecule to molecule during photosynthesis and respiration have been determined by biophysical methods, especially those utilizing radioactive isotopes.

An investigation of the natural metabolic products of plants requires, in general, certain standard biochemical techniques—*e.g.*, gas and paper chromatography, electrophoresis, and various kinds of spectroscopy, including infrared, ultraviolet, and nuclear magnetic resonance. Useful information on the structure of the extremely large cellulose molecule has been provided by X-ray crystallography.

Ecological aspects. When plant ecology first emerged as a subscience of botany, it was largely descriptive; today, however, it has become a common meeting ground for all the plant sciences, as well as for other sciences. In addition, it has become much more quantitative. As a result, the tools and methods of plant ecologists are those available for measuring the intensity of the environmental factors that impinge on the plant and the reaction of the plant to these factors. The extent of the variability of many physical factors must be measured. The integration and reporting of such measurements, which cannot be regarded as constant, may therefore conceal some of the most dynamic and significant aspects of the environment and the responses of the plant to them. Because the physical environment is a complex of biological and physical components, it is measured by biophysical tools. The development of electronic measuring and recording devices has been crucial for a better understanding of the dynamics of the environment. Such devices, however, produce so much information that computer techniques must be used to reduce the data to meaningful results.

The ecologist, concerned primarily with measuring the effect of the external environment on a plant, adapts the methodology of the plant physiologist to field conditions.

The plant sociologist

The plant sociologist, on the other hand, is concerned with both the relation of different kinds of plants to each other and the nature and constitution of their association into natural communities. One widely used technique in this respect is to count the various kinds of plants within a standard area in order to determine such factors as the percentage of ground cover, dominance of species, aggressiveness, and other characteristics of the community. In general, the plant sociologist has relatively few quantitative factors to measure and must therefore take a subjective and intuitive approach, which, nevertheless, gives extremely useful results and some degree of predictability.

Some ecologists are most concerned with the inner environment of the plant and the way in which it reacts to the external environment. This approach, which is essentially physiological and biochemical, is useful for determining energy flow in ecosystems. The physiological ecologist is also concerned with evaluating the adaptations that certain plants have made toward survival in a hostile environment.

In summary, the techniques and methodology of plant ecology are as diverse and as varied as the large number of sciences that are drawn upon by ecologists. Completely new techniques, although few, are important; among them are techniques for measuring the amount of radioactive carbon-14 in plant deposits up to 50,000 years old. The most important new method in plant ecology is the rapidly growing use of computer techniques for handling vast amounts of data. Furthermore, modern digital computers can be used to simulate simple ecosystems and to analyze real ones.

Taxonomic aspects. Experimental research under controlled conditions, made possible by botanical gardens and their ranges of greenhouses and controlled environmental chambers, has become an integral part of the methodology of modern plant taxonomy.

A second major tool of the taxonomist is the herbarium, a reference collection consisting of carefully selected and dried plants attached to paper sheets of a standard size and filed in a systematic way so that they may be easily retrieved for examination. Each specimen is a reference point representing the features of one plant of a certain species; it lasts indefinitely if properly cared for, and, if the species becomes extinct in nature—as hundreds have—it remains the only record of the plant's former existence. The library is also an essential reference resource for descriptions and illustrations of plants that may not be represented in a particular herbarium.

One of the earliest methods of the taxonomist, the study of living plants in the field, has benefitted greatly by fast and easy methods of transportation; botanists may carry on fieldwork in any part of the world and make detailed studies of the exact environmental conditions under which each species grows.

New approaches in systematic botany

During the present century, many new approaches have been applied to the elucidation of problems in systematic botany. The transmission electron microscope and the scanning electron microscope have added to the knowledge of plant morphology, upon which classical taxonomy so much depends.

Refined methods for cytological and genetical studies of plants have given the taxonomist new insights into the

origin of the great diversity among plants, especially the mechanisms by which new species arise and by which they then maintain their individuality in nature. From such studies have arisen further methods and also the subdisciplines of cytotaxonomy, cytogenetics, and population genetics.

Phytochemistry, or the chemistry of plants, one of the early subdivisions of organic chemistry, has been of great importance in the identification of plant substances of medicinal importance. With the development of new phytochemical methods, new information has become available for use in conjunction with plant taxonomy; thus has arisen the modern field of chemotaxonomy, or biochemical systematics. Each species tends to differ to some degree from every other species, even in the same genus, in the biochemistry of its natural metabolic products. Sometimes the difference is subtle and difficult to determine; sometimes it is obvious and easily perceptible. With new analytical techniques, a large number of individual compounds from one plant can be identified quickly and with certainty. Such information is extremely useful in adding confirmatory or supplemental evidence of an objective and quantitative nature. An interesting by-product of chemical plant taxonomy has resulted in understanding better the restriction of certain insects to specific plants.

Computer techniques have recently been applied to plant taxonomy to develop a new field, numerical taxonomy, or taximetrics, by which relationships between plant species or those within groups of species are determined quantitatively and depicted graphically. Another method measures the degree of molecular similarity of deoxyribonucleic acid (DNA) molecules in different plants. By this procedure it should be possible to determine the natural taxonomic relationships among different plants and plant groups by determining the extent of the relationship of their DNA's: closely related plants will have more similarities in their DNA's than will unrelated ones.

The use of nucleic acids in taxonomy

ECONOMIC ROLE

Botany has been a source for other arts and sciences, such as medicine and organic chemistry; it still provides the base upon which depend various applied plant sciences—agriculture, agronomy, horticulture, forestry, pharmacology, and other related fields.

In early civilizations, as among primitive peoples today, knowledge about plants, especially those of medicinal importance, lent special prestige and power to the priests, medicine men, and other practitioners who often cloaked their knowledge with magic, superstition, secrecy, religious rituals, and other manifestations of professional mystery.

Gardens have been an integral part of every civilization from early times. When contrasted with agriculture, gardening is a more specialized pursuit that lends itself to both avocation and vocation. Many centuries before written history, gardens of various kinds existed, from the Garden of Eden to the Hanging Gardens of Babylon; the forerunners of modern botanical gardens, these were devoted to ornamental plants, vegetables, culinary herbs, fruit trees, and interesting plants. See BOTANICAL GARDEN; GARDEN AND LANDSCAPE DESIGN; and GARDENING.

Agricultural products. As with many other aspects of the plant sciences, the origins of agriculture precede recorded history. Most of today's cultivated plants were domesticated in prehistoric times. In fact, it is remarkable that so few important agricultural plants have been domesticated within historical times; on the other hand, most crop plants have been greatly improved through hybridization, selection, and other technological advances in breeding. The questions of where and how plants were domesticated are obscured as much by the absence of "missing links" in the sequence from wild plants to cultivated ones as by the total lack of any written record. See DOMESTICATION, PLANT AND ANIMAL.

Food. The historical record, both written and archaeological, shows that at least 3,000 species of plants have been used as food; early man undoubtedly ate what he could of every plant he encountered. Most present knowledge of edible wild plants has been gained from aboriginal people around the world. Of the 1,000 or so species that truly have been domesticated and cultivated intensively, only about 200 have become productive enough to enter into international commerce. The rapid growth of world population has inevitably set the trend through the centuries to reduce or eliminate the cultivation of less efficient crops and to concentrate on the more productive ones. As a result, the majority of the world's population is now nourished by only 12 plant species, which include three cereals, rice, wheat, and corn (maize); two sugar plants, sugarcane and the sugar beet; three "root" crops, the potato, the sweet potato, and the cassava; two legumes, the common bean and the soybean; and two "tree" crops, the coconut and the banana. The next three most highly utilized species are the peanut, sorghum, and barley. These few crop plants stand between most men and starvation.

Beverages. Early centres of civilization developed their own plant-derived stimulating beverages, both fermented and nonfermented. The stimulants found in nonalcoholic drinks include caffeine, as found in coffee, which was developed in Abyssinia and Arabia; tea, developed in Southeast Asia; guarana and maté, in Paraguay and Argentina; cola, in tropical Africa; and kat, in Arabia. Fermented alcoholic beverages also precede history; although certainly much older, wine is first recorded before 4000 BC. Mead, fermented from honey, and palm wine, as well as the fermented juice of other fruits, are also very ancient alcoholic drinks. The use of pulque, the fermented juice of *Agave*, long antedated the arrival of Europeans in the New World. Beers, made from rice in the Orient (sake), from maize in South America (chicha), and from other grains in Europe, must first be malted to change the starch into sugars, which are then fermented; despite the two-stage process, which is more difficult than that of wine making, beers are extremely ancient. Distillation was also known to the ancients: apparently cloth and sheepskins were held over boiling fermented mash to condense the alcohol, which was then wrung out of them.

The ubiquity of stimulating beverages

Fibres. In addition to food and shelter, man needs clothing, especially in cooler climates. The inner bark of many species of trees was once beaten into a natural cloth; in fact, this technique may have antedated the weaving of plant fibres into cloth. Tapa cloth so fabricated is still used in the South Pacific, and other bark cloths persist elsewhere.

Fibres are long cells or clusters of cells that give strength to the stems, leaves, and roots of a plant. Thousands of plant species yield useful fibres and have been used locally by primitive peoples all over the world. Fibres still in use were discovered in prehistoric times and were already highly refined by the earliest historic times. Cotton is the world's chief fibre plant and one of the oldest; two different types originated in India and in the Americas. Flax has been cultivated for at least 10,000 years. It is frequently mentioned in the Bible and was cultivated in prehistoric times by the Swiss Lake Dwellers and by the Egyptians. Hemp, the fibre from *Cannabis sativa*, has been used since ancient times for the production of rope and cordage. In addition to hemp fibre, *Cannabis* contains various hallucinogenic compounds perhaps most commonly called hashish and marijuana. Other important fibres of great economic importance are jute, from which burlap is made, and ramie. Manila hemp, or abaca, is made from the leafstalks of a banana relative, *Musa textilis*. In the New World, several important fibres have been used since prehistoric times, including sisal, henequin, istle, and pita; all are from the leaves of species of *Agave* and its related genus, *Furcraea*. In tropical Africa and Asia, a strong fibre is produced from the leaves of the bowstring hemp, *Sanseverinia*. Filling fibres for pillows are furnished by kapok (the silk-cotton tree), milkweeds, and cattails. Coir, the important fibre produced from the husk of the coconut, has long been used locally for many purposes.

The importance of *Cannabis*

Lumber industry and forest products. By the early Stone Age men were already proficient in the manipula-

tion of wood for a wide range of purposes—making small objects such as bows and arrows, making boats, and building shelters.

Civilization today depends on wood and wood products at great cost to the world's natural resources. The original forests of Europe, especially, have been severely depleted because they have long been utilized for wood, as well as being cleared for agriculture. And in the time that has elapsed since the English colonized the United States, at least half of its forests have disappeared as well.

Forest trees provide man with a number of useful products including wood, food, fibres, gums, and resins. Some aboriginal groups in tropical America, Africa, and Asia still depend entirely on the forest for all their needs and do not attempt any agriculture. The prehistoric discovery that hardwood subjected to distillation, or incomplete combustion, produces charcoal is said to be the oldest chemical process known to man. Modern technology has increased the efficiency of wood distillation as well as the number of products that can be recovered during that process; among them, in addition to charcoal, are acetic acid, acetone, methanol, or wood alcohol, wood gas, and wood tar and oils. Softwood from conifers, especially old pine stumps, is distilled to produce turpentine, rosin, pine oil, and creosote, as well as charcoal and wood gas. Many modern techniques have been developed to give wood greater strength or to enhance other properties. Several chemical processes remove lignin and other materials from wood fibres, leaving almost pure cellulose ready for manufacture into paper. Other processes utilize cellulose to manufacture fibres such as rayon, films such as cellophane, and many different types of wood and plastic products. Discovered as part of the normal process of manufacturing ("cooking") paper pulp from wood, the partial or complete hydrolysis of cellulose has assumed considerable economic importance. In northern Europe, especially in Scandinavia, wood is cooked under pressure to produce an edible, pulpy, starchlike food for cattle and other livestock. If cooked long enough, the cellulose can be converted into simple sugars, which can then be fermented by yeast to produce alcohol.

Chemical rendering of wood into cellulose

Modern forestry now has a much broader scope than it once did, when improved timber production was almost the sole aim. Today, forestry is concerned with the management of wooded lands of all types (including grasslands), not only for lumber production but also for a series of desirable but less tangible benefits, such as water yield, watershed protection, grazing, protection of wildlife, scenic values and recreation, and game and fish production.

Other products. *Essential oils.* The most important sources of perfumes, spices, and many kinds of flavourings for food and beverages are an enormous variety of essential oils produced by a vast array of plants. From earliest times, essential oils have also been used for religious offerings, for medicinal purposes, and for embalming the dead. Many plant families produce their own easily recognizable essential oils; best known are those of the pines and other conifers, the laurels, the myrtles (including *Eucalyptus*), the mints, and the citrus fruits.

Medicinal plants. The number of plants that have been used for medicinal purposes is nearly as large as the list of edible plants. Root drugs that date back to 5000 BC include aconite, colchicum, gentian, squill, and valerian. Other root drugs in use are goldenseal, ginseng, ipecac, licorice, jalap, podophyllum, rhubarb, and senega; several have their origin in the New World and were well known in aboriginal medicine. All bark drugs in common use are from the New World; they include cascara sagrada, curare, and quinine. Of drugs extracted from stems and wood, ephedrine is of Chinese origin, and guaiacum and quassia are from tropical America. Many drugs occur in leaves, which are the primary source of chemical compounds in plants; such are aloe, belladonna, cocaine, digitalis, eucalyptus, witch hazel, henbane, horehound, lobelia, pennyroyal, senna, stramonium, and wormwood. A few drugs occur in flowers, of which the best known are chamomile and hops. Many seeds and fruits that are poisonous contain ingredients that, in moderation, may be of medicinal importance; examples are croton oil, nux vomica, opium, psyllium, strychnine, strophanthus, and wormseed.

Plant poisons of medicinal value

Narcotics. Narcotics are closely related to medicinal plants in their physiological and biological effects. Most aboriginal peoples discovered some such plant that eased the cares of everyday life. These drugs were often under the control of chiefs or medicine men and were sometimes of religious importance. Examples are coca from the Andes; opium from the Orient; betel from Indonesia; cola from tropical Africa; *Cannabis* from Asia; peyote from Mexico; fly agaric (*Amanita muscaria*) from Siberia; datura from Asia; henbane from the Mediterranean area; kavakava from Oceania; and tobacco from the New World.

Insecticides. Many narcotic plants and their products, such as nicotine, have been used to control insects; in fact, the distinctions between poisonous plants, medicinal plants, narcotic plants, and insecticidal plants are uncomfortably narrow or even nonexistent. Pyrethrum, the dried powdered flower heads of certain composite plants, has the advantage of killing insects without being strongly toxic to humans and other warm-blooded animals. Rotenone, derived from derris root in Asia and from several species of *Lonchocarpus* in tropical America, has an action very similar to pyrethrum. Rotenone is also widely used as a fish poison; since it causes suffocation by inhibiting oxygen absorption, the fish killed in this way are edible.

Fuel. The two major types of fossil fuels, coal (including lignite) and petroleum (including natural gas), are both derived from plant deposits accumulated millions of years ago and transformed into their present fuel state by heat and pressure.

BOTANICAL SOCIETIES AND PUBLICATIONS

Societies and journals devoted largely, or entirely, to plant science began to emerge in the late 19th and early 20th centuries. Partly because of the vast expanse and large population of the United States and partly because of the exuberance of American science, a surfeit of botanical societies exist today in the United States; each has its own journal. Some of the more important ones are the Botanical Society of America (*American Journal of Botany*), American Society of Plant Physiologists (*Plant Physiology*), Torrey Botanical Club (*Bulletin* and *Memoirs*), American Society of Plant Taxonomists (*Brittonia*), and Society for Economic Botany (*Economic Botany*). Several important journals are published by institutions other than societies, as *Botanical Gazette* (University of Chicago) and *Botanical Review* (New York Botanical Garden).

The United Kingdom produces several publications, among which *Annals of Botany* and the *Journal of Experimental Botany* are published by Oxford University; *New Phytologist* is published commercially.

In Canada, several botanical periodicals are published by the National Research Council.

All older and well-established countries of the world have their own botanical societies and publications. In addition to the serial publications issued by societies for their members, many important contributions to botany, especially monographic works, are published in the memoirs, annals, transactions, and proceedings of national and local academies of science, by individual universities, by botanical gardens, and by other types of organizations and institutions. In addition, several major botanical journals are issued by commercial publishers. A list of some of the 8,000 major periodicals in biology published around the globe appears annually in *Biological Abstracts*, which reviews all publications in the life sciences. A compilation of all the world's botanical writings from the beginnings of botanical literature was published by the Hunt Botanical Library in 1968.

BIBLIOGRAPHY. H.S. REED, *A Short History of the Plant Sciences* (1942), an interesting and thought-provoking account with many useful insights; K.V. THIMANN, *The Plant Sciences, Now and in the Coming Decade* (1966), a thought-

ful and persuasive statement, well written and readable; J.R. GREEN, *A History of Botany, 1860–1900* (1909, reprinted 1967), a scholarly treatment designed to supplement the classic work of Julius von Sachs (*History of Botany, 1530–1860*), arranged by botanical structure and function; A. ARBER, *Herbals, Their Origin and Evolution: A Chapter in the History of Botany, 1470–1670*, 2nd ed. rev. (1938), the most readable and authoritative work on this topic; E. HAWKS and G.S. BOULGER, *Pioneers of Plant Study* (1928, reprinted 1969), an interesting account of major historical figures.

(W.C.St.)

Botswana

Botswana is a landlocked republic in southern Africa with an area of about 220,000 square miles (569,800 square kilometres) and a population of about 600,000. The greater part of the country is covered by the Kalahari. It is bounded by South Africa to the southeast and south, South West Africa (Namibia) to the west and north, Zambia to the north, and Rhodesia to the northeast and east. Zambia is the only independent black state on which Botswana fronts, but the actual border along the Zambezi River, at the end of the thin finger of South West African territory known as the Caprivi Strip, is only several hundred yards long. This part of the border, which is not yet established by international treaty, is a source of controversy among Botswana, Rhodesia, and South Africa (the latter acting as trustee for South West Africa).

Until its independence in 1966, Botswana was a British protectorate known as Bechuanaland; one of its first acts was to move the capital from Mafeking in South Africa to Gaborone (formerly Gaberones). The country is named after its people, the Batswana, or Tswana. The language is Setswana, or Siswana.

Botswana is a member of the Commonwealth of Nations, the Organization of African Unity (OAU), and the East and Central African Regional Organization, to which 14 nations belong. It maintains economic and diplomatic links with South Africa as well as with black states to the north. Lacking adequate water and with a small population, Botswana is primarily a stock raising country; its substantial reserves of nickel and copper await large-scale exploitation. Associated physical features can be found under KALAHARI (DESERT); OKAVANGO RIVER; and ZAMBEZI RIVER; for historical aspects, see SOUTHERN AFRICA, HISTORY OF.

The landscape. *Relief and drainage.* Botswana extends from the Chobe River (which drains into the Zambezi) in the north, to the Molopo River, a tributary of the Orange River, in the south. Most of the national territory forms part of the Kalahari, a semidesert in the west. A plateau, with an altitude of about 4,000 feet, divides the country into two distinctive regions, each with its own drainage system. After forming the watershed between the Molopo just to the south and the Notwani River to the southeast, the plateau extends northward from a point about 20 miles west of Kanye, a town in the southeast, to the border of Rhodesia in the northeast. The area to the east of the plateau is crossed by ephemeral streams that flow latitudinally into the Marico, Limpopo, and Notwani rivers; the western system, which once drained the tableland into the Makgadikgadi Pans, is now covered with deep sand.

The plateau

The country has a mean altitude of 3,300 feet and is almost entirely flat or gently undulating, with Kalahari sands overlying Precambrian rock (from 570,000,000 to 4,600,000,000 years old). The greater part of the south has no surface drainage, and the rest of the country's drainage, except for the Limpopo and Chobe rivers on the borders, does not reach the sea.

The main drainage system is provided by the Okavango River, which, after flowing southeastward for 90 miles from the Angola border in the northwest, drains into a vast depression to form the 4,000-square-mile Okavango Swamp, as well as Lake Ngami, a 70-square-mile pan. This system seasonally drains eastward along the Boteti River to Lake Xau (Dow) near the centre of the country, and finally flows into the Makgadikgadi Pans farther east. The Molopo and Ramatlabama, which form the southern boundary, are both tiny streams.

The Kalahari is a "thirstland," rather than a true desert, being covered with grass and acacia thorn scrub; its tsama melons (a species of watermelon) help to sustain the Bushmen who live there. In areas where underground water is close to the surface it resembles parkland. The only typical desert occurs in the southwest corner, where there are sand dunes.

Climate. Temperatures vary from temperate to subtropical. In summer (which lasts from October to March), temperatures rise to 100° F (38° C); in winter (which lasts from April to September), there is frequent frost, and temperatures fall to below 32° F (0° C). Hot August winds carry sand from the Kalahari across the entire country. The average annual rainfall is 18 inches, representing a variation from 25 inches in the north to five inches or even less in the southwest. Most rain falls in

heavy downpours between December and the end of April. Cyclical droughts, often lasting several years, are calamitous for both crops and cattle. One such occurred in 1965 to 1966.

Vegetation. Woodland savanna (grassy parkland), in which species of acacia predominate, covers much of the country. In the northeast the most characteristic vegetation cover consists of mopane (African ironwood), mogonono (country almond), and mokusi (Rhodesian teak), while morukuru (*Spirostachys africanus*) frequently occurs in the central Kalahari. In the abundant grazing areas grasses include lovegrass, panicum, crabgrass, and bristlegrass. True forest, which occurs only on the banks of the Chobe, consists mainly of mokwa or bloodwood, mokusi, and monato or Rhodesian ash.

The game reserves

Animal life. Herds of wild game teem on the plains, and the national parks and game reserves are well stocked. National parks and game reserves include the Chobe and Moremi; other wildlife areas are the Okavango delta, Lake Ngami, the Makgadikgadi Pans, and the Kalahari. Besides many species of large and small antelopes, there are lions, elephants, leopards, hippopotamuses, giraffes, buffalo, and crocodiles. Poisonous snakes, among them the cobra and puff adder, abound; and there are many varieties of scorpions, tarantulas, spiders, and termites. Bird life is prolific, and includes ostriches, pelicans, and bustards. The principal fish, especially in the Okavango and Chobe rivers, are tilapia, tiger fish, and catfish.

The landscape under human settlement. The Batswana people are divided into eight principal tribal groups, each occupying its own separate territory with its own traditional chiefs and retaining a communal ownership over its tribal lands that is inalienable. Associated with each of the dominant tribes are smaller related or formerly subjected tribes. Only the nomadic Bushmen of the Kalahari and the few thousand Europeans are not included in this traditional system. The largest tribe is the Ngwato (Bamangwato), which, numbering about 200,000, comprises about one-third of the total population and owns one-fifth of all the land; its territory lies to the east. The Ngwato capital, Serowe in eastern Botswana, is spread out beneath rocky hills and is a large circular town consisting mostly of thatched huts. The next two largest tribes are the Kwena (Bakwena) and the Ngwaketse (Bangwaketse), who live in the southeast, near Gaborone; both tribes number about 70,000. The other smaller tribes are the Kgatla (Bakgatla), numbering 32,000, the Bamalete, numbering 14,000, and the Tlokwa (Batlokwa) numbering 4,000, all of whom live in the southeast; the Rolong (Barolong), numbering 11,000, who overspill into South Africa; and the Tawana (Batawana), numbering 42,000, who live on the South West African border.

In the 19th century, several large blocks of land were transferred from African to European ownership around Lobatse, Gaborone, and Tuli in the southeast; Ghanzi in the west; and on the banks of the Molopo River in the south. The Tati Concession in the Francistown District (now North East District) gave a private company the right in 1869 to exploit a potentially rich mining area of more than 2,000 square miles. A company formed in 1914 still exercises the right to grant farming and mining concessions, and holds land rights in the district.

The Batswana way of life

Unlike most African tribes, the Batswana have a tradition of living in large towns, often located at great distances from their grazing lands. The inhabitants are largely cattle farmers, some with herds numbering thousands of head but the majority having only a few cattle. The cattle are often located in remote areas where cattle posts, providing shelters for herdsmen and watering places for cattle, are maintained. Richer cattle farmers have a large number of cattle posts, which are sometimes spread out at distances of 100 miles or more from each other. The farmers' practice is to spend several days of each week at their cattle posts, returning to their central village and families for long weekends.

Each village has its subchief, headmen, and *kgotla* or *lekhotlo* (a court and public meeting place, situated near the chief's house, usually under a large tree and always beside the communal cattle enclosures, or kraals). The *kgotla* remains the centre of daily social life, at which disputes are settled in public and matters of local importance discussed. Most villages have a school, a store, and sometimes a dispensary. Villages, small or large, are always divided into wards comprising the extended family, each part of which lives within its own compound. In the larger villages each ward tries to have its own borehole for water. Watercarrying still forms a large part of the daily routine of women and girls, just as cattleherding occupies the lives of boys, often conflicting with their schooling. The outlying villages relate closely to their tribal capital, which is the seat of the paramount chief and the royal *kgotla*. This system of village democracy has so far survived the politicizing of the nation and forms an integral part of the contemporary political structure.

Cattle, land, and rain are the most important factors in the lives of the people. Because the lives of people and cattle both depend on an unpredictable climate, rain (*pula*) is of particular significance. *Pula* is the people's familiar greeting on meeting each other.

Although thousands of young people leave their villages every year to seek work in South Africa, or in pursuit of further education in the towns, there is still little urbanization. The only local magnets for employment outside the traditional sector are the six small towns stretched along the railway line that runs across the country and links it to South Africa and Rhodesia. These towns represent points of tribal disintegration where modern-minded Batswana groups may free themselves from the constraints of the tribal village; they also constitute points of national political integration and are the focus of contending nationalist forces.

The towns

The capital, Gaborone (18,000), although it has grown rapidly into an administrative centre since becoming the capital, is still much smaller in population size than Serowe (population 36,000), the Bamangwato capital, which lies 35 miles from the nearest railhead. Francistown (population about 19,000) is the commercial centre of the Tati Concession area, which is dominated by Europeans, mainly from South Africa. Lobatse (12,000), the nearest of the six towns to Mafeking across the South African border, is another centre of commerce.

People and population. *Ethnic groups.* The original inhabitants were the Bushmen (known locally as the Sarwa or Masarwa), who now number about 29,000; about 5,000 of them follow a nomadic way of life in the Kalahari, moving across the South West Africa border; they belong to the Naron, Auen, Kung, and Heikum groups. Those who have abandoned nomadism are mainly employed in servile positions by the dominant tribes. The Batswana group, who include the Ngwato and other tribes described above, number about 500,000;

they are composed of a cluster of tribes closely related in culture and language to the western Sotho.

The European population, mainly from South Africa, totals only about 4,000; it consists of farmers, traders, public officials, missionaries, and teachers, mostly confined to European agricultural zones and to the towns along the railroad. European-occupied areas cover about 9,700 square miles. Coloureds, or Eurafricans, who are of mixed descent, number about 3,500. There are also about 400 Asians.

The two official languages are Setswana and English. English is spoken only among the educated Africans or those who have worked for some time in South Africa. Afrikaans is spoken only by sections of the white community. Approximately 35 percent of the population is literate in Setswana and 24 percent in English.

Religious groups. The majority of people are nominal Christians, although only a minority are active churchgoers; many are nominal Christians in the sense that they still show some attachment to traditional religion, based on ancestor worship. Between 20 and 30 percent are practicing Christians. The majority of these are Anglicans, Congregationalists, Methodists, and Presbyterians; these four groups have united to worship as a single congregation. There are also smaller communities of the Dutch Reformed Church, African Methodist Episcopal Church, and Roman Catholic Church.

Demography. The country is sparsely populated, largely because of the shortage of water. Population growth is 3 percent per annum. Only 5 percent of the area suitable for cultivation is actively farmed. Over 80 percent of the people are concentrated in the eastern region, which has a population density of about seven persons per square mile, compared with less than one per square mile over the rest of the country.

The cattle industry

The national economy. Botswana's 1,500,000 head of cattle dominate the country's economy. The animals are mostly crossbreeds; attempts are being made to introduce quality cattle based on herds imported from South Africa. Although cattle provide Botswana's main exports, mining is likely to expand in future. About 37,000,000 tons of nickel and copper deposits located about 100 miles from Francistown are to be exploited. Except for European farming, there are few cash crops; most agriculture is grown on a subsistence basis. Periodic droughts necessitate the importation of food and wreak havoc among the cattle population.

The gross domestic product is less than $40,000,000, and the per capita annual income is about $100. The annual budget is approximately $10,000,000, of which only slightly more than half comes from local revenue. The balance is made up by international aid (mainly British) and from customs dues and revenues derived from the country's membership in the South African Customs Union. The annual balance of trade runs at a deficit of about $7,500,000.

The National Development Plan, adopted in 1970, envisages a growth rate of 15 percent per annum, concentrating on improving agriculture, developing mining and water resources, and expanding secondary education and communications. It anticipated eliminating the need for foreign budgetary aid by the mid-1970s.

The country's two greatest shortages are of water and of people. It has considerable agricultural and mineral potential, but only one-twentieth of the 8,000,000 acres suitable for cultivation is utilized. While considerable effort has gone into developing water boreholes and dams, nothing has yet been done to exploit the great water resources of the Okavango Basin, which have been described by some geographers as having a potential significance for the continent second only to that of the Nile River Valley.

Mining. The country stands at the beginning of a new era in the exploitation of its mineral resources. The Orapa diamond mines, worked by the Anglo-American Corporation, started production in 1971. The most important growth area is the Shashi mining complex, which will exploit nickel and copper ore; it is operated under the Bamangwato Concessions by an international consortium headed by the American Metal Climax, Inc. The Botswana government has a 15 percent interest in this development. The mine's initial annual output will, it is estimated, be 15,000 short tons of nickel and 19,000 tons of copper.

Nickel and copper

Industry. Except for meat processing and a few small-scale industries associated with mining, prospects for industrial development are poor.

Foreign aid. Britain is Botswana's most important source of foreign aid. The United States has provided a $6,000,000 loan for an international highway, mentioned below, and Canada has provided an $18,000,000 loan for a power station, scheduled to open in 1972, to serve the Shashi complex. Sweden has provided aid for development and education. The International Development Association has provided $7,500,000 to build a water-transmission line to supply the mines at Shashi.

Taxation and revenue. Local tax is levied at the rate of about $32 a year on incomes over about $450. Income tax begins at 6 percent and is on a rising scale. Mining and company taxes are paid on variable scales.

The annual budget, as already mentioned, is financed partly by local revenues and partly by foreign aid. Its annual growth rate is about 5 percent. More than $11,000,000 is allocated annually to development, mainly for mining, agriculture, and education; the development budget depends largely on overseas aid. Remittances from nationals working in South Africa contribute an important share to foreign earnings.

Management of the economy. In the public sector, the government, employing about 6,000, is the largest employer of wage-earning labour and is active in promoting cooperative societies and water-development projects.

In the private sector, the bulk of import and export trade is in European, mainly South African, hands. About three-quarters of all trading licenses are held by Europeans, about 15 percent by Africans, and about 10 percent by Asians. The two commercial banks are owned by overseas companies.

Employment. The total labour force is estimated at 250,000, of whom about 90 percent are employed in agriculture, forestry, and hunting; 1 percent in manufacturing; 1 percent in mining and quarrying; 1 percent in commerce; 1 percent in transport and communica-

tions; and 4 percent in services. About 35,000 Batswana leave annually to work in South Africa.

Transport. The country has about 5,000 miles of roads, mostly made of gravel or earth. A new 311-mile road links Francistown in the east to Maun in the Okavango region in the northwest. A major international road is being built to link Francistown with Livingstone in Zambia—the first major artery leading away from the South African road network. It will cross the Zambezi at Kazungula, using the ferry instead of a bridge, since bridge construction is opposed by South Africa pending clarification of the frontier at this politically sensitive point.

The only railway line, 394 miles of which traverses the country, is owned by Rhodesia Railways and is operated in conjunction with the South African Railways and Harbours Administration.

Botswana Airways Corporation links the main towns by domestic flights, and flies to Johannesburg, Bulawayo, and Gaborone. South African Airways and Zambia Airways both operate services to and from Gaborone, Francistown, and Lobatse.

Administration and social condition. *The structure of government.* Legislative power is vested in the Parliament, which consists of the president and the National Assembly of 31 elected members, four especially elected members, and the attorney general. The president is the executive head of government; he is a member of and presides over a Cabinet, consisting of the vice president and eight other ministers drawn from the National Assembly. Elections for the presidency and National Assembly are held every five years. A House of Chiefs advises the government; no legislation affecting tribal affairs may be passed without reference to this House. A code of human rights is enforceable by the High Court. A nonpolitical public service commission controls all matters relating to the public service. The local government system operates throughout nine district councils, as well as three town councils located in Gaborone, Francistown, and Lobatse.

The House of Chiefs

There are three nationalist parties, which claim to represent more militant ideas than the ruling Botswana Democratic Party; they are the Botswana People's Party, the Botswana Independence Party, and the Botswana National Front. All four parties are national in the sense of having multitribal members; they usually attract both modern and traditional-minded supporters. The ruling BDP won the elections in 1969 with almost 70 percent of the vote.

Justice. The High Court, consisting of a chief justice and puisne (associate) judges, exercises jurisdiction over all criminal and civil cases. The Court of Appeals deals with matters emanating from the High Court. Further appeals, in certain circumstances, lie with the Judicial Committee of the Privy Council in the United Kingdom. Subordinate courts and African courts with limited jurisdiction exist in the 12 administrative districts.

Education. There are 280 primary schools, with an enrollment of about 80,000 children. About 3,000 children are enrolled in the 10 secondary schools, of which six are run by mission societies and four by the government. Only about 4 percent of primary pupils later receive secondary education. Higher education is provided by the University of Botswana, Lesotho, and Swaziland, located at Roma in Lesotho.

Health. The main prevalent sicknesses are tuberculosis, gastroenteritis, pneumonia, and food deficiency diseases. Malaria is endemic in Chobe and Ngamiland, which is also infected by sleeping sickness. Bilharzia (a parasitic disease) occurs in the eastern area and in the Okavango Basin. While the country has 36 doctors—giving an average ratio of one doctor to 17,475 persons—in some areas the ratio is as low as one doctor to 67,000 people. Registered nurses and midwives number about 500. There are 12 hospitals and several health centres, dispensaries, and clinics.

Cultural life and institutions. The life of the majority of the people is still strongly influenced by tribal institutions and cultures; there is a rich tradition of folklore, music, and dancing. The only strongly competitive cultural institutions are those provided by the churches and by some of the schools; Swaneng Hills School, an imaginative institution started by a South African expatriate, Patrick van Rensberg, may be especially mentioned. While not much vernacular literature of exceptional quality exists as yet, there are the beginnings of a modern vernacular literary tradition.

The press. The government publishes the *Daily News* in Setswana and English, as well as a monthly journal, *Kutlwano.* A bilingual weekly is published in Mafeking in South Africa for Botswana circulation. The three nationalist parties publish their own monthly journals, *Masa* ("Dawn"), *Puo Pha* ("Straight Talk"), and *Therisanyo* ("Consultation").

Radio. Radio Botswana broadcasts daily services on shortwave and very high frequency in both English and Setswana. Farm broadcasting is a special feature. There are about 8,500 radio sets in the country. There is no television.

Prospects for the future. Botswana's strategic position in southern Africa requires that it remain balanced on a political tightrope; it nevertheless pursues a vigorously independent foreign policy aimed at increasing its links with the rest of the continent while reducing its economic and physical ties (*i.e.*, communications and electric power links) with South Africa. Internally, it is committed to building a multiracial society in open rivalry to the system of apartheid (separation of races) adopted by South Africa. Mining development should considerably strengthen Botswana's economic position, enabling it to make a much greater use of its considerable untapped agricultural potential. The country's small population is, nevertheless, a factor that severely limits development.

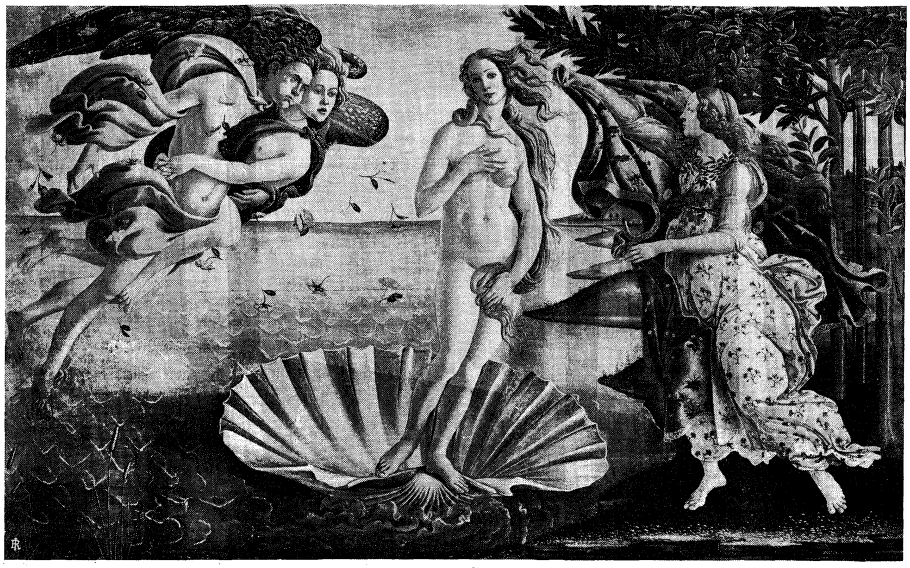
Botticelli, Sandro

Living in late-15th-century Italy at a time of profound change in the course of art, Botticelli proved himself to



"The Birth of Venus," oil on canvas by Sandro Botticelli, *c.* 1485. In the Uffizi, Florence, Italy. 1.72 m × 2.79 m.
Anderson—Alinari

be a painter of individual sensibilities of the highest order—although he belonged to a slightly older generation than the creators of the High Renaissance style, he may be seen in his paintings to have been fully abreast of the currents of his day. Nonetheless, his reputation remained in eclipse for several hundred years after his death, until he was rediscovered at the end of the 19th century. At that time, in addition to an appreciation of his paintings for their exquisite linear rhythms and deep-hued colour, there evolved a highly romantic and subjective conception of their subjects. Despite the clarifications of 20th-century scholarship, much of this mysticism still remains in attempts to reach an understanding of his work. There is no doubt, however, that Botticelli was seeking in his painting to express the gods as the living and potent spirits they had been to the ancient peoples who had conceived them. To this end he sought, in ancient and contemporary authors, not a simple text to illustrate but rather a deeper understanding of Venus and her fellow Olympians as gods. He was so successful in this attempt that his "Birth of Venus" continues to express to modern viewers the very spirit of the Renaissance itself.

Early development. Reliable biographical information concerning Botticelli is, unfortunately, in short supply, a fact that is important to keep in mind, for he has been characterized variously as a painter of great erudition, as a pure aesthete who was indifferent to subject matter, as an artist imbued with Neoplatonic philosophy, and as a saintly spirit who, toward the end of his life, was profoundly affected by the theology of the reforming monk Savonarola. His very name is derived from his elder brother Giovanni, a pawnbroker who was called Il Botticello ("little barrel").

Birth and early training

Documentary evidence has established that Botticelli was born Alessandro di Mariano Filipepi in 1445 and that he was still in school in 1458 at the relatively advanced age of 13. Giorgio Vasari, a biographer of Renaissance Italian artists, reports that Botticelli's earliest training was in a goldsmith's shop, and a slender thread of evidence suggests that this may have been the shop of Apollonio di Giovanni and Marco del Buono, who are primarily known as manuscript illuminators and as painters of panels for wedding chests and furniture. Stock motifs from this shop recur in works that were produced by Botticelli and his shop, notably in the architectural frieze portraying the story of Horatius. Of Botticelli's subsequent apprenticeship to the painter Fra Filippo Lippi there is no doubt; most of Botticelli's earliest works have at one time or another carried an attribution to Lippi or his school, and in many cases the final attribution is still under debate. From Lippi, Botticelli learned a more intimately conceived version of the monumental and generalizing manner of the great innovator of Florentine painting Masaccio; the style that Botticelli learned owed much to Masaccio's handling of light and shade but was more concerned with detail and was directed to a softer sentiment. The influence of his Florentine contemporary Andrea del Verrocchio also is felt in Botticelli's earlier painting.

First commissions

By 1470 Botticelli had his own workshop. In that year he painted the "Fortitude" for the hall of the Arte di Mercanzia, a commission for which Piero Pollaiuolo, who painted six other Virtues, was primarily responsible; from this time the influence of the Pollaiuolo brothers may be seen in Botticelli's work. In 1472 Filippino Lippi (Fra Filippo's son) is mentioned as an apprentice in Botticelli's shop.

By January 1474 Botticelli had finished the "St. Sebastian," now in Berlin. From the beginning of the decade, the development of Botticelli's painting was characterized by a steady progression away from a full three-dimensional conception of a figure, lighted with softly blurred shadows, toward a conception based on low relief, bounded by continuous and rhythmic outline, the figure being lighted with bright and steady illumination. The "St. Sebastian" represents an early phase of this latter style, which is in close sympathy with the linear style of the Pollaiuoli.

Also in January 1474, Botticelli went to Pisa hoping to complete a series of frescoes begun by Benozzo Gozzoli for the Campo Santo, but he lost the commission, evidently because of dissatisfaction with an "Assumption of the Virgin" that he began for the Cappella dell'Incoronata in the Duomo, which he never finished and which was later destroyed.

The culmination of his career. "The Primavera," or "Allegory of Spring," painted about 1477, illustrates the next stage of Botticelli's development and "The Birth of Venus" (*c.* 1485) its culmination. Both were painted for the villa of Lorenzo di Pierfrancesca de' Medici at Castello; both are now in the Uffizi (Florence). The influence of the International style, a late-14th-century Gothic style in which natural details were rendered with vivid colour and realism, is a great part of the conception of "The Primavera" but is softened and subjected to Botticelli's new understanding of the art of antiquity. These three paintings—"Fortitude," "The Primavera," and "The Birth of Venus"—present Botticelli's art at its most familiar and most famous and are expressive of that quality for which it has always been primarily valued, whether characterized as "grace" as it was by Vasari in the 16th century, or described in terms of linear rhythm, as it was first by the English critic John Ruskin and later by art historians of the 20th century.

Characteristic paintings

In 1478 Botticelli painted a fresco (destroyed in 1494) of the conspirators hanged in the Pazzi uprising in 1478 in Florence. In 1480 he was commissioned by the Vespucci to paint, in competition with Ghirlandajo, the fresco of St. Augustine in the Church of the Ognissanti (where his father was buried two years later); and in 1481 he painted a fresco of the "Annunciation," which has since been detached, for the church of S. Martino della Scala.

From the summer of 1481 until the spring of 1482, Botticelli was in Rome at the invitation of Pope Sixtus IV to paint some of the papal portraits and three of the large frescoes on the wall of the Sistine Chapel, a commission in which such eminent painters as Perugino, Ghirlandajo, Cosimo Rosselli, Signorelli, Pinturricchio, and Piero di Cosimo also took part. While in Rome, he also painted a "St. Jerome" (now lost). The new understanding of ancient art that Botticelli combined with his earlier manner in "The Birth of Venus" was undoubtedly the result of this trip to Rome. In fact, his new acquaintance with the art of ancient Rome is strikingly evident in the frescoes he painted there, especially in the "Punishment of Korah" (Sistine Chapel, Vatican); in it a pedantic presentation of Roman forms and schemata (akin to Pinturricchio) is combined with harsh naturalism and monumentality. Although undoubtedly dictated by the nature and scale of the commission, these paintings are nonetheless counter to the direction his art had been taking and are among Botticelli's less happy efforts. It was not until several years after his return to Florence that he fully assimilated and most nobly expressed what he had learned in Rome with the paintings of the "Mars and Venus" and "The Birth of Venus" in 1485–86.

Botticelli returned to Florence by October 1482 with Perugino and Ghirlandajo; they were commissioned to paint, together with Piero Pollaiuolo and Biagio d'Antonio Tucci, the walls of the Sala dei Gigli in the Palazzo della Signoria, a project that was never realized. In 1483 Botticelli designed and supervised the painting of four panels for two wedding chests (cassoni) commissioned for the marriage of Giannozzo Pucci to Lucrezia Bini, and, at about the same time, he was again at work on a major fresco cycle with Perugino, Ghirlandajo, and Filippino Lippi, for Lorenzo the Magnificent's Villa della Spadaletto near Volterra.

By the end of 1484, Botticelli was at work on the "Virgin and Child with St. John the Baptist and St. John the Evangelist" for the Cappella di Agnolo de' Bardi in S. Spirito. The detached frescoes from the Tornabuoni-Lemmi Villa (now in the Louvre) were most probably painted in commemoration of the wedding of Lorenzo Tornabuoni in 1486. In 1487 he painted a tondo (circular painting), probably "The Madonna of the Pomegranate," for the Massai della Camera in the Palazzo della Signoria, and between 1488–90 he painted "The Annunciation" for the Guardi chapel in the Sta. Maria Maddalena dei Pazzi, as well as a "Coronation of the Virgin" for the Cappella di S. Eligio of the goldsmiths in the church of S. Marco.

In 1491 Botticelli served on a committee to decide upon a design for the facade of the Duomo of Florence, and in the same year he was commissioned to design the mosaic decoration for two vaults in the Cappella di S. Zenobius, which he did not complete. He and his brother Simone bought a house and some land near the gate of San Frediano in 1494. In 1495 he had an uncertain commission from Lorenzo di Pierfrancesco de' Medici to paint some things for his villa at Trebbio. In the summer of 1496 he painted a "St. Francis" in the convent of Sta. Maria di Monticelli near San Frediano, and in 1497 he was at work with some assistants on decorations for Lorenzo di Pierfrancesco's villa at Castello. He was living in Florence, in the quarter of Sta. Maria Novella, in 1498 (as is known from a tax return), and an entry in his brother's diary for 1499 indicates that Botticelli felt Savonarola's execution to have been unjust. In the same year he joined the Arte dei Medici e degli Speziali.

Late style and last years. Botticelli's late style—that is, his work of the last decade of the 15th century and the first decade of the 16th—is difficult to define, and its development is difficult to trace, in part because of the scarcity of fixed dates as points of reference. Early in the 1490s Botticelli worked to a grandeur of scale and conception that brought him, undoubtedly under the influence of new ideas being formulated in particular by Leonardo da Vinci, to the very brink of a High Renaissance style without quite passing into it.

Leonardo's influence

Although Botticelli's carefully orchestrated sequences of formal and emotional themes and responses reflect the influence of Leonardo, the latter's treatment of light and deep shadow, his sfumato, did not interest him. Particularly revealing in this respect are two paintings of the "Pietà," one in Munich (Alte Pinakothek) and the other in Milan (Museo Poldi Pezzoli). In these examples Botticelli's use of colour and light, his handling of masses, and his low-relief style much more closely anticipate the youthful manner of Michelangelo, as exemplified by his "Doni Madonna," than the manner of Leonardo. The Munich "Pietà" presents a grouping of figures and poses that is unmistakably related to the Flemish master Rogier van der Weyden's "Descent from the Cross" (Prado, Madrid) but conceived in a native Italian style, a hairbreadth away from the High Renaissance.

The extraordinary "Mystic Nativity" in London, dated to 1501, occupies a pivotal point in Botticelli's development. It shows him at work on a smaller scale, working with a richer and more deeply saturated colour scheme. His brushwork is looser, his forms more abstractly modelled, and space is conceived in a conventionalized manner, which has been described as archaic but which also, together with his new colour scheme, owes something to a renewed interest in the art of northern Europe. The painting carries an inscription in Greek, which indicates that the subject is not based on the biblical accounts of the Nativity in the Gospels but on the book of Revelations; moreover, the apocalyptic vision of St. John is recreated in the Italy of 1500.

This painting has been cited as evidence of Botticelli's involvement with Savonarola's theology (which also was apocalyptic), an argument that is fortified by the account of Botticelli's sympathy with Savonarola in his brother's diary and by Vasari's statement that he was a follower of him. The issue is not settled, however, and, while the "Mystic Nativity" is most unusual in its treatment of the subject, it also bears important iconographical parallels with the Flemish Hugo van der Goes's "Portinari Altarpiece," for example. The identification of the Madonna with the Apocalyptic Woman, moreover, is commonplace in 15th-century Italian art. Thus, the notion that Botticelli is creating a mystic style on Savonarolan example must remain suspect.

From a point in the mid-1490s, when he seemed on the verge of achieving a style in the "grand manner," Botticelli inexplicably retreated, beginning with "The Calumny of Apelles" of *c.* 1495, continuing with "The Tragedy of Lucretia" and "The Story of Virginia Romana," the "Mystic Nativity" of 1501, the "Magdalene at the Foot of the Cross," and ending with the latest paintings known by him, the series devoted to the life of St. Zenobius, now in London, New York, and Dresden. His progression is marked by an increasing diminution of scale and the adoption of consciously old-fashioned formats modelled on northern examples and on the conventions of the cassoni painters of his youth. He uses expressively and decoratively distorted figures conceived with no regard for anatomical verisimilitude. Also evident in his later work is the more deeply saturated colour scheme, based on rainbow hues, which has already been mentioned with reference to the "Mystic Nativity." Nothing, however, quite anticipates the St. Zenobius panels. In them Botticelli painted a series of visions in which the stylistic characteristics outlined above may roughly be said to apply but with significant modifications: the settings are rendered in a way that recalls the clarity of the earlier architectural perspectives attributed to the architect Luciano Laurana, and the works are painted in purely abstract and non-naturalistic colour planes that resemble the early-15th-century paintings of Fra Angelico. Botticelli

Retreat from the "grand manner"

peopled these panels with figures of the most intense simplicity and emotion.

Last years

Even in the last decade of his life, facts about Botticelli are still meagre. A letter of 1502 from Francesco de' Malatesti to Isabella d'Este suggested that she commission Botticelli to complete the decoration of her *studiolo,* noting him to be an excellent painter and at the moment unoccupied. In November of the same year Botticelli was accused of sodomy, but the charges were evidently dropped. He was a member of a commission appointed in 1504 to decide where to place the "David" of Michelangelo. That his financial situation was less than prosperous during these last years is demonstrated by the fact that, between 1503 and 1505, when he settled the account, he was behind in his payment of dues to the Compagnia di San Luca, the artists' confraternity. Botticelli died on May 17, 1510, and was buried in the Church of the Ognissanti, Florence.

The evidence clearly indicates that Botticelli had a successful career, following conventional lines, which brought him important patrons and financial rewards. The slight indications of financial unsteadiness from the last decade of his life tend to support Vasari's claim that Botticelli was careless of his money. His ecclesiastical commissions included work for all the major churches of Florence and were crowned by his being summoned to Rome on a papal commission to take part in the decoration of the Sistine Chapel; his private commissions included work for the Palazzo della Signoria, the administrative centre of Florence, and for various members of the Medici family. His chief patron was Lorenzo di Pierfrancesco, for whom, in addition to the works mentioned above, he undertook an important series of illustrations for Dante's *Divina commedia.*

Posthumous reputation. Botticelli lived in a time that saw a rapid and profoundly considered change in painting. Because he was of an older generation than the great fathers of the High Renaissance style, he cuts rather a poor figure in the criticism and historical accounts of the centuries following his death, insofar as he is mentioned at all. Not until the Pre-Raphaelite artists of late-19th-century England, particularly Dante Gabriel Rossetti, were his due merits recognized and acclaimed. The critics of that day and afterward, such as John Ruskin, Walter Pater, and Bernard Berenson, wrote the pioneering accounts analyzing his style, and these still form the foundation of modern criticism.

Botticelli's restoration to fame derived, however, from an aesthetic and historical attitude that was itself of a very particular colour and bias, one based on a highly romantic conception of the Florence in which he lived. Thus, there grew up around Botticelli an aura of myth and fantasy that arose from a highly individual and subjective reading of both the subjects and formal content of his paintings. Although modern art history has since done much to dispel this aura, part of its mystery and mystification still remains.

In the 20th century a great amount of scholarly attention has been concentrated on the complex problem of Botticelli's subject matter. Scholars have sought to isolate its sources in particular poetic and philosophical texts and in the understanding of these texts by the Humanists of the Medici circle. This done, they have gone on to seek an understanding of Botticelli's art through the measurement of the system of thought expressed in these texts against their expression in the style of Botticelli's paintings.

The most brilliant example of this approach was an essay by the German art historian Aby Warburg, which, of itself, established an entire school of art history. In an attempt to understand the historical and psychological import of the linear style of Botticelli and his contemporaries, Warburg subjected the texts behind "The Primavera" and "The Birth of Venus" to close philological scrutiny and then incorporated his findings into an analysis of Renaissance formulas for expressing emotion. Subsequent studies sought the basis of Botticelli's pictures in the poetry, philosophy, and scholarship of Humanists contemporary with him.

Warburg's contribution

Although the complexities of the imagery of Botticelli's paintings with religious subject matter have been fully appreciated, if not completely understood, primary attention has been focussed upon his paintings with Classical and mythological subject matter—in particular the "Mars and Venus," "The Primavera," and "The Birth of Venus."

The precise significance of the subjects of these paintings still remains a matter of vigorous debate, but this much can be said with confidence. The approach to the subject matter of these paintings is as new and as radically conceived as any of the contemporary innovations in style. The paintings are not mere illustrations of particular texts; rather, each depends upon several texts and upon attempts to define fully the particular nature of the subject depicted. Therefore, in "The Calumny of Apelles," some elements derive from the ancient Greek satirist Lucian, some derive from Guarino Veronese's translation of Lucian, and some derive from Leon Battista Alberti's paraphrase of Lucian, and other sources may be ascertained as well. Thus, Botticelli's conception of the painting may be seen to depend upon the disciplined gathering and collation of several texts. The same is true for "The Primavera" and "The Birth of Venus," which are founded in Lucretius, Horace, Ovid, and other Classical authors severally. Even these texts alone may be insufficient to explain Botticelli's imagery: contemporary philosophical exegeses of the gods may be required in order to reach a complete understanding of his remarkably unique paintings.

MAJOR WORKS

"The Madonna of the Guides of Faenza" (*c.* 1468; Louvre, Paris); "Judith and Holofernes," 2 panels (*c.* 1469; Uffizi, Florence); "Fortitude" (1470; Uffizi); "St. Sebastian" (1474; Staatliche Museen Preussischer Kulturbesitz, Berlin); "The Adoration of the Magi" (*c.* 1475; Uffizi); "The Primavera" ("Allegory of Spring"; 1477–78; Uffizi); "Portrait of a Young Man" (National Gallery, London); "Giuliano de' Medici" (probably after 1478; National Gallery of Art, Washington, D.C.); "Madonna of the Eucharist" (Isabella Stewart Gardner Museum, Boston); Sistine Chapel frescoes (1481–82; Vatican); "The Adoration of the Magi" (1482; National Gallery of Art, Washington, D.C.); "Pallas and the Centaur" (*c.* 1485; Uffizi); "The Madonna of the Magnificat" (*c.* 1485; Uffizi); "Mars and Venus" (*c.* 1485; National Gallery, London); "The Birth of Venus" (*c.* 1485; Uffizi); "Virgin and Child with St. John the Baptist and St. John the Evangelist" (1484–85; Staatliche Museen Preussischer Kulturbesitz, Berlin); "The Madonna of the Pomegranate" (*c.* 1487; Uffizi); "The Annunciation" (1488–90; Uffizi); "Coronation of the Virgin" (1490; Uffizi); "The Calumny of Apelles" (*c.* 1495; Uffizi); "St. Augustine in His Cell" (*c.* 1495; Uffizi); "The Tragedy of Lucretia" (*c.* 1499; Isabella Stewart Gardner Museum, Boston); "The Story of Virginia Romana" (1499; Accademia Carrara, Bergamo); "Magdalene at the Foot of the Cross" (*c.* 1500; Fogg Art Museum, Cambridge, Massachusetts); "Scenes from the Life of St. Zenobius" (*c.* 1500–05, including his latest known works; Gemäldegalerie, Dresden; National Gallery, London; and Metropolitan Museum of Art, New York); "Mystic Nativity" (1501; National Gallery, London).

FORSTER in *Jahrbuch der königlich preussischen Kunstsammlungen* (1887); EDGAR WIND in *Pagan Mysteries in the Renaissance,* rev. ed. (1967); and articles in the *Journal of the Warburg and Courtauld Institutes* by RUDOLF WITTKOWER, vol. 2 (1939), by E.H. GOMBRICH, vol. 8 (1945), and by CHARLES DEMPSEY, vol. 31 (1968). For further documentation Horne is especially valuable; see also the bibliographical references cited in the works of Salvini and Levey.

Bourbon, House of

The House of Bourbon is one of the greatest of the formerly sovereign dynasties of Europe. It provided reigning kings of France from 1589 to 1792 and from 1814 to 1830, after which another Bourbon reigned as king of the French until 1848; kings or queens of Spain from 1700 to 1808, from 1814 to 1868, and from 1874 to 1931; dukes of Parma from 1731 to 1735, from 1748 to 1802, and from 1847 to 1859; kings of Naples and of Sicily from 1734 to 1808 and of the Two Sicilies from 1816 to 1860; kings of Etruria from 1801 to 1807; and ducal sovereigns of Lucca from 1815 to 1847. The present article attempts a rapid survey of the dynasty as a whole, relying mainly on genealogical tables to display necessary details. In these tables the names and titles of sovereigns are mostly anglicized, but those of other persons are mostly given in the original form, except where princesses, having married into another country, are better known under that country's name for them. The tables also omit perforce the Bourbon bastards, whose multitude lends some colour to the popular notion that the "Bourbon nose" (larger and more prominent than the normal aquiline) betokens a "Bourbon temperament" or enormous appetite for sexual intercourse.

Origins. The House of Bourbon is a branch of the House of Capet, which constituted the so-called third race of France's kings. King Louis IX, a Capetian of the "direct line," was the ancestor of all the Bourbons through his sixth son, Robert count of Clermont (see Table 1). When the "direct line" died out in 1328, the House of Valois, genealogically senior to the Bourbons, prevented the latter from accession to the French crown until 1589. The Valois, however, established the so-called Salic Law of Succession, under which the crown passed through males according to primogeniture, not through females. On this principle, the senior Bourbon became the rightful king of France on the extinction of the legitimate male line of the Valois.

The first ducs de Bourbon

Robert of Clermont had married the heiress of the lordship of Bourbon (Bourbon-l'Archambault, in the modern *département* of Allier). This lordship was made a duchy for his son Louis I in 1327 and so gave its name to the dynasty. From this duchy, the nucleus of the future province of Bourbonnais, the elder Bourbons, mainly through marriages, expanded their territory southeastward and southward. On their western frontier, meanwhile, the countship of La Marche (acquired by Louis I in 1322 in exchange for Clermont) was held from 1327 by a junior line of Louis I's descendants, who soon added the distant countship of Vendôme to their holdings.

The title of duc de Bourbon passed in 1503 to Charles de Bourbon-Montpensier, who was to become famous as constable of France. His later treason led to the confiscation of his lands by the French crown in the year of his death, 1527. Headship of the House of Bourbon then passed to the line of La Marche-Vendôme (see again Table 1).

Table 1: The Bourbon Descent from Louis IX of France

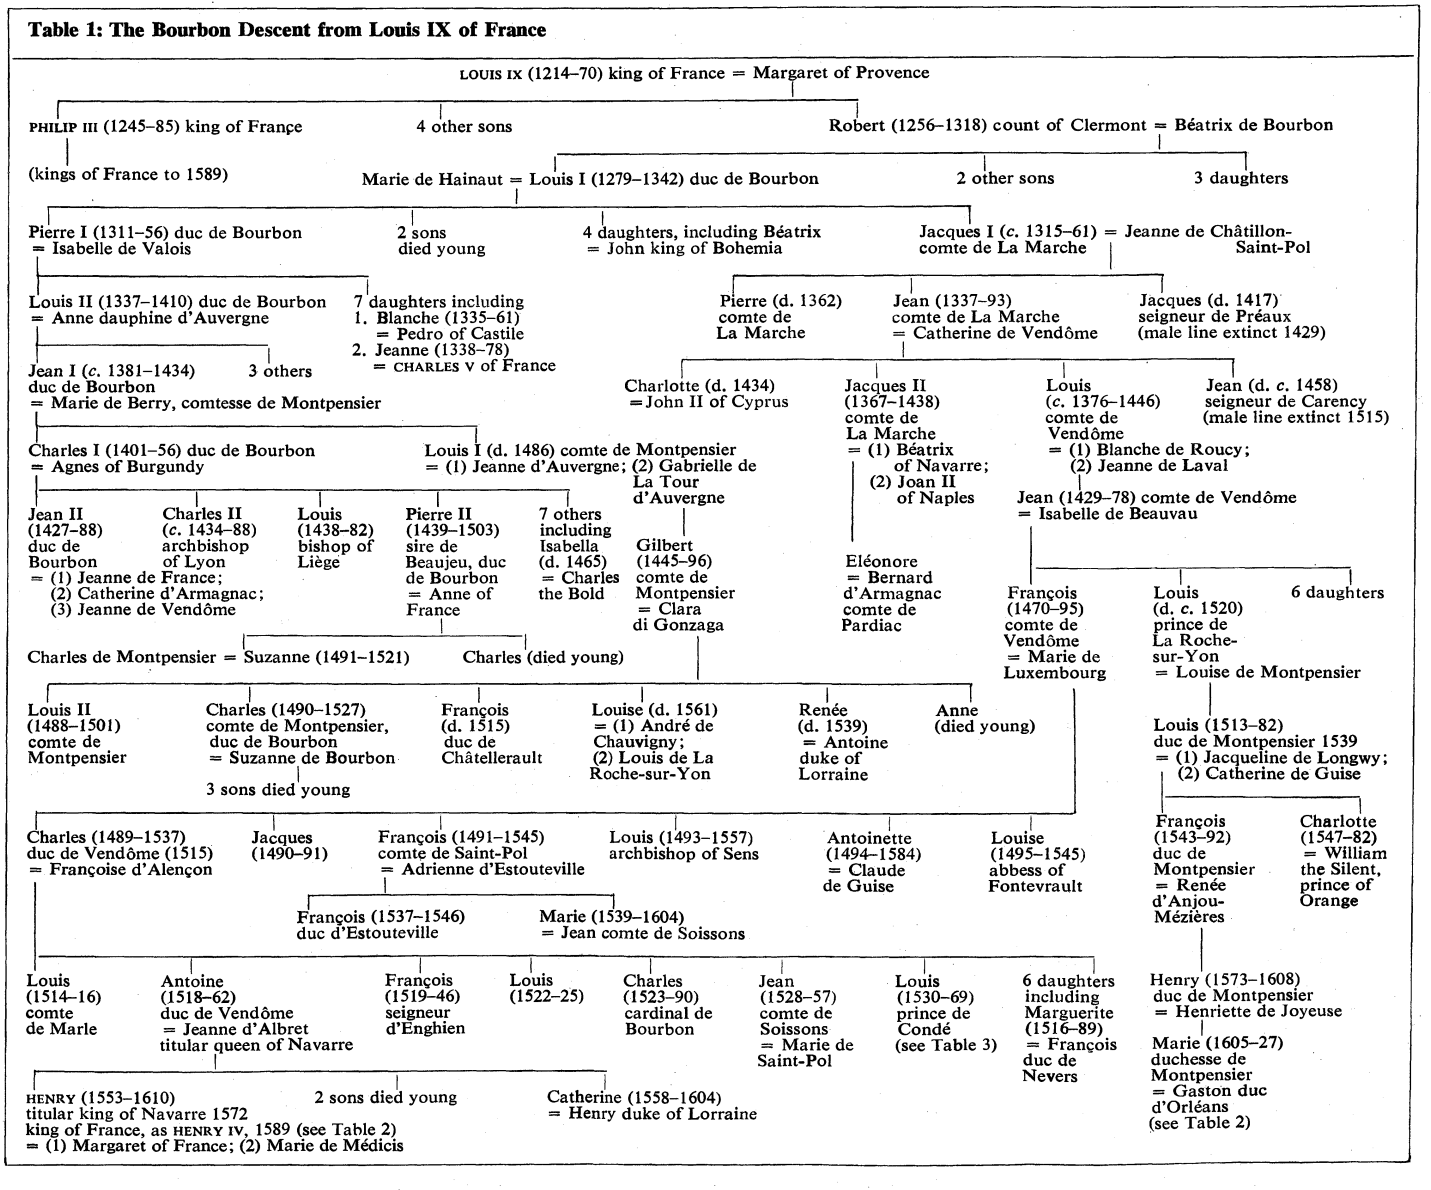


Table 2: The Bourbon Kings of France, with the House of Orléans to 1830

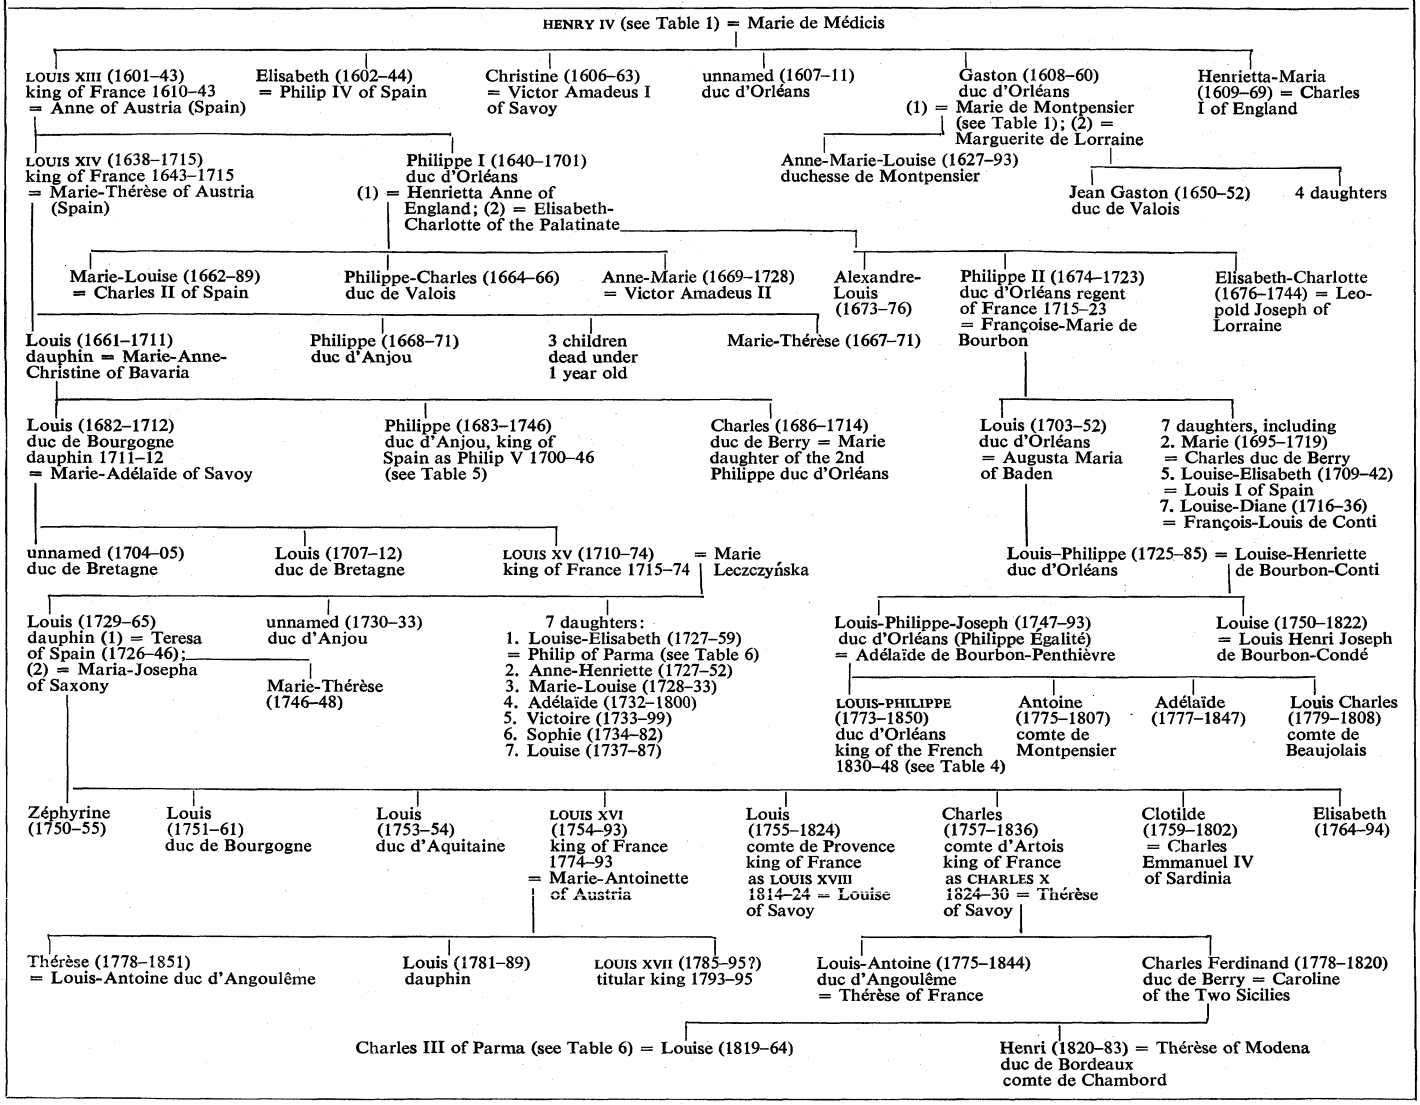

The line of La Marche-Vendôme had been subdivided since the end of the 15th century between a senior line, that of Vendôme (with ducal rank from 1515 onward), and a junior one, that of La Roche-sur-Yon. The latter line obtained Montpensier from the constable's forfeited heritage (with ducal rank from 1539).

Antoine de Bourbon, duc de Vendôme and head of the House of Bourbon from 1537, became titular king-consort of Navarre in 1555 through his marriage in 1548 to Jeanne d'Albret. The son of that marriage, titular king of Navarre in succession to his mother from 1572, became king of France, as Henry IV, on the death of the last Valois king in 1589. From Henry IV descend all the Bourbon sovereigns (see Tables 2 and 4–7). The great House of Condé, with its ramifications of Soissons and of Conti (see Table 3), was descended from one of Henry IV's uncles.

The French kingdom

The Bourbon Sovereignties. Henry IV's heirs were kings of France uninterruptedly from 1610 to 1792, when the monarchy was "suspended" during the first Revolution. Most illustrious among them was Louis XIV (*q.v.*), who brought absolute monarchy to its zenith in western Europe. Table 2 displays (1) the senior line of Bourbon, or House of France, as descended from Henry IV, the succession running directly down to Louis XVII (who never reigned), and thereafter being resumed in Louis XVIII (brought to the throne in 1814 and again in 1815), Charles X, and the pretender Henry V (the comte de Chambord); (2) the connection, through Louis XIV's grandson Philippe duc d'Anjou, of the Spanish Bourbons with the House of France; and (3) the descent of the collateral House of Orléans from Louis XIV's brother Philippe I to Louis-Philippe king of the French. Louis-Philippe's descendants, including not only the potential pretenders to the French succession but also the Bourbon descendants of the heiress of the last emperor of Brazil, are shown in Table 4. The last-mentioned princes constituted the House of Bourbon-Brazil, or of Orléans-Braganza, which is not to be confused with the House of Borbón-Braganza, a Spanish branch originating in the Portuguese marriage of the infante Don Gabriel (a son of Charles III of Spain; see Table 5).

Accession in Spain

The Bourbon accession to Spain came about partly because the descendants of Louis XIV's consort, the Spanish infanta Marie-Thérèse, were in 1700 the closest surviving relatives of the childless Charles II of Spain (see HABSBURG, HOUSE OF; SPAIN, HISTORY OF); and partly because, although at her marriage the Infanta had renounced her Spanish rights, Charles by his testament named one of her descendants as his successor. Since the other powers, however, would not have tolerated the union of the Spanish kingdom with the French, Charles named neither Louis XIV's heir apparent nor the latter's eldest son, but rather the second of Louis XIV's grandsons, namely Philippe duc d'Anjou, who became king of Spain as Philip V. After the War of the Spanish Succession, the Peace of Utrecht (1713) left Philip in possession of Spain and Spanish America but obliged him to re-

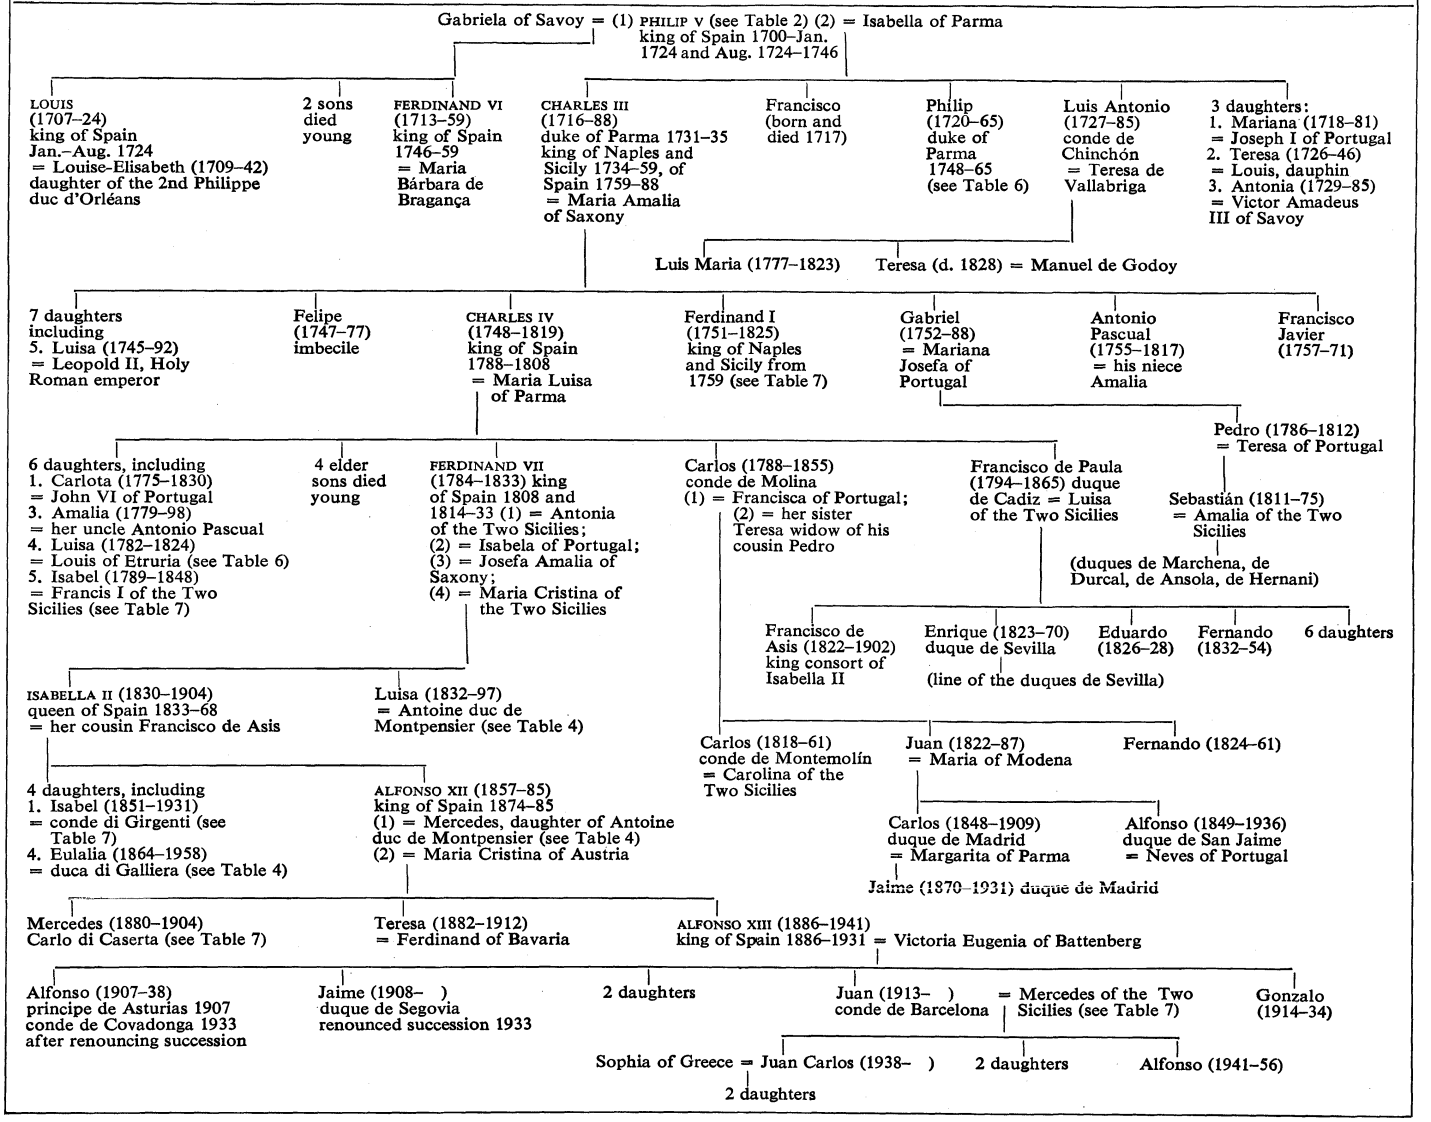
Table 5: The Spanish Bourbons



nounce any natural right that he or his descendants might have to France. Table 5 shows how the Spanish Bourbons all descend from Philip V; it also shows the origin of the branches of Parma and of Naples-Sicily.

Parma and Naples-Sicily

The infante Don Carlos, the future Charles III of Spain, was the founder of the Bourbon fortunes in Italy. The eldest son of Philip V's second marriage, he became duke of Parma in 1731 by right of his mother, heiress of the last Farnese dukes; and in 1734, during the War of the Polish Succession, he conquered the Kingdom of Naples-Sicily (Kingdom of the Two Sicilies) for himself. Though the settlement of 1735–38 obliged him to renounce Parma in order to win international recognition as king of Naples-Sicily, Parma was eventually secured for his brother Philip (Don Felipe) under the Treaty of Aix-la-Chapelle in 1748—with the proviso, however, that he and his heirs should renounce it in the event that they succeeded to Naples-Sicily or to Spain. Finally, when Don Carlos became king of Spain as Charles III in 1759, he resigned Naples-Sicily to his third son Ferdinand on the express condition that that kingdom and Spain should never be united under one sovereign.

Table 6 shows the descendants of Philip of Parma, Table 7 those of Ferdinand I of Naples–Sicily.

Etruria and Lucca

The Kingdom of Etruria (1801–07) was a contrivance of the Napoleonic period. Devised by the French for the House of Bourbon-Parma in compensation for the impending annexation of Parma to France at a time when France still needed the goodwill of the Spanish Bourbons, it was dissolved as soon as Napoleon was ready to depose the latter. The Bourbon Duchy of Lucca (1815–47), on the other hand, was a creation of the Congress of Vienna: having assigned Parma to Napoleon's estranged consort Marie-Louise for her lifetime, the Congress had to find some alternative compensation for the still-dispossessed Bourbons. The Treaty of Paris of 1817, however, prescribed that on Marie-Louise's death Parma should revert to the Bourbons, who in 1847 renounced Lucca to the Habsburgs of Tuscany nine weeks before succeeding her (see again Table 6).

In France, the senior or "legitimate" line of the Bourbons, restored to sovereignty in France after the Napoleonic Wars, was deposed at the Revolution of 1830. The House of Orléans, which took the legitimate line's place, was in turn deposed in the Revolution of 1848. The Bourbons of Parma and of the Two Sicilies were dethroned in 1859–60, in the course of the unification of Italy under the House of Savoy. The Spanish Bourbons, after many disturbances in the 19th century, lost their sovereignty in 1931; but the Law of Succession promulgated in Spain in 1947 and General Franco's subsequent gestures in favour of Don Juan Carlos (see again Table 5 and SPAIN, HISTORY OF) gave solid grounds for expecting a Bourbon restoration in the 1970s.

Solidarity and discord. The accession of the duc d'Anjou to Spain would never have been secured without the

resolute support of his grandfather, the French king; and similarly the Bourbon sovereignties in Italy owed their establishment chiefly to the Bourbon power in Spain. Dynastic harmony between France and Spain, however, was momentarily suspended in 1718–20, when France took part in the War of the Quadruple Alliance against Spain—for reasons arising in part from the internal affairs of the House of Bourbon. A series of sudden deaths in the French Royal House between 1704 and 1714 had produced a situation in which, on Louis XIV's death in 1715, no one but a five-year-old child, Louis XV, stood before Philip V of Spain in the natural line of succession of France; and Philip, though he had renounced that succession, still felt himself better entitled, as the child's uncle, to exercise the regency in France than the child's cousin twice removed, Philippe duc d'Orléans, against whom Spanish agents promoted a plot. The marriage (1722) of the Spanish king's son to a daughter of the French regent sealed the reconciliation.

In 1733 the Treaty of the Escorial pledged the French and the Spanish Bourbons to collaborate with each other notwithstanding any previous obligations. This treaty and the similarly conceived Treaty of Fontainebleau (1743) are sometimes called the "First" and the "Second Family Compact"; and the term Family Compact, or Pacte de Famille, was actually used in a third treaty, signed in Paris in 1761, during the Seven Years' War. By this last treaty France and Spain not only guaranteed one another against all enemies but also promised like protection to the Bourbon states in Italy in the event of their acceding to the compact; and no state not belonging to the House of Bourbon was to be allowed to accede.

Cooperation between French and Spanish Bourbons came to a miserable end in the French Revolutionary and Napoleonic Wars (*q.v.*), and the later decades of the 19th century brought new complications. A French Bourbon prince led a force into Spain in 1823 to crush the liberalism to which Ferdinand VII was succumbing; but such Bourbon solidarity could not survive two events which were to rend both the Spanish and the French houses.

First, in March 1830, Ferdinand VII of Spain announced the revocation of the Salic Law of Succession, which Philip V had introduced into Spain in 1713. This meant that the sonless Ferdinand could be succeeded not by his brother Don Carlos conde de Molina but by his elder daughter Isabella (born after the revocation); and though Ferdinand temporarily reinstated the Salic Law in September 1832, he revoked it again 13 days later. On his death in 1833 the partisans of the disappointed Don Carlos started the first of the Carlist Wars in protest against Isabella's accession (see again SPAIN, HISTORY OF).

Carlism and the House of Orléans

Secondly, in France, the July Revolution of 1830 overthrew the "legitimate" Bourbon monarchy and transferred the throne to Louis-Philippe, head of the collateral line of Orléans. Odious enough already because Louis-Philippe's father, the self-styled Philippe Égalité, had voted in 1793 for the death sentence on Louis XVI, the House of Orléans became, by the usurpation of 1830, so much more odious to the Legitimists that some of the latter, when the "legitimate" male of France died out with the comte de Chambord in 1883, declined to recognize the head of the House of Orléans as the rightful pretender to France, as indeed he now was if the renunciation of 1713 was still to be observed (see again Tables 3 and 4); instead they preferred to disregard that renunciation and so to regard a Spanish prince as their rightful king. These Legitimists were known in France as "Blancs d'Espagne" ("Spanish Whites"). Most Legitimists, however, followed the final advice of the comte de Chambord by recognizing the rights of the House of Orléans to France.

While the dispossessed Bourbons—Spanish Carlists and French Legitimists—naturally sympathized with each other, their opponents—Queen Isabella and the House of Orléans—conversely gravitated together. One result was the crisis of the "Spanish Marriages" in the 1840s. While both Queen Isabella and her sister Luisa remained unmarried, the Spanish succession was an open prospect of great interest to governments concerned with maintaining the balance of power in Europe. If both sisters had married princes of the House of Orléans, as Louis-Philippe and the sister's mother, Maria Cristina, had originally suggested, French influence over Spain would have become too strong for the liking of the British government, which proposed instead that Isabella should marry Prince Leopold of Saxe-Coburg (more intimately linked with Great Britain than with France). Then, in 1843, the French and the British came to an understanding: Isabella should marry some "neutral" prince, preferably a Spanish Bourbon cousin; and only after the birth of a child to Isabella should Luisa marry Louis-Philippe's son Antoine duc de Montpensier. Of Isabella's eligible cousins, the conte de Montemolín was disfavoured by the Spanish government as a Carlist; the next senior was the doubtfully virile Don Francisco de Asis, who was generally thought unlikely to become a father; the third was

Table 6: The Bourbons of Parma

PHILIP (see Table 5) = Louise Elisabeth of France (see Table 2)
duke of Parma 1748–65

- Isabella (1741–63) = Joseph, later Holy Roman emperor

  - 4 daughters, including: Carolina (1770–1804) = Maximilian of Saxony
  - LOUIS (1773–1803) king of Etruria 1801–03 = Luisa (1782–1824) regent of Etruria 1803–07, duchess of Lucca 1815–24
    - Teresa of Savoy = CHARLES (1799–1883) king of Etruria 1803–07, duke of Lucca 1824–47, duke of Parma 1847–49
      - Luisa Francesca (1821–28)
      - CHARLES III (1823–54) duke of Parma 1849–54 = Louise daughter of last duc de Berry (see Table 2)
        - Margarita (1847–93) = Carlos duque de Madrid (see Table 5)
        - ROBERT (1848–1907) duke of Parma 1854–59
          - 11 children by Pia of the Two Sicilies, including
            1. Maria Luisa (1870–99) = Ferdinand of Bulgaria
            4. Enrico (1873–1939)
            8. Giuseppe (1875–1950)
            10. Elias (1880–1959)
          - 12 children by Antonia of Braganza, including
            2. Sixtus (1886–1934)
            3. Francis Xavier (1889–
            5. Zita (1892–) = Charles emperor of Austria
            6. Felix (1893–1970) = Charlotte of Luxembourg
        - Alicia (1849–1935) = Ferdinand IV of Tuscany
        - Enrico (1851–1905) conte di Bardi
    - Luisa (1802–57) = her aunt's widower Maximilian of Saxony

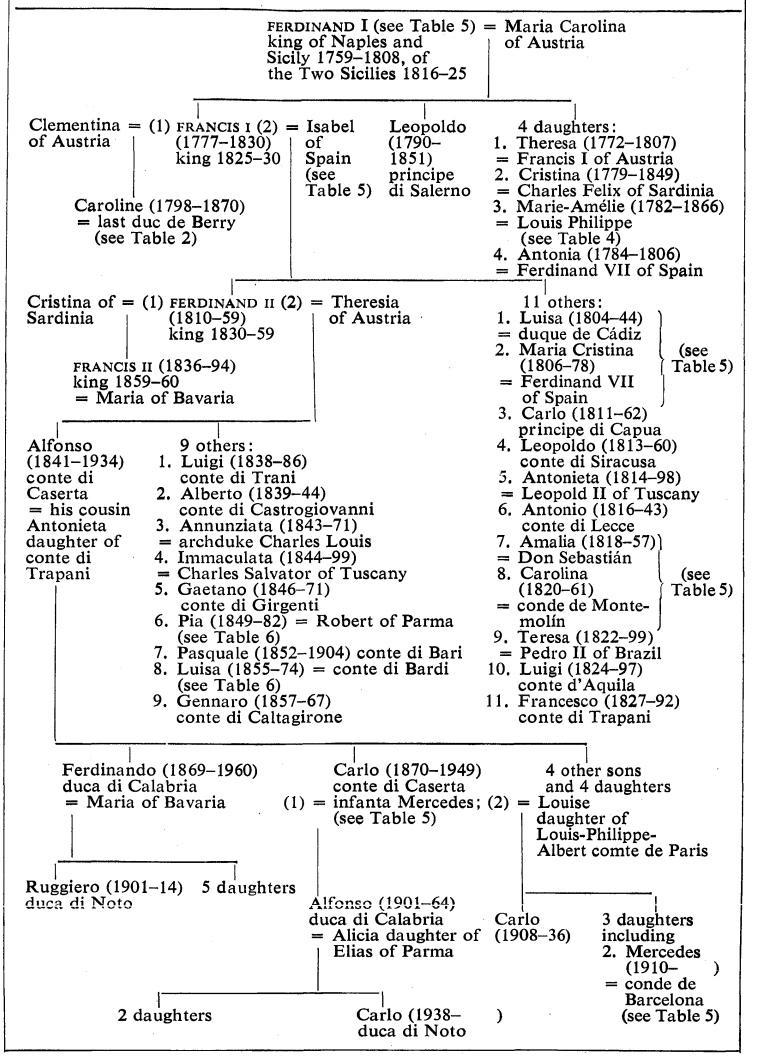
Don Enrique duque de Sevilla, whose outspoken liberalism recommended him to the British government but not to the Spanish. Inadvertently, however, the British government in 1846 gave the French the impression that it was still secretly trying to press Prince Leopold on Spain, and the French reacted by arranging the Spanish marriages in a way quite contrary to British desire: Isabella and Luisa were married on the same day, Oct. 10, 1846, to Don Francisco de Asis and to Montpensier respectively. The immediate upshot was that the House of Orléans, apparently intending that Montpensier or a son of his should eventually be king of Spain, incurred the serious resentment of its former friends in Great Britain.

Isabella, who would have preferred to marry Don Enrique, spent conspicuously long periods apart from her consort and behaved indiscreetly with other men. When she bore a son in 1857, ill-wishers were able to cast doubts on his paternity. These doubts served the purposes of the extreme Carlists when the male line of Don Carlos died out in 1936, because they could argue that Isabella's male descendants were not those of Don Francisco de Asis—whose issue, under Salic Law, would have been the next male heirs. Nearly all the other Bourbon princes, however, either had already recognized Isabella's rights or were maintaining incompatible pretensions to other thrones. The Carlists therefore had to look far afield in their search for a new pretender.

Carlism and Bourbon-Parma

Certain princes of Bourbon-Parma responded to Carlist overtures but did not at the same time renounce their Parmesan titles, which under the settlement of 1748 were

Table 7: The Bourbons of the Two Sicilies



incompatible with pretension to Spain. Thus they incurred the displeasure of the House of Orléans, which had to respect the settlement of 1748 because its own pretension to France depended on the analogous settlement of 1713.

BIBLIOGRAPHY. For the English reader in the 20th century, an introduction is provided by SANCHE DE GRAMONT, *Epitaph for Kings* (1968). Those interested in genealogy may readily consult H. VRIGNAULT, *Généalogie de la maison de Bourbon*, 2nd ed. rev. (1957), with 12 tables; and, on the bastard branches, *Légitimés de France de la maison de Bourbon de 1594 à 1820* (1965). Vrignault's work of 1957 may be brought up to date through the successive volumes of the periodical *Genealogisches Handbuch des Adels*, series "Fürstliche Häuser," whose first article "Bourbon" appeared in 1953 (vol. 2 of the series, 3 of the collection). While the story of the French Bourbon sovereigns is too vast to be resumed collectively in any single work other than a history of France, there are helpful works in English on the Spanish Bourbons and on the Neapolitan: SIR CHARLES PETRIE, *The Spanish Royal House* (1958), supplemented by T. ARONSON on the Carlist question, *Royal Vendetta: The Crown of Spain, 1829–1965* (1966); and HAROLD ACTON, *The Bourbons of Naples, 1734–1825* (1956) and *The Last Bourbons of Naples, 1825–1861* (1961). Of the many popular and suggestive writings on the physiological aspect, the reader may first consult A. DE MARICOURT and M. DE BERTRANDFOSSE, *Les Bourbons, 1553–1830: hérédité, pathologie, amours et grandeur* (1937).

(J.R.-S.)

Bourguiba, Habib

Habib Bourguiba, the architect of Tunisia's independence, and its first president, combined great gifts of leadership with rare organizational ability to free his country from French rule. He was born, the seventh child of Ali Bourguiba, a former lieutenant in the army of the bey (ruler) of Tunisia, at al-Munastīr, a small fishing village, on August 3, 1902. Sent to Tunis at an early age, he received a good education in Arabic and in the foundations of Islām, as well as in French and in Western thought.

Between 1924 and 1927 Bourguiba studied law and po-

Bourguiba.

litical science at the Sorbonne, in Paris, where he established contacts with a number of French liberals and with Algerians and Moroccans who were working for the independence of their countries.

For seven years after his return to Tunis, in 1927, Bourguiba practiced law and founded, in 1932, a nationalist newspaper in French. In 1934, when it became apparent that the leading nationalist political group, the Destour (Constitution) Party, was unable to make headway in the struggle for independence, Bourguiba and his younger colleagues seceded and established the Neo-Destour Party, with Bourguiba as its secretary general. He would become its president 14 years later.

Role in the struggle for independence

From 1934 onward, Bourguiba was the central figure in the Tunisian national struggle. In his work he showed integrity, persistence, consistency, and courage. A practical man, he believed in doing things in stages, and his gradualist policy came to be known as "Bourguibism." It was he who in one word formulated the demands of the Tunisians: independence. Under him the people came to identify with the national movement that had been almost a monopoly of the urban elite. An exceptionally able organizer, Bourguiba not only established branches of the party in out-of-the-way villages, but, realizing that the French government would resort to repressive measures, he also saw to it that a new set of party executives would always fill the vacuum created by arrest or exile. Between 1934 and 1952 nine such groups succeeded one another, thus keeping the struggle alive; Bourguiba himself spent about ten years in detention during this period (1934–36, 1938–42, 1952–55).

Imprisoned in Vichy, France, at the outbreak of World War II, Bourguiba refused to throw in his lot with the Axis powers unless they declared Tunisian independence first. He was convinced that the Allies would win the war and strove to keep Tunisia neutral.

In 1945–46 and 1951 Bourguiba travelled extensively in the Middle East, the United States, the Far East, and Europe, publicizing the cause of Tunisian independence.

When, in 1952–54, the nationalists increasingly took to terrorism, the French government became seriously concerned. Repression ceased to be effective, and in 1954 the government of Pierre Mendès-France began negotiations with Bourguiba; in April 1955 he secured autonomy for his country from Edgar Faure, Mendès-France's successor. Foreign affairs and defense were reserved for France.

President of Tunisia

On March 20, 1956, Bourguiba, following his policy of gradualism, concluded, with Guy Mollet, the French premier, a treaty giving Tunisia its independence. In 1957 agreement in principle for evacuation of the French forces from Tunisia, except Bizerte, was reached. Since the abolition of the monarchy in 1957, Bourguiba has been elected three times president of Tunisia. In 1959 he gave Tunisia a constitution in which, while retaining Islām as the state religion, he abolished polygamy, controlled divorce, and would not allow the month-long fast of Ramaḍān to curtail workers' productivity.

Bearing in mind the need to economize as well as the danger from military coups, Bourguiba has kept the Tunisian army small. Tunisia's defense expenditures have never exceeded 5 percent of the budget, while education and agriculture usually receive 25 percent each and health even a little more. One of the most successful of his projects is the settlement of about 50,000 nomads in southern Tunisia, which under French rule was under military administration. He divided the country into 14 provinces under civilian administration with modern administrative laws.

Since Tunisia depends for its development on foreign aid from various sources, Bourguiba observes a policy of neutrality. Intellectually, culturally, and educationally, however, Tunisia leans toward France. Yet after independence two incidents imperilled Tunisia's close ties with that country.

In 1961, probably in response to pressures by other Arab leaders, Bourguiba asked France to evacuate Bizerte, which, according to the agreement on independence (1956), was to remain a French military and naval base. When the French did not immediately respond, he ordered an attack on their forces, which returned the fire. Over two years later Bizerte was evacuated, but at the cost of more than 1,000 Tunisian lives. The nationalization of all land still owned by French settlers in 1964 further strained relations with France. The evacuation of Bizerte caused economic loss to Tunisia by cutting off a source of revenue from France, but Bourguiba apparently gained in prestige.

For many years Bourguiba has been a controversial figure in Arab politics, primarily because he takes a courageous and independent stand against "unanimous" decisions or dictates by the Arab League, but also possibly because he cuts a figure on the international scene far bigger than in his own country.

Bourguiba believes in a moderate form of socialism, which he is trying to introduce into Tunisia. In the mid-1960s Tunisia tried a strict form of agricultural cooperatives and state control of trade and industry, but the result was disastrous and Bourguiba has gone back to his more deliberate methods. There is, however, far from unanimous agreement that Bourguiba owes his overall success, both domestically and in foreign affairs, to his gradualist approach. Some feel that his method would not work for a leader who did not possess both Bourguiba's fighting spirit and his great gifts as a negotiator, as well as an integrity that has made some of his former opponents, even such as Premiers Mendès-France and Edgar Faure, his friends and admirers.

> He achieved stability for his regime by a combination of moderation in all things and shrewdness in judging men and events. . . . he judiciously permitted private capital to operate side by side with government-run economic enterprises. He shied away from creating a military Frankenstein monster, and succeeded in obtaining economic assistance from France, the United States, West Germany, and other nations. In his dealings with his benefactors he is dignified, appreciative, and gracious; he often goes out of his way to demonstrate his deep gratitude. (Samuel Merlin in *The Search of Peace in the Middle East.*)

BIBLIOGRAPHY. Unfortunately there is not as yet a really good biography of Bourguiba, although there are a number of essays on him: FELIX GARAS, *Bourguiba et la naissance d'une nation* (1956), an attempt to explain Bourguiba's struggle and his leadership of the national movement in Tunisia to the beginning of the serious negotiations with France; JEAN LACOUTURE, *Cinq hommes et la France* (1961), a work that explains the role of Bourguiba in Tunisian national life; SAMUEL MERLIN, *The Search for Peace in the Middle East*, ch. 13–32 (1968), a penetrating study of Bourguiba's Arab policy and of his statements on Arab-Israeli relations made on his tour of the Arab East, Iran, Turkey, and Greece in 1965.

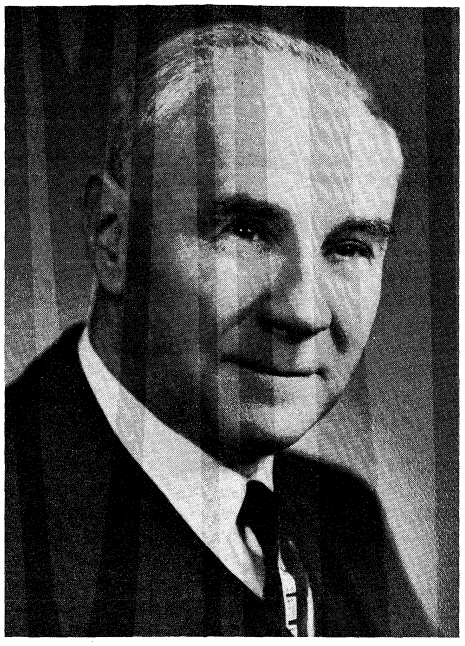
(N.A.Z.)

Bowen, Norman Levi

Norman Levi Bowen, petrologist and mineral chemist, ranks as the great pioneer investigator in the field of experimental petrology, the science that deals with the origin, history, occurrence, structure, chemical composition, and classification of rocks. His contributions in this field were unique; no one else broke so much new ground or contributed in such rich measure to the solution of fundamental problems of petrogenesis (rock origins).

Bowen was born at Kingston, Ontario, on June 21, 1887, the son of W.A. Bowen, who had emigrated to Canada from London. Educated at Queen's University, Kingston, he specialized in chemistry, mineralogy, and geology. When he won an 1851 International Exhibition Scholarship, he proceeded to the Massachusetts Institute of Technology, Cambridge. He spent 1910–11 at the Geophysical Laboratory of the Carnegie Institution of Washington, D.C., undertaking experimental studies of a mineral group (a silicate system, nepheline–anorthite), which formed part of a thesis submitted for his Ph.D. degree at the Institute in 1912. In all, Bowen spent six summers in the field during his university career (1907–12), working in Canada for the Ontario Bureau of Mines and for the Geological Survey of Canada in British Columbia along the Canadian Pacific Railway.

After completing his doctorate, Bowen returned to the Geophysical Laboratory in Washington. The nature of



Bowen.
By courtesy of Queen's University at Kingston, Ontario

the work at the laboratory enabled him to avoid having to make an outright choice between geology and chemistry. By 1915 he had executed a group of experimental studies that proved to be critically important to petrology and formed the basis of his critical review *The Later Stages of the Evolution of the Igneous Rocks* (1915), a paper of such outstanding merit that it established Bowen's position at the age of 28 as an international figure in petrology.

The United States' entry into World War I in 1917 deflected Bowen's researches into the study of optical glass, which had become a research priority, and he worked for a time in the glass plant of the Bausch and Lomb Optical Company.

After the war ended, he resigned from the Geophysical Laboratory to return briefly to Queen's University, as professor of mineralogy (1919), but after two years he returned again to the laboratory in Washington.

Work on silicate systems

There he remained for 16 years, broadening his attack on silicate systems. His researches carried great weight when he applied his experimental physicochemical data to field petrological problems. To this end he diligently visited classical localities relating to problems of igneous rocks: the Bushveld of South Africa, the alkalic lavas of East Africa, and the peridotites of Skye and the Fen area of Norway. He was perfectly suited to a lifetime of work in a research institution. Quiet and retiring in disposition, he enjoyed the sheltered environment such an institution can offer, one in which he could spend his days almost uninterruptedly on the research he loved.

In the spring of 1927, Bowen delivered a course of lectures to advanced students in geology at Princeton University, the substance of which was published in 1928 as *The Evolution of the Igneous Rocks.* In this vigorous presentation, Bowen provided a survey and a synthesis that have exerted a profound influence on petrologic thought. Later Bowen collaborated extensively with J.F. Schairer, a young and able experimenter who had joined the laboratory from Yale University. Together they worked on silicate systems containing iron oxide, beginning with ferric oxide and later ferrous oxide.

Work at the University of Chicago

Bowen made a second and more extended break from the Geophysical Laboratory when he was attracted to fill the Charles L. Hutchinson Distinguished Service Professorship of petrology at the University of Chicago, where he remained from 1937 to 1947. He rapidly developed a school of experimental petrology there and produced a succession of papers by his pupils that dealt with equilibrium studies of alkali systems. Bowen himself presented a synthesis of these results in their bearing on the origin and differentiation of alkaline rocks (1945).

After World War II, Bowen was induced to return once more to the Geophysical Laboratory in 1947 to cooperate in research on mineral systems embracing volatiles, particularly water. This work culminated in studies (published in 1958), with O.F. Tuttle as a collaborator, on the granite system.

Bowen's association with the Geophysical Laboratory extended in all more than 35 years, and his long and splendid record was recognized by the award of honours from learned societies in the United States and Europe.

After his retirement in 1952, he moved to Clearwater, Florida, but a year later returned to Washington. Despite poor health, he was still active and had an office in the Geophysical Laboratory as research associate until his death on September 11, 1956.

(C.E.T.)

Bowling

The name bowling covers a number of games of common but complex origins in which a ball is rolled down a long narrow lane with one of two general aims. One of these, in the game of bowls or lawn bowling, is to have the ball come to rest near a stationary ball called a jack; the other, in tenpins, commonly known as bowling, is to knock down more wooden pins than an opponent. One form or another of these games is probably played by more peoples of the world than any other, with the possible exception of soccer football. Tenpins, the most widely played variation, is the principal form of bowling in the United States, Canada, Japan, the Scandinavian countries, Mexico, Australia, and Central and South America. Its many variations include duckpins, candlepins, fivepins, skittles, and ninepins, and differences within the framework of each of the games. Lawn bowling, the most widely played of bowls games, in a sense is akin to curling on ice. Both are among the earliest known outdoor pastimes.

HISTORY

Origins and early history. Bowling has been connected to articles found in the tomb of an Egyptian child buried in 5200 BC. The primitive implements included nine pieces of stone, to be set up as pins, at which a stone "ball" was rolled, the ball having first to roll through an archway made of three pieces of marble. Another ancient discovery was the Polynesian game of Ula Maika, also utilizing pins and balls of stone. The stones were rolled a distance of 60 feet (18 metres), a distance which is, by coincidence, the regulation length of the modern tenpin bowling lane.

Still another ancient form of bowls was played in the Italian Alps about 2,000 years ago. It involved the underhand tossing of stones at an object, differentiating it from the rolling of the stones, and is believed to have been the origin of boccie, still a widely played game in Italy and among persons of Italian descent around the world. The Basque *quilles*, another of the ancient European games, originated as an outdoor pastime using a wooden ball, probably made from tree roots, with a slot-like grip. The player held onto the ball as he swung it against the first of nine three-foot-tall pins arranged in a large rectangular court. As that pin fell, hopefully to knock down its neighbour, the player rolled the ball toward the center of the court, trying to apply reverse spin that would send the ball ricocheting against several other pins. The pins were arranged in three rows of three each.

Origin of boccie

Bowling at pins. Bowling at pins probably originated in ancient Germany, not as a sport but as a religious ceremony. It has been conjectured that as early as the 3rd or 4th century AD, in rites held in the cloisters of churches, parishioners placed their ever-present club or *Kegel* (the implement most Germans carried for sport and, certainly, self-protection) at one end of a runway resembling today's bowling lane. The *Kegel* was said to represent the *Heide*, the "heathen." A stone was rolled

at the *Heide*, and those successfully toppling it were believed to have cleansed themselves of sin. The practice, described in the chronicles of Paderborn, evidently lasted less than two centuries. But the activity persisted as a pastime and eventually was taken up by the nobility and landed gentry. Although the peasants' club evolved into pins, the association remained and even today bowlers often are referred to as "kegelers."

The passage of time brought an increase in the size of the stone rolled at pins and eventually the ball came to be made of wood. In 1300, according to German historians, in some sections of Germany a game was played with three pins; in others as many as 17 were used. Martin Luther is credited with settling on the idea that nine was the ideal number of pins. A biographer of the 16th-century cleric has written that Luther found little time for recreation, yet

> to the young people in his family and household he gladly allowed recreation and even built a bowling lane for them and occasionally visited them while they were bowling and now and then threw the first ball . . . .

There are numerous ancient references to bowling, among them an account of a great feast given the citizenry of Frankfurt in 1463, at which the venison dinner was followed by bowling. Notations on papers dating to 1325 in which "gambling on bowling" was limited to five shillings have been discovered. In 1518, the city of Breslau (now Wrocław, Poland) gave an ox to the winner of a bowling competition.

In the 15th, 16th, and 17th centuries, the game spread into the lowland countries and also into Austria and Switzerland. The playing surfaces were usually cinders or clay, specially treated and sun-baked to a hardness resembling concrete. When the lanes were covered or put into sheds, the playing surface usually was wood. The roofing over of the lanes, first done in London for lawn bowls around the year 1455, was the true beginning of modern bowling as an all-weather, around-the-clock game.

Bowling on the green. Though most of the Continent was taking to bowling at pins in the Middle Ages, there is little evidence that residents of the British Isles were changing from their historic preference for bowls or lawn bowling. Originally, the game probably consisted of two or more persons using rounded stones or pebbles. Evidence that a form of bowls was known in ancient Egypt has been cited above. Later it was developed by the Greeks and Romans. Scenes of lawn bowls have been depicted on pottery and tapestries dating to ancient times. The Romans developed the game into boccie, which they carried into Northern Europe as early as the 10th century, and the British are thought to have refined the Italian version of "tossing" the ball at the object into the one of rolling it on the lawn, or green, in the game originally called "bowles." Evidence in 13th- and 14th-century manuscripts depicts the game being played on lines similar to those employed today. One manuscript of that period, preserved in the Royal Library at Windsor, shows two players delivering one bowl each toward a small conical marker. A link with those times is provided by the Southampton Town Bowling Club, founded in 1299 and still in existence.

From the first days of the game's popularity, kings frowned upon it as likely to seduce men from archery, a pastime deemed in those days to be the chief guarantee of England's integrity and safety. In 1388 Richard II prohibited the game. Further acts in the reigns of Henry IV and Edward IV renewed the ban on the game for commoners. The sport also was criticized because of its gambling aspects. In 1511 King Henry VIII issued an edict declaring

> the game of bowles is an evil because the alleys are in operation in conjunction with saloons, or dissolute places, and bowling has ceased to be a sport, and rather a form of vicious gambling.

Though it was not rescinded until 1845, the ban was seldom observed, and that bowls continued to flourish is seen from a famous game played on "Plymouth Hoe" in 1588 by Sir Francis Drake and Sir John Hawkins, when even the news of the Spanish Armada's impending arrival was not allowed to interrupt the play. Shakespeare mentions the game in several of his plays. In *Richard II* a lady at court suggests the queen should play a game of bowls and Queen Isabella replies "Twill make me think the world is full of rubs, and that my fortune runs against the bias." It is apparent that, by that time, ladies played as well as men, and that bias (shaping or weighting the bowls so that they would swerve when rolled) had been introduced. In *The Book of Sports* (1618) James I recommended the game to his son, and the 17th-century diarist Samuel Pepys several times records meeting personalities at bowls. But more and more the game became associated with pothouses and taverns, and the excesses of drinking and gambling by the shady characters who met there caused bowls to fall into disrepute. (J.B.P.)

Development of modern lawn bowls. *Bowls in Scotland.* The game was preserved in Scotland, which took to bowls in the 16th century and where, stripped of its undesirable surroundings, it was for some time the national sport. Two main factors led to the revitalization and spread of the game. The Scots decided to formulate rules, and in 1849 a code of laws was produced, so excellently constructed that basically there has been little cause to change it ever since. The Scots also produced truly level greens, often using sea-washed turf for the purpose. Good conditions for play made the game one of scientific and strategic skill, while surpassing other pastimes in the promotion of social fellowship.

Spread of the game. Scots emigrants were responsible for the spread of the game to British Commonwealth countries, particularly Australia, New Zealand, and South Africa. It was in New South Wales and Victoria that the first bowling associations were formed in 1890. In 1892 the Scottish Bowling Association came into being. In 1903 the English Bowling Association was established. Two years later the International Bowling Board encompassing all of the associations in England and those of Scotland, Ireland, and Wales was set up. Although colonists also took the game to North America, where a park at the lower end of Broadway in New York and several small American towns still bear the name of Bowling Green, it was only in 1915 that the American Lawn Bowls Association was formed, and affiliation to the International Bowling Board was delayed until 1938. (See further under *The modern game* below.) Nevertheless, many municipalities in the U.S. maintain public bowling greens. The game is also played in parts of the Middle East and South America.

Tournaments and championships. The Irish and Welsh associations were formed in 1904, and international matches have been played between Scotland, England, Ireland, and Wales (the Home Countries) since 1903, except during the World War years. Teams of bowlers from Australia and New Zealand visited Great Britain in 1901, and from Canada in 1904. Since then teams from the British Isles, Australia, New Zealand, Canada, South Africa, and the United States have exchanged visits at regular intervals. All of them hold national championships. In the British Isles, each Home Country holds annual championships in singles, pairs, triples, and fours, qualifying for the British Isles championships, established in 1959, in which the national champions meet to decide the overall winner in each event. The popularity of competitive bowls can be measured by the fact that entries in the English National Championships in the 1970s exceeded in singles 11,000, in pairs 10,000, in triples 6,000, and in fours 4,000, involving more than 70,000 players from more than 2,500 clubs covering 34 countries. Entries in the championships continued to increase every year.

International matches

Lawn bowls was one of the sports included in the quadrennial British Commonwealth Games (inaugurated 1930). The first World Bowling Championships were held in 1966, in Sydney, Australia, with 16 national teams taking part. The second World Championships were held in 1972 in Worthing, England.

Outstanding bowlers. Bowls, highly organized for competition play, has produced outstanding bowlers.

These have included Percy Baker, for several years the supreme English bowler. An international (*i.e.*, selected to represent his nation in international play), he won the English national singles championship on four occasions and pairs, triples, and fours. He has been superseded by David J. Bryant, who won the inaugural World Championship singles and claimed gold medals in the 1962 and 1970 Commonwealth Games. He has won all the English National titles and is an indoor champion too. He was awarded the Order of the British Empire in 1969 for his services to bowls.

Glyn Bosisto dominated the Australian scene for nearly 30 years, and his achievements include four wins in the Australian singles. Norman White represented South Africa in three Commonwealth Games series, and on four occasions won the South African National singles and fours. Roy Fulton (Northern Ireland) is an international, both indoor and outdoor, who has won national titles and has also been successful in the British Isles singles and pairs. He also holds bronze medals for singles in Commonwealth Games and World Championships. Harry Reston (Scotland), an indoor and outdoor international, holds a bronze medal for the World Championships and is a triple winner of the Scottish Indoor singles.

For a list of world champions, see SPORTING RECORD in the *Ready Reference and Index*. (G.T.F.)

THE MODERN GAME

Bowls and pins in North America. There is confusion about how and when bowling at pins was carried to North America, arising from the interuse of the terms bowl, bowler, and bowling in referring both to ninepins (and tenpins) and lawn bowling. The early British settlers brought lawn bowls with them to America because that was the game they knew best. Dutch explorers under Henry Hudson, however, were said to have been just as instrumental in bringing with them some form of pin bowling, probably one called Dutch skittles and played principally outdoors. While some say bowling at pins came to America about 1650, the fact remains that many parts of Europe, even bowls-oriented England, had known a game in which pins were used for at least a century before. This was skittles, or a variation thereof, a game somewhat akin to boccie because the "ball" was tossed at the pins, rather than rolled. In the English version, the bowl or "cheese"—so called for its resemblance to a large Edam cheese—weighs between eight and 16 pounds (3.6 and 7.2 kilograms). It is hurled at the pins, which vary in height and dimension in relation to the size of the bowl, from a distance of 21 feet (6.4 metres). The nine pins are arranged in the standard diamond-shaped formation found in all ninepin games. The object in skittles is to knock down all the pins with the fewest throws.

Early pin games

Another pin game of the England of the Middle Ages was half-bowl, played with half a sphere of wood. The object was to roll the ball past a setup of 15 small conical pins and "bring it back" in a wide arc into the pins. As in skittles, one point, or "chalk," is scored for each pin knocked over. The game in each is 31 pins.

Most of the early European pin games involved rolling the ball along a wooden plank, 12 to 18 inches (30 to 46 centimetres) wide and 60 to 90 feet (18 to 27 metres) long, toward a diamond-shaped formation of nine pins. If the ball fell off the plank before reaching the pins, it was charged as a delivery against the player, but any pins knocked down were reset. The plank, or raised centre, still is used in several kinds of ninepin games in Europe and parts of the United States. For no known reason the flat-suface lane, then called an "alley bed," gained early usage in the "American" game, although when the tenth pin was added still is a mystery. It is believed tenpins was played in New York City in the 1820s; the earliest known reference to bowling at pins was made by Washington Irving in *Rip Van Winkle* (about 1818) in which he likens thunder to the sound of a ball rolling at pins.

Emergence of the tenpin game. By the mid-1830s, bowling at pins was flourishing. It was then that the same scourge that struck lawn bowling in medieval England—gambling—became the evil of the American bowling scene. The situation became so critical in Connecticut that the state legislature passed an act in 1841 banning the game. Myth has it that some quick-witted genius, to circumvent the prohibition which was popularly supposed to refer only to the ninepin diamond formation, added the tenth pin and arranged them in an equilateral triangle. Regardless of how tenpins came into being, it became so popular by mid-19th century that indoor lanes were being built throughout New York City, Syracuse, Buffalo, Cincinnati, Chicago, Milwaukee, and other cities with large German populations. Many bowling lanes were built and operated by Turnvereins—fraternal gymnastic societies—but they quickly spread to wide public usage. While gambling continued to be a problem in some areas, it was the lack of uniform playing rules and equipment specifications that stifled the development of the game as a whole. In 1875 delegates from nine bowling clubs in New York and Brooklyn organized the National Bowling Association. Some of the legislation agreed on then is still in effect in modified form, but the group lacked breadth and was followed in 1890 by a short-lived American Amateur Bowling Union.

Organization: tournaments. Disagreement continued between East and West, principally an alignment of New York state bowlers against everyone else. On September 9, 1895, the American Bowling Congress (ABC) was organized in New York City. Rules and equipment standards were developed—and adhered to—and the game as it finally was organized has remained basically unchanged, except for alterations adopted to meet the changes brought on by technological advancements such as automatic pin setters and other equipment, and the introduction of plastics, nylon, and other synthetics.

Once the ABC came into the picture, bowling began its growth. Two early technological developments helped. Pins had been set mostly by hand; machines were designed to do the job. Balls had been made of lignum vitae, a tropical wood that was almost indestructible, except that it chipped and lost its shape: suddenly all sorts of balls made of hard rubber, still the basic ingredient, appeared. As many as 16 to 24 lanes were built into one building—pin palaces they were called—and nationally known players began to emerge. In 1901 the ABC started its national tournament, drawing a turnout of 41 five-man teams to a four-day contest in Chicago. In 1953, at its Golden Jubilee tournament (three years having been lost to World War II), the ABC tournament drew an entry of 8,180 teams or upwards of 41,000 individuals.

The Women's International Bowling Congress (WIBC), organized in 1916, has conducted annual national championships since 1917. More than 48,000 women took part in the largest single tournament, the 1973 event in Las Vegas, Nevada.

The largest individual event is the Petersen Classic, for both men and women, held since 1921 for about 10 months each year in Chicago, and offering a first prize in excess of $50,000 and attracting more than 20,000 entrants, most of them men.

The Professional Bowlers Association (PBA) was organized in 1958. It quickly developed a star system and a tournament tour fashioned after that of professional golf. Helped by television, PBA members were soon playing for more than $1,000,000 in yearly prize money. Don Carter became the leading winner in the 1950s and was succeeded by Dick Weber. The Professional Women's Bowling Association (1959) began modest tournament play in the early 1960s.

Professional tours

A major influence at the structural level of the game has been the Bowling Proprietors Association of America, founded in 1932. In addition to its trade association functions, it formerly conducted a number of tournaments for both men and women. Its most notable was the All-Star tournament, a match game event that began in 1941 and continued until 1970, when it was given over to the Professional Bowlers Association, renamed the U.S. Open, and made a part of the PBA tour. The National Bowling Council, founded 1943, is made up of

the manufacturers, proprietors, and membership groups. It concerns itself with national promotional campaigns and other activities requiring joint application of the industry's efforts.

League bowling. Nearly 52,000,000 persons are said to bowl at least once or twice a year in the United States. But while the thousands of occasional weekend and holiday bowlers swell the total number, the backbone of the sport continues to be its highly organized, competitive league structure. This structure is based on the members of the major bowling congresses who participate in leagues organized in cities and towns throughout North America. The American Bowling Congress has a male membership of more than 4,000,000. The Women's International Bowling Congress has reached a membership of nearly 3,500,000 women.

Most men's and women's leagues consist of eight to 12 teams. Some leagues have 40 or more teams, depending on the number of lanes in the bowling centre. Both the ABC and WIBC sanction more than 100,000 leagues each year, almost half of which are mixed.

League play in the three major membership organizations is conducted under rules laid down by the parent bodies including the handling of prize funds by the adult leagues. The latter helps illustrate the magnitude of bowling. About $150,000,000 in league prize money is disbursed at season's end. Upwards of $50,000,000 in women's league prize funds is also distributed.

Tenpins in other countries. *Europe.* As membership in the three bowling groups—ABC, WIBC, and AJBC (American Junior Bowling Congress), plus the Youth Bowling Association of the Bowling Proprietors Association of America—peaked at 8,000,000 in the mid-1960s, the leading manufacturers of equipment in the United States began to look elsewhere for markets. So did investors in other countries. Suddenly tenpins, the game that had crossed the Atlantic as a ninepin game years and years before, was on its way back to Europe. Foreseeing the development, some British bowlers asked the American Bowling Congress to lend its aid in the formation of an association. The British Ten Pin Bowling Association came into being in 1961, its equipment specifications exactly those of the ABC, its rules only slightly modified. Australia followed suit and other countries hurried to restructure their regulations as tenpin centres were built in Paris, Antwerp, Berlin, and so on. Two chains of British film makers turned many of their cinemas into bowling centres. The British alone reached a playing membership of more than 40,000 in five years.

British Ten Pin Association

Until the advent of American-style centres in the early 1960s, tenpins was little known in Europe outside Sweden. Two lanes for tenpins in a basement near the Rue de Saint-Petersburg in Paris in 1909 were an unsuccessful experiment. In the same year 12 lanes were installed for the White City Exhibition in London. The builder dismantled the lanes after the exhibition season ended, then installed ten lanes the next year (1910) in the Piccadilly area. This project was unsuccessful too, and the next "invasion" of tenpins in the British Isles came during World War II when hundreds of lanes were installed on American bases.

Japan. Japan in the 1970s has experienced the kind of bowling boom that swept the United States in the 1960s. Early in the decade there were more than 10,000 lanes in 2,800 establishments; one centre in Tokyo, the world's largest, has 504 lanes on four floors. Some centres open at 6 o'clock in the morning and operate all day and night at near capacity. The Japan Bowling Congress reports 70,000 male and 7,000 female members. Bowling also is growing in popularity in other Asian countries including Hong Kong, Thailand, Singapore, and Indonesia.

The game's growth in Sweden has been less phenomenal, though in 1909 it had the first tenpin lanes in Europe. The Federation has 21,000 members and modern tenpin centres in more than two dozen cities. Canada has the largest tenpin population outside the United States; its 50,000 male and 17,000 female players belong to the ABC and WIBC, respectively. Some other leading areas are Australia, 13,000 men, 11,000 women; Mexico, 9,000 and 2,500; Finland 9,000 and 1,000; and Venezuela, 6,500 and 1,200.

International bowling. Informal international bowling competition had been held as early as 1892, when a team of Americans played in a bowling "festival" in Hamburg, Germany. After the turn of the 20th century, teams from New York made several more trips to Germany. An international event was held in Union Hill, New Jersey, during the summer of 1900, but the use of the word "international" was only thinly justified by the appearance of some teams from Canada; the rest were Americans. A group of Americans toured Sweden in 1923 and 1929, then hosted a number of European teams in matches held in New York in 1934. The first attempt to create a tenpin bowling organization on the Continent came in 1925. The group sponsored some scattered competition and in 1936 staged a series of bowling events concurrent with the summer Olympic Games in Berlin. More than 50 Americans made the trip. It was the last international get-together of any consequence until the Fédération Internationale des Quilleurs (FIQ) came on the scene in 1951, as a reorganization of the Continental group.

The international federation

Seven European nations sent teams to the first world tournament of the FIQ in Helsinki, Finland, in 1954. Nine teams took part at Essen, Germany, in 1955, a dozen at Hälsingborg, Sweden, in 1958 and 15 at Hamburg, Germany, in 1960. The world meet moved to Mexico in 1963, when it was put on a four-year basis, and back to Malmö, Sweden, in 1967. Milwaukee, Wisconsin, was the site in 1971 with 32 nations sending teams from an organization that had grown to 48 members. Competition is held in zones—American, European, and Asian—also at four-year intervals. The headquarters of FIQ is in Zürich, Switzerland. The organization has four sections, the principal one being devoted to tenpins. The other three are "small ball" games, those using a duckpin-type ball that can be held in the palm of the hand and has no finger holes. They are schere, bohle, and asphalt, the latter an outdoor game played on an asphalt surface. All are little known or played outside of Germany, Austria, and some of the eastern European countries such as Hungary, Yugoslavia, Poland, Romania, and Czechoslovakia. FIQ competition is for nonprofessionals; and gold, silver, and bronze medals are awarded to champions and runners-up. The American style of alternating lanes after each frame is used, plus two European styles, one in which an entire game is bowled on one lane, the other in which half the game is bowled on one lane, the second half on the other.

For listing of world champions, all-time records for U.S. league and tournament play, and all-events champions, see also SPORTING RECORD in the *Ready Reference and Index*.

Other bowling games. In addition to the "small ball" games recognized by the international federation, many other variations are played regionally and locally in the countries of their origins, and many have been introduced to other countries by emigrants. These include versions of the early prototype games discussed above under the history and development of bowls and bowling—skittles and boccie, for example. The latter, controlled by the Unione Federazioni Italiane Bocce, is popular in Piedmont (where the first organization was formed in Turin, in 1898) and Liguria, and is also played in Italian communities throughout the United States and Australia and has a large following in South America. All of the variants are based on the principles either of bowls or of bowling, and use either "small ball" or regulation size equipment. (J.B.P.)

THE GAME OF BOWLS

The green and equipment. By far the most widely played form of bowls is the flat green game that, as its name implies, is played on a green, 40 to 42 yards (37 to 38 metres) square with a flat, level playing surface. The green is surrounded by a ditch approximately one foot (30 centimetres) wide, beyond which are grassed banks not less than nine inches (23 centimetres) above

the level of the green. The green is divided into six rinks each 18 to 21 feet (5.5 to 6.4 metres) wide.

The bowls, or woods, are oblate spheroids that have a standard bias, produced by skilled craftsman who turn them on a lathe to make one side more convex than the other. Weighting of bowls in any way, to produce bias, is illegal. Originally, practically all bowls were made from lignum vitae, but the modern trend, especially among competition bowlers, is to play with composition bowls that are molded from a plastic compound and then turned on a lathe to produce the required bias. These appear to suit all climatic conditions, and hold a course more firmly on rougher types of turf. The maximum measurements for composition bowls are a diameter of 5⅛ inches (13 centimetres) and a weight of 3½ pounds (1.6 kilograms). The target, called the jack, is a white sphere with a diameter of 2½ inches (6.4 centimetres). Players deliver their bowls with one foot on a mat 24 inches (61 centimetres) long and 14 inches (35.6 centimetres) wide.

Composition bowls

Principles of play. To begin play for an end, one player, called the leader, places the mat and rolls the jack. It must come to rest at least 25 yards (23 metres) from the mat, and then serves as the target.

The players then deliver their woods in turn by rolling them along the turf, their primary object being to position the bowls as near as possible to the jack. The end is completed by a point or points being scored for the bowl or bowls nearer the jack than any bowl played by the opposing players. The next end is begun by a player rolling the jack back to the opposite end of the rink.

In national competitions, in singles events each player has four bowls and 21 points constitute a game; in pairs two players on-a-side each use four woods and a game is 21 ends; in triples three players on-a-side each use three woods and a game is 18 ends; and in fours four players on-a-side each use two woods and a game is 21 ends.

A team, known as a rink, consists of a number of fours, usually four or six, and the winners are the side with the highest aggregate score. Variation and interest in the game is heightened by the fact that the jack can be moved by a bowl, and is still alive if run into the ditch, within the confines of the rink. Any bowl in its original course touching the jack is termed a toucher. This is indicated by a chalk mark on the bowl and the toucher is counted live as long as it stays within the confines of the rink, including the ditch.

East Anglian bowls. A variation of the flat green game was adopted by the English Bowling Federation, which came into being in 1926. This game is played in ten counties in eastern England, and is sometimes referred to as East Anglian bowls. The essential difference is that the order of players may be altered at any stage of a game, whereas in the English Bowling Association the players must always keep the order in which they start. In the team only three players constitute a rink and usually six rinks take part. "Touchers" are not given any special consideration, and if the jack goes into the ditch the end is dead and must be replayed. Only bowls within six feet (1.8 metres) of the jack are allowed to count, and the minimum length of throw of the jack is 21 yards (19 metres).

The Crown green game. In North Wales, the Isle of Man, North Midlands, Lancashire, and part of Yorkshire, the Crown green game is very popular. Here the green is six inches to 13 inches (21 to 33 centimetres) higher in the centre and slopes away gradually to the edges of the green. Slightly smaller bowls with rather less bias are used, and, in this game, the jack is biassed. Whereas on a flat green play takes place up and down the green on a line parallel to the sides, crown green play may be in any direction. The game is essentially a singles event with each player using two bowls, and only rarely are pairs events staged.

Indoor bowls. The British outdoor season normally lasts from May to September. To pass the winter months, bowlers derived amusement and companionship by making use of any available hall with space enough to play a modified game of bowls. Most surfaces were much too short and inaccurate, and consisted of matting that could be put down and rolled up at will. Despite this, the short green game became very popular. During the last 20 years, a vast improvement has taken place. Stadiums with full-sized greens have been constructed for indoor play. An increasing number are being used in England and Scotland, and Cardiff and Belfast provide excellent facilities. These stadiums allow the game to be played under normal rules. Standard bowls are used, but the jack is heavier than the outdoor type, to reduce the number of dead ends that tended to occur when the normal outdoor jack was used. A hard, durable level bed is laid and covered with a pliable underlay over which is placed a surface of felt or jute threaded with nylon. The thickness of the underlay controls the running speed of the green. Indoor associations have been formed in the four Home Countries, and international matches, national championships, and British Isles championships are played annually. (G.T.F.)

Bowling stadiums

THE GAME OF TENPINS

Lanes and equipment. The American game of tenpins is played according to the rules and specifications of the American Bowling Congress. The game is played indoors on wooden lanes with maximum dimensions of 62 feet 10 11/16 inches (19 metres) in length and 42 inches (107 centimetres) in width. The surface, coated with lacquer or plastic-type material, must be free of continuous grooves and be within 40/1,000th inch (1 millimetre) of perfect levelness. The distance from the foul line, past which the player may not slide when delivering the ball, to the centre of the spot on which the headpin stands is 60 feet (18 metres). The approach on which the player advances to the foul line has a minimum length of 15 feet (4.6 metres).

The pins are 15 inches (38 centimetres) tall and arranged in a triangle formation with the point or No. 1 pin at the head of the formation facing the bowler. The centres of the pin spots are 12 inches (30.5 centimetres) apart. The pins are made of maple, either in a single piece or laminated, and most are covered by a plastic coating. The weight ranges between three pounds two ounces and three pounds ten ounces (1.4 kilograms and 1.6 kilograms), although the maximum allowed for synthetic (nonwood) pins is three pounds six ounces (1.5 kilograms).

The ball is of nonmetallic composition, usually hard rubber, with a circumference of 27 inches (68.6 centimetres) and a weight limit of 16 pounds (7.3 kilograms). There is no minimum weight; a number of women and children use regulation-size balls weighing ten pounds (4.5 kilograms) and less in sanctioned competition.

Principles of play. A game of tenpins consists of ten frames. Two deliveries per frame are allowed, the ideal being to knock down all pins on the first (roll of the ball) for a strike. If the pins are left standing after the first delivery, the fallen or "dead" wood is removed and a second delivery permitted. If successful, a spare has been recorded. A miss also is called an error. A split can occur on the first ball when two or more pins are left standing, separated by at least one fallen pin. Stepping over the foul line is a foul and results in loss of all pins knocked down. There are depressed troughs on each side of the lane; a ball falling therein is a "gutterball" and out of play, with resulting loss of one delivery.

Both a strike and a spare count ten pins, or points. If two strikes in a row are recorded (a double), the player counts 20 pins in the first frame plus the number of pins he knocks down on his first delivery in the third frame. Should he score another strike (triple, or turkey), he will have 30 pins in his first frame. A perfect game is 300 and consists of 12 strikes in a row, two additional deliveries being permitted in the tenth or final frame. In scoring, the number of pins knocked down by the first ball in each frame is marked in the first small box on the score sheet; the number of remaining pins knocked down with the second ball, including the making of a spare, is indicated in the second small box. The score

of each bowler for a frame is recorded in the large box.

Competition in league and tournament play includes individual, two-man, three-man, four-man, and five-man, the latter having been most prevalent. Two teams are assigned to a pair of lanes and bowl in the order in which their captain lines them up on the scoresheet. The first or leadoff man for each team bowls on his assigned lane, then the second man, third man, and so on through the fifth or anchorman. After the five men on each team have completed their frame, they switch lanes for the second frame. A complete game consists of five frames on each of the two lanes. Most competition is three games in league play. Tournaments range between three games for individuals through as many as 20 or 40 in marathon events. A common format is three games per five-man team player in the team, doubles, and singles events, the total of the nine games being the individual's all events total. The listing of winners for each of the four separate events is most common in tournaments.

Boxing

Boxing is the art of attack and defense with the fists in which the two contestants wear padded gloves, box bouts of three to 15 rounds (each round normally of three minutes duration), and generally observe the code set forth in the Marquess of Queensberry rules (see below *The bare-knuckle era*). Contestants are matched in weight and ability, each trying to land hard and often with his own fists and to avoid the blows of his opponent.

The terms pugilism and prizefighting in 20th-century usage are practically synonymous with boxing, though the first indicates the ancient origins of the sport in its derivation from the Latin *pugil*, "a fighter with the cestus (a hand covering)," related to the Latin *pugnus*, "fist," and derived in turn from the Greek *pyx*, "with clenched fist"; while "prizefighting" emphasizes the pursuit of the sport for gain. Samuel Johnson in his *Dictionary* (1755) defined a prizefighter as "one that fights publicly for a reward."

This article is intended for the general reader who many have no knowledge of boxing. Therefore, in addition to tracing its history and outlining its present status, the article is designed to help a spectator understand a match he may be watching. For information on specific rules or how to box, the reader should consult works listed in the bibliography. For lists of world professional boxing champions, see SPORTING RECORD in the *Ready Reference and Index*.

HISTORY

Early History. Presumably men resorted to their fists to settle arguments for many centuries before anyone thought of staging bouts for the entertainment of others. There is evidence that boxing existed in ancient Crete, where a civilization was established by about 1500 BC. Centuries before the arrival of the Greeks, boxing was known in the Aegean.

The descriptions of fighting in ancient Greece are not evocative of Queensberry skill. The Greeks believed in fine development of physical as well as mental abilities. But the young Greek was always conscious of his possible role as a soldier or warrior and it was with this sort of destiny in mind that he exercised. Therefore, the fighting the Greeks did was largely to prove their courage, strength, and endurance—not their agility or cleverness. They fought in the open air, bounded by spectators, with no resined surface to manoeuvre upon, no corners or ropes to employ in their strategy. There were no rounds —the bout continued until one of the fighters admitted himself beaten.

In the early days, fighters wore thongs of soft leather bound about their fists and (often) two-thirds of the way up their forearms to protect hands and wrists. Beginning in the 4th century BC, harder leather was used for the thongs, with the result that they became weapons as well as protection. And finally, late in the history of the Roman Empire, the Greeks adopted the hand covering called the cestus, which was studded with iron or brass nuggets and was used in battles to the death in the Roman arenas.

Ancient Olympic boxing

Although fist fighting was supposed by the Greeks of the classic period to have been a feature of the mythological games at Olympia, it was not actually introduced into the historic Olympic contests until the XXIII Olympiad (688 BC) after the re-establishment of the famous Games, traditionally in 776 BC. Onomastos of Smyrna was one of the first Olympic victors. A sport called pancratium ("complete contest"), which combined boxing and wrestling, was introduced in the XXXIII Olympiad (648 BC). In the XLI Olympiad boxing competition for youths was added. There were no weight divisions, and size and strength were prime qualifications for the pugilist.

The first Greek fighters were not paid; glory was the only reward they sought. Later, wealthy men trained their slaves as boxers and had them perform for special entertainments. In the 1st century AD, Romans forced cestus-

clad slaves to bludgeon one another to death in a gruesome perversion of sport for the entertainment of crowds who thronged to arenas to see the kill. With the rise of Christianity and the concurrent decline of the Roman Empire, pugilism as entertainment apparently ceased to exist. At least, there is no record of it.

The bareknuckle era. With the rise of London as a major city came a type of encounter called a prizefight. Prizefighters were strong men from different sections of the city, whose admirers were willing to bet that they could beat one another and arranged fights to settle the issue. The fighters performed for whatever purses were agreed upon plus stakes (side bets). At first there were few tactics that were not allowed. Wrestling was permitted and it was common to fall on a foe after throwing him. It also was common practice to hit a man who was down. The fighters wore no gloves of any kind and welcomed variations upon punching because their hands could not take the punishment involved in delivering many hard punches consecutively. Nevertheless, by 1719 one man had so captured public imagination that he was acclaimed champion of England. His name was James Figg and he held the title for a span that may have been as great as 15 years, turning back during this time an Italian challenger named Tito Alberta di Carni. For years the only outstanding fighters were English. Occasionally an Irishman or American came to London to ply his trade. These invasions increased as the popularity of prizefighting (and the size of prizes offered) grew.

The first fighter greatly to aid the sport itself was Jack Broughton (1704–89), a 200-pound Englishman who won the championship of his country sometime between 1734 and 1740 (versions differ) and lost it in 1750. Broughton's reign was long enough and his character good enough to win a new respect for prizefighting. He discarded the barroom techniques, which his predecessors favoured, and relied primarily on his fists. (He did, however, like all fighters of the time, also use wrestling holds.) He brought some degree of order out of a brawling chaos not only by the way he fought but by a set of rules that so clarified the proper conditions for a bout that they governed boxing, with only minor changes, until the more detailed London Prize Ring rules superseded them in 1838. Under Broughton's rules, a round continued until a man went down; after 30 seconds of rest he had to square off a yard from his opponent or be declared beaten. Also, one could not hit an opponent who was down or grasp him below the waist.

Broughton's rules

Broughton capitalized upon his good name among sportsmen by conducting classes in "the mystery of boxing . . . that wholly British art," as he advertised it, for gentlemen at his Haymarket academy in 1747. To attract pupils, he devised "mufflers," ancestors of modern boxing gloves, with the assurance that these would be used in all bouts to protect against bruised faces and hands. This contribution alone established his importance to modern boxing. But the man who beat him inaugurated a period of dishonesty, in which one fixed bout followed another and sportsmen lost faith entirely in the sport. Prizefighting was re-established in good repute by Tom Johnson, who became champion in the 1780s and lost the title, in an unquestionably honest bout, in 1791 to Ben Brain.

The man who succeeded Brain was the first scientific fighter in the history of pugilism. He was an English Jew named Daniel Mendoza (1763–1836) who weighed only 160 pounds (a middleweight by modern standards) but beat the best and biggest fighters in England. Mendoza had good, quick footwork and a swift, straight left jab. By combining agility with the jab, he easily befuddled his lumbering opponents. After losing his title to John Jackson (1769–1845), known as "Gentleman Jackson," in 1795, Mendoza opened a school in London at which he coached young noblemen in fighting techniques.

Jackson's chief contribution in the transformation of prizefighting into boxing was to gain friends of distinction for the sport of fist fighting—people who were interested in seeing it progress and who could give it a badly needed aura of respectability.

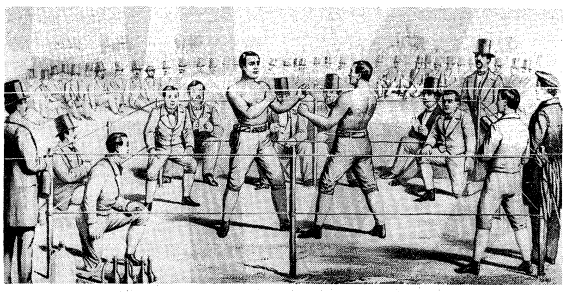
Of the bareknuckle champions who followed, the first to assure himself sports immortality was Tom Cribb (1781–1848), who defeated two American-born former slaves, Bill Richmond (1763–1829) and Tom Molineaux (1784–1818). Richmond was the first man born in America to win acclaim in England as a first-class pugilist. Gen. Hugh Percy, who commanded some of the British troops occupying New York, discovered Richmond's talents and took him to England in 1777. Cribb beat Richmond in 90 minutes in 1805. Later, after winning the English championship, he twice beat Molineaux in his greatest performances.

In 1839, new London Prize Ring rules were first used in a championship fight in which James ("Deaf") Burke lost the English title to William Thompson ("Bendigo"). These rules (later revised in 1853) provided for a ring 24 feet square and bounded by ropes. When a fighter went down, the round ended and he was helped to his corner. Time was called after 30 seconds, and, if he could not get unaided to a mark in the centre of the ring by the end of eight additional seconds, he was declared "not up to scratch" and beaten. Kicking, gouging, butting with the head, biting, and low blows were all declared fouls. The London rules governed pugilism in England and America for over 50 years.

London Prize Ring rules

By 1860 America had produced a number of good fighters. One of them, the handsome John C. Heenan, not content with the championship of the United States, challenged English champion Tom Sayers. They met at Farnborough, Hampshire, April 17, 1860. There was a great difference in weights—195 pounds for Heenan to the Englishman's 149 pounds—but Sayers held Heenan to a 42-round draw, the last five rounds fought after a crowd entered the ring.

The Bettmann Archive



Bareknuckle championship match between John C. Heenan and Tom Sayers at Farnborough, Hampshire, April 17, 1860. Lithograph by Currier and Ives.

Although the Heenan–Sayers bout attracted a good deal of attention, the brawling that distinguished old-time pugilism continued to alienate most of the better people of England. It became apparent that if a widely popular sport was to emerge and endure it would have to be extracted from, rather than preserved in, the hurly-burly of prizefighting. When John Graham Chambers of the Amateur Athletic Club devised a new set of rules, he tried to emphasize aspects of pugilism that Daniel Mendoza had first exploited—that is, boxing technique and skill. These attributes were expected to draw a better class of patron than the old London rules.

The rules appeared in 1867 and differed from the London rules in four major respects: contestants wore padded gloves; each round consisted of three minutes of fighting followed by a minute of rest; wrestling was illegal; and any fighter who went down had to get up unaided within ten seconds—if he could not do so, he was declared knocked out and the fight was over.

Queensberry rules. John Sholto Douglas, 9th marquess of Queensberry (1844–1900), lent his name to Chambers' rules so that they would be associated with the nobility. At first professionals scorned the new code and thought its practitioners somewhat effete. But gradually, although championships among professionals continued to be decided by the London rules, more and more fighters who were quick with their hands and feet and preferred

punching to wrestling learned the Queensberry style. Prominent among these was James ("Jem") Mace (1831–1910), who, though weighing only 160 pounds, won the English heavyweight title in 1861 through judicious use of a good left jab and a quick pair of feet. Having proved that he could win under the London code, he was more or less free to do as he pleased and he chose to do two things that had a vast influence on the course of boxing history. The first was to go abroad to fight. The second was to show growing interest in the Queensberry style of fighting.

It was only a matter of time before Mace arrived in America, since prizefighting was then frowned upon by the clergy and the law in England. He actually was at his best when sparring with gloves. His enthusiasm for glove fighting did much to advance the Queensberry code, for it was generally conceded that there was nothing effete about Jem Mace. Both the London and Queensberry rules were followed by a new generation of fighters in America and the time for decision between them was near.

John L. Sullivan, who claimed the world's heavyweight championship in 1882, made the move that finally aligned professional fighters on the side of the Queensberry rules. He did so not out of a desire to benefit sport but because he felt he could not afford to do otherwise.

Having won the American heavyweight title at the age of 23, Sullivan squandered remarkable speed of hands and feet on the London era, when these qualities were less appreciated than might later have been the case. Luckily, he also had great strength and a mighty punch. These latter qualities made and kept him a bareknuckle champion. Public authorities had, however, grown increasingly hostile to pugilism. In 1889, when Sullivan defended against Jake Kilrain in the last heavyweight championship bareknuckle fight to be held in America, prizefighting (London rules) was illegal in every state of the union. Subsequent to the Kilrain fight, Sullivan was arrested and plagued with legal actions that interfered with his making a living for the next year. He complained that it cost him $18,670 to settle for the Kilrain match. Therefore, when at the age of 33 Sullivan agreed to defend his title against quick, clever "Gentleman Jim" Corbett, he insisted on Queensberry rules. Sullivan lost to the epitome of Queensberry skill. Corbett in a five-year reign (1892–97) proved that a big man could be highly scientific and launched boxing on a lucrative new era.

Economic impetus. When Victorian boxers left England, they went not only to the United States but to Australia and Canada and, occasionally, to continental Europe. The reasons that professional boxing became centred in the United States were chiefly two: first, the expanding American economy made it possible for promoters to conduct bouts fairly regularly for the entertainment of factory hands, miners, lumberjacks, and other workers who flooded into the new country and demanded excitement in their off hours; second, successive waves of immigration provided husky, hungry boys who had little education and were willing to fight for quick money. Boxing became a shortcut to riches and social acceptance for those near the foot of the economic ladder.

Immigrant boxers

The famines that drove thousands of Irish to seek refuge in America furnished important raw material for the greatest era professional boxing has known. Before 1915, the Irish had become dominant in every division from heavyweight through bantamweight. Terry McGovern, "Philadelphia" Jack O'Brien, Mike ("Twin") Sullivan and his brother Jack, Packey McFarland, Jimmy Clabby, Jack Britton—these were only a few of the colourful, courageous, and highly skilled men who made a profession of boxing.

German, Scandinavian, and central European immigration, which increased after the political troubles of 1848, also contributed greatly to this golden age of boxing in the United States. Polish-American Stanley Ketchel and German-Americans Billy Papke, Frank Klaus, and Frank Mantell dominated the middleweight division 1908–13. Danish-American Battling Nelson and German-American Ad Wolgast ruled the lightweights 1908–12. Such outstanding Jewish fighters as Joe Choynski, Abe Attell, Battling Levinsky, and Harry Lewis were active before 1915, but even more outstanding Jewish fighters fought from 1915 to 1930, when Benny Leonard, Sid Terris, Lew Tendler, Al Singer, Maxie Rosenbloom, and Max Baer were in the ring.

Beginning about 1920, Italian-Americans assumed an importance in boxing. Their influence has continued great and has produced such champions as featherweight and lightweight Tony Canzoneri, heavyweight Rocky Marciano, and featherweights Johnny Dundee (nicknamed the "Scotch Wop") and Willie Pep.

Meanwhile, American Negroes also turned to boxing to fight their way to the top. Foreign-born Negroes (such as Peter Jackson, Sam Langford, Joe Walcott, and George Dixon) came to the United States to capitalize on the opportunities offered by boxing. Lightweight Joe Gans, born in Baltimore, was perhaps the cleverest boxer, pound for pound, in professional annals. He became world champion (1902–08), as did heavyweight Jack Johnson (1908–15). Prejudice against black fighters at times was great. John L. Sullivan found it convenient to "draw the colour line" in refusing to defend against Peter Jackson, and Jack Dempsey would not fight Harry Wills. But Joe Louis won complete acceptance, and his reign as heavyweight champion (1937–49) was one of the most popular in boxing history. Greatly encouraged, and further prompted by the rigours of depression years, Negroes flooded into the ring beginning in the mid-1930s to start a domination comparable to that enjoyed by the Irish prior to 1910. Among them were Henry Armstrong, who held the featherweight, lightweight, and welterweight titles simultaneously; "Sugar" Ray Robinson, welterweight and five-time middleweight champion; Archie Moore, light-heavyweight champion; and heavyweight champions Ezzard Charles, "Jersey" Joe Walcott, Floyd Patterson, Charles "Sonny" Liston, Cassius Clay (Muhammad Ali), and Joe Frazier.

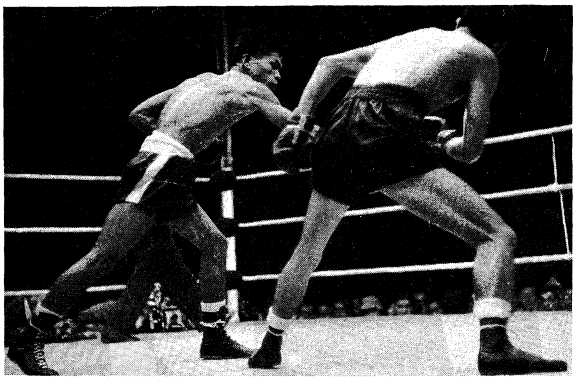
The rise of black fighters to prominence

Spread of boxing. In the 18th century, British boxers including Daniel Mendoza visited France, but it was not until late in the following century that a real interest in boxing developed on the Continent. In France it replaced *savate*, or *la boxe français*, which permitted kicking as well as hitting with the fists. Swiss boxer Frank Erne, who won the world lightweight title in 1899, was a leading instructor as gymnasiums and coaching schools were opened. Eight years later, Victor Breyer and Theodore Vienne opened the Wonderland Francais arena, and some of the world's best heavyweights visited France. The famous French boxer Georges Carpentier fought in every

weight division from 1907 to 1926 and won the world light-heavyweight title in 1920.

In most of Asia the sport developed more slowly. In 1909 Frank Churchill formed the Olympic Club in Manila and, with American Eddie Duarte, taught boxing to the Filipinos. Previously there had been only occasional contests when British and American battleships came to ports like Manila or Hong Kong. The first boxer of note in the Philippines was Pancho Villa, who won the world flyweight title in 1923. Since then boxers from the Oriental countries have specialized in this division, winning several world titles in recent years. Japan, especially, and Thailand, which also developed a sport similar to the French *savate*, made great progress in boxing.

PHOTOWORLD



Leo Espinoza (left) of the Philippines fighting Yoshio Shirai of Japan for the world flyweight title at Tokyo, May 24, 1954. Shirai, who was titleholder from 1952–54, retained title in the match.

Development of amateur boxing. During the 19th century, boxing was a favourite sport among the gentry of Britain. In 1867 the first amateur championships took place under the Marquess of Queensberry rules, with the Marquess himself presenting cups to the winners. The rules however, came in for criticism because they forbade infighting. Boxers who, because of their shorter stature, had to work at close quarters to be effective, were cautioned, and one prominent amateur, T. Anderson, was disqualified for "fighting." Criticism became so strong that a number of influential men with a love of boxing met in London in 1880 and devised new rules. Thus the Amateur Boxing Association (ABA), the world's first amateur governing body, was formed. The following year the ABA staged its first official championships. Originally there were 12 member clubs, and the number rose to 46 by 1906. Today, there are thousands and for the ABA championships each year boxers throughout Britain must qualify on a regional basis.

In 1888 the Amateur Athletic Union (AAU) of the United States was formed, instituting its annual championships in boxing the same year. The AAU has remained the ruling body for the United States. In 1923 another amateur competition was started by the *Chicago Tribune*. Called the Golden Gloves (the name was first used in New York in 1927), it grew quickly into a national competition rivalling that of the AAU.

Golden Gloves

Amateur boxing spread rapidly to other countries and resulted in several major international competitions, taking place annually, every two years, or, as in the case of the Olympic Games, every four years. Important events are the European Championships, the British Empire and Commonwealth Championships, the Pan American Championships, and more recently the All-Africa Championships and the World Military Championships. All international matches and competitions of this nature are controlled by the Association Internationale de Boxe Amateur (AIBA), formed in 1946 with headquarters in London.

Because of their political and economic structures, the U.S.S.R. and other Communist countries do not have professional sportsmen. One notable exception was the Hungarian boxer Laszlo Papp, winner of Olympic gold medals in 1948, 1952, and 1956. Papp was permitted to turn professional at the age of 31 and won the European middleweight title in 1962, retiring undefeated some three years later to coach the Hungarian amateur team.

Although there is a record of boxing schools in Moscow at the turn of the 20th century, national championships were not instituted until 1933. The U.S.S.R. joined the AIBA in 1950 and entered the Olympic Games in 1952 to emerge, together with other Communist countries such as Poland and Hungary, as one of the strongest amateur boxing nations in the world. There are over 300,000 boxers in the U.S.S.R., which has three main sources for subsidizing sport—government allocations, trade union allocations, and dues paid by members of voluntary sports societies. No boxer has to pay for coaching or for gymnasium use, and all equipment and medical advice is free. These factors give Communist countries a distinct advantage over other countries, whose amateurs must pay for everything out of their own pockets, and the best of whom invariably turn professional, thus making team building an impossibility.

African countries advanced considerably after gaining their independence in the 1950s and 1960s, thanks mainly to former professionals Hogan Bassey of Nigeria and Roy Ankrah of Ghana, who were appointed as national coaches to their respective teams. Bassey was world featherweight champion (1957–59), and Ankrah was Empire titleholder. Africa dominated the 1970 British Commonwealth Games in Edinburgh, winning eight of eleven gold medals. In addition, six Africans were losing finalists. Uganda and Kenya joined Nigeria and Ghana among the top amateur boxing nations of the world.

African champions

Professional purses. In 1860 John C. Heenan and Tom Sayers fought for $2,500 a side and a championship belt. John L. Sullivan fought Corbett in 1892 for a $25,000 purse and a $10,000 side bet. The man who made boxing big business was George ("Tex") Rickard, the first great promoter of the sport. After staging the world's lightweight championship bout between Joe Gans and Battling Nelson to publicize the mining town of Goldfield, Nevada, in 1906, he saw that boxing as spectacle had great potential. Through clever press agentry Rickard made it fashionable to be seen at ringside at major bouts. Five of the fights he promoted for Jack Dempsey, heavyweight champion 1919–26, drew over $1,000,000 in receipts. They were two bouts against Gene Tunney (1926 and 1927) and one each against Georges Carpentier of France (1921), Luis Angel Firpo of Argentina (1923), and Jack Sharkey (1927). A natural showman and gambler, Rickard made an art of boxing publicity, playing on people's prejudices in pitting Negro against white (Gans–Nelson and Jack Johnson–Jim Jeffries), alleged slacker against war hero (Dempsey–Carpentier), and American against foreigner (Dempsey–Firpo). His fortunes were tied to Dempsey, however, and after Dempsey's retirement Rickard began to lose money and dropped from his position of prominence.

In the depression years that followed, receipts from boxing shows dwindled greatly. The financial centre of boxing remained the United States, although the bout between Primo Carnera of Italy and Paulino Uzcudun of Spain fought in 1930 in Barcelona drew more ($110,000) than all but a few U.S. bouts that year. In 1935 Mike Jacobs, who had been associated with Rickard, signed Joe Louis to a contract and thus launched a new boxing era. With Louis fighting exclusively for him, Jacobs had the best drawing card since Dempsey. In two years he was promoting for Madison Square Garden in New York. Louis fought in three bouts that grossed over $1,000,000: Max Baer (1935), Max Schmeling (1938), and Billy Conn (1946). In 1945 the receipts from a year of boxing at Madison Square Garden exceeded $2,000,000 for the first time.

Some lucrative bouts were also staged outside the United States. British light heavyweight Freddie Mills drew crowds paying $200,000 and $182,000 respectively in London bouts against Americans Gus Lesnevich and

Joey Maxim. In 1953 English Randy Turpin drew $238,000 in London against French Charles Humez. When Thai bantamweight Chamrern Songkitrat developed into a contender for the world championship, he drew receipts of over $200,000 in 1954 Bangkok bouts against Australian Jimmy Carruthers and Frenchman Robert Cohen.

Influence of television

Beginning in the late 1940s, boxing in the United States underwent a great change brought about by televising of bouts. Attendance fell off sharply for all but the most attractive matches, as people preferred to watch televised bouts at home or in theatres. Receipts from the crowd attending became steadily of less importance. When Charles "Sonny" Liston defended his title against former champion Floyd Patterson in 1963, live gate receipts were only $247,690, but closed circuit TV and other media fees raised the total to $4,747,690, of which each fighter's share was $1,434,000.

Professional organization. World professional boxing has no single controlling body that is universally recognized. The situation started in the U.S., where two organizations were set up in 1920: the National Boxing Association, a private body, which at that time had a membership of 13 states; and the New York State Athletic Commission, a state agency. Divided control led to a situation in which competing organizations sometimes recognized different boxers as world champion at the same weight.

In Europe the ruling body was the International Boxing Union, which in 1948 became the European Boxing Union. Several attempts were made to induce all major organizations to agree to the formation of one international ruling body, but to little avail. There were always differences over voting power. In 1963, however, the World Boxing Council was formed. It includes the British and Commonwealth Boards of Control, Continental European Boxing Union, and the North American, Central American, South American, Oriental, Pan Pacific, and African Boxing federations.

The National Boxing Association changed its name to the World Boxing Association in the early 1960s and currently has control over most of the United States. Eleven states are not members of the WBA, however, and they stage most of the professional boxing events that take place in the U.S. The WBA still names its world champions, and there are still cases of two world champions at the same weight—one WBA and the other WBC.

At its 1970 annual congress, the World Boxing Council stated its aim to formulate one standard set of rules for boxing in all countries.

MODERN BOXING

Weight divisions. During the 19th and again at the beginning of the 20th century, the increasing popularity of professional boxing brought about the formation of weight divisions other than heavyweight class to obviate the handicap of a contestant having to concede excessive weight, sometimes two or three stones (28–42 lb, or 11–18 kg), to his opponent. Some divisions originated in the U.S., others in Great Britain. Title fights usually were arranged, but in many cases a boxer simply claimed a championship and held it until he was beaten. If he found he could no longer meet the required weight limit, he would simply alter the limit to suit himself. As long as he did not go to extremes, this was considered in order.

Gradually this practice ceased, the rules governing world championship bouts became more strict, and eight weight divisions came to be universally recognized with the limits as follows: flyweight (not over 112 lb), bantamweight (118 lb), featherweight (126 lb), lightweight (135 lb), welterweight (147 lb), middleweight (160 lb), light-heavyweight, or cruiserweight (175 lb), and heavyweight (any weight).

In all world and national title fights the above weight limits must be strictly observed. If a boxer is over the limit, he is normally given a short time in which to make the stipulated weight. If he still fails, the bout ceases to be regarded as a championship contest and the champion, if he was at fault, forfeits his title.

Two additional divisions, junior lightweight (130 lb) and junior welterweight (140 lb), were introduced in the U.S. in the 1920s. These still exist and world champions at these weights are recognized by some federations. Also, a junior middleweight (154 lb) division was introduced in the U.S. and a junior featherweight division in Oriental countries. The term junior in boxing has nothing to do with age. These divisions were formed for the benefit of boxers who were too heavy for one of the eight recognized divisions and too light for the next higher division.

There were seven divisions in the Olympic Games of 1904, and five in 1908. When the Games were resumed in 1920, there were eight, and the required weights were the same as for professionals. This situation continued until the European Championships of 1951, when the Association Internationale de Boxe Amateur (AIBA) instituted ten weight classes. This procedure was followed in the Olympic Games from 1952 until 1968, when yet another division was added. The AIBA weights, however, were almost entirely different from the professional weights and officially expressed in kilograms, instead of pounds. The 11 divisions now recognized in all major international amateur competitions are as follows: light-flyweight, 48 kg (105 lb 13 oz); flyweight, 51 kg (112 lb 7 oz); bantamweight, 54 kg (119 lb 1 oz); featherweight, 57 kg (125 lb 10½ oz); lightweight, 60 kg (132 lb 4½ oz); light-welterweight, 63.5 kg (140 lb); welterweight, 67 kg (147 lb 11 oz); light-middleweight, 71 kg (156 lb 8½ oz); middleweight, 75 kg (165 lb 5½ oz); light-heavyweight, 81 kg (178 lb 9 oz); and heavyweight (no limit). These divisions are also adopted in principle for the ABA Championships in Great Britain and the AAU Championships in the U.S., except that their limits are taken to the nearest pound and there are slight variations in the four divisions from featherweight to welterweight.

AIBA amateur classes recognized

Rules and equipment. Because there is no accepted world ruling body for professional boxing, each country has its own rules, and in the United States there are different rules for each state. Generally speaking, however, bouts take place in a "ring" that is 14 to 20 feet square and surrounded by three strands of ropes to stop the contestants' falling out. Professional bouts are from 4 to 15 rounds in duration, which is the usual distance for world championship contests.

In Britain the referee, who works in the ring with the boxers, is the sole adjudicator and regulates the bout. In most other countries, two judges outside the ring also keep scorecards, and a fighter must win on two of the three cards to score a decision. National championship bouts vary from 15 rounds in Great Britain to 10 in Japan and Korea. Padded gloves, ranging from six to eight ounces in weight, are worn by the boxers.

A bout ends in a knockout when a boxer is knocked down and is adjudged not ready to resume the contest at the count of "ten," whether he still be down or in the act of rising. A fight can be stopped (called a technical knockout in the United States) when a boxer is deemed by the referee to be incapable of defending himself, even though he has not been counted out; when a boxer is deemed by the referee to have sustained too serious an injury for him to continue, or to be too far behind in ability to have a chance of winning; or when a boxer himself retires. A bout may also end in a decision, when a bout goes the scheduled number of rounds and is won on points awarded by the referee and judges; in a draw, when the referee and judges agree that both boxers fought equally well; in a "no contest," when the referee deems that both men are not giving their best or are persistently infringing the rules; or in a disqualification.

Disqualification may be made by the referee for fouls such as hitting below the "belt" (an imaginary line drawn across the body from the top of the hip bone); hitting on the back of the head or neck; punching to the lower back, the region of the kidneys; hitting with the open glove, the inside or butt of the hand, or with the wrist or elbow; holding, butting with, or careless use of, the head; shouldering, wrestling, or roughing; not trying; persistently

ducking below the waistline; intentionally falling without receiving a blow; failing to separate when ordered to do so, or striking, or attempting to strike an opponent while separating; deliberately striking an opponent when he is falling or when he is down; or ungentlemanly conduct. A boxer is usually penalized at first by having marks deducted from his score and then disqualified if he persists. It is accepted in the United States that, since a boxer must wear a protective cup, disqualifications for low punching are rare, although the offending boxer would be penalized. In other nations, however, referees are often stricter in dealing with this offense, and a low blow considered deliberate could bring immediate disqualification.

Amateur rules

The rules for conducting amateur boxing are very similar in Great Britain, the United States, and continental Europe, with the main difference being that in America referees manually separate the boxers; elsewhere, on the command "break," the boxers would be expected to do so themselves, and also to take one step back. Bouts are normally three rounds, fought in rings 12 to 20 feet square, using eight- to ten-ounce gloves. Bending below the waist is prohibited by international rules, because it may lead to butting with the head. Voting, under international rules, is carried out entirely by three judges; the referee simply supervises the boxing. In the U.S., however, the scoring is done by the referee and two judges, with each scorer awarding a maximum of 20 points for each round.

Technique. No one phase of boxing is more important than another. Boxing demands coordination of hands, feet, and brain. Good footwork is as important as being able to punch correctly, defense as important as attack. Perfect balance is essential at all times. The two generally recognized stances are "orthodox" and "southpaw." The former has the left hand and left foot forward, the latter the right hand and right foot forward. A boxer adopts the stance he finds most natural and effective. For the orthodox stance, the right heel is in a line behind the left heel, knees slightly bent, and all movements carried out on the balls of the feet. The hands are held in front of the body, left hand shoulder high and extended about 12 inches. The left hand is slightly higher than the right, with the left forearm held across the chest, right fist almost touching it, and both elbows bent and resting lightly against the ribs. The right fist is held near the chin for protection, chin tucked into the chest and shoulders hunched.

There are three basic punches: the straight, hook, and uppercut. All others, such as the jab, swing, bolo, and cross, are modifications of the basics. The straight punch moves directly out from the shoulder, the back of the hand facing upwards. The hook is a short, lateral movement of arm and fist, elbow bent and wrist twisted inwards at the moment of impact. The uppercut is an upward blow delivered from the direction of the toes. The jab, a shortened version of the straight punch that reaches its target before the arm can be fully extended, is the punch most used in boxing. The swing is a long-range hook, a desperation punch used when a fighter cannot reach his opponent by any other method. The bolo is an uppercut that starts from behind the body, with the arm wound up as if to throw a baseball. The cross is similar to a straight punch or a hook, and used mainly as a follow-up to a lead from the other hand.

Changing styles. In bareknuckle fighting the accent was on power of punch, since bouts ended when one contestant could not continue. The hands were held in front of the body in no particular position, and footwork was nonexistent. With the advent of padded gloves and contests decided on points, boxing skill and footwork became more important. More regard was paid to defense to prevent an opponent's landing scoring punches. James J. Corbett was the first of the modern heavyweight champions to concentrate on technique. Ten years after Corbett lost the title, heavyweight champion Jack Johnson showed that he too could box as well as punch. Spectators were divided; they enjoyed watching clever boxers, but when it came to the heavyweights they looked for the "big punch." Hence the tremendous popularity of Jack Dempsey, an exciting, aggressive fighter who always sought to knock his man out. He fought from a crouch, bobbing and weaving to leave as little of himself exposed as possible. His style was later adopted by many other American boxers.

Heavyweights are not expected to move quickly, but a notable exception is Cassius Clay (Muhammad Ali), who won the world title in 1964 but forfeited it in 1967 when he refused to be inducted into the U.S. armed forces. He made a comeback in 1970 and in 1971 met Joe Frazier, then recognized as world champion. Clay was outpointed, and obviously three years of inactivity had taken their toll. But at his peak he was probably the fastest and the most skillful heavyweight champion of all time. He finished every fight unmarked and had a style all his own, dancing around, arms dangling by his sides, but always in position to attack or defend at the right time. It has been alleged that he did not possess a heavy punch, but his record before his fight with Frazier of 31 victories in 31 professional bouts, 25 being gained inside the scheduled number of rounds, suggests that there was plenty of power there.

Styles remain a matter of individual choice. In Britain many still adopt a form of the traditional upright stance originated by bareknuckle fighters, but in the United States a modified Dempsey-style crouch is more prevalent.

BIBLIOGRAPHY. BOHUN LYNCH, *The Prize Ring* (1925), traces the history of boxing from the bareknuckle period to the time when gloves were substituted for bare fists; descriptions of some of the most notable fights with relevant background details, all in chronological order, are included. NAT FLEISCHER, *Black Dynamite*, 5 vol. (1938–47), is a history of the Negro in boxing from 1782 to 1938, with biographies of the most important fighters and descriptions of their leading fights. *Heavyweight Championship*, rev. ed. (1961), by the same author, deals with all champions in this division from 1719, describing how they won their titles and how they fared in title defenses. Full statistical data is supplied for each title fight, along with different sets of rules that have been formed and reformed for the sport. RON OLVER and TIM RILEY, *Boxing* (1962), is written for the young man who wishes to take up boxing as an amateur. Basic blows are described in simplified language, together with stance, training, diet and weight, tactics, and technique, with chapters on professional boxing and the special problems of the left-handed boxer. *The Ring Record Book and Boxing Encyclopedia* (annual) is the most comprehensive work on boxing statistics currently published, with complete records of every world champion at every weight; *Boxing News Annual and Record Book* (annual) is the British counterpart to the *Ring Record Book* of America, providing all relevant historical data and statistics plus complete records of all current world, European, Commonwealth, and British champions.

(R.O.)

Boyle, Robert

A 17th-century natural philosopher, Robert Boyle devised many original experiments and developed a corpuscular concept of matter. He contributed much toward overthrowing the ancient Aristotelian view of nature based on forms and qualities, and substituting instead a particulate explanation in terms of matter and motion. All the intellectual interests of his day were harmonized in his twin enthusiasms, religion and experimental science. His attitude toward the study of nature in all its aspects was that it helped to reveal the greatness of the Creator. He was a leading member of the Royal Society of London.

Early life

Boyle was born on January 25, 1627, in Lismore, County Waterford, Ireland, being the 14th child of a family of wealth and influence. In 1635 he was sent to Eton College, which was in favour for the education of gentlemen's sons. He spent the years 1639 to 1644 with a tutor on the Continent, for the most part in Switzerland, though they also toured France and Italy.

On his return to England during the Civil War, Boyle reunited with his sister Katherine, Lady Ranelagh. Through her his circle of acquaintances was extended,

Boyle, oil painting by an unknown artist after F. Kerseboom (1632–90). In the National Portrait Gallery, London.
By courtesy of the National Portrait Gallery, London

and some of them, including Samuel Hartlib, certainly stimulated his interest in experimental work. Between 1645 and 1655, Boyle lived partly in Dorset, where he wrote moral essays, some of which appeared in 1655 in *Occasional Reflections upon Several Subjects.* One of his essays is reputed to have inspired the writing of *Gulliver's Travels* by Jonathan Swift. He spent some time in Ireland in connection with his estates, engaged in anatomical dissection. There was also a brief visit to the Low Countries in 1648.

The air pump

From 1656 to 1668 he resided at Oxford, where he had the good fortune to secure the assistance of Robert Hooke, the able inventor and subsequent curator of experiments to the Royal Society, who helped him to construct an air pump. Recognizing at once its scientific possibilities, Boyle conducted pioneering experiments in which he demonstrated the physical characteristics of air and that air is necessary for combustion, respiration, and the transmission of sound. Boyle described this work in 1660 in *New Experiments Physio-Mechanicall, Touching the Spring of the Air and its Effects.* In a work appended to the second edition in 1662, he published his report of 1661 to the Royal Society on the relationship, now known as Boyle's law, that at a constant temperature the volume of a gas is inversely proportional to the pressure. In *The Sceptical Chymist,* Boyle in 1661 attacked the Aristotelian theory of the four elements (earth, air, fire, and water) and also the three principles (salt, sulfur, mercury) proposed by Paracelsus. Instead, he developed the concept of primary particles which by coalition produce corpuscles. Different substances result from the number, position, and motion of the primary matter. All natural phenomena were therefore explained not by Aristotelian elements and qualities, but by the motion and organization of primary particles. Thus, Boyle did not postulate different kinds of primary elements—the 19th-century view—but his ideas are valid within certain limits.

Beginning in 1668, he resided with his sister Katherine in London. In this final period of his life he continued his experimental work with the help of laboratory assistants, one of whom founded a chemical manufacturing firm that had an independent existence until the early part of the 20th century.

In his experimental work he studied also the calcination of metals and proposed a means of distinguishing between acid and alkaline substances, which was the origin of the use of chemical indicators. He was also interested in trades and manufacturing processes. In an age that was not noted for its humanitarianism, Boyle not infrequently was compassionate enough to refrain from subjecting a living creature to the rigours of experiment for a second time.

Boyle acquired great renown in his lifetime, and foreigners of distinction invariably tried to visit him. Numerous poetical references were made to him, before and after his death. His many scientific and religious writings never led to acrimonious controversies. As a devout Protestant, he took a special interest in promoting the Christian religion abroad, giving money to translate and publish the New Testament into Irish and Turkish. He contributed also to the transcription, revision, and printing of an existing Irish version of the Old Testament. In 1690 he developed his theological views in *The Christian Virtuoso,* which he wrote to show that the study of nature was a central religious duty. In his view of divine providence, nature was a clocklike mechanism that had been made and set in motion by the Creator at the beginning and now functioned according to secondary laws, which could be studied by science. But the soul of man was incorporeal and nobler than the moving corpuscles of which his body was composed.

Interest in religion

During the final years of Boyle's life, he continued to take interest in the Royal Society, in the New England Company, and in his charitable activities. By his will he endowed a series of Boyle lectures, or sermons, which still continue, "for proving the Christian Religion against notorious Infidels."

Robert Boyle, who never married, died on December 31, 1691. He was buried in the church of St. Martin-in-the-Fields, Westminster, London.

BIBLIOGRAPHY. T. BIRCH (ed.), *The Works of the Honourable Robert Boyle, to Which Is Prefixed the Life of the Author,* 5 vol. (1744, reprinted 1965–66), a collection of Boyle's publications, and *The Life of the Honourable Robert Boyle* (1744), still an indispensable biographical study; J.F. FULTON, *A Bibliography of the Honourable Robert Boyle, Fellow of the Royal Society,* 2nd ed. (1961), an indispensable guide to serious study; M.B. HALL, *Robert Boyle and Seventeenth-Century Chemistry* (1968), an excellent account of the subject; R.E.W. MADDISON, "The Portraiture of the Honourable Robert Boyle, F.R.S.," *Ann. Sci.,* 15:141–214 (1959), and *The Life of the Honourable Robert Boyle* (1969), an exhaustive biographical study, which supplements Birch's *Life;* F. MASSON, *Robert Boyle* (1914), a pleasing, romantic account; L.T. MORE, *The Life and Works of the Honourable Robert Boyle* (1944); R. PILKINGTON, *Robert Boyle: Father of Chemistry* (1959), a useful general introduction to Boyle and his scientific work.

Brachiopoda

The Brachiopoda are a phylum of marine invertebrates that are covered by two valves, or shells; one valve covers the dorsal, or top, side; the other covers the ventral, or bottom, side. The valves, of unequal size, are bilaterally symmetrical; *i.e.,* the right and left sides are mirror images of one another.

Brachiopods occur in all oceans. Although no longer numerous, they were once one of the most abundant forms of life.

Brachiopods (from the Greek words meaning "arm" and "foot") are commonly known as lamp shells, because they resemble early Roman oil lamps.

Earliest fossil forms

Members of this phylum first appeared rather early in zoological history. It is possible, by means of fossil representatives, to survey their evolution from the Cambrian Period (about 570,000,000 years ago) to the present. Although some of the evolutionary development is revealed, it is still imperfectly understood. Other than their usefulness in dating geological periods, members of this phylum have no economic value, except as curios and museum pieces.

General features. *Size range and diversity of structure.* Most brachiopods are small, 2.5 centimetres (about one inch) or less in length or width; some are minute, measuring one millimetre or slightly more; some fossil forms are relative giants—about 38 centimetres (15 inches) wide. The largest modern brachiopod is about ten centimetres (four inches) in length.

Great diversity existed among brachiopods in the past; modern brachiopods, however, exhibit little variety. They are commonly tongue-shaped and oval lengthwise and in cross section. The surface may be smooth, spiny, covered with platelike structures, or ridged. Most modern brachiopods are yellowish or white, but some have red stripes

or spots; others are pink, brown, or dark gray. The tongue-shaped shells (*Lingula*) are brown with dark-green splotches; rarely, they are cream yellow and green.

Distribution and abundance. Today, brachiopods, numbering about 300 species representing 75 genera, are abundant only locally. In parts of the Antarctic they outnumber all other large invertebrates. They are common in the waters around Japan, southern Australia, and New Zealand. Although rare in the Indian Ocean, some unusual types are common along the coast of South Africa. In Caribbean and West Indian waters, 12 species occur. The east and west coasts of the North Atlantic Ocean are sparsely occupied by brachiopods; the waters around the British Isles contain a few species, and a few genera live in the Mediterranean Sea. The West Coast of the United States and Hawaii have a number of brachiopod species, and the coasts of Chile and Argentina have a considerable variety, including the largest living species. Some live in the polar regions, and a few are abyssal; *i.e.*, they inhabit deep parts of the ocean.

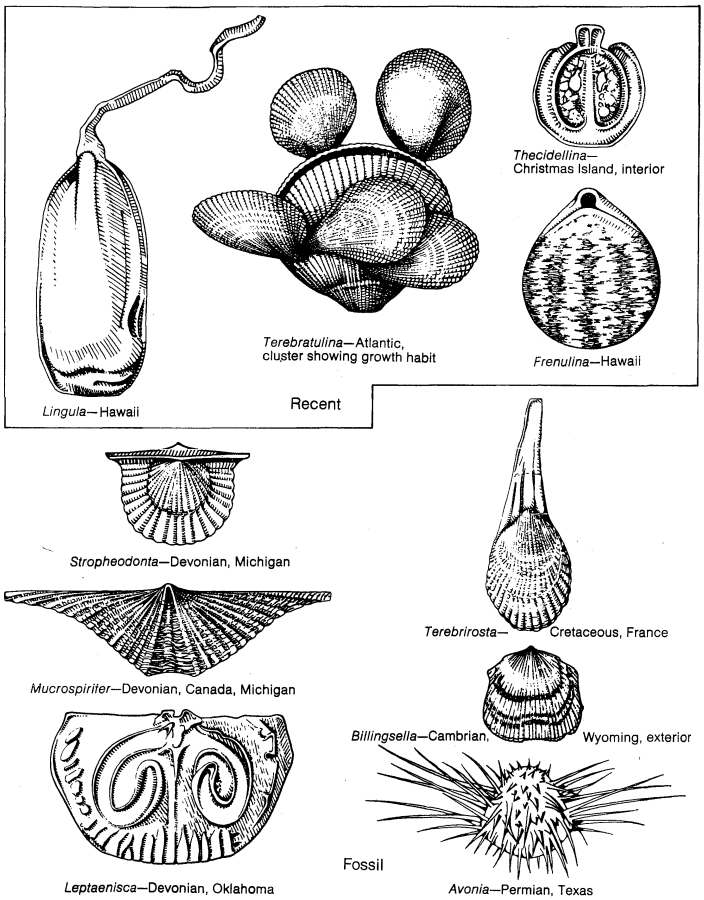

Figure 1: Representative brachiopods, fossil and living.

Natural history. *Reproduction.* Not much is known about the reproduction of brachiopods. Except in three genera, the sexes are separate. Eggs and sperm are discharged into the mantle cavity through funnel-shaped nephridia, or excretory organs, on each side of the mouth. Fertilization takes place outside the shell. In a few genera the young develop inside the female in brood pouches formed by a fold of the mantle, a soft extension of the body wall. Some fossil forms had internal cavities that may have served as brood chambers. The egg develops into a free-swimming larva that settles to the bottom. The free-swimming stage of the articulate brachiopods (whose valves articulate by means of teeth and sockets) lasts only a few days, but that of the inarticulates may last a month or six weeks. In inarticulate larvae the pedicle, a stalklike organ, develops from a so-called mantle fold along the valve margin; in articulates it develops from the caudal, or hind, region.

Articulate and inarticulate forms

Behaviour and ecology. About 60 percent of brachiopods live in shallow water (less than 100 fathoms—about 180 metres [600 feet]) on the shelf areas around the continents. More than 35 percent occupy waters deeper than 100 fathoms, and a few live in the abyss down to more than 6,000 metres (about 20,000 feet). *Lingula* lives from the tidal zone to 23 fathoms (about 42 metres [138 feet]). Most modern branchiopods anchor by the pedicle to pebbles, to the undersides of stones, or to other hard objects. They prefer quiet water and protected surroundings. *Lingula* lives in mud or sand and is attached at the bottom of its burrow.

Brachiopods feed by opening the shell and bringing in food-bearing currents by lashing of the cilia (hairlike structures) attached to the filaments of the lophophore, a horseshoe-shaped organ that filters food particles from the seawater. Cilia in lophophore grooves bring food particles, often trapped in mucus, to the mouth. Brachiopods feed on minute organisms or organic particles. Articulate brachiopods, which have a blind intestine, may depend partly on dissolved nutrients.

Shells of some articulate brachiopods have a fold, which forms a trilobed anterior that helps keep lateral, incoming food-bearing currents separated from outgoing, waste-bearing currents. When feeding, *Lingula* protrudes its anterior (front) end above the mud and arranges its setae (bristle-like structures) into three tubes. These channel the water into lateral incoming and medial, or central, outgoing currents. Some coralliform brachiopods of the Permian Period (280,000,000 to 225,000,000 years ago) are thought to have fed by rapid beating of the dorsal valve, causing a sucking in and expulsion of food-bearing water. Some ostreiform (oyster-shaped) types of the same period are believed to have fed by gentle pulsation of the dorsal valve.

Form and function. Two major groups of brachiopods are recognized, based on the presence or absence of articulation of the valves by teeth and sockets. The valves of inarticulate brachiopods are held together by muscles. *Lingula*, with its elongated, tonguelike shell, is an example of such an inarticulate. Its convex valves bulge outward at the middle and taper posteriorly, or away from the hinge. A long, fleshy pedicle protrudes between the valves at the tapered end. The pedicle of *Lingula* differs from that of most other brachiopods in being flexible and capable of movement—an aid in burrowing and in attaching the animal in its burrow. The shell interior is divided into posterior coelomic (internal-body) and anterior mantle cavities. The internal organs are located in the coelom. The digestive system consists of mouth, gullet, stomach, intestine, and anus, all surrounded by a liver, or digestive gland. A complex set of muscles opens the valves and slides them laterally, or sideways, when feeding. The mantle cavity is occupied by the lophophore. *Lingula* lives in a burrow in mud or sand with the tip of its pedicle attached in mucus at the bottom of the burrow. The contractile pedicle permits extension of the shell when feeding or retraction if the animal is startled.

The cavities within the shell

The articulate-brachiopod shell is typified by *Waltonia*, which is small (about two centimetres [¾ inch]) and red in colour, with a smooth or slightly ridged shell. This type of shell is more highly specialized than that of most inarticulate species and is composed of three layers. The outer layer, called periostracum, is made of organic substance and is seldom seen in fossils. A middle layer consists of calcium carbonate (calcite). The inner layer is composed of calcite fibres and may be punctate—*i.e.*, perforated by minute pits—or it may be pseudopunctate, with rods (taleolae) of calcite vertical to the surface. Impunctate shells have neither pits nor taleolae.

Many hinged brachiopods attach to the substrate, or surface, by a tough, fibrous pedicle; but some specialized forms are cemented to the substrate by the beak of the ventral valve. Cemented forms are commonly distorted, scalelike, or oyster shaped or resemble a cup coral. The pedicle of some brachiopods is atrophied; their shells lie loose on the sea floor.

The shell of an articulate brachiopod tapers posteriorly to a beak. The ventral valve is usually the larger. The

hinge may be narrow or wide. Many hinged genera have a flat or curved shelf, called the palintrope, between the beak and the hinge line. The ventral palintrope is divided at the middle by the delthyrium, a triangular opening for the pedicle. The delthyrium may remain open or be wholly or partly closed by small plates growing from its margins. In some families the delthyrium is closed completely or partly by one plate, the pseudodeltidium, anchored to the delthyrial margins. The articulating teeth occur at the angles of the delthyrium and may or may not be supported by vertical dental plates, which may be separate or united to form a so-called spondylium. Teeth are of two types, deltidiodont and cyrtomatodont. Deltidiodont teeth grow anteriorly with the palintrope and leave a growth path along the delthyrial edge; cyrtomatodont teeth are knoblike and occur in shells without a hinge line. They grow anteriorly but are kept knoblike by posterior resorption.

Muscles, sockets, and related structures

The dorsal valve contains structures called crura that diverge from the beak. In some fossil forms the crural bases (brachiophores) bound a triangular cavity, the notothyrium, in which the diductor, or opening, muscles are attached onto the floor or to a ridge, or boss, called the cardinal process at the apex. The notothyrium may be closed by a solid plate, the chilidium. In more highly developed genera a hinge plate bearing the pedicle or dorsal adjustor muscles occurs between the crural bases. The hinge plate is said to be divided when it is incomplete but undivided when it forms a flat or concave structure. The hinge plate is often supported by a median septum, or wall. The hinge sockets are located between the inside shell wall and a socket ridge to which the hinge plate is attached. In many specialized genera the crura support calcareous loops or spires (brachidia), the inner skeleton of the lophophore. Structures corresponding in function but of different origin and with different names occur in the pedicle region of some inarticulate brachiopods.

The fleshy body of the articulate brachiopod is divided transversely by the body wall into a posterior visceral cavity filled with coelomic fluid and an anterior mantle cavity filled with seawater. The visceral cavity contains the U-shaped digestive canal, four reproductive glands, and a liver, or digestive gland, held in place by mesenteries (sheets of tissue). Extensions of the coelom into the mantle hold the eggs and sperm. The mouth leads into a saclike stomach that ends in an intestine; there is no anus. The liver surrounds the stomach. Waste is excreted through the mouth. The nervous system, which consists of two principal ganglia, or nerve centres, encircles the esophagus and sends branches to other parts of the body. One pair of excretory organs (nephridia) occurs in most brachiopods, but two pairs may be present.

The mantle cavity is lined by the thin, shell-secreting mantle that is fringed by setae at its edges. Within the mantle cavity is the lophophore, which may be a simple or complicated loop, often horseshoe-shaped. Ciliated filaments along the loop direct food-bearing currents to the mouth, which is located on the body wall between the branches of the lophophore and crura.

The shell opens by contraction of diductor muscles that extend from near the centre of the ventral valve to the process under the dorsal beak. These muscles pull the dorsal beak forward, rotating it on a line joining the hinge teeth. Contraction of the adductor muscles closes the valves; in the ventral valve these are located between the diductors. Pedicle muscles or adjustors extending from the pedicle to the hinge plate of the dorsal valve rotate the shell on the pedicle. Where the muscles are attached to the shell there are scars, which are helpful in the identification of genera.

Early evolution

Paleontology. Brachiopods were among the first animals to appear at the beginning of the Cambrian Period (570,000,000 years ago). Their evolution and distribution was wide and rapid. More than 30,000 species in more than 2,100 genera are known, and the number of described species increases yearly. Articulate and inarticulate brachiopods appeared at the same time in a relatively advanced state of development, indicating a long evolution from forms without shells, an evolution apparently lost or unrecorded in Precambrian times.

The Inarticulata, the most abundant brachiopods of the Cambrian, soon gave way to the Articulata and declined greatly in number and variety toward the end of the Cambrian. They were represented in the Ordovician (500,000,000 to 430,000,000 years ago) but decreased thereafter. In the Cretaceous (136,000,000 to 65,000,000 years ago) the punctate calcareous Inarticulata proliferated, but this trend soon ended. The Inarticulata dwindled through the Cenozoic (65,000,000 years ago) to the Recent. Only nine genera are known during the Recent Epoch (last 10,000 years). Inarticulate genera represent about 6.5 percent of all brachiopod genera.

The Articulata, diverse and most numerous from Ordovician times to the present, were, in the Cambrian, represented by several specialized forms. Articulate evolution tended toward shell elaboration for bottom dwelling and perfection of feeding mechanisms from the simple looped lophophore to the elaborate lobate and spiral forms. The Orthida, the most common articulate brachiopods of the Cambrian and Ordovician, decreased in numbers after the Ordovician, and the impunctate Orthida became extinct in the Early Devonian (about 395,000,000 years ago); the punctate Orthida lingered into the Permian Period (280,000,000 to 225,000,000 years ago). The Strophomenida appeared in the Early Ordovician and increased rapidly. They were abundant and varied in the Devonian, becoming even more so by Permian times. This large order became greatly reduced at the end of the Permian Period. The Pentamerida, never prolific, flourished in the Ordovician; an evolutional burst of huge forms occurred in the Silurian (430,000,000 to 395,000,000 years ago), but after that the pentamerids decreased into the Devonian (395,000,000–345,000,000 years ago) and became extinct early in the late part of that period. The Spiriferida are conspicuous for the great elaboration of the spiral brachidium. They appeared in the Ordovician, were widely distributed into the Permian, and survived into the Jurassic, which began 190,000,000 years ago. The Rhynchonellida were abundant from mid-Ordovician throughout the Paleozoic. They survived into the Triassic (225,000,000 to 190,000,000 years ago) and had a rebirth in the Jurassic, after which they declined into the Cenozoic. They now number only 12 genera.

Development of modern dominant forms

The Terebratulida, now the dominant group, appeared in the early Devonian and rapidly expanded in the mid-Devonian to produce a number of gigantic forms; a few long-looped and short-looped genera persisted into the

Permian. The Terebratulida survived the Permian and were widely distributed in the Triassic and evolved into a great variety of forms in the Jurassic, especially the short-looped types. Decline of the short-looped terebratulids began in the Late Cretaceous (75,000,000 years ago); they have continued to dwindle into the present and are now outnumbered by the long-looped terebratulids.

Classification. *Distinguishing taxonomic features.* Brachiopods possess a lophophore (a feeding structure that filters food from seawater), excretory organs (nephridia), and simple circulatory, nervous, and reproductive systems. Brachiopods have usually been divided into two classes, Articulata and Inarticulata.

Annotated classification. The classification below is based on that proposed by A. Williams and A.J. Rowell in 1965 in *Treatise on Invertebrate Paleontology*.

PHYLUM BRACHIOPODA (lamp shells)
Marine invertebrates with two valves, or shells; lophophore horseshoe-shaped; about 300 living species known; more than 30,000 extinct species described; occur in all oceans.

Class Inarticulata
Shell does not articulate, is usually composed of chitinophosphatic material; shell muscles complex; pedicle (stalk) develops from ventral mantle, a soft extension of the body wall; intestine with anal opening.

Order Lingulida
Shell usually contains phosphate, rarely calcareous, biconvex (*i.e.*, both valves convex), beak for attachment to surface apical, or located at the tip, in both valves; fleshy pedicle emerging between the valves at the tapered end; about 51 genera; Cambrian to Recent.

Order Acrotretida
Usually circular in outline; shell either contains phosphate or is punctate calcareous; pedicle opening confined to the ventral valve; 62 genera; Early Cambrian (550,000,000 years ago) to Recent.

Order Obolellida
Mostly calcareous, biconvex, shape nearly circular to elongated; position of pedicle opening variable; dorsal valve with marginal beak; 5 genera; Early to mid-Cambrian.

Order Paterinida
Shell with phosphate, rounded or elliptical; pedicle opening partly closed by a cover called a homeodeltidium; dorsal valve similar to the ventral one but with a convex homeochilidium; 7 genera; Early Cambrian to mid-Ordovician (450,000,000 years ago).

Class Articulata
Shells articulate by means of teeth and sockets; shells always calcareous; musculature less complicated than in Inarticulata; larval pedicle develops from rear region; no outside opening from intestine.

Order Kutorginida
Calcareous, biconvex interarea (smooth surface in area between beak and hinge line) present; delthyrium (opening in the pedicle) closed by a plate, the pseudodeltidium; dorsal valve with interarea; muscle area narrow and elongated in both valves; 3 genera; Early to mid-Cambrian.

Order Orthida
Usually biconvex, wide-hinged, with interareas in both valves; teeth deltidiodont (leave a growth path along the margin of the pedicle opening); hinge structures consist of brachiophores (supporting structures), shell substance punctate or impunctate—*i.e.*, with or without pits; more than 200 genera; Early Cambrian through Permian (225,000,000 years ago).

Order Strophomenida
Teeth deltidiodont when present; ventral muscles large; shell substance pseudopunctate (with rods of calcite), rarely impunctate; more than 400 genera; Early Ordovician (490,000,000 years ago) to Early Jurassic (180,000,000 years ago).

Order Pentamerida
Biconvex, ventral valve usually with a spondylium (united dental plates); delthyrium usually open; dorsal-valve brachiophores supported by bracing plates; impunctate; nearly 100 genera; mid-Cambrian to Late Devonian (350,000,000 years ago).

Order Rhynchonellida
Narrow-hinged with functional pedicle; dorsal valve with or without a median septum; lophophore (of Recent genera) dorsally spiral and attached to crura (supporting structures); spondylia rare; nearly 300 genera; Ordovician to Recent.

Order Spiriferida
Lophophore supported by a calcareous spiral structure (brachidium); punctate or impunctate, usually biconvex; delthyrium open or closed; more than 300 genera; mid-Ordovician to Jurassic (136,000,000 years ago).

Order Terebratulida
Pedicle functional, cyrtomatodont teeth; lophophore supported wholly or in part by a calcareous loop, short or long and free or attached to a median septum; more than 300 genera; Early Devonian to Recent.

Critical appraisal. The classes Articulata and Inarticulata were first proposed by T.H. Huxley in 1869. Before 1932 they were further subdivided into four orders based on the imperfectly known larval development and formation of the shell around the pedicle opening. In 1927 a fifth order was proposed, and it was suggested that a classification be based on the pedicle development of the larvae.

The great majority of brachiopods are extinct forms whose larval development can only be conjectured. Because of this and other inadequacies, the early classification schemes have been abandoned. Eleven orders distributed in Huxley's classes have been retained in the present classification, which is still being modified. On the basis of hinge and tooth types some systematists have divided the Articulata into two subclasses, Protremata and Telotremata. The Protremata are wide-hinged forms with deltidiodont teeth. The Telotremata are narrow-hinged brachiopods with cyrtomatodont teeth.

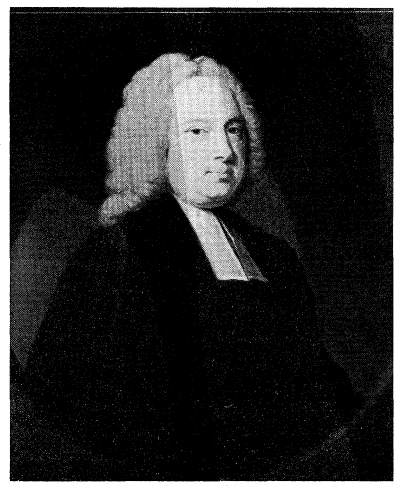
Bradley, James

James Bradley was an 18th-century English astronomer noted for his accurate stellar observations that confirmed the theoretical celestial mechanics of Sir Isaac Newton. By skillfully using improved telescopes, he detected the aberration (apparent displacement of an object) of light, which was the first observational proof for the revolution of the Earth around the Sun; measured nutation, the slight change in the direction of the Earth's axis that is caused by the gravitational pull of the Moon; and cataloged positions of 3,000 stars.

By courtesy of the National Portrait Gallery, London



Bradley, oil painting after Thomas Hudson, c. 1742–47. In the National Portrait Gallery, London.

Born at Sherborne, Gloucestershire, in March 1693, Bradley was educated at Balliol College, Oxford, where he received the B.A. in 1714 and the M.A. in 1717. He was instructed in observational astronomy at Wanstead, Essex, by his uncle, the Rev. James Pound, clergyman

and skilled amateur astronomer, who introduced him to the famous astronomer Edmond Halley.

Bradley's scientific acumen was stimulated by his membership in the Royal Society, to which he was elected a fellow in 1718 on the recommendation of Halley. Bradley took church orders and became vicar of Bridstow in 1719. The income from that position was augmented by a sinecure as an absentee rector in a parish in Pembrokeshire, Wales, which was procured for him by his friend and astronomical collaborator, Samuel Molyneux. Bradley resigned his church offices when he was appointed in 1721 to the Savilian chair of astronomy at Oxford and henceforth devoted his full time to astronomy.

Measuring the parallactic displacement of a star

After the publication of *De revolutionibus orbium coelestium* by Copernicus in 1543, it became increasingly imperative for astronomers to be able to observe and measure the parallactic displacement of a star—the change in a star's position over a six-month period—to confirm the orbital motion of the Earth around the Sun. Such information would provide the empirical evidence needed to augment the mathematical and conceptual arguments hitherto advanced for the idea that the Sun does not revolve around the Earth. In the absence of such evidence for parallax, Tycho Brahe, the 16th-century astronomer, had not been favourably disposed to Copernican theory. Ole Rømer, a Danish astronomer, measured an apparent displacement of the stars Sirius and Vega in the 17th century, but his observations were found to be erroneous. Robert Hooke, one of the founding members of the Royal Society, measured the star Gamma Draconis in a series of observations in 1669 for a similar attempt but was forced to report failure.

In 1725, using Molyneux's house as an observatory, Bradley attempted to repeat Hooke's measurements on Gamma Draconis with a telescope aimed so as to avoid any error resulting from the refraction of light. Although he failed to detect parallax because the star was too far away, Bradley made one of the two discoveries for which he is famous. He observed that Gamma Draconis shifted south in position by an astonishing 1″ of arc in three days —the wrong direction and by too large an amount to be accounted for by parallax. It is said that the explanation for this phenomenon came to Bradley as he sailed on the Thames, observing how the wind vane on the mast shifted position with the varying motion of the boat, even though the wind had not changed direction. He concluded that the apparent stellar shift was brought about by the aberration of light, which was a resultant of the velocity of light and the forward motion of the Earth in its orbit. Bradley communicated this discovery to the Royal Society in 1728, shortly after the death of Molyneux. Based upon his quantitative observations of aberration, Bradley confirmed the velocity of light to be 295,000 kilometres (183,000 miles) per second and gave a proof for the Copernican theory.

Calculation of the speed of light

Bradley's star measurements in 1727–32 also revealed what he called the "annual change of declination in some of the fixed stars," which could not be accounted for by aberration. He concluded that this was caused by the slight and uneven, nodding motion of the Earth's axis (nutation) and resulted from the changing direction of the gravitational pull of the Moon. But he withheld this announcement until he had made careful confirmatory observations during one complete set of revolutions of the Moon in its orbit. For this achievement the Royal Society of London awarded him the Copley Medal in 1748.

Members of the Royal Society in their function as "visitors and directors" of the Royal Greenwich Observatory recommended Bradley in 1742 to succeed Halley in the post of astronomer royal. (Halley, the second astronomer royal, had followed John Flamsteed, the first.) Bradley received £250 a year and the then sizable grant of £1,000 for instruments, notably an eight-foot (2.4-metre) quadrant for more precise measurements. In 1744 he married Susannah Peach, by whom he had one daughter. He held his important scientific, administrative, and consultative position at Greenwich until a few years before his death in Chalford, in his native Gloucestershire, on July 13, 1762.

The bulk of Bradley's observations was published after his death in an atmosphere of acrimony. Dispute between his heirs and the British Admiralty over the ownership of his work delayed publication until 1798–1805. The German mathematician Friedrich Bessel analyzed and organized his data, first detecting Bradley's instrumental errors, which were relatively few in number, and then computing the actual astronomical values.

Bradley was one of the first post-Newtonian observational astronomers who led the quest for precision.

BIBLIOGRAPHY. No complete biography exists. Additional information may be found in the preface to Bradley's *Miscellaneous Works and Correspondence*, ed. by S.P. RIGAUD (1832); and in the article, "James Bradley, 1693–1762: Bicentary Contributions," *Q. Jl. R. Astr. Soc.*, 4:38–61 (1963).

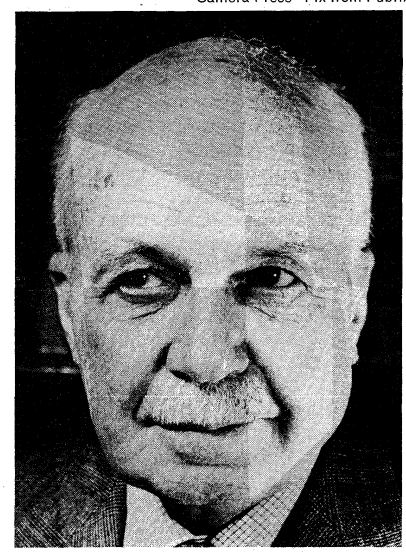
Bragg, Sir Lawrence

William Lawrence Bragg, who discovered a fundamental law of physics—Bragg's law—only three years after he took up study in that field, continued a long, distinguished career in physics, especially in the X-ray analysis of crystals. He later founded three famous research schools for the study of silicates, metals and alloys, and protein crystals.

Camera Press—Pix from Publix



Sir Lawrence Bragg, 1962.

"Willie" Bragg was born in Adelaide, Australia, on March 31, 1890, the eldest child of Sir William Henry Bragg (*q.v.*). His maternal grandfather, Sir Charles Todd, was postmaster general and government astronomer of South Australia. Educated at St. Peter's College, Adelaide, and then at Adelaide University, Bragg gained high honours in mathematics at an age when most boys were still in secondary school.

In 1909 he went to England to enter Trinity College, Cambridge. He began the study of physics, which he had not studied earlier, although he had taken some chemistry. During the summer vacation of 1912, his father discussed with him a recent book on the work of the German physicist Max von Laue, who asserted that X-rays could be diffracted by passing them through crystals. Upon his return to Cambridge, young Bragg, believing that Laue's explanation was incorrect in detail, carried out a series of ingenious original experiments, as the result of which he published the Bragg equation, which tells at what angles X-rays will be most efficiently diffracted off of a crystal when the X-ray wavelength and distance between the crystal atoms are known. This equation is basic to X-ray diffraction, a process used to analyze crystal structure by studying the characteristic patterns of X-rays that deviate from their original paths because of the closely spaced atoms in the crystal. He also showed that in rock salt the two kinds of atoms, sodium and chlorine,

The Bragg equation

are arranged alternately, so that atoms of the same element never touch each other. Meanwhile, his father had designed the X-ray spectrometer, a device to make exact measurements of X-ray wavelengths. The two scientists then spent vacations using the Bragg spectrometer to determine many other atomic arrangements, including that of diamonds.

In 1914 Bragg became a fellow and lecturer in natural sciences at Trinity College. Later that year he and his father were jointly awarded the Barnard Gold Medal of the U.S. Academy of Sciences, the first of many such honours and awards. From 1915 to 1919 Bragg served in World War I as technical advisor on sound ranging (determining the distance of enemy artillery from the sound of their guns) in the map section of British army headquarters in France, and he was there when the 1915 Nobel Prize for Physics was awarded jointly to his father and himself for demonstrating the use of X-rays for revealing the structure of crystals.

After the war Bragg succeeded Ernest Rutherford as professor of physics at Victoria University of Manchester, and there he built his first research school, for the study of metals and alloys and silicates. His work on silicates transformed a chemical riddle into a system of simple and elegant architecture. In 1921 he married Alice Hopkinson, a doctor's daughter, by whom he had two sons and two daughters. His wife's charm and character greatly helped him throughout his professional career. In the same year he was elected a Fellow of the Royal Society.

From 1937 to 1938 Bragg was director of the National Physical Laboratory, but he was impatient with committee work. About this period of his life he often used to remark that he found the engagement book, the in-tray, and the list of matters requiring urgent attention to be the deadly enemies of scientific work.

So he gladly left pure administration to succeed Rutherford again, this time as Cavendish Professor of Experimental Physics at Cambridge. Here he founded a second flourishing research school to study metals and alloys, silicates, and proteins, but he was also deeply concerned that science students should have time to enjoy a full education and come to understand something of the meaning and purpose of life.

School for research in metals and minerals

In January 1954, Bragg became director of the Royal Institution, London, as his father had been before 1940. He introduced several successful innovations: year-round lectures for schoolchildren, illustrated by demonstrations requiring apparatus too large or too costly for school resources (some 20,000 children attended each year); courses for science teachers; and lectures for civil servants whose early training had not included science. Popular and successful as a lecturer, Bragg was also in great demand for radio and television appearances. At an age at which many scientists lose interest in research, he built up a third research team, some of whose members successfully tackled the structures of complex organic crystals. Bragg retired from active scientific work in 1965 and died in Ipswich on July 1, 1971.

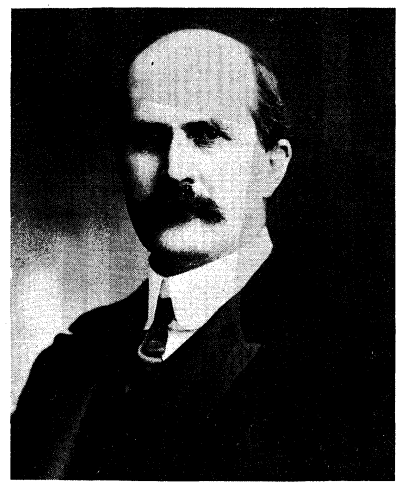
(K.Lo.)

Bragg, Sir William

William Henry Bragg, later Sir William Bragg, made his international reputation as a scientist with his son, William Lawrence Bragg (*q.v.*), by showing that X-rays could be used to determine the patterns of atoms and molecules in crystalline solids. They were thus the founders of the modern science of solid-state physics, the study of the atomic structure of solids, which led to the development of transistors and other solid-state devices.

W.H. Bragg was born in Cumberland in northwestern England on July 2, 1862. He came on his father's side from a family without academic traditions, mainly yeoman farmers and merchant seamen. His mother was the daughter of the local vicar. Upon her death, when he was barely seven, he went to live with two paternal uncles



Sir William Bragg.
By courtesy of the Nobelstiftelsen, Stockholm

who had set up a pharmacy and grocery shop in Market Harborough, Leicestershire. There he attended an old school re-established by one of his uncles. He did well, and in 1875 his father sent him to school at King William College, Isle of Man. At first he found it difficult to adjust himself, but he was good at his lessons and at sports and finally became head boy. During his last year, however, the school was swept by a storm of religious emotionalism. The boys were frightened by the stories of hellfire and eternal damnation, and the experience left a strong mark on Bragg. Later he wrote, "It was a terrible year . . . for many years the Bible was a repelling book, which I shrank from reading." And in a lecture *Science and Faith* at Cambridge in 1941, he said, "I am sure that I am not the only one to whom when young the literal interpretation of Biblical texts caused years of acute misery and fear." On the other hand, he attributed his clear, balanced style of writing to his early grounding in the Authorized (King James) Version of the Bible; in *The World of Sound* he wrote, "From religion comes a man's purpose; from science his power to achieve it."

In 1882 he was granted a scholarship at Trinity College, Cambridge; and two years later he obtained third place in the Mathematical Tripos (final examinations), a splendid achievement that led to his appointment, in 1885, as professor of mathematics and physics at the young University of Adelaide, South Australia. He then not only trained himself to become a good, lucid lecturer but he also apprenticed himself to a firm of instrument makers and made all the equipment he needed for practical laboratory teaching. It was this early training that enabled him, later (in 1912), after his return to England, to design the Bragg ionization spectrometer, the prototype of all modern X-ray and neutron diffractometers, with which he made the first exact measurements of X-ray wavelengths and crystal data.

Bragg ionization spectrometer

It was not until 1904, when Bragg became president of the physics section of the Australian Association for the Advancement of Science, that he began to think about original research. His subsequent work on α (alpha), β (beta), and γ (gamma) rays led the renowned British physicist Ernest Rutherford to propose him for fellowship of the Royal Society. He was elected in 1907 and within a year was offered a professorship in Leeds, England, where he developed his view that both γ rays and X-rays have particle-like properties.

In 1912 the German physicist Max von Laue announced that crystals could diffract X-rays, thus implying that X-rays must be waves like light but of much shorter wavelength. As a consequence, Bragg and his elder son, William Lawrence, who was studying physics at Cambridge, then began to apply X-rays to the study of crystal structure. These researches earned them jointly the award of the 1915 Nobel Prize for physics.

After World War I, during which he worked on anti-submarine devices, Bragg established a school of crys-

tallographic research at University College, London; and then, upon the death of the chemist and physicist Sir James Dewar, he succeeded him as director of the Royal Institution and of the Davy Faraday Research Laboratories, London. To these institutions he attracted many young scientists whose researches he inspired and stimulated and who subsequently achieved fame. Bragg was also a popular scientific lecturer and writer. He gave "Christmas Lectures" for children, which, when published, became best sellers. With Lady Bragg, he established a salon to which famous scientists came from far and wide. He was president of the Royal Society from 1935 to 1940 and received many other honours, but, to the last, he remained simple, gentle, and humble about his own success and proud of his son's. He died in London on March 12, 1942.

Brahe, Tycho

The observations made by the 16th-century Danish astronomer, Tycho Brahe, were the most accurate possible before the telescope came into use. His observational work eventually helped thoughtful Europeans to accept the Copernican system and became the basis for the 17th-century reformation of astronomy.

Brahe, engraving by H. Goltzius of a drawing by an unknown artist, c. 1586.

Youth and education

Tycho was born on December 14, 1546, in the town of Knudstrup in Scania, Denmark. His father was a privy councillor and later governor of the castle of Hälsingborg, which controls the main waterway to the Baltic Sea. His wealthy and childless uncle abducted Tycho at a very early age and, after the initial parental shock was overcome, raised him at his castle in Tostrup, Scania, also financing the youth's education, which began with the study of law at the University of Copenhagen in 1559–62.

Several important natural events turned Tycho from law to astronomy. The first was the total eclipse of the Sun predicted for August 21, 1560. Such a prediction seemed audacious and marvellous to a 14-year-old student, but when it arrived on schedule Tycho saw and believed—the spark was lit—and, as his many later references testify, he never forgot the event. His subsequent student life was divided between his daytime lectures on jurisprudence, in response to the wishes of his uncle, and his nighttime vigil of the stars. The professor of mathematics helped him with the only printed astronomical book available, the *Almagest* of Ptolemy, the astronomer of antiquity who described the geocentric conception of the cosmos. Other teachers helped him to construct small globes, on which star positions could be plotted, and compasses and cross-staffs, with which he could estimate the angular separation of stars.

In 1562 Brahe's uncle sent him to the University of Leipzig, where he studied until 1565. Another significant event in Brahe's life occurred in August 1563, when he made his first recorded observation, a conjunction, or overlapping, of Jupiter and Saturn. Almost immediately he found that the existing almanacs and ephemerides, which record stellar and planetary positions, were grossly inaccurate. The Copernican tables were several days off in predicting this event. In his youthful enthusiasm Brahe decided to devote his life to the accumulation of accurate observations of the heavens, in order to correct the existing tables.

Between 1565 and 1570 (or 1572?) he travelled widely throughout Europe, studying at Wittenberg, Rostock, Basel, and Augsburg and acquiring mathematical and astronomical instruments, including a huge quadrant. Inheriting the estates of his father and of his uncle Jørgen, Tycho then settled in Scania in 1571 (?) and constructed a small observatory on property owned by a relative. Here occurred the third and most important astronomical event in Brahe's life. On November 11, 1572, he suddenly saw a "new star," brighter than Venus and where no star was supposed to be, in the constellation Cassiopeia. He carefully observed the new star and showed that it lay beyond the Moon and therefore was in the realm of the fixed stars. To the world at the time, this was a disquieting discovery, because the intellectual community protected itself against the uncertainties of the future by confidence in the Aristotelian doctrine of inner and continuous harmony of the whole world. This harmony was ruled by the stars, which were, hopefully, perfect and unchanging. The news that a star could change as dramatically as that described by Tycho, together with the reports of the Copernican theory that the Sun, not the Earth, was the centre of the universe, shook confidence in the immutable laws of antiquity and suggested that the chaos and imperfections of Earth were reflected in the heavens. Tycho's discovery of the new star in Cassiopeia in 1572 and his publication of his observations of it in *De nova stella* in 1573 marked his transformation from a Danish dilettante to an astronomer with a European reputation.

Discovery of the nova in Cassiopeia

By marrying a peasant's daughter, named Kirstine, in 1573, Tycho—as a nobleman's son—scandalized most of his contemporaries. He seldom mentioned her in his extensive correspondence (which still exists), and it is probable that he was interested mainly in a companion who would superintend his household without being involved in court functions and intrigues. Tycho and Kirstine had eight children, six of whom survived him.

The new star in the constellation Cassiopeia had caused Tycho to rededicate himself to astronomy; one immediate decision was to establish a large observatory for regular observations of celestial events. His plan to establish this observatory in Germany prompted King Frederick II to keep him in Denmark by granting him title in 1576 to the island of Ven (formerly Hven), in the middle of the Sound and about halfway between Copenhagen and Helsingør, together with financial support for the observatory and laboratory buildings. Tycho called the observatory Uraniborg, after Urania, the Muse of astronomy. Surrounded by scholars and visited by learned travellers from all over Europe, Tycho and his assistants collected observations and substantially corrected nearly every known astronomical record.

Tycho was an artist as well as a scientist and craftsman, and everything he undertook, or surrounded himself with, had to be innovative and beautiful. He established a printing shop to produce and bind his manuscripts in his own way; he imported Augsburg craftsmen to construct the finest astronomical instruments; he induced Italian and Dutch artists and architects to design and

decorate his observatory; and he invented a pressure system to provide the then uncommon convenience of sanitary lavatory facilities. Uraniborg fulfilled the hopes of Tycho's king and friend, Frederick II, that it would become the centre of astronomical study and discovery in northern Europe.

But Frederick died in 1588 and under his son, Christian IV, Tycho's influence dwindled; most of his income was stopped, partly because of the increasing needs of the state for money. Spoiled by Frederick, however, Tycho had become both unreasonably demanding of more money and less inclined to carry out the civic duties required by his income from state lands.

Move to Prague

At odds with the three great powers—king, church, and nobility—Tycho left Ven in 1597, and, after short stays at Rostock and at Wandsbek, near Hamburg, he settled in Prague in 1599, under the patronage of Emperor Rudolf II, who also in later years supported the astronomer Johannes Kepler.

The major portion of Tycho's lifework—making and recording accurate astronomical observations—had already been done at Uraniborg. To his earlier observations, particularly his proof that the nova of 1572 was a star, he added a comprehensive study of the solar system, his proof that the orbit of the comet of 1577 lay beyond the Moon, and accurate positions of more than 777 fixed stars. He proposed a modified Copernican system in which the planets revolved around the Sun, which in turn moved around the stationary Earth. What Tycho accomplished, using only his simple instruments and practical talents, remains an outstanding accomplishment of the Renaissance.

Tycho attempted to continue his observations at Prague with the few instruments he had salvaged from Uraniborg, but the spirit was not there, and he died on October 24, 1601, leaving all his observational data to Johannes Kepler, his pupil and assistant in the final years. With these data Kepler laid the groundwork for the work of Sir Isaac Newton.

BIBLIOGRAPHY. J.A. GADE, *The Life and Times of Tycho Brahe* (1947), is the best account in English of Tycho's life and contains a fairly complete bibliography. J.L.E. DREYER, *Tycho Brahe* (1890), presents an authoritative picture of his work and his astronomical instruments, by the astronomer who also prepared his collected works for publication. Any volume on the history of scientific ideas contains some account of Tycho's work.

(O.J.E.)

Brahmaputra River

The mighty Brahmaputra River flows for 1,800 miles (2,900 kilometres) from its source in the Himalayas to its confluence with the Ganges, after which the mingled waters of the two rivers empty into the Bay of Bengal. Along its course it passes through the Tibetan Autonomous Region of China; the union territory of Arunachal Pradesh (NEFA) and the state of Assam, India; and Bangladesh. It is known to the Tibetans as the Tsangpo, to the Chinese as the Ya-lu-ts'ang-pu, to the Indians as the Brahmaputra, and to the people of Bangladesh as the Jamuna. For most of its length, the river serves as an important inland waterway; it is not, however, navigable between the mountains of Tibet and the plains of India. In its lower course, the river is both a creator and a destroyer—depositing large amounts of fertile alluvial soil but also causing disastrous and frequent floods. (For associated physical features, see BENGAL, BAY OF; GANGES RIVER; and HIMALAYAN MOUNTAIN RANGES.)

The course of the river. The river's source lies in the Chema-Yungdung Glacier, which covers the slopes of the Himalayas about 60 miles southeast of Lake Manasarowar in southwestern Tibet. The three headstreams are the Kubi, the Angsi, and the Chema-Yungdung. From its source the river runs for nearly 700 miles in a generally easterly direction between the main Himalayan range to the south and the Nien-ch'ing-t'ang-ku-la Shan (Nyenchen Tangla) to the north. Throughout its upper course the river is generally known as the Tsangpo (the Purifier); it is also known by the Chinese name Ya-lu-tsangpu Chiang and other local Tibetan names along its course.

The river's upper course

In Tibet the Tsangpo receives a number of tributaries. The most important left-bank tributaries are the Jo-k'a tsang-pu (Raga Tsangpo), which joins the river west of Jih-k'a-tse (Zhikatze), and the La-sa Ho (Kyi Chu), which flows past the Tibetan capital of Lhasa and joins the Tsangpo at Ch'ü-shui. The Ni-yang Ho (Gyamda Chu) joins the river from the north at Tse-la (Tsela Dzong). On the right bank the Nien-ch'u Ho (Nyang) meets the river at Jih-k'a-tse.

After passing P'i (Pe) in Tibet, the river turns suddenly to the northeast and cuts a course through a succession of great, narrow gorges between the mountainous complex of Gyala Peri (23,458 feet, or 7,150 metres, in height) and Na-mu-cho-pa-erh-wa Shan (Namcha Barwa) (25,446 feet, or 7,756 metres, in height) in a series of rapids and cascades. Thereafter, the river turns south and forces its way through the eastern extremity of the Himalayas to enter the Assam Valley of northeastern India as the Dihāng River.

At the town of Sadiya, India, the Dihāng turns to the southwest and is joined by the two mountain streams of Luhit and Dibang. After the confluence, about 900 miles from the Bay of Bengal, the river is known as the Brahmaputra (the Son of Brahmā [the Creator]). In Assam the river is mighty, even in the dry season, and during the rains its banks are more than five miles apart. As the river follows its braided, 450-mile course through the valley, it receives several rapidly rushing Himalayan streams, including the Subansirī, Bhareli, Dhansiri, Manās, Chāmpamāti, Saralbhānga, and Sankosh rivers. The main tributaries from the hills and from the plateau to the south are the Burhi Dihing, the Disāng, the Dikhu, and the Kāpili.

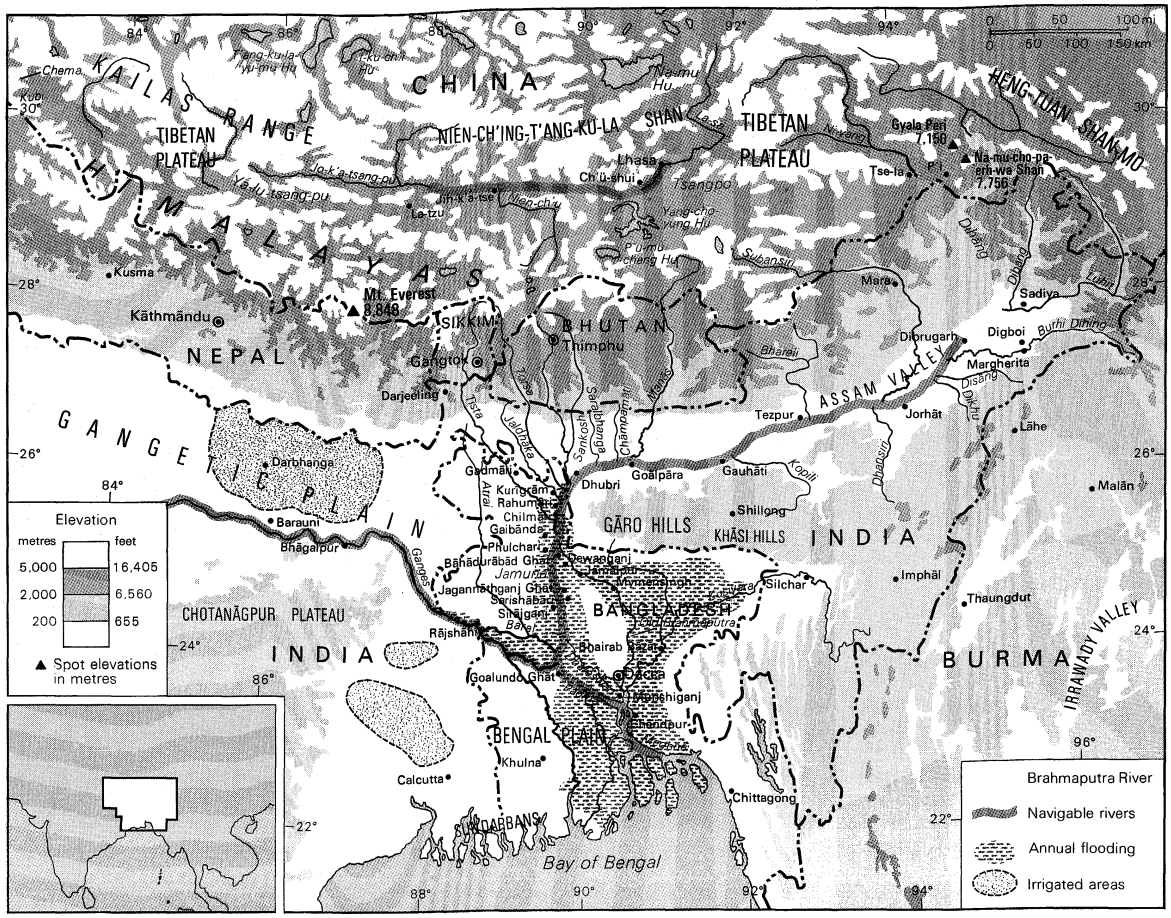
The Brahmaputra enters the plains of Bangladesh after turning south around the Gāro Hills below Dhubri, India. After flowing past Chilmāri, Bangladesh, it is joined on its right bank by the Tīsta River, following a 150-mile course due south as the Jamuna River. (South of Gaibānda, the Old Brahmaputra leaves the left bank of the main stream and flows past Jamālpur and Mymensingh to join the Meghna River at Bhairab Bāzār.) Before its confluence with the Ganges River, the Jamuna receives the combined waters of the Baral, Atrai, and Hurāsāgar rivers on its right bank and becomes the point of departure of the large Dhaleswari River on its left bank. A distributary of the Dhaleswari, the Burhi Ganga, flows past Dacca and joins the Meghna River above Munshiganj.

The complex lower course

The Jamuna joins with the Ganges north of Goalundo Ghāt, after which, as the Padma, their combined waters flow to the southeast for a distance of about 65 miles. The Padma reaches its confluence with the Meghna River near Chāndpur and then enters the Bay of Bengal through the Meghna Estuary and lesser channels.

The natural environment. *Climate.* The climate of the Brahmaputra Valley varies from the harsh, cold, and dry conditions found in Tibet to the generally hot and humid conditions prevailing in the Assam Valley and Bangladesh. Tibetan winters are severely cold, with minimum temperatures below 32° F (0° C), while summers are mild and sunny. The river valley lies in the rain shadow of the Himalayas; there is little rain in the summer, but some snow and rain falls during the winter. In the Indian and Bangladesh part of the valley, the monsoon climate is somewhat modified; the hot season is shorter than usual, and the average temperature is 82° F (28° C). Precipitation is relatively heavy, and humidity is high throughout the year. The annual rainfall of between 70 and 150 inches falls mostly between June and early October; light rains also fall from March to May.

Vegetation and animal life. Large areas in Assam are covered with sal (valuable timber trees that yield resin) forests, and tall reed jungle grows in the swamps and depressed, water-filled areas (*jhīls*) of the immense floodplains. Around the settlements in the Assam Valley, the many fruit trees yield plantains, papayas, mangos, and jackfruit. Bamboo thickets abound everywhere.



The Brahmaputra River Basin.
Flooding data from R. Rawson, *The Monsoon Lands of Asia*; irrigation data from L. Cantor, *A World Geography of Irrigation* (1970), Oliver and Boyd, Edinburgh

The most notable animal of the swamps in Assam is the one-horned rhinoceros, which has become extinct in other parts of the world. Tigers and elephants are also found. Numerous varieties of fish include the betki, pabda, ruhi, chital, and mrigal.

Hydrology. Constant changes of the river's course constitute a significant factor in the hydrology of the Brahmaputra; the most spectacular of these changes was the eastward diversion of the Tīsta River and the ensuing development of the new channel of the Jamuna, which occurred in 1787 with an exceptionally high flood in the Tīsta. The waters were suddenly diverted eastward into an old abandoned course, causing the river to join the Brahmaputra opposite Bāhādurābād Ghāt in Mymensingh District. Until the late 18th century the Brahmaputra flowed past the town of Mymensingh and joined the Meghna River near Bhairab Bāzār (the path of the present-day Old Brahmaputra Channel). At that time, the course of the Jamuna River (now the main Brahmaputra Channel) was a minor stream called the Konai-Jenai, which was probably a spill channel of the Old Brahmaputra. After being reinforced by the Tīsta flood of 1787, the Brahmaputra began to cut a new channel along the Konai-Jenai and gradually converted it after 1810 into the main stream, now known as the Jamuna.

Changes in the river's course

Along the lower courses of the Ganges and Brahmaputra and along the Meghna, the land is subjected to constant erosion and deposition of silt because of the shifts and changes in these active river courses. Vast areas are subject to large-scale inundation during the monsoon months from June to September. The oscillations of the Jamuna since 1787 have been considerable, and the river is never in exactly the same place for two successive years. Islands and sizable newly deposited lands (*chars*) in the river appear and disappear seasonally. The *chars* are valuable to the economy of Bangladesh as additional cultivable areas.

In Tibet the waters of the Brahmaputra are clear because little silt is carried downstream. As soon as the river enters the Assam Valley, however, the silt charge becomes heavy. Because of the speed and volume of water in the northern tributaries that flow down from the rain-soaked Himalayan slopes, their silt charge is much heavier than that carried by the tributaries that cross the hard rocks of the old plateau to the south. In Assam the deep channel of the Brahmaputra follows the southern bank closer than the northern bank. This tendency is reinforced by the silt-laden northern tributaries that tend to push the channel to the south.

Another important hydrographic feature of the river is its tendency to flood. The quantity of water carried by the Brahmaputra in India and Bangladesh is enormous. The Assam Valley is enclosed by hill ranges on the north, east, and south and receives over 100 inches of rainfall annually, while in the Bengal Plain heavy rainfall (70 to 100 inches) is reinforced by the huge discharge of the Tīsta, Torsa, and Jaldhāka rivers. This results in heavy annual floods and an estimated discharge during the rainy season of 500,000 cubic feet per second. The Assam earthquake of 1950 led to numerous landslides on the Himalayan slopes of the Assam Valley; the resulting enlarged discharge, combined with enormous amounts of silt, caused extraordinary floods. Between 1950 and 1970 there were heavy flood conditions every year except 1951, 1952, and 1958.

The imprint of man. *The people of the river valley.* The people living in the different sections of the Brahmaputra Valley are of diverse origin and culture. North of the Himalayan rampart, the Tibetans practice Buddhism and speak the Tibetan language. They engage in animal husbandry and cultivate the valley with irrigation water taken from the river.

The Assamese are a mixture of Mongolian–Tibetan, Aryan, and Burmese ethnic origins. Their language is

akin to Bengali, which is spoken in West Bengal, India, and Bangladesh. From the late 19th century a vast number of immigrants from the Bengal Plain of Bangladesh entered the valley; they settled there to cultivate the almost empty lands, particularly the low floodplains. In the Bengal Plain itself the river flows through an area that is densely populated by the Bengali people, who cultivate the fertile valley. The hilly margins of the plain are inhabited by the hill tribes of the Garos, Khāsis, and Hajangs.

Irrigation and flood control. Flood-control schemes and the building of embankments were initiated after 1954. In Bangladesh the Brahmaputra embankment will run west of the Jamuna River from north to south for about 135 miles to help to control floods. The Tīsta Barrage Project is to be both an irrigation and a flood-protection scheme; it is to consist of a barrage across the Tīsta near Gadmāri, about two miles from the Hātibāndha railway station in Rangpur District, as well as of a main canal, which will be about 30 miles long and will drain southward into the Karatoya River near Khānsāma. The project will irrigate about 800,000 acres during the dry winter season from November to February and will also produce hydroelectricity (total capacity 10,000 kilowatts).

The Tīsta Barrage Project

By the early 1970s, little power had been harnessed along the Brahmaputra or the Assam Valley, although the estimated potential is great. The tributaries that drain the Shillong plateau have deep stretches and a series of rapids and falls that are suitable for hydroelectric development. Actual development is so far limited to the Barpani Dam and the Umiam Project near Gauhāti, which have a total capacity of almost 60,000 kilowatts and which serve areas of the Khāsi Hills in Meghalaya. There is little demand for electric power in the Brahmaputra Valley because manufacturing is limited and there is relatively little urbanization. Power needed on the tea estates in the Assam Valley is locally generated by thermal sources, which mainly use crude oil.

Navigation and transport. The river is navigable in Tibet for about 400 miles between La-tzu (Lhatse Dzong) and Lhasa. Coracles (boats made of hides and bamboo) and large ferries ply its waters at 12,000 feet above sea level. The Tsangpo is spanned in several places by suspension bridges.

Because it flows through a region of heavy rainfall in Assam and Bangladesh, the Brahmaputra is more important for inland navigation than for irrigation. The river has long formed a waterway between West Bengal and Assam. It is navigable throughout the Bengal Plain and Assam upstream to Dibrugarh, 800 miles from the sea. Besides all types of local craft, powered launches and steamers may easily ply up and down the river, carrying bulky raw materials, timber, and crude oil. After the conflict between India and Pakistan in 1965, however, heavy traffic was suspended.

The Brahmaputra remains unbridged throughout its course in the plains. Roads and railroads run along the river but never cross it; ferries carry traffic between its banks. Sadiya, Dibrugarh, Jorhāt, Tezpur, Gauhāti, Goālpāra, and Dhubri are important towns and ferry-crossing points in Assam, while Kurīgrām, Rahumāri, Chilmāri, Bāhādurābād Ghāt, Phulchari, Sarishābāri, Jagannāthganj Ghāt, Nagarbāri, Sirājganj, and Goalundo Ghāt are important crossing points in Bangladesh. The railheads are located at Bāhādurābād Ghāt, Phulchari, Jagannāthganj Ghāt, Sirājganj, and Goalundo Ghāt.

History. The upper course of the Brahmaputra was unknown until the 19th century. The explorations of the Indian surveyor Kinthup in 1884 and of J.F. Needham in Assam in 1886 established the Tsangpo as the upper course of the Brahmaputra. Various British expeditions in the first quarter of the 20th century explored the Tsangpo upstream to Jih-k'a-tse, as well as the river's mountain gorges.

Economic resources and the future. The main economic resources of the Lower Brahmaputra Valley are the tea estates, the forests, and the oil, coal, and natural gas deposits of Assam, as well as the jute of Bangladesh. These resources could be further developed if the river itself could be used for heavy transport. The creation of Bangladesh in 1971 and the hope of good economic and commercial relations with India offer promising possibilities of future growth.

(N.A.)

Brahms, Johannes

In a period that emphasized the need for revolution and progress in art, Johannes Brahms preserved the great musical traditions of the past. His compositions, though using the Romantic idiom of his time, show the unmistakable classical influence of Bach, Haydn, and Beethoven. Out of new and old elements, however, he created a strongly personal style, characterized by warmth and fire yet often imbued with strangely ambivalent moods. He was extremely versatile, writing symphonies, concerti, chamber music, piano works, choral compositions (among them the famous *German Requiem*), and more than 200 songs; but it is characteristic of his reticent and introverted nature that he avoided opera, although this form stood in the forefront of artistic interest during the 19th century.

Brahms, lithograph by Rudolf Fenzl, 1897.

Youth. Johannes Brahms was born on May 7, 1833, in Hamburg, Germany. His father, Johann Jakob, had run away from the village where his family kept an inn to become a musician. Eventually, he gained a modest foothold in Hamburg as a horn and double-bass player performing in various places of entertainment, in the militia, and ultimately in the opera orchestra. Brahms's mother, who was 17 years older than her husband, had from the age of 13 supported herself as a seamstress and general maid. Though poorly educated, she was a woman of great sensitivity and spiritual resources. The couple had

to live in Hamburg's poorest district and exercise the utmost frugality to raise their three children on Johann's modest earnings. Yet their home was a happy one, for both drew enjoyment from the simplest pleasures. It was their aim to give their children a good education and see them rise in the world. In the case of Johannes, who at an early age displayed outstanding musical talent, it was not hard to secure a first-rate teacher. From the age of seven he was instructed by a fine German pianist, F.W. Cossel, and made such progress that within three years he could successfully take part in a chamber-music concert. An impresario tried to induce the Brahms family to travel to the United States, where the young pianist could have become rich. The temptation was great, but Cossel, aware that a concert tour at this early stage would endanger Johannes' artistic growth, pleaded against the plan. To enlist moral support, he induced Eduard Marxsen, Hamburg's most renowned music teacher, to take over the boy's education without pay, and this decided the matter.

First lessons in composition

Marxsen, a competent composer, instructed Johannes in music theory and thus laid the groundwork for Brahms's future career. He developed into an outstanding pianist but considered this an avocation since he was determined to devote himself mainly to composition. During these formative years, however, his piano playing secured the family an added, badly needed income. From the age of 13, Johannes performed in taverns, restaurants, and nightclubs, often late into the night. While contributing to household expenses, he kept some of the money for buying books, which he avidly devoured; he even copied favourite passages into special notebooks. He also worked for a music publisher, doing arrangements and supplying fashionable drawing-room compositions under a pseudonym. These activities did not seem likely to lead to a successful career.

A recital he gave in 1848 made little impression on the Hamburg public, who were used to the appearance of more glamorous virtuosos, and hardly anybody was aware of the youth's ability to compose. Convinced that he had reached a dead end, Brahms wanted to leave home and prove himself in the musical world. At the age of 20, his wish was granted when Eduard Reményi, a Hungarian violinist whom Brahms had previously accompanied in a recital, invited Brahms to join him on a concert tour. They started on April 19, 1853, a date that marked a turning point for Brahms. The venture itself was not particularly successful and ended in a quarrel, but Brahms met three musicians who were to play highly important parts in his artistic and personal life. He became a close friend of a famous violin virtuoso, Joseph Joachim, who from the outset recognized Brahms's genius. Even more important, however, was Brahms's visit at the Düsseldorf home of the composer Robert Schumann and his wife, Clara, a magnificent concert pianist. Both were deeply impressed by his works, and Schumann immediately decided to recommend their publication to his own publishers, Breitkopf and Härtel, in Leipzig. He also decided to tell the musical world of the genius he had discovered and published an article entitled "Neue Bahnen" ("New Paths") in a widely circulated periodical named *Neue Zeitschrift für Musik* ("New Magazine for Music"), which he had founded years earlier. In his essay he glowingly described the impressions received of Brahms's compositions and prophesied a splendid career for the youth "called forth to give us the highest expression of ideals in our time." The article created a sensation, though some critics were inclined to distrust so enthusiastic an encomium. But Brahms's personality quickly silenced the opposition. The remarks in a lady's diary written after the composer had performed in her salon suggested the prevailing attitude:

Encouragement from Robert Schumann

> There he sat . . ., Schumann's young Messiah . . .; his face showed the triumph of his spirit. Purity, innocence, naturalness, power, and depth—this describes his character. Schumann's prophecy tempts one perhaps to . . . be severe with him, but one forgets everything, and loves and admires him without restraint.

The young composer himself felt somewhat crushed by the great responsibility laid on him by such a forecast. He reacted by applying relentless self-criticism to the works he prepared for publication and discarded several, as he was wont to do also in later phases of his development. Finally, he entrusted Breitkopf and Härtel with the publication of his first two piano sonatas, six songs, and the *Scherzo in E Flat Minor*.

The years 1854–56 were mostly devoted to studies and creative work carried out while he was staying with Joachim at Göttingen or near the Schumanns' home in Düsseldorf. It was a time of deepest emotional turmoil for the young composer. In February 1854 Robert Schumann, tormented by a nervous disorder of increasing proportions, attempted suicide and had to be removed to an asylum. His wife, a mother of six children, with a seventh on the way, was in despair. Brahms felt he had to help in whatever way he could and stayed near Clara, supporting himself modestly through music lessons. He continued his creative work, finishing his *Trio in B Major* for piano, violin, and cello and composing piano variations on a theme by "him" (Robert Schumann) dedicated to "her" (Clara).

Brahms fell more and more under the spell of Clara, who, at the age of 35, was still a very beautiful woman. His initial reverent friendship turned into ardent love. But Clara was the loyal wife of his great friend, for whose suffering he felt the deepest compassion and whose recovery he desired with all his heart. His mental agony was described by Brahms himself when explaining the meaning of his *Piano Quartet No. 3 in C Minor* conceived at that time: "Just picture a man who is going to shoot himself and has no other choice left." Yet, when Schumann died in July 1856, Brahms and Clara did not marry. Clara probably decided that she could not burden the young genius with a wife 14 years his senior and with seven children. Brahms himself may have felt too immature and unsettled in his career to undertake such responsibilities. Most of all, he was by nature unable to accept any encroachment on his freedom. He had to go through an agonizing struggle between his love and his zest for independence until the latter won. This pattern was to repeat itself. Brahms often fell in love with beautiful girls—though never so intensely as with Clara—but ultimately he could never commit himself. The relationship with Clara gradually changed into a lifelong friendship. She was privileged to watch the growth of his mastery: she was introduced to any new work as soon as the ink was dry, and her sensitive comments meant a great deal to Brahms.

The transitional phase. In 1857 Brahms obtained his first official position when he was engaged for three months by the princely court of Detmold as pianist-in-residence and conductor of the choral society, part-time duties he performed for three years. This post provided valuable practical experience and left him enough time for his own work. Now that the emotional conflict was to some extent resolved, his productivity increased. Apart from the two delightful *Serenades* for orchestra and the colourful first *String Sextet in B Flat Major*, the turbulent *Piano Concerto No. 1 in D Minor* was completed after undergoing various changes and revisions. Brahms's main aim at that time was to gain a permanent position in his native town. He was gradually establishing contacts with leading musicians in Hamburg, and it was his hope that on the retirement of Friedrich Wilhelm Grund, conductor of the Philharmonic Concerts, the post would be offered to him. To pass the time and also to increase his standing in Hamburg by winning success in a famous music centre, Brahms left for Vienna in September 1862. The Viennese musicians showed great interest in his work, and before long he had opportunities to reveal in various concerts his mastery both as a pianist and a composer. But this eventful time was overshadowed by inner tension while he waited for the decision in Hamburg and finally by the severe disappointment when, in May 1863, the position was offered not to him but to a singer, his friend Julius Stockhausen. Under the first impact he wrote to Clara:

Completion of first piano concerto

> This is a much sadder business for me than you think. . . . As I am altogether a rather old-fashioned person, so I am

in this, that I am not a cosmopolitan, but love my native town as a mother . . . And now this hostile friend comes and ousts me . . . perhaps for ever. How rare it is for one of us to find a permanent niche and how glad I should have been to find mine in my native town! . . . One wants to be bound, and to acquire the things that make life worth living, and one dreads solitude. Work in active association with others, with live social intercourse, and family happiness . . . who is so little human that he does not long for these things?

Brahms longed at times for such security, yet as events in his life were to reveal again and again, he was fundamentally unwilling to be "bound," be it in his human relationships or in a permanent position. This great disappointment decisively contributed to a change in Brahms's personality. He grew more reserved, ironical, and even maliciously sarcastic in his utterances. It is significant that he eventually hid his sensitive features under a large beard. Brahms the artist, however, may have benefitted from Hamburg's rejection. Looking for a new home, he chose, after some years of wandering, the one place that differed decisively from Hamburg: Vienna. For the narrow provincial atmosphere of his native town he substituted that of the cosmopolitan imperial city with an abundant musical life and inhabitants more outgoing and friendly than the cool, reserved northern Germans. Under the impact of Vienna's peculiar atmosphere, his artistic personality was enriched, and this led to the peak of achievements in his work, which won him outstanding renown.

Move to Vienna

Maturity. Vienna certainly offered Brahms what Hamburg had denied him. In 1863 he accepted an invitation to take over direction of the Singakademie, a fine choral society; his concerts, distinguished by interesting programs, were appreciated by critics and audiences alike, Yet some aspects of the position, such as arguments about program policy, irked him, and after a year, he declined to continue directing the group. He showed somewhat more perseverance when, in 1872, he was appointed artistic director of the Vienna Gesellschaft der Musikfreunde (Society of Friends of Music), a venerable organization founded in 1812 that had counted Beethoven and Schubert among its members. Brahms remained with this group for three years, and in his sensitive interpretation of music from different epochs he exerted a lasting educational influence on Viennese music lovers. He was sometimes criticized for planning unvaried programs, with a serious mood predominating. This led to a jesting remark that circulated in Vienna's musical circles: "When Brahms is in extra good spirits, he sings 'The grave is my joy'." Whether as a result of this criticism or because he was impatient with routine administrative duties, Brahms resigned in 1875, greatly relieved to have regained his independence. It was the last time in his life that he held a position of this kind, although offers were received from German cities such as Cologne (three times) and Düsseldorf (twice). Nevertheless, he maintained cordial relations with the Vienna Gesellschaft, which elected him an honorary member, and proved his attachment by making the society his sole heir.

In between the two appointments in Vienna, Brahms's work flourished and some of his most significant works were composed. The year 1868 witnessed the completion of his most famous choral work, *Ein deutsches Requiem* (*A German Requiem*), which had occupied him since Schumann's death and was taken up again in 1865 when Brahms's mother died. The work, based on biblical texts selected by the composer, made a strong impact at its first performance at Bremen on Good Friday, 1868; after this, it was performed all over Germany. With the *Requiem*, which is still considered one of the most significant works of 19th-century choral music, Brahms moved into the front rank of German composers.

Completion of the *German Requiem*

Brahms was also writing successful works in a lighter vein. In 1869 he offered two volumes of *Hungarian Dances* for piano duet, brilliant arrangements of gypsy tunes he had collected in the course of the years. Their success was phenomenal, and they were played all over the world. Similarly, in 1868–69 he paid a gracious compliment to his adopted hometown by presenting his *Liebeslieder* (*Love Song*) waltzes, Opus 52, for vocal quartet and four-hand piano accompaniment—a work sparkling with humour and incorporating graceful Viennese dance tunes.

Among the songs Brahms wrote during these years are the deeply felt "Die Mainacht" ("May Night"), Opus 43, No. 2; the dreamy "Feldeinsamkeit" ("In Lonely Meadow"), Opus 86, No. 2; the humorous "Vergebliches Ständchen" ("Unavailing Serenade"), Opus 84, No. 4; and the most famous of all, "Wiegenlied" ("Lullaby"), Opus 49, No. 4, which he sent in July 1868 to his Viennese friend Bertha Faber to congratulate her on the birth of her child. Into the rocking accompaniment he wove an Austrian ländler dance Bertha had sung to him long before.

Brahms also wrote several significant chamber works in this period. He completed his powerful *Piano Quintet in F Minor;* the *String Sextet No. 2 in G Major*, quieter and more restrained in character than the first one, and, inspired by his mother's death, the *Trio for French Horn, Violin, and Piano*, a work imbued with a delicate melancholy but also with a deep feeling for the beauty of nature. A climax of stylistic perfection and artistic economy was reached with the magnificent *String Quartets in C Minor* and *A Minor*, Opus 51, soon followed by the joyful and bucolic third *Quartet in B Flat Major*, Opus 67. Brahms was moving with great deliberation along the path to purely orchestral composition. In 1873 he offered the masterly orchestral version of his *Variations on a Theme by Haydn*. After this experiment, which even the self-critical Brahms had to consider completely successful, he felt ready to embark on the completion of his *Symphony No. 1 in C Minor*, the opening movement of which he had shown Clara Schumann six years earlier. The magnificent work was completed in 1876 and first heard in the same year. Now that the composer had proved to himself his full command of the symphonic idiom, within the next year he produced his *Symphony No. 2 in D Major*. This is basically a serene and idyllic work, avoiding the heroic pathos of the *C Minor Symphony*. He let six years elapse before his *Symphony No. 3 in F Major*. In its first three movements this work, too, appears to be a comparatively calm and serene composition—until the finale, which presents a gigantic conflict of elemental forces. Again after only one year, Brahms's last symphony, *No. 4 in E Minor*, was begun. This work may well have been inspired by the ancient Greek tragedies of Sophocles that Brahms had been reading at the time. The symphony's most important movement is once more the finale. Brahms took a simple theme he found in Bach's Cantata Number 150 and developed it in a set of 31 highly intricate variations, but the technical skill displayed here is as nothing compared with the clarity of thought and the intensity of feeling.

Composition of the first symphony

Materially, too, his music proved most successful. The compositions published since the 1860s by Fritz Simrock in Bonn were widely performed and brought Brahms a sizable income. Strangely enough, the composer who had grown up in poverty treated his fortune rather carelessly. He left its management to the publisher and had no complaint when Simrock lost substantial sums through speculation on the stock market. Although Brahms spent little on himself, feeling most comfortable when leading a simple life, free of luxuries, he derived pleasure from his vast earnings when he had a chance to help others. He was generous to his family, especially to his father and to his stepmother, whom Johann Jakob had married after his wife's death. Even when his father died, Johannes continued providing for the second Mrs. Brahms and her relatives. Moreover, many young musicians secretly received financial assistance.

International renown

Gradually, Brahms's renown spread beyond Germany and Austria. Switzerland and The Netherlands showed true appreciation of his art, and Brahms's concert tours—partly in the company of Joachim—to these countries as well as to Hungary and Poland won great acclaim. Urgent invitations reached him from England, too, and in April 1876 the University of Cambridge offered him the honorary degree of doctor of music. At first Brahms was

delighted, but when he found out that the degree had to be conferred on him in person, he tried to persuade the authorities to change this condition. As the university's statutes made this impossible, he declined to attend. Apparently, fear of seasickness made him reluctant to cross the English Channel; and his poor English, as well as an aversion to formal ceremonies, may also have played some part in his decision. Brahms's English admirers had to accept the composer's idiosyncrasy. To make up for the loss of the Cambridge degree, the Philharmonic Society of London awarded him their gold medal in 1877. Brahms was not, moreover, to be deprived of a doctor's title, for the University of Breslau (now Wrocław, Poland) conferred an honorary degree on him in 1879. The composer thanked the University by writing the *Academic Festival Overture* based on various German student songs, the first performance of which he conducted himself in Breslau.

Brahms's followers and detractors

By now the composer's contemporaries were keenly aware of the outstanding significance of Brahms's works. Following the example of the German conductor Hans von Bülow, they spoke of the "three great B's" (Bach, Beethoven, and Brahms), who were given the same rank of eminence. Yet, despite his honours from various quarters, there was a sizable circle of musicians who did not admit Brahms's greatness. Fervent admirers of the avant-garde composers of the day, most notably Franz Liszt and Richard Wagner, looked down on Brahms's contributions as too old-fashioned and inexpressive. Brahms himself was to some extent to blame for their hostile attitude, because as early as 1860 he had prepared, in conjunction with Joachim and two other composers, a "manifesto" expressing an unfriendly attitude toward the tenets of the progressive "Neo-German" school of composition. Brahms became, in Vienna, a good friend of Eduard Hanslick, an eminent critic and one of Wagner's most outspoken adversaries; this alone would have prompted the Wagnerites to vilify Brahms. The most vicious attacks came from the pen of Hugo Wolf, the German lied (song) composer, who during 1884–87 served as music critic of the fashionable weekly *Wiener Salonblatt* and in this position launched fierce assaults against the works of his older contemporary. Brahms was not upset by these diatribes but instead found them amusing.

With advancing age he established a certain pattern in his way of life that seemed to be beneficial for his creative work. After 1871 he lived in Vienna close to his beloved Gesellschaft der Musikfreunde in a simple three-room apartment kept up by a friendly and helpful landlady. When he went on concert tours, he conducted or performed only his own works, and so many demands reached him that he often had to decline them. In spring he loved to travel to Italy, to "bathe in beauty," as he wrote. Between 1871 and 1893 he made nine such trips, often in the company of an eminent surgeon, Theodor Billroth, himself a sensitive musician to whom Brahms dedicated his *String Quartet*, Opus 67. Another welcome companion was a Swiss poet, J.V. Widmann, who left an interesting account of these trips. Brahms prepared himself thoroughly for every journey and received lasting inspiration from Italian art. Reverberations of his first experience in Italy are noticeable in his *Piano Concerto No. 2 in B Flat Major*, which is imbued with a beautifully balanced serenity.

Travel in Italy

The summer was always spent in the country. Like Beethoven, Brahms was an outdoor person who worked best on extensive walks. He responded deeply to nature, which acted as the most powerful stimulant on his creative process; and many of his works bear the imprint of specific summer resorts. The pastoral *Second Symphony*, the romantic *Violin Concerto*, and the sparkling *Rhapsodies* for piano were written near charming Wörther See (Lake Wörther) in southern Austria, where Brahms stayed during 1877–79. The grandiose Lake Thun in Switzerland was likewise enjoyed for three summers (1886–88), and there Brahms composed the boldly conceived *Double Concerto in A Minor for Violin and Cello*, the *Cello Sonata in F Major*, the powerful *Piano Trio No. 3 in C Minor*, and the *Violin Sonata in D Minor*. The charming Austrian spa Bad Ischl, summer residence of Emperor Francis Joseph I, was another Brahms favourite. He visited it for the first time in 1880 and spent the last eight summers of his life there. It was there that he completed the radiantly joyous first *String Quintet in F Major*, Opus 88, and years later the energetic second *String Quintet in G Major*, Opus 111.

Final years. It was Brahms's intention to conclude his creative work with the second *String Quintet*, which he finished in 1890, but during the following summer he felt inspired to start on a new experiment. He began to include the clarinet in his chamber music because of his acquaintance with an outstanding clarinetist, Richard Mühlfeld, whom Brahms had heard perform some months before. With Mühlfeld in mind, Brahms wrote at Bad Ischl his *Trio for Clarinet, Cello, and Piano*, Opus 114; the great *Quintet for Clarinet and Strings*, Opus 115; and two *Sonatas for Clarinet and Piano*, Opus 120, Nos. 1 and 2. The works are perfect in structure and beautifully adapted to the potentialities of the wind instrument.

Clarinet works

In 1894 Brahms saw his lifelong wish fulfilled. Hamburg, most eager to make amends for its previous behaviour, offered him the position as conductor of its philharmonic orchestra, after having awarded to him, five years earlier, the honorary freedom of the city. At the age of 61, Brahms felt less inclined than ever before to shoulder new responsibilities, but when he refused, he could not refrain from the following remarks:

> There are not many things that I have desired so long and so ardently at the time—that is at the right time. Many years had to pass before I could reconcile myself to the thought of being forced to tread other paths. Had things gone according to my wish, I might today be celebrating my jubilee with you, while you would be, as you are today, looking for a capable younger man. May you find him soon, and may he work in your interests with the same good will, and the same modest degree of ability, and the same wholehearted zeal, as would have done yours.

On his 63rd birthday, Brahms completed his *Vier ernste Gesänge* (*Four Serious Songs*), for bass voice and piano, on texts from both the Old and the New Testament, a pessimistic work dealing with the vanity of all earthly things and welcoming death as the healer of pain and weariness. In the last song, however, the power of love is rapturously glorified in words from the First Letter of Paul to the Corinthians. The conception of this work arose from Brahms's thoughts of Clara Schumann, whose physical condition had gravely deteriorated. He was aware that he was soon to lose his dearest friend (who, in his own words, was "the most beautiful experience of his life, its greatest wealth, and its noblest content"). On May 20, 1896, Clara died, and Brahms, receiving the news in Ischl, travelled for 40 hours by train to Bonn to attend her funeral. On his return, his changed appearance alarmed his friends. He believed he was suffering from what he called a "petty bourgeois jaundice," but the doctors recognized an advanced state of an incurable liver disease. In the summer of 1896 Brahms was still able to write his *Eleven Chorale Preludes* for organ, the last of these a fantasia on "O Welt, ich muss dich lassen" ("Oh World, I Must Depart from Thee"). On April 3, 1897, he died in Vienna, mourned by music lovers all over the world. His funeral was attended by representatives from music centres in various countries, and in Hamburg the flags were flown at half-mast on all the ships in the harbour. He was buried in Vienna, the city he had adopted as his home, near the graves of Beethoven and Schubert.

Brahms is one of the few composers whose greatness was recognized in his lifetime, and it has not been questioned by later generations. The solid craftsmanship displayed in his compositions, their decided intellectual qualities, and his richly flowing, Romantic inspiration have made Brahms as much appreciated today as he was in the 19th century.

MAJOR WORKS

Orchestral music

SYMPHONIES: *No 1 in C Minor*, op. 68 (1876); *No 2 in D Major*, op. 73 (1877); *No. 3 in F Major*, op. 90 (1883); *No. 4 in E Minor*, op. 98 (1885).

CONCERTOS: (PIANO): *No. 1 in D Minor*, op. 15 (1854–58); *No. 2 in B Flat Major*, op. 83 (1881). (VIOLIN): op. 77 in D major (1878). (VIOLIN AND CELLO): *Double Concerto in A Minor*, op. 102 (1887).

OTHER ORCHESTRAL WORKS: Two overtures: *Academic Festival*, op. 80 (1880) and *Tragic*, op. 81 (1880); two serenades: *No. 1 in D Major*, op. 11 and *No. 2 in A Major*, op. 16 (1857–59); *Variations on a Theme by Haydn* (Chorale St. Antoni), op. 56a (1873); *Hungarian Dances* arranged from his own piano duets (published 1873).

Chamber music

SONATAS: Three for violin and piano: *No. 1 in G Major*, op. 78 (1879), *No. 2 in A Major*, op. 100 (1886), and *No. 3 in D Minor*, op. 108 (1886–88); two for cello and piano: *No. 1 in E Minor*, op. 38 (1862–65) and *No. 2 in F Major*, op. 99 (1886); two for clarinet and piano, op. 120 (1894), *No. 1 in F Minor* and *No. 2 in E Flat Major*.

OTHER CHAMBER WORKS: Two string sextets, two string quintets, and three string quartets, one clarinet quintet, one piano quintet; three piano quartets for violin, viola, cello, and piano; three trios for violin, cello, and piano; one trio for clarinet (or viola), cello, and piano; one trio for violin, horn (or cello or viola), and piano.

Solo Piano Music

SONATAS: *No. 1 in C Major*, op. 1 (1852–53); *No. 2 in F Sharp Minor*, op. 2 (1852); *No. 3 in F Minor*, op. 5 (1853).

VARIATIONS: Five sets, including *Variations on a Theme by Schumann*, op. 9 (1854); *Variations and Fugue on a Theme by Handel*, op. 24 (1861); *Variations on a Theme by Paganini*, op. 35 (1862–63).

OTHER SOLO PIANO WORKS: Numerous ballads, capriccios, fantasies, intermezzos, and rhapsodies, including *Four Ballads*, op. 10 (1854); two *Rhapsodies*, op. 79 (1879); op. 116, 117, 118, 119 (1891–93).

PIANO DUETS: *Variations on a Theme by Schumann*, op. 23 (1861); various waltzes, including *Liebeslieder* waltzes, op. 52a (1874) and *Neue Liebeslieder* waltzes, op. 65a (1877); four sets of *Hungarian Dances*.

MUSIC FOR TWO PIANOS: *Variations on a Theme by Haydn*, op. 56b (1873); *Sonata in F Minor*, op. 34b (1864; an arrangement of his *Piano Quintet*, op. 34).

Organ music

Two preludes and fugues; *Fugue in A Flat Minor; Chorale Prelude and Fugue in A Minor;* and *Eleven Chorale Preludes*, op. 122 (1896).

Vocal music

ACCOMPANIED CHORAL MUSIC: *Ein deutsches Requiem*, op. 45 (1857–68); various sacred and secular works for female, male, and mixed voices; some arrangements.

UNACCOMPANIED CHORAL MUSIC: 117 German folk songs for four-part chorus; various sacred songs, motets, secular part-songs, and canons for female, male, and mixed voices.

SONGS: 214 solo songs with piano, composed throughout the course of his life, published in 32 sets, including *Vier Ernste Gesänge*, op. 121 (1896).

DUETS AND QUARTETS: 25 duets, mostly for soprano, contralto, and piano; 16 quartets for soprano, contralto, tenor, and bass; *Liebeslieder* waltzes, op. 52 (1868–69), and *Neue Liebeslieder* waltzes, for piano duet and voices ad lib, op. 65 (1874); and 11 *Zigeunerlieder*, op. 103 (1887).

BIBLIOGRAPHY. JOSEPH BRAUNSTEIN (ed.), *Thematic Catalog of the Collected Works of Brahms*, enl. ed. based on the 4th ed. of Simrock's *Thematisches Verzeichnis* (1956), is a complete list of Brahms's works. The most important collection of his memorabilia may be found in the Gesellschaft der Musikfreunde (Society of Friends of Music) in Vienna, which owns autographs of the *German Requiem*, the *Double Concerto*, the *Piano Trio in C Minor*, the *Clarinet Quintet*, the *String Quintet in G Major*, and of many other works, in all more than 600 sheets. The Gesellschaft preserves the personal copies of Brahms's printed works with the composer's autograph corrections and changes; Brahms's own library is to be found there, including his collection of autographs by other composers and the large collection of letters he received from various writers and carefully preserved. The DEUTSCHE BRAHMS-GESELLSCHAFT published Brahms's correspondence (in German) in 16 vol. (1908–22). A small selection of outstanding letters addressed by Brahms to various friends may be found in the appendix to KARL GEIRINGER, *Johannes Brahms: Leben und Schaffen eines deutschen Meisters* (1935; Eng. trans., *Brahms: His Life and Work*, 2nd ed., 1947), which was written by the curator of the Gesellschaft der Musikfreunde, who has drawn extensively on the unpublished material in this collection. MAX KALBECK, *Johannes Brahms*, 4 vol. (1904–14), is the most extensive Brahms biography (in German). HANS GAL, *Johannes Brahms: Werk und Persönlichkeit* (1961; Eng. trans., *Johannes Brahms: His Work and Personality*, 1963), is a sensitive account by one of the editors of the collected edition of Brahms's compositions. EDWIN EVANS, *Historical, Descriptive and Analytical Account of the Entire Works of Johannes Brahms*, 4 vol. (1912–36, reprinted 1970), is very thorough, though somewhat pedantic.

(K.G.)

Braille

Braille, the universally accepted system of writing used by and for blind persons, consists of a code of 63 characters, each made up of one to six raised dots arranged in a six-position matrix or cell. These Braille characters are embossed in lines on paper and read by passing the fingers lightly over the manuscript. Louis Braille (1809–52), who was blinded at the age of three, invented the system in 1824 while a student at the Institution Nationale des Jeunes Aveugles (National Institute for Blind Children), Paris.

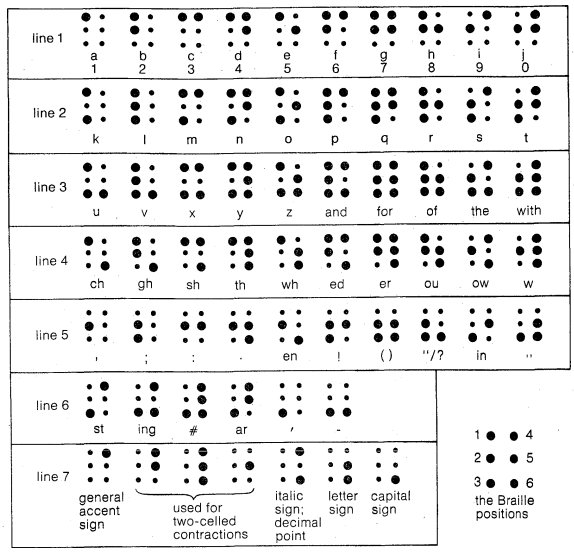
Early systems of writing for the blind. Before the invention of Braille, various forms of tangible alphabets had been devised for the use of the blind, including letters engraved in wood, cast in lead, and cut in cardboard. The Frenchman Valentin Haüy (1745–1822) was the first person to emboss paper as a means of reading for the blind. His printing of normal letters in relief led others to devise simplified versions and modifications of the alphabet that could be more readily identified by touch than facsimile letters. Most of these early systems were cumbersome to handle and difficult to learn. With one exception, they are no longer in use. The single exception is Moon type, invented in 1845 by William Moon (1818–94) of Brighton, England, which partly retains the outlines of the Roman letters and is easily learned by those who have become blind in later life. Books in this type are still in limited use by elderly people, particularly in Great Britain.

Alphabets for the blind

Braille's invention. When Louis Braille entered the school for the blind in Paris, in 1819, it had 14 books in embossed characters available for the students, but they were rarely used. In addition to the difficulty encountered by even the best readers using this system, and the slow pace at which they had to proceed, there was another disadvantage of which the young Braille and his classmates were keenly aware: there was no way for them to write using the raised lines of this system. Braille learned of a system of tangible writing using dots, invented in 1819 by Capt. Charles Barbier, a French army officer. It was called night writing and was intended for nighttime battlefield communications. In 1824, when he was only 15 years old, Braille developed a six-dot "cell" system. He used Barbier's system as a starting point and cut its 12-dot configuration in half. The system was first published in 1829; a more complete elaboration appeared in 1837.

Description of Braille. To aid in identifying the 63 different dot patterns, or characters, that are possible within the six-dot cell, Braille numbered the dot positions 1–2–3 downward on the left and 4–5–6 downward on the right. The illustration shows the formation of each cell and its simplest designated meaning. The first ten letters of the alphabet are formed with dots 1, 2, 4, and 5. When preceded by the numeric indicator diagrammed in line 6, these signs have number values. The letters *k* through *t* are formed by adding dot 3 to the signs in line 1. Five of the remaining letters of the alphabet and five very common words are formed by adding dots 3 and 6 to the signs in line 1. When dot 6 is added to the first ten letters, the letter *w* and nine common letter combinations are formed (see line 4). Punctuation marks and two additional common letter combinations are made by placing the signs in line 1 in dot positions 2, 3, 5, and 6 (line 5). Three final letter combinations, the numeric indicator, and two more punctuation marks are formed with dots 3, 4, 5, and 6 as shown in line 6. The last seven dot patterns indicated in line 7 are formed by dots 4, 5, and 6 and have no true equivalents in ordinary written language. Like the numeric indicator, these signs serve as

Braille system explained



The Braille characters.

modifiers when placed before any of the other signs. Through the application of this principle, the various signs can function in multiple ways. For example, dot 5 added before the sign for the letter *a* forms the Braille contraction for "day."

Diffusion of Braille. Braille's system was immediately accepted and used by his fellow students, but wider acceptance was slow in coming. The system was not officially adopted by the school in Paris until 1854, two years after Braille's death. In the United States, in the 1860s, another dot system, known as New York point, was developed by William B. Wait at the New York Institute for the Education of the Blind. In the 1870s a modification of Braille, called American Braille, was invented by a blind teacher, Joel W. Smith of Boston. These codes were used by many of the schools for the blind in the United States until 1916, when Braille's original alphabet and a series of contractions were officially adopted. A universal Braille code for the English-speaking world, however, was not adopted until 1932, when representatives from agencies for the blind in Great Britain and the United States met in London and agreed upon a system known as Standard English Braille, grade 2. In 1957 Anglo-American experts again met in London to further improve the system.

In addition to the literary Braille code, there are other codes utilizing the Braille cell but with other meanings assigned to each configuration. The "Nemeth Code of Braille Mathematics and Scientific Notation" (1965) provides for Braille representation of the many special symbols used in advanced mathematical and technical material. There are also special braille codes or modifications for musical notation, shorthand, and, of course, many of the more common languages of the world.

Handwritten Braille. Writing Braille by hand is accomplished by means of a device called a slate that consists of two metal plates hinged together to permit a sheet of paper to be inserted between them. Some slates have a wooden base or guide board onto which the paper is clamped. The upper of the two metal plates, the guide plate, has cell-sized windows; under each of these, in the lower plate, are six slight pits in the Braille dot pattern. A stylus is used to press the paper against the pits to form the raised dots. A person using Braille writes from right to left; when the sheet is turned over, the dots face upward and are read from left to right.

Writing with Braille

Machine-produced Braille. Braille is also produced by special machines with six keys, one for each dot in the Braille cell. The first Braille writing machine, the Hall Braille writer, was invented in 1892 by Frank H. Hall, superintendent of the Illinois School for the Blind. A modified form of this device is still in use today as are later, similar devices like the Perkins Brailler and the Lavendar Braillewriter. A recent innovation for producing Braille is electric embossing machines similar to electric typewriters.

Multiple copies of Braille materials are made with embossed zinc plates that are used for press masters. These plates are produced by a stereograph machine invented by Hall in 1893. In the 1920s the interpoint system was developed to emboss both sides of a sheet of paper without the dots on one side opposing those on the other side. Recently, a computer program for automatically translating printed English into contracted Braille has been used to produce stereograph plates and to provide Braille feedback from a standard teletypewriter keyboard.

BIBLIOGRAPHY. *Proceedings of the International Congress on Technology and Blindness*, 4 vol. (1963), ed. by L.L. CLARK, is a collection of papers on the relationship of man and machines, sensory loss, and the use of aids and appliances, including the latest findings on Braille writing and reading. The last volume is a catalog-appendix listing appliances available from sources all over the world. *Understanding Braille* (1968), prepared by the AMERICAN FOUNDATION FOR THE BLIND, describes the workings of the Braille system and its use by blind persons. A manual for learning to read and write Braille is *Braille in Brief* (1968) by B.M. KREBS. The following publications treat the Braille notations of English and other languages: C.N. MACKENZIE, *World Braille Usage: A Survey of Efforts Towards Uniformity of Braille Notation* (1954); L.H. GOLDISH, *Braille in the United States: Its Production, Distribution and Use* (1967); JOINT UNIFORM BRAILLE COMMITTEE, *English Braille, American Edition, 1959* (1959); and NATIONAL INSTITUTE FOR THE BLIND, *Standard English Braille: Grades I and II* (1932). In *As I Saw It* (1955), R.B. IRWIN, a prominent figure in the development of the uniform Braille code, tells the story of that struggle, plus the progress in braille embossing and the development of libraries for the blind. The original work on Braille is LOUIS BRAILLE, *Nouveau Procédé pour représenter par des points la forme même des lettres . . .* (1839); *Les doigts qui lisent* (1951; Eng. trans., *The Reading Fingers: Life of Louis Braille, 1809–1852*, 1952), by J. ROBIIN is Braille's biography.

(M.R.B.)

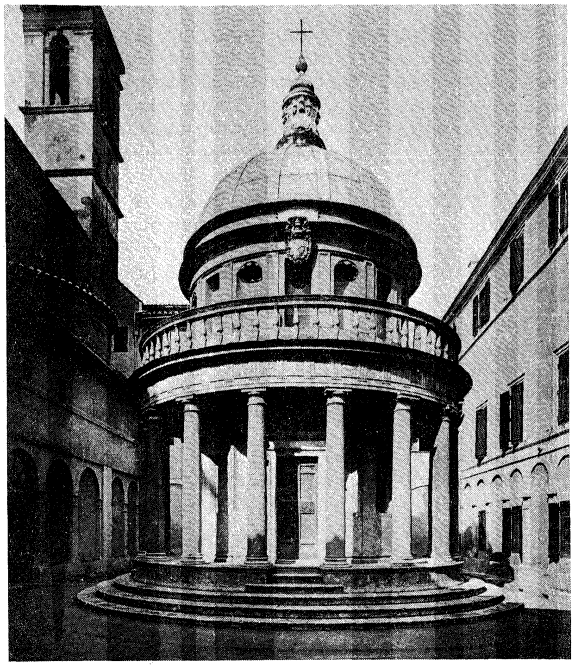
Bramante, Donato

Through his last works in Rome, from 1500 to 1514, Donato Bramante introduced what came to be known as the High Renaissance style in architecture, which rapidly spread throughout Italy and the rest of Europe. His works, which include the design for St. Peter's Basilica, synthesized early Renaissance ideas with the fruits of his own ceaseless experimentation. The result was a style that continued to exercise a powerful influence over architects until the end of the 18th century.

Early years and training. Donato (Donino, Donnino) Bramante was probably born at Monte Asdruvaldo (now Fermignano, near Urbino, Italy) in 1444 of a family of well-to-do peasants. In his childhood, says the 16th-century biographer and artist Giorgio Vasari, "besides reading and writing, he practiced much at the abacus." His father probably directed him toward painting.

Little is known of Bramante's life and works before 1477. He probably served as an assistant to Piero della Francesca in Urbino, which under the nobleman Federico da Montefeltro (died 1482) had become a Humanist centre of considerable importance. In 1477 Bramante was working in Bergamo as a painter of illusionistic murals of architecture. He probably derived his training not only from the works of artists active in Urbino but also from those of other artists he may have observed in his travels, such as those of Leon Battista Alberti (in Rimini and Mantua), Andrea Mantegna (in Mantua and Padua), Ercole de'Roberti (in Ferrara), and Filippo Brunelleschi (in Florence).

None of Bramante's youthful productions has survived, though some historians attribute various architectural perspectives to him. Almost all of them show some characteristics of Bramante's work, but they appear very different from each other. Before 1477, Bramante may have been primarily a planner, designer, and painter of architectural perspectives that other artists partly modified and inserted into their own paintings or carried out in construction; there are a number of later instances



Tempietto, S. Pietro In Montorio, Rome, designed by Bramante, 1502.
Anderson—Alinari

in which he is known to have furnished painters with such architectural perspectives.

Lombard period. By 1477 Bramante had left Urbino for unknown reasons and had settled in the northern Italian province of Lombardy. He worked on frescoes for the facade of the Palazzo del Podestà (later altered) in Bergamo showing classical figures of philosophers in a complex architectural setting. Vasari (though poorly informed on this period) says that Bramante, after working in various cities on "things of no great cost and little value," went to Milan "to see the cathedral." The cathedral workshop, in which Italian, German, and French craftsmen worked by turns, constituted an important centre for the exchange of knowledge, planning methods, and techniques. Moreover, Milan was a large and wealthy metropolis, the capital of a state ruled by Ludovico Sforza, called Il Moro, and Renaissance architecture was a commodity to be imported. Thus the city represented an opportunity for a young and up-to-date architect like Bramante.

Early work in Milan

The first architectural work that can be definitely attributed to Bramante is a design: a print made in 1481 by a Milanese engraver, Bernardo Prevedari, from a Bramante drawing representing a ruined temple with human figures. About the same time, Bramante was working on the church of Sta. Maria presso S. Satiro, the first structure definitely attributed to him. Along with a certain adherence to local taste, this church shows traces of the influence of Alberti, Mantegna, Brunelleschi, and the Urbino school. This last influence is particularly evident in its choir, which was painted in perspective to give an illusion of a much larger space. Perhaps from the same period (*c.* 1480–85) is Bramante's decoration of a room in Casa Panigarola in Milan (fragments in the Brera, Milan) that consists of architectural settings and the figures of men at arms rendered by means of illusionistic perspective. Similar experiments, perhaps also in the same years, seem to have been carried out by Bramante on the facades of buildings, such as Casa Fontana, later called Silvestri, in Milan.

In 1488 Bramante, along with a number of other architects, was asked by Cardinal Ascanio Sforza, brother of Ludovico Sforza and bishop of Pavia, to draw up a new plan for the cathedral of Pavia. Bramante went many times to that city during this period, and it was probably under his direction that the crypt and the lower portion of the building were executed.

Plan for the cathedral of Pavia

Bramante appears to have had close relations with Leonardo da Vinci. In 1482 Leonardo had visited Milan from Florence, and in 1490 both Bramante and Leonardo were occupied with stylistic and structural problems of the *tiburio*, or crossing tower, of the cathedral of Milan. From 1487 to 1490 a number of mutual exchanges can be documented. The only written evidence of Bramante's ideas on architecture goes back to this time (1490) and consists of a report on the *tiburio* problem. Bramante examined various solutions (among them one of his own, a square plan), demonstrating a conception of architecture remarkably like that of Alberti.

Bramante by now enjoyed the favour of both Ludovico and Ascanio Sforza, as well as that of influential courtiers. His modest salary and the irregularity of payment, however, did not allow him to live luxuriously. He came in contact not only with artists but also with Humanists and poets of the Sforza court, and he himself wrote verses. Like Leonardo, he was involved in the staging of spectacles at the Sforza court, such as one on the occasion of a baptism in 1492.

Architecture increasingly dominated his interests, but he did not give up painting. Of the many works attributed to him by various 16th-century writers, however, none seems to have been preserved. The only extant easel picture that has ever been attributed to him is the "Christ at the Column" ("Cristo alla colonna") of the Abbey of Chiaravalle (*c.* 1490, now in the Brera, Milan). A fresco in a complex architectural setting (*c.* 1490–92) in the Castello Sforzesco in Milan is probably his, with the collaboration of his pupil Il Bramantino.

Starting in 1492, Bramante was entrusted by Ludovico and Ascanio Sforza with the reconstruction of the *canonica* (rectory) of S. Ambrogio in Milan. The work was interrupted by the fall of Ludovico, and, though resumed in the 16th century, only one side of the building was executed. Though Bramante's responsibility cannot be proved, the idea for the new *tribuna* (chancel) for Sta. Maria delle Grazie probably originated with him; destined to be the burial mausoleum of the Sforzas, the *tribuna* was in an overall project of reconstruction, begun in 1492, for the entire church. Bramante also may have planned the painted decoration of the interior, but the execution and the clarification of details, particularly on the exterior, were probably done by Lombard masters.

Bramante's activities in the 1490s, before he left Milan finally for Rome, are sporadically documented. It has been conjectured that in the summer of 1492 he was in Florence studying the work of Brunelleschi, in view of the emphatic Brunelleschian character of the S. Ambrogio *canonica*. In 1493 he made a report on certain fortifications on the Swiss border for Ludovico.

His last few years in Lombardy were marked by the restless activity that characterized the remainder of his career. He was probably responsible for the designs of the piazza of Vigevano (carried out between 1492 and 1494, partly transformed in the late 17th century), of the painted architectural decoration on the arcaded facades that marked its limits, and for the designs of other structures of the Vigevano complex, as well as the painted decoration (now disappeared) for the interior of the castle of the same city. His covered passageway (*ponticella*) for the Castello Sforzesco in Milan must also be from this period, and the facade of the church of Sta. Maria Nascente ad Abbiategrasso (near Milan) dates from 1497. Between 1497 and 1498, in addition to a chapel (later altered) of S. Ambrogio in Milan, he worked on the Cistercian Monastery being erected in Milan under the auspices of Ascanio Sforza; like his work on the *canonica*, it was suspended in 1499 and is unfinished.

Influences on Bramante

Endowed with an extremely receptive character, Bramante was by no means immune to the influence of other artists active in Milan. He was also influenced by his study of Lombard monuments dating from the late ancient and Carolingian periods, the memory of which was to be useful to him in Rome. Conversely, Bramante's presence (together with Leonardo's) in Milan was of fundamental importance for the later artistic developments in that city.

Roman period. Bramante probably remained in Milan until Ludovico was forced to flee before the city was occupied by the French in September 1499. Bramante appears to have been active from the first in Rome on a variety of projects, such as a painting (now lost) at S. Giovanni in Laterano celebrating the Holy Year 1500. As under-architect of Pope Alexander VI, he probably executed the fountains in Piazza Sta. Maria in Trastevere and in St. Peter's Square (later altered) and served on several architectural councils. It is probable that in these years he had reduced his activity as a designer and was devoting himself to the study of the ancient monuments in and around Rome, even ranging as far south as Naples. In the meantime, he had come in contact with Oliviero Carafa, the wealthy and politically influential cardinal of Naples, who had a deep interest in letters, the arts, and antiquity. Carafa commissioned the first work in Rome known to be by Bramante: the monastery and cloister of Sta. Maria della Pace (finished 1504). Bramante seems to have been engaged in 1502 to begin the small church known as the Tempietto in S. Pietro in Montorio, on the site where St. Peter was said to have been crucified.

The patronage of Julius II

The election of Pope Julius II in October 1503 began a new phase in Bramante's work—the grand, or mature, manner. Almost immediately he entered the service of the new Pope, one of the greatest patrons in art history. Bramante became the interpreter, in architecture and city planning, of the pontiff's dream of re-creating the ancient empire of the Caesars (*renovatio imperii*). Bramante planned gigantic building complexes that adhered as never before to the idiom of antiquity. At the same time, the buildings often represented an unbiased, personal, and contemporary interpretation of that idiom.

Perhaps as early as 1505, Bramante designed the immense courtyard of the Belvedere, extending the nucleus of the older Vatican palaces to the north and connecting them with the pre-existing villa of Innocent VIII. Though the work was carried forward with great speed, the scale was so large that on the death of Julius II, in 1513, and of Bramante himself, in 1514, it was still far from completion. The project, which continued throughout the 16th century and later, suffered so many changes that today Bramante's concept is almost unrecognizable.

Basilica of St. Peter

Beginning in 1505, at first in competition with two other architects, Giuliano da Sangallo and Fra Giocondo, Bramante planned the new Basilica of St. Peter in Rome—his greatest work and one of the most ambitious building projects up to that date in the history of mankind. The first stone was placed on April 18, 1506 (after Bramante's first plan had been rejected by the Pope, according to a contemporary). The project's site had to be cleared first of the old, crumbling Basilica of Constantine. Bramante's part in its demolition earned him the nicknames of "Maestro Ruinante" or "Maestro Guastante"—"Master Wrecker" or "Master Breaker." At the time of his death the new construction had scarcely begun to take shape.

Named general superintendent of all papal construction, a well-paid office, Bramante was not only the Pope's principal architect and the engineer at the service of his military enterprises but also his personal friend. Concurrent with his work on the Belvedere and St. Peter's, Bramante presented Julius with a highly ambitious plan for the complete remodelling of the Vatican palaces, which was, however, set aside.

Despite the grandiose scale of the St. Peter's undertaking, Bramante continued to work on lesser projects. Between 1505 and 1509 he carried out an enlargement of the choir of the church of Sta. Maria del Popolo, some construction work in Castel Sant'Angelo, and a remodelling of the Rocca di Viterbo. In addition, in 1506, as a military engineer, he accompanied the Pope to Bologna (where the grand staircase of the Palazzo degli Anziani has been attributed to him).

City plan for Rome

About 1508, when Julius II's new city plan for Rome began to be put into effect, Bramante played an important role as architect and town planner. Within the framework of an organic plan, the Via Giulia (from the Ponte Sisto to the Vatican) was laid out with a large piazza that was to constitute a centre of activity for the city government; the Via della Lungara (from the Vatican across Trastevere to the river port installations of Ripa Grande) was begun; the Via dei Banchi, on which were erected the offices of the most important banks of the time, was widened at the entrance of the Ponte Sant'Angelo; and several streets in the old structure of the medieval city were modified. On the Via Giulia, Bramante designed a huge new Palazzo dei Tribunali (1508), incorporating the church of S. Biagio (1509, also by Bramante). The structure is notable as a model for 16th-century architecture.

Within the framework of Bramante's overall plan, the basin of the port was dug out, and a marine fortress was built at Civitavecchia. The west facade of the Vatican Palace (now the side of the S. Damaso courtyard) was also constructed according to his design, though it was later taken up and completed by Raphael. Around the year 1509, Bramante probably furnished a plan for the church of Roccaverano, whose facade anticipates certain solutions of the late-16th-century architect Andrea Palladio.

Another noteworthy design was that of the Palazzo Caprini (House of Raphael; later destroyed) in the Borgo, which became the model for many 16th-century palaces. This palazzo was later acquired by Raphael. According to Vasari, Bramante, around 1509, had designed the architectural background for the "School of Athens" by Raphael (1508–11; Vatican, Rome), and in return, Raphael represented Bramante in the fresco in the guise of Euclid.

Bramante and Raphael

After the death of Julius II, Bramante, though elderly and perhaps in declining health, remained in favour under Pope Leo X. According to a late and uncertain source, in 1513 he presented to Leo X an audacious water-control plan for the city, designed to avoid the periodic floodings of the Tiber. At the end of 1513, however, when consulted about the cathedral of Foligno (S. Feliciano), he was too ill to accept the commission. Bramante died on April 11, 1514, and was buried in St. Peter's. He was carried there, according to Vasari, "by the papal court and by all the sculptors, architects, and painters."

Personality and interests. Even though he was called unlettered (as were Leonardo, Julius II, and others), probably because he was ignorant of Latin and Greek, Bramante must have acquired considerable learning, however fragmentary. His contemporaries esteemed him not only as an architect and painter and for his knowledge of perspective but also as a poet and an amateur musician. He had an almost fanatical interest in Dante. He also wrote some 20 sonnets on amorous, humorous, and religious themes, and, though somewhat crude in style, they are full of spirit.

His theoretical writings, apart from his report on the *tiburio* of the Milan cathedral, have all been lost, but their subjects are indicative of his interests; *e.g.*, works on perspective, on the "German manner," (*i.e.*, on Gothic architecture), on fortification methods, and others.

Bramante seems to have been an extrovert. He was said to be very friendly to persons with talent, and he did much to help them. Humour, irony, a taste for intelligent jokes, and mockery of himself as well as others often appear in his sonnets. Full of faith in himself, he was an irreverent person who took pleasure in proposing paradoxical ideas. He was critical of priests and courtiers but also capable of deep religious feeling. In the treacherous atmosphere of courts, he was able to manoeuvre skillfully. He must have been highly ambitious and not overscrupulous when it came to securing an important commission. His biographers emphasize his impatience and speed in the conception and conduct of his work (Vasari calls him a "resolute, rapid, and excellent inventor"). This quality was combined with imaginative genius and an artful and lively curiosity. His insatiable thirst for experiment and for new knowledge forced him, as Bramante himself remarks in one of his sonnets, to "change himself" continually ("as time

changes in a moment / my thought, its follower, changes too"). This trait of instability and inconstancy seems to have led him away from convention in his works to a multiplicity of attitudes and expressions. Perhaps these characteristics indicate a certain dissatisfaction, an inner melancholy, or a deep sense of solitude. He apparently never married or had children. In unceasing experiments in his work, he may have been seeking a remedy for his incurable restlessness.

MAJOR WORKS

Frescoes on the facade of the Palazzo del Podestà, Bergamo (1477); Sta. Maria presso S. Satiro, Milan (*c.* 1480); cathedral at Pavia (plan, crypt, etc., 1488); *tribuna* of the Sta. Maria delle Grazie, Milan (1492); *canonica* and cloisters at S. Ambrogio, Milan (1492–99); cloister, Sta. Maria della Pace, Rome (1500–04); Tempietto, S. Pietro in Montorio, Rome (1502); Belvedere courtyard, Vatican, Rome (begun *c.* 1505); plans for rebuilding St. Peter's, Rome (1505–06); Sta. Maria del Popolo, Rome (new choir, 1505–09); Palazzo dei Tribunali, Rome (never completed, 1508); House of Raphael (formerly Palazzo Caprini), Rome (*c.* 1510? destroyed).

BIBLIOGRAPHY. The most important general biographical and critical publications with extensive bibliographies on the life and work of Bramante are COSTANTINO BARONI, *Bramante* (1944), in Italian; OTTO FORSTER, *Bramante* (1956), in German; F.G. WOLFF METTERNICH, "Der Kupferstich . . .," in *Römisches Jahrbuch für Kunstgeschichte*, 11:9–108 (1967–68), for the Urbino and Milanese periods; ARNALDO BRUSCHI, *Bramante architetto* (1969); "Bramante" in the *Dizionario biografico degli Italiani*, vol. 13 (1971); F. SANGIORGI, *Bramante "hastrubaldino," documenti per una biografia bramantesca* (1970), for the problem of his birthplace and biographical dates for the Urbino period; and *Bramante tra Umanesimo e Manierismo* (1970), the catalog of the historical and critical exhibition commemorating Bramante, held in Rome, September 1970. More recent works dealing with specific aspects include PASQUALE ROTONDI, *Il palazzo ducale di Urbino*, 2 vol. (1950–51), on Bramante's early years in Urbino; JAMES S. ACKERMAN, *The cortile del Belvedere* (1954), and by the same author, various essays on particular themes and his effective critical evaluation of Bramante in *The Architecture of Michelangelo* (1961); and PETER MURRAY, "Bramante milanese: The Printings and Engravings," *Arte lombarda*, 7: 25–42 (1962); "Leonardo and Bramante," *Archit. Rev.*, 134: 346–351 (1963); and "Observations on Bramante's St. Peter's," in DOUGLAS FRASER, HOWARD HIBBARD, and MILTON J. LEWINE (eds.), *Essays in the History of Architecture* (1967), which also contains other important essays on Bramante.

(Ar.B.)

Branchiopoda

The four living orders of the invertebrate subclass Branchiopoda (class Crustacea) have few common features. The back of the head in the Notostraca, or tadpole shrimps, for example, is expanded into a broad thin plate, or carapace, that projects backward over the trunk. In the Conchostraca and Cladocera, however, the carapace is folded into two valves that enclose the trunk limbs. The Anostraca, which lack a carapace, have elongated wormlike bodies and stalked eyes; the eyes of the other three orders lack stalks. The main structural feature that links these diverse forms is the typically flattened and paddle-like trunk limbs, which are used as part of an elaborate filter-feeding mechanism.

Four living orders and one extinct order form the branchiopods. They range in size from 0.25 millimetre (0.01 inch) in *Alonella* to ten centimetres (about four inches) in *Branchinecta gigas*. Branchiopods are abundant in all types of freshwater, from temporary desert pools to great lakes. A few species are found in the sea.

Natural history. *Reproduction and life cycle.* A typical branchiopod begins its life cycle as a nauplius larva, which has a simple undivided body and three pairs of appendages: antennae, antennules (smaller antennae), and mandibles. The antennae are used for swimming. As the nauplius feeds and grows, it gradually changes into the adult form—the body becomes segmented, or jointed, and additional limbs appear. In the orders Anostraca and Notostraca, the antennae lose their swimming function, but, in the orders Conchostraca and Cladocera, they remain large and functional. One conchostracan (*Cyclestheria*) and all cladocerans except one do not hatch as nauplius larvae; rather, they develop directly in the egg and hatch as miniature adults.

Branchiopods mature rapidly. A small cladoceran can lay eggs in the warm water of a temporary desert pool when only two days old. In temperate latitudes in the summer, a cladoceran may become mature in less than a week.

The sexual arrangement in some branchiopods is that of separate males and females. Some populations of the brine shrimp, *Artemia salina*, have both sexes; others are parthenogenetic—*i.e.*, producing only females without fertilization of eggs. Some populations of *Triops cancriformis* have the sexes separate, others are hermaphroditic (*i.e.*, the individuals contain functional reproductive systems of both sexes).

Among the branchiopods, the Cladocera show the greatest variety of reproductive habits. Under favourable conditions the eggs are laid in a brood pouch between the carapace and the trunk. There they develop rapidly and, after about two days, hatch as females, which, in turn, lay eggs that give rise to more females. No males are necessary for this process. When food is scarce, or when there is a sudden temperature change, some of the eggs develop into males, and some of the females begin producing eggs that must be fertilized by sperm from the males. These fertilized eggs are remarkably resistant to unfavourable environmental conditions; even if frozen or dried, they will hatch when returned to favourable conditions. Many Cladocera go through the winter as fertilized eggs; species dwelling in temporary pools lay such eggs to survive periods of drought. Certain Arctic Cladocera produce resistant eggs that do not require fertilization. The resistant, or resting, eggs normally hatch in the following spring, giving rise to the usual miniature adult females. In *Leptodora* the resting egg hatches into a nauplius larva.

Resistance of eggs to environmental hazards

From L. Borradaile and F. Potts, *The Invertebrata*; published by Cambridge University Press

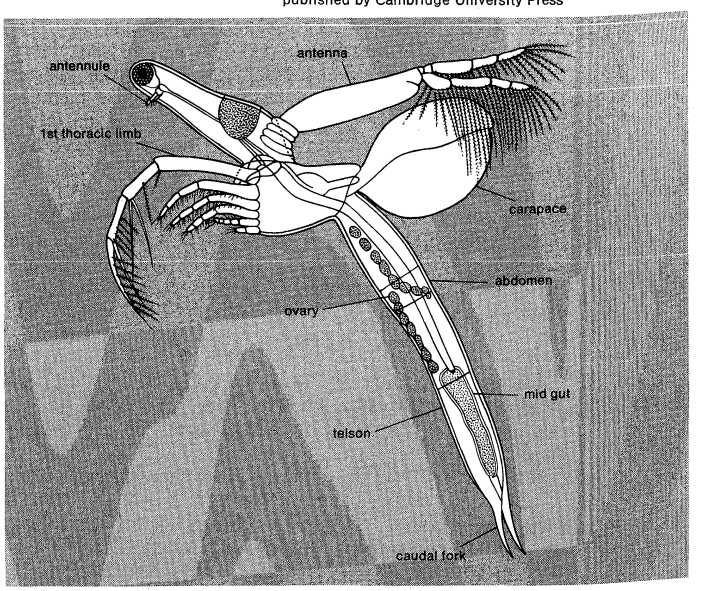


Figure 1: A female *Leptodora kindtii*, a cladoceran branchiopod.

Members of the other branchiopod orders can also produce resting eggs. Many desert-pool species produce only resting eggs. They must abbreviate their life cycles to coincide with the brief period of favourable conditions, and their eggs must be capable of remaining dry for long periods. Sometimes several years elapse before conditions are again favourable.

Ecology. Some species of *Daphnia* in temperate lakes show a remarkable seasonal change in form. In the winter the females have rounded heads, but the females of generations in late spring and summer have pointed heads. It has been demonstrated that high temperature and water turbulence favour the development of a point-

ed head. The most plausible explanation seems to be related to predation by fish. The feeding activity of plankton-eating fish decreases in winter and increases rapidly in the spring and summer. The fish select the large conspicuous *Daphnia*, the most conspicuous part of which is the carapace with its enclosed limbs and eggs. When the head is enlarged, the size of the carapace is reduced, so that an overall decrease in conspicuousness occurs in the summer forms. A change in form in relation to the environment also takes place in the *Artemia salina*. This species lives in very saline water, and the proportions of the body vary with the salinity of the water.

Food gathering

The trunk limbs of all branchiopods are used to gather food. Most commonly, small particles are collected from the water passing between the limbs, filters formed by setae, or fine hairs, separate the particles from the water, and an elaborate mechanism shifts food from the filters forward to the mouth. The filters, which may be very efficient, enable branchiopods to collect material as small as bacteria for food. The ability to utilize bacteria is important in the cleansing of water in reservoirs, where Cladocera are often abundant.

The notostracans *Triops* and *Lepidurus* can collect small particles, but they can also act as predators. *Triops* eats small oligochaete worms and the larvae of chironomid midges. *Lepidurus arcticus* has been observed feeding on another arctic branchiopod, the anostracan *Branchinecta paludosa*, which often lives in the same tundra pools.

Predators are also found among the Cladocera. In *Leptodora* and *Polyphemus* the carapace forms only a brood pouch and does not cover the trunk limbs. In these forms the limbs are not paddle-like but are modified and used for grasping other small Crustacea.

Locomotion. The Notostraca and Anostraca swim with their trunk limbs, which beat in a rhythm so that jets of water are forced out sideways and backward from the spaces between the limbs to drive the animal ahead. Some of the anostracans, such as *Chirocephalus*, have a complex system of flaps and muscles in the trunk limbs, and they modify the limb movement in order to hover in one position for long periods.

The Conchostraca and Cladocera swim by means of their antennae, which have two branches bearing feather-like setae that increase the effective area of the antenna. Because the Conchostraca are slow, clumsy swimmers, they are highly vulnerable to predation by fish; thus, they are most commonly found in temporary pools, where fish are absent. The Cladocera, although smaller, are much livelier swimmers. In some of the larger forms, the rate of limb movement may be one beat per second, but, in smaller forms, there may be several beats per second.

Responses to light. The most notable behavioral responses of branchiopods are in relation to light. The Anostraca are remarkable in showing a ventral light response: when light is directed from above, they turn their ventral surface toward the light. If they are artificially lit from below, and not from above, they will turn over. In the Cladocera the response to light is complex and varies with the colour of the light. In red light, *Daphnia* maintains its position in the water by a hop-and-drop type of swimming. In blue light, it swims more rapidly in a horizontal direction. These two types of swimming are related to the presence of food. When foods such as small green algae are present in the water, they absorb most of the blue light, and the light that penetrates is mainly red; remaining in one place is advantageous to *Daphnia*, and it maintains its position. In the absence of food such as green algae, more blue light is present in the water; as a result, *Daphnia* is stimulated to swim horizontally and to search a wider area. If *Daphnia* is starved and kept in red light, it eventually swims horizontally; *i.e.*, starvation blocks out the normal response to red light.

Form and function. *Structural features.* The number of trunk limbs in the branchiopods varies greatly. The Cladocera have four to six pairs; the Anostraca 11, 17, or 19 pairs; and the Conchostraca between ten and 27 pairs. Among the Notostraca there is little apparent correlation between the number of trunk segments and the number of trunk limbs. Some of the posterior segments may have three or four pairs of limbs; as a result, some notostracans have up to 71 pairs of trunk limbs.

Excretion. The excretory organ in the branchiopods is the maxillary, or shell, gland, so-called because loops of the excretory duct can be seen in the wall of the carapace. Some excretion also occurs in the wall of the gut, which transfers substances from the blood into the gut lumen, from which it passes to the outside.

Vision. The most conspicuous sense organs of the Branchiopoda are the eyes. The four living orders show notable differences in eye arrangement. The large paired eyes of Anostraca are on movable stalks; the paired eyes of Notostraca lie close together on the top of the head; in Conchostraca and Cladocera, the two eyes are joined together in the midline. The process of fusion of the eyes can be seen in the developing embryo of the cladocerans; the organs appear as small red dots that enlarge, darken, and then join together. *Polyphemus* is unique in having green eye rudiments that darken and fuse to form its large multilensed eye. All branchiopod eyes are provided with muscles and show rather rapid trembling movements, thought to be part of a scanning process that gives more information about the surroundings than could be gained with a stationary eye.

Biochemistry. The branchiopods are unusual among crustaceans in possessing the pigment hemoglobin in their blood. The pigment is dissolved in the plasma rather than contained in blood cells as in man and other vertebrates. The concentration of hemoglobin in branchiopod blood varies inversely with the oxygen content of the surrounding water. When little oxygen is in the water, the blood contains a large quantity of hemoglobin and is bright red. A branchiopod whose blood contains a high concentration of hemoglobin can be made to change its blood colour from bright red to pale by transferring it to well-aerated water; the transformation requires about ten days.

Presence of hemoglobin

From L. Borradaile and F. Potts, *The Invertebrata*; published by Cambridge University Press

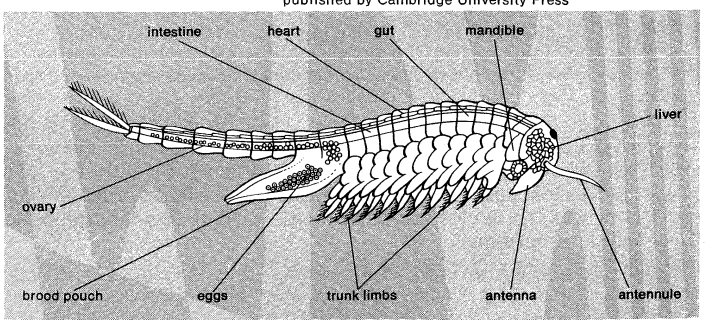

Figure 2: *Chirocephalus diaphanus*, an anostracan branchiopod.

The chemical breakdown of hemoglobin in *Daphnia* is unusual in that it does not involve bile pigments. Hemoglobin in all other animal groups breaks down into green, red, or yellow bile pigments.

Evolution and classification. *Paleontology.* The order Lipostraca is represented only by the remarkable fossil of *Lepidocaris rhyniensis* from the Devonian Period (345,000,000 to 395,000,000 years ago), which was discovered in the Old Red Sandstone of Scotland. The fragmentary remains of this minute branchiopod are so perfectly preserved that its structure is known in greater detail than is that of any other fossil crustacean. Many other forms probably failed to leave any fossil record because of their small size and delicate structure.

Distinguishing taxonomic features. Branchiopods are free-living forms, the most primitive members of the phylum Crustacea. They have compound eyes and usually a protective plate, or carapace. There are many body segments and four or more pairs of trunk limbs that are usually lobed, broad, and fringed on the inner side. The mouthparts are small and simple, and the nervous system is primitive. Most species occur in freshwater.

Annotated classification. The group indicated by a dagger (†) is extinct and known only from fossils.

SUBCLASS BRANCHIOPODA

Four distinct living types, 1 extinct; distinguishing features include form of trunk limbs and carapace; more than 800 species.

†Order Lipostraca

Includes only the fossil *Lepidocaris rhyniensis*, about 3 millimetres (0.12 inch) long; no carapace; 11 pairs of trunk limbs, 1 pair of large branched antennae resembling those of the Cladocera and probably used in swimming; the 1st maxillae (head appendages) of the male were enlarged as claspers, probably to hold the female during mating; eggs carried in a pouch behind the last pair of trunk limbs.

Order Anostraca

Elongated forms, with paired stalked eyes, no carapace; eggs carried in pouch behind the last pair of trunk limbs; up to 19 pairs of trunk limbs; antennae in the male modified as claspers for holding the female during mating, some species in family Thamnocephalidae having elaborate branched outgrowths from head; freshwater and inland saline waters.

Order Notostraca

Large horseshoe-shaped carapace extending back over trunk, up to 71 pairs of trunk limbs; antennae reduced or absent; 1st trunk limb elongated, functions as a tactile organ; eggs carried in pouch on the 11th pair of trunk limbs; 2 genera, *Triops* and *Lepidurus;* fossils known from the Permian Period (280,000,000 to 225,000,000 years ago), 1 living species, *Triops cancriformis*, known from the Triassic Period (225,000,000 to 190,000,000 years ago); freshwater habitat.

Order Conchostraca

Large carapace with 2 valves enclosing head and trunk (except in *Lynceus*, where head is free); up to 32 pairs of trunk limbs, antennae large, used in swimming; eggs carried between trunk and carapace; 1st trunk limb of the male modified to clasp carapace of female during mating; among earliest fossil Crustacea, known from the Cambrian Period (570,000,000 to 500,000,000 years ago); about 200 species divided into 5 families; freshwater habitat.

Order Cladocera

Carapace with 2 valves not enclosing head; the number of trunk limbs reduced to 4, 5, or 6 pairs; eggs carried between trunk and carapace; antennae large, used in swimming; males often with hooks on 1st trunk limbs for coupling with females; earliest fossils reported from the Permian; many species, identified from glacial and postglacial deposits, have been used in conjunction with pollen analysis to study the histories of lakes; mainly freshwater; some marine species; about 430 species divided into 9 families.

Critical appraisal. The above orders are clearly defined and generally accepted, but some schemes acknowledge the close relationship between the Cladocera and Conchostraca by uniting them in a single order known as the Diplostraca, and then regarding the two groups as suborders.

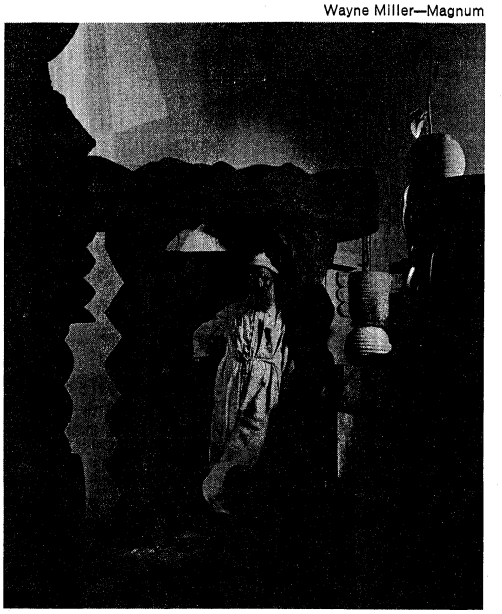
Brancusi, Constantin

A Romanian who lived the greater part of his life in France, Constantin Brancusi occupies a primary place in the history of modern sculpture because of his influence on artists who were trying to free themselves from representation of the subject. Historically, the evolution of his work paralleled that of sculpture, from figurative to abstract, as he gradually developed forms that were very close to pure abstraction, although always linked in some way with the human or animal figures that had served as their model. His work, extending throughout the first half of the 20th century, was marked by the use of perfectly polished surfaces and by the search for an ever more rigorous synthesis of form.

Wayne Miller—Magnum



Brancusi, 1955.

Early life and works. Constantin Brancusi (properly pronounced brahn koosh′) was born on February 21, 1876, in Hobiţa, a small hamlet belonging to the village of Pestisani, in the Oltenia region, between plain and mountain. His parents, Nicolas and Maria Brancusi, were poor countryfolk, and, like other village children of that time, Constantin did not go to school. From the age of seven he worked as a herdsman, first watching the family flock, then working for other countrypeople in the Carpathian Mountains. It was then that the young shepherd learned to carve wood by fashioning tools and implements. This popular art had always been very widespread in the Romanian countryside, not only for making spoons, bedposts, or cheese presses, all of which were ornamented with carvings, but also for making the facades of homes. The style of these ornaments would influence several of Brancusi's works. And he himself maintained in his tastes, his carriage, and his way of life the mark of his country origins: simplicity, good sense, love of nature, and a side to his character that was at once both childlike and crafty.

He was no older than nine when he went to Tîrgu Jiu, a town near Pestisani, to look for work. First he worked for a dyer; two years later he went into the service of a grocer in Slatina; and then he became a domestic in a public house in Craiova, Oltenia's chief town, where he remained for several years. His taste for working in wood, however, did not abandon him. On one occasion he even undertook the construction of a violin from an orange crate. Later he would become a violinist and he would always remember his country's popular melodies. On another occasion he carved a lily. Such apparently small feats attracted the attention of an industrialist, who, in 1894, entered him in the Craiova School of Arts and Crafts, where Brancusi was particularly interested in woodwork. He had to learn how to read and write on his own.

In 1896, at the age of 20, he began to travel for the first time: he went to Vienna on the Danube and hired himself out as a woodworker to earn money for his stay. Nevertheless, since his ambition was to be a sculptor, in 1898 he entered the contest for admission to the Bucharest School of Fine Arts and was admitted. Although he was far more attracted to the work of the "independents"

than to that of the academicians at his school, he nevertheless studied modelling and anatomy seriously. Among the sculptures of his school period, an "Anatomical Model" ("Ecorché," 1902) was bought by the school and served it a long time for the teaching of anatomy. In 1903 he received his first commission, a bust of Gen. Carol Davila, a founder of medical pedagogy in Romania.

Academic training and early sculptures

In that same year, on return from his military service, Brancusi's interest was aroused by the fame of Auguste Rodin, which reached from Paris even to Bucharest. Rodin's audacious conceptions inspired the enthusiasm of the avant-garde and the indignation of the academicians. Brancusi became curious about what was going on beyond the boundaries of his country. First he went to Munich, where he stayed until the spring of 1904, and then he decided to go to Paris, a costly trip for one of modest means. He made the greater part of the trip on foot, with his pack on his back, and still had to sell his watch to pay for a boat crossing on Lake Constance. He arrived in Paris in July.

Brancusi entered the École des Beaux-Arts, and there he again entered an academician's workshop, that of Antonin Mercié (died 1916), who derived his work from Florentine Renaissance statuary. Brancusi worked with him for two years, but in order to earn a living he was, in succession, a dishwasher in a restaurant at night and the cantor of the Romanian Orthodox chapel. Orders for portraits from a few compatriots also helped him through those difficult times.

In 1906 he exhibited for the first time in Paris, in the Salon (Salon de la Société Nationale des Beaux-Arts) and then at the Salon d'Automne. With a spirit that was still quite classical but showing great energy, his first works were influenced by the sinewy work of Rodin. In order to get away from that influence, Brancusi refused to enter Rodin's workshop, for, he said, "one can do nothing beneath great trees."

In 1907, charged with executing a rich landowner's funeral monument in the Buzau Cemetery in Romania, he sculptured a statue of a young girl kneeling, "The Prayer," which represented the first stage of his evolution toward simplified forms. He participated for the first time in the Tinerimea Artistica exposition, an annual exhibition of new talent, in Bucharest, and he rented a workshop in Montparnasse, in Paris. Rodin's influence appeared for one last time in 1908 in the first version of the "Sleeping Muse," a woman's face in which the features suggest an unformed block of marble. In that same year, Brancusi executed his first truly original work, "The Kiss," in which the vertical figures of two entwined adolescents form a closed volume with symmetrical lines. Here he affirmed the geometrization that was to become his trademark and that would influence the work of numerous artists, most immediately a series of sculptures executed, following his advice, by his friend Amedeo Modigliani starting in 1910.

Evolution from Rodin's influence to works in simplified forms

Mature life and works. An important work executed by Brancusi in 1910 was a new version of the "Sleeping Muse," a bronze in which the head is isolated, with all relief reduced so as to make it egg shaped. The "Sleeping Muse" was treated in this form by the artist in a dozen ways up to 1912, with variations in both plaster and bronze. The egg theme reappeared frequently in his sculpture, sometimes with a very light relief: to suggest the features of "Prometheus" in 1911; to break the curves of "The New-Born" in 1915. These tendencies finally led to the creation in 1924 of a pure marble egg shape, "The Beginning of the World," which the sculptor called "sculpture for a blind man." It may be Brancusi's most representative and most accomplished work.

Another theme occupying a privileged place in his work was that of the bird. It appears in 1912 with "Maiastra," the name of a miraculous bird in Romanian popular legends. This first version in marble, in which the bird, purified in form, is represented with its head raised in flight, was followed by 28 other versions until 1940; after 1919 "Maiastra" became the "Bird in Space"—a polished bronze, the elliptical, slender lines of which put into concrete form the very essence of rapid flight.

"Bird in Space"

In 1912 Brancusi received the first prize for sculpture of the official Bucharest Salon. In 1913, while continuing to exhibit in the Paris Salon des Indépendants, he participated in the Armory Show in New York, Chicago, and Boston with five works including "Mademoiselle Pogany," a schematized bust that would have numerous variations until 1933. Already known in the United States, Brancusi found faithful collectors there. Meanwhile, the critics maintained their attacks.

Above all, Brancusi loved carving itself, which required, he said, "a confrontation without mercy between the artist and his materials." Passionately fond of working in wood, he often created in oak or in chestnut objects that he would later treat in bronze or marble. His first sculpture in wood, "The Prodigal Son," in 1914, was very close to abstraction: a piece of rudely carved oak with the scarcely perceptible features of a person. This would be the way with a whole series of wood sculptures that are among his strangest works. He attached great importance to the base of a work and always constructed it himself, sometimes of five or six superimposed pieces, making frequent changes. He constructed his furniture with his own hands, even his bed, and most of his utensils, including his pipe.

In 1918 he sculptured in wood the first version of the "Endless Column." Created through the repetition of superimposed symmetrical elements, this column, inspired by the pillars of Romanian peasant houses, could, in fact, have been extended into the sky to infinity. It answered a need for spiritual elevation that Brancusi often expressed in his works. For, with the simple means that suited his attachment to the rustic life, he was always preoccupied with expressing a certain metaphysical relationship between man and the universe.

His contribution to the Salon of 1920, "Princess X," a portrait of an imaginary person in a curiously phallic form, created a scandal. The police intervened and forced him to retire a work that allowed for improper interpretation. In Bucharest he exhibited with the Arta Romana group. In 1922 he sculptured the first versions of "The Fish" in marble and the "Torso of a Young Man" in wood. In 1924 he returned to Romania for the first time, and in 1926 he visited the United States for an important exhibition of his works at the Brummer Gallery in New York. His shipments from France involved him in a two-year court case with U.S. customs officials, because a work in copper, "Bird in Space," was so abstract that customs refused to believe it was sculpture: Brancusi was accused of clandestinely introducing an industrial part into the United States. In 1928, he again travelled to the United States, where he had numerous buyers, and won his court case.

Court case with U.S. customs officials

Late life and works. The Maharajah of Indore went to see him in Paris in 1933 and commissioned him to create a temple that would house his sculptures. Brancusi worked several years to create this Temple of Contemplation and Deliverance, and in 1937 he went to India on the Maharajah's invitation. The latter's death, however, prevented Brancusi from realizing the project. In the meantime he had returned to New York for a new exhibit at the Brummer Gallery in 1933, and in 1934 he participated in the exhibition "20th Century Painting and Sculpture" at the Chicago Renaissance Society. He returned to Romania again in 1937 and in 1938 for the inauguration of three monumental works in a public garden in Tîrgu Jiu: a new version, 30 metres (100 feet) high and in steel, of the "Endless Column"; "Gate of the Kiss"; and "Table of Silence."

In 1939 he made his last trip to the United States to participate in the "Art in Our Time" exhibition at the Museum of Modern Art in New York. His last important work was the "Flying Turtle" in 1943. Henceforth, numerous expositions in the United States and in Europe would secure his fame. The largest was an exhibit of all of his work at the Solomon R. Guggenheim Museum in New York in 1955. By a naturalization decree dated June 13, 1952, he acquired French nationality.

Brancusi died March 16, 1957, in Paris. He left to the Musée d'Art Moderne de la Ville de Paris everything his

workshop contained (more than 80 sculptures) on the condition that the workshop itself be removed to the museum and restored to its original condition. His rustic furniture and his tools can be seen there, as well as his golf clubs, even though he never played golf once in his life.

MAJOR WORKS

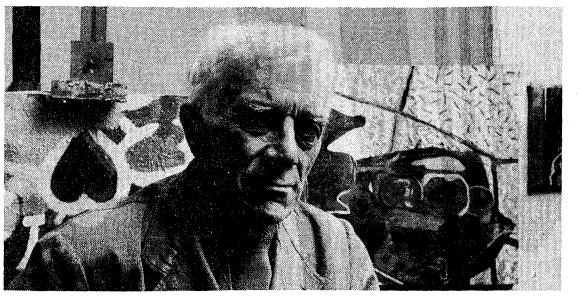
"General Dr. Carol Davila" (1903; bronze, Military Hospital of Bucharest); "The Prayer" ("La Prière"; 1907; bronze, Muzeul de Artă R.S.R., Bucharest); "Portrait of Nicolae Darascu" (1908; bronze, Muzeul de Artă, Bucharest); "Sleeping Muse" ("La Muse endormie"; 1908; marble, Muzeul de Artă, Bucharest; other versions in bronze—1910, 1911, 1912); "The Kiss" ("Le Baiser"; 1908; plaster, Muzeul de Artă, Craiova; another version in stone, 1910, funeral monument, Montparnasse Cemetery, Paris); "The Wisdom of the Earth" (1909, stone, Muzeul de Artă, Bucharest); "Prometheus" (1911; marble, Philadelphia Museum of Art); "Muse" (1912; marble, Solomon R. Guggenheim Museum, New York); "Maiastra" (1912; marble, Museum of Modern Art, New York); "Mlle. Pogany" (1913; marble, Philadelphia Museum of Art); "The Prodigal Son" ("Le Fils prodigue"; 1914, oak, Philadelphia Museum of Art); "The New-Born" ("Le Nouveau-né"; 1915; marble, Philadelphia Museum of Art); "Princess X" (1916; polished bronze, Philadelphia Museum of Art); "The Sorceress" (1916; wood, Solomon R. Guggenheim Museum, New York); "Golden Bird" (1919; polished bronze, Arts Club of Chicago); "Adam and Eve" (1921; wood, Solomon R. Guggenheim Museum, New York); "The Fish" ("Poisson"; 1922; marble, Philadelphia Museum of Art); "The Cock" (1924; wood, Museum of Modern Art, New York); "The Beginning of the World" ("Le Commencement du monde"; 1924; marble, Philadelphia Museum of Art); "Miracle" ("The White Seal"; 1936; marble, Solomon R. Guggenheim Museum, New York); "Endless Column" ("La Colonne sans fin"; 1937; steel, Tîrgu Jiu); "Flying Turtle" ("La Tortue volante"; 1943; marble, Solomon R. Guggenheim Museum, New York).

BIBLIOGRAPHY. CAROLA GIEDION-WELCKER (ed.), *Constantin Brancusi* (1958; Eng. trans., 1959), is the most important work on the sculptor, comprising a serious analysis of his work and numerous photographic documents. SIDNEY GEIST, *Brancusi* (1968), is also an excellent monograph. IONEL JIANOU, *Brancusi* (1963), contains a biographical study, a descriptive catalog of his work, a list of his exhibitions, and 109 reproductions. Other well-documented works include V.G. PALEOLOG, *Brancusi* (1947); DAVID LEWIS, *Constantin Brancusi* (1957); and CHRISTIAN ZERVOS, *Constantin Brancusi* (1957), in French. The first study to reveal the sculptor to the United States was "Brancusi," by EZRA POUND, in *The Little Review* (Autumn 1921), with 24 reproductions. JEAN SELZ, *Modern Sculpture: Origins and Evolution* (1963), contains an analysis of Brancusi's work, a biography, three reproductions in black and white and a plate in colour. Also of interest are ATHENA SPEAR, *Brancusi's Birds* (1969); and the prefaces to certain catalogs: PAUL MORAND, exposition at the Brummer Gallery, New York (1926); ROGER VITRAC, exposition at the Brummer Gallery, New York (1933); HANS BOLLIGER, exposition "Begründer der modernen Plastik," Zurich (1954); H.P. ROCHE and MICHEL SEUPHOR, exposition "Sept Pionniers de la sculpture moderne," Yverdon (1954); SIDNEY GEIST, expositions at the Solomon R. Guggenheim Museum, New York; the Philadelphia Museum of Art; and the Art Institute of Chicago (1969). See also the catalogs of the Brancusi exhibitions at the Arts Club of Chicago (1927); at the Solomon R. Guggenheim Museum, New York (1955); and at the Staempfli Gallery, New York (1960).

(Je.S.)

Braque, Georges

Co-launcher with Pablo Picasso of the Cubist movement in the years just preceding World War I, and thus one of the important revolutionaries in 20th-century cultural history, the French painter Georges Braque was an artist for whom "distinguished" seemed, to many contemporaries, the most appropriate adjective. During a career of 60 years he attracted attention only with his works, which are predominantly still lifes, remarkable for robust construction, subtle, low-keyed colour harmonies, and an air of integrity and reticence. Although thoroughly modern in his style, Braque has often been compared with an earlier meditator before a quiet, domestic world: the 18th-century master Jean-Baptiste Chardin.



Braque, photograph by Arnold Newman, 1956.
© Arnold Newman

Braque was born on May 13, 1882 (seven months after Picasso), at Argenteuil, a small community on the Seine near Paris and one of the centres of the Impressionist movement in the 1870s. His father and a grandfather were the owners of a prosperous house-painting firm, and both were amateur artists. In 1890 the family moved to Le Havre, which had also been, back in the time of the seascapist Eugène Boudin and the young Claude Monet, an early centre of Impressionism. The boy attended the local public school, accompanied his father on painting expeditions, and developed an interest in sports, including eventually boxing, that gave him, as an adult, the look of a professional athlete. He also learned to play the flute. At 15 he enrolled in the evening course at the Le Havre academy of fine arts. He left school at 17 for a year of apprenticeship as a house painter and interior decorator, first in Le Havre and then in Paris; during this period he picked up his solidly professional handling of materials and his knowledge of the artisan's tricks—the imitation of wood grain, for instance—frequently utilized in his Cubist pictures. After a year of military service he decided, with the help of an allowance from his family, to become an artist. Between 1902 and 1904 he studied in a Paris private academy and, very briefly, at the official École des Beaux-Arts; in his free hours he frequented the Louvre, where he admired especially Egyptian and archaic Greek works.

Early training and influences

His early paintings reveal, as might be expected from a childhood spent in Normandy, the influence of the Impressionists, in particular that of Monet and of Camille Pissarro. A little later came the revelation of the firm structures and the union of colour and tone values in the work of Paul Cézanne. But Braque can be said to have begun to find his way only in 1905, when he visited the Paris Salon d'Automne and saw the violent explosion of arbitrary colour in the room occupied by the paintings of the group nicknamed the Fauves (Wild Beasts). During the next two years he was a convinced, if rather prudent and tradition-minded, Fauvist, working for a while at Antwerp and then on the Mediterranean coast near Marseilles, at L'Estaque and La Ciotat. Representative pictures from this period are "Le Port d'Anvers," "The Port of La Ciotat," and "View from the Hôtel Mistral, L'Estaque."

In the spring of 1907 he exhibited six paintings at the Paris Salon des Indépendants and sold them all. Later that year he signed a contract with a dealer, David Henry Kahnweiler, who had recently opened a small Paris gallery destined to play an important role in the history of modern art. Kahnweiler brought around the avant-garde poet and critic Guillaume Apollinaire, who introduced Braque to Picasso in the latter's Montmartre studio. Braque was at first disconcerted by Picasso's recently painted "Demoiselles d'Avignon" (Museum of Modern Art, New York City). "Listen," he is reported to have said, "in spite of your explanations your painting looks as if you wanted to make us eat tow, or drink gasoline and spit fire." But the two artists became close friends, and within a few months they were engaged in the unprecedented process of mutual influence from which Cubism emerged.

Meeting with Picasso

It is impossible to say which of the two was the principal inventor of the revolutionary new style, for at the height of their collaboration they exchanged ideas almost daily and produced pictures so alike as to be practically indistinguishable. Picasso provided, with his proto-Cubist

"Demoiselles," the initial liberating shock. But it was Braque, largely because of his admiration for Cézanne, who provided much of the early tendency toward geometrical forms. During the summer of 1908 in southern France, he painted a series of radically innovative canvases, of which the most celebrated is "Houses at L'Estaque"; here already can be seen the slab volumes, sober colouring, and warped perspective typical of the first part of what has been called the analytical phase of Cubism. That fall he had a show at Kahnweiler's gallery and provoked from the Paris critic Louis Vauxcelles a remark about "cubes" that soon blossomed into a stylistic label.

By 1911 Braque—now teamed, as he said later, with Picasso as if they were roped alpinists—was well into the so-called hermetic part of the analytical phase of Cubism, of which "Man with a Guitar" is an example; here the colours are brown, gray, and green, the pictorial space is almost flat, viewpoints and light sources are multiplied, contours are broken, volumes are often transparent, and facets are turned into apparently illogical simultaneous views. Also in 1911, Braque stencilled letters into "The Portuguese" and thus significantly strengthened the idea, full of consequences for the future of art, that a picture was not a representation but an autonomous object. In 1912 he went further in the same direction and created what is generally considered the first *papier collé* (pasted-paper picture) by attaching three pieces of wallpaper to the drawing "Fruit Dish and Glass."

During the early part of the Cubist adventure, he had a studio in Montmartre but often worked elsewhere: in 1909 at La Roche-Guyon, on the Seine, west of Paris; in 1910 back at L'Estaque; and in 1911 at Céret, a village on the Mediterranean side of the foothills of the Pyrenees. In 1912 he married Marcelle Lapré and rented a house at Sorgues, a small town in the Rhône valley near Avignon. With the outbreak of World War I he entered the army as an infantry sergeant and served with distinction, being decorated twice in 1914 for bravery. In 1915 he suffered a serious head wound, which was followed by a trepanation, several months in the hospital, and a long period of convalescence at home at Sorgues. During this period he added to the aphorisms he had been in the habit of scribbling on the margins of drawings; and in 1917 a collection of these sayings, put together by his friend the poet Pierre Reverdy, was published in the review *Nord–Sud* as "Thoughts and Reflections on Painting." Even a brief sampling can suggest the quality, at once poetic and rational, of Braque's mind and the sort of thinking that lay behind Cubism:

Aphorisms on painting

> New means, new subjects .... The aim is not to *reconstitute* an anecdotal fact, but to *constitute* a pictorial fact .... To work from nature is to improvise .... The senses deform, the mind forms .... I love the rule that corrects emotion.

Released from further military service, the artist rejoined the Cubist movement, which by then was in what is sometimes called its synthetic phase—a not very adequate way of referring to a tendency to use more colour and to represent objects not by the previous spider web of analytical signs but by relatively large emblematic planes. In 1917–18 he painted, partly under the influence of his friend Juan Gris, a Spanish-born Cubist master whose paintings were strongly Synthetic Cubist, the geometrical, strongly coloured, nearly abstract "Woman Musician" and some still lifes in a similar manner. Rapidly, however, he moved away from austere geometry toward forms softened by looser drawing and freer brushwork; an example of the change is the 1919 "Still Life with Playing Cards." From this point onward his style ceased to evolve in the methodical way it had during the successive phases of Cubism; it became a series of personal variations on the stylistic heritage of the eventful years before World War I.

International acclaim and prosperity

By now he was a prosperous, established modern master, much in the favour of the well-to-do, up-to-date members of postwar French society. Working again much of the time in Paris, he transferred his studio from Montmartre to Montparnasse in 1922 and three years later moved into a new Left Bank house designed for him by a modern-minded architect, Auguste Perret. In 1923 and again in 1925 he had commissions from Sergey Diaghilev, the great ballet impresario, for the design of stage sets. In 1930 he acquired a country residence at Varengeville, a group of hamlets on the Normandy coast near Dieppe. His painting during these years is most easily classified, because of its stylistic variety, on the basis of subject matter. From 1922 to around 1926 he did a series of *canéphores*, pagan-looking women carrying fruit. Overlapping with this group in time is the series of *cheminées*, fireplace mantelpieces laden with fruit and perhaps a guitar. By 1928 he was doing a series of *guéridons*, pedestal tables holding the material previously assigned to mantelpieces.

In 1931 he undertook a new medium of expression: incised, white drawings, reminiscent of ancient Greek pottery designs, executed on plaster plaques painted black. Later in the 1930s he began a series of figure paintings; first-rate examples are "Le Duo" and "The Painter and His Model." In 1937 he won the Carnegie Prize with "The Yellow Tablecloth." During World War II he produced a collection of small, generally flat, very decorative pieces of sculpture, in a style recalling again ancient Greece and on vaguely mythological themes. After the war he resumed his practice of doing a number of paintings on a single subject: first came a series of billiard tables, then one of studio interiors, and then one of birds —large, lumbering creatures that seem charged with some forgotten archaic symbolic meaning.

During the last years of his life Braque was honoured with important retrospective exhibitions throughout the world. In December 1961 he became the first living artist to have his works exhibited in the Louvre. He died in Paris on August 31, 1963.

MAJOR WORKS

"Le Port d'Anvers" (1906; National Gallery of Canada, Ottawa); "L'Estaque, l'embarcadère" (1906; Musée National d'Art Moderne, Paris); "The Port of La Ciotat" (1907; John Hay Whitney Collection, New York); "View from the Hôtel Mistral, L'Estaque" (1907; Werner E. Joster Collection, New York City); "Houses at L'Estaque" (1908; Hermann Rupf Collection, Bern, Switz.); "Piano and Lute" (1910; Solomon R. Guggenheim Museum, New York); "Violin and Jug" (1910; Kunstmuseum, Basel); "Man with a Guitar" (1911; Museum of Modern Art, New York); "The Portuguese" (1911; Kunstmuseum, Basel); "Fruit Dish and Glass" (1912; Douglas Cooper Collection, France); "Composition à l'as de trèfle" (*c.* 1912–13; Musée National d'Art Moderne, Paris); "Jeune Fille a la Guitare" (1913; Musée National d'Art Moderne, Paris); "The Musician's Table" (1913; Kunstmuseum, Basel); "Music" (1914; Phillips Collection, Washington, D.C.); "The Woman Musician" (1917–18; Kunstmuseum, Basel); "Musical Forms" ("Guitar and Clarinet," 1918; Philadelphia Museum of Art); "Café bar" (1919; Kunstmuseum, Basel); "Still Life with Playing Cards" (1919; Rijksmuseum Kröller-Müller, Otterlo, The Netherlands); "The Mantelpiece" (1922; Richard K. Weil Collection, St. Louis, Missouri); "Nude Woman with Basket of Fruit" (1926; National Gallery of Art, Washington, D.C.); "Black Rose" (1927; Burton Tremaine Collection, Meriden, Connecticut); "Still Life: The Table" (1928; National Gallery of Art, Washington, D.C.); "Lemons and Napkin Ring" (1928; Phillips Collection, Washington, D.C.); "Boats on the Beach, Dieppe" (1929; Willy Schniewind Collection, Neviges); "Still Life: Le Jour" (1929; National Gallery of Art, Washington, D.C.); "The Round Table" (1929; Phillips Collection, Washington, D.C.); "The Bathers" (1931; Walter P. Chrysler, Jr. Collection, New York); "Still Life" (1934; Kunstmuseum, Basel); "The Yellow Tablecloth" (1935; Samuel A. Marx Collection, Chicago) "Still Life with a Mandolin" (1935; Louis Bergman Collection, New York); "Woman with Hat" (1937; Jacqueline Delubac Collection, Paris); "Le Duo" (1937; Musée National d'Art Moderne, Paris); "The Studio" (1939; private collection, U.S.); "The Painter and His Model" (1939; Walter P. Chrysler, Jr. Collection, New York City); "La Table de cuisine au gril" (1942; Gustav Zumsteg Collection, Zürich); "Le Tapis vert" (1943; Musée National d'Art Moderne, Paris); "Le Billard" (1945; Musée National d'Art Moderne, Paris); "The Studio, VI" (1950; Aimé Maeght Collection, Paris); "The Shower" (1952; Phillips Collection, Washington, D.C.); "Seascape" (1953; private collection, Paris); "The Black Birds" (1957; Aimé Maeght Collection, Paris).

BIBLIOGRAPHY. Standard biographies are JOHN RUSSELL, *Georges Braque* (1959); and JEAN LEYMARIE, *Braque* (1961), although written before the painter died. EDWIN B. MULLINS,

The Art of Georges Braque (British title, *Braque;* 1969), provides a basic introduction to the subject. Good analyses of the work are DOUGLAS COOPER, *Georges Braque: Paintings, 1909–1947* (1948); and H.R. HOPE, *Georges Braque* (1949). The best study of the period of Braque's collaboration with Picasso is in JOHN GOLDING, *Cubism: A History and an Analysis, 1907–1914* (1959).

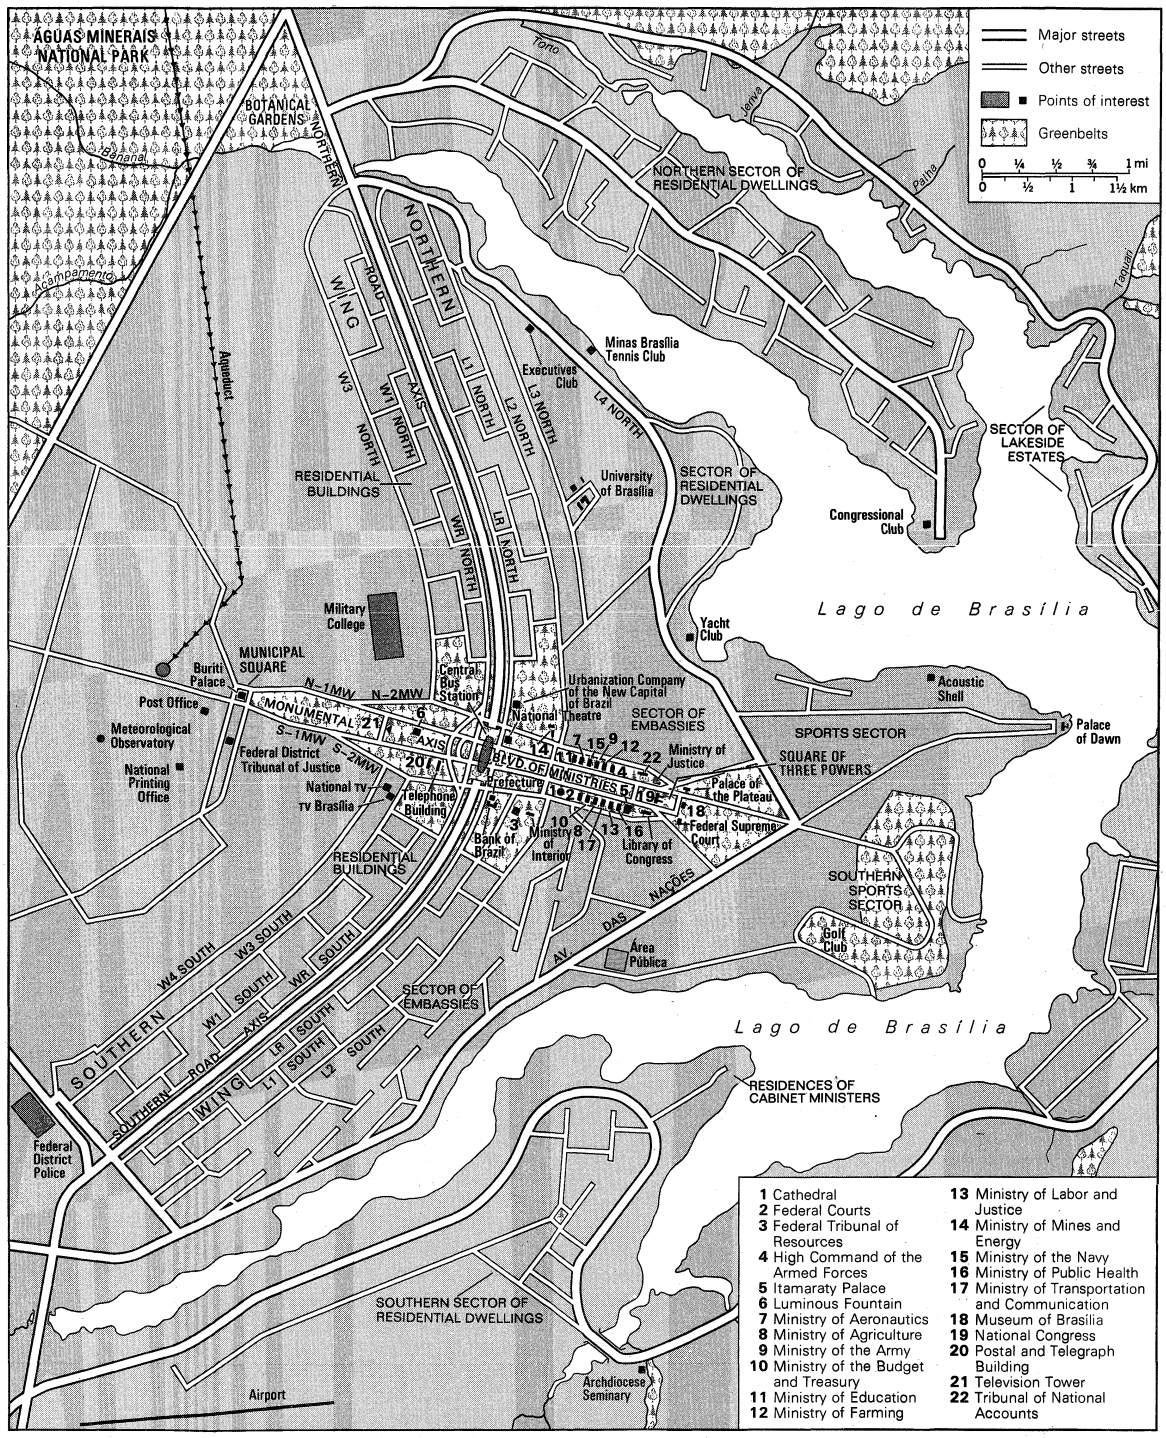
(R.McMu.)

Brasília

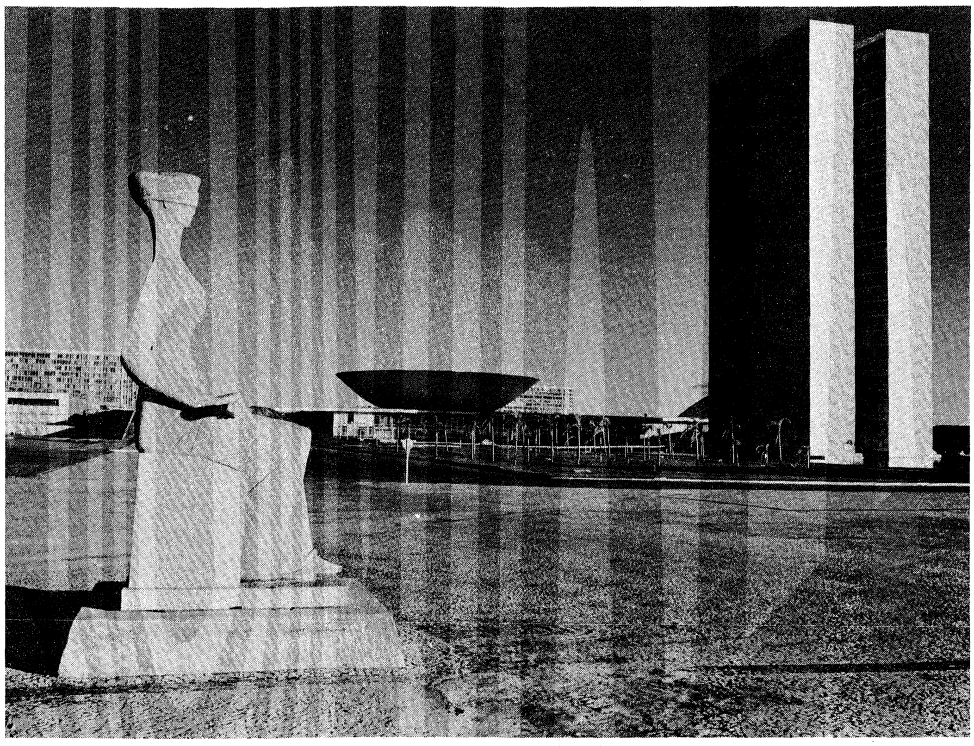
In 1957 Brasília was no more than an architect's dream on a drawing board, a city that was to be raised in the middle of a virtual wilderness. In 1960, however, it was inaugurated as the newest capital in Latin America, and by 1970 almost 550,000 Brazilians and foreigners crowded the federal district and over 272,000 inhabitants lived in the as yet unfinished city. Its master plan, drawn by the urban designer Lúcio Costa, and its major buildings, designed by the world-famous Brazilian architect Oscar Niemeyer, had no need to accommodate within themselves remnants of the past or to work around its errors. The city stood as a symbol for Brazilians of the national will to overcome chronic economic and social problems by bringing together the resources of the country's vast untapped interior and the large coastal populations living on the boundaries of poverty. As the city went forward toward its completion in the 1970s, it remained one of the rare opportunities in world history for an orderly total-city design in terms of physical layout, architecture, and human habitation. (For additional details, see the related articles BRAZIL; SOUTH AMERICA.)

Municipal planning

Environment. Brasília and its eight satellite towns are located in the federal district of 2,245 square miles (5,814 square kilometres) carved out of Goiás state on the cen-



The city of Brasília.



Government buildings in Brasília, Brazil's federal capital. "Goddess of Justice" (foreground), with the National Congress Building (centre) and legislative office buildings (right).
Per Olle Stackman—Tiofoto

tral plateau of Brazil at an altitude of about 3,500 feet (1,100 metres). The region was formerly one of mining and cattle raising. The climate is dry and mild with a dry season from March to October and average minimum and maximum temperatures of about 57° F (14° C) and 81° F (27° C), respectively.

History. The idea of a capital city located in the interior had been proposed in 1789, was reiterated in 1822 when Brazil gained its independence from Portugal and was embodied in the constitution of 1891. Eight years of surveying and testing in the interior preceded the selection of Brasília's present site in 1956 and the beginning of work under Pres. Juscelino Kubitschek de Oliveira. In April 1960 the central Square of Three Powers was dedicated and the federal government began its move from Rio de Janeiro. In 1962 the University of Brasília began academic activities, one of its main objectives being to provide scientific and cultural assistance to the city and government. In accordance with a governmental decree all foreign embassies were to begin operations in Brasília starting in September 1972.

Physical layout. An artificial lake surrounds much of the city and separates it from the suburban towns to the north. The cross-shaped plan of the central city is emphasized by the North–South Axis, Brasília's main transportation artery, and the East–West, or Monumental Axis, lined by the federal and civic buildings. At the west end of the Monumental Axis are municipal buildings, while at the east end, around the Square of Three Powers, stand the executive, judicial, and legislative buildings. The National Congress Building comprises dome and saucer forms atop a huge concrete platform and central twin administration towers. The cathedral is considered by many to be Niemeyer's finest achievement.

Design

Transportation and utilities. Highways and air routes link Brasília with the rest of Brazil, and there is regular national and international air service. A network of roads connects central Brasília, and its suburbs and bus services are extensive—both necessitated by the great distances within the district. The water supplies are treated in two modern plants, and 60 percent of the garbage is transformed into fertilizer. The city is entirely electrified, and telephone service is widespread.

The people and conditions of life. Brasília's approximately 200,000 inhabitants include both foreigners and Brazilians, many of whom came from economically impoverished areas in the east to take part in the city's building. Both low-cost and luxury housing were built by the government in the central city area. In the suburbs private building has been augmented by federal support for low-cost units.

Economic life. The major roles of construction and of food and related services in Brasília's economy are natural in view of the city's growth and its status as a governmental, rather than an industrial, centre. Industries connected with construction and furnishing are booming, as are publishing and printing. Many nationwide companies and associations are headquartered there, as are the legations of foreign governments. The average per capita income is high, accounting for the rapid development of local commerce and banking.

Economic boom

Local government. The governor of the federal district, who is appointed by the Brazilian president and confirmed by the Senate, is the chief administrative officer in charge of numerous secretaries responsible for public works, welfare, education, law enforcement, and the like. The Senate acts as the legislative branch of local government. Monies and courts are under control of the federal district. A regional administrator appointed by the governor provides decentralized government for the satellite communities.

Education. The educational council of the federal district administers a diversified school system from kindergarten through high school, with broad extracurricular programs in physical training and the arts. Business and technical skills are also taught at the higher levels. School placements and enrollments were carefully planned in the early stages. The federally founded University of Brasília is divided into a number of separate institutes and faculties with their own departments. The buildings, between North–South Axis and the lake, were still under construction in the 1970s. It was hoped that the university would play a leading role in the nation's development.

Health and safety. Six municipal hospitals supplement a broad system of preventive medicine, health care under

a federal social security system, clinics, outlying health centres, and private and religious hospitals. Fire and police services are extensive and modern, the latter connected with both the territorial government and the federal Ministry of Justice.

Cultural life and recreation. The university is central to much of Brasília's cultural life. The Cultural Foundation of the federal district sponsors many national meetings in the arts and letters, and several foreign information centres are available. The two auditoriums in the National Theatre (Teatro Nacional) have more than 1,700 seats for dramatic, symphonic, and operatic works as well as modern staging facilities. Historical institutions include the Museum of Brasília, with a historical record of Brasília's creation, and the Institute of History. The university library is open to the public, and other libraries are being developed throughout the area.

The newspaper *Correio Brasiliense* supplements other dailies from Rio de Janeiro and São Paulo. Numerous publications and magazines originate in the governmental departments. Television and radio stations present local programs and material transmitted from coastal cities.

An early lack of recreation facilities has been overcome in Brasília by numerous cinemas and night clubs and a proliferation of sporting grounds in the city and suburbs. The city has more swimming pools than any other Brazilian city. A zoological park and forest reserves are under development, and boating and fishing are popular on the lake and the numerous nearby rivers.

BIBLIOGRAPHY. R.M. FRONTINI, "The Achievement of Brasília," in *Optima* (1968), a quarterly publication of the Anglo-American Corporation and of De Beers and Chartered Consolidated Groups of Companies, is a full account with illustrations. See also WILLY STAUBLI, *Brasília* (1966), a well-illustrated general account of the city; MARCEL GAUTHEROT, *Brasília* (1966), a brief description (in English, German, and French) and itinerary with excellent colour photographs; ANDRE MALRAUX, *Brasília, la capitale de l'espoir* (1959), a historical and literary account (in French, Spanish, and German) suggested by the author's visit, as French minister of culture, to the city shortly before its dedication; OSCAR NIEMEYER, *Minha Experiência em Brasília* (1961), a well-illustrated account by the city's architect; and DAVID G. EPSTEIN, *Brasília, Plan and Reality* (1973), an urban development study. GREGORIO ZOLKO and ALFREDO WIESENTHAL (eds.), *Brasília: História, Urbanismo, Arquitetura, Construção,* 2nd ed. (1960), provides a complete historical survey in Portuguese and English of the creation of Brasília as capital.

(C.B.D.)

Braun, Wernher von

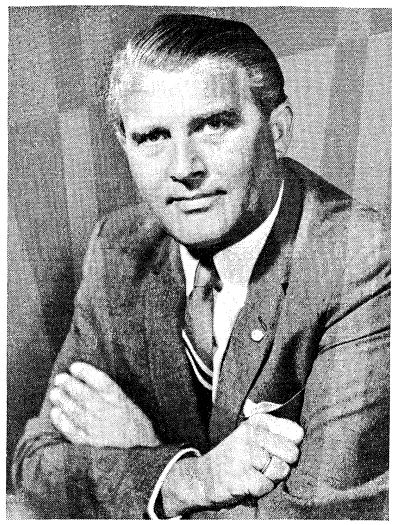
Wernher von Braun, rocket engineer and proponent of space exploration, conducted some of the first rocket experiments in Germany and contributed substantially to the coordination of personnel and technology in the successful effort of the United States to land a man on the moon. He played a leading role in the development of all aspects of rocketry.

Early years

Braun was born in Wirsitz, Germany, now Wyrzysk, Poland, on March 23, 1912. One of three boys, he had an older brother, Sigismund, and a younger one, Magnus. Both his parents came from prosperous, aristocratic families. His father, Baron Magnus von Braun, was a cabinet member of the Weimar Republic and later minister of agriculture and a banker. His mother, the former Emmy von Quistorp, encouraged young Wernher's curiosity by giving him a telescope upon his confirmation in the Lutheran Church. Braun's early interest in astronomy and the realm of space never left him.

In the spring of 1920, his family moved to the seat of government in Berlin. He did not do well in school, particularly in physics and mathematics. A turning point in his life occurred in 1925 when he acquired a copy of *Die Rakete zu den Planetenräumen* ("The Rocket into Interplanetary Space") by a rocket pioneer, Hermann Oberth. Frustrated by his inability to understand the mathematics, he applied himself at school until he led his class.

In the spring of 1930, while enrolled in the Berlin Institute of Technology, Braun joined the German Society for Space Travel. In his spare time he assisted Oberth in liquid-fuelled rocket motor tests. At about this time he took gliding lessons and eventually obtained his pilot's license in powered aircraft. In 1932 he was graduated from the Technical Institute (B.S. in mechanical engineering) and entered the University of Berlin.



Braun, 1962.

By the fall of 1932 the rocket society was experiencing grave financial difficulties. At that time Capt. Walter Dornberger (later major general) was in charge of solid-fuel rocket research and development in the Ordnance Department of Germany's 100,000-man Reichswehr. He recognized the military potential of liquid-fuelled rockets and the ability of Braun. Dornberger arranged a research grant from the Ordnance Department for Braun, who then did research at a small development station that was set up adjacent to Dornberger's existing solid-fuel rocket test facility at the Kummersdorf Army Proving Grounds near Berlin. Two years later Braun received a Ph.D. in physics from the University of Berlin. His thesis, which, for reasons of military security, bore the nondescript title "About Combustion Tests," contained the theoretical investigation and developmental experiments on 300- and 660-pound-thrust rocket engines.

Early rocket tests

By December 1934 Braun's group, which then included one additional engineer and three mechanics, had successfully launched two rockets which rose vertically to more than 1.5 miles (2.4 kilometres). But by this time there was no longer a German rocket society; rocket tests had been forbidden by decree, and the only way open to such research was through the military forces. Fifteen years later, Braun pointed out in a paper, "Weltraumfahrt—eine Aufgabe für die internationale wissenschaftliche Zusammenarbeit" ("Space Flight—a Program for International Scientific Research"), that the rocket motor was like the ancient Roman god, Janus, depicted as having two faces pointing in opposite directions. The rocket could be used for peaceful purposes in the exploration of space, or it could be used for war. Just as with the airplane, the actual use was controlled by the sponsor of the development, not by the inventor or engineer who designed the equipment.

Since the test grounds near Berlin had become too small, a large military development facility was erected at the village of Peenemünde in northwest Germany on the Baltic Sea, with Dornberger as the military commander and Braun as the technical director. Liquid-fuelled rocket aircraft and jet-assisted takeoffs were successfully demonstrated, and the long-range ballistic missile A-4 and the supersonic anti-aircraft missile Wasserfall were developed. The A-4 was designated by the Propaganda Ministry as V-2, meaning Vengeance Weapon 2. By 1944 the level of technology of rockets and missiles at Peenemünde was many years ahead of that in any other country.

Braun always recognized the value of the work of the U.S. rocket pioneer Robert H. Goddard. "Until 1936," said Braun, "Goddard was ahead of us all." At the end of World War II, Braun, his younger brother, Magnus, Dornberger, and the entire rocket development team surrendered to U.S. troops. Within a few months Braun and about 100 members of his group were at the U.S. Army Ordnance Corps test site at White Sands, New Mexico, where they tested, assembled, and supervised the launching of captured V-2's for high-altitude research purposes. Developmental studies were made of advanced ramjet and rocket missiles. Moving to Huntsville, Alabama, in 1952, he became technical director (later chief) of the U.S. Army ballistic-weapon program. Under his leadership, the Redstone, Jupiter-C, Juno, and Pershing missiles were developed. In 1955 he became a U.S. citizen, and, characteristically, accepted citizenship wholeheartedly. During the 1950s Braun became a national and international focal point for promotion of space flight. He was the author or co-author of popular articles and books and made addresses on the subject. Confident, persuasive, and eloquent, he was criticized by some scientists and missile men as a dreamer, wishful thinker, and salesman. Some of this criticism was founded on professional jealousy, lack of imagination, and remnants of wartime emotion. At the end of the war the United States had entered the field of guided missiles with practically no previous experience. The technical competence of Braun's group was outstanding. "After all," he said, "If we are good, it's because we've had 15 more years of experience in making mistakes and learning from them!"

In 1954 a secret army–navy project to launch an Earth satellite, Project Orbiter, was thwarted. The situation was changed by the launching of Sputnik 1 by the Soviet Union on October 4, 1957, followed by Sputnik 2 on November 3. Given leave to proceed on November 8, Braun and his army group launched the first U.S. satellite, Explorer 1, on January 31, 1958.

Work with NASA

After the National Aeronautics and Space Administration (NASA) was formed to carry out the U.S. space program, Braun and his organization were transferred from the army to that agency. As director of the NASA George C. Marshall Space Flight Center in Huntsville, Braun led the development of the large space launch vehicles Saturn I, IB, and V. The engineering success of each of the Saturn class of space boosters, which contain millions of individual parts, has not yet been equalled in rocket history. Each has been launched successfully and on time and has met safe performance requirements.

In March 1970, Braun was transferred to NASA headquarters in Washington as deputy associate administrator for planning. He resigned from the agency in 1972 to become vice president for engineering and development at Fairchild Industries Inc., an aerospace company. In 1975 he founded the National Space Institute, a private organization whose objective was to gain public support and understanding of space activities.

Physically active, Braun enjoyed skin diving, sailing, and the outdoors; he also had an airline transport pilot's rating. In 1947 he married his cousin, Maria Louise von Quistorp, and he was devoted to her and to their two daughters, Iris and Margrit, and son, Peter Constantine. He held strong religious beliefs in the existence of God and the order of the universe. He justified his involvement in the development of the German V-2 rocket with a credo that in times of war a man has to stand up for his country, regardless of whether or not he agrees with the policy it is pursuing. Despite the fact that during World War II he fully dedicated himself to the development of the long-range rocket as a weapon, he was arrested by the Gestapo and accused of having space flight really in mind.

In 1971 he said,

> Science, by itself, has no moral dimension. The drug which cures when taken in small doses may kill when taken in excess. The knife in the hands of a skillful surgeon may save a life but it will kill when thrust just a few inches deeper. The nuclear energies that produce cheap electrical power when harnessed in a reactor may kill when abruptly released in a bomb. Thus it does not make sense to ask a scientist whether his drug . . . or knife or his nuclear energy is "good" or "bad" for mankind.

Braun, who believed that it is in the nature of man to be curious and to explore, pointed out that social problems existed in the times of Columbus and other explorers and that it would have been as foolish then as now to have ceased exploration until all social ills were eliminated. Rather, he insisted that, quite apart from the new understanding of nature obtainable from space research, satellites increasingly will be necessary tools in the management of world resources.

Braun received numerous high awards from U.S. government agencies and professional societies in the U.S. and abroad. He died of cancer on June 16, 1977, in Alexandria, Virginia.

BIBLIOGRAPHY

Books by Braun: *Das Marsprojekt* (1952; Eng. trans., *The Mars Project,* 1953), a technical treatise, written in 1952, on an expedition of 10 spacecraft with 70 men to Mars (a brilliant "tour de force"); *Space Frontier,* rev. ed. (1971), an easily understandable discussion of the fundamental principles of rocketry and space flight.

Books by Braun and others: *Across the Space Frontier* (1952), *Conquest of the Moon* (1953), and *Exploration of Mars* (1956), a series of three popular books describing concepts for the exploration of space (beautifully illustrated by CHESLEY BONESTELL); *First Men to the Moon* (1960), an early popular work for young people; *History of Rocketry and Space Travel,* rev. ed. (1969), an excellent history and reference work, profusely illustrated; *Moon* (1970), a beautiful tribute to the Apollo 11 lunar landing, including a history of man's study of the Moon (lavishly illustrated).

Biographies: ERIK BERGAUST, *Reaching for the Stars* (1960), a definitive and authoritative biography; HEATHER M. DAVID, *Wernher von Braun* (1967), and JOHN C. GOODRUM, *Wernher von Braun: Space Pioneer* (1969), two popular biographies written for young people.

(F.C.D.III)

Brazil

Brazil (Brasil) is a federal republic occupying nearly half the continent of South America. Its population in 1976 was estimated at more than 109,000,000. Among the nations of the world, it is exceeded in area only by the Soviet Union, the People's Republic of China, Canada, and the United States. It has an area of 3,286,487 square miles (8,511,965 square kilometres) and extends for almost 2,700 miles from north to south and about the same distance from east to west. Its territory touches that of all the other South American countries except Chile and Ecuador; the greater part of the Amazon River Basin lies within northern Brazil. The republic is bounded north by Venezuela, Guyana, Surinam, and French Guiana; east by the Atlantic Ocean; to the south by Uruguay; southwest by Argentina and Paraguay; west by Bolivia and Peru; and northwest by Colombia.

In many fundamental ways Brazil stands in strong contrast to the other countries of the Western Hemisphere. Brazil is made up of the former colonies of Portugal in South America; unlike the Spanish colonies, which became separate countries, the Portuguese colonies became united into one huge country. The language of Brazil is Portuguese. Since 1960 the federal capital has been Brasília, replacing Rio de Janeiro. Since 1964 military officers have controlled the government. (For articles on associated subjects, see BRASILIA; RIO DE JANEIRO; SAO PAULO; and articles on the component states of the Brazilian federation; for physical features, see AMAZON RAIN FOREST; AMAZON RIVER; IGUACU FALLS; PARAGUAY RIVER; PARANA RIVER; and SAO FRANCISCO RIVER; for historical aspects, see BRAZIL, HISTORY OF.)

The landscape

THE NATURAL ENVIRONMENT

Relief. The greater part of the area of Brazil consists of hilly uplands, plateaus, and low mountains. Very little of the national territory can be described as plain. The largest area of plain is in the Upper Amazon Basin, and Brazil shares with Bolivia a part of the basin of the Up-

per Paraguay River. There is no extensive coastal plain. The Guiana Highlands north of the Amazon and the Brazilian Highlands south of the Amazon are similar in geology and surface features. Underlying them are some of the oldest geological formations on Earth. Constituting what has been described as the Brazilian complex, these consist of ancient rocks, which are igneous (solidified from the molten state) and metamorphic (formed by heat and pressure); they date from the early part of the Precambrian Era (from 4,600,000,000 to 570,000,000 years ago). The rocks are granites, gneisses (coarse-grained rocks in which alternate bands of granular minerals and schistose minerals are found), and metamorphic schists (medium- or coarse-grained rocks containing micaceous minerals) folded and faulted and cut in many places by veins of pegmatite (a coarsely crystalline granite containing much silica) in which are found gold, diamonds, and a variety of semiprecious stones. The ancient crystalline rocks weather rapidly under the rainy conditions of the tropics, forming convex slopes, rounded hilltops, and narrow valleys.

Rocks of the Brazilian complex

More resistant than these Early Precambrian rocks are Late Precambrian formations, consisting of phyllites (clayey metamorphic rocks, intermediate in grade between slates and schists), quartzites, and limestones. Where these formations occur, they include massive mountains that stand rounded and low above the general level of the Early Precambrian rocks. The Serra do Espinhaço and Serra Geral running northward from central Minas Gerais into Bahia are made up of Late Precambrian rocks, as also is the Pico da Bandeira, one of Brazil's highest peaks (9,482 feet, or 2,890 metres), located near the border of Minas Gerais and Espirito Santo. In these rocks are found the chief occurrences of iron ore, gold, and manganese.

A large part of the Brazilian and Guiana highlands consists of tabular landforms. Here the Brazilian complex is covered by sedimentary rocks of the Paleozoic Era. The Permian beds of southern Brazil contain seams of low-grade coal and the remains of plants, some of which belong to the *Glossopteris* genus. In some of the Permian formations, also, there are traces of ancient glaciation. When the limestones are exposed, as in the Middle São Francisco Valley, karst landforms (in which the limestone rock forms an irregular topography, honeycombed with sink holes and tunnels) are developed.

Overlying the Paleozoic rocks, especially in São Paulo and the southern states, there are soft, reddish sandstones of Triassic age interbedded with sheets and flows of diabase lava. The diabase is very resistant, and wherever it occurs it holds up prominent cuestas (gently sloping surfaces, terminated on one side by a steep slope) and mesas (flat-topped plateaus), and the rivers are frequently interrupted by falls and rapids.

The great waterfalls (Salto das Sete Quedas, or Guairá Falls) of the Paraná River and the Iguaçu Falls on the Rio Iguaçu are formed where the rivers pour over the edge of the diabase. One of the world's largest lava plateaus, the Paraná Plateau, is located in southern Brazil.

Still more recent rocks of the Cretaceous Period (from 136,000,000 to 65,000,000 years ago) and the Tertiary Period (from 65,000,000 to 2,500,000 years ago) occur along parts of the Brazilian coast, especially in the Northeast. These sedimentary strata create mesa-like forms, called *tabuleiros* (low plateaus), along the coast.

From the vicinity of Salvador a sedimentary basin filled with Tertiary strata extends northward across the Lower São Francisco.

Brazilian and Guiana highlands

The Brazilian and Guiana highlands are made up of an intricate pattern of hilly upland, low mountain, and tabular uplands. Each surface form reflects its underlying geological structure. The hilly upland, associated with Early Precambrian rocks, stands at a general elevation of about 2,600 feet above sea level. The low mountains on the Late Precambrian formations stand about 1,000 feet higher, with a few peaks that are just under 10,000 feet. The highest tabular uplands, such as Monte Roraimã (9,094 feet, or 2,772 metres), are also just under 10,000 feet, but the general elevation of the plateaus is between 3,000 and 4,000 feet.

The remarkable similarity of the landforms of southern Africa and Brazil has frequently been commented upon. The various levels, such as the conspicuous summit level at about 2,600 feet, are the result of successive cycles of

erosion. The oldest cycle, now preserved on a few of the highest summits, was probably developed in the Cretaceous Period—so that these highest surfaces have been exposed to erosion for a very long period of time. As the rock material was stripped off during each cycle of erosion, the land rose higher because of the effect of isostatic compensation (an equilibrium condition in which such elevated masses as continents and mountains are compensated by a mass deficiency in the crust beneath them). Each rise of the land initiated a new cycle, which cut back into the older and higher lands, thus creating a landscape that looks much like a relief model when the layers have been put together but before the edges have been smoothed over.

The Great Escarpment. The eastern margin of the Brazilian Highlands descends abruptly to the sea. In some places the descent is over a series of steps; but in back of Rio de Janeiro, Santos, and Paranaguá, there are places where the descent from about 2,600 feet to sea level is accomplished in one steep slope. Whether there is one slope, or a series of steps, the eastern edge of the highland is sharply marked all the way from Salvador to Pôrto Alegre. This feature is called the Great Escarpment. In back of Santos it was given the name Serra do Mar, although incorrectly described as a mountain (*serra*). According to some, the Great Escarpment is not a fault scarp but rather a monoclinal flexure (a fold in which strata dip in one direction). The same erosion levels that stand at different elevations in the interior are warped down below sea level along the eastern margin of the highlands. From Cabo Frio (Cape Frio) southward the Great Escarpment is unbroken by rivers; but north of Cabo Frio a succession of rivers have cut back across the escarpment, from the Rio Paraíba in the south to the Rio Paraguaçu in the north, west of Salvador. The Rio Doce, which reaches the sea north of Vitória, provides a relatively easy route back into the highlands from the sea.

The coast. Although there is no true coastal plain along the Brazilian coast, there is a zone of varying width in which there are sandbars and lagoons. There are many miles of white, sandy beaches, and many places where there are sand dunes. The largest zone of sandbars and lagoons is in the south, where two large lakes are separated from the ocean by bars—the Lagoa dos Patos and Lagoa Mirim. But the bar and lagoon coast is interrupted in a few places where the rocky slopes of the Great Escarpment plunge directly into the ocean, as they do east of Santos. The coast, 4,603 miles (7,408 kilometres) in length, has several very fine, deep harbours. Most famous are the Baía de Guanabara, on which Rio de Janeiro and Niterói are situated, and the Baía de Todos os Santos (All Saints Bay) on which Salvador is located. But there are also many smaller harbours from São Francisco in the south to São Luís in the north. Especially important among these smaller harbours are Paranaguá, Vitória, Ilhéus, and Recife. The Amazon itself is drowned at its mouth, providing deep water for ocean-going ships as far inland as Manaus, and for ships drawing 14 feet of water as far as Iquitos in eastern Peru.

The three major river systems

Drainage and soils. The Brazilian Highlands are drained by three major river systems. In the north is the great Amazon River, with its succession of great tributaries, such as the Tocantins–Araguaia, the Xingu, the Tapajós, and the Madeira on the southern side, and the Rio Negro on the northern side. The headwaters of the Amazon collect the water from the Andes all the way from Bolivia to Colombia. The Amazon lowland has the peculiarity of being widest along the eastern base of the Andes. It becomes narrower toward the east, until, east of Manaus, only a narrow ribbon of floodplain separates the Guiana Highlands to the north from the Brazilian Highlands to the south. At Óbidos the floodplain is less than a mile wide. The floodplain opens up again as it approaches the Atlantic. The main river, as noted above, is navigable all the way into eastern Peru. But the tributaries are all interrupted by falls and rapids where they descend from the Brazilian Highlands.

The second of the great river systems of Brazil is that of the Paraguay–Paraná–Plata. From southwestern Minas Gerais southward, the highlands are drained into the Paraná. The water that falls at the crest of the Great Escarpment overlooking the Atlantic Ocean in back of Santos flows westward and then southward, eventually reaching the sea through the Río de la Plata, near Buenos Aires. The two southernmost states are drained through the Uruguay River (Portuguese Rio Uruguai; Spanish Río Uruguay) also to the Plata. None of these rivers in Brazil is navigable except for short stretches.

The third of Brazil's great river systems is that of the São Francisco River, the largest river wholly within Brazil and a river for which many Brazilians have an almost mystical feeling. The São Francisco, like the Paraná and the Tocantins, rises in the Brazilian Highlands in western Minas Gerais and southern Goiás, inland from Rio de Janeiro. A place on the high country, about 4,000 feet above sea level, where the three great rivers have their origin, was selected as the site for Brasília, the new capital. The São Francisco flows for over 1,000 miles northward into the state of Bahia and the border of Pernambuco before it turns eastward to the ocean. The great river is navigable for shallow-draft riverboats between Pirapora in Minas Gerais north of Belo Horizonte and Juàzeiro in Bahia. Below Juàzeiro the river current becomes swifter as it approaches the Cachoeira de Paulo Afonso (Waterfalls of Paulo Afonso), 279 feet high, where the water plunges into a deep trench. Only the last 172 miles of the lower river are navigable for ocean ships. The Brazilian government has built a hydroelectric plant at Paulo Afonso.

The smaller rivers

There are also a number of smaller rivers that drain more directly to the Atlantic, and, because they pass through the most densely populated part of Brazil, they are of great importance. In the state of Piauí, the Rio Parnaíba flows northward to the ocean and is navigable for hundreds of miles for river barges. South of the Rio Paraguaçu, which drains into the Baía de Todos os Santos, there are several short streams descending from the Serra do Espinhaço across the Great Escarpment to the coast. Among these are the Rio de Contas, the Rio Jequitinhonha and the Rio Doce—the latter by far the most important. The Rio Paraíba rises in São Paulo state and starts flowing toward the west. A little east of São Paulo city the river turns completely around and flows eastward parallel to the coast. In its middle course it meanders across a wide floodplain used now for the production of rice. It then plunges on eastward through a narrow gorge, finally to emerge on its delta near Campos. The headwaters of the Rio Paraíba, which flow toward the west, were formerly a part of the Rio Tietê, a tributary of the Paraná, but were captured by the Paraíba. In the far south, in the state of Rio Grande do Sul, the Rio Jacuí drains eastward past Pôrto Alegre into the Lagoa dos Patos (Lagoon of Patos). The water of both Lagoa Mirim and Lagoa dos Patos enters the sea through an opening in the bar near the port of Rio Grande do Sul. The Jacuí together with the Lagoa dos Patos is the inland river system of Brazil that carries the largest tonnage of goods, partly because of coal shipments to Pôrto Alegre.

The soil of Brazil's southern plateau is famous as a producer of coffee; known as *terra roxa*, because of its dark-purple colour, it results from the weathering of the plateau's diabase. The northeastern coastal strip is characterized by a rich clay soil, but in the immediate hinterland the soil is poor.

Climate. The climate of Brazil contains no extremes of temperature or rainfall. Contrary to popular opinion, the temperatures of the equatorial regions are not excessively high. The average annual temperatures in the Amazon Basin are between 77° and 79° F (25° and 26° C), with ranges between warmest and coldest months of about 4.7° F (2.6° C). Temperatures as high as 100° F (about 38° C) have never been experienced in the Amazon, nor are there temperatures below 50° F (10° C). In the Northeast of Brazil temperatures of more than 100° do occur during the dry season each year, but this is the hottest part of the country. At Rio de Janeiro the average temperature of the warmest month is 80° F (27° C). The average of the coldest month in Rio de Janeiro is about

71° F (22° C). The temperatures on the highlands are several degrees lower than those of the coast, with frosts occurring every winter as far as the southern border of São Paulo state. Frosts also occur at sea level in southern Rio Grande do Sul.

Rainfall patterns

Most of Brazil receives moderate rainfall. Very heavy rains are received in the Upper Amazon and near its mouth; and along the sea-facing slope of the Great Escarpment in São Paulo state. Moisture deficiency is encountered in the Northeast, and in this region there is a record of recurring droughts that cause great distress for the inhabitants. Over most of Brazil the rainfall is between 40 and 60 inches (1,000 to 1,500 millimetres). In the Amazon the rainy season is from January to June, but there is also rainfall during the rest of the year. In most of the country the rains come in summer (*verão*) from December to April, and the winters (*inverno*) are dry.

Vegetation and animal life. *Vegetation.* The various conditions of the climate together with those of soil and drainage are reflected in the cover of vegetation. Seven major kinds of vegetation are found in Brazil. In the Amazon Basin and in those places along the Atlantic coast where the rainfall is very heavy, there is a tropical rain forest, or *selva*, composed of broadleaf evergreen trees growing luxuriantly. The *selva* is made up of a great many different species—as many as 3,000 in a square mile. The trees have tall, straight trunks, and the branches are interlaced overhead, with foliage so thick that little light reaches the ground below. The soil under the *selva* is deeply leached, and when the forest is cleared the land quickly loses its capacity to produce shallow-rooted crops.

Where the rainfall is slightly less and the dry season is really dry, there is a semideciduous forest, composed of broadleaf trees most of which are evergreen but a few of which lose their leaves in the dry season. The trees are smaller than in the *selva*, and the land is easier to clear. This type of forest extends in a narrow band from near Natal southward to Pôrto Alegre. It covers a wide area in southern Minas Gerais and in São Paulo state. This kind of land supported Brazilian agriculture during the 400 years of Portuguese settlement, but because of the lack of soil conservation techniques it is now largely destroyed.

In the dry area of the Northeast, inland from the semideciduous forest, there is a scrubby thorn woodland, or *caatinga*, consisting of gnarled low broadleaf trees that lose their leaves in the dry periods. The land is of little value except for the grazing of goats.

The *campo cerrado*

The greater part of the interior of Brazil, south of the forest of the Amazon Basin and west of the semideciduous forest, is covered with a woodland savanna known as *campo cerrado*. This is a mixture of scrubby deciduous woodland and savanna (grassy parkland). There are patches of pure savanna (*campo limpo*), probably produced by repeated burning of the grass, and patches of uninterrupted woodland (*cerradão*). Where rivers have cut back into the upland surface, the valleys are often covered with semideciduous forest. Without fertilizers, attempts to use the *campo cerrado* for the growing of crops have not been successful, nor is this vegetation good for cattle grazing. The soils are very poor, and the grass is lacking in essential minerals.

In the floodplain of the Upper Paraguay River, the area that is covered annually with floodwaters is covered with a mixture of wet savanna and palms—known as *pantanal*. In the dry season the savanna can be used for the grazing of cattle.

In the southern part of Brazil two vegetation types reflect the recurrence of frosts. Where the land is covered with grass, the *campo cerrado* gives way to a tall-grass prairie with little clumps of trees on the hillsides where water emerges in springs at the valley heads. These open prairies extend southward from the vicinity of Sorocaba in São Paulo state through Rio Grande do Sul into Uruguay. These prairies have long been used by the Portuguese for pasture land. There has been some effort to use these lands for wheat, but with uncertain results.

Where the land is covered with forest, recurring frosts limit the southward extension of the semideciduous forest. This tropical type of forest is replaced by an *Araucaria*, or Paraná-pine, forest, consisting of evergreen needle-leaved trees, which are taller and thus form an "upper story," and broadleaf deciduous trees, which do not grow so high and form a "lower story"; among the lower trees is the tree (*Ilex paraguariensis*) that is used to produce Paraguay tea known as maté. The Paraná pine is not a producer of high-grade lumber, but the better stands are used for this purpose. A paper mill makes use of this pine in the state of Santa Catarina.

The part of Brazil that has been used most completely for agriculture is the semideciduous forest, and this forest, also, has furnished most of the cabinet woods for which Brazil is famous. A serious problem has arisen as this forest has been largely destroyed, partly through burning to clear the land and partly through charring wood for charcoal, which is used both for cooking throughout Brazil and in some of the steel plants for fuel. It is uncertain whether any of the other kinds of land in Brazil can be developed for agriculture. Many Brazilian political leaders are urging the advance of farmers onto the *campo cerrado*.

Animal life. Brazil has no large game animals of the type found in the savannas and forests of Africa. Several species of the cat family (including the jaguar) are found, as well as sloths, anteaters, tapir, and armadillos. Among the members of the monkey family in Brazil, about 50 species of broad-nosed monkeys are found in the Amazon region. There is also a large variety of snakes and rodents. Many kinds of birds are to be seen, a large number of which are multicoloured; there are several kinds of parrot. In the waters of the Amazon River, the manatee (an aquatic mammal) is encountered; there are many kinds of river fish. Gigantic leeches also occur, and there is a great variety of insects.

THE LANDSCAPE UNDER HUMAN SETTLEMENT

The six major regions

The vast national territory of Brazil may be divided into six major regions. These are the North, the Northeast, the Southeast, São Paulo, the South, and the Central-West. While these regions are shown on the map as states or groups of states, in most cases the more accurate construction of regional boundaries would cut across state territories, but for census purposes whole states are placed in one or another region.

The North. The largest of Brazil's regions includes the world's most extensive area of tropical rain forest, or *selva*, and the central part of the Amazon Basin. There are low-lying alluvial lands around the embayed mouth of the great river and in a narrow ribbon along the floodplain. But most of the surface of the North consists of low plateaus, or low, rolling hills. Very little of the area is subject to floods, for the floodplain of the Amazon in the vicinity of Óbidos is scarcely a mile wide, and the tributary rivers occupy narrow valleys and descend to the main stream over falls and rapids. The rain forest, consisting of enormous trees with boughs interlaced overhead and with little undergrowth, covers most of the North. The dense tangle of vegetation, sometimes described as "steaming jungle," exists only in old clearings or along the river banks. The soil, except on the floodplains, has been so deeply leached during long exposure to heavy rainfall that it has little sustained fertility for shallow-rooted crops.

Developmental problems of the North

The main problem in the economic development of the North is the lack of inhabitants. A million rice-growing farmers working the floodplain as is done in East Asia might make this region highly productive; but the few thousand Brazilians and foreign immigrants, limiting their agriculture to the high ground away from the river where soils are poor, are lost in the great forest. At one time this was the world's only source of natural rubber. Rubber workers went along the rivers and into the forest to look for rubber trees growing wild. The rubber boom ended in 1910, when rubber was produced more cheaply on plantations in Southeast Asia. Attempts by the Ford industries to plant rubber in the Amazon failed not be-

cause of climate or health or agronomical problems but because there were not enough workers in the whole basin to clear land and plant enough trees. In the late 1950s there was a new speculative boom of planting along the Lower Amazon where Japanese settlers were raising jute and black pepper. The manganese deposits in Amapá were being rapidly developed. But most of the region remained unexploited. A new pioneer zone was appearing in the early 1970s along an east–west highway being built westward from Belém.

The Northeast. There are two contrasted parts of the Northeast. Along the east coast there is a belt of dependable rainfall, supporting a strip of forest running northward from Bahia as far as Natal. The rest of the region is one of recurring calamities of flood or drought, which, in this densely populated area, cause widespread suffering. The rainy belt was originally occupied by a semideciduous tropical forest not so dense as the *selva*. Most of this forest has been cleared away for crops or pastures. The other part of the region is covered with a thorny deciduous scrub woodland known as *caatinga*. The western part of Maranhão is covered with *selva* and resembles the North; and the southern part of Bahia, south of Salvador, resembles the Southeast. Bahia and Sergipe have been included in the Northeast, being typical of this region; only the southern part of Bahia really fits the geographical characteristics of the Southeast.

The sugar-growing tradition

The Northeast was the first part of Brazil to achieve great wealth. In the 16th century the Portuguese established the world's first large-scale sugarcane plantations with imported African slave labour in the forested areas of Pernambuco and Bahia. This part of the Northeast still produces sugar, largely, but not exclusively, for the Brazilian domestic market. In Rio Grande do Norte large areas are used to grow cotton. The chief profits are made from the sale of cottonseed cake to the cattlemen. In the State of Paraíba there is a boom area of sisal planting; and in Pernambuco there are coffee plantations. In the State of Bahia, west of the sugarcane plantations, there is a tobacco-growing area. The greater part of the Northeast, however, is used for a shifting cultivation of food crops and for the pasture of animals. Cattle can only be raised where the rainfall is adequate; the dry interior is mostly used for goats. In Maranhão there is an area where the babassu palm (a source of oil) grows wild; and Ceará is the world's chief source of carnauba wax, derived from the leaves of a palm.

Politically, the states of the Northeast often cooperate to decide national issues in their favour. The region has a sense of unity, based on long history and cultural tradition, far stronger than any other Brazilian region.

The Southeast. This is a region of complex terrain. Immediately in back of the swampy lowlands along the coast, the Great Escarpment rises like a wall, breached in only a few places by rivers. From the top of the Great Escarpment, 2,600 to 2,800 feet above sea level, the land rises in a series of steps to the top of the Serra do Espinhaço, between 6,000 and 6,500 feet above sea level. Most of the Southeast receives abundant rainfall, but toward the interior the rains are concentrated in a rainy season from October to April. The slopes of the Great Escarpment and the uplands to the east of the Serra do Espinhaço were originally covered with a tropical semideciduous forest, most of which has now been cleared. Western Minas Gerais is within the area of the *campo cerrado* characteristic of the Central-West.

Settlement of the Southeast

The settlement of the Southeast took place largely between 1700 and 1800. Gold was discovered in the stream gravels in 1698 and diamonds soon after. Rio de Janeiro was selected as the outlet of the mining region and made its start as a great city when a road was built to Ouro Prêto in 1701. But gold mining declined about 1800, and the 19th century was one of decline. Sugarcane and coffee were planted and remained productive for a time. The major use of the land in this region remains the grazing of cattle on planted pastures. The shifting of the cultivation of such food crops (maize [corn], rice, beans) to ever-changing areas has resulted in the widespread destruction of the forest. In the 20th century the Southeast has again become an important mining region. Now iron and manganese are of major significance. Iron ore is mined at Lafaiete for use in the steel plant at Volta Redonda in the Paraíba Valley. Other ore bodies are used to supply the large charcoal-burning steel plants in and around the Serra do Espinhaço. Just north of Vitória is a new port for the shipment of iron ore, chiefly to Japan. Manganese and limestone are also supplied from this region; and other minerals include semiprecious stones, industrial diamonds, and quartz crystals. Rio de Janeiro is second only to São Paulo in manufacturing industry, and in southern Minas Gerais and Rio de Janeiro states there are many industrial towns, such as Juiz de Fora.

São Paulo. Although administratively a part of the Southeast, São Paulo is identified as a separate region because of its outstanding economic development. It was formerly classified as part of the South, to which it bears many physiographic similarities. Immediately in back of Santos the Great Escarpment stands like a wall, rising to 2,600 feet. Transportation up or down this steep slope has always been a problem. In 1867 a British company completed a cable railroad to connect São Paulo with its port, and until 1946 this railroad had a monopoly of all shipments in or out. In the 1950s a four-lane highway was built for motor vehicles. The escarpment, too, is used for Latin America's largest single hydroelectric installation at Cubatão. The greater part of the interior of the state is a hilly upland, covered with semideciduous forest or woodland savanna.

During the gold period of the 18th century, São Paulo was a frontier. The cities of Sorocaba and Campinas were on the margin between settled country and the wilderness. São Paulo as a geographical region was created during the coffee period from 1850 to 1930. The rise of São Paulo city as an industrial centre came after 1930, and only in 1954, at its 400th anniversary, did São Paulo declare itself larger than Rio de Janeiro. Coffee is produced in the interior and also sugarcane, cotton, oranges, and cattle. São Paulo leads Brazil in the production of almost everything except cacao (from Bahia), tobacco (from Bahia and Rio Grande do Sul), and minerals.

The South. The surface features of this region in many ways resemble those of São Paulo. The Great Escarpment continues southward as far as Pôrto Alegre. Along the southern border of São Paulo is the northern limit of occasional winter frosts, marking the southern limit of such tropical products as coffee. The forest in the South consists of a mixture of pine and deciduous broadleaf trees; but a large part of the area, especially of Rio Grande do Sul, is a tall-grass prairie.

The Portuguese gave scant attention to this part of Brazil. Finding no source of wealth in the forested areas, they left this part of the South to the Indians. They settled on the prairies and raised cattle and mules to supply the miners of the Southeast. Starting in 1822 in Rio Grande do Sul and in 1850 in Santa Catarina, German colonists were settled in the previously unoccupied forests. Later came colonists from Italy, Poland, and other European countries. The South is today very largely populated by the descendants of these European colonists. Lacking the speculative profits from sugarcane or coffee, the South has developed a less spectacular kind of agricultural economy, producing pork and lard, rice, cattle and sheep, and manufactured products based on these raw materials. Rio Grande do Sul supplies a quarter of the rice needed in São Paulo and the Southeast and a large part of the *carne seca*, or "dried beef." From the Paraná pine forests come timber, charcoal, and *yerba maté* (or Paraguay tea). The Italian settlements in Rio Grande do Sul produce most of Brazil's wines. And in both Santa Catarina and Rio Grande do Sul there are coal mines. Pôrto Alegre is a rapidly growing industrial city.

Colonization of the South

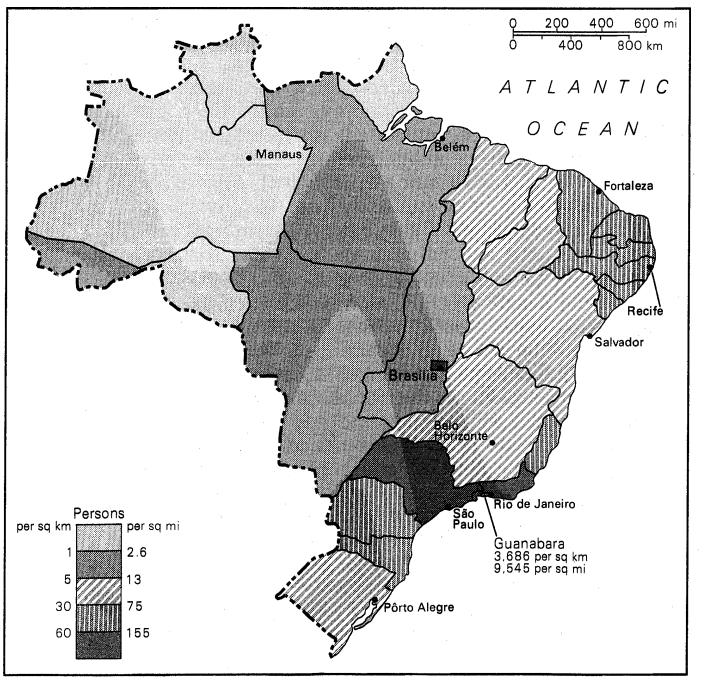
The Central-West. This region includes a vast area of the Planalto Central, or Central Plateau, an old erosion surface standing now about 3,300 feet above sea level. Into this old erosion surface the numerous streams are in the process of extending their valleys. Where the valleys have been cut into the high surface, the land is hilly and the streams torrential; but the high country along the

drainage divides is conspicuously level. The old erosion surface has probably been exposed to the work of the weather since the Cretaceous Period, during which time the soils have been deeply leached. The undissected part of this surface is covered with a woodland savanna, or *campo cerrado;* however, where the stream valleys have been cut below this surface, the valleys are filled with semideciduous forest. The annual rainfall is about 40 inches but is concentrated in the rainy season from October to April. In the dry season the woodlands lose most of their leaves, and the savanna grasses turn brown.

Although the Central-West has been crossed over in search for gold or other sources of wealth, it has been settled only in a few places, these mostly in the patches of forest. The campo cerrado has never been easily occupied by farmers or cattlemen. (P.E.J.)

People and population

Brazil has the largest population of any Latin American state. It equals the combined population of the three most populous Latin American states after Brazil—Mexico, Argentina, and Colombia—and is equal to half of the entire population of South America. Though it has increased very rapidly (10,000,000 inhabitants in 1872, 42,000,000 in 1940, 99,000,000 in 1972), its mean density remains low, amounting to 30 inhabitants per square mile (12 inhabitants to a square kilometre). It is, moreover, spread very unequally over the territory. In contrast to the vast emptiness of the interior, there are great concentrations of people on the Atlantic coast. Formed by numerous ethnic groups which are diverse, unequal, and often antagonistic, it has however given birth to a homogeneous community, thanks to the intermingling over a long period of Amerindian, white, and black, and thanks to the almost general adoption of the Portuguese language and of the Catholic religion.



Population density of Brazil.

GROUPS HISTORICALLY ASSOCIATED WITH THE CONTEMPORARY COUNTRY

The indigenous peoples. When, after the discovery of Brazil by the 16th-century navigator Pedro Álvares Cabral, the Portuguese penetrated into the country, they did not find there the elaborate Indian civilizations that the Spaniards found in Mexico or in the Andes. With the exception of some more developed tribes—settled along the Lower Amazon and on the Ilha de Marajó—they found there were only nomads, who were numerically less important and widely scattered. These tribes practiced food gathering, hunting, fishing, and, as they moved around, cultivated manioc and sweet potatoes on patches of ground cleared by burning. The most numerous of these tribes belonged to the Tupí–Guaraní groups.

As long as the Portuguese limited their activities to barter, their relationship with the Indians remained peaceful. But it changed quickly the moment the colonizers decided to use the indigenous population either as soldiers in battles against their French and Dutch competitors or as manual workers—first for the exploitation of Brazilwood and afterward for the cultivation of cane sugar. Incapable of submitting to the economic and social constraints of the plantation system, the Indians died or fled. They buried themselves in the interior and took refuge in the most distant and inaccessible areas—in the forest regions between the rivers of the Amazon Basin or in the savannas of the Mato Grosso. They did not, however, find themselves completely sheltered there, for, from the 16th to the 18th century, the Portuguese organized to hunt down Indians. The first form of penetration toward the west and the north were the *bandeiras* ("raids"), launched from São Paulo or the northeastern towns, to seize manual workers. These raids contributed to the decimation of the Indian tribes, either by the massacres which were entailed, or by simple contact between white and Indian, since the Indians were very sensitive to European diseases (influenza, measles, smallpox) and had little resistance to alcohol. On the whole and although there are no precise data available about the Indian population either at the time of the conquest or even at the present time, one can nevertheless affirm that Portuguese colonization resulted in the disappearance of certain Indian groups, and in the general diminution in their numbers, which dropped from some millions in the 16th century to approximately 200,000 today.

The flight to the interior

The black slaves. In face of the partial failure of the attempts to enslave the Indians and because of the increasing need for slaves due to the exploitation of the coastal areas in the Northeast, the Portuguese turned, as early as 1538, toward new sources of manual labour. The slave trade, between the 16th and the 19th century, brought 3,000,000 to 4,000,000 African Negroes to Brazil, chained in the holds of the caravels. Their origin and their destination varied according to the time. The principal groups imported came from West Africa (Dahomeyans and Yorubas) and from Angola. It was often a question of poor peasants selling themselves voluntarily in times of famine; others were captured by trick or violence. But Brazil also received small but complete Negro communities, sold as prisoners of war by victorious native chiefs. Unlike the Indians, the Africans gave good results as labourers. Most who worked on the plantations or in the sugar mills, notably those from Angola and elsewhere, were good farmers; others were employed in domestic service. Some, however, refused to be confined by the large plantation system and fled into the interior. These *quilombolas*, or "fugitive Negroes," taught the Indians their agricultural technique.

Historic distribution of the Negro population

During the 16th and 17th centuries, the main body of Negroes went to the Northeast, from Bahia to Maranhão, and were employed in the sugarcane plantations. Then, from the 18th century onward, when the mining of gold and diamonds began, Minas Gerais became the principal area of attraction. After the abolition of slavery in 1888, many Negroes left the regions where they had worked as slaves, either for other agricultural regions—such as the cocoa region of Bahia—or, more frequently, for the towns. Finally, the black population became scattered to all parts of Brazil, although its status remained very unequal.

The Europeans. White, and European, elements constitute the majority of the Brazilian population. These elements resulted from the steady influx of the Portuguese to all regions. For three centuries Lusitanian (*i.e.*, Portuguese) immigrants were practically the only Europeans to enter Brazil, and no limitation has ever been placed on their coming. They quickly became attached to this tropical land, they were found in all classes of society, and they were anxious to obtain wealth quickly in the

plantations or in commerce. They largely contributed to the creation of the Brazilian community, of which they form the root and foundation.

It was only after the proclamation of independence in 1822 that immigrants of diverse origins were added to the Portuguese. The immigrant influx grew, little by little, reaching a peak at the end of the 19th century (1,200,000 people entered the country between 1890 and 1900), after which the flow varied, according to the international situation, dropping to its lowest level in the years 1940–45. Since the end of World War II, Brazil only received a few tens of thousands of immigrants each year. In all, one may estimate at 4,000,000 the number of persons who, since the beginning of the 19th century, have definitively settled in Brazil. The Portuguese always formed the majority of these arrivals. But they were followed by the Italians, particularly numerous in the State of São Paulo where they represented a third of all immigrants, and where the coffee planters employed them as agricultural workers. Other Italians became small landowners in the Rio Grande do Sul or shopkeepers in the southern towns. The Germans were asked by the Brazilian authorities to pacify, populate, and farm the southern states. They have cleared and developed the plateaus of Santa Catarina and of Rio Grande do Sul, where they are grouped into "colonies" of small landowners. They have also contributed to the development of commercial and industrial activities at Pôrto Alegre. Among other immigrants, mention must also be made of Syrians and Lebanese, who specialized in commercial activities; Asians (Japanese), who entered the State of São Paulo and the north of Paraná mainly between 1928 and 1935; and eastern Europeans.

The contemporary ethnic mix. The different ethnic groups have progressively melded together, thanks to a repeated intermixing over a long period. At a very early stage the Portuguese mixed with the Indians, as well as with the Africans. Ethnic elements that have remained unmixed are rare today. On the contrary, all kinds of categories are represented, and the Brazilian population offers an infinity of shadings. The official statistics, which report 62 percent white, 27 percent of mixed origin, and 11 percent black, therefore have little significance. In the first place, the estimate is subjective: in a predominantly white society, it is normal that, in a census, people should have a tendency to declare themselves white; in the second place, the terminology covers extremely varied realities—thus the same term, mixed blood, designates an Indian of mixed blood in Amazonas, while it would mean a mulatto in Bahia.

It is more important to note the unequal distribution of ethnic groups according to regions, and the fact that the Brazilian population is becoming progressively white. The blacks are more numerous in the states of Bahia, Rio de Janeiro, Maranhão, and Minas Gerais. They form, in certain sectors of these states, more than half the total population. The south, on the contrary, which has acquired almost all recent immigrants, is predominantly white (85 percent), and few blacks are seen outside the towns. The areas controlled by Indians are always restricted to the most remote parts of Amazonas.

Because of the progressive disappearance of the Indians and the reduction in the black population, the Brazilian population, as mentioned, is becoming increasingly white. Most blacks belong to the less favoured sectors of society, and their conditions of life are inferior to those of the whites. Mortality, and especially infant mortality, therefore strikes them harder. Thus the "whitening" process, begun by the mixing of blood and accentuated by immigration, is continued by the demographic process, linked with economic and social structures.

The influence of language and religion on the population

The Brazilian population has succeeded in preserving its unity in spite of the heterogeneity of the elements which constitute it. This result has been achieved by imposing the Portuguese language and the Catholic religion on Brazilian society. With the exception of some Indian tribes and a few groups of immigrants, the great majority of Brazilians understand and speak a Portuguese that has been somewhat transformed and enriched, notably under African influences. In the same way, more than nine out of ten Brazilians profess the Roman Catholic religion; this makes Brazil the largest Catholic nation in the world. Catholicism ceased to be the official religion after the proclamation of the republic in 1889, and since then the close links which existed between church and state have been loosened. But the predominance of Latins among the immigrants of the 19th and 20th centuries has allowed the supremacy of the Catholic religion to be maintained.

Religious cults

Neither the Indians nor the Africans, however, have completely abandoned their worships and their beliefs, although evangelization of the former has been attempted, and baptism has been imposed on the latter. Thus the Yorubas have preserved their ancestral religion; the Dahomeyan cult of Voodoo has survived; fetish societies remained. A mixture of the gods of Europe, Africa, and America, moreover, has given birth to "strange cults, with crucifix and Latin words, with drums and Bantu chants, with totems and Indian dancers." In their turn, the immigrants have brought new religions: German and Anglo-Saxon Protestantism, East European Catholic Orthodoxy, the Maronite Catholicism of the Syrians, the Buddhism and Shintō of the Japanese, and Islām. These only concern small groups, however, mainly in the towns. The Protestant minorities, which, it must be stressed, are growing, and the Spiritualists (as the adherents of the "strange cults" are called) together make up more than 1,000,000 members.

Finally, by the early 1970s, the assimilation of the different groups seemed to have been achieved. The Germans and the Japanese who had, up to World War II, resisted integration, no longer pose a separatist problem, since the laws of 1934 have limited their entrance, and the government has made great efforts to spread the Brazilian language in their communities. The most serious question remains that of the integration of the American Indians. Neither the efforts of the Jesuits, undertaken since the beginning of colonization, nor the action of the Service for the Protection of the Indians, established in 1911, have succeeded in integrating this group into the Brazilian community. Some tribes, certainly, are more or less integrated. But others continue to live away from the population centres, and on the edge of a contemporary civilization from which they expect nothing, except to have to flee before the advance of pioneers or of a new road through the Amazonian forest.

DEMOGRAPHIC TRENDS

The present Brazilian population is characterized by rapid growth, by its youth, by diverse distribution, and by mobility. The strong and continued increase in the number of Brazilians has tended to accelerate since the 1950s. Within a century, the population has multiplied by ten. After the first census, the population doubled within 33 years (1872–1905); it doubled a second time, again in 33 years (1905–38), and doubled once more in 27 years (1938–65). The natural high rate of increase—about 3 percent a year—shows this demographic evolution. The birth rate remains at a high level (about 38 per thousand), and no widespread action to lower it has been undertaken. In consequence about 3,000,000 children arrive annually to increase the Brazilian population—in spite of the persistence of a high rate of infant mortality. The death rate, on the other hand, has been progressively reduced in the course of the last few years, without, however, being as low as the level in Mexico, Argentina, or Venezuela. As further progress is still possible in this domain, the rapid increase of population in Brazil can only be accentuated in the years to come.

Appreciable differences exist between the demographic patterns prevailing in town and countryside, but the fundamental contrast lies between the already industrialized South and the still underdeveloped Northeast. The highest birth rates and consequently the most rapid rate of increase correspond with the poorest regions. In these same regions, the infant mortality rate is also the highest: that of Recife, for example, is triple that of São Paulo.

The youthfulness of the population results directly in a high birth rate. A breakdown of the population into age groups shows that more than half of it is under 20 years of age, while only 5 percent is aged 60 or more. Youth, as a whole, represents an important asset for the future of Brazil. But, for the present, the immediate result is to increase the proportion, already excessive, of those who do not work, thus imposing heavy charges on the state.

Patterns of settlement

The human distribution over the territory remains extremely irregular and is still strongly marked by the historical conditions under which the land was peopled. The Atlantic states (from Maranhão to Rio Grande do Sul, including the Minas Gerais) were the first to be developed; they only cover 35 percent of the area, but contain 90 percent of the population of Brazil. The interior, on the contrary, not yet developed, only has 10 percent of the population on 65 percent of the area (Amazonas and the Central-West region). The same contrasts are found within individual states. In Pernambuco, as in the other states of the Northeast, a coastal belt to a depth of 60 to 90 miles comprises the sugar plantations of the Mata and the transitional zone of the Agreste and contains four-fifths of the population, while the vast *sertão* ("wasteland") has only a limited and scattered number of people. In Minas Gerais, the districts of the southeast often have more than 20 inhabitants per square mile; those of the Northwest have almost always less than 2 inhabitants to the square mile. Even the State of São Paulo, although relatively densely settled at the time of the expansion of the coffee plantations, has strong concentrations of people next to empty regions. In the Rio Grande do Sul, the southern Campanha—land of the gauchos (cowboys or herdsmen)—has a much lower density of population than that of the cultivated plateaus of the North. Finally, the zone of high density only covers a strip along the Atlantic coast, narrow to the north, wider to the south, together with a few isolated enclaves lost in the middle of the interior desert.

This distribution is not, however, permanently fixed. The movements of men are transforming it, little by little, to the benefit of the regions of the South and the Central-West region. These migrations have resulted from the advance of pioneers in the west of the States of São Paulo, Paraná, and Santa Catarina, and in the south of the states of Mato Grosso and Goiás; other migrations were caused by the creation of the new federal capital of Brasília; and still others by the building of great interior roads. Thus the Central-West region has the strongest percentage of population growth in Brazil: in 30 years, the population of Goiás has grown by more than 300 percent. But it is the South and São Paulo that benefit from the most substantial influxes. It is the richest, the best equipped, the most industrialized, and the most vital region of Brazil; it receives at the same time the greater part of the flow of international immigration, as well as that of domestic immigration. Foreigners, who today constitute only 2 percent of the population of Brazil, represent 7.5 percent of the population of the State of São Paulo. This group is principally composed of Mediterranean elements (Portuguese, Spaniards, Italians, Lebanese) to whom are added Japanese, Americans from the United States, and Germans. The technicians and skilled workers among them now hold a much more important place than they did in the 19th century. The domestic movement of population, however, does not follow the same social pattern, and misery and hunger remain. The domestic migrations are, in effect, motivated primarily by the lowering of rural income, affecting above all the northeastern states and Minas Gerais; they are also due to the persistence of an archaic agrarian structure and to an increase in demographic densities. Bahia and Minas Gerais provide the largest contingents of migrants. Whole families of miserable *sertanejos* ("inhabitants of the wasteland"), and also farmers from the Mata and the Agreste areas, flee towards the towns, the population of which is thus swelled by a mass of unqualified, underemployed people with a very low standard of living. São Paulo, Rio de Janeiro, Brasília, and the pioneer towns receive immigrants from all parts of the country. The other towns attract primarily the rural populations of their regions. But, if in the South the urban industrial jobs justify the rural exodus, in the other parts of the country, urbanization is not accompanied by the emergence of new professional opportunities. In the old littoral capitals of the Northeast, in particular, the population is growing at a high rate, without any relation to urban or regional economic growth. The immigrants only occasionally find work and crowd together in nondescript and pitiable inhabitations similar to those of shantytowns. In 1960, 40 percent of the population of Recife were living in *mocambos* (shanty towns), the poorest of the Brazilian *favelas* ("slums").

Urban growth

Migration is responsible for two-thirds of urban growth. In 1940, the urban population constituted only 30 percent of the total population. In the early 1970s urban population slightly exceeded rural population. Already at this time, Brazil counted 25 municipios of more than 250,000 inhabitants, which constituted more than half of the whole urban population. São Paulo, which had only 31,000 inhabitants in 1872, in the early 1970s had more than 5,000,000. Rio de Janeiro had passed a peak of 4,000,000. In five other towns, the number of inhabitants is around 1,000,000—Belo Horizonte (which had only 13,000 inhabitants in 1900), Recife, Pôrto Alegre, Salvador, and Fortaleza. But apart from these very large cities, and, since 1940, medium and small centres have also shown spectacular increase. These include cities which act as gateways to the *sertão*, like Campina Grande; crossroads cities such as Governador Valadares; pioneer cities like Londrina; or cities situated in the middle of rich agricultural zones, like Presidente Prudente; industrial cities like Santo André, São Bernardo do Campo, São José dos Campos, or Campinas; and, lastly, tourist cities, like Petrópolis.

A strong movement, therefore, carries Brazilians toward the cities and accelerates the mixing process, placing regional groups, which for a long time have not known each other, in contact again. It also induces—notably among the poorest people—a consciousness of regional economic imbalances and of excessive social inequalities.

If the present rate of growth continues—and there appears to be no prospect of it slackening—Brazil, in the year 2000, will have more than 200,000,000 inhabitants. It will by then have become one of the great demographic world powers. Will this growth be accompanied by a territorial redistribution ending in a more harmonious and more balanced reapportionment? Will it be accompanied by an economic development sufficiently wide and sufficiently speedy, not only to give work to all new citizens, but also to ameliorate the standard of living of the whole community? Such are the two fundamental questions which emerge from the examination of the present demographic situation. Brazil has succeeded in giving to racial, linguistic, and religious groups, differing greatly from each other, the consciousness of belonging to the same nation. The nation is now left with the task of removing the spatial and social imbalances and of harmonizing demographic as well as economic growth.

(M.Mi.)

The national economy

A COMPARATIVE VIEW OF THE COUNTRY'S REGIONAL AND WORLDWIDE STANDING

The sheer extent of Brazil's primary resources places its economy, despite its lack of development, among the world's leading producers of a number of important commodities. In 1970, for example, it was the world's leading producer of coffee, edible beans, corn (maize), and bananas; third in cocoa, tobacco, cattle, asbestos, and manganese; and fourth in cotton and sugar. It is the largest rice producer outside Asia. It is also important for what it has not yet fully exploited—about one-half of the world's total high-grade iron-ore deposits, its vast hydroelectric potential, its hardwood forests, and some 2,100,000,000 acres (850,000,000 hectares) of soil, most of which could be fertile given adequate water and fertilizer. As its manufacturing sector develops, Brazil is also taking a significant place among the world's industrial producers. It is the leading manufacturer of vehicles, merchant vessels, crude steel, and cement in Latin America, and the city of São Paulo is the largest industrial centre in the region.

Economic growth

Mainly as the result of industrial development, Brazil's economy recorded real growth of around 9 percent in both 1969 and 1970, which placed it among the fastest expanding economies in the world. Gross domestic product (GDP) per head in São Paulo, where most industry is concentrated, reached some U.S. $550 in 1970—about the overall average for Latin America, and a figure typical of intermediate economies. The national average was, however, U.S. $385 because large areas of the country are developing at a much slower rate from a much less developed base. GDP per head in the Northeast, for example, was around U.S. $180 in 1970—comparable to South and Southeast Asian levels.

The Brazilian economy is also renowned for a negative achievement—a phenomenal rate of inflation, which accelerated to an annual rate more than 100 percent in 1964, but which had been brought down to a near-acceptable level of 25 percent by the end of the 1960s.

THE EXTENT AND DISTRIBUTION OF RESOURCES

Mineral resources. Brazil is known to possess extremely rich mineral deposits, although the country's resources have yet to be comprehensively surveyed. The country's known iron-ore reserves, at 40,000,000,000 tons, are second only to those of the Soviet Union: around 30,000,000,000 tons, three-quarters of these reserves, are located in what is known as the Iron Quadrilateral Zone of Minas Gerais and the remainder in Mato Grosso. Known manganese-ore deposits are estimated at 152,500,000 tons—more than two-thirds in Mato Grosso and the remainder in Amapá and Minas Gerais. Low-quality coal resources of 3,200,000,000 tons are located in Rio Grande do Sul and Santa Catarina, but only about a third of this—found in the latter state—is suitable for processing to produce metallurgical coal for steel manufacture. About 300,000 tons of thorium (a radioactive metallic element), almost a third of the world's known deposits, exist in the form of continental deposits and monazite (phosphate of the cerium metals—the most abundant elements of the rare-earth group—and of thorium) sands. In addition the country is thought to possess substantial reserves of tungsten (an element used for hardening steel), rock crystal, salt, nickel, tin, lead, bauxite, graphite, chrome, steatite (soapstone), zirconium (a strong ductile metallic element with many industrial uses), silver, gold, and diamonds.

Oil and natural gas

Brazil has extensive oil and natural-gas reserves. In 1971 recoverable oil reserves were estimated at 177,900,000 cubic yards (136,000,000 cubic metres), of which 77.2 percent is located in the Recôncavo (Bahia) and 22.8 percent (including 6,500,000 cubic yards from the continental shelf) in the Alagoas–Sergipe area. Natural-gas reserves were estimated at 34,000,000,000 cubic yards in 1971, located mainly in Bahia.

One peculiar feature of Brazil's mineral resources is that they tend to be located far from their internal market. Thus there are no natural-gas deposits in the highly industrialized Southeast, while the coal that could conveniently be used in steel manufacture is located in the South.

Biological resources. Nearly two-thirds of the country is under forest, providing about a tenth of the world's total forest area. Hardwoods predominate in the Amazon and Atlantic coastal zone, and Paraná pine in the South. The timber stand was estimated by the United Nations Food and Agriculture Organization in 1963 at 2,800,000,000,000 cubic feet. Exploitation of the Amazon rain forest, however, has been hampered by the inadequacy of transport facilities and by the large variety of species of vegetation, estimated at an average of 40 per acre (100 per hectare).

At the 1960 census nearly 620,000,000 acres—just under a third of the country's total area—was classified as agricultural. Of this, 11 percent was under permanent or temporary crop cultivation, nearly half was used for livestock production and the rest was forest and waste land. Of the crop area (nearly 75,000,000 acres) 45 percent was in the South and São Paulo together, about 30 percent in the Northeast and about 15 percent in the Southeast, excluding São Paulo.

Livestock

Brazil has one of the largest livestock populations in the world, with about 217,000,000 head recorded in 1970. Cattle numbered 98,000,000 in the same year. Although pure-breed cattle are reared in the temperate regions of the South and Southeast, most cattle are of the zebu (humped Asiatic ox) variety; the Brazilian Highlands—Minas Gerais, Mato Grosso, and Goiás—accounts for almost half of all cattle raised. The rearing of hogs (66,-

000,000 in 1970) is important in Paraná, Minas Gerais, and Rio Grande do Sul, while the latter two states are the most important producers of horses (more than 9,000,000 in 1970), and more than half of all sheep (24,000,000 in 1970) are raised in Rio Grande do Sul.

With a coastline of more than 4,600 miles, Brazil has access to very substantial fishing grounds. Activity is concentrated in the Northeast (Pará and Maranhão) and in the South (Rio Grande do Sul and Santa Catarina), but as yet this resource is underdeveloped. Of about 55,000 fishing boats registered in 1968, only 4,600 were motorized.

Hydroelectric resources. With one of the most extensive river systems in the world and plentiful rainfall in the whole of the country except the Northeast, Brazil is one of the four countries with the largest hydroelectric potential in the world. It is estimated at 150,000,000 kilowatts, although much of this capacity cannot readily be developed because of its remoteness—for example, the 44,000,000 kilowatt estimated capacity for the State of Amazonas. At the beginning of the 1970s, installed generating capacity was concentrated in the Southeast and the South, which consume over three-quarters of all power produced in Brazil.

The 1950s and 1960s saw very rapid expansion in total power capacity, mainly through hydroelectric development; capacity rose from 1,900,000 kilowatts in 1951 to 11,233,000 kilowatts in 1970; about 75 percent is hydroelectric. Government plans called for an increase to 17,300,000 in 1973 and 25,400,000 in 1976. Most of this development will be hydroelectric, as the scope for expansion in thermal capacity is limited by the poor quality of Brazilian coal and the inadequacy of crude-oil supplies to meet refining demand. The country's first nuclear power plant, of 600,000 kilowatts, was planned to begin operations in Rio de Janeiro in the mid-1970s.

SOURCES OF NATIONAL INCOME

Agriculture, forestry, and fishing. Agriculture is the most important single sector of the economy, accounting for about 20 percent of the gross domestic product and 80 percent of exports. It provided employment for some 15,500,000 people in 1960—more than half the active labour force. By the beginning of the 1970s, however, it represented only about 45 percent of the total force. Agriculture, forestry, and fishing have lagged behind the expansion of the rest of the economy. In the decade 1958 to 1967, the gross domestic product rose by 59 percent, while the primary sectors expanded by 49 percent. The increase in agricultural production has in general been the reflection not of greater labour productivity through the use of machinery nor of higher plant yield through improved seeds or fertilizer but of the increase in the area under crops—from 47,000,000 acres (19,000,000 hectares) in 1950 to 75,000,000 acres in 1960 and 89,000,000 acres in 1967. Much of this expansion has been in the states of Maranhão (in the Northeast) and Paraná (in the South), in the form of small farms of under 25 acres, while cultivation on very large farms, of 2,500 acres or over, has taken place in Acre, Rio Banco, and Amapá (in the North).

The agricultural sector

The agricultural sector is still very backward. Despite the high acidity of soils throughout most of Brazil, the country is one of the lowest users of fertilizer per crop acre in the world. Even with a doubling in commercial fertilizer consumption in the 1960s, less than 5 percent of farms use commercial fertilizer. Out of 3,000,000 farms in 1960, only 116,000 used electric power, and over half of these obtained it from their own sources. In the same year, about three-quarters of all farms used only human labour, and less than 1 percent used any mechanized power. Labour productivity is thus very low, and one rural worker is estimated to produce enough for five inhabitants—compared with a 1 to 30 ratio in the United States. The more advanced techniques (fertilizer, power, machinery) tend to be concentrated in one area—the São Paulo–Paraná–Minas Gerais triangle, which provides the bulk of the country's agricultural production. In 1965 the states of São Paulo, Paraná, Santa Catarina, and Rio Grande do Sul accounted for more than half of all the agricultural land, three-quarters of all buildings, and nearly half of all the equipment used in Brazil's farming sector.

Farm sizes also vary widely among the different regions of Brazil. The national average in 1969 was 196 acres (79.4 hectares), but in the three states of the South and São Paulo over half of all farms are single-family units and only 2 percent extensive, whereas in the densely populated Northeast more than half are below the size needed to keep one family fully occupied; in the underdeveloped, sparsely inhabited North, large farms predominate.

Major crops

Coffee is the most important single crop, accounting for over a third of all export earnings in 1970; its cultivation employs about 1,000,000 people. Output has, however, been falling steadily—from 4,400,000 tons in 1959 to 1,510,000 in 1970—largely as the result of government policies encouraging crop diversification; prices paid to coffee producers are held down, and the destruction of plantings subsidized. The area planted to coffee therefore declined from 10,600,000 acres (4,300,000 hectares) in 1959 to 5,900,000 acres in 1970, and the introduction of higher yield strains in the 1960s was insufficient to balance the consequent decline in production.

The next most important agricultural exports, cotton and sugar, have expanded production as the area cultivated approximately doubled between 1950 and 1970, with the area increasing to 10,600,000 and 4,300,000 acres, respectively. Cotton production reached 1,950,000 tons in 1970, compared with 1,400,000 tons in 1959, and sugarcane increased to 79,750,000 tons, from 53,500,000 tons. Sugar has benefitted from the extension of cultivation in the fertile São Paulo area, while planting in the Northeast has declined. The fourth-ranking export crop —cocoa—fell in relative importance in the 1960s, as its output fluctuated around the 160,000-tons-a-year level, to which it was held by low levels of technology and by tree aging. Production of edible beans rose steadily in the same period—from 1,500,000 tons in 1959 to 2,200,000 in 1970—as the area cultivated expanded by about half, to 8,600,000 acres.

Spectacular expansion has been recorded in the production of rice and corn (maize), essentially for the domestic market and achieved mainly through colonization in the states of Mato Grosso and Goiás. Output of rice rose from 4,100,000 tons in 1959 to 7,600,000 tons in 1970, and the area cultivated increased from 6,700,000 to 12,300,000 acres. Corn production rose from 7,800,000 tons in 1959 to 14,200,000 tons in 1970, and the area cultivated expanded from 6,200,000 to 24,300,000 acres. Brazil is nearly self-sufficient in basic foodstuffs; in value terms, rice and corn ranked first and second in the country's agriculture in 1970.

About a third of total agricultural income is derived from livestock, whose contribution to the domestic food supply was expanding appreciably in the early 1970s. Total output rose by about a fifth in the 1960s—the most significant feature being the rapid rise in milk production, from 1,300,000,000 gallons (4,900,000,000 litres) in 1960 to 1,884,000,000 gallons in 1970. But no clear distinction is made between beef and dairy cattle, and the return from beef-cattle raising is poor; the slaughter rate is about 9 percent a year, and carcasses on an average weigh a fifth less than in the United States.

Fish output doubled in the 1960s, reaching almost 530,000 tons in 1970; productivity, however, is low—about one ton per fisherman per year.

Forest resources

Much of the country's forest resources remain untapped, as about 75 percent of them are inaccessible; moreover, only about 75 percent of the accessible area is in commercial production. This sector is, however, an expanding one, with log output of 177,000,000 cubic yards (135,000,000 cubic metres) in 1970, and sawn timber around 1,600,000 tons. While most hardwood is consumed locally, with much being used as fuel, pinewood ranked eighth among all of Brazil's exports in 1970.

With few exceptions, agricultural and forestry production suffers from inadequate capital investment. Savings

tend to be attracted to the higher yields offered by industry, and—in time of inflation—real estate; therefore investment in agriculture has generally taken the form of increasing the area of land under cultivation instead of investing in the technology needed to increase productivity. Farm income cannot expand significantly nor can rural areas provide a wider basis for industrial development until agriculture utilizes improved technology.

Mining and quarrying. Although the country's mineral resources are still largely undeveloped, and mining provided employment for only about 45,000 people (about 2 percent of the labour force) in 1969, mining output more than doubled between 1960 and 1968, as the result of rising demand from domestic industry and a firm export market. Iron ore, mined chiefly in Minas Gerais, is the most important single metallic mineral product; production rose from 9,300,000 tons in 1960 to 32,500,000 in 1971. About 60 percent of output is exported. The second ranking is manganese, output of which rose from 1,000,000 tons in 1960 to 2,000,000 in 1969—more than half for export. About 80 percent of the ore is produced in Amapá. Other minerals produced in significant quantities include bauxite, apatite (a mineral used in the manufacture of phosphate fertilizers), dolomite (used for building stone), lead, magnesite (magnesium carbonate, used in manufacturing), tin, chromite, and asbestos. Production of raw coal rose from 2,300,000 tons in 1960 to 5,200,000 in 1970; the coal, however, is of limited significance because of its poor quality.

Manufacturing. Manufacturing has been the most dynamic sector of the economy since World War II, with an average annual growth of nearly 10 percent in the period from 1947 to 1961; during the same time industrial employment rose by about a quarter. Development took the form primarily of import substitution, which was encouraged by protective tariffs, tax concessions, and a multiple exchange rate that reduced the cost of foreign capital equipment. The 1960s saw widely fluctuating trends: the immediate scope for import substitution was exhausted, the phenomenal rate of inflation discouraged investment in production, and the austerity program of 1964 to 1966 reduced the home market. From 1962 to 1966 output of the manufacturing and mining sectors rose by only 3 percent a year. In the final years of the decade, as domestic demand recovered and export production was stimulated, annual industrial expansion strengthened to about 10 percent, and at the beginning of the 1970s manufacturing was the strongpoint of the economy. In 1970 it was estimated to represent about 25 percent of the country's gross domestic product—just exceeding the contribution of agriculture, forestry, and fishing. It was, however, much less significant as a source of employment, continuing to provide jobs for only about a sixth of the labour force. It also displayed, in the most exaggerated form, the unevenness of distribution characteristic of the Brazilian economy. More than 90 percent of the country's industrial output comes from the São Paulo area, which employs only half the total industrial labour force.

In the 1960s very rapid growth was experienced in four crucial sectors—iron and steel; vehicles; ships; and petroleum products. By the beginning of the 1970s, Brazil was self-sufficient in steel ingots, after output rose from 1,800,000 tons in 1960 to 5,400,000 tons in 1970. In 1967, a total of 131 iron and steel mills were in operation. In the same year, 20 large shipbuilding yards were in production; by the early 1970s, shipbuilding had become an important export industry. The petroleum-refining industry had also expanded rapidly, with output up from 64,000,000 barrels in 1960 to 186,000,000 barrels in 1970. Much more spectacular growth has been recorded by the Brazilian motor-vehicle industry, whose output rose from about 31,000 units in 1957 (its first year of large-scale operation) to nearly 420,000 in 1970, making Brazil the leading vehicle manufacturer in Latin America. Other significant industries are textiles (accounting for nearly a fifth of all employment in manufacturing), tobacco (Brazil is among the top ten cigarette-producers in the world), cement, and chemicals (particularly caustic soda, soda ash, and nitrate and phosphate fertilizer).

The motor vehicle industry

Energy. Total energy production in 1969 was 19,054,000,000 tons (coal equivalent), of which electricity accounted for 40 percent, liquid fuels (domestic and imported) about 21 percent, coal 13 percent, and natural gas nearly 9 percent. While electricity probably maintained this share in the final years of the 1960s, as production rose from 22,900,000,000 kilowatt-hours in 1960 to 45,460,000,000 in 1970, the percentage contribution of domestic petroleum and natural gas also increased. Crude-oil production doubled in the 1960s, to reach about 60,000,000 barrels by 1970—about 40 percent of domestic demand. The demand for natural gas expanded very rapidly in the late 1960s—to 1,653,000,000 cubic yards (1,264,000,000 cubic metres) in 1970, compared with roughly 720,000,000 cubic yards (550,000,000 cubic metres) annually earlier in the decade.

Financial services. The banking and financial structure is based on the banking reform introduced in 1965. The functions of a central bank—the issue of currency and overall control of banking operations—were then vested in the Central Bank of Brazil. The National Monetary Council, a technically independent body headed by the Minister of Finance, formulates the monetary policies to be implemented by the Central Bank, while the Bank of Brazil (which the Central Bank replaced in 1965) is the main instrument of government credit policy. The Bank of Brazil remains by far the largest bank in the country, operating 750 agencies, six of them in other Latin American countries.

Banking institutions

The financial system also includes more than 200 private and state commercial banks, development banks, private investment banks, savings banks, and the National Housing Bank (BNH), as well as specialized operations such as the Industrial Finance Fund, insurance companies, and real estate finance companies. The National Bank for Economic Development (BNDE) channels official funds to development projects (chiefly, utilities, basic industries, and agriculture) in the form of loan guarantees and equity investment. The commercial banks operate mainly in the field of short-term finance, typically (for working capital) in loans of under 90 days. They are not allowed to accept savings accounts and more than 90 percent of deposits are sight. The high rate of inflation in the late 1950s and early 1960s stimulated rapid expansion by the banks, and in the early 1970s the Central Bank was trying to reduce their numbers, mainly through mergers.

In the early 1970s, commercial banking was dominated by the public sector. The federally owned Bank of Brazil and the commercial banks owned by the state accounted for more than half the deposits of the banking system, while long-term financing came from official institutions, especially the BNDE and the BNH, although private investment banks were growing in importance. There were about 30 such banks, chiefly providing medium-term loans (one to two years) at free-market rates and funding their operations by selling acceptances and certificates of deposit on the open market. Among its other roles, the Bank of Brazil acts as an agricultural bank and extends medium- and long-term export credits.

Capital financing institutions in Brazil in the early 1970s were not adequate to meet the economy's medium- and long-term funding requirements, and much long-term investment had to be financed by short-term domestic and foreign borrowing. The government's financial intermediaries (BNDE and BNH) remained the main sources of long-term finance, and private institutions were as yet lesser sources; institutional investors (such as life-insurance companies or pension funds) were of little significance. The private capital market dealt largely in equity shares. There was consequently a critical need for some form of fixed-yield, long-term securities (with correction for inflation) to stimulate the financing of private investment.

The most important of the numerous stock exchanges in Brazil is that of Rio de Janeiro. It expanded rapidly after 1967, and about 100 stocks were actively traded at

the beginning of the 1970s: the average daily volume rose from about U.S. $40,000 in 1967 to U.S. $10,000,000 at the beginning of 1971. Most of the buying was for speculative purposes (capital gains are not taxed), and much of the increase in activity was due to the operations of about 90 mutual funds. Many observers felt that the Brazilian stock exchange as a whole should be more strictly regulated and should have more underwriting support.

Correction for inflation is an important feature of financial life. Since 1964 this has been applied to business assets, government bonds, mortgages, urban rents, and *letras de cambio* (the most common short-term instrument for private finance) to counteract the distorting effects of inflation. Despite the easing in the rate of inflation in the final years of the 1960s, effective interest rates remained high because of the rising demand for credit in a restimulated economy.

Foreign trade. The contribution of exports to the national income is not high—about 10 percent—but is significant in view of the country's need to import capital equipment and raw materials, including crude oil.

Exports

After virtual stagnation in the 1950s, export earnings expanded 116 percent between 1960 and 1970. While coffee remains the major single export, the near-stagnation of its output has resulted in a decline of its relative importance from 56 percent in 1960 to 36 percent in 1970. Other traditional agricultural exports—cotton, cocoa, sugar—have on the whole kept pace with the overall expansion, while sales of iron ore have been extremely buoyant, rising 293 percent in value between 1960 and 1970. The second traditional mineral export, manganese, has declined both absolutely and relatively, to less than 1 percent of all export earnings. But the most significant trend in the 1960s was the very rapid expansion in nontraditional exports. Among agricultural products, meat, which accounted for an insignificant 0.2 percent of exports in 1960, had risen to almost 4 percent in 1970. This trend was even more marked in manufactured goods, which in 1970 ranked second only to coffee. The export recovery dates from the 1964 revolution, when the government adopted export promotion as one of its fundamental policy objectives: it ended the system of license allocation that had favoured the domestic market at the expense of exports; it gave tax incentives to export manufacture; and it established (in 1968) a flexible exchange rate resulting in a continuous devaluation of the cruzeiro. (The new cruzeiro [NCR$], equal to 1,000 old cruzeiros, became the monetary unit in 1967.)

Imports in the 1960s showed similar upward movement, although they fluctuated widely in the mid-1960s as a result of the austerity program introduced in 1964 and of devaluation in 1965. On the whole, however, their growth slightly exceeded the overall growth of national income, since they reflected very closely the pace of industrial development. Thus machinery and vehicles accounted for over a third of all imports in 1970, while crude oil—the most important single import—accounted for 9 percent. At the beginning of the 1970s, foreign trade was approximately in balance, with exports showing more dynamic growth.

The pattern of Brazilian trade underwent significant changes in the decade. While the United States remains by far the most important single market for Brazilian exports, taking 25 percent of all shipments in 1970, it was superseded in that year by the European Economic Community (EEC), which bought 28 percent. Another regional grouping with a strong demand for Brazilian goods is the Latin American Free Trade Area (ALALC); Brazil is a founder member of this group, which came into force in 1961. Brazilian sales within ALALC were U.S. $303,000,000 in 1970, or 11 percent of all exports: they have benefitted particularly from the tariff reductions negotiated in 1968, which affected a large number of relatively sophisticated manufactured goods. On the import side, the United States' position of predominance, maintained throughout the 1960s, was also being challenged by the EEC; their respective shares of imports in 1970 were 32 and 22 percent.

MANAGEMENT OF THE ECONOMY

The private and public sectors and the role of government. A central element in all government policy since 1964 has been the reduction in the role of the government in the national economy; the aim is to achieve this by reversing the trend toward the nationalization of certain industries, by cutting down the budget deficit, and by stimulating the private sector, specifically through providing incentives to investment. Nevertheless, through direct participation in certain sectors and through its own infra-structure investment program, the government's share of total fixed capital formation was expected to match that of the private sector by the beginning of the 1970s.

Development planning

Three agencies coordinate development planning at federal, state, and substate level—the Ministry for Planning and Economic Coordination, the Consultative Council on Planning (CONSPLAN), and the Ministry of the Interior—but their role is seen as supplementary to that of the free market. Thus, while development programs incorporate growth targets for sectors of private industry, it is assumed that these will be achieved as a voluntary response to fiscal incentives offered by the government.

These are offered for four purposes: the establishment and expansion of industries important to national economic development; the development of agriculture, forestry, and fishing; the curbing of inflation; and the stimulation of backward regions (the Northeast, administered by Superintendency for Development of the Northeast [SUDENE], and the North, administered by Superintendency for Development of Amazonia [SUDAM]). The incentives take the form of exemptions from specific taxes (such as import duties and the tax on industrial goods) and rebates on income tax, up to a 50 percent limit, provided the rebate is reinvested in approved projects. Agriculture incentives also take the form of minimum commodity prices, credits, and subsidies for fertilizer use.

There are few restrictions on private enterprise, with the exception of the crude-oil industry. Mining, hydroelectric development, and certain sectors of communications and transport are reserved for Brazilian citizens and companies organized in accordance with Brazilian legislation.

Only one sphere of productive activity is reserved to the government—the prospecting and exploration of oil deposits, the refining of crude-oil and the coastal and pipeline transportation of petroleum and its products by coastal shipping. This monopoly has been operated, since 1953, by Petrobrás—a mixed corporation in which the federal government has a majority holding. Petrobrás also has a monopoly of oil imports; their transportation is carried out by the National Fleet of Petroleum Tankers (FRONAPE), a state company affiliated to Petrobrás. A subsidiary, Petroquisa, may associate with private capital in petrochemical developments.

The government also participates in certain public utilities. The Federal Railway Network, RFFSA, operates 13 of the 25 railway companies active in Brazil, while the Merchant Marine Commission (CMM) is responsible for the supervision of all maritime shipping (and shipbuilding) and of the five government companies operating in this field. The government participates in the electricity-generating industry through Electrobrás, a mixed company set up in 1961. One of the largest enterprises in Latin America, Electrobrás operates about a fifth of the country's capacity through 17 subsidiaries, acts as financing agency for all electric utilities, and is responsible for the planning of national power development.

Taxation. One of the major causes of the economic crisis of 1963 to 1964 was the massive budget deficit, financed by inflationary borrowing from the Bank of Brazil. The government subsequently succeeded in reducing the deficit by holding down the rate of growth in public spending and by a very substantial increase in government revenues.

The present system of taxation was introduced in 1965

The tax structure

and incorporated in the 1967 constitution. The federal government is empowered to decree taxes on imports, exports (when prices rise above 5 percent over a base price set by the Central Bank), rural land, incomes (a withholding tax on salaries was introduced), industrial goods, financial operations, transport and communication services, and the production, import, distribution, and consumption of fuels, lubricants, electricity, and minerals. A proportion of the yield of these taxes is then allocated to the states and municipalities; the states levy taxes on merchandise transactions (rates are set by the federal government) and on the transfer of real estate, and the municipalities tax urban real estate.

The most important indirect taxes are the federal industrial goods tax, which by the early 1970s amounted to about 15 percent of the value added in various stages of production, and the merchandise-transaction tax of the states, varying from 15 to 18 percent of value added. Exemption from a large proportion of these taxes is offered under the government's incentive program for manufactured exports. Direct taxes are levied at the rate of between 3 and 50 percent, on personal income, and 30 percent on company profits; a reduced rate operates for public utilities, certain professional services, and firms adhering to the price-control program.

The total government revenues amount to some 30 percent of GDP—a rate well above that of most developing countries and comparable to that of many advanced industrial nations. Steps were taken at the beginning of the 1970s to reduce the tax burden: the industrial goods tax and the merchandise-transaction tax were both reduced by 0.5 percent each year. Credits against income tax will be allowed for contributions to the literacy campaign. In addition, the Workers Participation Fund, inaugurated in 1971, required companies to direct tax credits (rising from 2 percent in 1971 to 5 percent in 1973) as well as an amount equal to a fixed proportion of gross sales to the Social Integration Program, which aims to redistribute income to wage earners and to channel low-cost credit to small enterprises.

Trade unions and employer associations. In 1969 there were almost 2,000 trade unions registered in Brazil, of which 400 were in the São Paulo area: registered members numbered 1,953,000, of which 1,100,000 were in the manufacturing industry. Labour courts and labour conciliation boards have exclusive jurisdiction over labour disputes. The power of the unions has been greatly reduced since 1964. While the right to strike, except in public services and "essential activities" defined by law, is acknowledged by the constitution, strikes are legal only after they have been approved by a general assembly of the union involved, with at least ten days' notice of the meeting and with at least a two-thirds vote in favour of the strike, taken in a secret ballot. Written notice of the union's demands and of its intention to strike if settlement is not reached within five days must then be given to the employer or employer's association. The five-day period is reduced to three days when the strike is caused by nonpayment of wages or when the employers fail to comply with a labour-court decision.

In 1969 there were almost 1,200 employer associations, of which about 250 were located in São Paulo.

Contemporary economic policies. The revolution of 1964 was economic as well as political. The new regime immediately attacked the runaway inflation by reducing the budget deficit, increasing government tax revenues, and reducing expenditure. In 1966 the real value of government receipts was 60 percent above that of 1963, while the tax burden rose from 18 percent of GNP in 1963 to 30 percent in 1970. Spending restraint mainly took the form of eliminating wheat and petroleum import subsidies, raising railway, shipping and postal rates, and holding down pay increases. At the same time the amortization of the treasury debt, from 1965 on, far exceeded new borrowings by the government, which by the early 1970s had come to rely, for deficit financing, on securities rather than loans from the banking system.

Wage controls

The second major instrument of economic stabilization is the stringent control of wage increases. In 1964 a formula was implemented for increases in the legal minimum wage; a minimum one year period was set between adjustments. In 1970 new minimum wage rates were established for three years, with no adjustment allowed. As a corollary to wage control, the government attempted—not very successfully—to operate price controls by setting maximum prices for certain foodstuffs, and by offering tax incentives to companies to hold down price increases.

The emphasis in the 1964 to 1967 period was on stabilization—at the cost of economic growth, which averaged less than 1 percent a year in this period. Since 1967 the government has pursued a policy of encouraging growth. Export manufacturing has benefitted from tax incentives and from the introduction in 1968 of the system by which the *cruzeiro* is devalued by small amounts (usually 1 to 2 percent) every four to eight weeks. Special incentives have also been given to investment in agriculture and in the backward regions. The development plan for 1969 to 1973 forecast an increase of more than half in the value of tax rebates in the Northeast and of 80 percent in the North. The location of the new capital of Brasília in Goiás, in the Brazilian Highlands, fits in with the continuing policy of integrating backward areas.

One of the government's priority aims has continued to be the improvement of the payments position—first by boosting exports and second by attracting foreign public and private capital (the latter through imposing a minimum of controls). In fact, the capital inflow was the major cause of the rapid rise in the country's reserves at the beginning of the 1970s. Brazil was the largest recipient of new lending commitments by the World Bank. The government intended to convert many of its substantial foreign obligations (which in 1969 were equivalent to about two years' export earnings) to medium- or long-term credits.

At the end of the 1960s there were some signs of a slight modification in government economic policies. The 1969 to 1973 development plan continued the expansionary policies introduced in 1967. The plan specified an increase in the GDP from 7 to 9 percent a year, in investment by 12 percent, in industrial production by 11 percent, and in exports by 10 percent—but more attention is being paid to sectors that are not immediately productive in accounting terms, such as roads, houses, and schools. Promotion policies in the Northeast were being modified in the early 1970s, with the maximum tax rebate on investment in the region being reduced from 50 to 35 percent in 1971; this was because the rebate system had encouraged capital investment at the expense of projects employing many people, which would be of more value in a densely populated area. Work also began in 1970 on the construction of the Transamazônica road which, together with the Cuiabá–Santarém highway, was designed to open up some 23,000 square miles for development. At the same time, the government appeared to have decided to ease the tax burden somewhat.

Problems and prospects. In the early 1970s short-term prospects for the Brazilian economy were extremely good. The country expected a rising inflow of medium- and long-term capital from abroad, reaching around $1,000,000,000 a year in the mid-1970s; reserves were therefore expected to more than double. While import demand would continue high, as the widening in local production was offset by the easing of some import restraints and the capital equipment needs of expanding industry, export prospects were also very good. World demand for iron ore was expanding and the flexible exchange rate increased the competitiveness of Brazilian manufactured goods; the ALALC was also expected to provide a market for commodities that were less competitive on international markets. Given overall buoyancy in world trade, Brazil's exports were expected to maintain a 10 percent growth rate in the 1970s. With the government operating its incentives for private sector investment and not seeking to restrict the expansion of credit, the prospect was that investment in the economy would expand, and a high rate of growth—9 to 10 percent—would be achieved by 1973.

But there were certain serious problems whose impact was felt increasingly in the 1970s. While export prospects were generally good, the economy's dependence on coffee was a major weakness. Brazilian coffee production was hit by the coffee rust in 1970, and the disease threatened to spread extensively. There was also great uncertainty about the future of the International Coffee Agreement and, specifically, the adherence of the United States —Brazil's major market—to the agreement. While the inflow of foreign capital was essential to the achievement of the country's investment targets, the external debt was expected to reach U.S. $6,000,000,000 by 1975, which would make the burden of debt service substantial, representing up to 25 percent of all current accounts. Internally, industry was approaching a crossroads. Its growth since 1967 had mainly taken the form of the utilization of idle capacity—both plant and manpower—in response to increased domestic and export demand. Bottlenecks were beginning to appear in the early 1970s, for example in steel. At the same time the shift within the agricultural sector to nontraditional and minor crops had to be accelerated if rural incomes were to rise enough to provide Brazilian manufacturing with a mass market to make its goods competitive. The current level of investment spending, at 17 to 18 percent of GDP, was not sufficient to generate the overall economic growth forecast. Inflation would remain a problem, although a far less serious one than it had been in the 1960s. The scope for further fiscal restraint was limited, and its impact could be only marginal. The government's target of a maximum rate of growth of 10 percent a year would be difficult to achieve when the currency was constantly being devalued.

External debt

But the single most serious problem was that of the discrepancy between the Southeast and the South, which both had reached an intermediate stage of economic development and had a GDP of about U.S. $450 per head in 1970, and the remainder of the country, which still had a backward economy, with GDP per head at the U.S. $200 level. Despite incentives and greater government participation in the Northeast and North, their economic growth in the 1970s was not expected to exceed the overall national rate and might well lag behind, widening the gap even further. Despite an ambitious road construction program, development of many potentially rich areas would continue to be hampered by their inaccessibility, yet with a growth in the labour force of near 1,000,000 people a year, it was essential that Brazil should exploit its basic resources effectively. (E.I.U.)

TRANSPORTATION AND COMMUNICATIONS

Road networks. One of Brazil's major problems of economic development is its inadequate transportation. Part of the lack of good inland transportation can be laid to the difficulty of climbing the Great Escarpment; but a part also is the result of a scarcity of domestic capital. The deficiency of other means of transportation has given considerable stimulation to highway construction. This development was accompanied by a substantial increase in the number of motor vehicles in use; there were over 2,700,000 by 1970. Highway construction is financed with the help of a gasoline (petrol) tax.

State of the roads

Most of the roads are unpaved, and many are in disrepair. Because of these conditions, the operating costs of the trucking (road haulage) industry are very high. This is important also from the viewpoint of Brazil's international financial position, because an estimated 70 percent of the operating costs of the trucking industry requires foreign exchange to pay for gasoline, lubricating oil, spare parts, and other necessities.

Inadequate railroad service has been responsible for the use of trucks for purposes that could more economically be served by railroad transportation. Timber, cereals, and sugar are sometimes shipped by truck over highways that run parallel with railroads, at double the expense.

Railways. The large area of Brazil is served by a railroad network of only about 20,000 miles. This mileage is distributed among some 40 lines, many of which are inadequately interconnected. There are more than three gauges. With only a few exceptions the lines are poorly built, badly maintained, and inefficiently operated. Routes often are tortuous, with many curves and steep grades. The equipment is old and poorly maintained; over half of the locomotives are over 30 years old. Many freight cars are of all-wooden construction.

Traffic density, while light in the Northeast, is very high in the South. The failure of the railroad system to expand with the growth of the Brazilian economy places it under a considerable strain. Approximately one-half of the railroads, with about 80 percent of the mileage, are owned by the federal government. The rest are owned by states, private companies, and mixed state and private organizations.

Shipping. Coastwise shipping is of great importance in Brazil, since it is the only means of communication for many regions. The total volume of freight thus carried is more than 9,000,000 tons per year. In terms of ton-miles of cargo, the Brazilian coastal fleet carries about as much as the railroads. There are two government-owned shipping companies, Lloyd Brasileiro and the National Company of Coastal Navigation, which together handle about 50 percent of all shipping operations. The remainder is distributed among one relatively large firm and a host of smaller companies. The government-owned concerns operate almost 90 ships out of a total of almost 300, which includes many small vessels.

The hub of the coastwide shipping is Rio de Janeiro. Except for the Amazon, which is open to ships of all nations, Brazilian coastal commerce is restricted to Brazilian-owned ships, but numerous foreign shipping lines connect Brazil with the rest of the world.

The extensive Brazilian river system has a total navigability of about 27,000 miles. The inland waterways, especially the Amazon, São Francisco, and Jacuí rivers, provide important communication and shipping routes.

Air transport. Commercial aviation came to the fore during the 1940s and 1950s. During the same period, air freight, though still less than 1 percent of the ton-miles handled by the railroads, also increased. The lack of alternative facilities has led to the use of airplanes as carriers of some bulk commodities, including certain minerals. There are more than 1,000 airports in Brazil, but only a small number have paved runways or are large enough for four-engine planes.

Telecommunications. There are radiotelephone connections between Rio de Janeiro, São Paulo, and Brasília and the major cities of North America, South America, and Europe. Submarine cables also link Brazil with countries of the Northern Hemisphere. (H.W.S.)

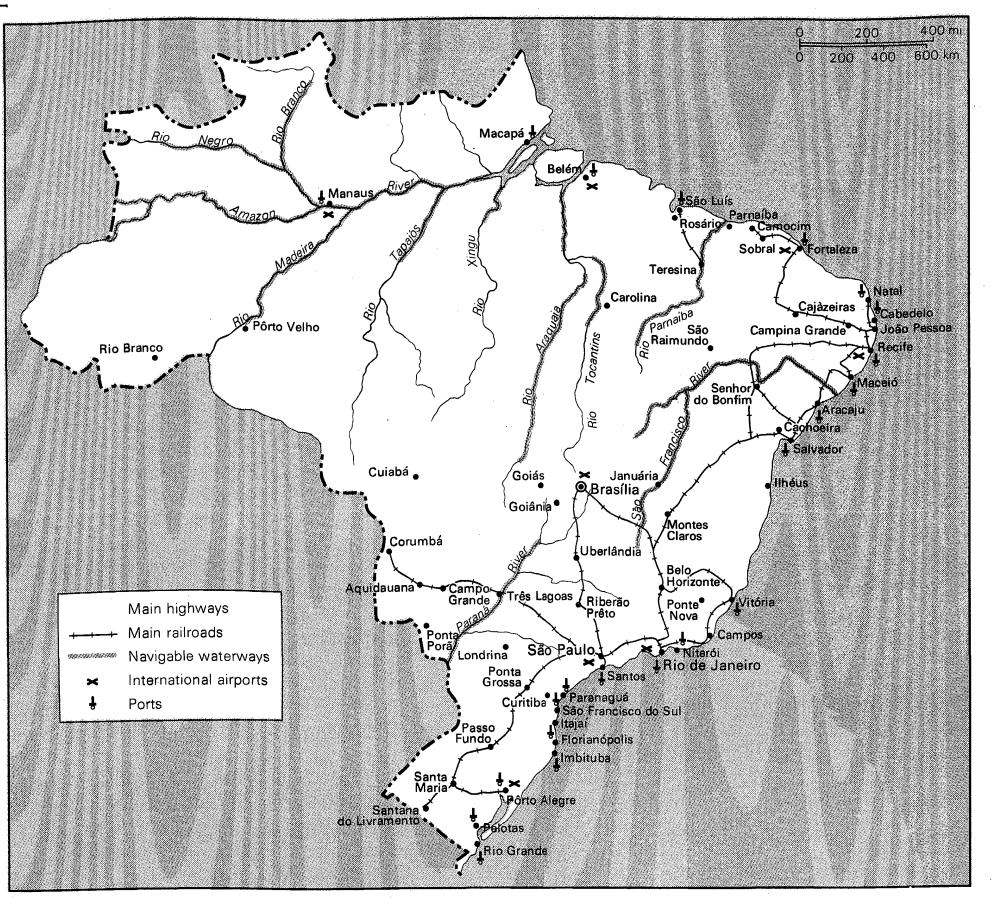
Administration, social conditions, and cultural life

THE STRUCTURE OF GOVERNMENT

The constitutional context. Brazil is a federal republic divided into 22 states (*estados*), four territories (*territórios*), and one federal district; the states and territories are subdivided into municipalities (*municípios*), and the municipalities into districts (*distritos*). The municipalities can be created by the states, on condition that they have a minimum of population and have their own fiscal resources; the municipalities constitute politico-administrative units. Municipal autonomy is assured by the election of mayors (*prefeitos*) and municipal councillors, whose number is in proportion to the strength of the electoral college. The mayors of the districts, who are considered important to national security, have been named, since 1964, by the president of the republic.

The Federal District (Distrito Federal), Brasília, is the capital of the union. Its *prefeito* is named by the president of the republic, as are the governors of the territories, with the approval of the Senate.

The states are ruled by the laws and constitutions that they have given themselves, within the framework of the principles defined by the federal constitution. The union can intervene in the internal affairs of the states, in cases foreseen by the federal constitution. Before 1966, the governors and vice governors were elected by direct vote with secret ballots. Since that date the governors are elected by the assemblies of the states, which are elected



Transportation system of Brazil.

by direct universal suffrage; the number of deputies is in proportion to the electoral college of each state.

The constitution

The constitution promulgated on October 7, 1969 was the seventh since the independence of Brazil (1822). As the fundamental law of the country, the federal constitution rules the respective functions of the executive, legislative, and judiciary powers. After the military takeover of 1964, however, two new politico-juridicial instruments were created—institutional acts (12 in number) and complementary acts (totalling 62). These acts, promulgated by the executive, sole arbiter of their continuation, cannot be submitted to the approval either of the legislative or of the judiciary power. The executive can also adopt certain measures, for example (since 1971) in the matter of national security, by the indirect means of "secret decrees."

Legislative power is exercised by the National Congress, composed of the Chamber of Deputies and the Senate. The Congress meets each year in two sessions of four months. It has the power to legislate, provided it has the approval of the president of the republic, in all matters which come under the jurisdiction of the union, particularly in fiscal and planning matters and in matters of regional economy, as well as those which concern the strength of the armed forces in time of peace. It is in the formal power of the Congress to rule on international treaties concluded by the president of the republic, to authorize him to declare or to end war, to approve federal intervention in the states, and on all modifications of politico-administrative boundaries in the country.

The Chamber of Deputies is composed of representatives of the states and territories elected by direct universal suffrage and by secret ballot. One of the institutional acts allows the president of the republic, with the advice of the National Security Council, to refuse the right to be elected to any person considered as constituting a threat to the security of the state. The number of deputies is in proportion to that of the electoral colleges of the states, but each territory can only elect one deputy. The legislature is elected for four years.

The Senate is formed by representatives of the states, elected by straight majority poll. Each state chooses three senators for a term of eight years. The Senate is renewed every four years, the first time by a third of its members, the second by the other two-thirds.

Each of the two assemblies that constitute the congress has its own allocation of duties. Thus, it is for the Senate to approve the nomination of magistrates and to suspend the carrying out of laws and decrees judged unconstitutional by the Supreme Federal Tribunal.

In comparison with the amended constitution of 1964, that of 1969 has weakened the power of the legislature by introducing procedures which accelerate and make automatic the adoption of projects presented by the executive. Members of Congress, moreover, are no longer protected by parliamentary immunity in case of libel, calumny, or accusation of interfering with national security.

Executive power

Executive power is exercised by the president of the republic, assisted by the ministers of state. From 1945 to 1964, the president was elected for a period of four years by direct universal suffrage with a secret ballot. Since 1964, the president of the Republic has been elected by an electoral college composed of members of Congress and representatives of the assemblies of the states. The constitution of 1969 confers wide powers on the executive, in particular in the economic and financial domain: Congress must approve or reject the budget en bloc, without having the right to amend it. In the same way, foreign policy and national security depend more closely than before on the power of the executive, while the rights of the president to intervene in the affairs of the states have grown.

The Brazilian judiciary power is complex. It is made up of the following six institutions:

1. The Federal Supreme Tribunal, which is composed of 11 members, named for life by the president of the republic, upon the recommendation of the Senate. Its function is to judge in the first and last instance the common-law crimes of the president of the republic, the

ministers of state, and the magistrates. It alone is entitled to have the right to decide—both in the first and last instance—on the one hand, on litigations between foreign states and the various politico-administrative departments of the union; on the other hand, on differences between these same departments; and, finally, on conflicts of jurisdiction between the different tribunals. The Tribunal is equally competent to deal with demands or with "mandates of safeguard" and of habeas corpus already judged by local or federal departments at a lower level. It is also within the competence of the court to pronounce on the constitutionality of laws and decrees. It must be noted that the institutional acts have given to the president of the republic the right to suspend Tribunal judges.

2. The Tribunal of Appeals, which is empowered to instruct and to judge in the first instance the lawsuits under revision in criminal matters and to rule on appeals in cases already judged in the first instance by the federal judges. Its 13 members are themselves also nominated for life by the president of the republic, on the recommendation of the Senate.

3. Federal judges. Each state or territory, as well as the Federal District, constitutes a judiciary section. The federal judges there have the power to instruct and to judge in the first instance certain cases of "mandate of safeguards," certain political crimes, crimes committed against the labour organization or crimes committed on the occasion of strikes, and cases related to public organizations.

4. Military tribunals and judges have the power to prosecute and judge members of the armed forces for crimes defined by the law; they may also prosecute civilians implicated in crimes against national security. The military judiciary comprises first of all the Superior Military Tribunal (composed of 15 members nominated for life by the president of the republic, on the recommendation of the Senate), and then tribunals and judges of inferior rank.

5. Electoral tribunals and judges, having for their first duty the registration of political parties and the control of their finances. They also fix the date of elections and proceed with the prosecution of and judgments on electoral crimes.

6. Labour tribunals and their judges, having the power to mediate in individual or collective conflicts between management and workers.

The political process. *The electorate.* Since the military revolution of 1964 presidential elections have been carried out by indirect suffrage, as (since 1966) have been elections of the governors of states. All citizens, over the age of 18, who are in possession of their civil rights and on condition that they are not illiterate, have the right to vote. Out of a population of 90,000,000 in 1969, the number of voters was about 29,000,000. Since 1964, electoral abstention has assumed a certain importance: for instance, in the legislative elections of 1970, the abstentions and the blank or void voting papers represented 30 to 50 percent of the electorate, the percentage varying according to the district.

Political parties. The political parties, which were to mark the political life of the country until 1964, were born in 1945. To understand the evolution which has led to the situation existing in the early 1970s, one must be familiar with the most important of these former political parties.

The former political parties

The Democratic Social Party (PSD), with conservative tendencies, was founded with the support of the majority of the states governors, and based its strength on the rural sectors. Until the 1962 elections, the PSD had a majority in Congress. The PSD, the party of the government, was a stabilizing factor, contributing by its conciliatory attitude to a resolution of the periodic crises which threatened the former regime. Dissolved in 1965, the PSD saw the majority of its members pass to the new governmental party, the National Renewal Alliance (ARENA).

The National Democratic Union (UDN) gathered together the majority of Brazilians who were opposed to the dictatorship that characterized the Estado Novo (New State) regime of 1937–45. It was the party most representative of the urban middle classes, but it also drew some strength from the rural areas. It defended economic liberalism and democratic liberties and sought to combat corruption in public administration. Once the second most important political party of Brazil, from 1962 onward it lost membership to the Brazilian Labor Party (PTB). After its suppression in 1965, its members were divided between the governmental party, ARENA, and the party in opposition, the Democratic National Movement (MDB).

The Brazilian Labour Party (PTB), founded in 1945, was that of the urban masses and of the "populist" movement. After 1962, it became Brazil's second political party. One of its tendencies then was a slight movement to the left, and it campaigned for agrarian reform, nationalization of foreign enterprises, and the extension of the right to vote to illiterates and soldiers. After 1964, the principal leaders of the PTB were deprived of their political rights, while other members of the party mostly went to swell the ranks of the new party in opposition, the MDB.

In addition to these large parties, one of the characteristics of the Brazilian political system, before 1964, was the proliferation of small parties—ten in all. Among the more important of these were the Democratic Christian Party (PDC) and the Social Progressive Party (PSP). The Brazilian Communist Party (PCB) had no legal existence after 1947 and thereafter assumed a semiclandestine or clandestine character, finally being split by multiple divisions. Some of its members have made common cause with the extra-parliamentary opposition groups that have obtained strong student participation. These groups threw themselves into urban guerrilla warfare, but, after a number of spectacular coups (such as the sequastration kidnapping of the United States Ambassador in 1969), their movement has been suppressed by the army.

In place of the old multi-party system, Institutional Act No. 2 of 1965 has substituted a bipartisan regime, while the law of November 20, 1965, has established the status of the parties. The National Renewal Alliance, the government party, had 220 deputies out of 310 elected in the elections of 1970, while the Brazilian Democratic Movement (MDB), which forms the parliamentary opposition, obtained 90 seats.

Organized labour

Participation of the citizen. In addition to participating in various elections, the Brazilian citizen also participates in the political process through the organization of labour. A 1942 law established the general principles of trade unionism by assigning the control of trade unions to the Ministry of Labour and Social Security, by forbidding strikes, and by entrusting the labour tribunals with the task of resolving conflicts between management and labour. Union dues are compulsory, and are fixed by the administration. The use of the financial resources of the trade unions is under the control of the Ministry of Labour and Social Security.

In spite of the legal prohibition against them, however, a number of strikes erupted between 1950 and 1964. During this period, the formation of the General Confederation of Labor (CGT) was effected, despite the law, with the tacit agreement of the authorities. The CGT was later dissolved by the military revolutionary government, which assumed control of labour organizations and applied the law forbidding strikes. Strikes nevertheless occurred in São Paulo and Belo Horizonte in 1968.

De facto political developments. It was the army as a whole that assumed power in April 1964, through the *grupo da Sorbonne* ("Sorbonne group"), so-named because of the officers' nuclei formed in the Superior War Academy who played the most active role in the takeover.

After stripping more than 1,000 citizens of their civil rights, Marshal Castelo Branco (confirmed as president of the republic in 1964) announced his intention of restoring democratic liberties at the right time. He held the

elections of the governors on the appointed date in 1965, but the victory of a few candidates who were opposed to the new regime led the president, under pressure from other military leaders, to modify his intentions. A new period of severity opened with the proclamation of Institutional Act No. 2. Measures taken in the act included the dissolution of political parties, the law restricting freedom of the press, a wave of political sanctions, and the annulment of the mandates of six federal deputies.

In 1967, the presidency was transferred from Marshal Castelo Branco to his War Minister, Marshal Costa e Silva who announced his wish to make "the revolution more human." The former governor of Guanabara, Carlos Lacerda, attempted a regrouping of the opposition, and sought the support of three ex-presidents, all of whom had been deprived of their political rights. This resulted in the formation of the "enlarged front," the *frente ampla*, which formulated four demands—a return to direct elections; the restoration of public liberties; moderate economic nationalism; and economic development. Student street demonstrations took place, supported by some of the clergy and some heterogeneous elements of the population. At first tolerated, these demonstrations were later repressed by the army. The "enlarged front" was banned, and Lacerda was stripped of his political rights.

In 1968, the chamber of representatives refused to cancel the parliamentary immunity of two deputies, which had been demanded by the government. Immediately, Institutional Act No. 5 sent congress on vacation for an indefinite period, gave full powers to the chief of state, and re-applied political sanctions. Violence from many sources completed the rupture with accepted Brazilian tradition.

In 1969, after the death of Marshal Costa e Silva, the ministers of the three armed forces provisionally assumed direction of the state. Congress was reopened, and General Garrastazu Medici was elected as president of the republic for four years.

The administrative structure. The administrative structure of the Federal Government is comprised of 17 ministries divided into five sections: These are (1) the political sector (Ministries of Justice and Foreign Affairs); (2) the planning sector (Ministry of Planning and General Co-ordination); (3) the economic sector (Ministries of Finance, Transport, Agriculture, Industry and Commerce, Mines and Energy, and the Interior); (4) the social sector (Ministries of Education and Culture, Labour and Social Security, Health, Communications); (5) the military sector (Ministries of the Army, the Navy, and the Air).

Literacy

Education. In 1970, about 32 percent of the population over 10 years of age was illiterate. In 1968, a national service of literacy was created to combat illiteracy. In 1970 the primary school system was made up of 145,500 units; in 1970 12,300,000 children were enrolled in primary schools, and 3,050,000 students were enrolled in secondary schools.

Health and welfare. Set up in 1930, the Social Security service has been slow and irregular in its expansion; in 1960 it only covered 6.5 percent of the population. Up until 1960 it was limited to workers in towns but was afterward extended to cover those in rural areas and certain other categories. Its cost is high and corresponds to about 22 percent of the total salary of the beneficiaries.

In 1969 the Ministry of Health established an ambitious program to control smallpox, a disease endemic in Brazil. There is also another program designed to combat malaria in several regions.

Housing. The National Housing Bank (BNH) was created in 1967 with a program for building 200,000 houses in ten years. The bank, which operates with medium and long term mortgages, later revised its programs, which were hampered by chronic inflation. To avoid a loss of capital by the BNH, the interest charges on the loans have been readjusted in keeping with the rate of inflation. The consequence is that only those social strata more favoured by salary scales have been able to continue to make applications to the bank. Progress made by the early 1970s had not, however, yet resolved the delicate problem of the *favelas* and the *mocambos* in Rio de Janeiro, in Recife, in Belo Horizonte, and in other big cities.

Social conditions. Measured in terms of individual living standards, social conditions vary considerably according to region, and strong social concentrations of income are also evident. The South and São Paulo regions, with 35 percent of the total population, have half of the gross internal revenue, while the North, Northeast, and Central-West regions, with 30 percent of the population, have less than 16 percent (1960 figures). Half the wage earners of Brazil receive 19 percent of the national revenue, while the 5 percent at the top of the social pyramid receive 31 percent of the total revenue. The expenses for food of 50 percent of the least favoured salaried population absorbed in 1960 between 50 and 60 percent of the wages. Inflation, although reduced from 80 percent in 1963 to 20 percent in 1970, has aggravated this disparity. The growth of a Brazilian middle class, which is above all urban, must be noted, though it is impossible to measure exactly the patterns of income and of its less wealthy members.

Public health

The amelioration of public health is one of Brazil's major problems. The difficulties inherent in the environment, the frequent isolation of rural populations, the mediocrity of nutrition, and the different living standards and cultural levels render the task of reformers difficult. In 1968, one could only number 3.6 hospital beds per 1,000 inhabitants (6.7 in administrative capitals) and 4.4 doctors for every 10,000 inhabitants, with great differences according to region. Yet the situation is improving, thanks to, for example, a notable diminution in the incidence of malaria and a lowering of the rate of infant mortality. (L.Ms.)

CULTURAL LIFE AND INSTITUTIONS

The cultural milieu. Just as three main racial stocks contributed physically to the Brazilian population, the cultures of the American Indians, the African Negroes, and the Portuguese have together formed the modern Brazilian way of life. By far the most important of these three elements is the cultural contribution of Portugal. Brazilians acquired their language, their religion, and most of their traditional customs from the Portuguese. Throughout the vast area of Brazil, the Portuguese were able to establish a remarkably homogeneous pattern of living.

From one end of the country to another, Brazilians share a common set of traditions either inherited from Portugal or formed in the New World during their own history as a nation. Among the important popular festivals is Saint John's Eve, or the Festa de São João (June 23), during which families and friends gather around bonfires to roast yams, set off fireworks, play with paper balloons, and sing. This is a Catholic festival, which is also celebrated in Portugal. Brazilians also celebrate their national Independence Day (September 7) in memory of their separation from Portugal, and other patriotic holidays.

Although the Portuguese were able so successfully to transmit their way of life to the Indians, the Negroes, and the mixed population, the influence of the aborigines and of Africa can be felt in the way of life of the Brazilian countryman. From the Indians, Brazilians learned much about their environment. Throughout the country, Brazilian farmers still use a rather wasteful type of aboriginal fire agriculture (slash-and-burn) and they plant manioc (cassava) and other crops that were cultivated by the Indians.

Tupi, the language that was spoken by most of the Indians along the Brazilian coast, was adapted as early as the 16th century by missionaries for teaching the catechism and came to be called the *lingua geral*, the general language. For a time, this language was spoken widely throughout the interior of northern Brazil by Indians, mestizos, Portuguese, and Negroes. From this

language come many of the names of plants, animals, and places in Brazilian Portuguese. Some of these terms of Tupi origin have come to be used in English, such as tapioca (a by-product of the manioc tuber) and cashew (*acajú* in Tupi). The Indian contribution to Brazilian culture is most apparent in the Amazon Valley, where many Indian customs and beliefs have been retained by the rubber collectors and isolated farmers.

African cultural influence

African influence on the Brazilian way of life is strongest in the old plantation region north along the coast from Rio de Janeiro. Particularly in Salvador, the capital of Bahia state, there are traditional dishes of African origin, such as *vatapá*—made of rice flour, coconut oil, fish and shrimps, red peppers, and many condiments—and *acarajé*, a beancake fried in coconut oil. In most northern coastal cities, there are religious cults of African origin, called *macumba* in Rio de Janeiro and *candomblé* in Bahia, which are analogous to the voodoo, or *vodum*, of Haiti. These cults worship West African deities as well as Catholic saints. Throughout Brazil, people tell folktales similar to the Uncle Remus stories told in the southern United States. African influence is apparent in Brazilian popular music, especially in the highly rhythmic sambas.

Because of the great environmental variation over this large country, there are marked regional differences in Brazilian culture. The extreme southern state of Rio Grande do Sul is known for the *gauchos*, the cowboys of the Pampas. The southern states of Rio Grande do Sul, Paraná, and Santa Catarina are known for their colonies of European farmers. The people of the progressive city of São Paulo have the reputation of being the energetic "yankees" of Brazil. Rio de Janeiro is known for the cosmopolitan charm of its people, spoken of as *cariocas;* for the gaiety of its pre-Lenten carnival; and, of course, for the beauty of the city and its setting at the foot of green mountains on the Baía de Guanabara. The northeastern semidesert is characterized by another type of cowboy, the *vaqueiro*, who dresses entirely in leather for protection against the thorny bushes of the region. The Amazon Basin has the lonely *seringueiro*, the gatherer of wild rubber from the tropical forest. The coffee plantations of São Paulo and Paranã states, the cocoa plantations in southern Bahia state, and the sugar plantations of the Northeast coast also provide distinctive settings for regional variations in the Brazilian way of life.

The state of the arts. The varied racial and cultural past of Brazil and the striking regional differences are reflected in Brazilian art, literature, and music. Without doubt the outstanding artist of the 18th century, during the colonial period, was the crippled mulatto architect and sculptor, Antônio Francisco Lisboa, who was known simply as Aleijadinho (the Little Crippled One). His famous carvings in soapstone may be seen in the 18th-century churches of Minas Gerais state.

The artistic and musical heritage

Brazil's most famous modern artist, Cándido Portinari, was the son of Italian immigrants; regional scenes are the subject of many of his paintings. The internationally famous contemporary composer, Heitor Villa-Lobos, incorporated folk music from the Brazilian Negroes and Indians into his compositions, as in his *Bachianas Brasileiras* and *Chôros*. Likewise, contemporary Brazilian architecture, which stresses open terraces and large windows that are shuttered against the sun, has become famous throughout the world; it is a new school of architecture well adapted to the tropical and semitropical climate.

In the field of literature, the mixed racial and cultural heritage of Brazil is also felt strongly. The poetic, imaginative novels of Joaquin Maria Machado de Assis won international acclaim during the late 19th century.

A series of outstanding writers have appeared in the 20th century, focussing upon regional subjects. A modern Brazilian classic is *Casa Grande e Senzala* (translated into English as *The Masters and the Slaves*) by Gilberto Freyre; it is a masterly social history of the Brazilian slave system of the northeast and the fusion of Indian, Negro, and Portuguese social patterns into the national culture. It is in the modern novel that this literary movement, however, has been most actively developed. Jorge Amado has written in *Terras do Sem Fim* (translated as *The Violent Land*) of the frontier days of the early 20th century in the cocoa growing region of Bahia; and, in *Jubiabá*, of a heroic Negro character from the slums of Bahia.

Cultural institutions. Among the many modern universities and scientific institutions is the Butanan Institute, in São Paulo, where important work on snake serum has been done. The Institute Oswaldo Cruz in Rio de Janeiro is famous for its scientific work in tropical disease.

Modern mass media, such as the press, radio, and television, have expanded rapidly. Television was introduced in 1950 in São Paulo. Twenty-one years later there were 56 television stations in the larger cities, with an estimated 6,500,000 (1969) television receiving sets. Brazilians have also become a more sports-loving people. Thousands crowd the beautiful beaches, and hundreds of thousands attend the soccer matches for which a stadium seating 200,000 was constructed in Rio de Janeiro.

(C.W.W./T.L.S.)

Prospects for the future

The armed forces have been the final arbiters of the political process in Brazil since the end of World War II, and they seem likely to retain that function indefinitely. Sharing similar points of view with the urban middle income groups that have come to prominence in the past generation, the military officers are convinced that Brazil is destined to become a world power and that it is the duty of the armed services to work toward that end by providing efficient, nation-wide administration. This attitude is reinforced by their long-standing low regard for professional politicians. Between 1945 and 1964 no single political party was able to elect a president of Brazil or a majority in Congress, a situation that encouraged political irresponsibility. In these circumstances, and always at the behest of civilian political elements, the armed forces intervened on four occasions to protect national institutions against the effects of what they considered to be civilian incompetence.

Since the revolution of March 31, 1964, in contrast to their earlier practice, military leaders have retained direct command of the government and have carried out a major revision of the political system, progressively enhancing the authority of the national executive at the expense of state governors, state and national legislatures, political parties, and the Brazilian electorate. Through rigorous fiscal austerity, revision of the tax structure, promotion of private enterprise, and heavy investment of public funds in the economic infrastructure, the post-1964 regimes have reversed the downward economic trend to give Brazil one of the highest rates of economic growth in the world. Ambitious highway-building and colonization programs in the interior of the country and more modest support of education and social welfare are designed to hasten the effective occupation and development of the national territory and the modernization of Brazilian society. Sustained economic growth and widespread public apathy in political matters will probably continue to be the norm in Brazil. The military may be expected to remain at the centre of the political stage until it feels that its "revolutionary" policies are irreversible by a successor regime.

Brazil, History of

This article covers the history of Brazil, with emphasis on the national period, and consists of the following sections:

Brazil to 1889
- Colonial period
- The independence of Brazil
- The Brazilian Empire (1822-89)

Brazil since 1889
- The early republican period
- Return to representative government
- Military intervention
- Social and political changes after 1945

BRAZIL TO 1889

The discovery and early settlement of Brazil appear in the larger perspective of history as episodes in the great movement of Portuguese colonial expansion to the east. Vasco da Gama's discovery in 1498 of an all-water route to the East Indies and Spice Islands by way of the Cape of Good Hope led the Portuguese crown to dispatch to India an imposing armada under command of Pedro Álvares Cabral. To avoid the calms off the Gulf of Guinea, Cabral bore so far to the west that on April 22, 1500, the mainland of South America was sighted; the region was promptly claimed by Portugal, as it lay well within the zone assigned to Portugal by the Treaty of Tordesillas (1494).

Colonial period. The coast of Brazil had been touched in January 1500 by the Spanish navigator Vicente Yáñez Pinzón, but the Spanish crown made no effort to follow up the discovery. Portugal's new possession was at first called Vera Cruz (the True Cross), a name soon abandoned in favour of Brazil after the valuable red dyewood (*pau-brasil*) with which the country abounded.

During the colonial period Brazil was expanded beyond the line of Tordesillas (a vertical line drawn 370 leagues west of the Cape Verde Islands) westward to the slopes of the Andes and northward and southward to the Amazon and the Río de la Plata. In the north the movement was led by missionaries, who established missions along the Amazon in the 17th century. In the northeast, cattlemen from the sugar zones of Pernambuco and Bahia pushed inland into the present area of Piauí, Maranhão, and Goiás in search of new pastures. The brunt of the "march to the west," however, was borne by the Paulistas, the settlers of São Paulo who organized great expeditions into the interior, known as *bandeiras*, to capture Indian slaves and to find gold and precious stones. Some of these expeditions, involving entire families, lasted for years.

During the 17th century, Paulistas explored the area of Mato Grosso and attacked the Indian missions of Misiones and southern Brazil, generally meeting resistance from the Indians and their Jesuit protectors; only along the Río de la Plata, in modern Uruguay, did the Spanish settlers eventually push the Paulistas back. The treaties of Madrid (1750), El Pardo (1761), and San Ildefonso (1777) with Spain gave some legality to Portuguese claims, including the conquests of the *bandeiras*.

An important factor in the unification of the people of Brazil was the heritage of Portugal; the Portuguese language formed a common bond between plantation residents, cattlemen, miners, slaves (both Indian and Negro), slave hunters, and city dwellers from the Amazon to the Río de la Plata and distinguished them from their Spanish-speaking counterparts elsewhere in South America. Although Tupí-Guaraní continued to serve as a sort of lingua franca throughout much of the interior of the colony, Portuguese remained the official and the common language.

The expanded, patriarchal family structure, also derived from Portugal, was nearly uniform throughout Brazil, and power was exercised by the heads of those families which controlled the land, slaves, cattle, and, later, mines that produced the wealth of the colony. Brazilian society and the economy were rurally based. The population was divided unevenly between those who possessed landed wealth and prestige and those who were dependent upon them. No great cities grew up during the colonial period. Moreover, contact with Portugal was maintained in all parts of Brazil, and little trade or other regular contact existed between Brazil and neighbouring Spanish colonies. These common factors proved far stronger than did regional variants when Brazilian unity was under severe stress in the second quarter of the 19th century. (See also LATIN AMERICA AND THE CARIBBEAN, COLONIAL.)

The independence of Brazil. In 1789 the first rebellion against Portuguese authority was instigated by José Joaquim da Silva Xavier, known as Tiradentes (Tooth Puller) because of his occasional practice of extracting teeth. The uprising was put down, and Tiradentes was executed.

Despite its isolation, Brazil could not escape the effects of the revolutionary and Napoleonic epoch in Europe. In 1807 Napoleon resolved upon the invasion and conquest of Portugal, a traditional British ally, largely to tighten the European blockade of Great Britain. The Portuguese prince regent Dom John, afterward King John VI, decided to take refuge in Brazil, the only time a colony ever served as the seat of government for its mother country. He sailed from the Tagus on November 29, 1807, under the protection of the British fleet. Accompanied by the royal family and a horde of nobles and functionaries, he arrived at Rio de Janeiro on March 7, 1808.

Arrival of Dom John in 1808

The colonists, convinced that a new era had dawned for

Brazil, welcomed their sovereign. The Prince Regent promptly decreed a number of reforms that radically altered the status of the colony. These included practical recognition of Brazil's position as seat of the Portuguese Empire and its new requirements in view of the war in Europe. The old Portuguese commercial monopoly was abolished and Brazilian harbours were opened to the commerce of all friendly nations. British trade with Brazil immediately took on important proportions, and a number of British trading companies established offices in the colony.

A ministry with four portfolios and a council of state were installed in Rio de Janeiro, and a supreme court of justice, a court of exchequer and royal treasury, the royal mint, the Bank of Brazil, and the royal printing office were established. A royal library, a military academy, and medical and law schools were founded. Industries were encouraged, foreign scholars and artists were welcomed, and immigrants from northern Europe were brought in at government expense. The changed status of Brazil was reflected in the decree of December 16, 1815, by which the Portuguese dominions were designated the United Kingdom of Portugal, Brazil, and the Algarves, thus making Brazil coequal with Portugal. In 1816 the queen, Maria I, died, and the Prince Regent became king.

Although John VI enjoyed a certain degree of personal popularity, his corrupt and extravagant government aroused much opposition, which was increased by the fermentation of liberal ideas produced by the French Revolution. In Pernambuco a revolt broke out in 1817 and was put down with difficulty after a republic had been formed that lasted for 90 days. After the departure of the French, Portugal had been governed by an arbitrary and tyrannical regency. A revolution in 1820 swept aside the regency, and the Cortes, which had not met for more than a century, was summoned to draw up a constitution.

The regency of Dom Pedro

The presence of John VI in Portugal was imperative if the revolutionary movement was to be kept in hand. On April 22, 1821, he appointed his son Dom Pedro regent, and two days later he set sail for Lisbon. Meanwhile, antagonisms between the Portuguese and Brazilians were becoming increasingly bitter, republican propaganda was active, and Dom Pedro had to face the responsibility of a separation of Brazil from Portugal as a result of the shortsighted policy of the Cortes at Lisbon. The majority of this assembly favoured the restoration of Brazil to its former status of colonial dependence. Without waiting for the Brazilian deputies, they proceeded to undo most of the reforms introduced into Brazil by John VI. Fearful that Dom Pedro might head a movement for independence, the Cortes ordered the prince to return to Europe.

Supported by the majority of Brazilians, Dom Pedro defied the Cortes by his refusal to return to Lisbon. In January 1822 he formed a ministry in which the chief portfolio was held by the distinguished Paulista, José Bonifácio de Andrada e Silva. On June 3 Dom Pedro convoked a legislative and constituent assembly. On September 7, on the plain of Ipiranga, near the city of São Paulo, he solemnly proclaimed the independence of Brazil, and on December 1, 1822, he was crowned the nation's emperor.

The strong Portuguese garrisons were forced to return to Europe. Before the end of 1823 independence had become an accomplished fact. The United States was first to recognize the new government, on May 26, 1824. Portuguese recognition was secured in 1825. The early resumption of formal relations with Portugal was due in large part to the influence and good offices of the British government.

The first years of independence

The Brazilian Empire (1822–89). The first years of independence were difficult. The nation was without experience in self-government, and the Emperor was inclined to be despotic and arbitrary. When the constituent assembly proved unmanageable, Pedro I dissolved it in 1823 and sent the radical Andrada e Silva and his two brothers into exile. Fortunately, however, he came to realize that the days of absolutism were past; a new and liberal constitution, drawn up by the Council of State, was submitted to the municipal councils of the provinces and sworn to by the Emperor on March 25, 1824. Pedro's remaining years saw a growing estrangement between the monarch and his subjects. Parliamentary government was little to his liking, and the opposition generally commanded a majority in the chamber of deputies. Brazil became involved in a disastrous war with Argentina resulting in the loss of the Provincia Cisplatina (the present republic of Uruguay). Finally, Pedro formally abdicated on April 7, 1831, in favour of the heir apparent, Dom Pedro de Alacântara, then only five years of age.

The regency (1831–40). The next decade proved the most agitated period in Brazilian history. From 1831 to 1835 a triple regency tried in vain to end civil war in the provinces and lawlessness and insubordination in the army. In 1834 the constitution was amended to grant a measure of decentralization to the provinces, through the creation of provincial assemblies with considerable local power, and to provide for a sole regent to be elected for four years. For this office in 1835 a priest, Diogo António Feijó, was chosen. For two years he struggled against disintegration, but he was forced to resign in 1837 and was succeeded by Pedro de Araújo Lima. As the end of the decade approached, sentiment began to crystallize in favour of a declaration of majority of the young Dom Pedro. The Brazilians, impatient with the regency, hoped to find in the Emperor a symbol to which the entire nation might rally. On July 23, 1840, both houses of parliament passed a declaration that Pedro de Alcântara had attained his majority.

Pedro II. The reign of Pedro II, lasting practically a half century, constitutes perhaps the most interesting and fruitful epoch in Brazilian history. The prestige and progress of the nation were due largely to the enlightened statesmanship of its ruler. Pedro cared little for the trappings of royalty. Though not without personal distinction he was always simple, modest, and democratic. He possessed an insatiable intellectual curiosity and was never more happy than when conversing with scholars. He was generous and magnanimous to a fault. One of his favourite occupations was inspecting schools. He was wont to declare, "If I were not emperor I should like to be a school teacher." Yet this kindly, genial, and scholarly ruler took his prerogatives and duties as sovereign with great seriousness, and in all matters of first importance he was the final arbiter. According to the moderative power granted to the executive under the constitution of 1824, the Emperor had the right to dissolve the Chamber of Deputies, to select the members of the life senate from triple lists submitted by the province, and to appoint and dismiss ministers of state. That parliamentary life in Brazil was pitched upon a high plane, that the highest officials in the state generally left office poorer than when they entered it, that the machinery of government functioned smoothly year after year was due in large measure to the vigilance of the Emperor.

Prestige and progress under Pedro II

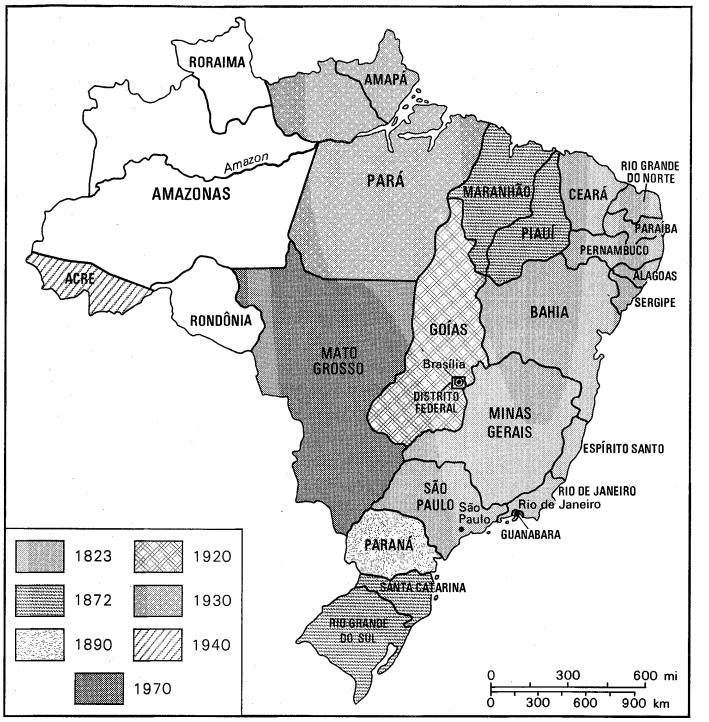
Pedro's government maintained an active interest in the affairs of the Plata republics, especially of Uruguay, which it sought to control through indirect measures. Brazil aided in the overthrow of the Argentine dictator Juan Manuel de Rosas in 1852. In 1864 Brazil intervened in Uruguayan internal affairs and brought about war with Paraguay. In alliance with Argentina and Uruguay, Brazil successfully waged the costly and bloody Paraguayan War of 1864–70, eventually overthrowing the Paraguayan dictator Francisco Solano López. The empire's relations with the United States and with Europe were generally cordial. Pedro personally did much to cement these international friendships, visiting Europe in 1871, 1876, and 1888 and going to the United States in 1876.

Slavery

The empire's major social and economic problems were related to slave-based plantation agriculture. Real political power remained with large rural landholders, who formed the core of the social and economic elite of Brazil. Industrialization was still economically insignificant, and, with the decline of gold mining, agriculture was un-

rivalled as the source of Brazil's wealth. Cotton, and increasingly coffee, cultivated by slave labour, competed with sugar as the leading export crop. The rural landholders were largely insulated from the antislavery current of the times. Although manumission was common, and the number of freedmen and their descendants far surpassed the number of slaves in Brazil, the slaveowners as a group resisted pressures for the complete abolition of slavery. Partly as a result of pressure from Great Britain, Brazil had agreed to abolish the slave trade in 1831, but it was not until 1853 that slave traffic completely ceased. Agitation to abolish slavery as such began in the 1860s. Pedro was opposed to slavery, but he had to reckon with the slaveowners. In 1871 a bill for gradual emancipation was passed by Parliament. The importance of this act lay in the provision that, henceforth, all children born of slave mothers should be free. But this concession did not satisfy many of the abolitionists, who, led by a young lawyer and writer, Joaquim Nabuco de Araújo demanded immediate and complete abolition. Nabuco's book *O Abolicionismo* (1883) endeavoured to prove that slavery was poisoning the very life of the nation. In 1884 Ceará and Amazonas freed their slaves; in 1885 all slaves over 60 years of age were liberated. Finally, complete emancipation without compensation to the owners was decreed by the Princess Regent in the absence of the Emperor on May 13, 1888. About 700,000 slaves were freed.

The collapse of the empire. Under Pedro II's wise guidance Brazil had made very real progress. His rule witnessed a growth in population from 4,000,000 to 14,000,000, a fourteenfold increase in public revenues, and a tenfold increase in the value of the products of the Empire. Railroad mileage in 1889 exceeded 5,000 miles (8,000 kilometres); that year more than 100,000 immigrants came to Brazil. Yet there were grave causes of dissatisfaction. Propaganda in favour of a republic, launched in 1871, had gained many recruits. The great landowners, who had lost their slaves without compensation, withdrew their support from the monarchy. The clergy had been antagonized by the punishment of several recalcitrant bishops. Isabel, the heiress to the throne, and her husband, the Conde d'Eu, were unpopular. Most serious, important elements in the army, which had become a political force after 1870, turned against the Emperor, largely because Pedro insisted that they stay out of politics. A conspiracy was hatched by these disgruntled military elements, and on November 15, 1889, a revolt of part of the army was the signal for the collapse of the empire. Pedro formally abdicated and, with his family, was banished to Europe.



Growth of population in Brazil: dates by which the states had achieved a population density of more than two persons per square mile.

BRAZIL SINCE 1889

Military autocracy

The early republican period. For the next 14 months Brazil was ruled by a military autocracy in which Marshal Deodoro da Fonseca, as chief of the provisional government, was virtually supreme. Decisions of great importance were reached. Church and state were separated, civil marriage was introduced, and a constituent assembly was summoned, which adopted in 1891 a constitution modelled closely on that of the United States.

The presidencies. As president, Deodoro da Fonseca employed the same dictatorial methods that he had followed as head of the provisional regime. On November 3, 1891, he forcibly dissolved Congress and proclaimed himself dictator. But opposition was so widespread that on November 23 he resigned in favour of the vice president, Marshal Floriano Peixoto. But Peixoto differed little in his methods from his predecessor. Of the meaning of constitutionalism in the strict sense, he had scant understanding. Growing opposition finally culminated in 1893 in a naval revolt and military uprising that lasted until the following year and were put down only with the greatest difficulty.

The advent of a civilian as president was hailed with undisguised relief. Prudente de Morais, who assumed office in 1894, was a distinguished lawyer of São Paulo and a republican of long standing. Though his intentions were excellent and his ability and honesty unquestioned, his administration was rendered largely sterile through the opposition of the disgruntled military elements and the necessity of putting down a rebellion in the hinterland of Bahia. His successor, Manuel Ferraz de Campos Sales (1898–1902), former president of the State of São Paulo, is chiefly remembered for his striking success in saving Brazil from the financial collapse threatened by the orgy of extravagance, inflated currency, and speculation, which had followed the overthrow of the monarchy. While still president-elect, Campos Sales in 1898 negotiated through the Rothschilds a funding loan of £10,000,000, interest on which was to be suspended for three years and amortization payments for ten. Because of the able and economical administration of Campos Sales and the marvelous recuperative power of the country, the credit and finances of Brazil were again placed on a sound foundation. Francisco de Paula Rodrigues Alves (1902–06), likewise a Paulista, is generally regarded as Brazil's ablest civilian president. During his term of office the capital was transformed into one of the world's most beautiful cities. Under the direction of the distinguished physician and scientist Oswaldo Cruz, Rio de Janeiro was completely freed from yellow fever. Some of Brazil's most thorny boundary controversies were settled during the presidencies of Campos Sales and Rodrigues Alves by the able minister of foreign affairs, José Maria de Silva Paranhos, barão de Rio Branco.

The development of Rio de Janeiro

President Afonso Pena (served 1906–09) took an important step toward the stabilization of the exchange through the creation of the so-called Caixa de Conversão, or Bank of Conversion, whose function was to redeem inconvertible paper currency by the issue of convertible notes secured through the deposit of gold. This project had to be abandoned on the outbreak of World War I. Pena died in 1909 and was succeeded by the vice president, Nilo Peçanha. In the campaign of 1910 the official candidate, Marshal Hermes da Fonseca, nephew of Deodoro da Fonseca, was opposed by Rui Barbosa, a noted lawyer and publicist. Though the conviction was general that Barbosa had received a majority of the votes cast, the official machine easily secured the election of Hermes da Fonseca, during whose administration (1910–14) the high standards set by the first three civilian executives were largely abandoned.

World War I and its aftermath. A change for the better came with the election of Wenceslau Brás (served 1914–18), a former governor of Minas Gerais. His administration was closely associated with Brazil's reaction to and participation in World War I. The sympathies of most Brazilians inclined toward the Allies. On April 11, 1917, Brazil broke off relations with Germany following the torpedoing of the steamer "Paraná" off France. On June 1 Brazil revoked its decree of neutrality in the war as a mark of continental solidarity and friendship with the United States. On October 26, following the sinking of more Brazilian ships, Brazil declared war on Germany. Brazil's participation in the war was confined to the dispatch of a part of its fleet to European waters and the sending of a medical mission and a number of aviators to the Western Front. Its chief contribution was the placing of its food supplies and other resources unreservedly at the disposal of the Allies. Brazil participated in the peace conference and was given a temporary seat on the Council of the League of Nations.

Postwar boom and bust

In the election of 1918 a precedent was established by the re-election of Rodrigues Alves. He was too ill to accept office, however, and died on January 18, 1919. In April, Epitácio Pessoa, a lawyer of note and head of the Brazilian delegation at the Versailles conference, was elected. His presidency, coinciding with a wave of postwar prosperity, was an era of reckless expenditure accompanied by an immense increase in both the internal and foreign debt. Large sums were absorbed by the Brazilian centenary exposition, which was celebrated in 1922. The presidency of Artur Bernardes (served 1922–26) was beset with difficulties. The collapse of the boom found Brazil in financial extremities, and the new executive endeavoured to carry out a policy of strict economy: governmental expenses were cut down, costly public works were postponed, and new sources of revenue, such as the income tax, were created. The success of this program of retrenchment and reform was compromised by a dangerous flareup of militarism. In the closing weeks of Pessoa's administration a military group made a desperate but fruitless attempt to prevent Bernardes' inauguration. Another revolt was launched in July 1924 at São Paulo city. This, too, was suppressed, but only after heavy loss of life and much property damage. In 1926 Washington Luís, minister of justice in the two preceding administrations, was elected president without a contest.

The shift from empire to republic produced little immediate change in Brazil's basic political or social institutions. Under the constitution of 1891, state and municipal governments were granted somewhat greater freedom from central control, with a consequent increase in the power of local bosses. But no significant new elements were added to the political spectrum, and the bulk of the population remained outside the political process. Rural landholders, particularly in the States of São Paulo and Minas Gerais, adjusted to the loss of slave labour and retained their pre-eminence. In São Paulo massive immigration from the Mediterranean area before World War I provided a new source of rural labour for the expanding coffee industry. By the late 19th century, coffee had become the outstanding export crop and source of government revenue. Diversification of agriculture and the expansion and diversification of the mining industry provided economic stimulus in Minas Gerais. The old areas of Bahia and Pernambuco gradually declined in political significance and were eventually replaced by the increasingly important state of Rio Grande do Sul, but the latter did not challenge the political hegemony of the central states until 1930. Thus, economic and political power was concentrated in São Paulo and Minas Gerais during the first four decades of the republic, and national policies usually reflected the interests of those states.

Political role of the military

The principal new factor was the political role of the military. After 1889 the armed forces asserted their claim as guarantors of the constitutional process and served usually as a check upon the civilian administrations. The military also provided the leadership of occasional protest movements. The first stirrings of social unrest and vaguely expressed demands for a modification of the institutional patterns of the republic were voiced by young military officers, the *tenentes*, in the mid-1920s; the movement they headed culminated in the revolution of 1930, which marked the end of the so-called old republic and the beginning of a new era.

The Vargas era. When the administration-sponsored presidential candidate was officially declared winner in the 1930 election, a revolt broke out. This successful rebellion was led by Getúlio Vargas, governor of the state of Rio Grande do Sul, who was to remain central in Brazilian national life until his suicide in 1954.

Vargas held office as chief executive on two occasions, 1930–45 and 1951–54. Early in the first of these periods, the country's difficulties were essentially economic, accentuated by a policy of subsidizing coffee production, and the tremendous powers of the states served as steady irritants to the country. In 1934 a new constitution gave the central government greater powers. Three years later, President Vargas suddenly seized practically absolute power and set up still another constitution, under which he continued as president. The new administration, known as the Estado Nôvo (New State), so concentrated power in Vargas' hands that he was able to suppress all manifestations of popular will. Vargas stripped Brazil of most of the trappings through which it might eventually hope to become a democracy. On the other hand, considerable social legislation was enacted, with positive benefits to the labouring man.

Vargas' policy concentrated upon curtailment of states' rights, emphasis on nationalism, and the transfer of the locus of power from the country to the city. The states were increasingly subordinated to the central government, politically, economically, and socially. The ruinous coffee policies of the past were discarded, manufacturing was advanced, and the diversification of agriculture was encouraged.

After the outbreak of World War II in 1939, Vargas' government supported inter-American solidarity; on August 22, 1942, it declared war against Germany and Italy. Besides participating in the defense of the South Atlantic against Axis submarines, Brazil sent an expeditionary force to Italy in July 1944 that distinguished itself in several battles. Brazil also allowed the United States to use certain Brazilian naval and air bases during the war. A number of agreements were signed between the two governments for the economic development and production of Brazilian raw materials.

Return to representative government. On October 29, 1945, Vargas was overthrown in a bloodless revolution. When it appeared that the President intended to continue indefinitely in power, a group of high army officers forced him to resign, transferring the government to Chief Justice José Linhares on an interim basis.

Overthrow of Vargas

Dutra and Vargas. On December 2, 1945, Gen. Eurico Gaspar Dutra, the former war minister and a loyal friend of Vargas, was elected to a five-year term as president. In September 1946 a constituent assembly at Rio de Janeiro adopted a new constitution, which confirmed and strengthened the civil and personal liberties and the multiparty system of representative democracy that had taken effect after the overthrow of Vargas. As was customary in Brazilian constitutions, it recognized the armed forces as permanent national institutions and the guarantors of constitutional powers.

Dutra showed a sincere determination to govern the country in harmony with the measures of the new constitution. He outlawed the Communist Party as an undemocratic, foreign-based organization in May 1947 but did not otherwise interfere with the free play of political expression or political party activities. Major accomplishments of the Dutra administration included the Paulo Afonso Dam on the São Francisco River, to provide electric power to northeastern Brazil, and the opening of an all-weather highway linking that region with the industrial zones of Minas Gerais and São Paulo.

The general elections of 1950 resulted in a substantial victory for Vargas. While he failed to secure a clear majority in the four-way race, he polled 1,500,000 more votes than the runner-up and nearly as many as the com-

bined total for the three rival candidates. Accordingly, despite serious reservations by the military leaders who had deposed him in 1945, he was installed in the presidency once more on January 31, 1951. During his second period in power, Vargas was unable to dominate the political forces of the country or to exploit social and economic trends to his advantage; he endeavoured to abide by the constitution of 1946 and was criticized in some quarters for weak leadership. Lacking a firm majority in the Congress, he could neither enact his own program nor resist the contradictory pressures of his supporters and opponents. The most serious continuing problem was economic. Brazilians were agreed upon the need for more rapid industrial development and measures to ameliorate the effects of gradual monetary inflation, which persisted as government expenditures consistently outran revenues. Vargas maintained a precarious balance between the advocates of greater state intervention in the economy and those who insisted upon a favourable climate for domestic and foreign private investment. The situation was complicated by the simultaneous emotional, antiforeign campaign to nationalize the natural resources of the country. The campaign culminated in the creation of the national petroleum corporation, Petrobrás, in 1953.

For three years Vargas' popularity largely protected him from attack by political adversaries, who directed their criticism against members of his administration. João Goulart, Vargas' young protégé and vice president of the Brazilian Labour Party (PTB), who became minister of labour in 1953, was accused of using his office to transform organized labour into a political machine loyal to Vargas. His sponsorship of a decree doubling the minimum wage, thus strengthening labour–administration ties and contributing to the inflationary spiral, led to his dismissal in 1954. A series of crises followed, climaxed on August 5, 1954, by the murder of an air force officer and the attempted assassination of opposition newspaper editor Carlos Lacerda. Investigation revealed that the assassins had been hired by the President's personal guard. The exposure of widespread corruption within the administration caused a wave of revulsion against the former dictator. A group of army officers presented Vargas with a demand for his resignation; Vargas complied on August 24, 1954, and later that day committed suicide.

Vargas' suicide

Kubitschek's administration. Vice president João Café Filho served out the remainder of Vargas' term. His Cabinet included military leaders who had been instrumental in removing Vargas and civilian moderates who generally favoured political democracy, limited social change, and an orthodox approach to economic ills. Marshal Teixeira Lott, a highly respected professional soldier not identified with any political group, was made war minister. Much of the Café Filho administration was occupied by preparations for the presidential election of October 3, 1955. After the failure of attempts to find a single candidate around whom all major political parties might rally, three strong candidates for the presidency emerged: former Minas Gerais state governor Juscelino Kubitschek de Oliveira, popularly regarded as Vargas' political heir; former São Paulo state governor Ademar de Barros, with broad backing from financial and commercial groups; and Marshal Juárez Távora, considered as the representative of conservative military and civilian groups. In the 1955 election Kubitschek was the victor with slightly more than one third of the total vote, Távora ran a close second, and Barros was a somewhat more distant third; in the separate vice-presidential election, João Goulart won with a large plurality. The election was widely interpreted as a popular vindication of the Vargas position. The illegal but active Communist Party, which had thrown its unsolicited support to Kubitschek, claimed to have provided his margin of victory. Rumours of a Café Filho administration plot to use unconstitutional means to prevent the inauguration of Kubitschek and Goulart were not proved, but the conservative press—which regarded Kubitschek as a dangerous radical—added to the tension. President Café Filho suffered a mild heart attack and on November 8, 1955, transferred power temporarily to his constitutional successor, Carlos Luz, speaker of the Chamber of Deputies. The following day Luz indicated that he would dismiss Marshal Lott to resolve a conflict of authority between the executive and the war minister. This was interpreted by Kubitschek's backers as the signal for a coup d'etat by anti-Kubitschek forces. On November 11, 1955, War Minister Lott and Marshal Odílio Denys, commander of army troops in Rio de Janeiro, staged a "countercoup" to guarantee Kubitschek's inauguration. Luz was deposed, his constitutional successor, Sen. Nereu de Oliveira Ramos, was installed as interim president under a state of siege, and Lott remained as war minister and the strongest figure in the government. Kubitschek and Goulart took office as scheduled and without incident on January 31, 1956.

During his term of office Kubitschek encouraged the widespread spirit of nationalism, appealing to the popular demand for economic development and to the belief that Brazil was destined to become a great power among the nations of the world. Kubitschek felt that the national government should play a vital role in economic areas unattractive to private capital; thus, his administration undertook ambitious developmental programs for the construction of interregional highways and vast hydroelectric power projects, the expansion of iron, steel, petroleum, and coal production, and assistance to the rapidly growing private industrial sector. Perhaps his outstanding accomplishment was the construction of Brasília on an inland plateau 580 miles (930 kilometres) northwest of Rio de Janeiro. Although not yet completed, Brasília was dedicated as the official capital of Brazil on April 21, 1960. The purpose of Brasília was to focus the attention of Brazilians on the interior of the country and to hasten settlement of the region and the development of its largely untapped resources. The new capital was denounced by residents of Rio de Janeiro, but Brazilians elsewhere generally regarded it as a symbol of the nation's future greatness. In inter-American relations, the Kubitschek administration proposed the adoption of Operation Pan America, a cooperative program for the economic development of Latin America, which foreshadowed the Alliance for Progress.

Spread of nationalism

The great material progress during the Kubitschek period was achieved at a high cost in terms of inflation and repeated foreign borrowing. The cost of living and the volume of currency in circulation tripled between 1956 and 1961, while Brazil's large foreign debt nearly doubled. The gross national product rose to unprecedented levels, but living standards for much of the population remained stationary or actually declined. At the same time, indications of large-scale graft and favouritism in public office disturbed even the normally tolerant Brazilian electorate.

Quadros and Goulart. This situation was debated in the electoral campaign of 1960. Again there were three candidates for the presidency: Marshal Teixeira Lott who had served as Kubitschek's war minister for more than four years; Jânio Quadros, the unorthodox former governor of São Paulo and at that time congressman from the State of Paraná; and Adhemar de Barros, then mayor of the city of São Paulo. It was soon clearly a race between Lott and Quadros. Lott received official backing and campaigned on the Kubitschek record. Quadros, who was not a regular member of any political party was supported by the largest conservative party, the National Democratic Union (UDN), and a heterogeneous grouping of lesser political factions. With a new broom as his symbol, Quadros caught the public's imagination as the candidate of the common man. He promised a scrupulously honest administration, curbs on inflation, effective economic development, dignity for the individual, and an aggressively "independent" foreign policy. Goulart was once more a candidate for the vice-presidency. At the polls on October 3, 1960, Quadros won election with a plurality of 48 percent of the popular vote. He received more than 5,600,000 votes, the largest number ever cast for a presidential candidate in Brazil.

Goulart, a political enemy of Quadros, won a narrow victory in the vice presidential race, polling slightly more than 4,000,000 votes. Quadros and Goulart were inaugurated on January 31, 1961.

Control by anti-Vargas groups

The election of Quadros was hailed as a revolution by ballot. For the first time in three decades, anti-Vargas political groups controlled the presidency. Quadros took office in an atmosphere of popular expectation, but almost immediately he encountered resistance from the Congress, where parties loyal to the Vargas tradition still commanded a large majority. Quadros' arbitrary and autocratic manner, which soon alienated many of his former adherents, further reduced the possibility of enacting a meaningful reform program or effective measures to retard inflation. In foreign affairs Quadros was more successful; his foreign policy, which was applauded by ultranationalists and deplored by moderates, seemed designed to move Brazil toward neutralist nations and away from the traditional ties with the United States. He opposed any inter-American action to censure the Castro regime in Cuba and initiated proceedings to resume or establish diplomatic and commercial relations with the Soviet Union and its European satellites. On August 25, 1961, after less than seven months in office, Quadros resigned unexpectedly, alleging that "terrible forces" had deterred him. The congress promptly installed Pascoal Ranieri Mazzilli, speaker of the Chamber of Deputies, as temporary president. Vice president João Goulart, the constitutional successor, was then en route home from a state visit to China.

Succession crisis

Brazil stood at the brink of civil war. Many military commanders and conservatives regarded Goulart as too radical to be entrusted with the nation's highest office, while the great majority of civilian political leaders upheld his constitutional right to the presidency. War Minister Odílio Denys now emerged as the chief spokesman of the anti-Goulart forces, demanding that the Congress declare the office of vice president vacant and hold new elections. The Congress refused. In southern Brazil the commanders of the powerful army and air force units defied orders from the capital and sided with Goulart. Goulart arrived in Pôrto Alegre, insisting that he was already president of Brazil. Faced with the imminent prospect of armed conflict, the Congress and the anti-Goulart group in the military agreed upon a compromise solution: that Goulart be allowed to take office, but only as a figurehead. On September 2, 1961, the parliamentary system of government was adopted by constitutional amendment; most presidential powers were transferred to the newly created post of prime minister. Provision was made for a national plebiscite on the parliamentary experiment before the end of the presidential term. Goulart accepted these conditions and was formally confirmed as president on September 7, 1961.

Once the immediate crisis of the presidential succession was settled, the political parties resumed debate on pressing national issues but postponed significant legislation pending the outcome of congressional elections in October 1962. When these failed to indicate a clear mandate for or against the administration's reform proposals, the opponents of parliamentarianism, led by Goulart, demanded a quick return to presidential rule. On January 6, 1963, a national plebiscite by a margin of more than five to one gave Goulart full presidential powers. Goulart was unable to secure majority support for his legislative program, however, and repeated Cabinet changes and new plans for economic and social development did nothing to restrict inflation and soaring living costs, which reached alarming proportions under Goulart. During the two and one-half years of his administration, there was a tenfold drop in the dollar value of the currency, the cost of living tripled, and the growth of the gross national product, which had been rising by 6 to 7 percent yearly, was brought to a complete halt.

Military intervention. As the situation grew more desperate, cooperation between the regime and its critics became more difficult. The administration identified itself increasingly with the ultranationalistic left, while most of the military officer corps sympathized with the moderate and conservative opposition. Goulart surrounded himself with left-wing advisers. He sought to neutralize the armed forces by frequent command changes and by developing a personal following among noncommissioned officers and enlisted personnel. After failing to obtain authorization for a state of siege, which would have enhanced his powers, Goulart appealed directly to the people for support. At a mass rally in Rio de Janeiro in March 1964, he instituted a controversial agrarian reform and nationalized certain privately owned oil refineries. Many military officers and opposition political leaders had already become convinced that Goulart was seeking to establish a dictatorship of the left. During 1963 active plotting began among separate civilian and military groups in different parts of the country. Gov. José de Magalhães Pinto of Minas Gerais state and Marshal Humberto de Alencar Castelo Branco, chief of staff of the army, emerged as the chief coordinators of the conspiracy. An attempt was made to find a formula to prevent a coup d'etat by the President and still permit him to complete his term in office. At the same time, plans were made to overthrow the regime if necessary. The administration's refusal to suppress a strike by naval enlisted men in late March 1964 was regarded by the opposition as intolerable, for military authority and discipline were considered the last check on Goulart's alleged ambitions. On March 31, 1964, Magalhães Pinto proclaimed a revolution against the government by the civil and military forces in Minas Gerais; the following day he was joined by the political leaders of the States of São Paulo and Guanabara and by the armed forces throughout most of Brazil. On April 2 Goulart fled into exile and two days later he reached Uruguay. The Congress declared his office vacant and designated Mazzilli as interim president until a successor could be chosen to serve out the remainder of term.

Opposition to Goulart

Castelo Branco's administration. With the fall of Goulart, real power passed to the leaders of the revolution, who instituted sweeping political changes. The revolutionary commanders set out to restore economic and financial order, to eliminate what the generals claimed was "Communist infiltration," and to purge corrupt and subversive elements. At the same time they desired to retain a modified form of representative government. On April 9, 1964, these goals were combined in the First Institutional Act, a modification of the 1946 constitution. The executive was granted temporary authority to cancel the mandates of elected officials, to dismiss public servants, and to revoke for ten years the political rights of those found guilty of subversion or misuse of public funds.

The First Institutional Act

During the six months these provisions were in effect, thousands were arrested, and hundreds of persons—including union and government officials and former presidents Goulart, Quadros, and Kubitschek—were deprived of political rights. The Congress was retained as a legislative body with power to debate and amend but not reject proposals submitted to it by the executive. On April 11, 1964, Castelo Branco was elected president by the Congress. José Maria Alkmin, finance minister under Kubitschek, was chosen as vice president. On July 22 the Congress extended the terms of Castelo Branco and Alkmin to March 15, 1967.

Castelo Branco's extended term was regarded by the revolutionaries as a transition period during which sweeping political and economic reforms should be enacted before the nation could again be entrusted to a popularly elected government. It was generally agreed by the new leaders that such alleged shortcomings of the political process as the multiplicity of small, regional, and personalist parties, opportunistic electoral coalitions, and the separate election of president and vice president must be corrected, but they were divided over the best means to attain these ends. The President's determination to achieve reform by legislation, while permitting normal political activities and full freedom of expression by critics of the regime, was challenged by civilian and military extremists who called for dissolution of Congress, abolition of political parties, and suspension of all par-

tisan activities until the revolutionary regime had enough time to consolidate its power.

The test came in October 1965, when gubernatorial elections were held in 11 states and opposition candidates were elected by substantial majorities in the key states of Minas Gerais and Guanabara. The extremists interpreted the results as a great setback for the revolutionary government. Accusing Castelo Branco of not pressing the revolutionary reform program with enough vigour, they blamed him for the defeat of their candidates and demanded that he annul the two elections. When he refused to comply with their demands, they plotted a coup d'etat. At this point, Marshal Artur da Costa e Silva, the minister of war, intervened and persuaded the dissident leaders to keep the peace in return for Castelo Branco's promise to take stronger measures to enact the revolution's reform program.

Emergency measures

On October 27, 1965, Castelo Branco signed the Second Institutional Act, which suspended all existing political parties, restored the president's emergency powers for the remainder of his term, and set October 3, 1966, as the date for new presidential elections. An artificial two-party system was imposed upon the country. The new political parties were the Aliança Renovadora Nacional (or National Renewal Alliance, called Arena), sponsored by the government, and an opposition party, the Movimento Democrático Brasileiro (or Brazilian Democratic Movement; MDB). A third party was theoretically possible, but as a practical matter all active political factions were required to function within those two parties. Arena soon attracted a heterogeneous grouping of pro-administration elements, while the MDB came to be composed largely of former followers of Goulart and of politicians who had broken with the revolutionary regime. Neither party enjoyed strong grass-roots support. Because the president was elected by the Arena-dominated Congress, the MDB refused to nominate candidates. The administration candidates, Costa e Silva and Pedro Aleixo, the minister of education, were elected.

Constitution of 1967

Castelo Branco in December 1966 called an extraordinary session of Congress to approve a new constitution drafted by a government-appointed commission. The new document, promulgated on January 24, 1967, incorporated much of the revolutionary reform program and confirmed the expansion of the power of the executive and of the central government. Important changes included the indirect election of the president and vice president from a single ticket; reduction of the presidential term from five to four years; the use of military courts to judge civilians charged with violation of national security laws; the granting of authority to the president to issue emergency decrees without consulting Congress; and denial to the Congress of the right to delay action on legislation requested by the executive.

The Castelo Branco administration engaged in unprecedented economic planning in order to contain inflation and to revive the flagging economy. It employed emergency powers to limit and regulate sources of credit, to restructure the tax system and collection procedures, and to impose wage and salary controls. These measures affected all sectors of society but bore most heavily on urban labour and white-collar workers, whose real income was held below the rising cost of living. The adverse effects were partially offset by tax incentives to encourage increased industrial and agricultural productivity. At the same time the government poured substantial investments into electric power and transportation to provide for continued orderly economic development. Although the administration did not achieve all of its goals, Brazil's credit rating abroad was firmly re-established, the annual rise in living costs fell from 86 percent in 1964 to 41 percent in 1966, and the increase in the gross national product rose significantly. With the exception of labour, every major sector of the Brazilian economy was on the upswing when Castelo Branco left office.

Administrations of Costa e Silva, Médici, and Geisel. Costa e Silva promised to humanize the revolution, and it was widely expected that he would soon relax the more severe political and economic policies. Yet he did not depart markedly from the course set by his predecessor. His administration rejected petitions for a general amnesty, resisted all proposals to amend the new constitution to restore direct elections, quashed attempts to form a second opposition party, and forcefully suppressed student disturbances. More serious political opposition, however, was muted in part by the government's achievements in the economic field.

Growing opposition

The political situation deteriorated rapidly late in 1968. Faced with a resurgence of public and congressional criticism, Costa e Silva, under strong pressure from the armed forces, seized emergency powers. The Fifth Institutional Act issued on December 13 suspended all legislative bodies indefinitely, authorized the executive to rule by decree, and provided the legal basis for a new purge of outstanding political critics.

When in August 1969 Costa e Silva suffered a paralytic stroke, the government was taken over by the three armed forces ministers, who held power till October when the government selected Gen. Emílio Garrastazú Médici as the new president. Elections for federal and state senators and deputies and municipal officials in November 1970 showed a clear victory for Médici and the Arena party. Disturbances continued, however, through 1970 and 1971, kidnapping of foreign consular and diplomatic officials being added to the arsenal of the dissidents.

Médici in 1971 presented the First National Development Plan, which was aimed at 8 to 10 percent annual economic growth and per capita income of at least $500 (U.S.) per year (in 1972 it was estimated to be $400). Development of the Northeast and the Amazon area, especially by means of a program of road construction and one of redistribution of land, was also planned.

In August 1973 a bill creating the electoral college that from 1974 onward would elect the president and vice president became law. In September the national convention of the Arena party selected as its candidates for president and vice president, respectively, Gen. Ernesto Geisel, a chief executive of the government-owned petroleum company, Petrobrás, and Gen. Adalberto Pereira dos Santos. They were duly elected by the electoral college on January 15, 1974.

The 10th anniversary of the revolution was celebrated by lifting the prohibition on political activities of 106 leaders of the former regime, among them Kubitschek, Quadros, and Goulart. The Fifth Institutional Act, however, remained in force. A surprising victory for the MDB in the congressional elections in November 1974, in which the opposition gained 20 seats in the Senate, was not repeated in the municipal elections of November 1976.

In April 1977 President Geisel dismissed Congress when it failed to pass judicial reforms that he had requested. Under the emergency powers of the Fifth Institutional Act, Geisel then issued decrees instituting those reforms and other electoral and constitutional changes. Among these were provisions for the indirect election of state governors and one-third of the federal senators and the increase of the presidential term to six years. The number of members of the Chamber of Deputies was to be based on the total population of the states instead of on the number of registered voters, and constitutional amendment could be effected by an absolute majority of Congress rather than the two-thirds vote of two successive sessions formerly required.

Brazil's phenomenal rate of economic growth in these years—the gross national product of 1973 was nearly double that of 1964—was halted by the petroleum crisis of 1973–74. Because the country imported 70 to 80 percent of its oil, the trade deficit had risen to $6,000,000,000 by the end of 1976 and inflation had reached an annual rate of 45 percent. A stringent program to reduce government spending and imports and to increase exports was introduced in 1977.

Social and political changes after 1945. In certain respects, the phase of Brazilian political history that began with the overthrow of the Estado Novo and the election of a president and Congress responsible to the electorate ended with the revolution of 1964. The latter event dispelled any lingering doubts that the armed forces were

the strongest political organization in Brazil. The ease with which military leaders assumed and retained power clearly revealed the failure of the postwar political parties to develop into cohesive national bodies capable of winning the respect and allegiance of the voting public and of resolving the critical problems of economic development and social justice. Charges made by the right-wing opposition of the ineffectiveness of populist civilian administrations in the early 1960s paved the way for the retreat after 1964 to paternalistic rule by a narrow elite.

Yet, in a deeper sense, fundamental economic and social trends encouraged by the Vargas regime after 1930 were only slightly modified by the representative governments after 1945 or by the revolutionary governments after 1964. The fact that the political forces that had just regained freedom of expression in 1945 were unanimously agreed upon the need for a new national charter dramatically illustrated their awareness that a return to the pre-1930 status quo was impossible. While the constitution of 1946 borrowed heavily from that of 1891 in certain exterior forms, a comparison of the two charters reveals the nature and extent of the socio-economic transformation that Brazil experienced after 1930. The constitution of 1891, despite its positivist trappings, was essentially a 19th-century liberal document that stressed the rights of the individual and of state governments as opposed to the national administration. The constitution of 1946 largely reaffirmed Vargas' concentration of power in the central government and acknowledged the federal responsibility for maintaining and fostering economic development and social welfare programs. These trends were accelerated under the military rulers in the new national charter of 1967.

Rural and urban developments. The changes that began in 1930 reflect basic socio-economic developments, such as population growth and an increase in urbanization and in participation in the political process, which gave new dimensions and added complexity to Brazilian politics. In 1930 Brazil had a population of about 33,500,000, of whom at least three-fourths were rural and illiterate, hence could not vote. By 1945 the population had risen to about 46,000,000; two-thirds of these were rural and largely outside the political arena. In 1964 the population surpassed 80,000,000 and was divided equally between rural and urban inhabitants; the proportion of literates was also about 50 percent, but at least half of these were under voting age. By the time of the election of 1974, the population had reached almost 105,000,000, of which 56 percent was urban. Attendance at the polls rose to 80 percent of the total of 36,000,000 registered voters. It appeared certain that the bulk of the voters enfranchised after 1930 belonged to the urban working class and government bureaucracy.

Urban proletariat

With the formation of government-directed trade unions in the 1930s, a politically conscious urban proletariat developed. This did not, however, signify the emergence of a true labour-based political movement or an authentic labour party. Leadership of this new political force was contested by the traditional elite, principally landowners and large merchants, and by a new middle class composed of industrial, commercial, and professional persons who had gained elite status. The governments after 1964 continued to control labour organizations in an effort to gain labour support while discouraging the formation of a potentially dissident labour movement.

Before 1966 the new middle class, which had not yet acquired a strong enough sense of class consciousness to regard itself as a distinct social element, did not seek a unified political expression. Rather, it vied with the traditional ruling groups for control of existing political organizations. Members of both groups were found in the leadership of virtually every party for two decades after 1945, although urban-oriented parties grew consistently at the expense of more traditional, rural-based parties. By and large the middle class endorsed the revolution of 1964, but many of its political spokesmen later broke with the revolutionary regime, and middle class political leaders were found in each of the new political parties created in 1965.

Extension of the franchise to illiterates would greatly enlarge the size of the electorate and increase the influence of the lower class on Brazilian politics. It would also enhance the political power of rural society at the expense of the city dwellers. But even though about 59 percent of the rural population was still unable to read and write in the early 1970s and was therefore still denied the vote, the political consciousness of the peasantry had been awakened. Through illegal peasant leagues, founded in the late 1950s, and legitimate rural unions, which were authorized in 1962, many peasants were able for the first time to make their needs known to the political leaders. Before the revolution of 1964, the Communists, a few clergymen, and members of nearly all legal parties were competing for the allegiance of the rural masses, appealing to their demands for social justice and higher standards of living. Although most peasant organizations were abolished and many agitators were jailed or exiled after 1964, limited measures were enacted by the federal government to assuage rural unrest. The peasantry remains potentially the most powerful political force in Brazil.

Rural political power

The church. After 1964 the Roman Catholic Church in Brazil, as one of the few effective institutions organized nationwide, was drawn into the partial political vacuum caused by the purge of populist civilian leaders and the abolition of established political parties. Several bishops led the secular and regular clergy in denouncing the government's apparent indifference to the vast inequities in Brazilian society. Clerics also served as champions of the right of dissent, and by the late 1960s the church had become a rallying point for political opposition.

The armed forces. The armed forces, final arbiters of the political process in Brazil, were neither blind nor indifferent to the objectives of the new groups that entered the political scene after 1945. The traditional alliance of the military forces and conservative rural landholders had long since been replaced by an informal similarity of views between military officers and urban middle class sectors. The armed services consistently defended centralized government, rapid industrialization, and the development of an efficient, organized labour force. They were quick, however, to resent the exploitation of organized labour by political leftists as a counterweight to the political influence of the military officers. Between 1945 and 1964 no single political party was able to elect a president or a majority in Congress. Because this situation encouraged political irresponsibility, the armed forces, always at the behest of civilian political elements, intervened on four occasions to protect national institutions against what they considered to be civilian incompetence. Beginning in 1964, military leaders initiated a major revision of the political system, which, in their view, would make it impossible for men who placed partisan before national interest to come to power.

Influence of the armed forces

Brecht, Bertolt

Twentieth-century German poet, playwright, and theatrical reformer, Bertolt Brecht expressed in his work the moral and political dilemmas of a mass society in which man is isolated and helpless. In turn influenced by the symbolist poetry of Paul Verlaine and Arthur Rimbaud, the expressionism of playwrights such as August Strindberg and Frank Wedekind, and the terminology of Marxism, in the end he arrived, like most great writers, at a language that was his alone: simple, precise, and blunt—a language that made him one of the masters of modern German.

Ullstein Bilderdienst

Brecht, 1931.

Eugen Berthold Friedrich Brecht (who later changed his name to Bertolt) was born on Feb. 10, 1898, at Augsburg, Bavaria, where his father was managing director of a paper mill. Both sides of his family were of peasant stock; his father was a Roman Catholic, his mother a Lutheran. Brecht himself was raised as a Lutheran and always acknowledged the influence of Luther's earthy and direct Bible translation on his own writing style.

After graduating from secondary school in Augsburg, Brecht entered the University of Munich in the fall of 1917 as a medical student. But from the first he showed a greater interest in literature and drama; he had already published poems in an Augsburg newspaper. When he was called for military service in the last year of World War I, the fact that he had studied medicine kept him from being sent to the front; he was inducted into the medical corps and through his father's influence was assigned to the military hospital of his home town. Although in later life he tended to exaggerate the horrors which he had witnessed in the military hospital (he had worked in the venereal disease clinic), there can be no doubt that his experiences in the military service made him a lifelong pacifist and determined his later political outlook.

Early career. In his early years Brecht was the centre of a circle of devoted followers, among them the painter and designer Caspar Neher, who was to remain Brecht's close collaborator to the end of his life. Brecht wrote, composed, and sang his songs and ballads to these friends, and he read them his early plays. In 1918 he completed his first play, *Baal*, a wild and powerful effusion on the life of a young poet, so drunk with life that he abandons all social convention and becomes a vagabond and murderer.

After the collapse of the Kaiser's Germany, Brecht returned to Munich, but devoted less and less time to his university studies, and more and more to the theatre; for a time he acted as drama critic for the left-wing Augsburg newspaper *Der Volkswille*. In 1919 Brecht submitted his second play, *Spartakus* (later renamed *Drums in the Night*) to Lion Feuchtwanger, then the literary adviser of one of the Munich theatres, the Kammerspiele, and later famous as a novelist. Feuchtwanger, who was also to become a lifelong friend of Brecht's, instantly recognized the great merits of the play, which, when it was performed on Sept. 29, 1922, brought the young playwright immediate recognition and the award of the coveted Kleist-Preis, a literary prize for the most promising young dramatist of the year. Having achieved his first decisive success Brecht, in November of that year, married the actress Marianne Zoff.

Pre-Marxist phase

Drums in the Night, a play about a German soldier who returns from World War I, finds his fiancée pregnant by another man but nevertheless elects a comfortable life by her side rather than joining the communist revolutionary uprising of the Spartakists in January 1919, was followed first by the equally cynical and disillusioned *In the Jungle of the Cities* (first performed at Munich in March 1923) and then by Brecht's own production of his adaptation—in collaboration with Feuchtwanger—of Christopher Marlowe's *Life of Edward II* at the Munich Kammerspiele in 1924. In 1924 Brecht moved to Berlin, Germany's political and theatrical capital. There he worked for a time as a dramaturg (a play reader and editorial assistant) in Max Reinhardt's Deutsches Theatre and again became the centre of a circle of left-wing artists and intellectuals. In 1928—having been granted a divorce from his first wife—he married the actress Helene Weigel.

The main impulse of Brecht's art is a violently antibourgeois attitude that reflects his generation's deep disappointment in the civilization that had come crashing down at the end of World War I. Among Brecht's friends were members of the Dadaist group that aimed at destroying what they condemned as the false standards of bourgeois art through derision and iconoclastic satire. Brecht's own antibourgeois attitude took the form of a cynical anarchism that found its most perfect expression in the poems of *Hauspostille* ("Domestic Breviary"; translated by Eric Bentley under the title *Manual of Piety*) which appeared in 1927; these are the poems of a young man who feels threatened by the irrational violence of nature, sex, aggression, and death, and yearns for a cynical detachment from these primordial forces. It was first through his discovery of Marxism and second through his commitment to the political discipline of a cause that promised a solution to the ills of mankind as based on an assertedly scientific analysis of history, that Brecht mastered the threat of anarchic nihilism. The man who taught him the elements of Marxism in the late nineteen twenties was Karl Korsch, an eminent Marxist theoretician who had been a Communist member of the Reichstag but had been expelled from the German Communist Party in 1926.

Marxist influence

The mature playwright. The transition from the wild exuberance, as exemplified in *Baal*, of his pre-Marxist phase (dominated by the influence of such writers as the French symbolist poets Paul Verlaine and Arthur Rimbaud, the English novelist Rudyard Kipling, and the German dramatists Georg Büchner and Frank Wedekind) to the severely controlled Marxist writings of the early nineteen thirties is marked by plays like *A Man's a Man* (first performed at Darmstadt in September 1926), *The Threepenny Opera* (which in its premiere at the Schiffbauerdamm Theatre in Berlin on Aug. 31, 1928, gave Brecht his first great popular success—though much of the success was due to Kurt Weill's music), and the opera *Rise and Fall of the City of Mahagonny* (music by Kurt Weill; first performed at Leipzig on March 9, 1930).

Didactic plays

In these plays the forces of chaos, sex, greed, and violence are already seen from the point of view of a personality who identifies them with the cruelty and selfishness of capitalism. In a series of *Lehrstücke* (didactic plays) and *Schulopern* (didactic operas) Brecht began to preach the Marxist gospel of self-discipline and self-denial in the interests of mankind in a new style of austerity and compression. The exuberant images of his earlier writing made way for the terse statement of the Marxist's "scientific fact." Foremost among the didactic plays are *The Flight of the Lindberghs* and the *Didactic Play of Baden on Consent* (in which consent stands for self-discipline even up to the point of agreeing to one's own

annihilation) which received their first performances in 1929; *He who says Yes* and *He who says No* (both variants of a Japanese No play, also concerned with the problem of suicide for the common good), *The Exception and the Rule* and *The Measures Taken* (all dating from 1930). *The Measures Taken* (*Die Massnahme*) a dramatic cantata—with music by Hans Eisler—is one of Brecht's masterpieces. It deals with a young Communist revolutionary in China who breaks party discipline and then asks to be liquidated so that the struggle he endangered can be continued.

These short didactic pieces were followed by two full-length plays of a severely didactic nature. The first, performed on Jan. 12, 1932, was *The Mother*, an adaptation of Maksim Gorky's novel of the same name. The second, *St. Joan of the Stockyards*, was an attempt to analyze the causes of the great depression through an account of meat speculation in the Chicago stock market. Owing to the political situation in Germany the play could not get a stage performance but was broadcast in a shortened version on April 11, 1932.

When Hitler came to power on January 30, 1933, it was clear that Brecht could not remain in Germany. A long period of exile began. Brecht first went to Denmark where he acquired a house near the town of Svendborg on the island of Fyn. In the first years after the Nazi rise to power, when Brecht was mainly occupied by the day-to-day struggle against Hitler, his work was primarily propagandistic, so much so that some of it remained largely ephemeral; *e.g.*, the play *The Roundheads and the Peakheads*, a satire on racism; *Fears and Miseries of the Third Reich*, a sequence of short scenes on life in Hitler's Germany; and *Señora Carrar's Rifle*, a play on the Spanish Civil War.

The great plays. After the occupation of Austria in March 1938, when it became clear to Brecht that war was inevitable and that nothing he could do could alter the course of events, he reverted to work that reflected his deeper personal and philosophical concerns. Thus began the fourth and most creative phase of his life; it produced plays that combine the exuberance of his youthful phase with the severe ideological discipline of his didactic period and fused these elements in a series of deeply felt poetic parables. Foremost among the plays of this period are: *The Life of Galileo*, which deals with the responsibilities of a man of genius in a hostile world; *The Good Woman of Setzuan*, a parable on the question whether it is possible to be a good human being in a society based on greed; *Mother Courage and her Children*, a bold canvas of the Thirty Years' War that shows that even simple people are responsible for war's brutalities if they contribute, in however small a way, to the war's conduct.

Poetic parables

As the Second World War approached, Brecht no longer felt safe in Denmark, and in April 1939 he moved to Sweden. A year later he was again on the move, this time to Finland, where he wrote a play with a Finnish setting, *Mr. Puntila and his Servant Matti*, another parable on the impossibility of combining human kindness with efficiency as a capitalist, and *The Resistible Rise of Arturo Ui*, the story of Hitler transferred to a setting among Chicago gangsters.

Brecht was determined to escape the horrors of war in Europe. It is notable that he, the committed Marxist sympathizer, and onetime co-editor of a German literary review published in Moscow from 1936 to 1939, did not even consider settling in the Soviet Union. Instead, after receiving his U.S. visa in Helsinki in May 1941 he travelled to the United States by crossing the entire Soviet Union and taking a ship from Vladivostok only a few days before the German invasion of Russia.

Brecht in the U.S. In the United States Brecht lived at Santa Monica, California, but visited New York several times for extended periods. He tried to work for the Hollywood film industry but sold only one script, *Hangmen Also Die*, which Fritz Lang directed in 1942. Yet it was in the United States that he completed his last great play, *The Caucasian Chalk Circle*, another bold treatment of the problem of goodness and the difficulties of achieving justice in a wicked world.

In Hollywood Brecht met the British actor Charles Laughton and worked with him on an English version of his *Galileo* which, Laughton realized, contained an ideal part for him. Laughton opened as Galileo in Los Angeles in July 1947; a Broadway production was due to open at the end of that year. It seemed that Brecht was at last to find fame and recognition in the United States. But on October 30, 1947 he appeared under subpoena as a witness before the House of Representatives' Committee on Un-American Activities, which was investigating Communist sympathizers in the Hollywood movie community. Brecht parried the inept questioning of the committee's investigators with such brilliant evasiveness that he was congratulated on being a cooperative witness. But the experience proved so distasteful to him that the following day he left for Europe.

Berliner Ensemble. With his usual caution he did not hurry to return to Germany, but settled first in Switzerland to explore the possibilities of finding a theatre where he could put into practice his theories about staging his plays. He was much attracted by Austria, as a German-speaking area from which he could visit both West and East Germany; at one time it looked as though he might be offered the post of artistic director of the Salzburg Festival, and he applied for Austrian citizenship. In October 1948 he was invited to East Berlin to produce his play *Mother Courage*. After the play opened, with immense success, on Jan. 11, 1949, Brecht returned to Zürich and continued to press for his Austrian citizenship; but when he was offered the chance to have his own company of actors, the Berliner Ensemble, in East Berlin, he finally decided to settle there instead. On Nov. 12, 1949, the Berliner Ensemble officially opened with *Puntila*. Yet even then, Brecht, who wanted freedom to travel wherever he wanted to go, persisted in seeking Austrian nationality, which was granted him in April 1950. He also vested the copyright of his plays with a West German publisher, thus retaining a measure of freedom from East German censorship and keeping his Western earnings in the West.

In East Berlin Brecht at last had an opportunity of testing his theories about the stage by producing the great plays he had written in the years of exile. His theory of drama is contained in *A Little Organum for the Theatre*, which he had completed in Zürich in 1948.

Theory of drama

The essence of his theory of drama is the idea that a truly Marxist drama must avoid the Aristotelian premise that the audience should be made to believe that what they are witnessing is happening here and now. For he saw that if the audience really felt that the emotions of heroes of the past—Oedipus, or Lear, or Hamlet—could equally have been their own reactions, then the Marxist idea that human nature is not constant but a result of changing historical conditions would automatically be invalidated. Brecht therefore argued that the theatre should not seek to make its audience believe in the presence of the characters on the stage—should not make it identify with them, but should rather follow the method of the epic poet's art, which is to make the audience realize that what it sees on the stage is merely an account of past events that it should watch with critical detachment. Hence, the "epic" (narrative, nondramatic) theatre is based on detachment, on the *Verfremdungs-Effekt* (distancing effect), achieved through a number of devices that remind the spectator that he is being presented with a demonstration of human behaviour in a scientific spirit rather than with an illusion of reality, in short, that the theatre is only a theatre and not the world itself.

In East Berlin Brecht, the Bohemian rebel of the Berlin of the 1920s, became the grand old man of the East German Communist régime. Under his direction, the Berliner Ensemble won worldwide acclaim and toured eastern and western Europe. But Brecht also had his share of difficulties with the Ulbricht régime. In 1951 the opera *The Trial of Lucullus* (based on a radio play by Brecht dating from 1940, with music by Paul Dessau) had to be withdrawn after a few performances because the government objected to its pacifism. In 1954 the Berliner Ensemble moved into its own theatre building, the old

Schiffbauerdamm theatre, where *The Threepenny Opera* had had its triumphant opening in 1928. In May 1955 Brecht went to Moscow to receive the Stalin Peace Prize. On Aug. 14, 1956, shortly before the Berliner Ensemble made its debut in London, Brecht died of a heart attack.

Assessment. Although his attempts to create a truly Marxist aesthetics of the drama are open to criticism, his importance as a playwright and, above all, as a poet, is beyond question. His later poetry, which expresses his melancholy disillusionment with the ideals of his youth, is, in its terseness and simplicity, among the greatest German verse of this or any other epoch. In his great plays Brecht's refusal to let his political commitment override his vision of the world produces a depth of insight and a richness of character rare in modern drama. Brecht's example illustrates the problem and the paradox of the committed writer: his commitment to Marxism gave him a strong motivation to write and a firm viewpoint from which he could survey the world; but at the same time his integrity as a poet prevented him from departing from the truth of characterization, the true dramatist's impartiality when dealing with his characters. Thus Brecht's later plays, though conceived as lessons in Marxism, transcend his intention and emerge as great drama.

MAJOR WORKS

THEATRICAL WORKS: *Baal* (published 1922, performed 1923; Eng. trans., 1970); *Trommeln in der Nacht* (performed 1922, published 1923); *Im Dickicht der Städte* (performed 1923, later revised, published 1927; trans. as *In the Swamp*, 1961; *In the Jungle of Cities*, 1970); (with Lion Feuchtwanger), *Leben Eduards des Zweiten von England* (1924, adapted from Marlowe's *Edward II; Edward II*, 1961; *The Reign of Edward the Second of England*, 1971); *Mann ist Mann* (performed 1926, later revised with music by Kurt Weill; 1st version published 1927, 2nd version published 1938; *A Man's a Man*, 1961; *Man is Man*, 1966; *Man Equals Man*, 1971), to which is attached the one-act farcical interlude or entr'acte, *Das Elefantenkalb* (*The Baby Elephant*, 1956; *The Elephant Baby*, 1971); *Die Dreigroschenoper*, a ballad opera based on John Gay's *The Beggar's Opera* (1728), with music by Kurt Weill (performed 1928, published 1929; later revised, *The Threepenny Opera*, 1955); *Aufstieg und Fall der Stadt Mahagonny*, opera with music by Kurt Weill (performed and published 1930; several later versions *Rise and Fall of the City of Mahagonny*, 1956; *Rise and Fall of the Town Mahagonny*, 1971, based on *Mahagonny* (trans. as *The Little Mahagonny*, 1957), a *Singspiel* (performed 1927, published posthumously 1965); *Die heilige Johanna der Schlachthöfe* (performed 1932, published 1933, later revised with music by Paul Dessau; *St. Joan of the Stockyards*, 1962); *Der Jasager* and *Der Neinsager*, two school operas intended to be performed together, based on Arthur Waley's Eng. trans. of the Japanese Nō play, *Taniko*, with music by Kurt Weill (*He Says Yes* and *He Says No*, 1960; *He Who Says Yes* and *He Who Says No*, 1971); *Die Massnahme*, a *Lehrstück*, or didactic piece, with music by Hanns Eisler (performed 1930, published 1931; trans. as *The Punitive Measures*, 1956; as *The Measures Taken*, 1959; and *The Expedient*, 1971); *Die Ausnahme und die Regel*, short *Lehrstück* for schools (published 1937, performed with music by Paul Dessau, 1947; trans. as *The Rule and the Exception*, 1939); *Die Mutter* (1932); *Lehrstück* based on Gorky's novel, with music by Hanns Eisler; *Die Rundköpfe und die Spitzköpfe*, with music by Hanns Eisler (first professionally performed in a Danish version, 1936, published 1938; *Round Heads and Pointed Heads*, 1958; *Round Heads, Peak Heads*, 1971); *Die sieben Todsünden der Kleinbürger* (1933), libretto for ballet with choreography by George Balanchine, based on 10 poems by Brecht with music by Kurt Weill, also known as *Die sieben Todsünden* and as *Anna-Anna* (trans. by Chester Kallmann and W.H. Auden, *The Seven Deadly Sins of the Petty Bourgeoisie*, 1959); *Furcht und Elend des dritten Reich* (performed 1937, partially published Moscow 1941, fuller version New York 1945, revised version Berlin 1948), consisting of 24 (or 32) short scenes linked by poem, with music by Hanns Eisler (1st version trans. as *The Private Life of the Master Race* (1944; revised version trans. as *Fear and Misery of the Third Reich*, 1970); *Die Gewehre der Frau Carrar*, one-act play based on J.M. Synge's *Riders to the Sea* (1904; first performed London 1937, *Señora Carrar's Rifles*, 1938); *Leben des Galilei*, with music by Hanns Eisler (1st version performed 1943, 2nd version written in English by Brecht and Charles Laughton and performed as *Galileo*, New York 1947; revised version performed and published in German 1955, *The Life of Galileo*, 1960); *Mutter Courage und ihre Kinder*, based on Grimmelshausen's *Die Landstörtzerin Courasche* (1669), with music by Paul Dessau (performed Zürich 1941, published 1949; *Mother Courage and Her Children: A Chronicle Play of the Thirty Years' War*, 1948; *Mother Courage and her Children*, 1962); *Das Verhör des Lukullus* (broadcast 1940, 1st version published Moscow 1940, expanded version with music by Roger Sessions performed London 1947, published London 1955; *The Trial of Lucullus*, 1960), the basis of the opera *Die Verurteilung des Lukullus*, with music by Paul Dessau (performed 1951); *Der gute Mensch von Sezuan*, parable play with music by Paul Dessau (performed 1943, published 1956, several revised versions; trans. as *The Good Woman of Setzwan*, 1961; *The Good Person of Szechwan*, 1962); *Herr Puntila und sein Knecht Matti*, a *Volksstück*, or "folk play," 12 short scenes linked by the "Puntila-Song," with music by Paul Dessau (performed 1948, published 1956; trans. as *Mr. Puntila and His Hired Man Matti*, 1954; *Herr Puntila and his Man Matti*, 1962); *Der aufhaltsame Aufstieg des Arturo Ui*, parable play (performed 1958 by the Staatstheater, Stuttgart; published posthumously 1957; *The Resistible Rise of Arturo Ui*, 1965; *Arturo Ui*, 1968); (with Lion Feuchtwanger), *Die Gesichte der Simone Machard*, with incidental music by Hanns Eisler (performed and published posthumously 1957); *Schweyk im zweiten Weltkrieg*, based on Jaroslav Hašek's novel *The Good Soldier Schweik* (pub. in Czech, 1920–23), with music by Hanns Eisler (performed 1956, published posthumously 1959; *Schweyk in the Second World War*, 1963); *Der kaukasische Kreidekreis*, parable play with music by Paul Dessau (first performed in English as *The Caucasian Chalk Circle*, Northfield, Minnesota 1948; published Berlin 1949, later revised, performed in German 1955; published 1956, Eng. trans. of revised versions 1960 and 1963); *Die Antigone des Sophokles*, based on Hölderlin's translation 1804 (performed 1948, published 1949; later revised as *Antigone*, 1956); *Die Tage der Commune*, unfinished, performed with music by Hanns Eisler (published posthumously 1957; *The Days of the Commune*, 1962); *Der Salzburger Totentanz*, unfinished morality play (published posthumously 1959). (ADAPTATIONS AND TRANSLATIONS): *Der Hofmeister* (performed 1950, published 1954), from Lenz's comedy of the same name, 1774; *Coriolan* (published posthumously 1959), from Shakespeare's *Coriolanus; Pauken und Trompeten* (performed 1956, published posthumously 1964), from George Farquhar's *The Recruiting Officer*, 1706; with songs added by Brecht and music by Rudolf Wagner-Régeny.

POETICAL WORKS: *Hauspostille* (1927, revised 1951, poems written 1913–26 and first collected in *Taschenpostille*, privately printed, 1926; Eng. trans. in Eric Bentley's bilingual ed., *Die Hauspostille: A Manual of Piety*, 1966); "Die drei Soldaten," narrative poems for children, published in Brecht's *Versuche #6* (1932); *Lieder, Gedichte, Chöre*, Paris (1934), songs from plays, etc., with settings by Hanns Eisler; *Svendborger Gedichte* (1939), poems written in exile in Denmark; *Gedichte im Exil. Buckower Elegien* (published posthumously 1964), poems written in exile in Denmark and Finland; *Hundert Gedichte, 1918–50* (1952); *Bertolt Brechts Gedichte und Lieder* (1956), a posthumous collection by Peter Suhrkamp; *Letzte Gedichte*, Brecht's last poems (written 1953–56, published 1957). Many of Brecht's poems were first published posthumously in *Gedichte*, 9 vol. (1960–65); Eng. trans. of 50 poems with German text in H.R. Hays (ed. and trans.), *Selected Poems of Bertolt Brecht* (1959).

PROSE (NARRATIVE): *Der Dreigroschenroman* (1934), novel with songs; trans. by Desmond Vesey and Christopher Isherwood as *A Penny for the Poor* (1937, retitled *The Threepenny Novel*, 1956). (TALES, NOVELLEN, and SKETCHES): *Geschichten vom Herrn Keuner* (1930 and 1958), aphoristic anecdotes; *Kalendergeschichten* (1948), short stories, Keuner anecdotes, with some narrative poems; *Tales from the Calendar* (1961); *Die Geschäfte des Herrn Julius Caesar. Romanfragment* (published posthumously 1957), unfinished historical novel in diary form. Many of Brecht's short stories and sketches were first published posthumously in *Prosa*, 5 vol. (1965–67). (WRITINGS ON THE THEATRE AND AESTHETICS): (Some of these works were first published in periodicals and newspapers, and first collected or published after Brecht's death. Prefaces, Notes, to his own works and Productions collected in *Schriften zum Theater*, 7 vol. (1964–67). Accounts of Productions containing early drafts, scenarios, and photographs: *Antigonemodell 1948* (1949), the first of Brecht's "modellbücher" of productions; *Die Geuehre der Frau Carrar* (1952); *Aufbau einer Rolle: Galilei* (1956); *Couragemodell 1949* (1958).

(OTHER PROSE): *Flüchtlingespräche* (published posthumously 1962), autobiographical and philosophical dialogues written in exile 1940–41; *Me-ti: Buch der Wendungen* (written 1934–51, unrevised), Brecht's unfinished philosophical, political, and ethical "breviary."

BIBLIOGRAPHY. A complete bibliography of Brecht's writings published up to the time of his death by WALTER

NUBEL may be found in the Second Special Brecht Number of the East German periodical *Sinn und Form* (1957); a concise summary of Brecht literature is contained in *Bertolt-Brecht-Bibliographie* by KLAUS-DIETRICH PETERSEN (1968). Brecht's voluminous literary remains are held in the Bertolt Brecht Archiv in East Berlin. The first volume of a catalog of these works, *Bertolt Brecht Archiv: Bestandsverzeichnis des literarischen Nachlasses* (1969), is devoted to Brecht's dramatic work. Collected works in the original German are available in an edition in 8 thin-paper or 20 paperback volumes: *Gesammelte Werke* (1967). This edition, however, is far from complete and the principles according to which it was edited are open to doubt. A major collected edition of Brecht's works in English, under the joint editorship of JOHN WILLETT and RALPH MANHEIM started publication with the first volume of *Collected Plays* (1970). ERIC BENTLEY has edited *Seven Plays by Bertolt Brecht* (1961), a series of paperback volumes of Brecht's plays, and has translated the poetry collection, *Hauspostille* (1927; *Manual of Piety*, 1966). A good selection of Brecht's theoretical writings is *Brecht on Theatre*, trans. by JOHN WILLETT (1964).

Critical and biographical works available in English include: JOHN WILLETT, *The Theatre of Bertolt Brecht* (1959); MARTIN ESSLIN, *Brecht: A Choice of Evils* (1959; revised edition under the title, *Brecht: The Man and His Work*, 1971); and FREDERIC EWEN, *Bertolt Brecht: His Life, His Art and His Times* (1967, 1970). MAX SPALTER, *Brecht's Tradition* (1967), analyzes the chief influences on Brecht in German literature. (M.J.E.)

Bremen

Bremen, situated on the Weser some 43 miles (70 kilometres) from the North Sea, is one of the largest ports of West Germany and one of the more dynamic of that nation's cities. It is also one of the major industrial cities of northern Europe. Together with the port of Bremerhaven, situated 37 miles (59 kilometres) to the north, it forms the *Land*, or state, of Bremen, smallest of the ten *Länder* of the Federal Republic of Germany but of vital economic significance. This article describes both the *Land* and the city that dominates it.

The earliest settlement (called *Breme* or *Bremum*) on the right bank of the river was favoured by an advantageous position at the junction of important early trading routes from the Rhine River to the Elbe and from the North Sea to southern Germany. In 787 Charlemagne, the Western (Holy Roman) emperor, established the diocese of Bremen (to become an archbishopric in 845), which became the base for missionary activity covering the whole of northern Europe. The market rights—including customs and coinage—that were conferred on Bremen in 965 brought increased mercantile activity, and the young city soon became one of the commanding religious and economic centres of north Germany, especially after entering the Hanseatic League—an economic and political association of the rising urban mercantile class—in 1358. The imperial free city, as Bremen became known, occupying a strongly fortified position on either side of the Weser, defended its independence in the Thirty Years' War (1618–48) and later repelled both Swedish and Hanoverian aggression. As an autonomous republic—the oldest in Germany—it joined the German Confederation in 1815 and the reconstituted German Empire in 1871. It attained increasing economic importance as a leader in international trade and world shipping by entering the German customs union (Zollverein) in 1888, through expanding its port facilities, and by developing manufacturing industry.

Medieval heritage

The city of the early 1970s is an interesting amalgam of medieval and modern architecture. The outstanding features in the Altstadt, or Old Town, in the restored heart of the city, are the famous marketplace with its 11th-century cathedral; the Gothic Town Hall with its Renaissance facade; the statue of Roland (1404), symbolizing market rights and imperial jurisdiction; a picturesque row of old, gabled houses; and the modern-style Parliament. Districts heavily bombed in World War II (69 percent of the houses were destroyed) have since been rebuilt, allowing for growing traffic and extensive public parks. About three miles from the city centre, the modern satellite town of Neue Vahr, built between 1957 and 1962, accommodates 40,000 people and is one of a ring of peripheral settlements that have coalesced with the expanding and dynamic city.

The site. Located at the first ford above the river estuary, the Old Town grew on a sand dune, sited above flood level on the Weser spillway, the glacially widened river channel. The windblown sand accummulated, in the postglacial period, up to a height of 45 feet (15 metres) above the flat marshes and moors of the Bremer Becken (lowlands). Because of the effect of North Sea tides and of the high subterranean water level, 71 miles of dikes, associated with a complicated drainage system, play an important role in the Bremen urban area. The dune—25 miles long and two miles wide—has thus decisively influenced the northward and southward expansion of the city. The territorial possessions of the city also included large sections of the swampy, cultivated lowlands and stretches along the Weser, which became associated with the rise of further smaller settlements. The gradual incorporation of these rural communities—which had always had close economic relations with Bremen—started in 1849 and in 1945 brought the administrative area of the city of Bremen to its contemporary size of approximately 125 square miles (324 square kilometres).

The people. With a total population that passed 600,000 in the late 1960s, Bremen ranks among the 10 largest cities in the Federal Republic of Germany. A small town of only 30,000 inhabitants a century and a half ago, its subsequent growth, closely linked with its economic development, occasioned a population rise that reached 162,000 by 1880 and 264,000 in 1920. By the end of World War II, the population of the war-torn city had dropped from 424,000 (1939) to 362,000, but it rose sharply with the extensive postwar reconstruction. By the early 1970s, Bremen population was characterized by an annual birthrate of less than 2%. This, together with an insignificant inward migration rate, made it one of the more demographically stable German cities. The age structure of the population shows that some 21% are under 15, 66% in the age group from 15 to 65, and 13% over 65. As might be expected in an industrial city nearly half of the 15 to 65 age group are employed (66% of the men and 34% of the women). Living as they are in the heart of the strongly Protestant north of Germany, some 83% of Bremen citizens are members of the Protestant Church, with only 10% adhering to the Roman Catholic faith.

Economic life. In the early 1970s, the economic life of the *Land* continued to reflect the historic interconnection of shipping, foreign trade, and industry. The port facilities of Bremen and Bremerhaven, which, administratively and economically, form one unit, incorporate free-port status, whereby imported goods can be handled and stored without time limits and without customs formalities. The turnover of goods in the two ports—some 16% of the national total—reached an annual total of 20,000,000 tons by the close of the 1960s, more than half of which were imported. Bremerhaven handles about a quarter of the total tonnage, just over half of which is mixed cargo, the remainder being composed of such bulk goods as grain, coal, ore, and oil. The merchant fleet of Bremen—whose number rose sharply after the foundation of the Norddeutscher Lloyd Shipping Company in 1857—consisted, by the early 1970s, of over 370 seagoing vessels (totalling 1,370,000 gross registered tonnage) and 30 barges (totalling almost 200,000 gross registered tonnage). The port of Bremerhaven was the home of the largest German fishing fleet, consisting of more than 85 trawlers of about 80,000 gross registered tonnage.

Traditional port function of the city

In Hanseatic times, Bremen's importance rested almost entirely on its character as a trading centre and as a seaport for handling raw materials and foodstuffs. Grain from the Baltic countries, for example, was sent to western Europe via the city, and, in return, wine, salt, and, later, colonial products—notably cotton, for which it was the European marketing centre—passed through it. Since the end of the 18th century, the port has handled, in in-

creasing quantities, grain (14% of the total West German imports by 1970), timber (19%), coffee (36%), tobacco (40%), wool (65%), and cotton (67%). These items are manufactured on a large scale by local firms, which are among the biggest of their kind in the country.

Originally, the city's entire industrial potential—except for food industries—depended upon the shipyards and their supporting firms. By means of industrial enterprises founded after 1900, the Bremen economy increasingly became more diversified, supplying the internal market and ensuring sufficient freight for outward-sailing ships. Steel for the city's shipbuilding industry—the seven major companies of which comprised more than 20 percent of the national shipyard capacity by the 1970s—derives from local steelworks, the output of which exceeds 2,000,000 tons annually. In addition, machine-building industries specialize in engines and equipment for ships and trucks and machinery for growth industries. The aircraft industry comprises more than one-third of the total German capacity. Production in the electrical industry ranges from industrial equipment to radio and television sets and modern electronic materials. By the early 1970s, about 700 industrial firms in the region employed 85,000 workers, with capital goods industries accounting for half of the workers, the food industry 21%, consumer goods industries 16%, and raw materials industries 13%.

Diversification

Political and governmental institutions. Bremen *Land*, the overall administrative unit, has a total area of 156 square miles (404 square kilometres), and the population exceeded three-quarters of a million by 1970. The city of Bremerhaven, which covers 31 square miles (80 square kilometres) and had a population of about 150,000 by the early 1970s, was founded as an outer port for Bremen because of the silting up of the lower Weser: it joined the Bremen *Land* in 1947.

A new constitution, adopted in the same year, placed the legislative power in the City Council (Bürgerschaft). The council appoints the executive body (Senate), which is composed of a president (Bürgermeister) and nine senators. Bremen entered the 1970s dominated by a left-centre coalition of Social Democrats (holding 50 council seats) and Free Democrats (ten seats). The right-centre Christian Democrats held 32 council seats; and others, eight seats. The council—which has 80 members from Bremen and 20 from Bremerhaven—and the Senate are elected every four years. The *Land* has three seats in the Upper House of the Federal Council (Bundesrat).

Services. In the early 1970s, more than 45 percent of all Bremen employees worked in commerce, transport, and various services. Bremen is the home of several banks, insurance companies, a stock exchange, and cotton- and tobacco-marketing centres. The importance of its overseas connections is illustrated by the presence of consulates of 30 countries. Warehouses, stores, and specialist shops also cater for people from the surrounding rural area, while imports and exports are dealt with by numerous shipping companies and agents. The railways are an important factor in the transportation of piece (cloth) goods, carrying 60 percent of the total, as other links between the port and its hinterland were slow to develop. Quick electric passenger trains and motorways link modern Bremen with the country's major cities; and, apart from direct flights to London and Amsterdam, Bremen airport is connected with many inland airports, handling more than a quarter of a million passengers annually by the 1970s.

Transportation links

The city has about 150 primary and secondary schools, 18 vocational schools, 14 academies, a number of technical schools—among which are a school of engineering, and a merchant marine school—and a teacher's training college. A university was under construction by the early 1970s. Bremen has a radio and television transmitting station, and three daily and two weekly newspapers are published.

Cultural life and recreation. Four theatres, 11 libraries and archives, and 19 museums and galleries contributed to the rich cultural life of Bremen in the early 1970s. Most of these facilities were concentrated in the pleasant surroundings of the old town, especially in the Schnoorviertel, a district that was restored to its original 16th- and 17th-century appearance in the post-World War II reconstruction. In keeping with the worldwide connections of the city, international congresses are often held in Bremen, which offers about 100 hotels, several conference halls, and a congress hall seating 10,000 people. As in many German industrial cities, there are extensive sports grounds, associated with 240 or more clubs. Parks, located all over the city, offer a relaxing contrast to the often hectic pace of economic activities. The best known are the Bürgerpark, with its famous rhododendron gardens, and the former ramparts, which were demolished in 1802 and which now form promenades surrounding the Old Town.

Brethren

The Brethren (Church of the Brethren, Brethren Church, National Fellowship of Brethren Churches, Old German Baptist Brethren), with a total adult membership of 266,000, trace their origin to Germany in 1708. In that year five men and three women covenanted to form a brotherhood following the commandments of Jesus Christ as revealed in the New Testament. Their course was shaped by three influences—the Protestant faith in which they had been raised, a reform movement known as Pietism, and Anabaptist teachings from the Radical Reformation of the 16th century.

The first Brethren were known in Europe as New Baptists (to distinguish them from the Mennonites, the direct descendants of the Anabaptists, whom they resembled in many ways) or as Schwarzenau Baptists (because of their place of origin). In North America they were commonly called Dunkers, Dunkards, or Tunkers, a reference to their distinctive practice of baptism by a threefold forward immersion. In 1836 they took the name Fraternity of German Baptists, which was replaced in 1871 by German Baptist Brethren.

Following a three-way split in the early 1880s a conservative wing called itself the Old German Baptist Brethren to emphasize the conviction that it was holding to the earlier beliefs. The liberal party chose to be called the Brethren Church. The middle-of-the-road majority continued as the German Baptist Brethren until 1908 when the title Church of the Brethren was officially adopted. In 1939 the Brethren Church divided into the Brethren Church (Ashland, Ohio) and the National Fellowship of Brethren Churches (Grace Brethren).

The Brethren are considered one of the three historic "peace churches," along with the Religious Society of Friends (Quakers) and Mennonites, because of a continuing (but not unanimous) adherence to the principle of conscientious objection to all wars.

History. In late-17-century Germany a reform movement led by Philipp Jakob Spener (1635–1705) and August Hermann Francke (1663–1727) attempted to restore religious vitality to Lutheran church life. Better education of theological students, more active congregations, more inspiring sermons, more piety in daily life earned for the movement the name Pietism. Most pietists remained within the church as a renewal element, but some were forced outside. Of the latter, many were driven from their homes because of their radical and

Pietism

separatist concerns, and some found asylum in Wittgenstein. The kindly disposed count, Henrich Albrecht, located them in the village Schwarzenau, on the river Eder. Subsequent differences in religious belief among those gathered at Schwarzenau caused some to become disheartened by the disunity and to return to German Lutheran or Reformed churches; others became religiously indifferent.

One small group led by Alexander Mack (1679–1735) determined to "establish a covenant of a good conscience with God, to accept all ordinances of Jesus Christ as an easy yoke, and thus follow their Lord Jesus . . . until a blessed end." They sought baptism from the German Mennonites but could not come to full agreement with them on church practices. The Brethren then decided to proceed with baptism themselves. They chose one of their number by lot to baptize Mack, who then baptized his baptizer and the remaining six.

These first Brethren developed great zeal for their cause and won converts in Wittgenstein and in other sections of Germany and Switzerland. The largest congregation after Schwarzenau was organized in the Marienborn area near Büdingen, Germany. In 1715 the Marienborn congregation was forced to leave because of a change in the religious policy of the local government. The members moved to Krefeld on the Lower Rhine, where they soon came into conflict with the authorities because of their proselyting. Several were sentenced to long terms of imprisonment. Added to this pressure was internal disagreement, which facilitated the decision of the majority of the congregation to move from Krefeld to Pennsylvania in 1719.

In the meantime, August, a brother of Henrich Albrecht, who was intolerant of the Schwarzenau Brethren, assumed co-regency. This, plus the low productivity of the land in Wittgenstein, caused them to leave. In 1720 the group under Mack's leadership migrated to West Friesland. In 1729 they joined the earlier migrants in America. Others left Europe in the 1730s with the result that no organized congregation of Brethren was left on the Continent after 1750, other than a group in Denmark that claims it can trace its origin to the Schwarzenau Brethren.

The American settlements

From the initial stronghold in Germantown, north of Philadelphia, the Brethren settled in the surrounding areas of Pennsylvania and New Jersey. Some moved into Maryland and the Southern colonies. By 1770 the Brethren had 1,500 adult members with a total following of about 5,000 in 28 congregations along the Atlantic seaboard.

An interesting offshoot of the colonial Brethren was the Ephrata Community in Lancaster County, Pennsylvania, a Protestant monastic establishment directed by Johann Conrad Beissel (1690–1768). At one time a minister of the Brethren congregation at Conestoga, Pennsylvania, Beissel broke with the Brethren and took with him a large number of the members. Ephrata became widely known for its cultural accomplishments, especially in choral singing and manuscript illustrating.

The most influential family connected with the 18th-century Brethren was that of Christopher Sower (Sauer; 1695–1758), the noted Germantown printer. Although the first Sower was a Separatist in his religious views, he shared many convictions with the Brethren. His namesake, Christopher Sower II (1721–1784), continued his father's business and became a Brethren elder. The Sower Press was famed for its three editions of the German Bible (1743, 1763, 1776). The Eliot Indian Bible of New England was the only previous biblical publication in the Colonies.

As followers of the doctrine of absolute nonresistance and therefore opposed to military service, the Brethren were put in a difficult position by the outbreak of the American Revolution. Some of them tended toward loyalism, because they were grateful to the British crown for freedoms enjoyed in America. There were scattered instances of mob violence and deprivation of Brethren property by action of the American revolutionary government. The shock that the Brethren suffered at this time may well have been a cause of their isolation and withdrawn character in the 19th century.

Westward movement in America

The Brethren joined in the general push westward following the Revolution and were the first settlers in some sections of Ohio, Indiana, and Illinois and other prairie states. Almost all Brethren were agriculturalists, and they sought good limestone soil to establish their fertile farms. They tended to settle in groups, often migrating as colonies to new locations. The first Brethren reached the Pacific coast by 1850. When the transcontinental railroads were completed, more Brethren moved west, settling in the Dakotas, the Pacific Northwest, and California.

Although the Brethren avoided schism during the Civil War (unlike most American denominations), the cultural changes of the latter half of the 19th century shattered their unity. A younger and progressive element pressed for the adoption of new methods and practices such as other American churches used. These included Sunday schools, revival services, institutions of higher learning, salaried pastors, foreign missions, and a free religious press. As the Brethren emerged from rural cultural isolation, which had been enhanced by their rural life and Germanic speech, such practices seemed essential to a vocal minority in the brotherhood. The periodicals of Henry Kurtz (1796–1874) and James Quinter (1816–1888), although moderate in their reform wishes, were influential in creating these demands.

Proposals such as these alarmed the conservative leadership, which insisted that the status quo be preserved. This "Old Order" group left the church when they saw they could not prevent the innovations. In 1881 they formed the Old German Baptist Brethren. Shortly thereafter the liberal wing, led by Henry Holsinger (1833–1905), was expelled for insubordination to church rulings. He and his followers organized the Brethren Church in 1883. Each of the factions numbered around 4,000.

These schisms left deep wounds in the brotherhood but, nevertheless, freed the main body from its previous paralysis. With both extremes gone, energies could be turned outward. The late 19th century was one of great activity in the areas of education, publication, foreign missions, and church extension. By 1900 the membership of the Brethren had reached 75,000. These developments and those coming later were effected in such a way as to preserve further unity, except for a minor split in 1928 of the Dunkard Brethren. At issue was a conference decision in 1911 that upheld the practice of using a plain style in dress, but most congregations had abandoned church discipline on this point, other than the Dunkard Brethren. During the 19th century the Brethren had uniformly worn the plain style of dress similar to the Amish, with beards and broad-brimmed hats for the men and aprons and bonnets for the women. This garb now has almost entirely disappeared, except for the Old German Baptist Brethren and in some parts of eastern Pennsylvania for the Church of the Brethren.

Beliefs and practices. Brethren beliefs and practices are historically rooted in the central Christian statements of faith as expressed by Protestantism, such as the centrality of Scriptures and the priesthood of all believers. Although they have ordained ministers, the Brethren have generally held the view that all Christians are ordained to the ministry through baptism, with some set apart for special functions. For many years Brethren had a "free ministry" in which ministers supported themselves by other jobs during the week, without formal theological study. Today seminary education is expected and usually completed before ordination (except among the Old Orders), although there are alternate methods of private study for the purpose of ordination. Brethren have avoided dogmatism in theological matters, and in fact there are extensive differences among Brethren in doctrinal belief. The Brethren are noncreedal; that is, they do not require adherence to the historic Christian creeds. They state that they have no creed but the New Testament.

Church rites are usually called ordinances (commandments of the Lord) rather than sacraments. These in-

clude baptism by trine (threefold) immersion of those old enough to confess their faith; the love feast, which is a semi-annual re-enactment of the Upper Room (Last Supper) experience of Christ and his disciples (John 13), consisting of an examination service, feetwashing, a fellowship meal, and the bread and cup as a memorial to Christ; anointing for bodily and spiritual health (James 5); and the laying on of hands in the ordination of the clergy and the commissioning of church workers. Traditionally, they have used affirmation in legal procedures rather than swearing oaths.

Church government is a combination of congregational and presbyterial patterns. Local churches have great independence but the Annual Conference has final authority over "procedure, program, polity, and discipline." In practice most congregations follow the decisions of the annual meeting, which is composed of congregational delegates, plus a Standing Committee of delegates from the several geographical districts into which the denomination is divided. A General Board of 25 persons administers the program of the church through an employed staff. The Brethren Church and the Grace Brethren are strongly congregational in polity, with a minimum of denominational machinery. Separate boards administer home and foreign missions, publications, and denominational institutions. The Old German Baptist Brethren, on the other hand, follow strictly the decisions of their annual conferences.

Social concerns

None of the above three groups is very active on social issues, unlike the Church of the Brethren, which has an extensive program of social concern. In 1941 the Brethren Service Commission was organized to work in the areas of peace and social service. It developed its program on a worldwide scale especially after World War II, when annual budgets of goods and services exceeded $1,000,000. Brethren were involved in other agencies, such as Church World Service and Christian Rural Overseas Program and initiated the Heifer Project, Inc., to send livestock to refugees and other needy people. The International Christian Youth Exchange, an ecumenical agency, was begun by Brethren initiative; and the Brethren helped to start International Voluntary Services, the forerunner of the Peace Corps.

All branches of the Brethren have been active in sponsoring missionaries with the exception of the Old German Baptist Brethren. Major areas of concentration have been India, China, South America, Europe, and Africa. The Brethren Church cooperates with the Church of the Brethren in supporting the fast-growing mission work in Nigeria.

Present state of Brethren communities. The Church of the Brethren numbers about 215,000 in 1,120 congregations, principally in the U.S. Congregations in Canada, India, Nigeria, and Ecuador have joined or were joining united churches in their nations. The general offices of the Brethren are in Elgin, Illinois, with suboffices in Washington, D.C., and New Windsor, Maryland. The denominational journal is *Messenger;* an independent quarterly, *Brethren Life and Thought,* carries articles of scholarship and opinion. The Church of the Brethren is affiliated in the U.S. with six liberal arts colleges, two hospitals, and numerous homes for the aging. It sponsors one graduate school of theology, Bethany Theological Seminary in Oak Brook, Illinois.

The Brethren Church has some 17,000 members in 120 congregations. Its boards have offices in Ashland, Ohio, the site of Ashland College and Seminary. The official periodical is the *Brethren Evangelist;* the seminary issues annually the *Ashland Theological Bulletin.* Grace Brethren offices are in Winona Lake, Indiana, the home of Grace College and Theological Seminary. The *Grace Journal* is published by the seminary three times yearly. The denominational periodical is the *Brethren Missionary Herald.* Membership of the Grace Brethren is about 29,500 members in about 200 congregations. The Old German Baptist Brethren number about 4,000 in 54 congregations. They publish the *Vindicator.* The Church of the Brethren joined the Federal Council of Churches (later National Council of Churches of Christ in the U.S.A.) in 1941 and the World Council of Churches in 1948. The Brethren Church cooperates with the National Association of Evangelicals. The other two groups remain independent.

Brewing

Brewing is the process of producing alcoholic beverages from starchy raw materials by steeping in water; boiling, usually with hops; and fermenting. In some countries beer is legally defined, as in Germany, where the standard ingredients, apart from water, are germinated barley, hops, and yeast.

HISTORY

Beer. Most of the beverages made from cereals over the past 8,000 years, especially those produced from malted barley, would now be considered "beers." According to Egyptian legend, Osiris, the god of agriculture, taught humans to prepare beer; besides Egypt, there were brewing operations in Babylon and Ur. Originally, barley was buried in pots to effect germination; the resulting malt, mixed with water, was allowed to ferment by the action of airborne yeasts. The addition of hops dates from between the 10th and 7th centuries BC. There are ancient references to millet beers in China and Japan, and the similar South African Kaffir beer is a traditional beverage of the Congo. Brewing probably reached Western culture from Egypt via Greece, where Pliny mentions the practice, including the use of hops. Brewing readily took hold in areas of northern and western Europe where grape culture for winemaking was impractical. According to Pliny, beer was known in Mediterranean countries before viticulture became popular. There are frequent references (*e.g.*, by Tacitus) early in the Christian Era to malt beverages consumed by Germanic and Nordic tribes, as well as by the Saxons and Celts, and even to the establishment of *tabernae,* or "taverns." Most of the common English terms used in modern brewing are of Anglo-Saxon or North European origin, including malt, mash, wash, wort, ale, and beer.

Britain's Domesday Book records 43 *cerevisiarii* ("breweries"). Medieval monasteries improved brewing techniques; and Trappist beer is still made in Belgium. "Home" brewing became important in Great Britain from about the 12th century AD, closely followed, with the growth of towns, by simple commercial operations with brewing and selling in the same establishment. Later, breweries ceased to be the point of sale and were usually centrally located to facilitate distribution in the town or city. Growth was slow until the Industrial Revolution made the large commercial brewery possible. The modern practice of national and international beer distribution is mainly a 20th-century development, although such terms as "India Pale Ale," referring to beer cargoes carried by shipping traders returning to Eastern markets, recall its earlier beginnings.

Other brewed beverages. Although beer usually implies a beverage of Western civilization, other cultures

employ procedures similar to brewing—often without systematized technology. Sake, the Japanese rice beverage, and the Mexican pulque, made from the agave plant, are produced by brewing methods, although the resulting beverage is sometimes considered closer to wines or spirits; pulque, for instance, becomes mescal on distillation. African beverages related to Western beers are *khadi* (Botswana), brewed from honey and wild berries, and two beverages made with sorghum, *burukutu* (Nigeria) and, probably best known, Kaffir beer (South Africa). The last two are essentially fermented extracts of malted sorghum seeds, widely used in Africa with the addition, especially in Nigeria, of *gari*, a starchy cassava preparation. The relatively crude extracts, or worts, are usually fermented directly, producing beers thick with undegraded starchy products. *Saccharomyces cerevisiae* is considered the main fermentative organism, though lactic organisms also play some part.

Distinctions in terminology

Such terms as ale, lager, stout, and porter are commonly applied to commercially produced beers, but in modern practice there are no strict definitions of these terms. "Beer" and "ale" are now almost interchangeable in English-speaking communities; the same is true of "beer" and "lager" in many European countries. "Beer" originally denoted a relatively weak beverage for regular consumption, with "ale" referring to a stronger liquor, presumably comparable to modern strong ale. Originally, hops were used only in ale preparation, and beers were brewed unhopped. Beers, ales, and lagers now usually have an alcohol content of about 3.5 percent by weight, and strong ales may contain 11–12 percent. "Near beer," rarely brewed commercially except in Belgium, has a maximum alcoholic content of 2 percent. Although lager often implies a beverage light both in colour and alcohol content, the word itself refers only to the method of brewing and particularly to the traditional long period of cold storage or "lagering." Commercial lagers, in fact, include some dark beverages of relatively high alcohol content.

Stout is brewed by methods similar to those employed in the modern brewing of ale, except that a proportion of roasted barley or malt is included with the normal malt and other ingredients before mashing to give the final beverage its dark colour. "Porter," a term now practically obsolete, apparently referred to a brew intermediate between ale and stout and is said to derive its name from the demand by market porters for a blend of ale and beer ("half-and-half"), later met by brewing an unblended ("entire") beer of appropriate strength, coloured by means of roasted cereal. "Cooper" refers to a mixture of stout and porter.

Both ales and lagers are described in a number of ways, often based on their individual characteristics, such as "brown ale," "mild," "bitter," and "stingo." Audit ale was a strong drink brewed to mark audit days in a number of colleges of ancient foundation. Pilsener (pale), Munich (dark), and the Scandinavian "Easter brews" reflect some of the many variants on the lager side.

Other beverages have been termed beers, including "spruce beer," a fermented, sugary solution flavoured with an extract of spruce leaves; "mum," a beer treated with fir bark and various herbs; "bragget," consisting of fermented honey and ale; "mulled ale," heated and flavoured with spices; and "lambswool," a beverage similar to mulled ale, containing roasted apples.

In modern practice, hops are used alone to give beer bitterness and aroma not provided by the cereals themselves nor by fermentation products. A variety of herbs and other materials were formerly added specifically to impart bitterness, including gentian, camomile, and quassia. Catechu resin may have been used more for its preservative value than its flavour, and the others probably produced a harsh bitterness rather than functioning as satisfactory substitutes for hops. Ferrous sulfate conferred a grating, harsh flavour, and was apparently used mainly to improve foam character. Many countries now prohibit use of these materials, and they were probably never used in organized industrial operations.

THE BREWING PROCESS

Most commercial brewing includes four stages: malting, mashing, wort boiling, and fermentation.

Malting. Cereal, usually barley, is converted into malt form, from which an extract is obtained for fermentation. Untreated barley produces an inferior wort (extract); grain steeped in water and germinated under controlled conditions develops a complex of enzymes, facilitating production of a satisfactory wort.

The steeping stage normally lasts for 40 to 80 hours under controlled conditions of temperature (usually 13°–15° C; 55°–59° F) and oxygenation. Alkalinity is sometimes controlled by the use of limewater. The grain, with water content ranging from 12 to 14 percent depending upon storage conditions, is allowed to take up further moisture to a level of 35–45 percent, depending upon the procedure to be used for the later part of the malting process.

Grain is sometimes dormant, exhibiting some unwillingness to germinate. Dormancy exhibits two phases. The first, common in all barleys, is evident for a few weeks immediately after harvesting, disappearing spontaneously during storage. Some barleys, especially those grown in maritime climates, retain a second type of dormancy, or "water sensitivity," and benefit from steeping to a low moisture content level, with more water being added after an air-rest period.

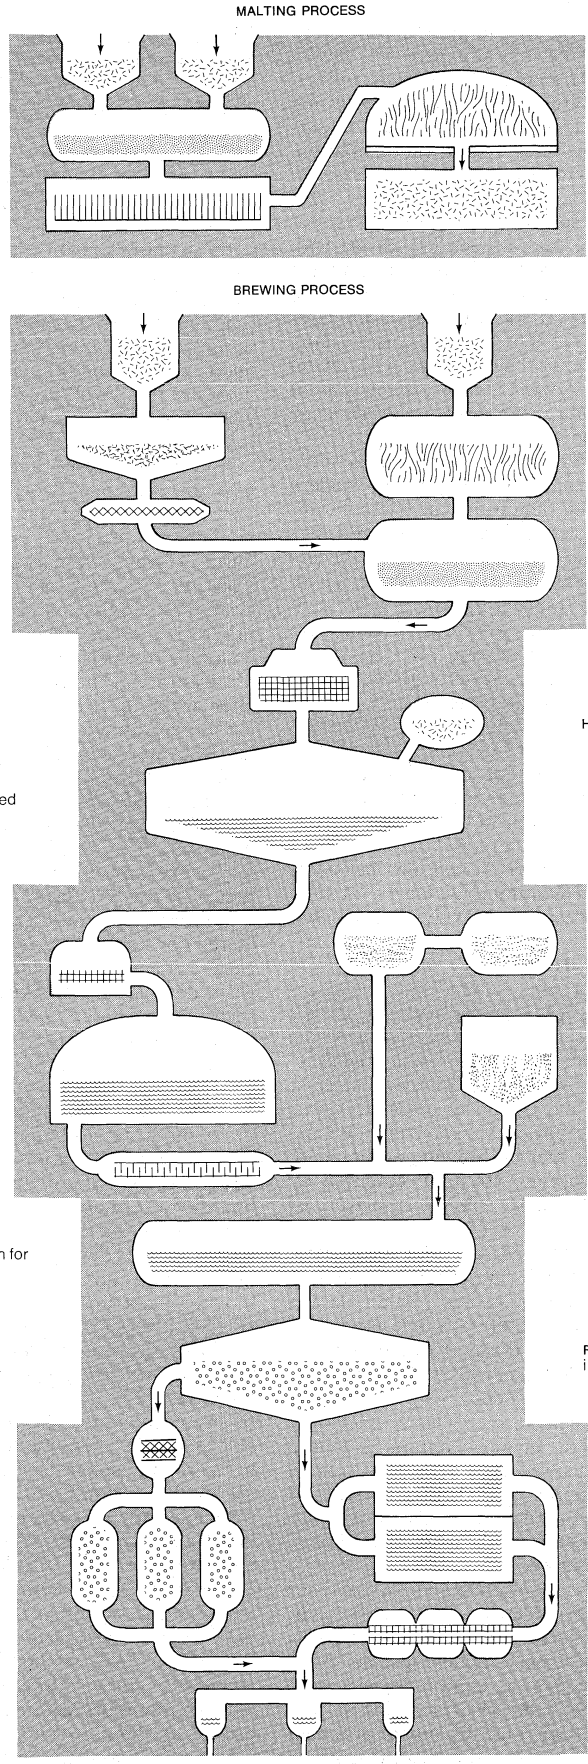
Germination

In traditional malting, steeped grain is spread on floors after draining. It is piled in thick heaps, or "couches," to initiate germination and, after about 24 hours, is spread more thinly, either by hand or mechanical raking, to moderate the temperature, which is maintained by the maltster at 15°–25° C (59°–77° F), depending on the nature of the malt being produced. The later stage formerly lasted ten or more days, but modern management of water uptake and other factors often reduces the germination period to five days.

In modern operations, the malting floors, which required considerable space for the spreading of grain, have been replaced by mechanical devices allowing greater grain depths. Germination is achieved in compartments, such as the Saladin box, or in drums and is controlled by mechanically turning the contents of the boxes or by rotating the drums on an inclined axis while aerating the grain with streams of humidified air. Malted wheat, rye, and oats are occasionally used in small quantities to improve the worts and, in the case of wheat, for the brewing of special beers. Various malting systems have been devised that control growth by allowing the respiratory carbon dioxide to accumulate; by exact control of the temperatures of successive steeps; by carrying out the combined steeping and germination steps in a single vessel; and by continuous means whereby the barley, placed on moving belts and treated by water sprays, is washed, steeped, and germinated.

Malting takes advantage of enzymes produced by the young plant. Starch-splitting enzymes, mainly α- and β-amylase, break down the residual starch of the malt, and of any unmalted grain mixed with it, to largely fermentable sugars. Proteolytic and other enzymes, such as ribonuclease, phosphatase and β-gluconase also help make the wort a suitable nutrient for the yeast, by providing for nucleoside and phosphate formation and by breaking down gums and thus avoiding difficulties that may arise from high viscosity. Production of a satisfactory level of enzymes formerly required considerable growth of rootlets and respiration, so that a given amount of barley gave only 90 percent or less of its dry content as malt, the rootlets being rubbed off and removed when the malt was dried. This "malting loss" has been reduced by more modern methods. Malting technique has been further improved by the use of minute amounts of gibberellic acid, a microbial product having plant hormone properties, used in the steeping water or as a spray during germination to accelerate malting. It appears identical with a material secreted by the barley embryo and is believed to trigger normal malting.

In most major beer-producing countries, barleys are es-



Brewing operations.
Drawing by D. Meighan

pecially selected for malting, and constant efforts are made to improve quality. Selection is based on agricultural, economic, and technical factors, such as agricultural yield and response to varying climatic conditions, and the amount of starch and eventually useful carbohydrate that can be extracted from the malt. Barleys of relatively high nitrogen content, while valuable as animal feedstuffs, are less desirable for malting; barleys of unusually low nitrogen content sometimes fail to yield malts of sufficiently high enzyme content and may produce worts deficient in nitrogenous yeast nutrients. Barleys containing 1.5–1.8 percent of nitrogen are usually preferred.

Most malts, termed "green" and containing about 45 percent of water after germination, are dried and given additional heat treatment, or "curing," before use. Controlled drafts of hot air, formerly from open fires but now mostly from oil-fired installations, are forced through the malt held in "kilns" on perforated floors. Designed for economical operation, kilns turn the malt so that the rootlets are rubbed off and also provide adequate hot-air distribution. Kilning consists of: (1) a phase of drying to about 10 percent of moisture at not more than 45–50° C and (2) a curing stage at 100° C or higher, depending on the purpose of the malt, when its moisture content is reduced to about 5 percent or, as in ale brewing, to about 2 percent. The remaining rootlets ("culms" or "kaulms") are removed by screening and polishing. Chemically, kilning results in: (1) a loss of about 30–60 percent of the enzymatic activity of the green malt, as well as arresting further enzyme activity in the malt itself, and (2) the development of a controllable degree of colour believed mainly due to formation of melanoidins, by the interaction of amino acids or similar compounds with sugars, and the formation of typical "malty" flavour and odour.

Kilning

Mashing. Physically, malt resembles the original barley but is friable and has a biscuity flavour. In brewing, the malt is ground in roller mills to provide a suitable mixture of husks, flour, and grits, then mixed with two to four parts of hot water, depending upon the procedure used. The hot water (or "liquor") usually contains, either originally or as a result of pretreatment, large amounts of calcium and frequently magnesium salts. Temperature is carefully controlled by simple operating steps. The whole process is carried out either in a single vessel (infusion mashing) at 63–68° C (145–155° F) as in ale brewing, or in an arrangement in decoction mashing for lager brewing. In this method, when the mash reaches around 45° C (113° F), a portion is withdrawn to a "mash kettle," boiled, and then added back to the main mash. By replication of this step the main mashing temperature of 62° C (144° F) is attained, usually followed by a final period at 70–75° C (158°–167° F).

As much as 50 percent of the mash grist may be composed of unmalted cereals such as rice, maize, wheat flour, barley grain, ground barley, or prepared forms of barley flakes, which sometimes need gelatinization before mixing with the main mash. Carefully chosen in relation to wort composition, these unmalted cereals improve the quality of the final beer, including foam character (head retention) and capacity to remain clear and free from off-flavours during storage (shelf life).

Preparing the wort

When mashing is complete, the aqueous solution, or wort, is separated from the spent grains by filtration, either in the mashing vessel itself through a slotted bottom plate or in a second vessel called a lauter tub. Wort collection is completed by freeing the spent grain from adherent wort by "sparging" with hot liquor. Many time-consuming variations in traditional methods add at least several hours to the process. The process is now commonly shortened by the adoption of shorter "stand-times," by the use of shallow depths of grain during filtration and by other means, allowing up to 12 mashes to be carried in a 24 hour period. Modern, fully continuous processes allow continuous brewery operation. There is also a trend toward preparing worts with extraneous enzymes of mold or bacterial origin, or with acid, which may be made elsewhere, then stored and transported to the brewery as wort syrups.

Mashing is largely a chemical process in which the malt enzymes act to convert the starch to a mixture of soluble carbohydrates. Ninety-seven percent or more of the starch is extracted; the wort for an average type of beer consists of perhaps a 10 percent solution of carbohydrates, about three-fourths of the carbohydrate material being fermentable sugar. It also contains about 0.08 percent of nitrogen, important in managing both the fermentation and final beer quality. The spent grains, or "brewers" grains, are useful as a nitrogenous addition to cattle feed.

Wort boiling. The wort is next boiled with hops for up to 2½ hours in large "kettles," formerly directly fired but now usually operated by oil firing. The amount and variety of the hops may vary from 200 to 700 grams per hectolitre (0.27 to 0.9 ounces per gallon), according to the beer. Boiling regulates composition and sterilizes the final wort so that some protein coagulates, removing a proportion of tannin, and the wort acquires the desired bitterness from the uptake of hop resins.

In addition to technical improvements of kettle design and greater understanding of the effects of boiling at various rates, degrees of evaporation, and boiling under pressure with varying access to air, extensive work has been done on the selection of hop varieties and their relative value. This is often linked with their agricultural characteristics and susceptibility to wilt and other plant diseases.

The role of hops

The hop, usually *Humulus lupulus*, is a perennial plant whose dried cones are used in brewing. More than 200,000,000 pounds are produced annually. A small proportion is used in "dry hopping," in which the beer at a late stage is kept in contact with hop cones for several days. Hops of especially agreeable aroma are selected, since their main purpose is to impart a small amount of the essential oil of hops to the beer. The oil, an exceedingly complex mixture, is sometimes added directly to the beer. The main role of the hops, however, is to impart an agreeable bitterness, effected chiefly through the "α-acids," a family of chemical compounds, the humulones, making up 5–10 percent of the whole cones and about one-third of the total resin content of the hops. The ultimate bitterness is not due directly to humulones but mostly to "isohumulones" derived from the α-acids during boiling. For some time, the isohumulones have been known to add the desirable constituents of hops to wort as an extract; and, more recently, the isohumulones usually have been added in the form of "isomerized extracts" at a suitable point, sometimes after fermentation.

When hop cones are used, they are eventually removed, traditionally on a "hop back" in which the debris forms its own filter bed. Spent hops, compounded with ferrous sulfate and other mineral salts, are a by-product of brewing, providing an artificial horticultural fertilizer.

Fermentation. Bittered wort, after any necessary storage at a high or a low temperature to inhibit infection, is brought to a selected temperature and transferred into large open or closed vessels for fermentation. The wort is "pitched" with a selected yeast used in varying forms of moisture content from "liquid" to "pressed," usually 250–400 grams of pressed yeast per hectolitre. Top fermentations are usually carried out using selected strains of *Saccharomyces cerevisiae*, botanically identical with bakers' yeast. Ales and stouts are usually fermented at 15°–20° C, formerly from four to six days but now shortened by modern methods to as little as one day. Much of the yeast, multiplying severalfold, rises to the surface (top fermentation) as the main part of the fermentation takes place. When the reaction has moderated, the yeast is separated either by running off the beer or by skimming or centrifuging the yeast. The brewer usually does this before fermentation is completed to allow for secondary fermentation or maturation in a separate vessel. In the case of cask beers, the small residual fermentation gives the natural "condition" of the beer. Most bottled beers are chilled, filtered, and carbonated, often with the carbon dioxide produced earlier in fermentation. They may

also be pasteurized and in some countries are sterilized by addition of specific inhibitory materials.

Lagers are fermented (bottom fermentation) 10 to 12 days at a lower starting temperature (6° to 8° C), using selected strains of *Saccharomyces carlsbergensis*, and are matured at 0° C, sometimes for several months. During fermentation, yeast is carried temporarily to the surface ("krausen") but most eventually flocculates, and the beer is run off into the conditioning vessel. The lager, or storage, cellar gives its name (derived from the German *lagern*, meaning "to store") to lagers in general.

Chemically, fermentation involves the conversion of glucose into ethyl alcohol, carbon dioxide, and water. Average beers contain around 3.5 percent of ethanol, but some contain up to 12 percent. During fermentation the specific gravity falls, average figures being from 1.045 to 1.012. The specific gravity never falls to one or less, as might theoretically seem possible, since unfermented carbohydrate always remains and nitrogen compounds also make a contribution. The strength of a beer, however, is usually quoted by reference to the original gravity. The glucose is not usually present in the wort but is formed by enzymatic action of the yeast on maltose and maltotriose, leaving 25 percent or more of the carbohydrates of the wort as unfermentable.

Both ales and lagers are sometimes produced by continuous fermentation, especially in New Zealand. The object of the commercial brewer is not merely to produce a solution of alcohol but to brew a generally agreeable beverage. His choice of yeast is based on the objective of producing beers with agreeable nuances of flavour and aroma, due in part to minor fermentation products (fusel oils; see below), and an avoidance of such undesirable minor products as acetaldehyde, diacetyl, and any excess of volatile sulfur compounds. In addition, he must ensure consistency of such qualities as colour, clarity, and foam character.

Importance of colour and flavour

Colour and flavour are distinctive features of beers. The basic pale-yellow colour results from the combination of malt with other cereals, and much of the colour results from the malt kilning. High kilning temperature usually produces deep colour in the final beer, the colour of the malt and wort being used to control the final beer colour. The incorporation of highly roasted barley or malt leads to very dark beers of the stout type. Light kilning alone is often insufficient to achieve the requisite degree of colour together with the appropriate composition of the derived wort to produce a desired degree of fermentation. In such circumstances the natural pale colour of the beer is usually darkened by the addition of caramel. Colour in beer results from the presence of melanoidins, substances formed by interaction of the carbohydrates present in malts and worts with amino compounds as typified by the α-amino acids also present in the same brewing materials. Some formation of melanoidins occurs on boiling wort; and even a very pale sweet wort, derived from unkilned malt, acquires considerable colour when boiled.

The characteristic flavour and aroma of malt is not identifiable in the final beer, since most of the aroma is removed during the boiling process. Malt "quality," although often partly reflected by malt flavour and aroma, mainly resides in the detailed composition of the wort, influencing formation of minor fermentation products contributing to the character of the final beer. These products are mainly "fusel oils" consisting of a mixture of compounds including normal propanol, isobutanol, 2- and 3-methylbutanols, ethyl, isobutyl, and isoamylacetates. The amounts of fusel oil in most beers range from about 50 to 150 parts per million. The varying nuances of flavour in beers result from both the amounts of fusel oil and the proportions of the individual components. The taste response to the latter is variable and is dependent on the other flavourful components present. The many delicate nuances of flavour are not formed by single compounds but by mixtures that, because they are still incompletely defined, cannot presently be controlled by instrumentation but only by subjective means such as taste testing.

ECONOMIC ASPECTS

Approximately 13,000,000,000 imperial gallons of beer are produced annually throughout the world. The three largest producing countries are the United States, West Germany, and Great Britain, with 3,200,000,000; 1,700,000,000; and 1,200,000,000 gallons, respectively. Annual per capita consumption ranges from little more than two imperial gallons in Italy and Argentina up to 28.4 gallons in Czechoslovakia. (An imperial gallon is four litres, or about 1.2 U.S. gallons.) The rates for the United States and Great Britain are 13.9 and 20.5 gallons, respectively. Beer drinking is increasing and fiscally encouraged in many countries, probably seeming sociologically less undesirable than spirit drinking. Apart from Denmark and Holland, the proportion of beer export to beer production is comparatively small though increasing. National distribution, however, has become more common than the earlier practice of local distribution.

In some areas of large geographic extent, such as the United States, distribution of beer concentrates intended for reconstitution has grown as an alternative to the more costly distribution of the beer itself or the duplication of a main brewery in a distant area. Such concentrates, usually 20–25 percent of the original beer volume, are obtainable either by limited distillation or by freezing the beer and separating the ice crystals from the concentrate. With the addition of both water and carbon dioxide, these concentrates are reconstituted into a beverage like the original beer.

Brick and Tile Production

The brick, first produced in a sun-dried form at least 6,000 years ago, and the forerunner of a wide range of clay building products used today, is a small building unit in the form of a rectangular block, formed from clay or shale or mixtures and burned (fired) in a kiln, or oven, to produce strength, hardness, and heat resistance. The original concept of ancient brickmakers was that the unit should not be larger than what one man could easily handle; today, brick size varies from country to country, and every nation's brickmaking industry produces a range of sizes that may run into the hundreds. The majority of bricks for most construction purposes have dimensions of approximately 2¼ × 3¾ × 8 inches (5.5 × 9.5 × 20 centimetres).

Structural clay tile, also called terra-cotta, is a larger building unit, containing many hollow spaces (cells), and

is used mainly as backup for brick facing or for plastered partitions.

Structural clay-facing tile is often glazed for use as an exposed finish. Wall and floor tile is a thin material of fired clay with a natural or glazed finish. Quarry tile is a dense pressed fired-clay product for floors, patios, and industrial installations in which a high resistance to abrasion or acids is required.

Firebrick is used in incinerators, boilers, industrial and home furnaces, and fireplaces. Sewer pipe is fired and glazed for use in sewage-disposal systems, industrial-waste systems, and general drainage. Drain tile is porous, round, sometimes perforated and is used mainly for agricultural drainage. Roofing tile is made in the form of half-round (Spanish tile) and various flat tiles made to resemble slate or cedar shakes; it is used extensively in the Mediterranean countries.

There are also many products made from cement and aggregates that substitute for, and generally perform the same functions as, the clay products listed above.

Data on the quantity of brick and tile produced throughout the world is not available. The United States Bureau of Commerce has fairly accurate data indicating that approximately 6,500,000,000 bricks are produced annually (1970s). Other data indicate that England produces about as many bricks per year as the United States, and it is probable that the large countries of western Europe produce as many bricks as the United States. Australia is high in per capita production. Many countries having hot and dry climates (including the southwest United States) still produce sun-dried bricks.

HISTORY

Mud brick (dried in the sun) was one of the first building materials. It is conceivable that on the Nile, Euphrates, or Tigris rivers, following floods, the deposited mud or silt cracked and formed cakes that could be shaped into crude building units to build huts for protection from the weather. In the ancient city of Ur, in Mesopotamia (Iraq), the first true arch of sun-baked brick was made about 4000 BC. The arch itself has not survived, but a description of it includes the first known reference to mortars other than mud. A bitumen slime was used to bind the bricks together.

Burned brick, no doubt, had already been produced simply by containing a fire with mud bricks. In Ur the potters discovered the principle of the closed kiln, in which heat could be controlled. The ziggurat at Ur is an example of early monumental brickwork perhaps built of sun-dried brick; the steps had to be replaced after 2,500 years (about 1500 BC) by burned brick.

As civilization spread eastward and westward from the Middle East, so did the manufacture and use of brick. The Great Wall of China (210 BC) was built of both burned and sun-dried bricks. Early examples of brickwork in Rome were the reconstruction of the Pantheon (AD 123) with an unprecedented brick and concrete dome, 142 feet (43 metres) in diameter and height, and the Baths of Hadrian, where pillars of terra-cotta were used to support floors heated by roaring fires.

Enamelling or glazing of brick and tile was known to the Babylonians and Assyrians as early as 600 BC, again stemming from the potter's art. The great mosques of Jerusalem (Dome of the Rock), Isfahan, and Teheran are excellent examples of glazed tile used as mosaics. Some of the blues found in these glazes cannot be reproduced by present manufacturing processes.

Western Europe probably exploited brick as a building and architectural unit more than any other area in the world. It was particularly important in combatting the disastrous fires that chronically affected medieval cities. After the Great Fire of 1666, London changed from being a city of wood and became one of brick, solely to gain protection from fire.

Bricks and brick construction were taken to the New World by the earliest European settlers. The Coptic descendants of the ancient Egyptians on the upper Nile called their technique of making mud brick *tōbe*. The Arabs transmitted the name to the Spaniards, who, in turn, brought the art of adobe brickmaking to the southern portion of North America. In the north the Dutch West India Company built the first brick building on Manhattan Island in 1633.

MANUFACTURING

Basically, the process of making brick has not changed since the first fired bricks were produced some thousands of years ago. The steps used then are used today, but with refinements. The various phases of manufacture are as follows: securing the clay, preparation, mixing and forming, drying, firing, and cooling.

Clays used today are more varied than those used by the first brickmakers. Digging, mining, and various methods of grinding enable the modern manufacturer to utilize many raw materials.

Clays used in brickmaking represent a wide range of materials that include varying percentages of silica and alumina. They may be grouped in three classes: first, surface clays found near or on the surface of the earth, typically in river bottoms; second, shales, clays subjected to high geologic pressures and varying in hardness from a slate to a form of partially decomposed rock; and third, fireclays, found deeper under the surface and requiring mining. Fireclays have a more uniform chemical composition than surface clays or shale. Classes of clays used

Securing (winning) the clay. Surface clays are typically recovered by means of power shovels, bulldozers with scraper blades, and dragline operations. Shales are recovered by blasting and power shovels. Fireclays are mined by conventional techniques.

Preparation. Raw clays are often blended to obtain a more uniform consistency. In many cases the material is ground to reduce large rocks or clumps of clay to usable size and is placed in storage sheds. As additional material is stored, samples are blended from a whole cross section of the storage pile. The material is then transferred to secondary grinders and screens (if necessary) to secure the optimum particle size for mixing with water. In certain processes (*e.g.*, soft-mud), the clay is transferred directly to the mixing area, eliminating all grinding, screening, and blending.

Mixing and forming. All clays must be mixed with water to form the finished product. The amount of water added will depend on the nature of the clays and their plasticity. This water is removed during drying and firing, which causes shrinkage of the units; to compensate for this shrinkage the molds are made larger than the desired finished products. Three basic processes are used in the forming and mixing phase. In the stiff-mud process, the clay is mixed with water to render it plastic, after which it is forced through a die that extrudes a column of clay like the toothpaste squeezed from a tube. The column gives two dimensions of the unit being manufactured; it is cut to give the third dimension. All structural clay tile is made by this process, as is a great percentage of brick. In the older method of forming bricks, the soft-mud process, much more water is used, and the mix is placed in wooden molds to form the size unit desired. To keep the clay from sticking, the molds are lubricated with sand or water; after they are filled, excess clay is struck from the top of the mold. It is from this process that the terms wood-mold, sand-struck, or water-struck brick were derived. Clays with very low plasticity are used in the dry press process. A minimum of water is added, the material is placed in steel molds, and pressures up to 1,500 pounds per square inch are applied.

Drying. After the bricks are formed, they must be dried to remove as much free water as possible (they could literally explode if subjected to fire without drying). Drying, apart from sun drying, is done in drier kilns with controlled temperature, draft, and humidity.

Firing and cooling. Bricks are fired and cooled in a kiln, an oven-type chamber capable of producing temperatures of 1,600° to over 2,000° F (870° to 1,100° C), depending on the type of raw material. There are two general types of kilns, periodic and continuous.

The earliest type of kiln, the scove, is merely a pile of dried bricks with tunnels at the bottom allowing heat

from fires to pass through and upward in the pile of bricks. The walls and top are plastered with a mixture of sand, clay, and water to retain the heat; at the top the bricks are placed close together and vented for circulation to pull the heat up through the brick. The clamp kiln is an improvement over the scove kiln in that the exterior walls are permanent, with openings at the bottom to permit firing of the tunnels.

A further refinement of the scove kiln, round or rectangular in form, is designated as updraft or downdraft, indicating the direction of heat flow. In these kilns the walls and crown are permanent and there are firing ports around the exterior.

In so-called periodic kilns, the bricks are placed with sufficient air space to allow the heat from the fires to reach all surfaces. They are placed directly from the drier, and heat is gradually increased until the optimum firing temperature is reached. When they are sufficiently fired, the heat is reduced, and they are allowed to cool gradually before removal from the kiln.

Series of kilns

The periodic kiln was improved in efficiency by placing several kilns in line with connecting passages. The first chamber is fired first and the excess heat passed to the next chamber to start heating. Successively, the various chambers are brought to optimum firing and cooling temperatures, until all bricks have been fired and cooled. This arrangement is known as the moving fire zone. In the more modern fixed fire zone, dried bricks are placed on cars carrying as many as 3,000 or more bricks; the cars are started at the cool end of a long tunnel kiln and moved slowly forward through gradually increasing temperatures until they reach the firing zone, pass and emerge through decreasing heat zones until cooled.

Automation. Since the development of the tunnel, kiln brickmakers have sought to increase automation in their plants. Handling of the finished product has been automated to the point that bricks emerging from the kiln are now automatically stacked in packages of approximately 500, strapped with metal bands, and stored, shipped, and delivered by mechanical equipment.

In some plants bricks are taken from the cutter machine, placed in the drier or on drier cars by mechanical means, placed on kiln cars by mechanical fingers, removed from the kiln cars mechanically, stacked, strapped, and prepared for shipment without being touched by hand.

COLOURS AND TEXTURES

Colour of clay products may be natural or applied.

Natural colours. These depend on the type of clay used in the production processes. They range from whites through grays, buffs, light to dark reds, and into the purple range. Fireclays are associated with the lighter colours such as the grays and buffs. Ordinary clays and shales are associated with the red ranges. By regulating the oxidizing conditions in the kiln, browns, purples, and blacks can be obtained. The process is known as flashing, and in general the change of colour of the bricks is only on the surface, the body of the unit retaining its natural colour. Some metals, such as manganese, are mixed with the clays to develop special colours.

Applied colours. Colours are applied to many brick products, particularly structural glazed tile, wall and floor tile, and brick. Ceramic glazes are applied to units before or after the firing and cooling stage. If after, the units must be refired. These glazes provide almost all of the basic colours plus some special colours used for "accent" in the design of a wall. The glazes become an integral part of the face of the units since they are burned to the same degree of heat as the units. Finishes and colours other than ceramic glazes are applied to the units either fired or unfired and are surface coatings that conceal the natural colour of the burned unit. In some countries a demand for old brick has led to application of mixtures of cement or lime and sand and many other combinations to give brick an aged appearance.

Types of finishes

Texture. The texture of clay products is directly associated with the manufacturing processes. The soft-mud process produces either a sand- or water-struck finish in a non-uniform texture, which gives the brick (only bricks are made under this process) the appearance of handmade or antique brick. The dry-press process, using steel molds, gives a smooth texture only. This process is seldom used in modern-day brick production but is used in the manufacture of quarry tile as well as floor and wall tile. The stiff-mud process offers the most possibilities for texturing brick. As the prepared clay is extruded through the die, the pressure produces a smooth surface similar to that of concrete when smoothed with a steel trowel. This surface is called the die skin; its removal and further treatment produce other textures.

In wire cutting, a wire placed in front of the column of clay as it comes from the die removes the die skin, creating a semi-rough surface.

In sand finishing, sand is applied to the column of clay by various means to give a very even surface of sand, which is fired into the unit. The desired texture is similar to a wood-mold brick except that the unit is much more uniform in size and in finish. Colour also may be changed by the type of sand used.

Scored finishing is used mostly on tile where the surface of the tile is grooved to give a better bond between the unit and plaster. This is also true of a roughened or combed finish produced by wire brushing or scratching.

Roughened finishing is used when the die skin is removed by various means. In one method, the material cut in removing the die skin may be rolled back into the face of the unit.

Other finishes are applied by rollers on the column to give certain effects such as bark, log, or emblems. Terracotta for architectural decoration is both machine extruded and handmade (molded or pressed). It is distinguished from other clay products by the generally larger size of the units. It may be hand carved and used mostly in murals as bas-relief. Both natural and glazed finishes are produced.

USES OF BRICK

By far the largest use of brick products is, as it always has been, in building construction. Many significant changes have taken place in building with brick.

Building construction. It may be roughly accurate to say that about 65 percent of all the brick in the world goes into dwellings, and 35 percent goes into commercial, industrial, and institutional buildings. Construction techniques change yearly and from country to country, but basically most brick and tile are used in walls, with lesser use in roofs and floors.

Walls may be classified in three general categories, load-bearing, non-load-bearing, and veneer. A load-bearing wall supports the loads of a structure, such as floors, equipment, furniture, and people. At one time, buildings were constructed with very thick brick walls carrying all floor and other loads. Design of these walls was not based on engineering data but only on well-intentioned but unscientific building codes. As buildings grew taller, the building code requirements for thickness of a brick wall became economically prohibitive. The last truly high-rise, load-bearing brick structure built under older codes was the Monadnock Building in Chicago (1889–91), 16 stories tall with the brick walls 6 feet (2 metres) thick at the base, tapering to 12 inches (30 centimetres) at the top story. The arrival of structural steel on the building scene put a temporary end to the brick bearing-wall skyscraper, but research in the 20th century has led to a resurgence. Thinner walls can be designed for high-rise buildings and built safely at a reasonable cost. Apartment buildings in Switzerland, Germany, Denmark, England, and other countries have risen 15 or more stories supported by brick bearing walls no more than 12 inches (30 centimetres) thick. The use of reinforced brickwork (a combination of brick, reinforcing steel, mortar, and cement grout) permits even thinner walls; a 17-story building designed to resist earthquake shocks uses only 11-inch walls.

Types of bearing walls

Bearing walls may be classified into five general groups: (1) brick, including brick tied together with cross brick (headers) or with metal ties; (2) composite walls of brick and tile tied together with headers or metal ties; (3) cavity

walls, in which the inner and outer wythes (tiers) of units are tied together with metal ties but separated by an air space usually two or more inches in width; (4) reinforced walls, similar to cavity walls except that steel is placed in the cavity and the cavity filled with a soupy mortar (grout); (5) single unit walls, using a unit of necessary thickness to meet design requirements.

Non-load-bearing walls carry only their own weight and may be any one of the types discussed under load-bearing walls. This type of wall is used to close in a steel or concrete frame building. It is usually carried by supports, normally steel shelf angles at each floor, and is called a panel wall. When the wall is supported at the base only, it is called a curtain wall.

Veneer walls are similar to non-load-bearing walls in that they carry no weight except their own. The brick or tile is fastened to a backing, but it does not exert a common action with the backing. Perhaps the most common use is brick veneer on wood frame dwellings. Other examples are architectural terra-cotta and thin ceramic veneer on monumental buildings.

Tile roofs are popular in the Mediterranean area and in the Low Countries of western Europe. In Italy, craftsmen have developed an art of using relatively thin tile to form self-supporting arches. Tile roofs in many other areas, particularly on residences, have been used extensively in the past, but economic considerations limit their use now; in addition to the cost of the tile is the cost of roof framing to support the heavier weight of the tile.

Miscellaneous uses in building construction include retaining walls, brick floors, patios, and walks. Most of these uses are decorative as well as utilitarian. The retaining wall of reinforced brick provides an economical means of restraining earth movement and at the same time maintains a continuity of architectural effect, particularly if the adjoining structure is built of brick.

Brick floors, patios, and walks utilize the physical properties of brick, such as resistance to abrasion and to the elements. Paving brick, per se, is practically nonexistent, except for replacement where roads and streets were brick paved long ago. Industrial floor brick, however, supplies many industries whose manufacturing and handling processes require floors that resist acids and provide a high degree of resistance to abrasion. Brick floors and patios, besides providing a long-lasting, low-maintenance material, offer the designer a medium for developing architectural effects in both colours and patterns.

Clay drainage products. Sewer pipe plays an important part in the world's ecology. An almost impervious material because of its firing, denseness, and glazing, it can carry highly corrosive waste materials that few other products can handle economically.

Drain tile performs a service that ensures a higher yield in farm production of food throughout the world. Many farming areas are plagued with too much water at the wrong times. Drain tile reduces the water level during these times, thereby allowing the root growth of plants to penetrate deeper into the soil, which, in turn, permits them later to resist hot dry weather.

Art in clay products. The walls of ancient Babylon were decorated work, and brick has served decorative and artistic purposes ever since. Terra-cotta, molded, formed, and glazed, has been used for years in murals. Many architects use patterns of brickwork to relieve the monotony of a large expanse of plain wall, while others deliberately use the starkness of large plain walls to emphasize form.

MANUFACTURING NONCLAY BRICK AND TILE

Following the introduction of portland cement in the 19th century, a growing number of products have appeared which resemble clay products in size and intended use. In some countries the production of them, if reduced to brick equivalents, exceeds that of clay products. A brief review of these products, the material used, and the manufacturing processes may serve to suggest the interrelation between these and clay products.

Concrete block is a large unit, usually 8 inches high, 16 inches long, and of various thicknesses, made from a mixture of cement and an aggregate, which may be cinders, limestone, or expanded clay or shale (burned in a rotary kiln). The mixture of cement, aggregate, and a minimum of water is placed in steel molds and vibrated to compact the mixture. The formed units are removed from the molds and cured either in air, steam, or under autoclaving processes (steam under pressure).

Concrete brick is a mixture of cement and aggregate, usually sand, formed in molds and cured. Certain mineral colours are added to produce a concrete brick resembling clay. Concrete pipe is made of cement and aggregate and cured as above. Used as a substitute for clay sewer pipe, it does not have as much resistance to the corrosive action of certain acids. Concrete drain tile and concrete roofing tile are produced similarly.

Sand–lime brick is a product that uses lime instead of cement. It is usually a white brick made of lime and selected sands, cast in molds and cured. Production is limited, with greater use in the United States and Germany.

Bridge

Bridge is the name applied to the modern card game of Contract Bridge and also to the earlier games of Auction Bridge and Bridge Whist. All are derived from the old English game of Whist and retain its essential features: four players participate, two against two in partnership; play is with a 52-card pack, divided into four suits—spades, hearts, diamonds, and clubs; each suit has 13 cards, ranking from the ace, king, queen, jack, ten, down to the two; the cards are dealt face downward one at a time, clockwise; when play begins, the object is to win tricks, consisting of a card from each player in rotation; players must, if able, contribute a card of the suit led, and the trick is won by the highest card; before play begins a suit may be designated the trump suit, in which case any card in it beats any card of the other suits.

Essential features of the Bridge games

Such are the elements of Whist, Bridge Whist, Auction Bridge, and Contract Bridge, which, from the early 18th century, have reigned in turn as the most intellectually stimulating of the card games. Successive improvements in other features of the games have greatly enlarged the scope for inferential reasoning, psychological stratagems, and partnership cooperation. In Whist the trump suit was settled arbitrarily by turning up a card; in Bridge Whist it was selected by the dealer or his partner; in Auction Bridge there was competition (bidding) for the right to choose trumps; and in Contract Bridge a side must try to judge the exact number of tricks it can take and bid accordingly. These and other developments have given rise to a very elaborate technique for skillful bidding and play.

Contract Bridge takes longer to learn than other card games but is by far the most fascinating and shows no sign of losing its appeal. By the 1970s it was played by 80,000,000 men and women in every part of the world. There were more than 5,500 clubs in North America alone, many national governing bodies and continent-wide leagues, and a World Bridge Federation whose Olympiads and annual championships were treated as seriously as other international sporting contests. More than 5,000 books on the game had been published, those still in print selling an estimated 1,000,000 copies an-

nually, and there were at least 60 periodicals. The majority of newspapers in the Western world carried Bridge articles, and the International Bridge Press Association had well over 200 members.

The first part of this article is a historical survey describing Whist and its development into Bridge Whist, Auction Bridge, and Contract Bridge. The second part describes the laws and strategy of Contract Bridge. A bibliography is provided for the reader who seeks instruction in this game.

The Whist and Bridge family is of English origin, having evolved gradually from several other games, principally Triumph, a name that became corrupted to Trump. Triumph was also known as English Ruff and Honours and was based on the concept of one card being able to beat another, with a particular suit predominating. It is referred to in a sermon preached by Hugh Latimer at Cambridge in 1529 and in Shakespeare's *Anthony and Cleopatra.*

WHIST

Origin. The name Whist, or Whisk, appears to have originated in the early 17th century. Whisk, as a game, is referred to in a poem (1621) by John Taylor, while Charles Cotton's *Compleat Gamester* (1674) devotes a section to it and says, "Ruff and Honours, [alias slamm] and Whist are games so commonly known in England in all parts thereof, that every child almost of eight years old hath a competent knowledg [sic] in that recreation." At first Whist was a game for the lower orders and also a rural accomplishment, but early in the 18th century it was taken up by gentlemen who frequented London's coffee houses. In 1742 the first book wholly devoted to it, Edmond Hoyle's *Short Treatise on Whist*, was published and was a best seller. The game then became extremely popular in the fashionable world, spreading quickly to Europe and America and remaining for one and a half centuries the king of card games.

Duplicate Whist, in which the same hands were played at two tables and the results compared, was played in London in 1857 under the direction of Henry Jones, who, under the pseudonym Cavendish, became the leading writer on the game. The duplicate principle (see below) became popular, and contests were held, resulting in the formation of the American Whist League in 1891.

Essential features. The two players facing each other are partners against the other two. The cards are dealt singly, and the last is turned up to determine the trump suit. The player at the left of the dealer leads by playing any one of his cards face upward on the table, and each player in turn, clockwise, contributes a card of the same suit if he can; if he cannot, he may play any card, including a trump. The four cards played constitute a trick, which is gathered up by the side that played the highest card of the suit led or the highest trump. The winner of a trick leads to the next, and play continues until every card has been played. The side winning the most tricks scores a point for each odd trick (*i.e.*, each trick over six).

Strategy. Best results are achieved by winning tricks with the lowest sufficient card and by capturing high cards played by the opponents whenever possible. The players try to gauge the whereabouts of the unplayed cards and, by collaborating with their partners, to win tricks, not only with high cards and trumps but with low cards that become winners when all of the higher cards in the suit have been played.

The development of an optimum strategy is difficult, for each player's hand is known only to himself, and information can be exchanged only by signalling; *i.e.*, playing one's cards in a sequence that, by convention, conveys a message. An example, proposed by Lord Henry Bentinck in 1834, is the "echo" or "peter" in a suit other than the trump suit—the play of an unnecessarily high spot card followed by a lower card in the same suit—asking partner to lead trump. Signalling became highly developed, and in 1883 Nicholas B. Trist proposed a complex schedule of opening leads that was enthusiastically adopted on both sides of the Atlantic.

Signalling conventions

With all hands concealed, however, even the greatest players could employ only the most elementary strategies. Hoyle and his successors, including William Payne (*Maxims*, 1773), Thomas Mathews (*Advice to the Young Whist Player*, 1804), James Clay, Guillaume Deschapelles (according to his contemporaries the finest of all Whist players), and finally Cavendish, concluded that it was expedient to assume that the best strategy, in most cases, was simply to lead first from one's longest and strongest suit in an attempt to establish it.

The widespread employment of this strategy led to a most valuable device, known as the rule of 11 and widely used in modern Bridge. It was published by Robert F. Foster in 1890 and was based on the mathematical fact that when a player leads the fourth highest card of a long suit, the number of higher cards held in the other three hands can be found by subtracting from 11 the number of the card led.

As signals became more and more elaborate, Whist became a ritual, and players were ready to turn to the new game, Bridge, which allowed more scope for reason. Whist still has a following in Great Britain and in certain areas of North America, but the status it enjoyed under Cavendish has vanished.

Variations. *Solo Whist.* Solo Whist differs from Whist in that, as in Bridge, each player in turn is entitled to make a call; *i.e.*, announce his willingness to attempt to take a certain number of tricks. The name Solo derives from the fact that, as a result of the calling, the subsequent play usually takes the form of one against three. The range of calls is limited and includes two, *misère*, in which the caller undertakes to win no trick against the combined efforts of the other players to make him take one, and *misère ouvert* (open *misère*), in which he undertakes to take no tricks even though he exposes his hand. The game is popular in Britain, where some devotees display a flair for card play equal to that of an expert Bridge player.

Boston Whist. This is said to have been invented by naval officers during the siege of Boston by the British and the terms great misery and little misery to have been derived from islands thus called in Marblehead harbour, where the French fleet lay for a time. William Tudor, in his *Letters on the Eastern States* (1820), wrote, however, that "A game of cards was invented in Versailles and was called in honour of the town, Boston. . . . It is composed partly of whist and partly of quadrille, though partaking mostly of the former." Boston, and a variation called Boston de Fontainbleu, was played for high stakes in Europe and to a lesser extent in the U.S. until the mid-19th century, when it declined. It was probably the precursor of Solo Whist and resembles it in that there are no partners, but it has many more calls: a player may bid to make any number of tricks from 5 to 13 with his own trump suit and may also bid to lose 12 or 13 tricks. Also, a suit is arbitrarily designated the first preference suit and any call in it beats a similar call in the second preference suit, which in turn beats either of the two remaining suits. After the hand the stakes are settled according to whether or not the player made his call.

Bidding to take or lose tricks

Boston and Solo are of significance in the development of card games since, like Contract Bridge, they employ the idea of a competitive auction in which players estimate how many tricks they can take and bid accordingly.

Vint. This is a partnership game that bears a marked resemblance to both Whist and Bridge. Now obsolete, it was popular in Russia during the period when bridge was developing in the Western countries. Writing in 1897, Foster, then the world's leading authority on card games, says of Vint:

> . . . this game is by some persons thought to be the forerunner of bridge, and might be classed as one of the whist family, but . . . it is at present . . . little known outside of Russia, where it is the national game.
>
> Vint has been variously described as bridge without a Dummy, and as auction whist. It resembles bridge in the making of the trump, and whist in the manner of the play.

The principal affinity with Bridge is that each player in

turn bids to make a certain number of tricks with a suit of his own choosing. But the suits rank differently—hearts, diamonds, clubs, and spades—and, as in Whist, each player can see only his own hand. The scoring too is different, and points are gained for holding a "coronet," a sequence of three or more cards in any suit or three or four aces. A distinctive feature is that every trick taken by either side is counted when it comes to the scoring. Thus, although the bidder's side may make their contract, their opponents may conceivably win the game.

BRIDGE WHIST

Bridge Whist dethroned Whist and, by introducing an exposed dummy, made it possible for the play of the cards to provide a more testing intellectual exercise. This important innovation presumably evolved from three-hand Whist games, resorted to by inveterate players when there were only three available to play; a fourth hand was dealt as usual, but for the play of the hand it was laid out face up on the table, providing much additional and very useful information to all three players, each of whom then could see the cards held in two of the four hands. This exposed hand, called the dummy, was incorporated into the four-handed game by the expedient of making the declarer's (*i.e.*, dealer's) partner the dummy, his hand being exposed upon the opponent's lead to the first trick and played by the declarer. The new game was known first simply as Bridge, the term Bridge Whist being coined later to distinguish it from Auction Bridge.

Origin. A similar game, Khedive, had been played in Constantinople before 1870 and another version in Greece before that. Khedive was played on the French Riviera in the 1870s under the name of Biritch and was called Bridge by the 1880s. It was played at the Whist Club of New York in 1893, and in the following year Lord Brougham, playing in a Whist game at the Portland Club, apologized for failing to turn up the trump card with the excuse that he had forgotten he was not playing Bridge, "the finest card game ever introduced."

Principal innovations. The trump suit was named by the dealer or, at the dealer's option, by his partner; there was also the option of requiring that the hand be played without a trump suit (no-trump); the dealer's partner always became the dummy, and his hand, exposed when the opening lead was made, was played by the declarer. The scoring was more elaborate than at Whist, for after the dealer (or his partner) had declared the trump suits, the player on his left (or his partner) could double; *i.e.*, double the scoring values of the tricks. Calls could then be redoubled and doubled again indefinitely unless limits were placed. The first side to score 30 or more points won a game, and the first to win two games won the rubber and a 100-point bonus.

Introduction of no-trump, exposed dummy, and doubling

Popularity. The new game appealed to women as much as to men and quickly became the favourite of the fashionable world. Although in its relatively brief reign it did not reach the middle and lower classes, as Auction Bridge did later, it provided the means for fuller intellectual and social enjoyment. The exposure of the dummy gave the other three players a basis for reasoning and inference that had previously been lacking and made the play of the hand a much more cerebral activity, while the new method of determining the trump suit introduced a further element of volition. In addition, the no-trump call brought with it a whole new range of tactical problems in the development of long suits. By 1897 almost all leading Whist players had gone over to Bridge, and even Cavendish, who refused for a period to enter the Portland Club because Whist had been all but abandoned there, was converted before his death in 1899.

AUCTION BRIDGE

Bridge Whist had been in vogue for only a few years when the great change was made that produced Auction Bridge—the introduction of competitive bidding for the right to name the trump suit (or no-trump). It quickly rendered the other game obsolete.

Origin. It is not certain to whom Auction Bridge should be credited. A letter in *The Times* (London), January 16, 1905, signed by Oswald Crawfurd, describes Auction Bridge for three players, while a book by "John Doe" (F. Roe), published in Allāhābād, India, in 1899, puts forward three-hand Auction Bridge as an invention of Roe and two other members of the Indian Civil Service, when, at an isolated post, they had no "fourth" for Bridge Whist. By 1904 the best club players in England and America were turning to it, by 1907 the Portland Club had adopted the game, and by 1910 Auction Bridge was king.

Principal innovations. The trump suit, instead of being named by the dealer or his partner, was determined by competitive bidding, as a result of which any one of the four players might become declarer. Thus a player who said "One spade" was bidding to make one-odd (six tricks, comprising a "book," plus one) with spades as trumps, while a player who said "Pass" (in Britain, "No bid") was signifying a disinclination to contract to win any number of tricks. The main principles of the auction remain good for Contract Bridge: a bid must name a greater number of odd tricks than any preceding bid or must name the same number in a higher suit (no-trump ranks highest, followed by spades, hearts, diamonds, and clubs). A player may double the last preceding bid if it was made by an opponent and had not previously been doubled, and a double, similarly, may be redoubled (by the bidder or his partner). A bid may be overcalled whether doubled or not, and the auction continues until three consecutive passes occur. The highest bid possible is seven-odd. The partner of the declarer (the player winning the auction) becomes the dummy, tabling his hand face up after the opening lead is made. If the declarer's side wins fewer odd tricks than it has bid for, the opponents receive points for each undertrick, but these do not count toward game.

Competitive bidding

Popularity of Auction Bridge. By the late 1920s Auction Bridge had become the most popular card game ever known, with at least 15,000,000 followers. This may be attributed to the fact that all four players were able to compete for the right to name the trump suit and become declarer and to the challenge offered to psychology and reason. The best players began to perceive that the combination of the auction principle and the new scoring (see below) gave rise to the concept of an "optimum contract," beyond which neither side could bid without losing more points than it gained, but this was fully understood only after Auction Bridge had been superseded by Contract. External social factors, such as the rapid growth of a leisured middle class, may also have played a part in the popularity of Auction Bridge, which still has a substantial although steadily declining following.

Scoring. In Auction Bridge, unlike Contract, all odd tricks count toward game, unless they are fewer than the number bid for. With clubs as trump, each odd trick counts six; diamonds, seven; hearts, eight; spades, nine; and no-trump, ten. These values are multipled by two if the contract is doubled, by four if it is redoubled. These trick scores are entered "below the line" (referring to the Bridge score pad, which is divided horizontally by a line, with all points counting toward game scored below that line and all other points scored above it).

Trick points and honour points

As in Bridge Whist, a game is won by scoring 30 or more trick points, a rubber by winning two out of three games, but the bonus for a rubber is 250 points instead of 100 as in the older game.

If the declarer's side does not fulfill its contract, its adversaries score 50 points for each undertrick (100 if doubled, 200 if redoubled). These points go in the honour score ("above the line") and do not count toward game. Other entries in the honour score are: for holding three or more of the honours (A, K, Q, J, 10 of the trump suit or the aces at no-trump), bonuses ranging from 30 points for three trump-suit honours in one hand or shared with partner to 100 points for all five trump-suit honours in one hand or all four aces in one hand at no-trump; for making a small, or little, slam (12 tricks), 50, and a grand

slam (all 13 tricks), 100. All of these scores are credited to the side earning them, regardless of who is declarer.

If the declarer fulfills a doubled contract, he receives a bonus of 50 points scored above the line, plus 50 points for each trick he wins above his contract, and 100 points in each case at a redoubled contract.

The side that scores the greater total of honour plus trick points is the winner, by the difference between the two total scores.

CONTRACT BRIDGE

As an intellectual pastime Auction Bridge was vastly superior to its forerunners, but a further great innovation remained: the principle that only the tricks contracted for could count toward game, overtricks as well as all bonuses being entered in the honour score scored above the line. With this innovation accuracy in bidding became immensely more important: the object now was to bid what could be made rather than to outbid the opposition as cheaply as possible. At the same time, a more definite target appeared in the play of the cards: the aim was to make or defeat the contract rather than simply to win as many tricks as possible.

Origin. The contract principle appears first to have become established in the French game, Plafond (literally, "ceiling"; *i.e.*, a player aimed to bid to his ceiling of tricks), which was played in Paris in 1918 and from about 1922 to 1931 was more popular than either Auction or Contract Bridge in French and Belgian clubs. Several unofficial attempts were made to introduce the same principle to Bridge, and the proposal was considered but rejected by the laws committee of the Whist Club of New York in 1917 and again in 1920.

In 1925 Harold S. Vanderbilt of New York, who had become convinced, as he later put it, that the time had come to take another step forward to perfect the successive games of the Whist family, incorporated the Plafond principle in a more deliberate way than had previously been attempted. He also proposed that slam bonuses should be awarded only when contracted for and added the intriguing new element of vulnerability, whereby a side that won a game became "vulnerable" and subject to heavier penalties for failure to make a contract. Finally, he introduced the decimal system of scoring (see below), later giving it as his opinion that this feature, by greatly increasing all trick values and bonuses, added enormously to the attraction of the new game, which he described as Contract Bridge.

In 1926 Vanderbilt tried out the game when voyaging from the Pacific Coast to New York, and back in New York he gave copies of the scoring table to some of his friends. Thanks to the combination of the Plafond principle and Vanderbilt's well-balanced scoring proposals, the game caught on immediately. Laws were proposed, and by 1928 the code issued by the Whist Club of New York had been accepted. By 1929 Contract had become the standard game on both sides of the Atlantic; the American Auction Bridge League had dropped the word Auction from its title; and Ely Culbertson, one of several then struggling for leadership in the new game, had founded the first Contract Bridge magazine, *Bridge World*.

Scoring. As mentioned above, trick values were greatly increased. A side fulfilling its contract for each odd trick scores, if trumps were clubs or diamonds, 20 points for each trick (instead of 6 or 7); if trumps were hearts or spades, 30 (instead of 8 or 9); and at no-trump, 40 for the first and 30 for each subsequent trick (instead of 10).

Higher trick values and bonuses

Such of these tricks as were included in the contract are scored below the line and count toward game. The remainder, if any, are scored above the line and do not count toward game.

If the contract was doubled, tricks scored below the line count twice the normal value, and overtricks count 100 each if not vulnerable, 200 if vulnerable. These values for overtricks are doubled if the contract was redoubled. For making either a doubled or redoubled contract a 50-point bonus is scored above the line.

Vulnerability is also a factor if declarer fails to fulfill his contract. His opponents score for each undertrick:

	if declarer were not vulnerable: undoubled	doubled	redoubled
First undertrick	50	100	200
Each subsequent undertrick	50	200	400
	if declarer were vulnerable: undoubled	**doubled**	**redoubled**
First undertrick	100	200	400
Each subsequent undertrick	100	300	600

For bidding and making a contract of six-odd (a small slam) a bonus of 500 is scored if not vulnerable, 750 if vulnerable. For seven-odd (grand slam), the bonus is 1,000 if not vulnerable, 1,500 if vulnerable. A side bidding six and making seven scores only the small-slam bonus plus one overtrick. A side bidding seven and making only six has not fulfilled its contract, and its opponents score an undertrick penalty.

Vulnerability does not affect bonuses scored for holding honours. The ace, king, queen, jack, and ten of the trump suit are honours. One player holding four of them scores 100 above the line; for five honours or four aces at a no-trump contract his side scores 150. Fewer than four honours and honours shared with partner do not count.

When either side totals 100 or more below the line it wins a game. Both sides then begin a new game. In Rubber Bridge, the first side to win two games wins the rubber and receives a bonus of 700 if the opponents have not won a game, 500 if they have. All points scored by each side are then totalled, and the side with the higher score wins the difference.

Development of Contract Bridge. Despite its immediate popularity in club circles, Contract Bridge did not progress rapidly elsewhere until Culbertson, who possessed great organizational ability and a flair for publicity, launched a series of manoeuvres designed to publicize the game and to establish himself as its principal authority. In 1930 his team won nearly every important American tournament, and he seized the occasion to publish his *Blue Book*, a revolutionary work setting out the principles that still underlie most bidding systems. He also went to England and defeated the leading British teams, including one headed by Lt. Col. Walter Buller, who had engaged the attention of the British public with bidding methods that were directly opposed to Culbertson's.

Role of Ely Culbertson

Culbertson sealed these achievements when at the beginning of 1932 he vanquished in a match of 150 rubbers a team representing the anti-Culbertson faction led by Sidney Lenz. American newspapers called the match "The Bridge Battle of the Century," and for more than a month it was featured on their front pages. The unprecedented publicity made Contract Bridge a fad not only in North America but also in Europe and South America.

For all the promotional aspects of Culbertson's campaign, his ideas were basically sound. He saw the fallacy in the British approach, which was to open with the bid that seemed most likely to represent the best final contract. He also saw that in the new game the search for a trump suit was more rewarding than previously. Auction Bridge did not favour trump contracts unless based on strong suits, for honour bonuses were high relative to trick values, and defenders who held honours could outscore a declarer who made only eight or nine total tricks. Players therefore opened at one no-trump almost indiscriminately when lacking a strong honour combination. Culbertson recognized that it was a serious error, in Contract, to open one no-trump on hands that might develop more tricks at a trump declaration, and he therefore formulated the "approach" principle: "Whenever a hand contains a biddable suit . . . that suit and not no-trump should usually first be bid." To enable the approach principle to be more safely employed, he stipulated that certain bids were "forcing"; *i.e.*, could not properly be passed by the partner. Hence his system and those like it are termed approach-forcing systems. Another of Cul-

bertson's achievements was a method of valuing the strength of a hand by "honour tricks," high cards or combinations of cards that could normally be expected to take tricks by force. It had long been known that, on average, just over eight tricks in each deal are won by high cards, and Culbertson's honour tricks corresponded with these. So long as the tricks won by lower cards accrued in the same proportion as those won by honour tricks, the method was accurate.

Culbertson's impact caused Contract to supersede Auction very rapidly. The game then settled down as an accepted form of social intercourse, and the next landmark did not occur until Culbertson, who had become interested in international relations, was succeeded in his position as the leading authority by Charles H. Goren, who in the late 1940s popularized an improved method of hand valuation (see below). This enabled even beginners to judge the strength of their hand and so reach reasonable contracts almost from the start instead of after a long period of study and practice. It thus removed an obstacle to the increased popularity of the game. The weight of Goren's authority as a player and writer also caused the bidding methods that he favoured to be termed Standard American.

Party Bridge, Chicago, and Duplicate. These are forms of Contract Bridge in which the method of scoring or the method of arranging partnerships used in Rubber Bridge is modified in some degree, either for social reasons or to emphasize the competitive element.

Party Bridge. This term may be used of any private Bridge game consisting of two or more tables, but it is also used in the laws of Duplicate Contract Bridge as a general term for special games of a social character and for Duplicate for home play.

Replay Duplicate enables one pair to play competitively against another. The same hands are played twice, first by one pair and then the other. The results are compared as at Duplicate (see below). The appeal of the game is limited by the fact that a retentive memory can count for more than skill. Both Pivot Bridge and Individual contests enable the players to play once with each other as partners and twice against each other as opponents. Progressive Bridge, in which partners change tables after every four deals, has enjoyed a vogue for larger gatherings not serious enough to warrant the use of the duplicate principle. A social desideratum is that pairs should consist of one member of each sex.

Chicago. In North America, especially, all forms of party Bridge lost ground in the 1960s to four-deal Bridge, called Chicago for the city in which it originated. Because it avoids long rubbers of uncertain duration, it became popular in clubs as well as for home play.

A rubber of Chicago consists of four deals. A passed-out deal does not count, and the same player deals again. On the first deal neither side is vulnerable; on the second and third deals dealer's side only is vulnerable (or, in some games, nondealer's side only); and on the fourth deal both sides are vulnerable.

A premium of 300 points is awarded for a nonvulnerable game, 500 when vulnerable. There is no further premium for winning two or more games. A part-score or scores made previously (earned for contracts worth less than game—*e.g.*, two clubs bid and made worth 40 points or one heart worth 30 points) may be combined with a part-score in the current deal to complete a game, in which case the game premium is determined by the vulnerability on the deal that completes it. A part-score made on the fourth deal receives a premium of 100 points.

Duplicate Bridge. Duplicate is the principle, developed in Whist, according to which all serious competitions (tournaments) are conducted: a hand that has been dealt and played at one table is played again at one or more other tables. The object is to reduce the element of luck and enable a direct comparison of skill to be made between players who hold identical hands.

Duplicate boards are used to keep the cards intact for replay. The board, or tray, is a rectangular container having four pockets, one for each hand (North, East, South, and West) and marked to indicate vulnerability and which hand is dealer (*i.e.*, opening bidder). After the play of a hand each player, who keeps his own cards directly in front of him, returns his original hand to the appropriate pocket of the board. The board is passed on to another table, and his table receives a new board. At the conclusion of play it is possible to compare results obtained on each deal by players who held identical cards under identical conditions. In pairs contests, the scores of each North-South pair are compared with those of all other North-South pairs; the scores of each East-West pair with those of all other East-West pairs.

Dealer and vulnerability for each board follow a schedule that is standard in most countries. North is dealer on board 1, East on board 2, and so on. The vulnerability of each 16 boards follows the mnemonic word square, ONEB, NEBO, EBON, BONE. O = neither side vulnerable; N = North-South vulnerable; E = East-West vulnerable; B = both sides vulnerable.

Each deal is scored as a separate event. To the usual trick scores and slam bonuses, 50 points are added for making a part-score. Premium for making game is as in Chicago, 300 for a nonvulnerable game, 500 if vulnerable. Honours do not count. The scores may be totalled to produce a winner, but in modern pairs Duplicate they are first converted to "match points" thus: the North-South pair with the worst score on a board receives no match points, the next pair gets one match point, and so on, each receiving one point for every score it betters and one-half point for every score it exactly equals. (To avoid fractions, scores for each deal are sometimes calculated by doubling the match point awards.) This method of scoring gives equal importance to each deal, whether a part-score or a grand slam, with far-reaching effects on the strategy of bidding and play. In a team event the points scored on each board may be converted to International Match Points in proportion to each team's margin of victory on each winning board on the basis of a scale ranging from 0–10 = 0, 20–40 = 1, and 50–80 = 2 and so on to 4,000 and up = 24.

Match points

Duplicate games require the use of a schedule for the movement of players and boards, known as a movement. The first pair movement was invented in 1892 by John T. Mitchell of Chicago for use in Whist. It is still the commonest movement today. With this movement, half of the pairs playing are assigned to North-South positions and half to East-West. The tables are numbered from one through whatever number is required. After every round (a round consists of the play of a specified number of boards, usually from two to four) North-South pairs remain seated, while all East-West pairs move to the next higher numbered table, those at the highest table going back to number 1, and each set of boards is moved to the next lower numbered table. If the number of tables is even, a relay stand is used to hold one set of boards out of play on each round, the set moving to the next lower numbered table on the next round. A game consists of all pairs playing all boards, but in tournaments with more than 13 tables in one section play is usually limited to 26 deals, two each against 13 opposing pairs. The Mitchell movement requires two independent winners, one pair for North-South and one for East-West. Other movements, permitting each pair to play against each other pair, for example, become more complex and usually require printed guides and often skilled directors to direct the movements of players and boards.

The use of the duplicate principle in Contract Bridge is very popular indeed. By emphasizing the competitive aspect it has greatly spurred the development of the game.

Tournament Bridge. This term is applied to the more serious competitions conducted according to the duplicate principle, usually under the auspices of a regional, national, or international league.

Regional and national tournaments. The first Auction Bridge tournaments were run by the American Bridge League, founded in 1927. In 1937 it amalgamated with the United States Bridge Association to form the Ameri-

can Contract Bridge League (ACBL), whose membership grew from 9,000 in 1940 to more than 175,000 by the late 1960s, its principal tournaments, called Nationals, attracting 5,000 or more players three times a year. Several hundred regional and sectional tournaments are held annually by local units. The ACBL is the governing body for North America, and its contributions to the development of the game include the ranking of players under a scheme, since adopted in many other countries, whereby success in tournaments is recognized by the award of master points for winning or placing high. Nearly every country in Europe and the Western Hemisphere, and many elsewhere, has its own national Bridge league, Sweden's being second in size to the ACBL. In Great Britain national championships are run by the English Bridge Union, whose membership was 10,000 early in the 1970s, and by the Northern Ireland, Scottish, and Welsh Bridge unions. County associations run their own championships, and the unions, with some overseas bodies, constitute the British Bridge League, which selects teams for European championships and world events.

International tournaments. The first international Contract Bridge matches were those played by Culbertson's team against three British teams in 1930. (In that year Culbertson's team played a Plafond match against leading French players including Baron Robert de Nexon, who subsequently became the first president of the World Bridge Federation.) A European Championship was held in 1932 and was won by Austria. In the two following years American teams beat Great Britain for a trophy given by Charles M. Schwab of New York, while in 1935 the first America versus Europe match took place when an American champion team, the Four Aces, beat France, the reigning European champions. In 1937 two American teams competed in the last pre-World War II European championship, which was won by Austria from a 16-team field.

Early international competition

International Bridge grew rapidly after World War II. In 1947 the European Bridge League was founded at Copenhagen, and European Championships, for both open and women's teams, became annual events except (beginning in 1960) in Olympic Team years. In 1950 the U.S. resumed international play by winning a three-cornered match at Bermuda against Britain and the rest of Europe. The trophy, the Bermuda Bowl, became the emblem of world Bridge supremacy, played for annually. For a time it was a two-team event between North America and the winners of the European Championship, but it became a three-cornered event in 1958 with the inclusion of the South American champions. In 1966 the winners of the Far East Bridge Championship competed for the first time; in 1971 the South Pacific zone champions joined in, making it a six-team event, including the defending champions.

In 1958 the World Bridge Federation was formed to control the Bermuda Bowl competition, also known as the World Team Championships, and to institute quadrennial Olympiad championships for open and women's teams, beginning in 1960 and replacing, in Olympic years, the Bermuda Bowl. The federation also arranged the first pair Olympiad in 1962 and at four-year intervals. For Bermuda Bowl and Olympiad winners, see SPORTING RECORD in the *Ready Reference and Index*.

LAWS OF BRIDGE

Bridge has never lacked well-drafted and comprehensive laws, although the legislative bodies have not always acted in concert. The first official laws were those for Bridge Whist, adopted by the Portland Club of London in 1895, but a different code was adopted by the Whist Club of New York in 1897. In 1909 the Portland Club published the first code for Auction Bridge (last revised in 1928), and in 1910 the Whist Club published its own Auction laws (revised in 1912, 1913, 1915, 1917, 1920, and, for the last time, 1926).

Development of the Contract Bridge laws. The first Contract Bridge laws were promulgated by the Knickerbocker Whist Club of New York in 1927 but were superseded in the same year by those issued by the Whist Club. The Portland Club issued a code in 1929. Since 1932, when representatives of the Portland and Whist clubs met and adopted the first international code, to which the Commission Française du Bridge also subscribed, the Rubber Bridge laws (though not the laws of Duplicate) have always been international, except for the single case of a 1943 American code issued unilaterally because of wartime circumstances. In 1947 three members of the Whist Club of New York were appointed to the ABCL's National Laws Commission, which became the sole American promulgating body. The laws were revised in 1948 and 1963 by the ACBL, the Portland Club, and the European Bridge League.

The first code for Duplicate was adopted by the American Bridge League in 1928 and revised in 1935 and 1943. In 1949 the first international Duplicate code was promulgated by the Portland Club, the European Bridge League, and the ACBL, remaining in force until revised in 1963. The Duplicate laws, known as the Laws of Duplicate Contract Bridge, follow the Rubber Bridge laws as closely as conditions permit, changes being made only where procedural differences in the game require them.

Principles of the laws. The laws are concerned with the procedure of the deal, auction, and play and with the imposition of appropriate penalties when an infringement has taken place. Few players find it necessary to learn them in detail, for in a friendly rubber, infringements, such as a call out of turn, are often overlooked. In clubs the published laws are always available and can be consulted if need be; disagreements, which rarely occur, are resolved by a committee of the club. In tournament Bridge a tournament director supervises the contest and applies the laws, subject to a right of appeal to a committee and thence to a national or international governing body.

The laws of Bridge are not intended to protect against intentional offences, for the integrity of everyone at the table is taken for granted. Cheating at Rubber Bridge is almost unheard of in recognized clubs, for the game does not lend itself to it: success achieved otherwise than by skillful bidding and play soon attracts attention. But cheating is not unknown at Duplicate, arising usually from the contravention of the principle that communication between partners during the auction and play periods may be effected only by means of the calls and plays themselves. Cases of purported cheating are heard by the responsible national or international governing body, which has power to suspend offenders from membership.

The laws themselves are intended to provide a remedy where a player accidentally, carelessly, or inadvertently disturbs the proper course of the game. Some of the more frequent infringements are as follows:

Revoke. A player who fails to follow suit when able to do so commits a revoke. The penalty varies according to whether the revoke is corrected within a certain period. For an "established" revoke the penalty may be the loss of as many as two tricks if these tricks are won subsequent to the infraction.

Common infringements

Exposed card. If a card is exposed otherwise than in the normal course of play, its owner may be liable to a penalty, depending on the stage reached in the bidding or play. For example, a defender who exposes a card may be obliged to leave it face up on the table and play it at the first legal opportunity.

Lead out of turn. Different penalties are provided for leads by the declarer and those by defenders and also for leading too soon and attempting to lead when it is another player's turn. The object is to redress the advantage the offender may wrongfully have gained. A lead out of turn is condoned (escapes penalty) if the next hand plays before attention is drawn to it. The same applies to a bid out of turn.

Improper remark. Should a player, by a thoughtless act or remark other than an illegal call or play, give his partner unauthorized information, that is an improper remark or gesture for which redress is provided by the laws.

Appended to the laws is a statement of proprieties covering violations of ethical conduct such as may lead to an unfair advantage and the observance of proper etiquette, the breach of which may spoil the pleasure of the game. An important propriety is that the intentional infringement of any law is a serious breach of ethics. In Rubber Bridge the laws provide no penalty for a breach of the proprieties as such, but in Duplicate the director may award an adjusted score if no adequate penalty is assessed by the laws.

The scope of the proprieties may be gathered from the fact that they specify seven types of violation of ethical conduct, one of which is "Any indication of approval or disapproval of partner's call, or of satisfaction with an opponent's call." As to conventions, the laws say that

> It is improper to use, in calling or play, any convention the meaning of which may not be understood by the opponents. Conventional calls or plays should be explained to the opponents before any player has looked at his cards. Advanced notice may be given of the intention to use certain conventions of which full explanation may be deferred until the occasion arises. The full explanation may be given only by the player whose *partner* made the conventional call or play. At any time this player must reply to an enquiry by an opponent as to the significance of a call or play that may be conventional, and should supply any information that may have been withheld.

Restrictions on use of conventions

Any sponsoring organization, club, or tournament committee or group of persons playing Contract Bridge may restrict the use of conventions in games under its jurisdiction. The view generally taken is that the use of conventions should be related to the seriousness of the occasion: at international level there are virtually no restrictions, while by 1970 the ACBL had named over 70 conventions permitted in its major tournaments. Fewer are permitted in local tournaments and fewer still in clubs where Rubber Bridge is played and where it is generally held that the unrestricted use of conventions would spoil the pleasure of the game.

CONTRACT BRIDGE BIDDING

In the course of the bidding each side estimates how many tricks it can take at its best contract. It then selects that call (or permits its opponents to play at that call) which, on a balance of probabilities, is likely to maximize its own score or minimize the opponents' score. This may involve making a bid that is expected to fail.

The strategy of bidding. Each player attempts to inform his partner as to the nature and strength of his hand, either by making one or more bids or by passing. When such information is given and received, it becomes possible to decide the best contract. Thus, if one player defines the strength and character of his hand by opening at one no-trump, his partner (the responder) may be able to determine the best contract without further exploratory bidding. Certain calls by responder would then be understood as a declaration of the intended final contract: for example, a bid that would give the partnership a game, such as three no-trump or four spades or a pass. Other calls would be understood as exploratory, indicating that the best contract was still uncertain.

Bids are selected with a regard for the realities of the scoring table: a game can be made by bidding four-odd at a major suit or three-odd at no-trump, and this provides a motive for describing those features of the hand most likely to lead to a no-trump or major-suit contract. The attempt to make game at five-odd of a minor suit is much less frequent.

More tricks may be taken if a satisfactory trump suit is present: the ideal is eight or more trumps in the combined hands, with at least four in each. Bids are therefore selected with a view to ascertaining whether such a suit is present.

Exchanging information with one's partner is not the only consideration, and bids may be made with the object of disrupting the opponents' exchanges. A recognized manoeuvre, though one employed by only a small minority of players, is the "psychic" bid: one that pretends to nonexistent values.

Bidding systems

Thus an optimum strategy of bidding must aim to reconcile conflicting factors, and that is what is attempted by a "system": a set of principles by which partners may express any two hands. Unlike a convention, which is a partnership arrangement whereby a special meaning, not obvious on the surface, is attached to a particular bid, a system covers the entire range of constructive bidding (*i.e.*, bidding to arrive at the best contract). To use a system effectively a player has to be able to assess the strength of his hand. By far the most popular way of doing so is by means of the Goren point count (described below), and the majority of players are not aware of any other. It is, however, possible to value a hand in quite different terms: for example, a method of assessing a hand in terms of losers for play at an agreed trump suit (the losing trick count) was put forward by F. Dudley Courtenay and later revived by British and Italian experts. The idea is to add the number of cards lower than the queen (up to a maximum of three in each suit) to the number of losers revealed by the partner's bidding. The total is subtracted from 18, and the answer indicates how many odd tricks the combined hands are likely to take.

The first bidding system was proposed by Harold S. Vanderbilt. A player with a strong hand opened one club: with a weak hand his partner responded one diamond, after which the bidding proceeded on the basis that the responder was known to be weak; with a stronger hand the first response would be other than one diamond, and in this case the exchanges would proceed on the basis that the responder was known to hold certain values. The Vanderbilt club also had the advantage that any opening bid other than one club was known to be limited in strength. Despite its technical excellence, the system was not widely popular, but the idea was later revived in the highly successful Italian systems (see below).

The most successful system of the first 20 years of Contract Bridge was devised by Culbertson, whose contribution to theory has already been described. Despite competition from other systems, his was paramount throughout the world until the late 1940s, when it was superseded largely because a new method of hand valuation was developed, superior to Culbertson's honour-trick method, rather than through any great improvement in the principles of bidding. The new method was put forward in 1949 by Goren, who proposed an extension of a method known since 1904 but one that reflected and measured in identical terms—point count—the power of long suits and trumps as well as high cards. It was immediately successful, and Goren's system (embracing both his method of valuation and principles of bidding) was swiftly adopted by the majority of players.

Comparison of principal systems. *Goren system.* This employs the concept of "distributional points," which are added to high-card points (one to four points for each J, Q, K, A held) to arrive at an overall valuation. The strength needed for every bid in a constructive auction is defined in these terms. Thus, the strength needed to raise an opening bid of one in a suit to three in the same suit is defined as 13 to 16 points, including distribution. (Other factors may be required; *e.g.*, for a raise from one to three, at least four trumps are needed.)

High-card and distributional points

Points are counted by adding to high-card points distributional points for a void suit (three points for an opening bid, for example, five when raising a partner's suit bid), for a holding of one card in a suit, a singleton (two points and three), and for two cards in a suit, a doubleton (one point).

In addition, opener adds a point for four aces and deducts one for an aceless hand. A player raising his partner's suit adds a point for an honour in it, unless he has already counted four or more for high-card points in the suit. A player rebidding after his partner has raised adds a point for a fifth trump and two for the sixth and subsequent cards. A point is deducted for an inadequately guarded honour, such as Q-x (queen and any one lesser card), or a singleton king, queen, or jack. A player raising his partner's suit deducts a point if he has only three trumps or if he has a 4-3-3-3 pattern.

The basis of this method of distributional valuation was devised by William Anderson of Toronto and was adopted and developed by Goren. The 4-3-2-1 count for high cards was previously publicized by Milton Work.

Point count is used not only to select single bids but also to select the level of the final contract. A total of 26 points is normally needed in a partnership's combined hands for a game at no-trump or a major suit, 33 points for a small slam, 37 points for a grand slam. Thus, when the bidding has indicated the number of points held in the combined hands, it is possible to decide at what level the deal should be played.

Other features of the Goren system are as follows: Most hands are opened with a bid of one in a "biddable" suit; *i.e.*, a suit containing five or more cards or four cards including, normally, at least four high-card points. Hands containing 14 or more points must be opened, while those containing 12 or less are usually passed. A 13-point hand may be opened if a suitably descriptive rebid (second-round bid) is available. A response in a new suit is forcing for one round, meaning that responder's partner must bid again to keep the auction open or to contribute additional information (*e.g.*, strength in another suit) to the partnership's joint effort to reach their optimum contract. An opening two-bid in a suit is forcing until the partnership reaches a bid of game or until the opponents have been doubled. Opening no-trump bids are based on a balanced hand pattern (4-3-3-3, 4-4-3-2, or 5-3-3-2) with a high point count and no doubleton weaker than Q-x.

Pre-emptive bids are used; *i.e.*, bids higher than the minimum legal level made in an attempt to obstruct the opponents. Pre-emptive openings usually indicate no more than ten points in high cards, with a seven-card or longer trump suit and the ability to win within two tricks if the contract is vulnerable or three tricks if not.

Acol system. This system is employed by the majority of British tournament players and by some elsewhere. Its name derives from a small London club where the system was developed in the 1930s by a group of young players who subsequently became famous. It was developed from the Culbertson system but has fewer forcing bids and employs in most cases the principle of bidding the full value of the hand when a trump suit has been agreed or when raising at no-trump. Holding four cards in the opener's suit, for example, and 10 to 12 points, an Acol player raises to three of that suit, a non-forcing (or "limit") bid indicating that the combined hands are likely to produce nine tricks if the opener has a minimum. (In standard American, a raise to three is forcing and indicates the ability to win more than nine tricks.) An opening two spades, two hearts, or two diamonds shows 18 to 22 points, with at least eight playing tricks (*i.e.*, tricks that a hand may reasonably be expected to take when playing at its own best trump suit). Stronger hands are opened with a conventional artificial bid of two clubs.

Bidding full value

Italian bidding systems. Italy's Squadra Azzurra (Blue Team), which held the Bermuda Bowl from 1957 to 1969, used two principal systems—the Neapolitan system and the Roman system. The Neapolitan system resembles the Vanderbilt system in that strong hands (17 points or powerful distribution) are opened with one club. Responses are by the step system to show strength and "controls"; ace counts as two controls; king as one control: one diamond—zero–five points; one heart—six or more points but fewer than three controls; one spade—three controls; one no-trump—four controls; two clubs—five; two diamonds—six; two no-trump—seven or more. The two hearts and two spades responses are reserved to show six-card suits with two honours but less than six points. Openings of one diamond, one heart, or one spade bids show limited hands.

The Roman system is more complicated, with many conventional bids. One club may show any of four types of hand, ranging from a balanced 12 to 16 points to an unbalanced strong hand similar to a standard American forcing two bid; responder cannot tell which until opener bids again. A set of conventional responses is prescribed. An opening bid of one diamond, one heart, or one spade is forcing for one round and usually shows a genuine suit. A bid in the next higher suit is the mandatory minimum response. Opening suit bids of two show specific holdings: for example, two hearts show at least five hearts and four clubs.

Other systems. Scores of systems are used, but the majority, like the British two club system, are based substantially on Culbertson's and Goren's methods. In France an idea popular with tournament players is that the opener should begin with the shorter of two biddable suits and rebid his stronger suit on the next round (the canapé principle).

The canapé, relay, transfer, and interrogator principles

In Sweden the Efos system (Economical Forcing System) makes intensive use of the "relay" principle: the responder, in many situations, does not attempt to describe his hand but makes a minimum bid in the next suit above the opener's suit, asking the opener to describe his hand further. Some European systems extend this idea, and serious tournament players in nearly every country make some use of the allied concept of the "transfer" principle, by which the responder can require his partner to make a certain bid: thus a bid of two hearts in response to one no-trump may require the opener, by arrangement, to bid two spades. Transfers have several theoretical advantages, including the more productive use of bidding space. Some theorists hold that the use of the "interrogator" principle, in which one player does all the asking and the other all the telling, may eventually predominate.

In North America some systems are designed for special effect in tournament play, such as the Roth–Stone system, which contains many original ideas and provides that an opening bid in a major suit is based on at least a five-card suit and that a one no-trump response is forcing.

Nonsystemic bidding. Some areas of bidding are nonsystemic in that they are regulated by separate conventions that can be used no matter which basic system is employed or because the practice is the same in nearly all systems, as with defensive bidding.

Conventions. Many hundreds of conventions have been proposed and a dozen or so have gained very wide acceptance. Conventions may be divided into five groups. (1) Slam conventions such as Blackwood, invented by Easley Blackwood of Indianapolis in the early 1930s: a conventional bid of four no-trump asks for aces: a response of five clubs shows no aces or four aces, five diamonds shows one ace, five hearts shows two aces, and so on. If the four no-trump bidder next bids five no-trump, his partner shows his kings according to the same schedule. (2) No-trump bidding: most conventions in this category are set in motion by the partner of a player who has opened at no-trump. They are designed to discover particular features in the opener's hand: thus, using the Stayman convention, responder bids two clubs over one no-trump to ask for a four-card major suit. (3) Suit bidding: an example is the Swiss convention, a direct bid of four of a minor in response to a major-suit opening, indicating at least the values for game and inviting opener to indicate if his hand is suitable for slam. (4) Suit openings of two: because the forcing-two opening evolved by Culbertson occurs infrequently, many systems employ a conventional two clubs for all hands that would be opened with a two bid in standard American, so freeing the opening bids of two diamonds, two hearts, and two spades for other purposes. (5) Competitive bidding: many conventions have been proposed for use in competitive auctions. Thus, the Roth–Stone system employs a double by opener's partner of an opponent's overcall as a takeout request, that is, a request that his partner make a bid. The same meaning is assigned to a "responsive double" when the partner of a player who has made a takeout double in turn doubles a pre-emptive raise of opener's bid made by his right-hand opponent. Many other bids with conventional meanings—for example, overcalls, doubles, and cue bids of the opponent's suit used to show certain two-suited hands—are also employed in defensive bidding.

Slam and no-trump conventions

Defensive bidding. This term covers all bidding by a side whose opponents have opened. Exploratory se-

quences have little place in defensive bidding, where players may have only a brief opportunity to show their hands. The common practice is similar in nearly all systems: a minimum overcall in a suit suggests a limited hand, no stronger than a sound opening. Playing tricks are the main consideration, and overcalls at the level of two are seldom made with less than five trumps. An immediate double of an opponent's low-level bid is a request for partner to name a suit. Occasionally an overcall may be made with the object of suggesting a good suit to lead.

Sacrifice bids

Apart from the attempt to reach a makable contract, the motives for defensive bidding may extend to the discovery of a satisfactory sacrifice: a contract the bidder knows cannot be made but that, if doubled, will result in a loss smaller than the score the opponents could have made. In deciding how far to bid in competition account is taken of hidden values that do not appear on the score sheet. Thus, a side scores nothing above the line for its first game, but the game has a mathematical value since it increases the chances of winning the rubber. In the same way a part-score is worth more than the points actually entered on the pad. These values cannot be exactly computed, but it is generally reckoned that, with neither side vulnerable, to save the first game at the cost of only 300 (down two tricks doubled, not vulnerable) shows a slight profit in real terms, while to save it at the cost of 500 (down three doubled, not vulnerable, or two doubled, vulnerable) shows a slight loss. A nonvulnerable side can afford to lose 500 to save the rubber, but the vulnerable side loses slightly if it goes down 500 to stop a nonvulnerable game. With both sides vulnerable, to save a game at a cost of 500 shows a profit, for the opponents would have had 500 for rubber, plus the trick score.

PLAY OF THE CARDS

At Rubber Bridge the declarer's first aim is to make his contract, overtricks being a minor consideration. For the defenders, the defeat of the contract is paramount. The same is not necessarily true in tournament Bridge, where the object is to outscore players holding the same cards at other tables. The principles of play described below hold good for all forms of Bridge.

The technique of card play is complex, rivalling that of Chess, but its elements have been analyzed so intensively since Contract became popular that a tournament player of average proficiency may execute, as a matter of course, plays that would have been beyond the finest players of earlier periods in the history of the game.

The declarer's strategy. When the opening lead has been made, the dummy is exposed, and the declarer plans the play of the two hands in concert. The initial approach is to count the tricks that can surely be won, as by playing a card that cannot be beaten or by leading from one hand and ruffing (playing a trump) in the other hand. If these tricks are not enough to fulfill the contract, the declarer may (1) try to win tricks with cards that are not the highest, as by leading toward a king in the hope that the ace is in the hand of the defender who has to play first, or (2) try to establish long cards, which are the cards remaining in one hand when the other three hands have been exhausted of the suit. A long card, if led, will win unless an opponent can trump it.

Sizing up the hand

The chances of success depend on how the unseen cards are distributed, and to fill in the gaps in his knowledge the declarer may make use of assumption. If his contract can be endangered only by a certain distribution of the unseen cards, he assumes that they are so distributed and endeavours to develop the play in such a way that the contract can be made in spite of that. If the contract cannot be made unless the cards are favourably distributed, the declarer assumes that the necessary distribution exists. Thus a relationship arises between the tricks required and the dangers that may prevent their being won, resulting in the formation of a tactical plan.

Declarer also makes frequent use of mathematical probabilities. As the play progresses, he also gains information that can be used as a basis for deduction: the opening lead may indicate the defender's holding in the suit; the bidding may indicate the nature of an opponent's hand, and so on.

The use of deduction is very highly developed among skillful players, who frequently determine the location of the material cards early in the hand, thereafter playing as effectively as if the opponents' hands were visible. Less proficient players can achieve a high measure of success by following well-established methods of play, such as the principle that it is usually more profitable to ruff in the hand that has fewer trumps than in the other hand.

The defender's strategy. The defenders have a harder task than the declarer, for it is more difficult to make the best of two hands when each is hidden from the other. To overcome this handicap the defenders exchange information, as was done in Whist, by means of signals and conventions. Like the declarer, they also follow certain principles of play, such as "Lead through strength and up to weakness."

Exchanging information

The exchange of messages begins with the opening lead. The leader may decide upon one of several tactical plans: against a trump contract, for example, he may simply try to take the tricks that are immediately available, while against a no-trump contract it is more common to lead from a long suit with the object of trying to establish it. In each case the suit led depends on the tactical plan, but the card led is determined by convention, with the object of indicating the leader's holding in the suit. The convention of leading the fourth best of the longest and strongest suit against no-trump and the rule of 11 have been discussed above, but if that suit is headed by A-K-J-x or better it is conventional to lead the king. Against a trump contract it is conventional to lead K from A-K-x or better, but to lead A from A-K bare. (Most treatises on Bridge include detailed tables of conventional leads: see *Bibliography* at the end of this article.)

The exchange of information continues throughout the play, based on the idea that since it is natural, if not trying to win a trick, to play the lowest card, a defender who does otherwise is conveying a message. Thus a defender who plays an unnecessarily high card when his partner leads a winner is asking for a continuation (a "come-on"); a defender who, when evidently not giving a come-on on the strength of high cards, plays high-low in a suit (an "echo") is indicating an even number of cards; a defender who echoes in trump is indicating at least three trumps. In winning or attempting to win a trick to which another player has led, it is conventional to play the lowest card in a sequence: the queen from K-Q-x (the K-Q forming the sequence) and so on.

A special manoeuvre, known as a suit-preference signal, makes it possible to request a partner to lead a suit other than the one being played. When a defender leads a suit for his partner to ruff he can, by playing an unnecessarily high card, ask his partner to lead, at his next opportunity, the higher ranking of the two remaining suits (the trump suit being excluded). The same idea can be extended to many other situations.

These and the many other signals and conventions in defenders' play (which also are covered in detail in the books in the *Bibliography*) do not violate the spirit of the game if they are known to the opponents but they do make possible more effective defense and, therefore, more exciting overall play.

Bridges, Construction and History of

A bridge is a structure surmounting an obstacle such as a river, declivity, road, or railway and used as a passageway for pedestrian, motor, or rail traffic. In this article, the development of bridge design and construction is dealt with chronologically from early times. Consideration is given to the wide variety of foundations required, the superstructures of all types of bridges (*i.e.*, girder, arch, suspension, and combinations thereof), the materials used in construction and their strength and properties, advances in theory and methods of calculation, and the evolution of erection techniques. Late developments and trends are discussed. The article is divided into the following sections:

I. Early bridge building
  Primitive bridges
  Roman bridges
  Bridge developments in Asia
  Medieval and Renaissance bridges in Europe
II. Development of the modern bridge
  The covered (timber-truss) bridge
  The iron bridge
  The modern suspension bridge
  The foundation problem: compressed air
  The steel bridge
  Reinforced-concrete bridges
  Movable and pontoon spans
  20th-century long-span bridges
III. Contemporary developments in bridge engineering
  Improved materials
  New designs
  Improvements in techniques
  Safety problems and solutions
  Future trends

I. Early bridge building

The first bridges were natural, such as the huge, pointed arch of rock that spans the Ardèche River in Ardèche *département*, France, or the rock bridge near Lexington, Virginia. The first man-made bridges were flat stones or tree trunks, laid across a stream to make a girder bridge, and festoons of creepers hung in suspension.

The three great bridge forms

Three types of bridge—beam or girder, arch, and suspension—have been known and built from the earliest times (see Figure 1). The essential difference among them is in the way they bear their own weight. The ends of beam or girder bridges simply rest on the ground, the weight thrusting straight down. Arch bridges thrust outward as well as down at the ends and are said to be in compression. The cables of suspension bridges pull inward against their anchorages and are said to be in tension. In their simplest forms, beam or girder bridges are known as simple spans; if two or more are joined together over piers, they become continuous. A more complex form, the cantilever, is based on the girder (see below). Later variations of the arch have taken the shape of the tied arch, in which a tension member is supplied, usually at deck level, to carry the horizontal component of the thrust, creating a form similar to that of a string bow. In an analogous variation of the suspension bridge, a strut is provided in the deck, between the two anchorages, to relieve them of horizontal pull. Such a bridge is called self-anchored. The three types—girder, arch, and suspension—may also be combined in a variety of ways to form a composite structure. Through the ages, materials of construction have evolved from those ready to hand, such as timber and stone, to manufactured materials, such as brick, dimension stone concrete, reinforced and precast concrete, iron, and steel.

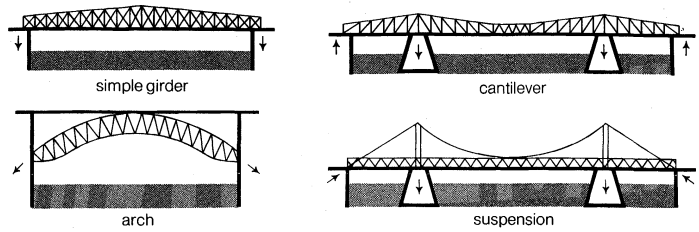

Figure 1: Principal types of bridge. Arrows indicate the forces each exerts onto or away from its foundations.

The type of bridge to be preferred at any site depends on the nature of the ground, the length of the span required, the kind of traffic anticipated, and the materials of construction available. For some of the early bridges in Persia (now Iran), where the riverbed was stony and no timber was available, a site was selected where there were outcrops of rocks across the river on which to build the piers. The resulting structures, such as the bridge over the Kārūn River at Shūshtar, were not straight but wound across from outcrop to outcrop. Alternatively, mounds of stone could be built up on the riverbed, or, if the ground was not too hard, timber piles could be driven through the water to form trestles, as in Caesar's bridge over the Rhine (55 BC).

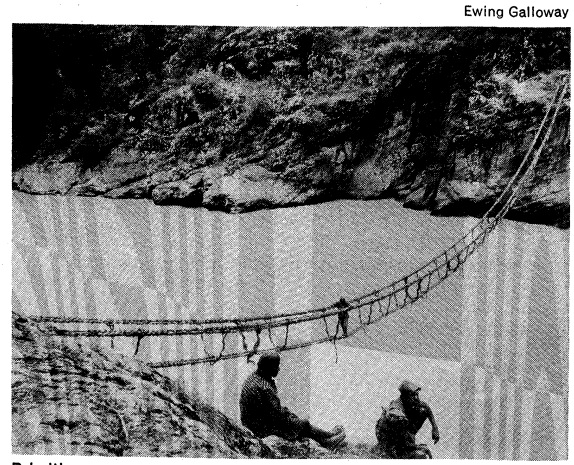
Accounts by Herodotus and others tell of a remarkable bridge built more than 4,000 years ago across the Euphrates in the city of Babylon. It is said that the river, which is very shallow in the dry season, was diverted well above the city so that the stone bridge piers could be built in the dry riverbed. Part of the timber roadway was removable and was taken up each night as a security measure.

Another prehistoric practice is believed to have been that of human sacrifice in the foundations of bridges to appease the river gods. Surviving into Roman times, the practice helped give rise to the Faust legend and is responsible for the many Devil's bridges that are to be found.

PRIMITIVE BRIDGES

Some of the simplest uses of beams are in the "clapper" bridges of Dartmoor, Devon. The beams are actually huge, flat boulders that outcrop on the surface. In the Postbridge over the East Dart River, for example, the three 15-foot- (5-metre-) wide openings of this bridge are spanned by unchiselled slabs of granite, 6 feet (2 metres) wide, on piers of piled-up stone. Elsewhere, as in southeast Cornwall, where timber is more plentiful than stone, primitive crossings take the shape of "clam" bridges, built of tree trunks laid side by side. "Clam" and "clapper" are Anglo-Saxon words denoting, respectively, timber and stepping-stones. Clapper-type bridges are also found in Spain and were probably used in Egypt, Babylon, and China.

Ewing Galloway



Primitive grass-rope bridge over the Indus River in western Tibet.

A special type of beam bridge is the pontoon. The earliest account of pontoon bridges of substantial size, again by Herodotus, describes a bridge of boats built by Xerxes, king of Persia, across the Hellespont at Abydos in 481 BC. No fewer than 674 vessels were used, tied together by ropes and securely anchored. Persian armies then crossed, for the invasion of Europe, on a roadway of earth and brushwood, supported by transverse tree trunks. Then, as in modern times, pontoon bridges probably had the same disadvantages: short life, costly maintenance, and, in most locations, obstruction to navigation.

Xerxes' pontoon over the Hellespont

Most primitive suspension bridges were supported by three cables, two on either side acting as handrails and a third, stouter one, on which the passenger walked. Twisted lianas, creepers, oxhide thongs, bamboo, cane, or similar materials made up the cables. In construction, they were towed across the river, hauled up, and tied high on tree trunks or posts driven in the ground, beyond which they were carried again and securely anchored. Such bridges are found in India, Africa, China, and South America. Built with spans of up to 500 feet (150 metres), they sway and sag in use in a manner to alarm timid passengers.

ROMAN BRIDGES

The Romans were among the greatest bridge builders of antiquity. Their three most important contributions to the art may have been the discovery of a natural cement; the development of the cofferdam, a temporary enclosure built in the stream, within which a concrete pier foundation could be built; and their exploitation of the circular masonry arch. The cement, known as pozzolana, was made by mixing finely ground tuff (a rock formed of compacted volcanic fragments) found near the Italian town of Pozzuoli with lime, sand, and water. The Romans also made pozzolanic cement from powdered pottery fragments. The pozzolanic cements were for a long time the only cements known to resist exposure to water. Their cofferdams were made by driving timber piles to enclose the site of the pier and then pouring in concrete through the water. Alternatively, if the riverbed was very soft, they drove a double row of sheathing piles and filled in the space between with clay to make the cofferdam watertight. They could then empty the cofferdam with waterwheels, dig out the greater part of the soft ground inside it, and pour the concrete for the pier in the dry. The Sant'Angelo Bridge in Rome stands on cofferdam foundations built in the Tiber River more than 1,800 years ago. Nevertheless, the Roman underwater foundations were rarely built deep enough or given sufficient protection against scour to enable them to survive for long. Most of the Roman bridges that remain were built on solid rock.

The superstructures of many Roman bridges, such as Emperor Trajan's bridge built by Apollodorus of Damascus over the Danube in AD 104–105, was of timber on stone piers. None of the bridges of this type has survived. The fame of Roman bridge builders rests largely on their majestic masonry bridges, built on the grand scale, always with circular arches (see Figure 2), which perhaps

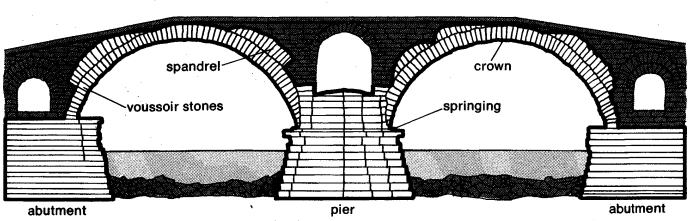


Figure 2: Roman circular arch as seen in the original Pons Fabricius, Rome, 62 BC.

reached the peak of achievement in a mighty bridge over the Tagus at Alcántara, Spain. Built by Caius Julius Lacer for Trajan, the tall granite piers and 98-foot- (30-metre-) wide arches that carry the roadway 170 feet (52 metres) above the river have stood for nearly 2,000 years. The huge stones forming the arch (voussoirs) weigh up to eight tons each and were so accurately shaped that no mortar was needed in the joints. The arches must have been built on temporary timber structures (falsework). The heavy arch stones were no doubt lifted by a system of pulley blocks, operated by means of a winch, probably powered by a treadmill.

Roman Alcántara bridge over the Tagus

Tools used by the Roman masons included saws, chisels, bevels, wedges, and trowels; their instruments for horizontal and vertical alignment included plumb bobs and levels.

Roman bridges required for a military campaign, such as that over the Danube, were usually built by legionaries and financed by the treasury; nonmilitary bridges employed forced labour and generally relied for finance on contributions by townships. Engineers and skilled workmen formed into semimilitary guilds were dispatched throughout the empire to supervise the work. By this means, engineering knowledge was spread and interchanged, and a foundation for schools in which professional standards were formulated was set down. From these fragmentary beginnings evolved the laws of the art of building drawn up by the Roman engineering authority Vitruvius in the 1st century AD in his work *De architectura.*

BRIDGE DEVELOPMENTS IN ASIA

A refinement of the beam that enables it to be used for longer spans is known as a cantilever. Primitive cantilever bridges were made wholly of timber; there are picturesque examples over the River Jhelum at Srīnagar, the capital of Kashmir. For the foundations of the river piers, piles were driven, and old boats filled with stones were sunk at the site, until a desired height above low-water level was reached. Then, on top of the piers, layers of rough-hewn logs were laid crisscross, in such a way that the logs on two adjacent piers jutted further toward each other as the height increased. The two ends of these projecting arms, or cantilevers, were then joined below roadway level by long tree trunks placed across the gap. The roadways on these bridges were usually lined with shops, and the skeleton piers were able to weather severe floods, because they offered less resistance to the flow of water than would a solid pier. Similar ancient bridges are to be found in Tibet and Scandinavia.

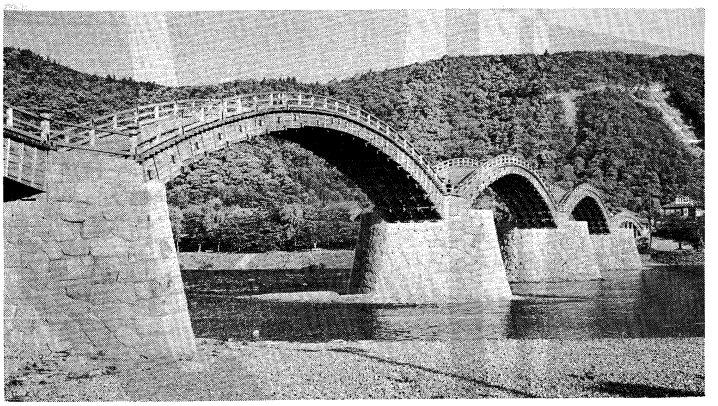
A stone cantilever bridge 1,100 feet (335 metres) long is said to have been built over the Dragon River in Poh Lam, Fukien Province, China. The spans, up to 70 feet (21 metres) in length, were composed of three huge stones, two of which rested on top of the pier at each end, while the third spanned the gap between them. How stones of such a size, weighing up to 200 tons, were quarried and transported in those times is not known.

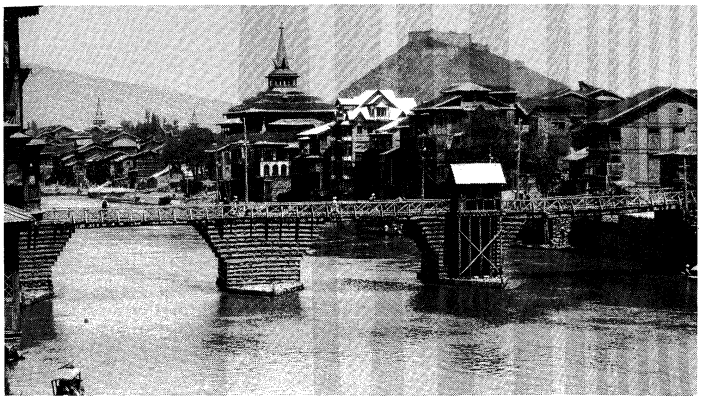
Chinese stone arches

In other parts of China, where bridges had to stand in the spongy, plastic silt of the river valleys, construction developed along very different lines. Here, masonry arch bridges were built of thin, curved slabs, jointed in such a way that they could yield to considerable deformation before failure. These bridges might be described as consisting of stone chains employed in compression. The arches were originally built in the Roman semicircular forms; the bridges were high and narrow, often covered, and with stone steps at the ends. Their amazing flexibility enabled them to adapt both to the rise and fall of the silt foundations and to the weight of the traffic.

Other fine medieval bridges were built in Persia, such as the Red Bridge, which consisted of four pointed arches, on the road from Tiflis (Tbilisi) to Tabriz. Even more distinctive were bridges such as the Allah Verdi Khan and the Pul Khajoo, which were designed as cool, shaded retreats, where the traveller could find rooms for rest and refreshment after crossing the hot desert sands. The two-storied Pul Khajoo at Isfahan (1642–67) is composed of 24 pointed arches that carry an 85-foot-wide roadway, with walled passageways above it, along the top of a pierced dam. Flanked by tall, hexagonal pavilions and watchtowers, the bridge constitutes a magnificent example of engineering and architectural harmony.

In Japan are to be found small, picturesque bridges of timber arches, such as the famous Kintai-kyo (Kintai





Timber bridges.

Bridge) at Iwakuni, which for centuries had its five arches rebuilt in succession, one every 5 years, so that the whole bridge was renewed every 25 years. Completely rebuilt in 1953, it now carries an automobile roadway across the Nishikigawa (Nishiki River).

MEDIEVAL AND RENAISSANCE BRIDGES IN EUROPE

After the fall of the Roman Empire, bridge building in Europe languished for some eight centuries. Its revival was marked by the spread of the ogival, or pointed arch, westward across the continent from Egypt and the Middle East, where it originated. Medieval workmanship was at first not as good as that of the Romans, and the pointed arch may have been preferred because it demanded less precision than the circular form. In the pointed arch, the tendency to sag at the crown is less dangerous, and there is less thrust on the abutments.

Medieval bridges had other functions besides carrying traffic. Chapels, shops, tollhouses, and customhouses were built on them, and they were used for fairs and tournaments. Fortified bridges, such as the Pont Valentré at Cahors, France, the bridge over the Gave de Pau at Orthez, France, or the bridge over the River Monnow at Monmouth, Monmouthshire, Wales, were defended by means of ramparts, towers with firing slits, and often a drawbridge, an original medieval invention. The upkeep of bridges was considered a pious work, for which money was obtained by alms, by endowment, or from tolls levied on both road and river traffic.

One of the most famous medieval bridges in Europe is the Pont d'Avignon over the Rhône at Avignon, France, which was begun under the direction of St. Bénézet in 1177 and completed ten years later. The bridge spanned the river by means of about 20 lofty, elliptical arches, each 100 feet (30 metres) wide. St. Bénézet, who believed that he had been divinely inspired to build the bridge, died before its completion and was buried in a chapel on one of the piers. Because of the ravages of war and damage from ice in the river, little more than the chapel at the Avignon end of the bridge, which has now become a place of pilgrimage, remains standing.

A year before the commencement of the Pont d'Avignon, Peter of Colechurch undertook a far more formidable task—the building of the Old London Bridge. This was the first stone bridge with masonry foundations to be built in a swiftly flowing river having a large tidal range. The bridge was to consist of 19 pointed arches, each with about a 24-foot (7-metre) span, built on piers 20 feet (6 metres) wide (see Figure 3). The 13th arch from the city was designed as a tollgate for merchant shipping with a military drawbridge. The foundations were built inside cofferdams made by driving timber sheathing piles, which held the pier stones in place. Obstructions encountered in

pile driving resulted in variations in the span of the arches of from 15 to 34 feet (5 to 10 metres). The width of the protective starlings (loose stone filling enclosed by piles at the base of each pier) was so great that the total waterway was reduced to a quarter of its original width, and the tide flowed under the narrow archways like a millrace. The bridge, nevertheless, was completed in 1209 and survived, together with its famous tunnellike street of shops and houses, for more than 600 years.

Leonardo's design for the Golden Horn

The confidence and the unbounded enterprise of the Renaissance is reflected in Leonardo da Vinci's offer in 1502 to build a masonry arch bridge with a clear span of 787 feet, over the Golden Horn at Istanbul. Leonardo's design appears to have been practical, except for the difficulty of supporting the falsework (centring), the temporary wooden supports on which the enormous arch would have been built. Less grandiose but more economically and technically feasible bridges were actually built; they included some of the most famous bridges in the world, such as the Pont Notre Dame and the Pont Neuf in Paris, the Rialto in Venice, Italy, and the Santa Trinità in Florence, Italy. Though engineers had learned much about bridge foundations since Roman times, they were still rarely able to excavate deep enough—*i.e.*, down to rock or really hard strata—but they had learned to spread the base of the pier over a wide area and to lay the foundation stones on a broad timber grillage, supported, if necessary, on piles. In the foundation of the Rialto Bridge, for example, Antonio da Ponte, the designer, had 6,000 timber piles driven under each of the two abutments and placed the masonry in such a way that the bed joints of the stones were perpendicular to the thrust of the arch. So well were these foundations built that, although they have to support in soft alluvial soil a wide arch carrying a street of shops, they stand today.

In his beautiful Santa Trinità Bridge in Florence, built 1567–69, Bartolomeo Ammanati, working on scientific principles, evolved a new type of arch. He adopted the ogival (pointed) shape, with the angle at the crown concealed and the curves of the arches starting vertically in their springings from the piers. This elliptical shape of arch, in which the rise-to-span ratio was as low as one to seven, became known as basket-handled and has been widely adopted since. Demolished by the retreating Germans in World War II, the Santa Trinità Bridge was later rebuilt exactly as it stood and, so far as possible, with the original materials, recovered from the bed of the river. An even earlier bridge in Florence, and one that was spared in World War II, was the Ponte Vecchio, ascribed to Taddeo Gaddi in the 14th century. Its three well-balanced arches, supported on peaked piers, are elliptical in shape. The narrow, gently sloping roadway is lined on both sides with tiny shops.

By the middle of the 18th century, bridge building in masonry reached its zenith. Jean-Rodolphe Perronet (1708–94), builder of some of the finest bridges of his day, developed very flat arches supported on slender piers. He served as director of the first engineering school in the world, the famous École des Ponts et Chaussées (School of Bridges and Highways), founded in 1747, and his works included the Neuilly Bridge, over the Seine, the Pont Sainte-Maxence, over the Oise, and the beautiful Pont de la Concorde, over the Seine, in Paris. In Great Britain, William Edwards built what many people consider the most beautiful arch bridge in the British Isles—the Pontypridd Bridge, over the Taff in Wales, with a lofty span of 140 feet (43 metres). In London, the young Swiss engineer Charles Labelye, entrusted with the building of the first bridge at Westminster, evolved a novel and ingenious method of sinking the foundations, employing huge timber caissons (boxes) that were filled with masonry after they had been floated into position for each pier. The twelve semicircular arches of Portland stone, rising in a graceful camber over the river, set a high standard of engineering and architectural achievement for the next generation and stood for a hundred years.

First Waterloo Bridge

Also in London, John Rennie, engaged by private enterprise in 1811, built the first Waterloo Bridge, whose level-topped masonry arches were described by Canova as "the noblest bridge in the world." It was replaced by a modern bridge in 1935–42. Rennie subsequently designed and built old Southwark Bridge (1814–19), which consisted of three cast-iron arches with spans of up to 240 feet (73 metres), and the New London Bridge of multiple masonry arches, which was completed in 1831, after his death, and subsequently widened.

II. Development of the modern bridge

In the 17th and 18th centuries, bridge building became a science. Early in this period, scientists, including Galileo, had investigated the theory of beams and framed structures, and before the end of the period bridge builders were required to work to detailed specifications.

THE COVERED (TIMBER-TRUSS) BRIDGE

The truss, a structural form based on the triangle, had long been used to support roofs when it was adapted to bridge design by the Italian Renaissance architect Andrea Palladio. In the 18th century, Swiss carpenters used it to build a covered timber bridge having spans of 193 feet (59 metres) and 171 feet (52 metres) over the Rhine at Schaffhausen, Switzerland. This feat was followed by a similar timber bridge with a 240-foot span at Reichenau, Switzerland. The barnlike covering of timber-truss bridges was necessary to protect the structural members against the weather. In North America, many outstanding timber-truss bridges were built, the first probably that over the Connecticut River at Bellows Falls, Vermont, in 1785. The so-called Colossus Bridge, with a 340-foot span over the Schuylkill River at Fairmount Park, Philadelphia, was constructed in 1812. One of the best long-span truss designs was developed by Theodore Burr, of Torrington, Connecticut, and based on a drawing by Palladio: a truss strengthened by an arch, which set a new pattern for covered bridges in the United States. Burr's McCall's Ferry Bridge (1815; on the Susquehanna River, Lancaster, Pennsylvania) had a record-breaking span of 360 feet (110 metres), and hundreds of his bridges are still in use.

THE IRON BRIDGE

It was not until late in the 18th century that iron came to be generally employed in structures, freeing bridge builders from their exclusive dependence on timber, brick, and stone. The possibilities opened up by the new material were quickly exploited, and by 1860 numerous iron arches, suspension bridges, and girders had been built. This period also witnessed the first use of compressed air in the construction of bridge foundations below water. Iron chains had been used in suspension bridges for centuries, but the world's first all-iron bridge was a semicircular arch with a 100-foot (30-metre) span, built over the Severn at Coalbrookdale, Shropshire, in 1779. It carried roadway traffic for more than 170 years. This was followed by a number of cast-iron arches designed by the gifted, self-educated Scottish engineer and road builder Thomas Telford, of which the first was the Buildwas Bridge, Shropshire, with a 130-foot (40-metre) span, and the most ambitious was a design for a high-level, 600-foot (180-metre) span (which was never built) to replace Old London Bridge.

In 1840 American patents were granted for a timber truss, in which the verticals consisted of iron ties. This was followed by numerous other trusses. The first major iron-truss bridge, with pin connections, was built in the United States in 1851, and the earliest iron-cantilever girder, which consisted of alternate cantilever and continuous spans, was built over the Main River at Hassfurt, Germany, in 1867.

Robert Stephenson's Britannia Bridge

The Britannia railway bridge (1845–50) across the Menai Strait, north Wales, was designed by Robert Stephenson and William Fairbairn. Employing the prototype of the box, or plate, girder of the kind now used throughout the world, it was originally intended to be a stiffened suspension bridge. It has four spans, each consisting of two wrought-iron tubes side by side, through which the trains run; the two spans over the water are each 459 feet (140 metres) long, and the shore spans are

230 feet (70 metres). In spite of the fact that L.-M.-H. Navier's lectures on the theory of elasticity and structures had been published some years earlier, so little was known of structural-design theory that Stephenson had to proceed empirically by testing, modifying, and retesting a series of models. Workshops were built at the site to fabricate the wrought-iron plates and sections (of the kind that had recently been produced for shipbuilding), which were raised and moved by means of overhead gantries. Rivetting was done mostly by hand but in part by hydraulic machines designed by Fairbairn. During the erection of the bridge, it was found to be possible to dispense with the suspending chains altogether, and the tubes for the spans over the water, each weighing 1,285 tons, were floated out on pontoons and raised to their final level by means of huge hydraulic jacks located on the piers. Carrying locomotives 12 times heavier than those in use when it was designed, the Britannia Bridge survived until it was severely damaged by fire in May 1970. Comprehensive reconstruction was at once undertaken with the object of reopening the bridge with the addition of a three-lane roadway above the two railway tracks.

A major early iron-bridge disaster occurred in December 1879, when the 13 high spans of the new railway bridge over the Firth of Tay, Perth, were blown down in a great gale 18 months after completion. The Edinburgh mail train was crossing the bridge at the time, and it is estimated that 75 persons lost their lives. Consisting of wrought-iron trusses 245 feet (75 metres) long, the girders that fell stood on cast-iron columns rising from piers of brick and concrete. At the time, little if anything was known of the wind pressures that should be considered in the design of bridges. There was no continuous, lateral wind bracing provided below the deck, and, in fact, the designer subsequently said that no special provision had been made for wind pressure.

The second half of the 19th century was outstanding for the advances made in the theory of design and knowledge of the strength of materials by scientists such as Karl Culmann of Germany, and James Clerk Maxwell and W.J.M. Rankine of Britain. As a result of work in basic science and mathematics, graphic methods of structural analysis were developed, and engineers were able to draw stress diagrams and influence lines; *i.e.*, curves showing, for one component part of a beam or truss, the resistance to various types of stress for all positions of a moving load.

THE MODERN SUSPENSION BRIDGE

In the design of the Menai suspension bridge (1820–26), a 580-foot (177-metre) span in north Wales, Telford used chains of wrought-iron links, all of which were tested and pinned together. The chains, laid out full length, were then towed across the waterway and hoisted into place; and the deck was suspended beneath them. The roadway was only 24 feet (7 metres) wide and, in the absence of any kind of stiffening girders or storm bracing, was highly vulnerable to damage by wind and had to be rebuilt at least twice before the whole of the bridge was reconstructed in 1940. In view of the fate of most of the early suspension bridges in both Europe and the United States, it is a credit to Telford that the Menai Bridge survived for 115 years. Another chain suspension bridge that had a long life was a span over the Danube at Budapest, Hungary. Completed in 1849, it survived for nearly 100 years, until it was destroyed in World War II.

The first engineer to employ wire cables instead of chains on suspension birdges was M. Chaley, a French engineer who not only built the bridges at Beaucaire, Chasey, and other places in the south of France but was also responsible for the Fribourg Bridge (1830–34) in Switzerland, which had a span of 870 feet, at that time the longest in the world. Each of the main cables, 1,280 feet (390 metres) long from anchorage to anchorage, was made up of 2,000 separate iron wires, which passed over the top of masonry towers, beyond which they were anchored in 58-foot-deep shafts. The bridge carried a roadway 16 feet (5 metres) wide, separated by oaken balustrades from footpaths three feet (1 metre) wide on either side, all at a height of 163 feet (50 metres) above the River Saône. Another early suspension bridge with iron-wire cables was the Bry-sur-Marne Bridge, opened to traffic in 1831 and destroyed during the war of 1870.

The multiple-span suspension bridge (*i.e.*, a bridge made up of more than three successive suspension spans without any intermediate anchorage) appeared as early as 1839 in the Dordogne River Bridge, with five equal spans of 357 feet (109 metres) each, supported on wire cables, at Cubzag, France; another was the Dnepr River Bridge (1853) at Kiev, Russia, with two spans of 226 feet (69 metres) and four spans of 400 feet (134 metres), supported by wrought-iron chains.

Early suspension failures

The weaknesses of the early suspension bridges in storms or under repeated rhythmic loads were fatal for most of them. In 1831 the Broughton suspension bridge collapsed because of oscillations set up by a body of troops marching in step. Four other bridges in the U.S. and Britain were destroyed simply by the impact of flocks of sheep or droves of cattle. The Chain Pier Bridge at Brighton, Sussex, and the Union Bridge over the Tweed at Berwick, Northumberland, were both blown down. The first railway suspension bridge, built in 1830 to carry the Stockton and Darlington Railway over the Tees, was hammered to destruction in a few years by the weight and impact of the trains. In the U.S., the Fairmount Bridge, supported by a number of small wire cables, over the Schuylkill River, was a success, but a 1,000-foot (300-metre) span over the Ohio River at Wheeling, West Virginia, survived only five years.

Credit for designing and building the first suspension bridge that was rigid enough to withstand not only wind action but also the impact of railway traffic belongs to John A. Roebling, an immigrant from Germany to the United States. In his Grand Trunk Bridge of 821-foot (250-metre) span below Niagara Falls, there were two decks, one above the other, for rail and road traffic, respectively, with a pair of stiffening trusses 18 feet (five metres) deep connecting them. In addition, the deck was braced by means of inclined wire stays overhead and others below, anchored to the sides of the gorge. For the four main cables, instead of the separate stranded or twisted ropes that had been used for cables in Europe, Roebling used parallel wrought-iron wires, spun in place, bunched together, and wrapped, a process he had patented in 1841; each cable was 10 inches (25 centimetres) overall in diameter. The bridge was completed in 1855 and survived for 42 years, although not without considerable repair work and reconstruction necessitated by the wear and tear of traffic.

The famous Brooklyn Bridge (1869–83), with a record-breaking span of 1,595 feet (486 metres), was designed by John Roebling and erected under the direction of his son, Washington. It has four cables with an overall diameter of 15.75 inches, built up of parallel steel wires. The method of cable spinning devised by Roebling was so simple and effective that it has been used in principle, although now much elaborated, for all the large suspension bridges subsequently built in the United States (see Figure 4). The wire is delivered to the site in reels, from which loops are carried over the tops of the towers to the far anchorage, where each loop is pulled off the sheave and placed around a strand shoe, by which it is anchored.

By the time of the Brooklyn Bridge, the stiffening truss had been established as an indispensable part of the suspension-bridge deck. In the Point Bridge at Pittsburgh, Pennsylvania (1877), an attempt was made to stiffen the cables instead of the deck, but this proved less effective.

THE FOUNDATION PROBLEM: COMPRESSED AIR

Up to the middle of the 19th century, cofferdams were the only means by which bridge foundations could be properly constructed below water. But, because of the limited length of the sheet piling and the difficulties caused by obstructions or by very hard or soft ground, cylinders or wells were employed and sunk either by dredging or under compressed air. The first use of pneu-

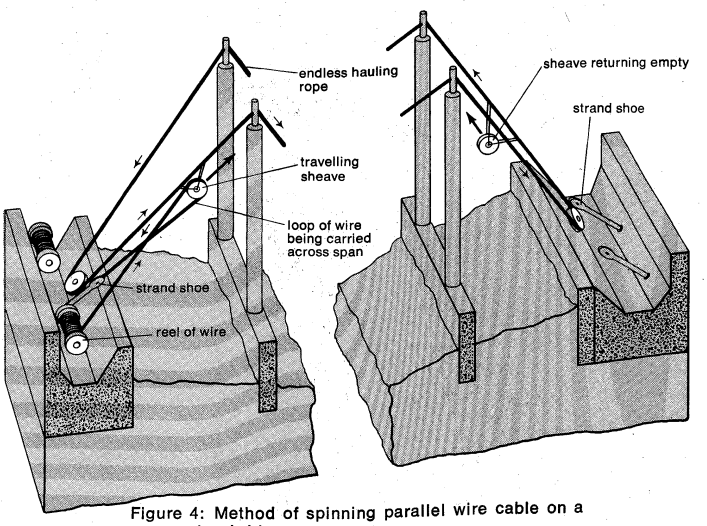

Figure 4: Method of spinning parallel wire cable on a suspension bridge.

Use of pneumatic caissons

matic caissons (Figure 5) for bridgework was on the foundations of a bridge over the Medway at Rochester, Kent, in 1851. Subsequently I.K. Brunel used this method for sinking the foundations of Chepstow Bridge, Monmouth, and, on a much greater scale, for the Royal Albert Bridge at Saltash, Cornwall (1855–59). In the latter, a wrought-iron cylinder 35 feet (11 metres) in diameter was designed for the central pier and sunk through 70 feet of water and 16 feet (5 metres) of mud to a rock bottom. Water was expelled by compressed air from the floorless working chamber at the bottom of the cylinder; workers entered the chamber through an air lock and excavated the mud and rock, causing the caisson slowly to sink until a hard stratum was reached. They then securely plugged the bottom of the foundation with concrete.

Many early tragedies in the use of compressed air were caused by men working excessively long shifts or coming out of the air lock and decompressing too quickly and being afflicted by caisson disease, or bends. With the limiting of the length of the working shift according to the air pressure and with slow decompression in the air lock, the incidence of caisson disease was reduced. Further investigations at the beginning of the 20th century robbed the disease of its worst terrors, except for the danger of bone necrosis, for which no cure has yet been found.

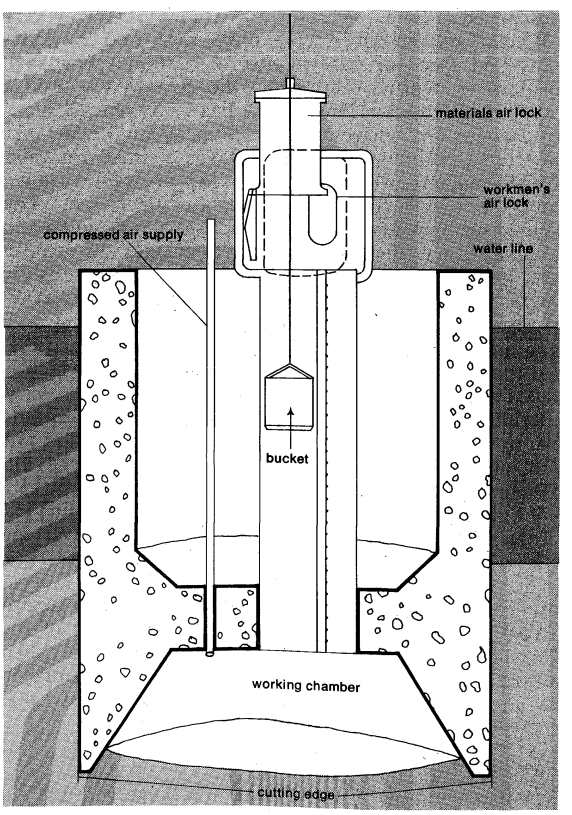

Figure 5: Pneumatic caisson.

Royal Albert Bridge over the Tamar at Saltash, Cornwall. Designer Isambard Brunel employed a wrought iron cylinder 35 feet in diameter for the central pier in this innovative design of 1855–59.

THE STEEL BRIDGE

The last 30 years of the 19th century saw the introduction of steel plates and rectangular, rolled-steel sections, which came to be mass-produced and fabricated in shops by standardized methods. This inevitably led to an enormous production of steel-truss and plate-girder bridges throughout the world and to spans of ever-increasing size. Arch and cantilever bridges were favoured for long spans in the railway era because they could withstand the impact of heavy railway traffic better than could suspension bridges.

The Eads Bridge

The first big bridge to be built of steel was the Eads Bridge built over the Mississippi River (1867–74) at St. Louis, Missouri. It was designed with three steel arches with spans of 502, 520, and 502 feet (153, 158, and 153 metres), respectively. The spans were made double-decked to carry wagon and pedestrian traffic on the upper deck and two railway tracks below. To reach bedrock, the foundations had to be excavated more than 100 feet deep, although this necessitated working under compressed air at depths greater than men had ever worked before. So little was known of the precautions needed under these conditions that, of the 600 men employed in sinking, there were 119 serious cases of bends and 14 deaths.

An innovation on this bridge that has since been widely copied was the erection of the arches by cantilevering. Arch ribs were built out in either direction from the pier and held by cables extending from a temporary wooden tower atop the pier. Halfway to the next pier (or abutment), the half-arch met and joined a half-arch similarly cantilevered out to meet it.

In 1898 an arch bridge with a span of 840 feet (256 metres) was completed below Niagara Falls; it stood for 40 years, until the ends of the steel ribs were wrecked by a huge ice jam in the river. In the same year, the first major steel bridge in France was opened, the Viaur Viaduct, which consisted of an arch 721 feet (220 metres) long, flanked by cantilever spans of 311 feet (95 metres). Seven years later the Victoria Falls Bridge, with a braced arch spanning 500 feet (152 metres), was built in Africa to carry the Cape-to-Cairo Railway, then projected by Cecil Rhodes, across the 400-foot- (122-metre-) deep gorge of the Zambezi River.

For the design of the Forth Railway Bridge between North and South Queensferry (1882–90), with two main spans of 1,710 feet (521 metres) each, in Scotland, the designer conducted an extensive series of wind-pressure

tests, using gauges installed at the site, over a period of two years. As a result, he was satisfied that the pressure of 56 pounds per square foot, specified for the design by the committee set up after the Tay Bridge disaster, was "considerably in excess of anything likely to be realised," and so it proved.

The two main spans of the bridge each consist of two 680-foot (207-metre) cantilever arms, with a 350-foot (107-metre) suspended span between them. About 54,000 tons of Siemens-Martin open-hearth steel, which has a substantially higher ultimate strength than modern, commercial mild steel, was used. The biggest compression members were designed as tubular struts 12 feet (4 metres) in diameter, and all of the steelwork was fabricated in shops built for the purpose at South Queensferry. The spans were built out as balanced cantilevers from each main pier, the tubular members being erected plate by plate by means of two-ton hydraulic cranes.

The latter half of the 19th century witnessed the construction in India of a large number of multispan railway bridges more than 1,000 feet long. Their British builders learned how to utilize the simplest kind of equipment and unskilled labour; they had to study and develop the use of guide banks as a means of keeping the rivers under the bridges and preventing them from meandering; and, sinking brick wells by dredging in the sand, they built the deepest foundations ever constructed up to then, as a safeguard against undermining when the sand of the riverbeds was scoured away during the flood seasons.

In 1896 the first Vierendeel truss, in which the bracing consisted of a series of framed portals with rigid verticals and no diagonal members, was built for the Brussels Exhibition.

REINFORCED-CONCRETE BRIDGES

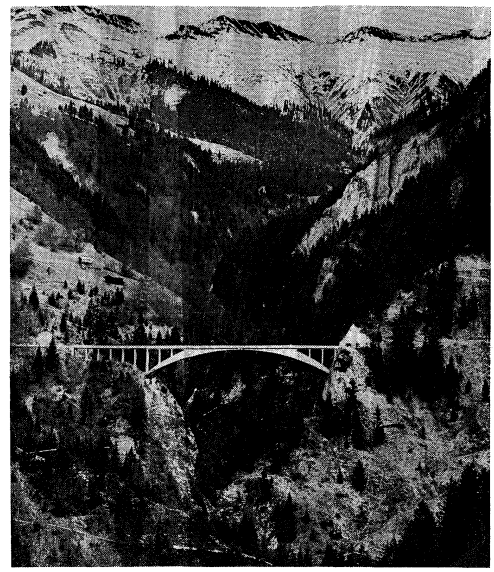
Engineers in the late 19th century first demonstrated the possibilities of reinforced concrete as a new structural material. Visualizing the novel forms that could be molded, with concrete resisting the compression forces and steel bars taking the tension, they designed bridges in sweeping curves. The basic element in reinforced concrete was the slab, which replaced the beams, posts, and ties associated with steelwork design. From the start, Switzerland, France, and the Scandinavian countries took the lead, and the longest and most impressive reinforced spans were built in those nations.

Robert Maillart's Pont de Chatellerault

The first notable reinforced-concrete arch, the Pont de Chatellerault (1898), was designed with a span of 172 feet (52 metres). Robert Maillart designed three-hinged arches, in which the deck and the arch rib were combined to produce closely integrated structures. The first of these was the Tavanasa Bridge, a span of 167 feet (51 metres) over the Vorderrhein, Switzerland, which was destroyed by a landslide in 1927. In these bridges, Maillart recaptured the beauty of the pointed arch of medieval times. He then developed arches of very thin reinforced-concrete slabs, typified by the Schwandbach Bridge (1924) near Schwarzenberg, Switzerland, which was curved in plan and carried a roadway across a deep ravine.

One of the biggest reinforced-concrete bridges in the United States, the Tunkhannock Creek Viaduct, Pennsylvania, was completed in 1915. Its overall length of 2,375 feet (724 metres) comprises ten semicircular arches that carry a double-track railway at a height of 240 feet (73 metres). In Great Britain, the first major reinforced-concrete structure was the Royal Tweed Bridge at Berwick. Completed in 1928, it has four arch spans varying from 167 feet (51 metres) to 361 feet (110 metres). It was followed in 1935–42 by the new Waterloo Bridge in London. Because of its slender simplicity and absence of decoration, it is frequently held to be the finest bridge over the Thames.

In France, a then record span of 430 feet (131 metres) was built in 1923 over the Seine at Saint-Pierre du Vauvray. It was surpassed seven years later by the Albert-Louppe (or Plougastel) Bridge at Brest. The latter had three arch spans of 567 feet (173 metres). The centring (supporting falsework) consisted of a timber arch 500 feet (152 metres) long and 90 feet (27 metres) high, the ends of which were tied together by cables. It was built on shore, floated out on pontoons, and secured in place for pouring each arch rib in turn.



Salginatobel Bridge near Schiers, Switzerland, a reinforced-concrete bridge designed by Robert Maillart and built 1929–30.
By courtesy of the Grisons Tourist Office, Chur, Switzerland

In Sweden, the Traneberg Bridge was built in 1934 in Stockholm. It has an arch 593 feet (181 metres) long. It was surpassed by the Esla Bridge in Spain, with a 631-foot (192-metre) span completed in 1942, but a year later Sweden regained the lead with an 866-foot (264-metre) span of the Sandö Bridge, over the Angermanälven River. In 1939, during the pouring of the rib, the wooden arch that formed the centring collapsed. Its failure was ascribed to persistent damp weather and the long loading period. New centring for the bridge had to be built in the form of huge timber trestles supported on 13 groups of piles 130 feet long, and the bridge was successfully completed in 1943.

Precast-concrete girders are sometimes used for economy and speed of construction in multiple short-span bridges. A typical example is the San Mateo Bridge across San Francisco Bay, which has 1,054 precast spans of 30 feet (9.1 metres) and 116 spans of 35 feet (11 metres). One of the main advantages claimed for reinforced-concrete bridges is that, if they are well designed and the construction is thoroughly supervised, they should be maintenance-free and not require cleaning and painting every few years, as do steel bridges. To achieve this, the concrete must have a solid, weather-resisting surface, free from cracks and honeycombs, or, alternatively, must be stone faced. Facing is costly but is a guarantee against deterioration of appearance. A successful example is the Waterloo Bridge in London, which is faced with slabs of Portland stone.

Reinforced-concrete bridges in the U.S.S.R. include the Saratov Bridge (1965), with five continuous trusses of 544 feet (166 metres) over the Volga River, and the old Dnepr Bridge (1952) at Zaporozhia, Ukrainian S.S.R., with an arch of 748-foot (228-metre) span. Two fine examples in Portugal are the low, slender arch over the River Tua at Abreiro (1957), which has a rise-to-span ratio of one to ten, and the 885-foot (270-metre) fixed arch of the Arrábida Highway Bridge over the Douro River. This span was surpassed in 1963 by that of the Foz do Iguaçu Bridge over the Paraná River between Brazil and Paraguay and by the Gladesville Bridge in Sydney, New South Wales (1964), with its span of 1,000 feet (305 metres) over the Parramatta River.

MOVABLE AND PONTOON SPANS

The bascule (draw) bridge, lifted on a hinge with the aid of a counterweight, was developed in the Middle Ages.

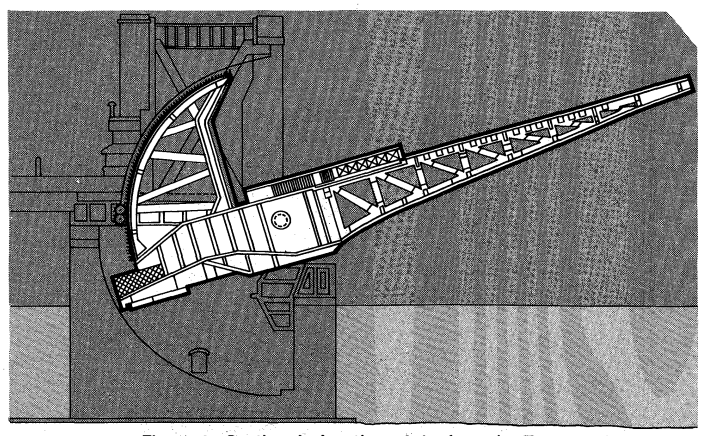


Figure 6: Sectional elevation of the bascule, Tower Bridge, London, 1886–94.
From O.E. Hovey, *Movable Bridges* (1927); John Wiley & Sons, Inc.

Old London Bridge had such a drawbridge. The first swing, or pivot, bridges appeared in London early in the 19th century. The heavy, powered bascule and the vertical-lift bridge were evolved in the latter half of the 19th century. The Tower Bridge in London (1886–94) is a double-leaf bascule that provides an opening 260 feet (76 metres) wide and is operated by hydraulic power derived from steam (see Figure 6). The biggest bascule span to date is the Sault Sainte Marie, Michigan (1941), which has an opening span of 336 feet (102 metres). A variety of bascule that requires no counterweight is the rolling lift bridge, in which the leaves roll back on tracks to open the bridge.

Notable modern bascules

In vertical-lift bridges, the span remains horizontal and is lifted by means of counterweighted cables that pass over the end towers. The Arthur Kill Bridge is of this type. Built in 1959 to link Staten Island, New York City, with New Jersey, it has a lifting span of 558 feet (170 metres).

The longest swing bridge yet built is the al Firdan Bridge over the Suez Canal, Egypt, composed of twin swing spans, pivoted on piers at either shore, 552 feet (165 metres) from turntable to turntable. Ordinary swing spans, pivoted on a central pier, cause more interference with river traffic than bascules and may obstruct valuable wharf space. Another advantage of bascules is that they can be partially opened to let small craft pass.

*Railway bridge. †Combined length, including both arms.

The longest floating spans in the world are clustered around Seattle, Washington; the longest, over the Hood Canal, measures 7,131 feet (2,139 metres). The second and third longest stretch side by side over Lake Washington, a distance of 6,560 feet (1,999 metres). Other famous floating bridges, since replaced by high-level fixed bridges, include a 3,165-foot (965-metre) curved pontoon span at Hobart, Tasmania, a pontoon bridge at Calcutta (built in 1874), and a 1,500-foot (457-metre) bridge over the Golden Horn at Istanbul. All these bridges had movable spans that could be opened to permit shipping to pass.

20TH-CENTURY LONG-SPAN BRIDGES

Loadings and forces. The most important weights and forces to which a bridge is subject are its own weight; the weight of the traffic and its dynamic effects; natural forces set up by wind, changes in temperature, snow loads, earthquakes, etc.; and stresses arising temporarily during erection. Railway bridges must withstand not only the weight of the locomotives and rolling stock but also the impact and effects of lurching and lateral motion of the locomotive. On the highways of several countries, automotive vehicles weighing up to 200 tons are not uncommon, and new bridges must be designed to support them.

Considerable research has been carried out on wind forces, which can now be closely estimated, but wind-tunnel tests on a model are still usually carried out to assess the effects of wind forces on a long-span suspension bridge. Although no bridge could withstand an earthquake of catastrophic force, bridges in India and New Zealand are designed to resist a horizontal force equal to one-tenth and, in Japan, Italy, and the U.S.S.R., to one-fifth of the weight of the superstructure. The designs of the Golden Gate and San Francisco-Oakland Bay bridges in San Francisco, the Auckland Harbour Bridge in New Zealand, and the Howrah and Ganga bridges in India were all calculated to resist earthquake shocks, which in the past have damaged or destroyed many bridges.

Wind-tunnel tests on models

It remains for the engineer to exercise his judgment in assessing future traffic developments and deciding what combinations of loading and forces should be adopted and the factor of safety applicable in each case. Factors of safety are now considered from the point of view of "limit states," which are states in which the structure in whole or in part threatens to cease to fulfill the function for which it was designed. The field is enormous, because the effect of numerous factors, such as loading,

impact, fatigue, and corrosion, must be assessed for different types of structures and materials of construction and suitable margins of safety provided for various causes of failure, such as deformation, buckling, fatigue, brittle fracture, or collapse of some element. While conferring greater uniformity of strength throughout all parts of the structure, this change in philosophy may also permit valuable savings to be made.

Table 2: Longest Span Reinforced-Concrete Arch Bridges

For a given ratio of strength to weight of materials there is a maximum span for each type of bridge beyond which it would have an insufficient margin of strength to support the weight of traffic in addition to its own weight and other forces to which it might be subject. For cantilever bridges built with modern high-tensile steel, the maximum span would approach 2,500 feet and, for arch bridges, 3,000 feet. On account of the much higher strength-to-weight ratio of steel-wire cables as compared with structural steel, suspension bridges can be built with much longer spans. In a period of 80 years, the maximum suspension span has increased from 1,500 to 4,260 feet (457 to 1,298 metres), bearing out predictions made by Roebling in 1855.

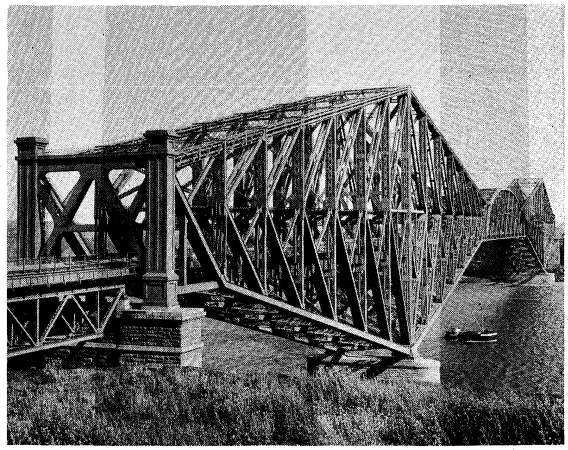
Cantilever bridges. In 1904 work began on the first Quebec Bridge, which was to carry two railway tracks on a cantilever span of 1,800 feet (549 metres). The two giant cantilevers were erected without incident, and the relatively short suspended span between was developed from both sides. Suddenly the whole of the structure on the south side, some 20,000 tons of steel, collapsed, killing 75 workmen, the most costly bridge-construction disaster on record. Investigation revealed that the failure was caused by buckling of web plates in which the lacing was too weak and by certain unrivetted connections. Other grave disclosures, however, were that the specifications were inadequate, the weight of the bridge was underestimated, and the working stresses were unwarrantably high.

The Quebec cantilever disasters

For the new design, made after an exhaustive series of tests on structural members and rivetted joints, high-tensile nickel steel was used for the main trusses, and the



Quebec Bridge across the St. Lawrence River, designed by Theodore Cooper. The steel cantilever railroad bridge, spanning 1,800 feet, was completed in 1918.
By courtesy of Canadian National Railways

width of the bridge was increased from 67 to 85 feet, greatly increasing its strength. The suspended span, 640 feet (195 metres) long, was built, floated out, and attached to lifting links at the four corners of the cantilever arms. As it arose, suddenly, one of the castings at the end of a lifting link failed, and the span tilted, broke, and fell into the water, carrying 11 workmen with it. Within 12 months, a new span had been constructed and successfully lifted into place. First opened to traffic in August 1918, it has remained the longest cantilever span in the world.

Another great cantilever is the Howrah Bridge (1936–43), over the Hooghly River at Calcutta, which has a span of 1,500 feet (457 metres). An interesting innovation on the Howrah Bridge was that the high-tensile steelwork was prestressed during erection; this measure obviated secondary bending stresses that would otherwise have occurred at the rivetted connections. The span of the Howrah Bridge has since been exceeded by the Greater New Orleans Bridge (1958), in Louisiana, and the Delaware River Bridge, in Chester, Pennsylvania, due for completion in 1971.

Arch bridges. The Sydney Harbour Bridge (1924–32), New South Wales, may be considered the world's greatest steel arch because of its immense carrying capacity and the difficulties overcome in erecting it across a deep harbour in which no temporary supports were practicable (Figure 7). With a span of 1,650 feet (503 metres), it was built to carry four interurban rail or streetcar tracks, in addition to a roadway 57 feet (17 metres) wide and two pedestrain walkways.

The two-hinged arch, flanked by granite-faced pylons, has a deck suspended at a height of 172 feet (52 metres) over the water. Most of the 38,390-ton arch is of rivetted, high-tensile silicon steel made in Britain and fabricated in shops built for the purpose in Sydney. The 11-foot-

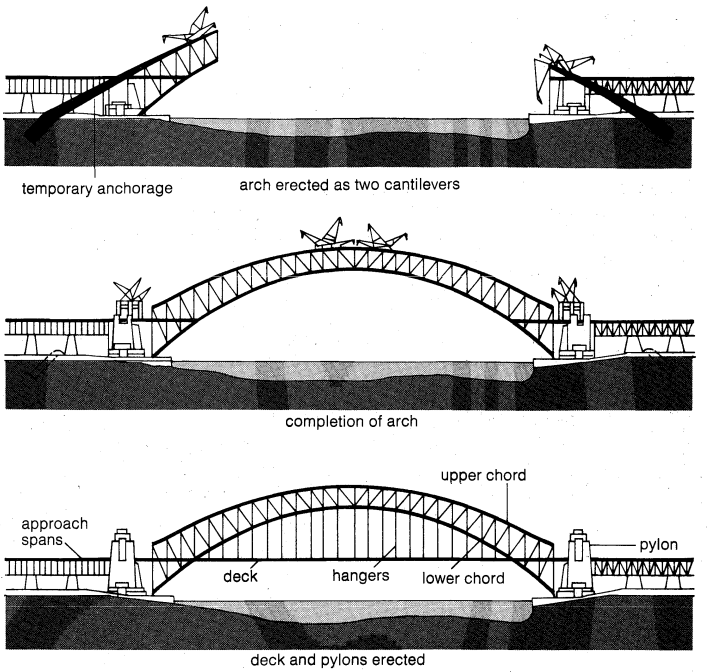

Figure 7: Erection of Sydney Harbour Bridge, New South Wales.

(3.5-metre-) wide webbed chords (top and bottom members) of the arch are the heaviest steelwork of this kind ever constructed. The two halves of the arch were built out as cantilevers, temporarily held back by wire-rope anchorages until they met and were joined in the middle. All of the steelwork was assembled by two cranes that moved out along the upper chords of the arch until it was complete and then erected the hangers and the deck as they retreated.

Another large steel arch, the Bayonne Bridge, over the Kill van Kull between Staten Island and Bayonne, New Jersey, was begun after the commencement of Sydney Harbour Bridge and completed a few months before. It was built over a waterway shallow enough to permit erection of the arch on temporary trestles. Twenty-five inches longer than the bridge at Sydney, it carries automobile and truck traffic.

Suspension bridges. In the series of suspension bridges of ever-increasing span built in the United States between World Wars I and II, cables of parallel wires were invariably used. Although the ultimate strength of a given weight of wire increases as it is drawn thinner, it is found most economical to use wire of about 0.19-inch (5-millimetre) diameter, because the thicker the wire the less length there is to be spun to make up a cable of the necessary diameter.

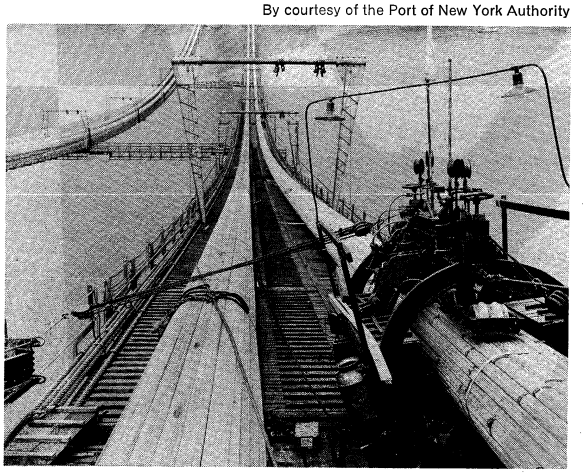
In Canada, cables of stranded-wire ropes have been adopted, notably on the Island of Orleans Bridge at Quebec (1935) and the 1,550-foot-(472-metre-) span Lions Gate Bridge at Vancouver, British Columbia (1939). A third variant, known as "locked-coil" cables, in which the wires of each strand are specially shaped so as to form a smooth circumference, was used in the Cologne–Mulheim Bridge over the Rhine in West Germany.

In the 1,750-foot (533-metre) span of the Philadelphia–Camden Bridge (1926) on the Delaware River, cold-drawn parallel wire continued to be used in the cables, and cellular construction, in which towers were built up of a number of vertical cells, was adopted for the first time.

To increase the allowable stress in the cables, heat-treated wires were introduced in the bridge at Mount Hope, Rhode Island, and in the 1,850-foot-(564-metre-) span Ambassador Bridge over the Detroit River in Detroit, both completed in 1929. During erection of the cables, however, a number of broken wires were detected at the bends around the strand shoes at the anchorages. Investigation showed that the fine-grained, heat-treated wires could not withstand the alternating stresses to which suspension cables were subject; they had to be replaced by cold-drawn wire, which has a tough, fibrous structure and can resist such stresses.

The next advance was the George Washington Bridge (1927–31), over the Hudson River at New York City. Designed by Othmar H. Ammann, Swiss-born U.S. engineer, it has a span of 3,500 feet (1,067 metres) and two roadways, one above the other. Four cables, 36 inches in diameter, each built up of 26,474 parallel galvanized wires with an ultimate strength of 98 tons per square inch, were used. Initially, there were no stiffening trusses; only the upper roadway was built. The construction of

By courtesy of the Port of New York Authority



Cable compactor working on the George Washington Bridge over the Hudson River, New York City, during its construction in 1930.

the lower deck and of stiffening trusses between the two decks was completed in 1962. The great mass of wire in the cables (a total of 105,000 miles) prompted a higher degree of mechanization in the cable erection than had ever been achieved before.

In 1933 work began in San Francisco on two major suspension bridges, the double-decked San Francisco-Oakland Bay Bridge, designed with an overall length of nearly 5.25 miles (8.45 kilometres), and the Golden Gate Bridge, with a span of 4,200 feet (1,280 metres), across the entrance to the harbour.

The Mackinac Bridge (1954–57), with a span of 3,800 feet (1,158 metres) across the Straits of Mackinac in Michigan, was, in the early 1970s, the third longest suspension span built.

The Forth Road Bridge (1958–64) and the Severn Bridge (1961–66) in Great Britain are the first major suspension bridges outside the United States to be built with parallel wire cables spun in place. Although both exceed 3,000 feet (914 metres) in span, they are lighter in weight, more slender, and more economical in cost

than any other suspension bridges of comparable size. The Forth Road Bridge, in latitude 56° N, the furthest north major bridge in the world and built in an area notorious for its high winds and storms, presented extraordinary difficulties during erection.

Verrazano Narrows Bridge

The longest single span so far built is the 4,260-foot (1,298-metre) Verrazano Narrows Bridge (1959–64), at the entrance to New York Harbor. A double-deck structure, it carries and was planned to take 12 lanes of roadway traffic. It has rivetted-steel towers 680 feet (207 metres) high, built up of square vertical cells. There are four main cables, each 36 inches (0.9 metres) in diameter and made up of a total of 142,500 miles (229,300 kilometres) of wire. On a span of this magnitude, the tops of the vertical towers are 1.6 inches further apart than the tower bases, owing to the curvature of the earth's surface, and the length of cable wire would stretch more than halfway to the moon. The total weight of steelwork in the bridge is 144,000 tons, a weight (and cost) many times greater than that of the contemporary Severn Bridge. In 1966 the Salazar Bridge was completed across the Tagus River at Lisbon, with a span of 3,323 feet (1,013 metres), the first major suspension bridge so designed that it could subsequently be double decked, if desired, to carry railway traffic.

Other recent suspension spans of between 2,000 and 3,000 feet are the Quebec Road Bridge, built alongside the existing railway crossing, and named at its opening in 1970 the Pierre Laporte Bridge; the second Delaware Memorial Bridge (1968), built alongside the first; the Angostura Bridge in Venezuela; and the Tacoma Narrows II Bridge at Puget Sound, Washington. The longest span in the U.S.S.R. is the Amu-Darja suspension bridge (1964), which has a 1,278-foot (390-metre) span, in Buhara-Ural; while the longest in Denmark is the Little Belt Bridge (1970) with a span of 1,968 feet (600 metres), designed to carry a six-lane motorway on a streamlined box deck. The towers are of reinforced concrete and the cables built up of strands of twisted wire.

Foundation techniques. For the main piers of the Howrah Bridge in Calcutta, huge monolith foundations measuring 180 feet by 81 feet (55 by 25 metres), in plan the biggest ever sunk on land, were required. Each reinforced-concrete monolith was divided into 21 wells 20 feet square and was sunk by open excavating. The monolith on the Calcutta side was set at a depth of 103 feet (31 metres) under compressed air. This technique was applied to each well in turn, after a temporary steel air deck was fitted near the bottom of the well to form the roof of a working chamber. This method was successfully used on a number of major bridges in India and Burma and also on the huge Lower Zambezi Bridge in Mozambique.

There is rarely much difficulty with the foundations for large arch bridges, because they are usually in rock and at no great depth. For the foundations of the Sydney Harbour Bridge, it was necessary only to excavate yellow sandstone rock some 30 to 40 feet beneath each bearing. On the Hell Gate Bridge (1917), over the East River in New York City, however, there was difficulty, because when rock was reached, at a depth of 70 feet, it was found to contain a wide crevasse that had to be bridged with concrete, all of this work being carried out under compressed air.

Among suspension bridges, the foundation for the New Jersey Pier of the George Washington Bridge (1931) was built inside two steel-piled cofferdams that were bigger and deeper than any previously used on bridge construction (Figure 8). The foundations for the San Francisco-

From A. Dana, A. Anderson, and G. M. Rapp, *Transactions*, vol. 97, p 113 (1933); American Society of Civil Engineers

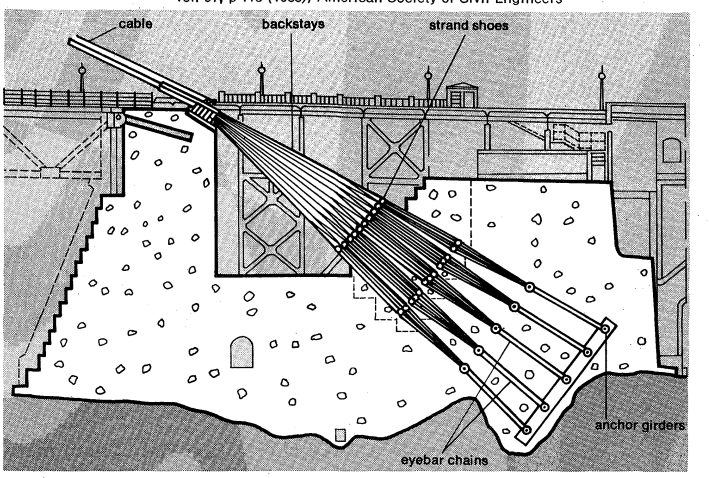

Figure 8: Cable anchorage of the George Washington Bridge, New York City.

The San Francisco-Oakland Bay Bridge

Oakland Bay Bridge, at San Francisco, presented extraordinary difficulties because caissons of unprecedented size had to be sunk through deep water and a current of 7.5 knots to a depth considerably deeper than men can work under compressed air. For the biggest caisson, at the central anchorage, connecting two suspension bridges, an entirely new technique was devised. The caisson was a honeycomb built up of 55 vertical steel cylinders, each sealed by means of a steel dome welded on top. Built on a slipway, it was launched, towed to the site, anchored, and sunk onto a sloping bottom more than 200 feet down, which had to be levelled so that the caisson could be founded on a horizontal plane. To provide buoyancy and control during the sinking, compressed air was used inside the cylinders in turn to enable muck to be grabbed out as sinking proceeded, and new steel lengths had to be welded on before the domes were replaced, as the depth increased. When rock was reached, it was broken up by dropping pointed, five-ton weights through the cylinder, after which the surface was cleaned up and levelled by divers. The middle 25 cylinders were then sealed by concrete deposited under water, followed by the sealing of the remaining 30.

Still different problems were presented by the foundation for the Golden Gate Bridge. For the south pier, located in deep water, virtually in the open sea and exposed to ocean swell, it was decided to build the foundations inside a huge elliptical cofferdam, founded on bedrock 100 feet (30 metres) below water level. The rock was first excavated some 15 feet deep all over the area; blasting was carried out by bombs of increasing size exploded in holes bored in the rock. After the cofferdam had been closed, its bottom was sealed by depositing a 65-foot depth of concrete below water. The water inside the cofferdam was then pumped out and the pier of the bridge built in the dry.

On the Verrazano Narrows Bridge in New York City, the foundations for the main piers were located in shallow water a few hundred feet off shore at the entrance to New York Harbor, where few difficulties were encountered. The site of each pier was enclosed by a rectangular cofferdam and the water inside pumped out. A reinforced-concrete monolith with a steel cutting edge,

measuring 130 feet by 230 feet (40 × 70 metres) in plan and enclosing 66 circular wells 17 feet (5 metres) in diameter, was sunk by open dredging, the walls being built up to keep them above water level. The monolith on the Staten Island side was finally founded at a depth of 170 feet (52 metres).

Tacoma Narrows failure, 1940; impetus to aerodynamics. The collapse of the Tacoma Narrows Bridge, at Puget Sound, in 1940, only 4 months after its completion and after more than 50 years of immunity from suspension-bridge failure of this kind, brought the study of aerodynamic stability sharply to the fore. This bridge was by far the most flexible among its contemporaries. It had a span of 2,800 feet (853 metres) with a width of only 39 feet (12 metres), and the deck was stiffened throughout its length not by the deep open trusses formerly used but by two plate girders only 8 feet (2.4 metres) deep. Under quite moderate winds, the deck not only swayed sideways but also was subject to severe torsional (twisting) vibrations, and ultimately, in a wind of only 42 miles (70 kilometres) per hour, the vibrations became so violent that the deck was torn away and crashed into the water. Other U.S. suspension bridges had also shown undesirable aerodynamic action, and further bracing or stiffening was quickly incorporated.

Sway and torsional vibrations

A committee appointed to investigate the Tacoma failure found that the oscillations caused by wind were due to (1) natural turbulence or gusts and (2) the eddies created by the solid cross section and shed from the bridge structure. A dangerous buildup of oscillations, possibly leading to collapse, might result if the frequency of the eddies coincided with any of the natural frequencies of oscillation of the bridge. Bridge designers thereafter reverted to the use of heavy, stiff deck structures to provide torsional rigidity and also left longitudinal openings or slots along the deck, between the dual roadways and the girders, similar to the antistall slots originally used in the wings of aircraft. All these modifications were adopted for the Tacoma Narrows II Bridge, completed in 1950, in which width and rigidity were considerably increased as compared with its predecessor, and also for the Mackinac Bridge, the Forth Road Bridge, and others.

Engineers completing the final design for the Severn Bridge, however, realized that serious eddy sheddings might well be avoided on bridge decks by adopting the principles that had been used for years to avoid it in aircraft structures. The deck of the bridge was designed as a box girder, shaped like an aerofoil, and enclosed by stiffened plates at the top and bottom and inclined plates at the sides, so as to make it in a large measure streamlined. The upper surface constitutes the deck, on which the roadway is constructed, projecting platforms being provided at the sides to carry cycle tracks and footways. Extending throughout the span, the deck is only 10 feet (3 metres) deep and is suspended from the cables by inclined hangers at 60-feet (18-metre) intervals. These triangulated hangers damp out the small degree of oscillation that might otherwise occur with winds blowing slightly upwards from the horizontal.

Considerable economy is achieved not only by the saving in weight in the deck itself but also by the fact that its shallow airfoil profile reduces the wind loads on the bridge and, thus, leads to further economies in the weight of cables and towers. Moreover, the tower legs are of single-box section, so that their weight is reduced to a minimum. These innovations have undoubtedly set high standards of economy and sophistication for the future of suspension-bridge design.

Aerodynamic action may also be a source of trouble during the erection of a suspension bridge. When the north tower of the Forth Road Bridge had reached a height of over 400 feet, it began to sway alarmingly under quite light crosswinds of only 20–25 miles per hour, although in a heavy gale it moved only a few inches. The sway developed an amplitude of over 7 feet (2.1 metres) at the tower top, with a period of 4.5 seconds, and built up and died down every few minutes. This novel phenomenon was quickly checked by means of a damping device consisting of a 16-ton counterweight that was connected to the top of the tower by long steel cables and arranged so that it could slide up and down a ramp inclined at 45° to the horizontal. Any movement of the tower top of more than a few inches began to pull the counterweight up the ramp; this interrupted the rhythmic buildup of the oscillations and brought the top of the tower to rest. The steelwork of the suspended deck of this bridge was erected in two passes by four 15-ton derricks, working outward from each of the towers to the centre and then returning again. Wind-tunnel tests made on models of the deck during erection demonstrated that it was necessary to leave a longitudinal strip 20 feet wide open along the centre line of the bridge, during the first pass of the derricks, in order to maintain the aerodynamic stability of the deck, until the first pass had been completed, connecting the stiffening trusses of the deck at midspan.

III. Contemporary developments in bridge engineering

The period since World War II has been the greatest bridge-building era in the history of the world. This is due partly to postwar reconstruction and urban development but even more to the unprecedented advance of motorways. In the U.S.S.R. the seven-year plan of the 1960s called for 650 large and 2,600 medium-sized bridges, four times as many as in the previous seven-year period. In China, too, there has been a great upsurge in the construction of roads and railways, all requiring their quota of bridges. This unprecedented activity has led not only to important improvements in materials available for bridge construction but also to novel types of foundations and superstructures and new techniques of calculation, fabrication, and erection.

IMPROVED MATERIALS

Steel. Research in steelwork has concentrated on the commercial production of structural steel of high-tensile quality that is also suitable for electric-arc welding and fabrication by flame cutting. Other important qualities sought include ductility and resistance to fatigue and corrosion. New forms of connection include welding, which reduces the weight of the structure, and the use of friction-grip bolts. Steel trusses may be built of all-welded, mild or high-tensile tubular members; hollow rectangular sections up to 13 inches (33 centimetres) square and one inch (2.5 centimetres) thick, which are seamless and rolled, can be obtained. Meehanite, a form of cast iron, is increasingly used for bearings of bridges, and expansion joints may be built up of layers of rubber bonded between steel plates.

For girder bridges of span greater than 300 feet (90 metres), steel is usually the most economical material to use; for arches, the economically critical span is longer. As the length increases, low-alloy or high-tensile steel is preferable. The saving in weight on long spans is suggested by the fact that, on the Sydney Harbour Bridge, every ton of steel in the arch required 0.7 tons to support it. The new, stronger, low-alloy steels can be used at substantially higher working stresses than mild steel. Low-alloy steels cost little more to produce than mild steel but are not usually as readily available. Other, even stronger special steels have been produced, but their cost is double that of mild steel. About 3,000 tons of such a steel were used in the second Carquinez Bridge (1958), near San Francisco.

Use of low-alloy steel

Laminations in steel plates are more serious in welded than they are in rivetted work, and a system of ultrasonic tests has been evolved whereby laminations can be detected before fabrication. Light alloys such as aluminum may play a greater part in bridge building when their elasticity and cost can be reduced. They have been used to make light service spans used in the erection of bridges and also to reconstruct the decks of old bridges at reduced weight. It has not yet proved possible to produce stainless steel of structural quality, but high-tensile weathering steel is being increasingly used. When exposed to weather, this kind of steel forms a coat of oxide on the surface, which inhibits any further corrosion.

Prestressed concrete. The process of prestressing concrete, which consists of putting it into a state of compression by tensioning steel bars or wires that pass through it, was conceived at the beginning of the 20th century and came to be recognized as the most important advance to have taken place in bridge construction since reinforced concrete came into general use. The economies in material that prestressing rendered possible led to its rapid development in the period of shortages during and after World War II.

To obtain the full benefits of the process, concrete of high quality and strength is necessary. Rapid advances in concrete technology have resulted in its strength being doubled and its surface greatly improved since World War II. The use of precast units, often of substantial size, supported on novel systems of cantilevered and suspended centring and thereafter prestressed, have led to a marked increase in the length of simple or continuous spans, which can now be built economically up to lengths of 400 feet or more.

Use of precast concrete units

Quality of concrete. Concrete can be made with an ultimate compression strength of 8,000 to 12,000 pounds per square inch. This permits working stresses in the range of 2,000 to 3,000 pounds per square inch, but the upper limit must not be exceeded because, beyond it, the rate of creep (*i.e.*, nonelastic deformation resulting from stress) of the concrete increases too quickly. This improvement in quality was achieved by further refinements in the water-to-cement ratio, the grading of the aggregate (by improvements in vibrating), and by innovations such as steam curing. Because of the thinness of the wire used in prestressed work, it is essential that it should be completely protected against corrosion. The elimination of cracks in the concrete and the production of a dense, flawless surface therefore become of first importance. The compression induced in the concrete tends to eliminate cracks, and new materials for forms, such as hardboard, have enabled the surface of the concrete, whether flat or curved, to be of good texture, free from imperfections, easy to clean, and pleasing to the eye.

Systems of prestressing. During World War II, when shortages of timber for forms and steel for reinforcement precluded the use of conventional reinforced-concrete design, Eugène Freyssinet reconstructed bridges in Tunisia by designing them to be built of precast blocks subsequently assembled on site and joined together by prestressing done by threading steel wires and grouting them in. Various systems of prestressing have since been evolved, but the most usual procedures are those outlined below. For reinforcement, narrow, high-tensile-steel bars with an ultimate strength of 64 to 72 tons per square inch are used at a working stress of about 45 tons per square inch. Alternatively, cables made up of a number of parallel steel wires, with an ultimate strength of 90 to 110 tons per square inch (similar to those used in the parallel-wire cables of suspension bridges), may be used at a working stress of about 70 tons per square inch. Another development has been the use of stranded-wire ropes. There is always a loss of about 15 percent in the working stresses due to shrinkage and creep of the concrete and relaxation (reduction in stress intensity) of the steel.

Before the concrete is cast, thin-gauge, flexible sheathing is fixed permanently in position in the molds for the bars or wires to pass through. When the bars or wires have been placed in position, they are tensioned; in bars, the tension is held by screwing nuts on the ends of the bar against steel anchor plates; if wires are used, the tensioning is done by means of hydraulic jacks, after which the wires are held by wedges. Cement is then forced into the sheaths under pressure to grout in the wires or bars and prevent corrosion or slip.

The amount of prestress is usually greater than the tension stress that would otherwise be induced under full dead load and live load. The methods can be applied to concrete, whether it is poured at the site or precast. On account of the great saving in material, which amounts to at least one-third of the volume of concrete and three-quarters of the weight of reinforcement that would otherwise be used, prestressed-concrete bridges are striking in their slender proportions. They are also economical in cost, provided the necessary trained labour is available, and in favourable circumstances may be competitive with structural-steel designs for spans up to about 500 feet. Because of the very high stresses employed, skilled supervision is, of course, essential throughout the work.

NEW DESIGNS

Battle decks and composite construction. Battle decks, first used in ships but adapted for bridges after World War II, consist of decks made of flat steel plates welded together and stiffened by means of flats, angles, or some other section welded on the underside. Further economy can be achieved by making the deck act integrally with the main members of the bridge, in effect becoming the top flange of a box girder. Battle decks are economical on long spans, where their saving in weight is important. They require more maintenance than do reinforced-concrete slabs.

In composite construction, the concrete roadway slab is anchored to the steel girders and made to act in conjunction with them. This form of deck was used on an all-welded steel highway bridge with a span of 334 feet over the Moscow River in the U.S.S.R. (1956). In the 1,240-foot Cologne–Rodenkirchen Bridge over the Rhine (1954) in West Germany, the concrete deck was prestressed; it not only carries the traffic but also acts as part of the upper chord (horizontal member) of the stiffening trusses and provides lateral bracing.

On both steel and concrete decks, waterproofing and wearing surfaces have to be provided. The most satisfactory solution appears to be a coat of mastic asphalt, a mixture of asphalt with fine aggregate rolled in, which produces a dense, hard-wearing surface and gives waterproof protection for the steel beneath.

Steel-plate and box girders. The modern tendency in steel-bridge design, particularly in western Europe, is towards box girders, of rectangular or trapezoidal section, in preference to simple or continuous trusses. The destruction of nearly 5,000 bridges in West Germany in World War II gave an opportunity for the development of new designs and techniques, and the fact that steel was then in short supply stimulated the search for economy in weight. The Cologne–Deutz Bridge (1947–48), the first of the big postwar box-girder spans over the Rhine, showed the sort of major advances in appearance, span, and economy that could be made by taking full advantage of modern techniques. In the triple box girders of this bridge, web plates 25 feet (8 metres) deep over the piers and only about 0.5 inch (1.27 centimetres) thick were first employed, stiffened both horizontally and vertically. Much of the 5,760 tons of steelwork is high-tensile, and its weight is only 61 percent of the steelwork in the old bridge it replaces. Three years later, the Düsseldorf–Neuss Bridge, with its 675-foot (206-metre) span and steel battledeck, was completed. Both these bridges were erected in heavy sections of 200 to 300 tons assembled on the riverbank, floated out, and lifted by cranes that had been used to clear away the debris of the old bridges.

The Cologne-Deutz Bridge

The longest plate-girder bridge built through 1970 was that across the Sava River at Belgrade, Yugoslavia, completed in 1957, which has a span of 856 feet (261 metres) and replaces the King Alexander suspension bridge. Designed in West Germany, it consists of an inverted-U-shaped girder of high-tensile steel. The new autobahn bridge over the Wupper Valley (1959) in West Germany, with seven spans varying from 144 to 239 feet (44 to 73 metres), has a reinforced-concrete deck slab in composite construction with steel box girders of novel trapeze-shaped section and inclined webs. The basic similarity of these modern box girders to the Britannia tubular bridge first conceived more than a century before is notable. Apart from materials and details of construction, the most significant difference is that in the first the trains ran through the boxes, whereas in the modern bridges the roadway traffic flows on top.

In comparison with plated I-girders, rectangular box girders have the advantage of reducing the initial cost

by providing stable compression flanges (horizontal surfaces) and torsional rigidity (resistance to twisting forces). They also conceal all the web and flange stiffeners and thus improve appearance and reduce maintenance charges. Trapezoidal sections, in which the outer web plates are inclined, may be used to limit the lower flange area to the desired amount while at the same time providing a wide flange plate for the deck, as in the 770-foot-(235-metre-) span Wye Bridge in England. While offering reduced wind resistance, these inclined webs tend to increase the cost of fabrication and erection, unless the bridges are erected in preassembled units or boxes. Preassembly has been generally adopted in the U.K., but on the Continent erection is usually done on the site, plate by plate. Thus, during the last decade, boxes with inclined webs have been favoured by British engineers (*e.g.*, the Beachley, Severn, Erskine, and White Cart bridges) but rectangular box girders have been employed on the Continent (*e.g.*, the Europa Bridge, the Fourth Danube Bridge in Vienna, Austria, the Zoo Bridge in Cologne, West Germany, and the Lehener Bridge in Salzburg, Austria). In the early 1970s, the Rio-Niterói high-level bridge over Guanabara Bay at Rio de Janeiro was the longest continuous box girder in the world.

Steel cable-braced bridges. A further development, in which the girders are supported by groups of prestressed cables passing over the tops of towers on the main piers, was first introduced in the Strömsund Highway Bridge in Sweden (1956). This method was adopted in the Theodore Heuss Bridge (1957) over the Rhine at Düsseldorf, West Germany, which has a main span of 853 feet (260 metres). The two box girders, of shop-welded low-alloy steel, are supported by three parallel tiers of cables that were prestressed during erection. In the Severin Bridge (1959) at Cologne, there is a cable-braced span of 991 feet (302 metres) supported by three sets of cables that pass over the top of an A-shaped tower built on a pier near the east bank. The first monocable bridge was built over the Elbe at Hamburg (1961). The 564-foot (172-metre) span was braced by cables only on the longitudinal centre line of the bridge. The towers over which they pass consist of single posts with roadways on either side. Since then, many cable-braced bridges have been built, mostly in western Europe, the longest being the Duisburg–Neuenkamp Bridge, in West Germany, with a span of 1,148 feet (350 metres), completed in 1970. Monocables have only about 70 percent of the weight of dual cables, because they are less affected by asymmetric live load.

The monocable bridge at Hamburg

Steel truss bridges. In the United States and Japan, continuous trusses are favoured for spans in the 700- to 1,250-foot range (about 210 to 380 metres). The longest span, of 1,232 feet (376 metres), is that of the Astoria Bridge in Oregon, completed in 1966. As will be seen in Table 9, eight of the longest steel spans are in the U.S., the longest elsewhere being the Tenmon Bridge (1966) of 984-foot (300-metre) span at Kumamoto, Japan. Two major bridges of this type in China are the huge double-deck rail and road bridges over the Yangtze River, the first completed in 1957 at Wu-han, Hupeh Province, and the second, replacing the train ferry and opening up a long-needed north–south route, at Nanking, Kiangsu Province, in 1968. Other great multispans built in the last 40 years include the 2.25-mile- (3.62-kilometre-) long Lower Zambezi railway bridge (1934) in Mozambique; the Ava Bridge, comprising nine spans of 350 feet (107 metres) carrying railway and road over the Irrawaddy River in Burma; the mile-long Ganga Bridge (1959) at Mokameh, India; and the Brahmaputra Bridge (1962) at Amingaon-Pandu in India, both of which carry road and rail traffic.

Steel truss bridge over the Yangtze River at Nanking, China. Completed in 1968, it carries rail and highway traffic.

Prestressed-concrete bridges. A wide variety of designs, including simple or continuous beams, cantilevers, arches, and girders, can be made with prestressed concrete. For spans of up to 140 feet (43 metres), simply supported beams are generally the most economical. The Vauban highway bridge (1956) in Strasbourg, France, has four simple spans of varying lengths, consisting of 8 beams of I-section, prestressed by 17 cables of 12 strands. As the span increases, continuous beams, as used in the Oléron Viaduct, France (1966), with 26 spans of 259 feet (79 metres), become economical (see Table 10). A bridge built over the Moscow River in 1957 has three continuous, prestressed-concrete spans, including a midspan of 485 feet (148 metres).

For still longer spans, cantilever bridges may be used. The 500-foot (152-metre) span of the Medway Bridge (1963) at Rochester has since been surpassed by the record 682-foot (209-metre) span of the Bendorf Bridge, completed in 1964 in Koblenz, West Germany. It is notable that the Bendorf Bridge, together with two other major cantilever bridges, the Eastern Scheldt Bridge (1965) in The Netherlands and the Öland Bridge in Sweden, were designed as twin cantilevers with no suspended spans. Work on the destruction of John Rennie's London Bridge, dating from 1831, began in 1967, and the masonry facades of the old arches were sold to a private developer and re-erected at Lake Havasu in Arizona. In 1972 London Bridge was replaced by a new prestressed concrete structure.

Concrete arch bridges are rarely prestressed to any significant extent, because an arch is normally in compres-

Concrete arch bridges

sion. The Luzhniki Bridge (1959) in the U.S.S.R. is a prestressed-concrete tied arch, with spans of 147, 354, and 147 feet (45, 108, and 45 metres). Portal bridges and multiple portals simply represent an angular type of arch, so shaped that prestressing is helpful to keep the resultant thrust due to dead load and external loads within allowable limits. A fine multiple portal with sloping legs is the Saint-Michel Bridge (1957), at Toulouse, France, which has one span of 197 feet (60 metres) and five of 214 feet (65 metres) each.

Bridges of latticed construction are economical in material, but the unit costs are high; the saving in weight, however, makes it possible to achieve longer spans. The first prestressed-concrete latticed girder constructed was the Mangfall Valley Bridge (1958–60), with three spans of 295, 354, and 295 feet (90, 108, and 90 metres) over the Munich–Salzburg highway in West Germany.

The first self-anchored suspension bridges with continuous stiffening trusses were built in Belgium. These are the Merelbeke and the Mariakerke bridges near Ghent, with main spans of 185 and 328 feet (56 and 100 metres), respectively. A novel method for prestressing the girders on the Merelbeke Bridge consisted in jacking up the towers, which were independent of the deck and stiffening girders. The jacks were afterwards replaced by permanent steel castings.

A novel form of construction was adopted for the five 775-foot (236-metre) navigation spans of the 5.5-mile-long multispan bridge over the Maracaibo Lagoon in Venezuela (1958–61). These are designed as six continuous beams in prestressed concrete, supported on double trestles below and by tension cables above. The cables pass over the top of A-shaped towers on the piers and are connected near the ends of each beam. Another bridge of this type, with a span of 983 feet (300 metres), was designed to cross over the Wadi Kuf Gorge in central Cyrenaica, Libya; construction was completed in 1971. Two notable new bridges in Mozambique are multispan suspension bridges of five spans each with inclined suspenders supporting prestressed-concrete decks. The first, the longest of its type in the world, is 2,860 feet (872 metres) overall and was completed in 1970 over the Save River; the second was planned for completion a year later at Tete over the Zambezi River.

edges bevelled for welding, if required; rotary jigs are used for the assembly of members, and automatic submerged-arc machines, which give complete penetration, are used for welding the seams of columns or girders. The quality of the welds can be determined by means of X- and gamma-ray photographs.

Methods of erection: steel bridges. For erection on the site, welding may be used for plate girders, but it is not usually suitable for trusses. Rivetting has been largely superseded by the use of friction-grip bolts which can be used in clearance holes and act as high-tension clamps. Pneumatic wrenches are used to tighten the bolts and calibrated torque wrenches to check their tension. The system is quicker, cleaner, more efficient, and more economical than rivetting. It was used in the erection of the Forth Road Bridge, the Mackinac and Carquinez bridges in the United States, and the Adomi Bridge (formerly Volta) in Ghana. The method employed in using these friction-grip bolts in the 805-foot (245-metre) steel arch of the Adomi Bridge represented a major advance in bridge-building technique. At the connections between the chord members in the bridge, four friction-grip bolts were used longitudinally as pretensioned ties, so arranged as to interconnect pairs of plates welded across the corners of the section. During erection of the two halves of the arch as cantilevers, therefore, the stability of the structure depended on these groups of bolts acting in tension in the connection of the upper chords.

Use of friction-grip bolts

Adomi (formerly Volta) Bridge in Ghana, completed in 1956. This steel arch bridge utilizes high-strength friction-grip bolts at the connections between the chord members.

On box girders, the tendency in the U.K. is to prefabricate the structure in large sections (*i.e.*, full-width steel boxes that may be 60 feet [18 metres] long and weigh up to 100 tons) before erecting them in position. This saves the cost of assembling many small sections in high and exposed places under awkward weather conditions. Cantilever erection may be adopted, as on the Wye and Erskine bridges, where the boxes were rolled out along the top of the cantilever arm, lowered into position by two heavy launching arms, adjusted against the section last erected, and connected by butt welding or bolting. On the Continent, the system of "pushing out" large lengths of superstructure on rollers over the tops of the piers has been successfully used. Assembly is carried out in an erection bay behind the abutment. This system was used in Switzerland in 1968 on the Veveyse Bridge, which consists of two box girders, built on a curve and supporting a composite slab deck. The box girders of the Lao Bridge in southern Italy in the early 1970s are supported on the highest piers in the world. The three spans of the bridge, which also curves, were erected to carry the motorway over a deep ravine, the bottom of which is 800 feet (244 metres) below roadway level.

Cable-stayed bridges are usually erected as cantilevers, temporary supporting trestles being used where necessary. The cables are assembled on the towers and connected to the box girders and tensioned at the appropriate stages of erection.

Methods of erection: prestressed-concrete bridges. Prestressed-concrete bridges can be built (1) by assembly of precast units at the site; (2) by casting in place; and (3) by a combination of precasting and casting in place.

The Narrows Bridge (1959) over the Swan River at Perth, Western Australia, is a good example of a bridge built up of precast units and subsequently prestressed after assembly at the site. The world's longest precast structure was the 24-mile (39-kilometre) Pontchartrain Causeway (1956) in Louisiana, until it was surpassed by a slightly longer sister span in 1969. The first causeway consists of a series of spans 56 feet (17 metres) long and 28 feet (8.5 metres) wide, supported by beams resting on hollow prestressed-concrete piles. Each span, made up of seven beams and the roadway slab, was precast in one piece and erected by means of a floating crane. So well was the work organized that eight spans weighing 180 tons each and comprising 448 feet (137 metres) of bridge were placed each day.

The world's longest precast structure

Precasting has been widely adopted in the U.S.S.R., an outstanding example being the huge two-level bridge

(1959) over the Moscow River at Luzhniki, Russian S.F.S.R., which, with its approaches, measures 6,650 feet (2,027 metres) and carries a six-lane roadway on the upper deck and interurban railways below. The three spans, of 147, 354, and 147 feet (45, 109, and 45 metres), over the river were assembled in halves longitudinally on the shore from large, precast units, floated out on barges, and set on piers. In the U.S.S.R., standardization developed to such an extent that, by 1958, reinforced-concrete designs were automatically adopted for new railway bridges with spans of less than 50 feet (15 metres) and prestressed-concrete designs for spans of 50 to 90 feet (15 to 27 metres). Methods of pouring concrete safely in cold weather were studied.

Casting in place is more likely to be economical when there is little, if any, repetitive work; this technique was adopted for the three arches of 499, 479, and 452 feet (152, 146, and 138 metres) designed in 1953 for the new Caracas–La Guaira highway in Venezuela. In these bridges, the decks were prestressed both longitudinally and laterally, and prestressing cables were used temporarily to relieve the arch ribs during erection. Cantilevered centring was built out from each arch pier for a quarter of the span. For the middle, timber forms were built in the valley below and hoisted into place.

A combination of precast and in place construction may be economically used for continuous and cantilever bridges, the concrete ends of the span near the piers being poured in place and the central parts precast. In the 214-foot (65-metre) spans of the Casalmaggiore Bridge, over the Po in Italy, the lengths over the piers and the cantilever arms were poured in place, and the 118-foot (36-metre) suspended beams, each weighing 65 tons, were precast and erected by floating cranes. In the Mancunian Way, opened in Manchester, Lancashire, in 1967, although a high degree of standardization of precast units was achieved, it was found preferable to cast certain lengths of the overpass in place.

Pile-cylinder foundations. The most significant trend in foundation design is the tendency to support bridge piers on groups of large-diameter piles or thin-shelled cylinders, where possible, in preference to using pneumatic caissons. In the foundations of the Narrows Bridge in Perth, 180 long piles nearly three feet (one metre) in diameter were driven as hollow cylinders by means of a hammer running inside the pile and striking near its foot and were subsequently reinforced and filled with concrete. For the huge Wu-han double-deck rail and road bridge built in 1955–57 over the Yangtze River in China, a new system of colonnade foundations on large-diameter piles was designed by Soviet specialists. In the Tasman Bridge, Hobart (1965), the foundations were of boxed cylinder piles, some of which penetrated to a depth of 260 feet (79 metres). The three cylinder piles used per pier of the three-mile-long Eastern Scheldt Bridge (1965) in The Netherlands are of 14-foot (4.3-metre) diameter and up to 165 feet (50 metres) in length.

In the U.S.S.R., thin-shelled reinforced- or prestressed-concrete cylinders are sunk by electric-powered vibro pile drivers.

Use of computers. In the last decade, computers have been increasingly used for making the calculations involved in the design and erection of both steel and concrete bridges. The most laborious and detailed calculations can thus be made quickly and economically.

During the erection of the Forth Road Bridge and the Severn Bridge, computers were used to calculate the shape of the suspension cables under the changing pattern of applied loads as the deck panels were assembled. Computers can be used just as efficiently in reinforced- and prestressed-concrete work and provide a full set of calculations and detailed instructions, which entirely replace traditional drawings and details of reinforcement.

SAFETY PROBLEMS AND SOLUTIONS

During the last few years, much more attention has been paid to reducing accidents on bridges and, indeed, on all engineering structures. Most failures occur during erection, and safety can be considered under three heads: the safety of the structure during erection or demolition, the safety of construction plant, and the safety of personnel. Statutory regulations, which are continually being widened, exist in all countries to ensure the safety of structures, plant, and personnel. But, in spite of these regulations, far too many accidents still occur.

The three main safety factors

The castastrophic failure of the all-welded Duplessis Bridge at Trois-Rivières, Quebec, at a temperature of −30° F (−34° C), in February 1951, followed by that of the Kings Bridge at Melbourne, Victoria, in July 1962, were ascribed to brittle fracture from the nature of the steel used and the low temperatures prevailing at the time. The failure of three Vierendeel truss bridges in Belgium in 1938–40 and 250 all-welded Liberty ships in 1942–52 had drawn attention to the liability of steel to brittle fracture. The flange plates of the 180-foot (55-metre) plate girders of the Duplessis Bridge that failed proved to be of poor-quality steel that was abnormally notch sensitive, even at ordinary temperatures. In June 1958, two spans of the six-highway Second Narrows Bridge in Vancouver collapsed, wrecking 2,500 tons of steel and killing 18 men, during the cantilevering of the 465-foot (142-metre) anchor arm. The cause was the failure of a steel grillage supporting one of the temporary trestles, on which the stiffeners had been omitted due to an error in calculations. During the erection of the Barton High Level Bridge, England, there were two accidents in February and December 1959, in which six men were killed. The first accident was due to the failure of two inadequately designed and braced temporary trestles, and the second was due to four steel girders standing side by side overturning because they were inadequately braced together.

A most unusual accident to a completed span was the 1967 collapse of the Silver Bridge over the Ohio River at Point Pleasant, West Virginia, with a loss of 46 lives. This was a chain-suspension bridge with a span of 698 feet (213 metres), built as recently as 1928, and its failure ruled out the building of any more bridges suspended in this way in the U.S. Another accident, but without any loss of life, occurred immediately after the closure of the Fourth Danube Bridge in Vienna in November 1969. This was a three-span motorway bridge of twin box girders. A sudden fall of temperature at night resulted in failure at the closing joint; the bridge sagged three feet, and within ten seconds two more bucklings occurred several hundred feet away on either side. In this case, the margin of safety was eroded by four different factors, one of which was the sudden temperature differential.

Two tragic collapses of sophisticated designs of trapezoidal-box-girder bridges, resulting in the death of 4 men and 35 men, respectively, occurred during erection in 1970. The first of these was the Milford Haven Bridge, Pembrokeshire, in which a 196-foot (60-metre) steel cantilever collapsed in June 1970, owing to the failure of the vertical steel diaphragm over the pier from which it was being cantilevered. The second was the collapse of a 367-foot (112-metre) steel span of the West Gate high level bridge over the Lower Yarra River in Melbourne, in October 1970. Failing at the middle, the span plunged to the water, bringing down the river pier in its collapse. Failures have also occurred on concrete bridges, one of the most recent, in which two men were killed, in August 1967, being the collapse of two completed sections of the Calder Bridge, which was being built to carry the M.1. motorway over the River Calder near Wakefield, Yorkshire. Here the collapse was caused by the failure of temporary supports due to mild-steel joists being used by mistake instead of joists of high-tensile steel.

In order to combat risk of brittle fracture, high-tensile steel has now been greatly improved in strength at low temperatures. Another most complex problem under research is that of metal fatigue, to which both steel and aluminum are prone, caused by undergoing continual variations of stress that reduce ultimate strength and cause cracks or failure. Susceptibility to fatigue is increased by welding; particularly, by welds across tension members; or by an abrupt change of shape or thickness. All possible data are being obtained as to the number and

The problem of metal fatigue

nature of the stress cycles to which bridges are subject and to types of construction and the quality of steel that can withstand them.

As a result of the tragic collapse of the box-girder bridges at Milford Haven and Melbourne, the government in Great Britain has appointed a team of experts to enquire into the safety of this type of bridge, which has been described as pioneer work pushed toward the limits of the engineer's knowledge, and to examine the design and construction methods.

Accidents caused by failure of plant are too varied to detail here. They can be largely avoided by ensuring that all plant and equipment is kept in good repair and used only within its capacity, with all moving parts adequately guarded and with fail-safe devices provided as necessary. The causes of accidents to personnel are also diverse. The first necessity is to provide safe means of access and safe place of work, by means of ladders, gangways, and working platforms with guardrails, toeboards, and cradles, as necessary. Accidents to men working aloft can be prevented by means of safety harness and safety nets; safety helmets should be worn by all men on site.

FUTURE TRENDS

Great suspension spans of the future include an accepted British design for the new Bosporus Straits Bridge, with a main span of 3,520 feet (1,073 metres), on which work started in 1970, and a new bridge over the Humber in England, with a span of 4,580 feet (1,396 metres), scheduled for construction in the 1970s. Both these designs are similar to that of the Severn Bridge. There are also projects for a bridge over the Messina Straits; where major difficulties are presented by the great depth of water (400 feet [122 metres]) and the fact that the site is in a recently active earthquake area. Far more ambitious schemes have been suggested for crossings of the English Channel and the Strait of Gibraltar, but neither seems likely for many years to come.

In Japan, studies have been made for a proposed suspension bridge of 4,200-foot (1,280-metre) span across the Akashi Straits between the islands of Honshu and Shikoku, which would have to withstand typhoons, in addition to seismic shocks; and another, even longer span has been proposed for a bridge over Tokyo Bay. With materials of the weight and strength available today, engineers could theoretically build a suspension bridge to carry normal traffic, with a single span two miles long. But there would be many imponderable factors to consider in such a vast enterprise, which must be many years ahead. In the near future, it appears that the system of cable spinning may soon be simplified by pulling across strands each consisting of some hundreds of parallel wires and subsequently compacting them together, instead of simply carrying over a few loops of wire at a time by means of spinning wheels. A major economy would also be achieved in the weight and cost of the main cables if some means could be found by which to vary their cross-sectional area, so that it would conform throughout the length of the cable to the actual section required, which is much smaller at midspan. Improved methods of protection will, no doubt, also be found, as was attempted in the Newport Bridge, Rhode Island (1967), where the cables were protected by a layer of glass-reinforced resin.

In trying to foresee the materials of the future, it must be borne in mind that all normal structural materials, such as steel, aluminum, glass, and wood, have very similar elasticity-to-weight ratios. To make lighter, stiffer structures, new materials are needed, with high elasticity and low weight. At the Royal Aircraft Establishment, Farnborough, Hampshire, a method has been developed by which carbon fibres and carbon-fibre plastics have been produced with these properties. Compared with a high-tensile aircraft steel, these carbon fibres have about a quarter of the weight and more than twice the tensile strength. At present they are being developed primarily for use in the aerospace field, in chemical plants where resistance to corrosion is important, and for bearing materials and marine purposes. But it would appear that the materials to be used in long-span bridges of the future will be evolved through development along the above lines. The essential reduction in cost of such new materials can be made only through large-scale production. But in the light of the immense diversity and the amazing advances in the production of plastics, which have led to their worldwide adoption in a very few years, for thousands of applications, there seems little doubt that the economic production of greatly improved bridge materials is only a question of time.

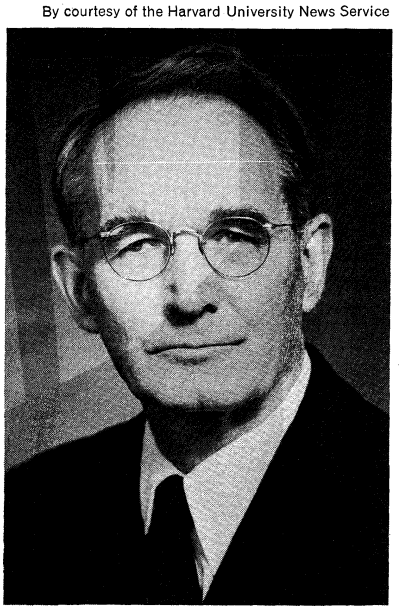
Bridgman, Percy Williams

One of the pioneering physicists of the 20th century, P.W. Bridgman devoted himself for 50 years with remarkable singleness of purpose to the experimental study of materials at very high pressures. He is remembered also for his contributions to the philosophy of science.

By courtesy of the Harvard University News Service



Bridgman.

He was born in Cambridge, Massachusetts, on April 21, 1882, the son of a journalist. He entered Harvard University in 1900, taking his M.A. in 1905 and his Ph.D. in 1908. His experimental work on static high pressures was begun in 1908. It was at first confined to pressures of about 6,500 atmospheres (one atmosphere = 14.7 pounds per square inch), but he gradually extended the range to over 100,000 atmospheres and ultimately reached about 400,000 atmospheres. In this unexplored field, he had to invent much of the equipment himself. His most important invention was a special type of seal, in which the pressure in the gasket always exceeds that in the pressurized fluid, so that the closure is self-sealing; without this his work at very high pressures would not have been possible. Later he was able to make full use

Laboratory work

of the new steels and of alloys of metals with heat-resistant compounds such as carboloy (tungsten carbide cemented in cobalt). Most of this work involved measurements of the compressibilities of liquids and solids, studies of the phase changes of solids under pressure (which included the discovery of new high-pressure forms of ice), and measurements of the physical properties of solids (such as electrical resistance). As the range of pressures was extended, new and unexpected phenomena appeared; thus he discovered that the electrons in cesium undergo a rearrangement at a certain transition pressure. Although he did not himself synthesize diamonds, despite repeated attempts, his pioneer work led directly to their synthesis by scientists of the General Electric Company in 1955. Many other minerals have been synthesized by the adoption and extension of his techniques; a new school of geology, based on experimental work at high pressures and temperatures, developed from his endeavours.

He was something of an individualist. He liked to work by himself, spending long hours in the laboratory and eschewing attendance at academic committees. He published over 260 papers (only two of which listed a co-author) and 13 books. His papers are a mine of information for the experimentalist; they also reveal a masterly grasp of mathematical physics.

Bridgman's "operational" philosophy of science

During a course of lectures he gave in 1914 on advanced electrodynamics, he was struck by the obscurities and ambiguities inherent in defining scientific ideas. This led him to the "operational" approach to scientific meaning, discussed in his first philosophical book, *The Logic of Modern Physics* (1927). He defined concepts (*e.g.*, length) in terms of the operations, both physical and mental, involved in their measurement. Since all measurements are relative to the frame of reference of the observer, concepts are also relative; length, for example, is a different concept when measured terrestrially than when measured astronomically. His views had affinities with those of the Austrian positivist Ernst Mach, the American empiricists Charles Peirce and William James, and the logical positivists of the Viennese school, although he retained an individual approach. He was motivated in his logical explorations by the uncritical use of the current language in physics. He noted that the apparent precision of mathematical equations concealed a mass of crude observations and approximate verbal explanations. He wrote in *The Logic of Modern Physics:*

> In general, we mean by any concept nothing more than a set of operations; *the concept is synonymous with the corresponding set of operations.* . . . If a specific question has meaning, it must be possible to find operations by which answers may be given to it. It will be found in many cases that the operations cannot exist, and the question therefore has no meaning.

He rose steadily through the hierarchical levels of university status, becoming a full professor at Harvard in 1919, Hollis Professor in 1926, and Higgins Professor in 1950. He was awarded the Nobel Prize for Physics in 1946 for his discoveries in the domain of high-pressure physics. After retirement, he continued his scientific work until he died in Randolph, New Hampshire, on August 20, 1961. He was married and had two children.

One of Bridgman's strongest characteristics was his concern for intellectual integrity in every activity, from the laboratory experiment to the conduct of life itself. When he found himself dying of cancer, he asked his doctors to put an end to his life; when they refused, he found his own way, leaving behind a two-sentence note: "It isn't decent for Society to make a man do this thing himself. Probably this is the last day I will be able to do it myself. P.W.B."

BIBLIOGRAPHY. Bridgman's scientific papers have been published in *Collected Experimental Papers*, 7 vol. (1964). Further biographical information may be found in the *Dictionary of Scientific Biography*, vol. 2, pp. 457–461 (1970); and in *Biog. Mem. Fellows R. Soc.*, vol. 8 (1962). The latter contains a complete bibliography of his papers and books. His best known book on philosophy is *The Logic of Modern Physics* (1927, reprinted 1960).

Bright, John

English reform politician, friend and chief lieutenant of Richard Cobden in the early Victorian campaign for free trade and internationalism, John Bright was a powerful orator on behalf of the Anti-Corn Law League (1839–46), against the Crimean War (1853–56), and in favour of parliamentary reform.

Bright, photographed by Herbert Barraud.

Bright was born at Rochdale on November 16, 1811, the eldest surviving son of Jacob Bright, a self-made cotton-mill owner. John Bright inherited bluntness of manner from his father, imaginative sensitivity from his mother. The Brights were Quakers, and John was educated at a succession of Quaker schools in the north of England, where, instead of receiving a classical education, he developed a lifelong love of the Bible and of the 17th-century English Puritan poets (especially Milton), a love often revealed in his speeches. Quaker beliefs shaped his politics, which consisted mainly of demands for an end to inequalities (social, political, or religious) between individuals and between peoples. While still in his 20s he had led a successful campaign in his native borough against the payment of compulsory taxes for the Anglican church.

In the same spirit he became a founder-member of the Anti-Corn Law League, which fought for lower grain prices, and by 1841 he had emerged as the chief supporting speaker to Cobden, the leader of the league. For five years, until repeal of the Corn Laws in 1846, Cobden and Bright spoke frequently together from platforms throughout the country. Cobden's speeches provided persuasive arguments; Bright concentrated upon denouncing the privileged political position of the agricultural landlords, which had enabled them to use Parliament to pass the Corn Laws. Although Cobden had taught Bright the high moral and economic case for free trade, Bright tended to speak in narrower terms on behalf of the manufacturers and mill hands, who (he insisted to the latter) shared a common interest in overturning the Corn Laws.

Partnership with Cobden

Bright became a member of Parliament for Durham in 1843 and for Manchester in 1847. In 1839 he had married a fellow Quaker, Elizabeth Priestman; but she died of consumption in September 1841, leaving Bright with one daughter. In later life he liked to tell an emotional story of how Cobden visited him after his bereavement and how the two friends made a compact together to crusade against the Corn Laws. Bright's old-age recollections, however, tended to be unconsciously self-inflating, sacrificing accuracy for effect. In reality, he had begun to work closely with Cobden well before his wife's death. He also deeply disliked being opposed, even by Cobden. This was an unfortunate product of his sensitive nature, and he often expressed his disappointment with a brusqueness that hurt the feelings of others.

In 1847 Bright married again; his second wife was Margaret Elizabeth Leatham, another Quaker, two of whose brothers later became Liberal members of Parliament. She, too, took an interest in politics, though Bright did little to encourage this. Certainly, he strongly disapproved discussion of "women's rights" by the females of his family. Four sons and three daughters were born to the Brights, their father adopting a typical Victorian patriarchal attitude, affectionate but dominating. As he grew older, Bright even came to look like an Old Testament patriarch, his striking appearance adding to the effect of his oratory.

During his prime in the 1850s and 1860s, Bright's speeches came to be widely reported, winning admiration even from opponents. He regarded his speaking powers as a gift from God, comparing himself on the platform to a clergyman in his pulpit. In this spirit the greatest of all his oratorical series was delivered against British involvement in the Crimean War. He variously denounced the war as un-Christian, contrary to the principles of international free trade, and harmful to British interests. "The Angel of Death," he said, "has been abroad throughout the land; you may almost hear the beating of his wings." He blamed Lord Palmerston and the aristocracy for deluding the British people; British foreign policy and the expensive network of diplomatic appointments constituted "a gigantic system of outdoor relief for the aristocracy."

Frustration at his failure to stop the war plunged Bright into a severe nervous breakdown (1856–58). His anti-war views also helped to lose him his Manchester seat in 1857; but within a few months he was elected member of Parliament for Birmingham, which he was to represent for the rest of his life. A speech-making campaign for parliamentary reform launched from Birmingham by Bright at the end of 1858 faded out within a few months, but it marked the beginning of the movement toward the great reform agitation of the mid-1860s.

Hero of the reformers

During the second half of 1866 Bright suddenly found himself the hero and chief mouthpiece of the reformers, accepted alike by those who demanded universal suffrage and those who wanted more limited reform. In terms of immediate influence this was the high point of his career. Paradoxically, his position was strengthened by the uncertainty of his own precise preference—he had always left details and close logic to Cobden, who died in 1865. But Bright was well satisfied with the household franchise introduced by the 1867 Reform Act, which extended the vote to skilled urban artisans but still excluded the town and country labourers. He was impressed by the artisans' intelligence and independence, and he recommended every man who wanted the vote to acquire these qualities. The Brights were benevolent employers, but this same faith in self-help and independence placed Bright at the head of those manufacturers who opposed factory legislation, trade unions, and social reform. This was the negative side of his belief in equality. Its positive side led him strongly to support the North against the slave-owning South during the American Civil War (1861–65) and to press both before and after the Indian Mutiny (1857) for less authoritarian British rule in India.

Government service

He entered Gladstone's Cabinet as president of the Board of Trade in 1868, but another breakdown forced his resignation in 1870. Although he served twice more in Gladstone cabinets (1873–74, 1880–82), the rest of his career was but an epilogue. His radicalism no longer seemed dangerous, allowing him during the last 20 years of his life to be widely accepted (as the economist and journalist Walter Bagehot remarked) as "a great institution." He helped to shape Gladstone's Irish land reforms of 1870 and 1881, but his pugnacious streak (always strong, even in the cause of peace) led him in 1886 to reject Gladstone's lead in proposing Irish Home Rule. Bright announced that he was not prepared to see power given to Irish nationalists who had insulted the Queen and made a mockery of parliamentary government. He died on March 27, 1889.

G.M. Trevelyan, his official biographer (1913), wrote of the "odour of sanctity" that surrounded Bright in old age. Trevelyan himself encouraged such an approach, but later historians have taken a more critical view of Bright's personality and achievement.

BIBLIOGRAPHY. G.M. TREVELYAN, *The Life of John Bright* (1913), is the official life; W. ROBERTSON, *The Life and Times of the Right Hon. John Bright* (1883), is the most voluminous of contemporary accounts. J. VINCENT, *The Formation of the Liberal Party 1857–1868* (1966), contains a penetrating analysis; D. READ, *Cobden and Bright: A Victorian Political Partnership* (1967), concentrates upon comparing the personalities and policies of the two men and also contains full primary and secondary references. Bright's *Speeches on Questions of Public Policy* (1868), his *Public Addresses* (1879), and *Public Letters* (1885), should be read for their omissions as well as their emphases.

(D.Re.)

Britain, Ancient

Apart from a few short references in the classics, knowledge of Britain before the Roman conquest (begun AD 43) is derived entirely from archaeological research. It is thus lacking in detail, for archaeology can rarely identify personalities, motives, or exact dates. All that is available is a picture of successive cultures and some knowledge of economic development. But even in Roman times, Britain lay on the periphery of the civilized world, and Roman historians, for the most part, provide for that period only a framework into which the results of archaeological research can be fitted. Britain emerged into the light of true history only after the Saxon settlements in the 5th century AD.

Until late in the Mesolithic (Middle Stone) Age, Britain formed part of the continental landmass and was easily accessible to migrating hunters. The cutting of the landbridge, *c.* 6000–5000 BC, had important effects: migration became more difficult and remained for long impossible to large numbers. Thus Britain developed insular characteristics, absorbing and adapting rather than fully participating in successive continental cultures. And within the island geography worked to a similar end; the fertile southeast was more receptive of influence from the adjacent continent than were the less accessible hill areas of the west and north. Yet in certain periods the use of sea routes brought these too within the ambit of the continent.

From the end of the Ice Age (*c.* 11,000 BC), there was a gradual amelioration of climate leading to the replacement of tundra by forest and of reindeer hunting by that of red deer and elk. Valuable light on contemporary conditions was gained by the excavation of a lakeside settlement at Star Carr, Yorkshire, which was occupied for about 20 successive winters by hunting people in the 8th millennium BC.

PRE-ROMAN BRITAIN

Neolithic Age. A major change occurred *c.* 4000 BC with the introduction of agriculture by Neolithic immigrants from the coasts of western and possibly northwestern Europe. They were pastoralists as well as tillers of the soil. Tools were commonly of flint, which toward the close of the period was won by mining, but axes of volcanic rock were also traded by prospectors exploiting distant outcrops. The dead were buried in communal graves of two main kinds: in the west, tombs were built out of stone and concealed under mounds of rubble; in the stoneless eastern areas the dead were buried under long barrows (mounds of earth), which normally contained timber structures. Other evidence of religion comes from campsites (*e.g.*, Windmill Hill, Wiltshire), which are now believed to have been centres of ritual and of seasonal tribal feasting. From them developed, late in the 3rd millennium, more clearly ceremonial ditch-enclosed earthworks known as henge monuments. Some, like Durrington Walls, Wiltshire, are of great size and enclose subsidiary timber circles. British Neolithic culture thus developed an individuality of its own.

Ritual centres

Bronze Age. Early in the 2nd millennium or perhaps even earlier, from *c.* 2300 BC, changes were introduced

by the Beaker folk from the Low Countries and the middle Rhine. These people, whose round skulls differentiate them from the long-headed Neolithic people, buried their dead in individual graves, often with the drinking vessel that gives their culture its name. The earliest of them still used flint; later groups, however, brought a knowledge of metallurgy and were responsible for the exploitation of gold and copper deposits in Britain and Ireland. They may also have introduced an Indo-European language. Control of the trade routes was soon taken over by the chieftains of Wessex, whose rich graves testify to their success as middlemen. Commerce was far-flung, in one direction to Ireland and Cornwall and in the other to central Europe and the Baltic, whence amber was imported. Amber bead spacers from Wessex have been found in the shaft-graves at Mycenae in Greece. It was, perhaps, this contact which enabled the Wessex chieftains to construct the remarkable monument of shaped sarsens (large sandstones) known as Stonehenge III. Originally a late Neolithic henge, Stonehenge was uniquely transformed in Beaker times with a circle of large bluestone monoliths transported from southwest Wales.

Stonehenge

Little is known in detail of the Middle Bronze Age and the Late Bronze Age. Because of present ignorance of domestic sites, these periods are mainly defined only by technological advances and changes in tools or weapons. In general, the southeast of Britain continued in close contact with the continent and the north and west with Ireland.

From about 1200 BC there is clearer evidence for agriculture in the south; the farms consisted of circular huts in groups with small oblong fields and stock enclosures. This type of farm became standard in Britain down to and into the Roman period. From the 8th century, expansion of continental Urnfield and Hallstatt groups brought new people (mainly the Celts) to Britain; at first, perhaps, these were small prospecting groups, but soon new settlements developed. Some of the earliest hill forts in Britain were constructed in this period (*e.g.*, Beacon Hill, near Ivinghoe, of Buckinghamshire; or Finavon, Angus); though formally belonging to the Late Bronze Age, they usher in the succeeding period.

Iron Age. The introduction of knowledge of iron was in fact merely incidental: it does not signify a change of population. The centuries 700–400 BC saw a succession of small migrations; the newcomers mingled easily with existing inhabitants. Yet the greater availability of iron facilitated land clearance and the growth of population. The earliest ironsmiths made daggers of the Hallstatt type but of distinctively British form; and the settlements were also of a distinctively British type with the traditional round house, the "Celtic" system of farming with its small fields, and storage pits for grain. Thus Britain absorbed the newcomers.

Celtic field system

Conditions in the 4th century grew more disturbed. By the year 300 BC, swords were being made once more in place of daggers; hill forts grew more numerous and elaborate. Finally, from the 3rd century, a British form of La Tène Celtic art was developed to decorate warlike equipment such as scabbards, shields, and helmets, and eventually also bronze mirrors and even domestic pottery. During the 2nd century, the export of Cornish tin, noted before 300 by Pytheas of Massilia, a Greek explorer, continued; evidence of its destination is provided by the Paul (Cornwall) hoard of north Italian silver coins. In the 1st century BC this trade was in the hands of the Veneti of Brittany; their conquest (56 BC) by Julius Caesar, who destroyed their fleet, seems to have put an end to it.

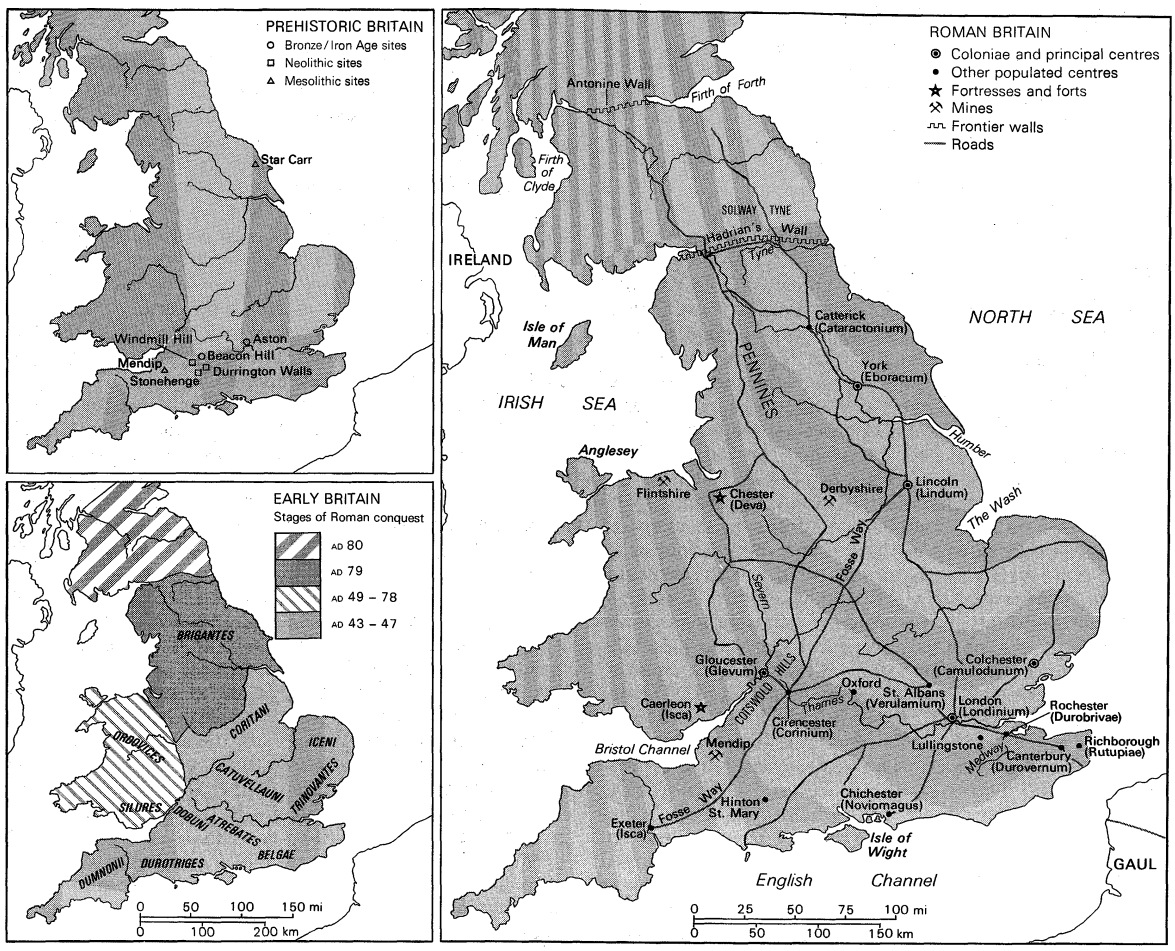
By 200 Britain had fully developed its insular Celtic character. The emergence, however, of the British tribes known to Roman historians was due to a further phase of settlement, by tribesmen from Belgic Gaul. Coin finds suggest that the earliest movements of this migration began before the end of the 2nd century; the decisive settlements were made in the 1st century probably as a result of pressures in Gaul created by Germanic and Roman expansion. The result was a distinctive culture in southeast Britain (especially in Kent and north of the Thames), that represented a later phase of the continental Celtic La Tène culture. Its people used coins and the potter's wheel, cremated their dead, and their better equipment enabled them to begin the exploitation of heavier soils for agriculture.

ROMAN BRITAIN

The conquest. Caesar's description of Britain at the time of his invasions of 55 or 54 BC is the first coherent account extant, and it was his conquest of Gaul that brought the island into close contact with the Roman world. From about 20 BC it is possible to distinguish two principal powers: The Catuvellauni north of the Thames led by Tasciovanus, successor of Caesar's adversary Cassivellaunus, and, south of the river, the kingdom of the Atrebates ruled by Commius and his sons Tincommius, Eppillus, and Verica. Tasciovanus was succeeded in about AD 5 by his son Cunobelinus, who, during a long reign, established a paramount power all over the southeast, which he ruled from Camulodunum (Colchester). Beyond these kingdoms lay the Iceni in what is now Norfolk, the Coritani in the Midlands, the Dobuni (Dobunni) in the area of Gloucestershire, and the Durotriges in that of Dorset, all of whom issued coins and probably had Belgic rulers. Behind these again lay further independent tribes—the Dumnonii of Devon, the Brigantes of Yorkshire, the Silures and Ordovices in Wales. It was the Belgic and semi-Belgic tribes who later formed the civilized nucleus of the Roman province: the Belgic contribution to Roman Britain is great.

The client relationships that Caesar had established with certain British tribes were extended by Augustus. In particular, the Atrebatic kings welcomed Roman aid in their resistance to Catuvellaunian expansion. The decision of the emperor Claudius to conquer the island was the result partly of his personal ambition, partly of British aggression. Verica had been driven from his kingdom and appealed for help, and it may have been calculated that a hostile Catuvellaunian supremacy would endanger stability across the Channel. Under Aulus Plautius an army of four legions was assembled, together with a number of auxiliary regiments consisting of cavalry and infantry raised among warlike tribes subject to the empire. After delay caused by the troops' unwillingness to cross the ocean, which they then regarded as the boundary of the human world, a landing was made at Richborough, Kent, in AD 43. The British under Togodumnus and Caratacus, sons and successors of Cunobelinus, were taken by surprise and defeated. They retired to defend the Medway crossing near Rochester but were again defeated in a hard battle. The way to Camulodunum lay open, but Plautius halted at the Thames to await the arrival of the emperor, who took personal command of the closing stages of the campaign. In one short season, the main military opposition had been crushed: Togodumnus was dead and Caratacus fled to Wales. The rest of Britain was by no means united, for Belgic expansion had created tensions. Some tribes submitted, and the overrunning of the rest remained the task for the year 44. For this purpose smaller expeditionary forces were formed consisting of single legions or parts of legions with their *auxilia* (subsidiary allied troops). The best documented campaign is that of Legion II under its legate Vespasian starting from Chichester, where the Atrebatic kingdom was restored; the Isle of Wight was taken, and the hill forts of Dorset reduced. Legion IX advanced into Lincolnshire, and Legion XIV probably across the Midlands toward Leicester. Colchester was the chief base, but the fortresses of individual legions at this stage have not yet been identified.

By the year 47, when Plautius was succeeded as commanding officer by Ostorius Scapula, a frontier had been established from Exeter to the Humber based on the road known as the Fosse Way; from this fact it appears that Claudius did not plan the annexation of the whole island but only of the arable southeast. The intransigence of the



Ancient Britain.
(Left) Adapted from *The Reader's Digest Complete Atlas of the British Isles*, published by The Reader's Digest Association Ltd., London, 1965; (right) based upon the Ordnance Survey Map with the sanction of the Controller of Her Britannic Majesty's Stationery Office, Crown copyright reserved

tribes of Wales spurred on by Caratacus, however, caused Scapula to occupy the lowlands beyond the Fosse Way up to the River Severn and to move forward his forces into this area for the struggle with the Silures and Ordovices; they were strengthened by the addition of Legion XX, released for this purpose by the foundation of a veteran settlement (*colonia*) at Camulodunum in the year 49. The *colonia* would form a strategic reserve as well as setting the Britons an example of Roman urban organization and life. A provincial centre for the worship of the emperor was also established. Scapula's right flank was secured by the treaty relationship that had been established with Cartimandua, queen of the Brigantes. Hers was the largest kingdom in Britain, occupying the whole area between Derbyshire and the Tyne; unfortunately it lacked stability, nor was it united behind its queen, who lost popularity when she surrendered the British resistance leader, Caratacus, to the Romans. Nevertheless, with occasional Roman military support, Cartimandua was maintained in power down to 69 against the opposition led by her husband, Venutius, and this enabled Roman governors to concentrate on Wales.

Boudicca's rebellion

By AD 60 much success had been achieved; Suetonius Paulinus, governor from 59 to 61, was invading the island of Anglesey, the last stronghold of independence, when a serious setback occurred: this was the rebellion of Boudicca, queen of the Iceni. This tribe had enjoyed a position of alliance and independence under its king Prasutagus; but on his death (60) the territory was forcibly annexed and outrages occurred. Boudicca was able to rally other tribes to her assistance; chief of these were the Trinovantes of Essex, who had many grievances against the settlers of Camulodunum for their arrogant seizure of lands. Roman forces were distant and scattered; and, before peace could be restored, the rebels had sacked Camulodunum, Verulamium (St. Albans), and London, the three chief centres of Romanized life in Britain. Paulinus acted harshly after his victory, but the procurator of the province, Julius Classicianus, with the revenues in mind and perhaps also because, as a Gaul by birth, he possessed a truer vision of provincial partnership with Rome, brought about his recall.

In the first 20 years of occupation, some progress had been made in spreading Roman civilization. Towns had been founded, the imperial cult had been established, and merchants were busily introducing the Britons to material benefits. It was not, however, until the Flavian Period, AD 69–96, that real advances were made in this field. With the occupation of Wales by Julius Frontinus (governor from 74 to 78) and the advance into northern Scotland by Gnaeus Julius Agricola (78–84), troops were removed from southern Britain, and self-governing *civitates*, administrative areas based for the most part on the indigenous tribes, took over local administration. This involved a large program of urbanization and also of education, which continued on into the 2nd century; Tacitus, in his biography of Agricola, emphasizes the encouragement given to it. The conquest of Wales was complete by 78, but Agricola's invasion of Scotland failed through shortage of manpower to complete the occupation of the whole island, and when the British garrison was reduced (*c.* AD 90) by a legion because of continental needs, it became evident that a frontier would have to be maintained in the north. After several experiments, the Solway–Tyne isthmus was chosen, and there the emperor Hadrian built his stone wall (*c.* 122–130).

Condition of the province. There was a marked contrast in attitude toward the Roman occupation between the lowland Britons and the inhabitants of Wales and of the hill country of the north. The economy of the former

was that of settled agriculture, and they were largely of Belgic stock; they soon accepted, and appreciated, the Roman way of life. The economy of the hill dwellers was pastoral; to them the urban civilization of Rome threatened their freedom of life. Resistance in Wales was stamped out by the end of the 1st century AD, but even so, Roman influences were weak except in the plain of Glamorgan. In The Pennines until the beginning of the 3rd century, there were repeated rebellions, the more dangerous because of the threat of assistance from free Scotland.

Army and frontier. After the emperor Domitian had reduced the garrison in about the year 90, three legions remained; their permanent bases were established at York, Chester, and Caerleon. The legions formed the foundation of Roman military power, but they were supplemented in garrison duty by numerous smaller auxiliary regiments both of cavalry and infantry, either 1,000 or 500 strong. These latter garrisoned the wall and were stationed in a network of other forts established for police work in Wales and northern England. With 15,000 legionaries, and about 40,000 auxiliaries, the army of Britain was very powerful; its presence had economic as well as political results. Hadrian's Wall was the most impressive frontier-work in the Roman empire. Despite a period in the following two reigns when another frontier was laid out on the Glasgow–Edinburgh line—the Antonine Wall, built of turf—the wall of Hadrian came to be the permanent frontier of Roman Britain. The northern tribes only twice succeeded in passing it, and then at moments when the garrison was fighting elsewhere. In the late Roman period, when sea-raiding became prevalent, the wall lost its pre-eminence as a defense for the province, but it was continuously held until the 5th century. But although they withdrew to Hadrian's line not later than the year 196, the Romans never abandoned interest in southern Scotland. In the 2nd century their solution was military occupation. In the 3rd, after active campaigning (208–211) by the emperor Septimius Severus and his sons during which permanent bases were built on the east coast of Scotland, the solution adopted by the emperor Caracalla was regulation of relationship by treaties. These, perhaps supported by subsidies, were enforced by supervision of the whole Lowlands by patrols based on forts beyond the wall. During the 4th century, more and more reliance was placed on friendly native states, and patrols were withdrawn.

Hadrian's Wall

Administration. Britain was an imperial province. The governor represented the emperor, exercising supreme military as well as civil jurisdiction. As commander of three legions, he was a senior general of consular rank. From the late 1st century, he was assisted on the legal side by a *legatus juridicus*. The finances were in the hands of the provincial procurator, an independent official of equestrian status whose staff supervised imperial domains and the revenues of mines in addition to normal taxation. In the early 3rd century, Britain was divided into two provinces in order to reduce the power of its governor to rebel as Albinus had done in 196: Britannia Superior had its capital at London and a consular governor in control of two legions and a few auxiliaries; Britannia Inferior, with its capital at York, was under a praetorian governor with one legion but many more auxiliaries.

Finance and taxation

Local administration was of varied character. First came the chartered towns. By the year 98, Lincoln and Gloucester had joined Camulodunum as *coloniae*, and by 237 York had become a fourth. *Coloniae* of Roman citizens enjoyed autonomy with a constitution based on that of republican Rome, and Roman citizens had various privileges before the law. It is likely that Verulamium was chartered as a Latin *municipium* (free town); in such a town the annual magistrates were rewarded with Roman citizenship. The remainder of the provincials ranked as *peregrini* (subjects). In military districts control was in the hands of fort prefects responsible to legionary commanders; but, by the late 1st century, local self-government, as already stated, was granted to *civitates peregrinae*, whose number tended to increase with time. These also had republican constitutions, being controlled by elected councils and annual magistrates and having responsibility for raising taxes and administering local justice. In the 1st century there were also client kingdoms whose rulers were allied to Rome; Cogidubnus, Verica's successor, who had his capital at Chichester, is the best known. But Rome regarded these as temporary expedients, and none outlasted the Flavian Period (69–96).

Society. Pre-Roman Celtic tribes had been ruled by kings and aristocracies; the Roman *civitates* remained in the hands of the rich because of the heavy expense of office. But since trade and industry now yielded increasing profits, and the old aristocracies no longer derived wealth from war but only from large estates, it is likely that new men rose to power. Roman citizenship was now an avenue of social advancement, and it could be obtained by 25 years' service in the auxiliary forces as well as (more rarely) by direct grants. Soldiers and traders from other parts of the empire significantly enhanced the cosmopolitan character of the population, nor should the large number of legionaries be forgotten: they were already citizens and many must have settled locally. The population of Roman Britain at its peak amounted perhaps to about 2,000,000.

Roman citizenship

Economy. Even before the conquest, according to the Greek geographer Strabo, Britain exported gold, silver, iron, hides, slaves, and hounds in addition to grain. A Roman gold mine is known in Wales, but its yield was not outstanding. Iron was worked in many places but only for local needs; silver, obtained from lead, was of more significance, but the basis of the economy was agriculture, and the conquest greatly stimulated production because of the requirements of the army. According to Tacitus, grain to feed the troops was levied as a tax; correspondingly more had to be grown before a profit could be made. The pastoralists in Wales and the north probably had to supply leather, which the Roman army needed in quantity for tents, boots, uniforms, and shields. A military tannery is known at Catterick. A profit could, nonetheless, be won from the land because of the increasing demand from the towns, and at the same time the development of a system of large estates (villas) relieved the ancient "Celtic" farming system of the necessity of shouldering the whole burden. Small peasant farmers tended to till the lighter, less productive, easier-worked soils. Villa estates were established on heavier richer soils, sometimes on land recently won by forest clearance, itself a result of the enormous new demand for building timber from the army and the new towns and for fuel for domestic heating and for public baths. The villa owners had access to the precepts of classical farming manuals and also to the improved equipment made available by Roman technology. Their growing prosperity is vouched for by excavation: there are few villas that did not increase in size and luxury as corridors and wings were added or mosaics and bath blocks provided. At least by the 3rd century, some landowners were finding great profit in wool; Diocletian's price edict (AD 301) shows that at least two British cloth products had won an empire-wide reputation. Archaeological evidence indicates that the Cotswold district was one of the centres of this industry.

Trade in imported luxury goods ranging from wine to table wares and bronze trinkets was vastly increased as traders swarmed in behind the army to exploit new markets. The profits of developing industries went similarly at first to foreign capitalists. This is clearly seen in the exploitation of silver-lead and even in the pottery industry. The Mendip lead-field was being worked under military control as early as the year 49, but under Nero (54–68) both there and in Flintshire, and not much later also in the Derbyshire lead-field, freedmen—the representatives of Roman capital—were at work. By Vespasian's reign (69–79) organized companies (*societates*) of prospectors are attested. Roman citizens, who must in the context be freedmen, are also found organizing the pottery industry in the late 1st century. Large profits were made by continental businessmen in the first two cen-

turies not only from such sources but also by the import on a vast scale of high-class pottery from Gaul and the Rhineland, and on a lesser scale of glass vessels, luxury metalware, and Spanish oil and wine. A large market existed among the military, and the Britons themselves provided a second. Eventually this adverse trade balance was rectified by the gradual capture of the market by British products. Much of the exceptional prosperity of 4th-century Britain must have been due to its success in retaining available profits at home.

A final important point is the role of the Roman army in the economic development of the frontier regions. The presence as consumers of large forces in northern Britain created a revolution in previous patterns of trade and civilized settlement. Cereal production was encouraged in regions where it had been unknown, and large settlements grew up in which many of the inhabitants must have been retired soldiers with an interest in the land as well as in trade and industry.

Urbanization

Towns. Belgic Britain had large centres of population but not towns in the Roman sense, which meant not merely streets and public buildings but also the amenities and local autonomy of a city. In Britain these had therefore to be provided if Roman civilization and normal methods of provincial administration were to be introduced. Thus an urbanizing policy existed in which the assistance of the legions, as the nearest convenient source of architects and craftsmen, played an organizing role. The earlier towns consisted of half-timbered buildings; before AD 100 only public buildings seem to have been of stone. The administrative capitals had regular street grids, a forum with basilica (public hall), public baths, and temples; a few had theatres and amphitheatres, too. With few exceptions they were undefended. Town walls were provided in the 3rd century, not so much as a precaution in unsettled times as a means of keeping operational the earthwork defenses already provided to meet a crisis at the end of the 2nd century. In size these towns grew to about 100–130 acres with populations of about 5,000; a few were twice this size. The majority of towns in Roman Britain seem to have developed out of traders' settlements in the vicinity of early garrison-forts: those that were not selected as administrative centres remained dependent on economic factors as centres of trade or manufacture or else as markets for the agricultural peasantry. They varied considerably in size. In the north, where garrisons were permanently established, quite large trading settlements grew up in their vicinity, and at least some of these would rank as towns.

Villas. Apart from the exceptional establishment at Fishbourne, in West Sussex, whose Italian style and luxurious fittings show that it was the palace of King Cogidubnus, the houses of Roman-British villas had simple beginnings and were of a provincial type. A few were prosperous enough in the 2nd century to afford mosaics; but the great period of villa prosperity lay in the 4th century, when many villas grew to impressive size. Their importance was economic and has already been described. Much remains to be learnt from full excavation of their subsidiary work buildings. Larger questions of tenure and organization are probably insoluble in the absence of documentary evidence, for it is dangerous to draw analogies from classical sources since conditions in Celtic Britain were very different from those of the Mediterranean world.

Religion and culture. A great variety of religious cults were to be found, for, in addition to numerous Celtic deities of local or wider significance, the gods of the classical pantheon were introduced and were often identified with their Celtic counterparts. In official circles the worship of the state gods of Rome and of the imperial cult was duly observed. In addition merchants and soldiers introduced oriental cults, among them Christianity. The latter, however, made little headway until the late 4th century, though the frescoes at Lullingstone in Kent and the mosaics at Hinton St. Mary in Dorset attest its presence among villa owners. Classical temples are sometimes found in towns, but the normal temple was of the Romano-Celtic type with a small square shrine and surrounding portico; these are found in town and country alike.

Romanization was strongest in the towns and among the upper classes, as would be expected; there is evidence that in the countryside Celtic continued to be spoken, though it was not written. Many people were bilingual: graffiti prove that even artisans wrote Latin. Evidence of the classical education of the villa owners is provided by their mosaics, which prove an aquaintance with classical mythology and even with the *Aeneid* of Virgil. Sculpture and wall painting were both novelties in Roman Britain. Statues or busts in bronze or marble were imported from Gaulish or Mediterranean workshops, but British sculptors soon learned their trade and at their best produced attractive works in a provincial idiom, very often for votive purposes. Many cruder works were also executed: their interest lies in the proof they afford that the conventions of the classical world had penetrated even to the lower classes. Mosaic floors are found in towns and villas, at first, as at Fishbourne, laid by imported craftsmen; there is evidence that by the middle of the 2nd century a local firm was at work at Colchester and Verulamium, and in the 4th century, a number of local mosaic workshops can be recognized by their styles. One of the most skilled of these was based in Cirencester.

Mosaics

Roman civilization thus took root in Britain. The resulting growth was more obvious in urban circles than among the agricultural peasants and weakest in the resistant highland zone. It was a provincial version of Roman culture, but one with recognizably British traits.

ROMAN BRITAIN AND THE SAXON CONQUEST

Britain, AD 286–410. The reforms of Diocletian ended the chaos of the 3rd century and ushered in the late imperial period. Britain, however, for a short period became a separate empire through the rebellion (286/287) of Carausius. This man had commanded against the Saxon pirates in the Channel and by his naval power was able to maintain his independence. His main achievement was to complete the new system of Saxon Shore forts around the southeastern coasts. At first he sought recognition as coemperor, but this was refused; in 293 the fall of Boulogne to Roman forces led to his murder and the accession of Allectus, who, however, fell in his turn when Constantius I invaded Britain in 296. Allectus had withdrawn troops from the north to oppose the landing, and Hadrian's Wall seems to have been attacked, for Constantius had to restore the frontier as well as to reform the administration. He divided Britain into four provinces, and in the same period, the civil power was separated from the military. Late Roman sources show three separate commands respectively under the *dux Britanniarum* (commander of the Britains), the *comes litoris Saxonici* (count of the Saxon Shore), and the *comes Britanniarum*, though the dates of their establishment are unknown and may not have been identical. The 4th century was a period of great prosperity in towns and countryside alike. Britain had escaped the invasions of the 3rd century and may have seemed a safe refuge for wealthy continentals. Its weakness lay in the fact that its defense was ultimately controlled by distant rulers rather than by local responsibility. The garrison was perhaps weakened by withdrawals for the civil war of Magnentius (350–351); at any rate in 367 there was a military disaster due to concerted sea-borne attacks from the Picts of Scotland and the Scots of Ireland. But, though the frontier and forts behind it suffered severely, there is little trace of damage to towns or villas. Count Theodosius in 369 restored the situation and strengthened the defenses of the towns with external towers designed to mount artillery. Prosperity continued, but there were ominous withdrawals of troops by Magnus Maximus in 383 and again at the end of the century by Stilicho. Thus, when in 407 Constantine III was declared emperor by the army in Britain and took further troops to Gaul, the forces remaining in the island were insufficient to provide protection against increasing Pictish and Saxon

raids. The Britons appealed to the legitimate emperor, Honorius, who was unable to send assistance but authorized the cities to provide for their own defense (410). This marks the end of Roman Britain, for the central government never re-established control: but for a generation there was little other outward change.

The rise of tyrants

Britain in the 5th century. Power fell gradually into the hands of tyrants. Chief of these was Vortigern (*c.* 425), but he, unlike earlier usurpers, made no attempt to become Roman emperor, being content with power in Britain. Independence was producing separate interests. By this date Christianity had made considerable headway in the island, but the leaders followed the heretical teaching of Pelagius, himself a Briton, who had emphasized the importance of the human will over divine grace in the achievement of salvation. It has been held that the self-reliance shown in the maintenance of national independence was inspired by this philosophy. Yet there was also a powerful Catholic party anxious to reforge the links with Rome, in support of whom St. Germanus of Auxerre visited Britain in 429. It may have been partly to thwart the plans of this party that Vortigern made the mistake (*c.* 430; the "traditional" date given by Bede is between 446 and 454) of inviting Saxons to settle and garrison strategic areas of the east coast, though he certainly also had in mind the need to ward off sea-borne raids by Picts, which at this time were troublesome. Planned settlement of this sort is the best explanation for the earliest Saxon settlements found around the mouths of the east coast estuaries and also in the central-southeast region around Oxford. For a time the system worked successfully; but when, in 442, these Saxon *foederati* ("allies") rebelled and called in others of their race to help them, it was found that they had been given a stranglehold on Britain. A long period of warfare and chaos was inaugurated that was economically disastrous. It was probably this period that saw the disintegration of the majority of the villa estates; with the breakdown of markets and the escape of slaves, villas ceased to be viable and must have gradually fallen into ruin, though the land itself did not cease to be cultivated. A few villas met a violent end. The towns, under the protection of their strong defenses, at first provided refuge at any rate for the rich who could leave their lands; but by degrees decay set in as trade declined and finally the supply of food was itself threatened. In about 446 the British made a vain appeal for help to the Roman general Aetius (the "Groans of the Britons" mentioned in the *De excidio et conquestu Britanniae* of the British writer Gildas). For several decades they suffered reverses; many emigrated to Brittany. In the second half of the 5th century Ambrosius Aurelianus and the shadowy figure of Arthur began to turn the tide by the use of cavalry against the ill-armed Saxon infantry. A great victory was won at Mons Badonicus (a site not identifiable) toward 500: now it was Saxons who emigrated, and the British lived in peace all through the first half of the 6th century, as Gildas records. But in the second half the situation slowly worsened.

The Anglo-Saxons. Except in outline, the history of the settlements before 600 is hard to assess; the evidence consists partly of archaeological material difficult to date with precision, partly of place-names and early traditions, royal pedigrees, and annals later written down and of dubious accuracy. The traditions of the Kentish kingdom can be linked with what is known of federate settlement as outlined above, and it is likely that the Kingdoms of Deira in East Yorkshire, Wessex, and East Anglia originated similarly. By the late 5th century the Kingdom of Sussex had been established by conquest. The division of the settlers into Angles, Saxons, and Jutes in Bede's *Ecclesiastical History of the English People* is oversimplified to judge by archaeological evidence, and perhaps reflects the origins of kings rather than of their subjects who were of much more mixed extraction; in addition to the three sources named, Frisian and also Frankish elements can sometimes be identified.

In the later 6th century, the picture becomes clearer. By 577 Ceawlin had extended the Wessex kingdom to the Bristol Channel, though the British Kingdom of Dumnonia still held Devon and Cornwall. Slightly earlier (547), Ida had established the nucleus of the Bernician kingdom at Bamburgh from which the British states in The Pennines and southern Scotland were by degrees subdued. Under Aethelfrith soon after 600, Bernicia and Deira were united as the Kingdom of Northumbria, and by this date Lindsey (south of the Humber), Essex, Mercia, Middle Anglia, and two small kingdoms on the Welsh border are known to have emerged as states. Lindsey too may go back to a federate settlement.

On these foundations the historical kingdoms of the Anglo-Saxons were built. But British resistance was lasting in the west and north. The highland zone still exerted its age-old influence.

Britain and Ireland, History of

This article deals with the history of Britain and Ireland in medieval and modern times, beginning with the Anglo-Saxon (Germanic) occupation of England. For the earlier history of what is now England, see the article BRITAIN, ANCIENT.

This article is divided into the following sections:

I. England to 1066
- The invaders and their early settlements
- The Heptarchy
- The period of the Scandinavian invasions
- The achievement of political unity
- The Anglo-Danish state

II. The Normans (1066–1154)
- William I (1066–87)
- William II Rufus (1087–1100) and Henry I (1100–35)
- The period of anarchy (1135–54)

III. The early Plantagenets (1154–1216)
- Henry II (1154–89)
- Richard I (1189–99)
- King John (1199–1216)

IV. The 13th century
- Henry III (1216–72)
- Edward I (1272–1307)

V. The 14th century
- Edward II (1307–27)
- Edward III (1327–77)
- Richard II (1377–99)

VI. Lancaster and York (1399–1485)
- Henry IV (1399–1413)
- Henry V (1413–22)
- Henry VI (1422–61 and 1470–71)
- Edward IV (1461–70 and 1471–83)
- Richard III (1483–85)
- England in the late Middle Ages

VII. England under the Tudors (1485–1603)
- Henry VII (1485–1509)
- Henry VIII (1509–47)
- Edward VI (1547–53)
- Mary I (1553–58)
- Elizabeth I (1558–1603)

VIII. Wales to *c.* 1540
- Wales before the Norman Conquest
- Wales from the 11th to the 16th century

IX. Scotland to 1603
- Early history
- The unification of the kingdom

The wars of independence
Scotland in the 15th century
Scotland in the 16th century
X. The early Stuarts and the Commonwealth (1603–60)
The condition of England in 1603
James I (1603–25)
Charles I (1625–49)
The Civil War
The Commonwealth (1649–60)
XI. The later Stuarts (1660–1714)
Charles II (1660–85)
James II (1685–88) and the Glorious Revolution
William III (1689–1702) and Mary II (1689–94)
Queen Anne (1702–14)
XII. Great Britain: 1714–1815

THE INVADERS AND THEIR EARLY SETTLEMENTS

Germanic tribes began to settle in Britain from about the middle of the 5th century AD. The first arrivals, according to the 6th-century British writer Gildas, were invited by a British king to defend his kingdom against the Picts and Scots. A tradition reached the historian Bede that the first settlers were from three tribes—the Angles, Saxons, and Jutes—which he locates on the Cimbric Peninsula and the coastlands of northwestern Germany, though the Jutes should perhaps be connected with the Rhineland rather than with Jutland, where Bede, by implication, puts them. Early settlements, near the coasts and the basins of navigable rivers in eastern and southern Britain, were halted about 500 by the Britons at the Battle of Mons Badonicus at an unidentified location; but a new Germanic drive began about 550, and before the century had ended the Britons had been driven west to the borders of Dumnonia (Cornwall and Devon) and to the Welsh Marches, while invaders were advancing west of the Pennines and northward into Lothian.

The distinction between the three Germanic tribes soon lost significance; certainly by the end of the 7th century men regarded themselves as "the nation of the English," though divided into several kingdoms. They were conscious of their kinship with the continental Germans and were little influenced by the civilization of the previous inhabitants (thus forming a striking contrast to the Germanic tribes that settled in Gaul); few Britons in England were above servile condition. This sense of unity was strengthened during long periods when all kingdoms south of the Humber acknowledged the overlordship (called by Bede an *imperium*) of a single ruler, known as a *bretwalda*, a word first recorded in the 9th century.

The first such overlord was Aelle of Sussex, in the late 5th century; the second was Ceawlin of Wessex, who died in 593. The third overlord, Aethelberht of Kent, held this power in 597 when the monk Augustine led a mission from Rome to Kent; Kent was the first English kingdom to be converted to Christianity. The Christian Church provided another unifying influence, overriding political divisions, although it was not until 669 that the church in England acknowledged a single head.

The social system. When Aethelberht set a code of laws down in writing, under Christian influence, the system underlying the laws was already old, in its main lines brought over from the Continent. Its strongest bond was that of kinship; every free man depended on his kindred for protection, and the social classes were distinguished by the amount of their wergild (the sum that the kindred could accept in place of vengeance if a man were killed). The normal free man was the *ceorl*, an independent peasant landowner; below him in Kent were persons with lower wergilds, who were either freedmen or, as were similar persons in Wessex, members of a subject population; above the *ceorls* were the nobles—some perhaps noble by birth but more often men who had risen by service as companions of the king—with a wergild three times that of a *ceorl* in Kent, six times that of a *ceorl* elsewhere. The tie that bound a man to his lord was as strong as that of the kindred. Both nobles and *ceorls* might possess slaves, who had no wergild and were regarded as chattels.

Anglo-Saxon England.

The king had special rights—compensations for offenses committed in his presence or his home or against anyone under his protection; rights to hospitality, which later became a food rent charged on all land; and rights to various services. He rewarded his followers with grants of land, probably at first for their lifetime only; but the need to provide permanent endowment for the church brought into being a type of land free from most royal dues and that did not revert to the king. From the latter part of the 7th century such land was sometimes conferred by charter. It became common to make similar grants by charter to laymen, with power to bequeath; but three services—the building of forts and bridges and service in the army—were almost invariably excepted from the immunity. The king received fines for various crimes; but a man's guilt was established in an assembly of freemen, where the accused tried to establish his innocence by his oath—supported by oath helpers—and, if this failed, by ordeal. On matters of importance, the king normally consulted his *witan* (wise men).

The rights of the king

There were local variations in the law. And over a period of time the law developed to meet changed circumstances. As kingdoms grew larger, for example, an official called an "ealdorman" was needed to administer part of the area, and, later, a sheriff was needed to look after the royal rights in each shire. The acceptance of Christianity made it necessary to fit the clergy into the scale of compensations and assign a value to their oaths and to fix penalties for offenses such as sacrilege, heathen practices, and breaches of the marriage law. But the basic principles were little changed.

The conversion to Christianity. Place-names containing the names of gods or other heathen elements are plentiful enough to prove the vitality of heathenism and to account for the slow progress of conversion in some areas. In Kent, the first kingdom to accept Christianity, King Wihtred's laws in 695 contained clauses against heathen worship. The conversion renewed relations with Rome and the Continent; but the full benefit of this was delayed by the conversion of much of England by the Celtic Church, which had lost contact with Rome.

Augustine's mission in 597 converted Kent; but it had only temporary success in Essex, which reverted to heathenism in 616. A mission sent from Kent under Paulinus to Northumbria that, in 627, converted King Edwin and many of his subjects in Northumbria and Lindsey received a setback in 632 when Edwin was killed and Paulinus withdrew to Kent. About 630 Archbishop Honorius of Canterbury sent a Burgundian, Felix, to convert East Anglia, and the East Anglian church thenceforth remained faithful to Canterbury. Soon after, the West Saxons were converted by Birinus, who came from Rome. Meanwhile, King Oswald began to restore Christianity in Northumbria, bringing Celtic missionaries from Iona. And it was the Celtic Church that began in 653 to spread the faith among the Middle Angles, the Mercians, and the peoples of the Severn Valley; it also won back Essex.

At first there was little friction between the Roman and Celtic missions. Oswald of Northumbria joined with Cynegils of Wessex in giving Dorchester-on-Thames as seat for Birinus' bishopric; the Irishmen Maildubh in Wessex and Fursey in East Anglia worked in areas converted by the Roman Church; and James the Deacon continued Paulinus' work in Northumbria. Later, however, differences in usage—especially in the calculation of the date of Easter—caused controversy, which was settled in favour of the Roman party at the Synod of Whitby in 664. The adherents of Celtic usage conformed or withdrew, and advocates of Roman practice became active in the north, the Midlands, and Essex. Theodore of Tarsus (arrived 669), the first archbishop to be acknowledged all over England, was active in establishing a proper diocesan system, whereas in the Celtic Church bishops tended to move freely without fixed sees and settled boundaries; he held the first synod of the English church at Hertford in 672, and this forbade a bishop to interfere in another's diocese or any priest to move into another diocese without his bishop's permission. Sussex and the Isle of Wight —the last outposts of heathenism—were converted by Bishop Wilfrid and his followers from 681 to 687 and thenceforth followed Roman usages.

The Anglo-Saxons attributed their conversion to Pope Gregory I, "the Apostle of the English," who had sent Augustine. This may seem less than fair to the Celtic mission, but modern scholars have tended to undervalue the work of the Roman Church. The Celtic Church made a great impression by its asceticism, fervour, and simplicity, and it had a lasting influence on scholarship. Yet the period of Celtic dominance was only 30 years. The decision at Whitby reunited the English to the universal church and made possible a form of organization better fitted for permanent needs than the looser system of the Celtic Church.

Early Northumbrian missionaries

The conversion of the English was hardly completed before they began to take the faith to the continental Germans. The earliest missionaries were Northumbrians who worked in Frisia. Wilfrid converted some Frisians in the winter of 677 on his way to Rome, but the permanent conversion began about 690 with the work of Willibrord, a Northumbrian missionary.

Willibrord converted Frankish Frisia and founded the see of Utrecht. He was joined by the West Saxon Wynfrith (better known as Boniface), who worked with him from 718 to 721. Boniface's main missionary work was in Thuringia and Hesse. The Pope consecrated him bishop to the Germans in 722, archbishop in 732. In addition to his success as a missionary and his founding of sees among the Germans, Boniface reorganized the church of Bavaria and helped the Frankish leaders Pippin and Carloman to reform the Frankish church, bringing it into relations with the papacy and thus profoundly affecting Frankish history. He was joined by many men and women from England, mainly from Wessex. Boniface was martyred by the heathens in northern Frisia in 754.

The "Golden Age" of Bede. Within a century of Augustine's landing, England was in the forefront of scholarship. This high standard arose from a combination of influences: that from Ireland, which had escaped the decay caused elsewhere by the barbarian invasions, and that from the Mediterranean, which reached England mainly through Archbishop Theodore and his companion, the abbot Adrian. Under Theodore and Adrian, Canterbury became a famous school, and men trained there took their learning to other parts of England. One of these was Aldhelm, who had been a pupil of Maildubh (the Irish founder of Malmesbury); under Aldhelm, Malmesbury became an influential centre of learning. Aldhelm's own works, in Latin verse and prose, reveal a familiarity with many Latin authors; his writings became popular among admirers of the ornate and artificial style he had learned from his Celtic teachers. Before long a liberal education could be had at such other West Saxon monasteries as Nursling and Wimborne.

The finest centre of scholarship was Northumbria. There Celtic and classical influences had met: missionaries brought books from Ireland, and many Englishmen went to Ireland to study. Other Northumbrians went abroad, especially to Rome; among them was Benedict Biscop. Benedict returned from Rome with Theodore (668–669) and spent some time in Canterbury, and he brought the learning acquired there to Northumbria. He founded the monasteries at Wearmouth (674) and Jarrow (682), where Bede spent his life. Benedict and Ceolfrith, abbot of Jarrow, brought books from the Continent and assembled the fine library that was available to Bede.

Bede (*c.* 672–735) is remembered as a great historian whose work has never lost its value; but he was also a theologian regarded throughout the Middle Ages as second only to the Church Fathers. Though he was outstanding, he did not work in isolation. Other Northumbrian houses—Lindisfarne, Whitby, and Ripon—produced saints' lives, and Bede was in touch with many learned men, not only in Northumbria; there are also signs of scholarly activity in London and in East Anglia.

Moreover, in this period religious poetry was composed in the diction and technique of the older vernacular, secular poetry. *Beowulf*, considered the greatest Old English poem, is sometimes assigned to this age, but the dating is uncertain. Art flourished, with a combination of native elements and of influences from Ireland and the Mediterranean. The Hiberno-Saxon (or Anglo-Irish) style of illumination was evolved, its greatest example—the Lindisfarne Gospels—also showing classical influence. Masons from Gaul and Rome built stone churches. In Northumbria stone monuments with figure sculpture and vine-scroll patterns were set up. Churches were equipped with precious objects—some from abroad, some of native manufacture (even in heathen times the English had been skilled metalworkers). Manuscripts and works of art were taken abroad to churches founded by the English missions, and these churches, in turn, became centres of production.

Visual arts and architecture

THE HEPTARCHY

The supremacy of Northumbria and the rise of Mercia. When Northumbria became eminent in scholarship, its

age of political importance was over. This political dominance had begun when Aethelfrith, ruling over the united Northumbrian kingdoms of Bernicia and Deira, defeated the Dalriadic Scots at Degsastan in 603 and the Welsh at Chester in 613–616. Aethelfrith was himself defeated and killed in 616 by Edwin, the exiled heir to Deira, with the help of Raedwald of East Anglia, then overlord of the southern peoples.

Edwin continued to defeat the Welsh and became the acknowledged overlord of all England except Kent: he annexed the British kingdom of Elmet, invaded North Wales, and captured Anglesey and the Isle of Man. But he fell at Hatfield in 632 before the forces of Cadwallon, king of Gwynedd, and of Penda, a Mercian chieftain. A year later Aethelfrith's son Oswald destroyed Cadwallon and restored the kingdom of Northumbria, and he became overlord of all the lands south of the River Humber. But Mercia was becoming a serious rival; originally a small kingdom in the northwest midlands, it had absorbed the peoples of the Severn Valley, including the Hwicce, a West Saxon people annexed in 628 after a victory by Penda at Cirencester.

Penda threw off Northumbrian control when he defeated and killed Oswald in 641. He drove out Cenwalh of Wessex, who took refuge in East Anglia from 645 to 648. Penda's control of Middle Anglia, where he made his son subking in 653, brought him to the East Anglian frontier; and he invaded this kingdom three times, killing three of their kings. He was able to draw an army from a wide area, including East Anglia, when he invaded Northumbria in 654; nevertheless, he was defeated and killed by Oswiu, Oswald's successor.

For a short time Oswiu was overlord of southern England; but a Mercian revolt put Penda's son Wulfhere on the throne in 657, and he greatly extended Mercian power to the southeast and south. Wulfhere became overlord of Essex, with London, and of Surrey; he held the West Saxon lands along the middle Thames and blocked any eastward advance of the West Saxons by capturing the Isle of Wight and the mainland opposite and giving them to his godson, Aethelwalh of Sussex. Yet Wulfhere's reign ended in disaster; the Kentish monk Aedde, in his *Life of St. Wilfrid*, said Wulfhere roused all the southern peoples in an attack on Ecgfrith of Northumbria in 674 but was defeated and died soon after.

Ecgfrith took possession of Lindsey, a section of modern Lincolnshire, but he lost it to Aethelred of Mercia after the Battle of the Trent in 678. Thenceforward Northumbria was no threat to Mercian dominance; it was occupied in fighting the Picts in the north, and after Ecgfrith was slain by them in 685, his successors took little part in external affairs.

Yet Mercian power was threatened from the south. Though Aethelred invaded Kent in 676 and though part of Kent was ruled after 686 in subordination to him by a member of the royal house of Essex, Caedwalla of Wessex also obtained some power in Kent. Caedwalla had added Surrey, Sussex, and the Isle of Wight to the West Saxon kingdom and thus came near to uniting all lands south of the Thames into a single kingdom, which might have held its own against Mercia. But this kingdom was short-lived (it was left to Egbert of Wessex to make such a kingdom a reality in 825). Kent became free from foreign interference in 694, two years after the accession of Wihtred, who re-established the Kentish royal line. Sussex appears again as an independent kingdom; and Caedwalla's successor, Ine, was mainly occupied in extending his territory to the west. After Wihtred's death in 725 and Ine's abdication in 726, both Kent and Wessex had internal troubles and could not resist the Mercian kings Aethelbald and Offa.

The reigns of Aethelbald and Offa

The great age of Mercia. Aethelbald succeeded in 716 to the rule of all the midlands and to the control of Essex and London. By 731 all provinces south of the Humber were subject to him. Some of his charters use a regnal style suited to this dignity, such as "king not only of the Mercians but also of all provinces . . . of the South English" and "rex Britanniae" (a Latinization of "bretwalda"). Aethelbald held this position, with only occasional warfare, until his death, in 757—far longer than any previous holder of the *imperium*. St. Boniface praised the good order he maintained in his kingdom, though complaining of his immoral life and his encroachment on church privileges. Aethelbald was murdered by his own household, perhaps suborned by Beornred, a rival who was driven out by Offa before the end of the year.

Offa did not at once attain the powerful position that later caused Charles the Great (Charlemagne) to treat with him on equal terms; Cynewulf of Wessex recovered West Saxon lands by the middle Thames and did not submit until 779. Offa was overlord in Kent by 764, in Sussex and the district of Hastings by 771; he apparently lost his authority in Kent after the Battle of Otford in 776 but recovered it in 785. His use of an East Anglian mint shows him supreme there. He claimed greater powers than earlier overlords—subkings among the Hwicce and in Sussex dropped their royal titles and appeared as ealdormen, and he referred to a Kentish king as his thegn. The English scholar Alcuin spoke of the blood shed by Offa to secure the succession of his son, and fugitives from his kingdom sought asylum with Charles the Great. Charles treated Offa as if he were sole king of England, at least of the region south of the Humber; the only other king he acknowledged was the Northumbrian ruler. Offa seemed not to have claimed authority beyond the Humber but instead allied himself with King Aethelred of Northumbria by giving him his daughter in 794.

Offa appears on the continental scene more than had any previous English king. Charles wrote to him as "his dearest brother" and wished for a marriage between his own son Charles and Offa's daughter. Offa's refusal unless Charles let one of his daughters marry Offa's son Ecgfrith led to a three-year quarrel in which Charles closed his ports to traders from England. This and a letter about regulating trade, written when the quarrel was over, provide evidence for the importance of cross-Channel trade, which was one reason for Offa's reform of the coinage.

Imitating the action of Pepin in 755, Offa took responsibility for the coinage, and thenceforward the king's name normally appeared on coins. But the excellent quality in design and workmanship of his coins, especially those with his portrait, served an additional purpose: they had a propaganda value in bringing home the preeminence of the Mercian king not only to his English subjects but also on the Continent. Pope Adrian I regarded Offa with awe and respect.

Because Offa's laws are lost, little is known of his internal government, though Alcuin praises it. Offa was able to draw on immense resources to build a dike to demarcate his frontier against Wales. In the greatness of its conception and the skill of its construction, the dike forms a fitting memorial to him. It probably belongs to his later years, and it secured Mercia from sudden incursions.

The church and scholarship in Offa's time. The missionary activities of Willibrord and Boniface were continued after their deaths by Lull, Boniface's successor at Mainz, and by the Northumbrians Willehad and Aluberht, who converted the Old Saxons. Northumbria was still pre-eminent in scholarship, and the fame of the school of York, founded by Bede's pupil Archbishop Egbert, attracted students from the Continent and from Ireland. Eventually it supplied Alcuin to take charge of the revival of learning inaugurated by Charles the Great; Alcuin's writings exercised great influence on theological, biblical, and liturgical studies, and his pupils carried on his work well into the 9th century.

The spread of missionary activities and learning

Learning was not confined to Northumbria; one Latin work was produced in East Anglia, and recent attribution of manuscripts to Lichfield suggests that Mercian scholarship has been underestimated. Offa himself took an interest in education, and men from all areas corresponded with the missionaries. The Mercian schools that supplied Alfred with scholars in the 9th century may go back to this period. Vernacular poetry was composed, perhaps including *Beowulf* and the poems of Cynewulf.

A steady advance was made in the creation of parishes, and monasticism flourished and received support from Offa. A great event in ecclesiastical history was the arrival of a papal legation in 787, the first since the conversion. It drew up reforming statutes, which were accepted by the two ecclesiastical provinces, meeting separately under the presidency of Offa and Aelfwald of Northumbria. Offa used the visit to secure the consecration of his son—the first recorded coronation ceremony in England—and also to have Mercia made into a metropolitan province with its see at Lichfield. The latter was because of Offa's dislike of the Kentish archbishop of Canterbury, Jaenberht, but it would also seem fitting to him that the leading kingdom should be free from external interference in ecclesiastical affairs. This move was unpopular with the church, and in 802, when improved relations with Canterbury had been established, the archbishopric of Lichfield was abolished.

The papal legation of 787

The decline of Mercia and the rise of Wessex. Offa died in 796, and his son died a few weeks later. Cenwulf, their successor, suppressed revolts in Kent and East Anglia, but he never attained Offa's position. Cenwulf allowed Charles to intervene in Northumbria in 808 and restore Eardwulf (who had been driven from his kingdom) to the throne—a unique incident in Anglo-Saxon history. Mercian influence in Wessex was ended when Egbert became king there in 802, though there is no recorded warfare between the kingdoms for many years, during which Egbert conquered Cornwall and Cenwulf fought in Wales. But in 825 Egbert defeated Beornwulf of Mercia and then sent an army into Kent, with the result that he was accepted as king of Kent, Surrey, Sussex, and Essex. In that same year the East Angles threw off the Mercian yoke, killing Beornwulf. In 829 Egbert became ruler of Mercia and all south of the Humber, which caused the chronicler to add his name to Bede's list of kings who held the *imperium*, calling him *bretwalda*. The Northumbrians accepted Egbert without fighting. Yet he held this proud position only one year; then Wiglaf recovered the Mercian throne and ruled without subjection to Egbert.

Mercian-West Saxon alliance

By this time Danish Viking raids were a grave menace, and Aethelwulf, who succeeded his father Egbert in 839, had the wisdom to see that Mercia and Wessex must combine against the Vikings. Friendly relations between them were established by marriage alliances and by a peaceful settlement of boundaries; this paved the way for the acceptance in 886 of Alfred, king of Wessex, as lord of all the English who had not fallen under Danish rule.

THE PERIOD OF THE SCANDINAVIAN INVASIONS

Viking invasions and settlements. Small scattered Viking raids began in the last years of the 8th century; in the 9th century, large-scale plundering incursions were made in Britain and in the Frankish empire as well. Though Egbert defeated, in 838, a large Viking force that had combined with the Britons of Cornwall, and Aethelwulf won a great victory in 851 over a Viking army that had stormed Canterbury and London and put the Mercian king to flight, it was difficult to deal with an enemy that could attack anywhere on a long and undefended coastline. Destructive raids are recorded for Northumbria, East Anglia, Kent, and Wessex.

A large Danish army came to East Anglia in the autumn of 865, apparently intent on conquest. By 871, when it first attacked Wessex, it had already captured York, been bought off by Mercia, and had taken possession of East Anglia. Many battles were fought in Wessex, including a Danish defeat at Ashdown in 871, before Alfred the Great, a son of Aethelwulf, who succeeded to the throne in the course of the year, made peace; this gave him a respite until 876. Meanwhile the Danes drove out Burgred of Mercia, putting a puppet king in his place, and one division of them made a permanent settlement in Northumbria.

Alfred's defense of Wessex

Alfred was able to force the Danes to leave Wessex in 877, and they settled northeastern Mercia; but a Viking attack in the winter of 878 came near to conquering Wessex. That it did not is to be attributed to Alfred's tenacity. He retired to the Somerset marshes, and in the spring he secretly assembled an army that routed the Danes at Edington. Their king, Guthrum, accepted Christianity and took his forces to East Anglia, where they settled.

The importance of Alfred's victory cannot be exaggerated. It prevented the Danes from becoming masters of the whole of England. Wessex was never again in such danger, and from Wessex, in the next century, the Danish areas were reconquered. Alfred's capture of London in 886, and the resultant acceptance of him by all the English outside the Danish areas, was a preliminary to this reconquest. That Wessex stood when the other kingdoms had fallen must be put down to Alfred's courage and wisdom, to his defensive measures in reorganizing his army, to his building fortresses and ships, and to his diplomacy, which made the Welsh kings his allies. Renewed attacks by Viking hosts in 892–896, supported by the Danes resident in England, caused widespread damage but had no lasting success.

Alfred's government and his revival of learning. Good internal government contributed to Alfred's successful resistance to the Danes. He reorganized his finances and the services due from thegns, issued an important code of laws, and scrutinized carefully the exercise of justice. Alfred saw the Viking invasions as a punishment from God, especially because of a neglect of learning, without which men could not know and follow the will of God. He deplored the decay of Latin and enjoined its study by those destined for the church; but he also wished all young free men of adequate means to learn to read English, and he aimed at supplying men with "the books most necessary for all men to know," in their own language.

Alfred had acquired an education despite great difficulties, and he translated some books himself, with the help of scholars from Mercia, the Continent, and Wales. Among them they made available works of Bede and Orosius, Gregory and Augustine, and the *De consolatione philosophiae* of Boethius. Compilation of the Anglo-Saxon Chronicle began in his reign. The effects of Alfred's educational reforms can be glimpsed in succeeding reigns, and his works continued to be copied. Only in an attempt to revive monasticism did he achieve little, for the monastic idea had lost its appeal—in England as well as on the Continent—during the Viking Age.

THE ACHIEVEMENT OF POLITICAL UNITY

The reconquest of the Danelaw. When Alfred died in 899 his son Edward succeeded him. Edward had to deal with a rival, his cousin Aethelwold, who obtained support from the Northumbrian and East Anglian Danes; but Aethelwold and the Danish king of East Anglia fell before Edward's forces in 902. A large-scale incursion by the Danes of Northumbria ended in their crushing defeat at Tettenhall in 910. Edward completed his father's plan of building a ring of fortresses round Wessex, and his sister Aethelflaed took similar measures in Mercia. In 912 Edward was ready to begin the series of campaigns by which he relentlessly advanced into the Danelaw (Danish territory in England), securing each advance by a fortress, until he won back Essex, East Anglia, and the east-midland Danish areas. Aethelflaed moved similarly against the Danish territory of the Five Boroughs (Derby, Leicester, Nottingham, Lincoln, and Stamford). She obtained Derby and Leicester and gained a promise of submission from the Northumbrian Danes before she died in 918. Edward had by then reached Stamford, but he broke off his advance to secure his acceptance by the Mercians at Tamworth and to prevent their setting up an independent kingdom. Then he took Nottingham, and all the Danes in Mercia submitted to him.

Edward's successes in England

Meanwhile another danger had arisen: Norsemen from Ireland had been settling for some time west of the Pennines, and Northumbria was threatened by Raegnald, a Norse leader from Dublin, who made himself king at York in 919. Edward built fortresses at Thelwall and Manchester, and in 920 he received Raegnald's submis-

sion, along with that of the Scots, the Strathclyde Welsh, and all the Northumbrians. Yet Norse kings reigned at York intermittently until 954.

The Kingdom of England. Athelstan succeeded his father Edward in 924. He made terms with Raegnald's successor Sihtric and gave him his sister in marriage. When Sihtric died in 927, Athelstan took possession of Northumbria, thus becoming the first king to have direct rule of all England. He received the submission of the kings of Wales and Scotland and of the English ruler of Northumbria beyond the Tyne.

Athelstan's ascendancy over all England

Athelstan was proud of his position, calling himself "king of all Britain" on some of his coins and using in his charters flamboyant styles with the same meaning; he held great courts attended by dignitaries from all over England and by Welsh kings; he subjected the Welsh to tribute and quelled a revolt of the Britons of Cornwall. His sisters were married to continental princes—Charles the Simple, king of the Franks; Otto, son of Henry the Fowler; Hugh, duke of the Franks. Among those brought up at his court were Louis, Charles's son; Alan of Brittany, Athelstan's godson; and Hakon, son of Harald Haarfager of Norway; they all returned to win their respective inheritances with his support. He received spectacular embassies from Harald Haarfager and Duke Hugh, and he was a generous donor to continental and English churches. But Athelstan is remembered chiefly as the victor at Brunanburh, against a combine of Olaf Guthfrithson, king of Dublin; Owain of Strathclyde; and Constantine, king of the Scots, whom Athelstan had defeated in 934. They invaded England in 937, and their defeat is celebrated by a poem in the Anglo-Saxon Chronicle.

Immediately after Athelstan's death in 939, Olaf seized not only Northumbria but also the Five Boroughs. By 944 Athelstan's successor, his younger brother Edmund, had retrieved the situation, and in 945 Edmund conquered Strathclyde and gave it to Malcolm of Scotland. But Edmund's successor, Eadred, lost control of Northumbria for part of his reign to the Norse kings Eric Bloodaxe (son of Harald Haarfager) and Olaf Sihtricson. When Eric was killed in 954 Northumbria became a permanent part of the kingdom of England.

Variant laws and customs within the kingdom

By becoming rulers of all England, the West Saxon kings had to administer regions with variant customs, governed under West Saxon, Mercian, or Danish law. In some parts of the area of Danish occupation, especially in Yorkshire and the district of the Five Boroughs, the evidence of place-names, personal names, and dialect proves a dense Danish settlement; but Danish law also prevailed in such other regions as Essex, Middlesex, and Buckinghamshire, with differences from the rest of England in procedure and in the system of fines, including much higher fines for serious crimes. There were other differences. Money was calculated in marks and ores instead of shillings in Danish areas, and arable land was divided into plowlands and oxgangs instead of hides and virgates in the northern and northeastern parts of the Danelaw; most important was the presence in some areas of a number of small landholders with a much greater degree of independence than their counterparts elsewhere where many *ceorls* had so suffered under the Danish ravages that they had bought a lord's support by sacrificing some of their independence.

The kings did not try to eradicate these local peculiarities. King Edgar (reigned 959–975) expressly granted local autonomy to the Danes. But from Athelstan's time it was decreed that there was to be one coinage over all the king's dominion, and a measure of uniformity in administrative divisions was gradually achieved. Mercia became divided into shires on the pattern of those of Wessex. It is uncertain how early the smaller divisions of the shires were called "hundreds," but they now became universal (except in the northern Danelaw, where an area called a *wapentake* carried on their fiscal and jurisdictional functions); an ordinance of the mid-10th century laid down that the court in each hundred (called "hundred courts") must meet every four weeks to handle local legal matters, and Edgar enjoined that the shire courts must meet twice a year, the borough courts three times. This pattern of local government survived the Norman Conquest.

The church and the monastic revival. To those who judged the church solely by the state of its monasteries, the first half of the 10th century seemed a period of inertia. In fact, the great tasks of converting the heathen settlers, restoring ecclesiastical organization in Danish areas, and repairing the damages of the invasions elsewhere must have absorbed much energy. Even so, learning and book production were not at so low an ebb as monastic reformers claimed. Moreover, new monasteries were founded and benefactions were made to older ones, even though, by post-revival standards, none of these was leading a strict monastic life and several were held by secular priests. Alfred had failed to arouse much enthusiasm for monasticism. The movement for reform began in England about 940 and soon came under the influence of reforms in Fleury and Lorraine. King Edgar, an enthusiastic supporter, promoted the three chief reformers to important positions—Dunstan to Canterbury, Aethelwold to Winchester, and Oswald to Worcester and later to York. The secular clergy were violently ejected from Winchester and some other places; Oswald gradually replaced them with monks at Worcester. All three reformers founded new houses, including the great monasteries in the Fenlands, where older houses had perished in the Danish invasion; but Oswald had no success in Northumbria. The reformers, however, were concerned with more than monasticism—they paid great attention to other needs of their dioceses; the scholars Abbot Aelfric and Archbishop Wulfstan, trained by the reformers, directed much of their writings to improving the education and morals of the parish clergy and, through them, of the people.

Movement for monastic reform

The monastic revival resulted in a great revival of both vernacular and Latin literature, of manuscript production and illumination, and of other forms of art. It reached its zenith in the troubled years of King Ethelred II (reigned 978–1016), after a brief, though violent, reaction to monasticism following Edgar's death. In the 11th century, monasteries continued to be productive and new houses were founded; there was also a movement to impose a communal life on bodies of secular priests and to found houses of secular canons.

THE ANGLO-DANISH STATE

The Danish conquest and the reigns of the Danish kings. Ethelred succeeded as a child in 978, after the murder of his stepbrother Edward. He took the throne in an atmosphere of insecurity and distrust, which partly accounts for the incompetence and treachery rife in his reign. Viking raids began in 980 and steadily increased in intensity. They were led by formidable leaders: from 991 to 994 by Olaf Tryggvason, later king of Norway, and frequently from 994 by Sweyn, king of Denmark. Ethelred's massacre of the Danes in England on St. Brice's Day, 1002, called for vengeance by Sweyn and, from 1009 to 1012, by a famous Viking, Thorkell the Tall. In 1013 the English, worn out by continuous warfare and heavy tributes to buy off the invaders, accepted Sweyn as king. Ethelred, his wife Emma, and his younger sons sought asylum with Richard, duke of Normandy, brother of Emma. Ethelred was recalled to England after Sweyn's death in 1014; but Sweyn's son Canute (Cnut) renewed the invasions and, in spite of valiant resistance by Ethelred's son and successor, Edmund, obtained half of England after a victory at Ashingdon in October 1016 and the rest after Edmund's death that November.

Revival of Danish attacks

Canute rewarded some of his followers with English lands, and he made the Viking leader Eric of Hlathir earl of Northumbria and Thorkell the Tall earl of East Anglia. He ruthlessly got rid of some prominent Englishmen, among them Edmund's brother Edwy, but Edmund's infant sons were carried away to safety in Hungary. Yet Canute's rule was not tyrannical, and his reign was remembered as a time of good order. The Danish element in his entourage diminished; and the English-

men, Leofric, earl of Mercia, and Godwine, earl of Wessex, became the most powerful magnates. Canute married Ethelred's widow, Emma, thus removing the danger of Norman support for her sons by Ethelred. Canute fought a successful campaign in Scotland in 1031, and Englishmen were drawn into his wars in Scandinavia, which made him lord of Norway. But at home there was peace. Probably under the influence of Archbishop Wulfstan, he became a stout supporter of the church, which in his reign had the vitality to engage in missionary work in Scandinavia. Religious as well as political motives may have caused his pilgrimage to Rome in 1027, to attend the coronation of the emperor Conrad; from the Pope, the Emperor, and the princes whom he met he obtained concessions for English pilgrims and traders going to Rome. Canute's laws, drafted by Archbishop Wulfstan, are mainly based on those of earlier kings, especially Edgar.

Already in 1018 the English and Danes had come to an agreement "according to Edgar's law." No important changes were made in the machinery of government except that small earldoms were combined to make great earldoms, which placed much power in the hands of their holders. No attempt was made to restore the English line when Canute died in 1035; he was followed by his sons Harold and Hardecanute, whose reigns were unpopular. Denmark passed to Sweyn, son of Canute's sister Estrith, in 1043. Meanwhile the Norwegians in 1035 had driven out another Sweyn, the son whom Canute had set to rule over them with his mother, Aelfgifu, and had elected Magnus.

Canute's successors

The close links with Scandinavia had benefitted English trade, but they left one awkward heritage: Hardecanute and Magnus made an agreement that if either died without a son, the survivor was to succeed to both kingdoms. Hardecanute died without a son in 1042, and he was succeeded by Ethelred's son Edward, who was known as the "Confessor" or the "Saint" because of his reputation for chastity. Magnus was prevented by trouble with Denmark from invading England as he intended in 1046; but Harold Hardraada inherited Magnus' claim to the English throne, and he came to enforce it in 1066.

The reign of Edward the Confessor and the Norman Conquest. It is easy to regard the years of Edward's rule simply as a prelude to the catastrophe of 1066, yet there are other aspects of his reign. Harrying caused by political disturbances or by incursions of the Scots or Welsh was only occasional and localized; friendly relations were usually maintained with Malcolm of Scotland, whom Earl Siward of Northumbria had supported against Macbeth in 1054; and in 1063 the victories of Harold, earl of Wessex, and his brother Tostig ended the trouble from Wales. The normal course of administration was maintained, with efficient mints, writing office, taxation system, and courts of justice. Trade was prosperous. The church contained several good and competent leaders, and bad appointments—like those of the Normans, Ulf to Dorchester and Robert to London and Canterbury, and of Stigand to Winchester—were the exception. Scholarship was not decadent, and manuscripts were produced in great number. English illumination and other forms of art were admired abroad.

The troubles of the reign came from the excessive power concentrated in the hands of the rival houses of Leofric of Mercia and Godwine of Wessex and from resentment caused by the King's introduction of Norman friends, though their influence has sometimes been exaggerated. A crisis arose in 1051 when Godwine defied the King's order to punish the men of Dover, who had resisted an attempt by Eustace of Boulogne to quarter his men on them by force. The support of Earl Leofric and Earl Siward enabled Edward to secure the outlawry of Godwine and his sons; and Duke William of Normandy paid Edward a visit during which Edward may have promised William succession to the English throne, if this Norman claim was not mere propaganda. Godwine and his sons came back the following year with a strong force, and the magnates were not prepared to engage them in civil war but forced the king to make terms. Some unpopular Normans were driven out, including Archbishop Robert, whose archbishopric was given to Stigand; this act supplied one excuse for the papal support of William's cause.

Harold succeeded his father Godwine as earl of Wessex in 1053; Tostig was made earl of Northumbria in 1055; and their younger brothers were also provided with earldoms. To settle the question of succession, negotiations were begun in 1054 to bring Edward, Edmund's son (nephew of Edward the Confessor), from Hungary; but he died in 1057, leaving a son, Edgar Aetheling, then a child, who was passed over in 1066. In about 1064 Harold of Wessex, when visiting Normandy, swore to support William's claim; only Norman versions of the incident survive and the true circumstances cannot be ascertained, but William used Harold's broken oath to help secure papal support later. In 1065 Harold had to acquiesce in the appointment of Morcar, brother of Earl Edwin of Mercia, to replace Tostig when the Northumbrians revolted against him, and thus Harold turned his brother into an enemy. King Edward when dying named Harold to succeed him, and he was universally accepted after he had overcome Northumbrian reluctance with the help of Bishop Wulfstan of Worcester.

Harold might have proved an effective ruler, but the forces against him were too strong. The papacy, without hearing the defense, gave its blessing to an invasion of a people who had always been distinguished for their loyalty to Rome, and this helped William to collect his army widely. The threat from Harold III Hardraade, who was joined by Tostig, prevented Harold from concentrating his forces in the south and took him north at a critical moment. He fought at Hastings only 24 days after the armies of Mercia and Northumbria had been put out of action by enormous losses at Fulford and only 19 days after he had defeated and killed Harold III Hardraade and Tostig at Stamford Bridge. Harold was slain at Hastings, and on Christmas Day, 1066, William of Normandy was crowned king of England. Unwise decisions and out-of-date methods of fighting may have played a part in Harold's defeat at Hastings, but it is not difficult to understand the English chronicler's view that God was angry with the English people. (D.W.)

The crowning of William

II. The Normans (1066–1154)

WILLIAM I (1066–87)

Scholars argue endlessly about the significance of the Norman Conquest: whether the results were good or bad, whether there was more continuity than change, whether feudalism existed in England before the Conquest, to what extent Anglo-Saxon institutions survived the Conquest, and so forth. No one doubts that there was change and also continuity, but on balance the argument seems to be in favour of change.

The introduction of feudalism. The major change was the subordination of England to a Norman aristocracy. William distributed estates to his followers on a piecemeal basis as the lands were conquered. Fewer than 180 great tenants in chief were given large parcels of land distributed about the country. Most of these, however, held concentrations of land in some one part of the country, where they centred their "honours," or feudal states. From these centres, usually fortified by a castle, the Norman tenants in chief conducted their administration and organized their military power. They held their land from the Conqueror in return for units of knight service; that is, in return for supplying a certain number of knights to the king's feudal army—which had no necessary relationship to the quantity or quality of land held. In the beginning of the reign, many tenants in chief maintained their quotas of knights out of their own households, but before the end of the reign they had subinfeudated portions of their lands to rear vassals. Private warfare, endemic in Normandy despite efforts of the Duke to suppress it, was, however, successfully prohibited in England. Castles could be built only with the King's license, and the only feudal army permitted was that of the King himself. As an added precaution, rear vassals were required to take an oath of fealty

Distribution of land

directly to the King. With the Conquest, England became that anomaly, a unified and centralized feudal state.

Government and justice. William professed a desire to govern England as it had been ruled by his Anglo-Saxon predecessors, and he tried to fulfill his promise. Under William the Anglo-Saxon *witenagemot*, the assemblage of the wise men of the realm, became the King's Curia Regis, an assemblage of the King's ecclesiastical and lay tenants in chief, called together in part or in full when occasion required. Three times in the year—at Christmas, Easter, and Whitsuntide—William was alleged by contemporary chroniclers to have held especially full and solemn assemblages of his court, to which were summoned all the great men of the realm and at which he wore his crown. Inevitably, because of the great number of disputes about land, the Curia Regis became a court for the administration of justice to the King's great tenants in chief. William tried to learn English in order to better his administration of justice, and he is said to have sat one Sunday "from morn to eve" to hear a plea between William de Braose and the Abbot of Fécamp.

William also tried at first to preserve Anglo-Saxon administrative organization. The central administration under Edward the Confessor had probably been quite similar to that of Normandy, except for the titles of the officers. At first, even the personnel did not change. But, by the end of William's reign, all important administrative officers were Norman, and their titles corresponded to the titles in the duchy administration. There were a steward, a butler, a chamberlain, a constable, a marshall, and, finally, a head of the royal scriptorium (or chancellor). The royal scriptorium was the source from which all writs (*i.e.*, written royal commands) were issued. At the beginning of William's reign the writs were in English, by the end of the reign in Latin.

Local government

In local government the Anglo-Saxon shire and hundred courts continued to function as units of administration and of justice but with important changes. Bishops and earls ceased to preside over the shire courts. Bishops henceforth were to have their own ecclesiastical courts. Earls exercised feudal jurisdiction in their honour courts but took as a prerequisite a third of the proceeds of the shire court. But the new earls created by the Conqueror did not wield the vast local power of their pre-Conquest counterparts.

The office of shire-reeve (or sheriff) was continued under William, as were many of the English incumbents in the early part of the reign. But soon the native sheriffs were replaced by men of the new Norman aristocracy, and the office came to resemble the office of the Norman *vicomte*, a title that also appears in English documents. Their duties remained those that they had exercised before the Conquest. Royal officers exercising the king's will, they were responsible for collecting the royal revenue, for administering local justice, and for keeping the castles that had been built to subdue and protect the country.

William made the most of the financial system that he inherited. In addition to customary dues, the revenues from justice, and the proceeds from their own estates, his predecessors had been able to levy a geld, or tax, distributed over the whole realm. This has been called the "first system of national taxation known to western Europe." William levied a geld at least four times during his reign. He was also able to levy extensive duties on trade with the Continent. Trade had been temporarily disrupted by the Conquest, but it recovered rapidly and proved to be an important source of revenue.

The Conqueror strengthened immensely the administration of justice in his new realm. He occasionally appointed justiciars to preside over local administration of justice and occasionally also sent down commissioners from the central administration. There were a number of great trials during the reign. The most famous of them was the trial at Pinnenden Heath of a case between Lanfranc, archbishop of Canterbury, and the King's half-brother, Odo, bishop of Bayeux and earl of Kent. To this trial came not only all of the Frenchmen of the shire but also a great number of Englishmen, especially those learned in the customary law. In these trials held before the king's officers, jurors were sometimes summoned to give a collective verdict under oath. It is debated among historians whether this institution of the jury was introduced by the Danish kings or was drawn from the Carolingian kings through the Normans. The important point, however, is that the jury came into common use under the Normans.

Church–state relations. The upper ranks of the clergy were Normanized and feudalized following the pattern of lay society. Bishops received their temporal estates and the symbols of spiritual office from the king. They owed service of knights in return for tenure of their temporal estates, and they were brought under firm royal control. In time, all the leading bishoprics were held by continental clergy. In 1070 Lanfranc replaced Stigand as archbishop of Canterbury. Ecclesiastical lawyer, teacher, and statesman of the church, Lanfranc was Italian in origin and had been a monk at Bec and abbot of Saint-Étienne's at Caen. Lanfranc and William understood each other and worked together to introduce discipline and order into the English church. The see of York was definitively subordinated to Canterbury, and the ecclesiastical affairs of Ireland and Scotland were brought under Lanfranc's control—this despite the fact that papal policy of the period was to bring each province directly under the control of Rome. Several church councils were held in England to legislate for the English church as similar councils did in Normandy. William refused to give homage to the pope for the realm of England, although he acknowledged papal support in winning the new realm. To further implement his headship of the English church, William laid down some general rules where disputes might arise. No pope was to be recognized in England without his decision. Without William's consent no papal letter was to be received, no ecclesiastical council was to legislate, and no baron or officer of the realm was to be excommunicated. William and Lanfranc resisted Gregory VII's claim to papal supremacy but based their resistance on English tradition. During William's reign the controversy over the right of lay rulers to invest ecclesiastics with the symbols of their spiritual offices did not affect England, as it did other parts of Latin Christendom.

William's accomplishments. In 1085 William, after "deep speech" with his assembled barons, ordered a general survey of the land, manor by manor and vill by vill. Historians have debated the purpose of this "Domesday" survey, some putting more emphasis on its usefulness for tax purposes, some emphasizing its importance as a basis for feudal rights and duties. It was probably, in fact, a multipurpose document with the main emphasis on resources for taxation. It constitutes a unique record for the time and offers rich materials for research.

The Domesday survey

One innovation of the Norman kings that caused deep resentment under William I and even more hatred under William II Rufus was the taking over of vast tracts of land for the king's forests. In some areas, whole villages were destroyed and the people driven out; elsewhere, people living in the forest areas were not necessarily removed, but drastic penalties were imposed for poaching.

William the Conqueror is presented in contemporary chronicles as a ruthless tyrant who rigorously put down rebellion and devastated vast areas, especially in his pacification of the north. He was, however, an able administrator. Perhaps his greatest contribution to England's future was the linking up of England with continental affairs. If the country had been conquered again by the Danes, it might well have remained in a kind of backwater of European development. As it happened, England was linked in economic and cultural development with France and the Mediterranean states, with a common Latin language and a common church organization.

WILLIAM II RUFUS (1087–1100) AND HENRY I (1100–35)

William II. Under William's two sons William II and Henry I strong, centralized government continued in a feudalized society. Under William II, a rebellion of

Norman barons led by the King's two half-uncles, Odo of Bayeux and Robert of Mortain, was put down with the help of the fyrd. The King promised good government, relief from taxation and from the severity of the forest laws in return for this valuable support and won a quick victory. Odo of Bayeux was banished, and William of St. Calais, bishop of Durham, was tried for treason. As an ecclesiastic he refused jurisdiction of the king's court. But Lanfranc pointed out that it was not as bishop but as lord of his temporal fiefs that he was tried. William threatened to take the case to Rome, but the matter was ultimately compromised by the permission given him to leave the the country in return for surrender of his fiefs.

The King forgot his promise and became a notoriously tyrannical ruler. His main preoccupation during his reign was the endeavour to recover Normandy and rejoin it with England. William I had given Normandy to Robert, the eldest and least able of his three sons, Robert, William, and Henry. William II preferred to use peaceful methods if possible.

After brief skirmishes in which he won from Robert the southern part of the duchy, William II joined Robert in warfare against Henry. William's plans were interrupted by a second rebellion of the Norman earls in 1095 but were furthered by Robert's decision to go on Crusade in 1096. Robert mortaged his Norman lands to William for 10,000 marks. William raised the money in England by drastic and unpopular taxation but died before he achieved his ambition. His death was the result of an "accident" in the New Forest in which he was shot through the back with an arrow. Henry, who was conveniently of the hunting party, rode posthaste to Winchester, seized the treasury, and was chosen king the next day.

Henry I. A good politician and a competent administrator, Henry I was the ablest of the Conqueror's sons. At his coronation on August 5, 1100, he issued a charter intended to win the support of the nation. In general this was a propaganda document, but it does show the extent to which feudal institutions had come to stay. Henry promised not to exploit church vacancies as his brother had done. He remitted debts due his brother as well as penalties for killing Normans due at the time of William's death. He promised a return to those practices of his Anglo-Saxon predecessors that had been superseded under his father and brother. He promised return to the laws of Edward the Confessor with only such amendments as had been made with the counsel of the barons in his father's time. The main provisions of the charter guaranteed feudal custom as it had developed in England and Normandy. Reliefs to be paid by feudal vassals to the king when they took over the estates of their fathers were to be "just and legitimate." Henry certainly did not mean this charter to be enforced literally. He did not return to the laws of Edward the Confessor nor did he afterward adhere rigorously to feudal law and custom.

Henry's coronation charter

Henry inherited from William II a quarrel with the church that became part of the Europe-wide Investiture Controversy. After Lanfranc's death, William had delayed appointing a successor, presumably for the privilege of wasting the resources of the province. After four years, during a bout of illness, he appointed Anselm of Bec, one of the greatest scholars of his time (1193). Anselm did homage for his temporalities but, in keeping with the decrees of Pope Gregory VII, refused to receive the symbols of his spiritual office from the King. Papal confirmation was complicated by the fact that there were two popes: Urban II, a reform pope in the tradition of Gregory VII, and Clement III, an antipope nominated by the Holy Roman emperor Henry IV. A church council was held to decide whether Anselm should go to Rome for confirmation. Anselm refused to accept a decision given by the King's supporters, and he finally got his pallium from a cardinal legate sent by Urban. Conflict between King and Archbishop flared up again in 1097 over what William considered to be an inadequate Canterbury contingent for the Welsh war. The upshot of this was that Anselm went into exile until William's death.

Anselm supported Henry I's bid for the throne and returned from exile at Henry's accession in 1100. But he quarrelled almost immediately with Henry over the homage for his temporal estates. After various ineffectual appeals to Rome, Anselm again went into exile. A compromise was finally arranged with the help of Ivo of Chartres in 1107. Although no authoritative text has survived of the terms of this compromise, it appears to have been agreed that the king would surrender investiture with the symbols of spiritual office in return for an agreement that the king should supervise the election and take homage for the temporalities before investiture with the spiritual symbols. The compromise, in fact, changed very little the king's power in ecclesiastical elections.

Henry continued and extended the administrative reforms of his father. He appointed a justiciar to be a kind of deputy king when he himself was occupied in Normandy. In his reign, the writ, or sealed royal letter of command, became the normal method of initiating judicial action. The Exchequer became organized as a department of government dealing with royal revenues and independent of the meetings of the Curia Regis. Justices in eyre (*i.e.*, itinerant justices) began to be sent out into the counties to inquire concerning crown pleas, the king's revenues, and other matters of interest to the king. This was a kind of extension of the procedure of the Domesday inquest, especially in its use of the jury procedure.

Henry's most spectacular success was his conquest of Normandy. His reign opened with a rebellion of Robert, newly returned from the First Crusade. Henry reissued his coronation charter, called out the shire levies to defeat the invading army, and, in two years of war, captured all the important castles in England. By Holy Week 1105, he was ready to take the offensive and began a severe onslaught on the Cotentin, the maritime province of Normandy. In September 1106 he won a decisive battle at Tinchebrai (modern Tinchebray) that gave him control of the whole of Normandy. Robert was captured and spent the remainder of his 80 years in castle dungeons. His son, William Clito, escaped and remained until his death in 1128 a thorn in Henry's flesh. Henry had won the support of the French king Philip I against Robert, but he was not so successful in winning the support of Philip's son and successor, Louis VI. A coalition of rebellious Norman barons with Louis VI, Fulk of Anjou, and the Count of Flanders temporarily kept Henry out of the county of Maine. But by 1120 Henry was everywhere successful both in diplomacy and war. He had arranged a marriage for William, his only legitimate son, to Matilda, daughter of Fulk of Anjou, and had received Fulk's homage for Maine. Pope Calixtus I, his cousin, gave him support for his control of Normandy on condition that his son William do homage to the French king.

Henry's conquest of Normandy

During the last 15 years of his reign, the most important question was the succession. William, Henry's only legitimate son, died in 1120, leaving Henry's daughter Matilda, wife of the Holy Roman emperor Henry V, as heir. When Henry V died in 1125, Matilda returned to England. Henry persuaded his barons to take an oath in her support in 1127 but did not consult them concerning her second marriage to Geoffrey Plantagenet of Anjou.

Geoffrey was 14, the Empress 25, and they took an instant dislike to one another. Geoffrey repudiated her within a year but was persuaded to take her back, just long enough for her to bear him three children. Henry spent his declining years doting on his grandchildren and died, probably of a heart attack, on December 1, 1135.

THE PERIOD OF ANARCHY (1135–54)

Matilda and Stephen. Henry's death precipitated a 20-year crisis. No one was very enthusiastic about accepting Matilda as queen, especially since her husband, Geoffrey, was tied in friendship to Henry's Norman enemies and was actually at war with Henry at the time of his death. Robert, earl of Gloucester, one of Henry's illegitimate sons, was an impressive candidate.

Then there were Henry's two nephews, Thibaut and Stephen of Blois. The matter took an unexpected turn: while Thibaut was receiving the homage of the con-

tinental vassals in Normandy, Stephen took ship for England and claimed the kingship. On December 22, having first secured the treasury at Winchester, he was crowned. The Pope confirmed him early in 1136, thus relieving the English barons of their oath to support Matilda.

Stephen's clash with King David

Stephen had shown himself quick in decision and resolute in securing the crown. But, after the first flush of victory, he seems to have expected to win support by concessions. King David of Scotland was an earl in England with respect to the honour of Huntingdon. When he heard the news of Stephen's accession, he crossed the border and took Carlisle and other northern fortresses. Stephen, surprisingly in view of his lack of feudal support, assembled an army consisting mainly of Flemish mercenaries and marched north. David was persuaded to negotiate an agreement under which Stephen surrendered Doncaster and Carlisle. King David's son was to have Huntingdon on the condition of doing homage to Stephen. To the church Stephen granted a charter forbidding simony and granting that all clerics should be tried under canon law.

Stephen's first concern in governing England seems to have been to get his own men into the main posts in central government, replacing Henry I's administrators. He increased the number of earls from seven to 16. These earls were evidently intended to exercise real power and to undermine that of the sheriffs. In the central government, power had become concentrated in the hands of Roger, bishop of Salisbury, and his family. Roger had been justiciar under Henry; his son Roger le Poer was chancellor, his nephew Nigel, bishop of Ely, was treasurer, and his nephew Alexander was bishop of Lincoln. The Beaumont earl of Leicester and his family on both sides of the Channel were jealous of this power and pressed Stephen to end it. The question was how to do so without incurring obloquy for attacking bishops of the church. An incident was planned for the Oxford meeting of the great council of magnates and prelates in June 1139. A street brawl broke out between Alan of Brittany's men and Bishop Roger's men. The King summoned the bishops before him to make satisfaction for the disturbance of the peace. They were to surrender their castles as a sign of their good faith. Nigel of Ely took refuge in Devizes Castle and prepared for a siege until the King appeared and threatened to hang the Chancellor if Nigel refused to surrender.

This whole episode constituted a turning point for Stephen. Henceforth he was in disfavour with the clergy. He had already forfeited the favour of his brother, Henry of Blois, bishop of Winchester, by failing to make him archbishop of Canterbury when the position fell open in 1137. Henry was papal legate throughout the pontificate of Innocent II and was the most influential member of the clergy in the realm.

Civil war. War for the succession in England did not begin until the landing of Matilda at Arundel in 1139, supported by her half-brother Robert of Gloucester. They established themselves in the southwest, seizing various castles. Stephen fought back in desultory fashion, besieging castles, then abandoning siege. He finally sent the Empress to Bristol under escort. The decisive year in the early part of the war was 1141, when Stephen, acting on information from the citizens of Lincoln that the castle there was lightly guarded, attempted to win it back from Ranulf of Chester and William of Roumare, his half-brother, who had seized it by strategy. Unfortunately for Stephen, Ranulf escaped and brought up troops to attack the royal army. Many of the great magnates deserted Stephen in the course of the battle. He was defeated and taken prisoner along with many lesser barons.

The revolt of London against Matilda

Matilda took advantage of the victory by going to Winchester, where, on March 3, 1141, she was received in state and then, on April 8, given the title *domina Anglorum*. Her great mistake, which ultimately turned the tide of war against her, was her treatment of the Londoners. When she demanded their allegiance and a tallage (tax) as well, they flew to arms "like a swarm of bees from a hive" and forced her to leave the city. Meanwhile, Stephen's queen had rallied the King's forces in Kent and moved into London. Stephen was exchanged for Robert of Gloucester, who had been captured at Winchester, and Stephen was again in the ascendant. He was supported by a church council and wore his crown at Westminster for the second time. Matilda's fortunes waned from this event on, although she continued to dominate the southwest. The deaths of Miles, earl of Hereford, in 1143 and of Robert, earl of Gloucester, in 1147 deprived her of two royal and able supporters. A brief and rash invasion on her behalf by her 14-year-old son, Henry, in 1147 did nothing to change the balance of forces. Henry lacked both troops and money. Early in 1148 Matilda left England for Normandy, never to return.

Her son Henry did return in 1153 and carried on a vigorous and successful campaign. This, the sudden death of his elder son, Eustace, and his precarious hold over the magnates persuaded Stephen to a compromise peace at the end of 1153. Stephen was to continue as king so long as he lived and to receive Henry's homage. In turn, Stephen was to recognize Henry as his heir. Certain of Stephen's castles were to be surrendered to castellans who took oath to turn them over to Henry at Stephen's death. The most difficult questions to be settled after the long period of "the Anarchy" were the titles to land of various members of the nobility. The general principle that was accepted was that whoever had held the titles in the time of Henry I had the best right. Clearly what was intended was that the feudal principle of succession should prevail. But this principle was not easy to enforce because so much land had changed hands during the reign of Henry I and after. In the last year of Stephen's reign many of the "adulterine castles" (those castles built during the Anarchy without royal license) were destroyed. They are said to have disappeared in 1154 like "wax before a flame," except for certain castles that Stephen continued to hold, somewhat to the distrust of his recognized heir.

The Anarchy was chiefly important in its effect on government. Henry I had left a tightly governed country in which a royally appointed bureaucracy carried on the functions of central government and supervised local government. Under Stephen this had broken down. And local offices such as that of sheriff and castellan had changed hands frequently with the change in the fortunes of war. On the other hand, it cannot be shown that the Exchequer or the regular administration of justice in the county and hundred courts had broken down. Power seems to have been fragmented and decentralized as in a typically feudal state, but order did not disappear altogether.

III. The early Plantagenets (1154–1216)

HENRY II (1154–89)

Matilda's son Henry Plantagenet, the first and greatest of three Angevin kings of England, succeeded Stephen in 1154. At age 21, he was in the prime of life and already possessed a reputation for restless energy and decisive action. He was heir to a vast feudal empire. As heir to his mother and to Stephen, he held England and Normandy; as heir to his father, he held Anjou (hence Angevin) and Touraine; as heir to his brother Geoffrey he got Brittany; as husband of Eleanor, divorced wife of Louis VII of France, he held Aquitaine, the major part of southern France. Altogether his holdings in France were far larger than those of the French king. From the beginning Henry showed himself determined to assert and maintain his rights in all these lands and to reassert in England the centralized power of his grandfather, Henry I. His success in these aims is the measure of his greatness.

Henry's reforms. After completing the destruction of the adulterine castles, Henry carried through certain changes in the military and in government administration. In 1166 he issued writs commanding his tenants in chief to disclose the number of knights they had subinfeudated on their lands in excess of their quotas of service owed to the king. Henry's intent was to demand the excess either in service or scutage (money payment in lieu of service). In principle, barons did not need feudal mili-

tary vassals for private warfare because it was forbidden. The evidence is that Henry preferred scutage to service because mercenaries were more efficient than feudal contingents. In the Assize of Arms of 1181, Henry required of every free man that he have and maintain arms appropriate to his rank based on his income from land. This measure was intended to provide the basis for the maintenance of the fyrd, which could be called to repress rebellion or meet invasion. Henry, no more than his Norman predecessors, depended on a feudal army for his wars. He did, however, try to make sure that he could tap all the existing sources of men or money to constitute his army.

The Inquest of Sheriffs

A major administrative reform of his reign was the so-called Inquest of Sheriffs in 1170. Inquiries were instituted into the details of local administration. Many sheriffs were dismissed, especially those in shires in which local barons had become too great in the control of the office. Henry revived the device of his grandfather of sending out itinerant justices to check on local administration and to hold the possessory assizes (see below). Royal writs were used, as in Henry I's time, to begin actions in the royal courts.

Henry greatly expanded royal powers of justice by bringing all land held in feudal tenure under royal jurisdiction. Sometime in his reign or earlier the grand assize was introduced. In order to call a grand assize, the plaintiff went to the chancery and got a writ to the sheriff calling on him to demand the attendance of the possessor of the land that the plaintiff claimed and to call four men who would then choose 12 men to determine the case. An alternative of this writ merely called on the lord of the complainant to do justice to him or appear before the king's officers. Various other actions less formidable in character than the writ of right and the grand assize were available to parties in land disputes at this time. These were the so-called possessory assizes. They determined who had the right to immediate possession of land rather than who had the best fundamental right. The result of these measures was that no freeman could be brought to answer for his freehold save in a royal court. The acceptance of these innovations indicates that feudal land tenure and feudal jurisdiction over land tenure were already on their way out.

Struggle with Becket. Henry attempted also to restore the close relationship between church and state that had existed under the Norman kings. His first move in this direction was the appointment in 1162 of Thomas Becket as archbishop of Canterbury. Becket had served as Henry's chancellor from 1155 and had proved to be an unusually efficient royal servant as well as the King's boon companion. Henry assumed that Thomas, as archbishop, would continue in these roles. Becket disappointed him. As soon as he was appointed archbishop, Becket became a militant defender of the church against royal encroachments and a champion of Pope Gregory VII's program of ecclesiastical supremacy over the lay world. Becket recognized the need for better church discipline but thought that reform should be carried out by the church itself. The struggle between Henry and Becket reached a crisis at the Council of Clarendon in 1164, the main issue proving to be the jurisdiction over "criminous clerks" (members of the clergy who had committed crimes). The King maintained that clergy should be subject to the same penalties as laymen. After accusation in the king's court, they should be turned over to the bishop's officers, tried in ecclesiastical court, and, if found guilty, should be returned to the king's officers to be punished. Other important principles laid down at Clarendon included the following: disputes concerning the right to present to eccesiastical office were to be tried in royal courts; appeals to the papal Curia should be undertaken only with royal premission; disputes as to whether land was of lay fee or free alms should be decided in royal courts. A clause concerning ecclesiastical elections simply reiterated current custom: elections were to be free, but the king was to have the revenues during vacancy.

The Council of Clarendon

Becket accepted this document verbally and led the other bishops to accept it also, but he later refused to seal it. In expiation of his previous consent, he suspended himself from office for the sin of yielding to royal will in the matter. He applied to the Pope for absolution, and Alexander III ultimately came to his support against the Constitutions. Later in the same year, the Archbishop was charged with peculation of royal funds during his chancellorship. Becket appeared briefly at the Council of Northampton but took flight to France when he became convinced that the King intended to destroy him. Henry confiscated the revenues of the province, exiled Becket's friends, and confiscated their revenues. And, most serious of his offenses, Henry had his eldest son crowned in 1170 by the archbishop of York, rather than by the archbishop of Canterbury, as was customary. Becket, in exile, appealed to Rome and excommunicated the clergy who had taken part in the offensive ceremony. A reconciliation between Becket and Henry at the end of the same year settled none of the points at issue. But when Becket returned to England he took further measures against those clergy who had taken part in the coronation. In Normandy the enraged King, hearing the news, burst out with the fateful words that incited four of his knights to take ship for England to murder the Archbishop.

Almost overnight the martyred Thomas became a saint in the eyes of the people. Henry repudiated responsibility for the murder and reconciled himself with the church at the expense of promising to go on a crusade, to allow appeals from English courts to Rome, to restore the possessions of Canterbury, and to renounce practices of his time that were detrimental to the church. He seems to have made no formal withdrawal of the Constitutions of Clarendon. But henceforth criminous clerks were to be tried in ecclesiastical courts except for treason, breach of forest laws, or petty misdemeanours. Disputes between laymen and ecclesiastics over land or over presentation to church offices were to be tried by lay courts. Finally, Henry did penance at Canterbury, allowing the monks to scourge him.

Rebellions of Henry's sons. Henry's sons, urged on by their mother and by a coalition of his enemies, took advantage of Henry's weakness in public opinion as a result of the Becket murder and in 1173 raised a rebellion throughout his domains. The lack of cooperation among the rebels allowed Henry to defeat them one at a time. Eleanor was retired to polite imprisonment for the remainder of Henry's life. The King's sons and his baronial rebels were treated with leniency. There followed a brief period of amity between Henry and Louis of France, and the years between 1175 and 1182 marked the zenith of Henry's prestige and power. In 1183 the younger Henry again tried to organize opposition to his father, but he died in June of that year. Henry spent the last years of his life locked in combat with the new French king, Philip II Augustus, with whom his son Richard had entered into alliance.

RICHARD I (1189–99)

Henry II died in 1189, an embittered old man. He was succeeded by his son Richard I, nicknamed the Lion-Heart. Richard was mainly interested in the crusade to recover Jerusalem and in the struggle to maintain his French holdings against Philip Augustus. During his ten-year reign Richard spent only about six months in England. During his frequent absences he left a committee in charge of the realm. Inevitably one or another of the group became dominant. Chancellor William Longchamp, bishop of Ely, dominated the early part of the reign until 1191, when a rebellion of the barons forced him into exile. Walter of Coutances, archbishop of Rouen, succeeded Longchamp and took the title of justiciar. But the most important and able of Richard's ministers was Hubert Walter, archbishop of Canterbury, justiciar from 1193 to 1198, and also chancellor from 1199 to 1205. These strong ministers kept government without the King from being catastrophic. A revolt led by Richard's brother John was put down with severe measures in 1193 by Hubert Walter and Eleanor, the King's mother. An oath of allegiance was required of all freemen and the royal castles were strengthened. The fyrd was called

Richard's ministers

out, and John's supporters were outlawed or excommunicated. But when Richard returned from abroad, he forgave John and promised him the succession.

Richard was responsible for some innovations in taxation and for an attempt at military reorganization. At the beginning of his reign, a tax levied by Henry II to support his proposed crusade had to be collected. This so-called Saladin Tithe was levied on personal property rather than real estate and was collected from both clergy and laity and on spiritual as well as temporal revenues. On his return from the crusade Richard was captured by Leopold of Austria and held for a high ransom. According to the chroniclers, the 150,000 marks demanded was five times the King's annual revenue, and its collection created a financial crisis. Traditional feudal revenues were insufficient. Heavy taxes levied on towns and on demesne serfs caused protests against its incidence on the poor of London. A general levy of one-quarter of all revenue on land in 1194 was more successful. And in 1198 a carucage, or a levy on all plowlands, was tried. The ransom, though never paid in full, caused Richard's government to become highly unpopular.

Richard's capture and ransom

Richard also aroused opposition by attempting to put an army on permanent standing. He found it increasingly difficult to maintain an army consisting of feudal contingents and foreign mercenaries. Daily wages for a knight had risen from eightpence a day in Henry II's time to one shilling, and other costs rose correspondingly. The English baronage began to resist the demand that they serve abroad. In order to deal with these problems, Richard tried to set up a standing army of 300 knights who were expected to serve a whole year. This was to be accomplished by asking each holder of a knight's fee to contribute enough to pay for such an army. The barons, led by the bishops of Lincoln and Salisbury, opposed Richard's scheme, preventing the most serious threat yet conceived against the feudal organization of society.

KING JOHN (1199–1216)

Richard, killed during a seige operation in France in 1199, was succeeded by his brother John, one of the most unpopular and unfortunate of English kings. John bears the main responsibility for his misfortunes, but it is only fair to recognize that he inherited some resentments built up against his brother and father. Henry had encroached on feudal jurisdictions, and Richard had drained England of money for his crusade, his ransom, and his war in France. John inherited also claims to the large and heterogeneous Angevin empire. In England and Normandy, he was recognized as heir to Richard. Brittany, Anjou, Maine, and Touraine recognized Arthur, son of John's brother Geoffrey, as heir. Arthur's mother, Constance of Brittany, saw to it that her 12-year-old son went to do his homage to his suzerain, Philip II. John's mother, Eleanor, held Aquitaine as dowager duchess, but the province would devolve upon John at her death.

Loss of French possessions. John had nothing like the military ability or reputation of his brother, although he could sometimes win a battle in a fit of energy, only to lose his advantage in a spell of indolence. Richard's ally, the Count of Flanders, decided that John was a bad risk. John alienated some of his vassals in Aquitaine by repudiating his first wife, Isabella of Gloucester, and then carrying off the fiancée of Hugh de Lusignan, one of his vassals in Poitou. For this offense he was summoned to answer to Philip II, John's feudal overlord for his holdings in France. He refused to attend. For the disobedience his lands in France were declared forfeit. John, in a brilliant spurt of energy, marched 80 miles (130 kilometres) in 48 hours, captured young Arthur near Poitiers along with 200 Poitevins, and retired to Rouen. There, if contemporaries can be believed, he murdered Arthur in anger during a bout of drunkenness. John failed to follow up his advantage, and he let a strategic castle, the Château Gaillard, fall to the enemy in March 1204. By 1206 all that was left of the inheritance of the Norman kings was the Channel Islands.

Struggle with the papacy. John returned to England and, unlike any king since the Conquest, devoted his undivided attention to the realm for the next few years. Immediately he became involved in a conflict with Pope Innocent III over the choice of an archbishop. At Hubert Walter's death in 1205, the monks of Canterbury had resorted to a secret election in the night in order to avoid participation of the clergy of the province and the interference of the King's officers. They elected the subprior and sent him to Rome to receive the pallium from the Pope. The secret got out, and John went angrily to Canterbury to force the monks to elect John de Gray, bishop of Norwich and one of John's close confidants. He, too, was sent to Rome. Pope Innocent III could not be expected to miss so good an opportunity to demonstrate the plenitude of papal power. He quashed both elections and persuaded a delegation of Canterbury monks sent by his command to Rome to elect the learned and talented Stephen Langton, an English cardinal. John refused to receive Stephen, who retired to Pontigny, where Archbishop Thomas before him had taken refuge. John seized the revenues of Canterbury. He had already quarrelled with his half brother Geoffrey, archbishop of York, over Geoffrey's leadership in 1207 of resistance to a tax on movables. Geoffrey fled to the Continent, where he died in 1212. England was without either archbishop. In March 1208 Innocent placed England under an interdict, or ban forbidding the administration of the sacraments and certain religious rites. All but five of the 16 bishops either died or fled to the Continent. In November 1209 Innocent excommunicated John. In response, the bishops of Bath, Salisbury, and Rochester left their posts. Peter des Roches of Winchester and John de Gray of Norwich remained the sole support of John's power in the church, and John made the most of the opportunity to gather in the revenues of the vacant ecclesiastical sees.

John's excommunication

John's excommunication freed his vassals from their oaths of fealty to him. Strangely, however, there was no immediate revolt. Indeed, the interdict seems to have had some popular support, perhaps because the King, by taking over ecclesiastical property, temporarily relieved the laity of burdensome taxes. John was able to conduct highly successful expeditions to Scotland, Wales, and Ireland in the period. It was not until 1212, when John's plans for the reconquest of his former French possessions began to reach the boiling point, that rebellion flared up. Ever since the loss of Normandy, John had been busy building up a coalition of German rulers to assist him against the French king. His chief ally was Otto of Saxony, claimant to the German throne, who became the Holy Roman emperor Otto IV. Meanwhile, John issued writs to the leading towns of England, demanding contingents for war on the Continent, and he ordered an inquest of fees under which each of his tenants in chief was required to report the service due from his fiefs.

At this point the Welsh raised a revolt with the support of Philip of France, and John's troops had to be diverted to Wales. But before he could take punitive measures against the Welsh, a plan of the barons to depose him was rumoured, and Robert Fitzwalter and Eustace de Vesci fled the country to the King's enemies. John's brilliant solution of the problem of multiple threats was to effect a reconciliation with the papacy. He agreed to receive Stephen Langton as archbishop, to reinstate the clergy in exile, and to compensate the church for his depredations on revenues. In addition, without papal prompting, John resigned his kingdoms in England and Ireland and received them back as fiefs from the Pope in return for an annual contribution of 1,000 marks. He now had an able ally against his adversaries at no great cost in terms of concessions on his own part.

John now made a second attempt to set out for Poitou. This time it was the northern barons who revolted and prevented him from going. John was furious and marched north to the attack. Only Stephen Langton's persuasion finally effected a reconciliation and made possible the Poitou venture. The campaign in Poitou failed when John's painfully assembled allies were decisively defeated at Bouvines on July 27, 1214. John was forced to withdraw from France and to return home to face his disgruntled barons.

Revolt of the barons and Magna Carta. Even so, rebellion developed slowly. Stephen Langton is alleged to have read to the barons a copy of Henry I's coronation charter as early as August 14, 1214, presumably to stir them to action. It was not until the spring of the following year that the opposition to John took shape, and the so-called Unknown Charter was drawn up. It was based on Henry I's charter but reflected more recent grievances. Resistance to the King came chiefly from the northern barons who had rebelled against service in Poitou, but by the spring of 1215 many others had joined to support the protest against the scutage for Poitou and John's abuse or disregard of feudal law and custom.

On June 15, 1215, the rebellious barons met John at Runnymede on the Thames near Windsor (modern New Windsor), and, on the basis of the Articles of the Barons presented to the King, Magna Carta was drawn up. For a document hallowed in history during more than 750 years and frequently cited as a forerunner of the Declaration of Independence and the Declaration of the Rights of Man and of the Citizen, Magna Carta is a singularly undramatic document. It is thorny with problems of a feudal age that are largely untranslatable into modern idiom. Read in its historical context, the charter was a guarantee against the sort of arbitrary disregard of feudal right that the three Angevin kings had made familiar. The main importance of Magna Carta derives first from the fact that it was agreed upon between the King's party and the baronial party and therefore has the character of a contract, and second that, even though John was released by the Pope from his obligations under it, the charter was reissued under John's son and so became a part of the permanent law of the land. The King's repudiation and the barons' reluctance to fulfill their part of the agreement of June 1215 led to renewal of civil war. The barons announced their *diffidatio* and chose Louis, son of Philip Augustus, as their king. But John's death in October of 1216 brought an end to the civil war.

IV. The 13th century

The 13th century was an important formative period in the history of England. It was during that century that the concept of the community of the realm developed in sufficient strength to provide the foundation for parliamentary government. Something like the phrase had first been used formally in clause 61 of Magna Carta. The barons, in devising a method of enforcement for the provisions of the charter, had provided that if grievances occurred they should be carried to a committee of four barons among 25 who were to enforce the charter, and that if the king or his justiciar, on being duly advised of the problem, did not provide a remedy, the 25 chosen barons "with the commune of all the land" were to distrain and distress the king in every possible way until he should offer remedy.

The notion of the community of the realm

The notion that the realm was a community and that it was governed by representatives of that community perhaps got its start in the period following Magna Carta in which a council of regency ruled on behalf of a child-king not yet able to govern in his own right. The phrase community of the realm used to mean just the totality of the baronage. Yet the representative idea had made some headway. In a writ of 1237 for the collection of a tax earlier granted to the King, the earls, barons, knights, and freemen are said to have acted "for themselves and their villeins." But it is in the conflict that broke out between the King and a party among the barons in the latter part of the reign that all these terms acquire some sophistication.

HENRY III (1216–72)

Early reign. The issue on which conflict centred in Henry III's reign was whether the King should be allowed to choose his own counsellors or whether he was bound to consult his barons. The King himself pointed out that the barons denied him the right of free choice of his servants that they exercised in conducting their own affairs. Men of the 13th century realized that the kingship was different from any other feudal lordship, but it was not clear to contemporaries in what precise way it differed.

So long as Henry was under tutelage the question did not become a critical one. Henry declared himself of age in 1227, but he did not immediately take control. After the death of the regent, William Marshal, in 1219, Hubert de Burgh, the justiciar, dominated the group of officers surrounding the King. Hubert was the King's chief minister until two others among Henry's close advisers engineered his fall. A subsequent revolt of the barons led by Richard, son of William Marshal, ended in tragedy. Richard was killed in Ireland, and Henry found that he had unknowingly signed an authorization for the killing. In 1236 Henry married Eleanor of Provence and introduced her relatives as a new element in English politics.

Simon de Montfort and the Barons' War. In all the crises of his younger years, Henry showed himself to be naïve; on the one hand he was overtrustful, and on the other bitter against those who betrayed his trust. The main crisis of his reign came in 1258, when he asked for taxes to pay the 135,000 marks he had promised the Pope as the price of making his second son king of Sicily. Henry had already made himself unpopular by asking for taxes to pay the costs of expeditions to Gascony in which he showed his incompetence as a military leader and failed to gain either vassals or prestige on the Continent.

The crisis began in May 1258, when the King was persuaded to agree to the meeting of a "parliament" and to the appointment of a joint committee of the dissident barons and of his own supporters. Twelve were to be elected by each side and were to recommend the necessary measures for the reform of the kingdom. Simon de Montfort, the King's brother-in-law, was the able but fanatical leader of the opposition party.

The Provisions of Oxford

The Provisions of Oxford, which the 24 drew up by mid-June, would have made the king a constitutional monarch if they had been permanently effective. The 24 were to choose four: two on the king's side, two on the barons' side. These four were to choose a 15-member council that would supervise the king's government. There were to be three "parliaments" a year—at Michelmas, Candlemas, and the first of June—to which were to come the 15 of the king's council and 12 to be elected by the "community" (*le commun* in the original French). The community was to accept as established what the 12 should do. The office of justiciar was to be revived, and this officer was to account at the end of his term of office before the council. The treasurer and the chancellor were likewise to account before the council, and the chancellor was to seal nothing merely by the king's will but was to act by advice of the council. The households of the king and queen were to be reformed. Sheriffs were to be knights of the shire and to hold office for one year only.

The Provisions of Oxford led to two years in which the King was again under tutelage, less even than a *primus inter pares* because he was not free to choose his own councillors. A Welsh truce was arranged against the opposition of the King's party. The King's men were dismissed from their positions as castellans and banished from the country. Discussions of aid broke down because the Sicilian project fell through and the King no longer needed the money. Peace with France had been arranged in November 1258 so that Henry was free of financial necessity for war in France. In October 1259 the *communitas bacheleriae* (a group of lesser vassals of the barons) petitioned for fulfillment of the promises of the magnates and King to remedy their grievances. The results were embodied in the Provisions of Westminster, mainly reforms of the common law in the interest of the knights bachelors of England—that is, the tenants of the magnates who had imposed the Provisions of Oxford on the King.

Breakdown of the Oxford settlement

The Oxford settlement began to break down in 1260. Henry became suspicious that his eldest son, Edward, had come to some agreement with the rebels. A reconciliation was arranged, and Edward, aged 21, went off to the Continent on a jousting expedition intending eventually to settle down to deal with the problems of governing Gascony. Odo Rigaud, archbishop of Rouen, arrived in

the summer of 1260 intent on reconciling Simon de Montfort and the King, and peace was temporarily restored. Then in April 1261 the Pope sent a bull absolving Henry from his oath to support the Oxford Provisions. The King, encouraged by this release, dismissed the baronial sheriffs, castellans, and other officers imposed on him by his council. Simon de Montfort returned from abroad and again raised rebellion against the King. In January 1264 Henry appealed to Louis IX of France, his fellow sovereign and his overlord with respect to his French holdings, to decide the case between him and his barons. In the Mise of Amiens, Louis released Henry from his commitments, insisting on Henry's right to appoint his own ministers. Louis incorporated a saving clause in favour of "charters, liberties, establishments, and praiseworthy customs . . . existing before the time of such provisions."

Inevitably war broke out, in April 1264. In the first phase of the war, Simon and his supporters were successful. Near Lewes, in May, Simon captured the King, the King's son Edward, and the entire leadership of the royal party. Henry was forced to agree to govern by the Charters and Provisions of Oxford, and in the King's name a "parliament" was called for June in which four knights from each shire were to assist in setting up a new form of government to control the King. Simon governed in the King's name, though still considering himself to be the King's loyal subject. Early in 1265 he called a second parliament, this time to include representative burgesses of the boroughs as well as knights of the shire. Simon's motivation was undoubtedly political, to win support from elements in the community of the realm below the baronage, especially the moneyed class in the towns. Peace negotiations with the royal party failed, despite the efforts of the papal legates, Gui and Ottobuono. But in May, young Edward escaped by collusion with his captors, and the war became Edward's war. He rallied the royal forces, particularly the Marcher earls, whom Simon had allowed to go free after Lewes, and in August he defeated Simon by turning against him his own tactics. Simon himself was killed.

Later reign. The rest of Henry's reign was spent in settling the problems created by the rebellion. Simon's supporters were deprived of their lands, and as "the Disinherited" they fought back from redoubts in forest or fens. The original of the Robin Hood legends may have been one of them. The Statute of Marlborough (1267) was the final document of the reign. It was a confirmation, restatement, and implementation of the Provisions of Westminster and of the peace terms ending the war. With it went a confirmation of the charters. The parliament that adopted it included representatives of the lower classes as well as the barons. It granted a subsidy for the crusade, and "Lord Edward" went off to war against the Muslims, not to return until two years after his father's death.

"The Disinherited"

EDWARD I (1272–1307)

Lord Edward, who became King Edward I in 1272, was in many ways the ideal medieval king. He had learned early in life, in the conflict with Earl Simon de Montfort and his followers, how to command an army and something about strategy and tactics. He was a good fighter, according to one contemporary "the best lance in the world." He had learned from his father's experience something about the mistakes a medieval king must avoid. He enjoyed both war and statecraft. He looked on kingship as good management of the king's possessions and prerogatives.

Statute law. In his reign, statute law began to take shape as a kind of supplement to the common law. Statutes remedied deficiencies in the "law and custom of the realm" either in protection of the king's rights or in remedy of grievances of his subjects. To protect his own rights, for example, there were the *quo warranto* proceedings under the Statute of Gloucester of 1278 and the Statute of Quo Warranto of 1290. Under these statutes, the king's subjects were asked by what warrant they claimed possession of royal franchises. Edward's object was not so much to recover such franchises as to discover which of them were held legitimately. It was found that over half the hundred courts were in private hands. By the Statute of Mortmain of 1279, it was provided that no more land might be given into the hands of the church without royal license. The Statute of Quia Emptores of 1290 had the effect of forbidding further subinfeudation of land. Two great statutes of Westminster, one of 1275 and one a decade later, remedied deficiencies in the common law and provided improvements in legal procedures on behalf of the king's subjects.

Edward also established an alliance between the king and the merchant class. He offered the merchants his protection in return for a grant of export duties on wool, wool-fells, and hides, payable at London and 12 other ports to royal customs officials. The tax brought in a good income—an average of £8,800 in a good year. In return for this new source of income, Edward granted royal favour to the merchants. The Statute of Acton Burnell (the name of a castle of Edward's chancellor, Robert Burnell) facilitated the collection of merchants' debts by establishing debtors' prisons. Finally, in 1303, Edward negotiated with the foreign merchants the so-called *Carta Mercatoria*, whereby he granted them freedom of trade in England in return for additional customs revenues. Despite this assured income from trade, Edward, in the critical period of the 1290s, seized the whole output of wool to support his wars in Wales or in France.

Edward's encouragement of merchants

The growth of Parliament. Edward also fostered the concept of the *communitas regni* and the practice of calling representative knights of the shire and burgesses of the borough. Of the 45 parliaments called during Edward's reign, knights and burgesses attended 17 of them. In 1295 Edward called the gathering that older historians have called the "Model Parliament," because it contained all the elements later associated with the word parliament and because the writs to the sheriffs to call knights and burgesses expressed the representative principle very clearly. They were to be summoned

The "Model Parliament"

> so that the said knights shall then and there have full and sufficient authority on behalf of themselves and the community of the county aforesaid, and the said citizens and burgesses on behalf of themselves and the respective communities of the cities and boroughs aforesaid, to do whatever in the aforesaid matters may be ordained by common counsel; and so that through default of such authority, the aforesaid business shall by no means remain unfinished.

So this parliament to Edward was representative of local communities and of the whole community of the realm.

Edward's wars. Edward aimed to be as successful in war as he was in peace, but only in relation to Wales did he succeed fully. There Llewelyn ap Gruffydd, prince of Snowdonia, had taken advantage of the Barons' War against Henry III to try to make himself ruler of all Wales. In 1277 Edward conducted a short and methodical war against Llewelyn. Using a fleet from the Cinque Ports and a paid army combined with feudal contingents from the Marcher lords, Edward won a quick victory and exacted from Llewelyn the Treaty of Conway, whereby Llewelyn agreed to take an oath of fealty, pay homage for his lands, surrender to Edward certain northern districts of Wales, hold all his other lands subject to Edward's justice, and pay a large indemnity.

David, the younger brother of Llewelyn, was responsible for the breach of the Treaty of Conway. He waged war against Edward and was joined by Llewelyn in 1282. David was captured and executed as a traitor; Llewelyn was killed in battle. The army with which Edward won his victory was a paid army rather than a feudal levy. In the peace following, North Wales was organized into counties and the whole realm was to become the appanage of Edward's son, Edward of Caernarvon, who was given the title Prince of Wales—a title borne ever since by the heir to the English throne. Edward built four great castles (Conway, Caernarvon, Criccieth, and Harlech) at strategic points in North Wales; founded merchant settlements that he colonized with English craftsmen and merchants; and revised Welsh law to bring it into conformity with the English common law. Archbishop Pe-

cham reorganized the Welsh church and brought it more fully under the sway of Canterbury. A final revolt in 1294–95 was quickly quelled, and Wales became the *communitas Walliae*, which granted its share of subsidies in support of the king.

Edward also tried to bring Ireland into closer relationship to England and to enforce some sort of peace and order there. The outcome was the establishment of the English Pale, an area in which English law, customs, and speech were enforced, and the establishment of an Irish Parliament on the model of the English Parliament, which met in 1297 to consider Edward's demands for troops for war in France.

Attempts to secure Scotland

Edward's efforts to bring Scotland under English suzerainty met with only temporary success. Alexander III (1249–86) had married Margaret, Edward's sister. During his reign, peaceful relations prevailed, and parliaments, or assemblies of prelates and magnates, met to consider the problems of the king and the kingdom. A crisis developed only when Alexander rode off a cliff in a wild storm in 1286, leaving as his only immediate heir his three-year-old granddaughter, Margaret, the "Maid of Norway." A regency council was set up and ruled the realm until 1290, when Margaret was brought from Norway to become queen. Edward had negotiated a marriage for her with his son Edward, and all seemed auspicious for a friendly and close relation between the two kingdoms. These plans were defeated by Margaret's death in September 1290. The whole question was thrown open to challenge and conflict. Edward claimed and received the right of arbitration. There were three main candidates, all descendants of David, earl of Huntingdon, the brother of William the Lion, king of Scotland from 1165 to 1214. John de Balliol was the grandson of David's eldest daughter; Robert de Bruce was the son of David's second daughter; and John de Hastings was the grandson of David's youngest daughter. A commission consisting of one-half chosen by Bruce and one-half by Balliol designated Balliol as king. Balliol took an oath of fealty and did homage to Edward and was accepted in Scotland.

This settlement by no means ended the problem of Scotland. In 1294 the Scottish lords' committee set up a system of restraints on the king modelled on the Provisions of Oxford. In 1295 a treaty was negotiated with France that provided for the marriage of John de Balliol's son Edward to the French king's niece. The king of England then demanded the surrender of three border castles and, on John's refusal, summoned him to his court. John did not appear and war became inevitable. Edward conquered the country in five months in 1296–97. But he appointed inept agents to enforce peace in Scotland. Revolt broke out again when William Wallace, a free tenant of the Scottish king's steward, slew an English official. Wallace was eventally captured and executed. Meanwhile, Robert Bruce, grandson of the original claimant to the throne, had taken over the leadership of the rebel party. War continued into the new reign when Edward II succeeded his father in 1307.

French campaign

In his war against Philip the Fair of France, Edward I encountered opposition both in raising men and money and he achieved little success. In the last years of the reign, a peace with France was negotiated based on a double marriage agreement: Edward himself was to marry Philip's sister Margaret, and the Prince of Wales was to marry Philip's daughter Isabella. This peace freed Edward for a stronger effort against Scotland. He died on campaign in the North.

V. The 14th century

The 14th century in English history is a difficult century to characterize. At the beginning and end of the century two kings' reigns ended in tragic failure. In between there was the 50-year reign of Edward III, the most popular with his contemporaries of England's medieval kings. Certain general themes are clear. There was continuous development during the century of the importance of the Commons in Parliament. War between England and France continued intermittently throughout the century, and that part of it from 1337 on is called the Hundred Years' War. The Black Death struck in 1348–49, remained endemic, and recurred several times during the latter part of the century, bringing with it profound economic and social change.

EDWARD II (1307–27)

Edward II's reign was an almost unmitigated disaster. He inherited some of his problems from his father. The most important were a treasury deficit of £60,000 and the Scottish war. He inherited none of his father's strengths and seems to have developed his own weaknesses in rebellion against his father. Surrounded with a ruling class strongly tied to his family by blood and service, he rejected the company of his peers, seeking that of the lower orders of society. He enjoyed swimming, ditch digging, thatching, theatricals, but not swordplay or tournaments. His "dear friend" Piers Gaveston, the son of a Gascon knight, was a man of simple birth and no claim to breeding. Edward's father had exiled Gaveston in an attempt to quash the friendship. Edward, the son, recalled him and conferred on him the highest honours he had to bestow; that is, the earldom of Cornwall and marriage with Margaret de Clare, sister of the Earl of Gloucester. Edward also recalled Archbishop Winchelsey and Bishop Bek of Durham, whom his father had banished. He dismissed one of his father's most trusted servants, Walter Langton, the treasurer.

Edward's ministers

Edward II failed as king, but his reign is important for a new attempt of the barons to set up a system of checks on the king's exercise of power similar to the system set up to control his grandfather. At the beginning of the reign, in the coronation oath—which he took in French rather than Latin—he was asked, in addition to the promises extracted from his ancestors, to promise to keep such laws "as the community of your realm shall have chosen."

From the beginning of the reign the hostility of the barons toward Edward was strong. The barons came armed to the 1308 Parliament and warned the king that "homage and the oath of allegiance are stronger and bind more by reason of the crown than by reason of the person of the king" and that "if the king by chance be not guided by reason, in relation to the estate of the crown, his liege subjects are bound by the oath made to the crown to guide the king back to reason and amend the estate of the crown." To the Parliament of 1310 they again came armed and forced the king to allow the election of 21 lords ordainers, "prelates, earls and barons," to make ordinances for the betterment of the estate of the realm.

The lords ordainers

Apart from a third banishment of Gaveston and the demotion of the Frescobaldi family from control over collection of the wool customs, the main provisions of the ordinances had as their object a reduction of the king's control over his own ministers. A long list of officers, including the chancellor, the treasurer, and the justices of both benches, were to be chosen with the advice and consent of the barons in Parliament. Parliament was to meet twice a year. Consent of the baronage was also required for participation in foreign war and in the appointment of a keeper of the realm in the king's absence. Letters of the king under privy seal were to be null and void if they interfered with justice. The ordinances, like the earlier Provisions of Oxford, if they had been fully enforced, would have created a constitutional monarchy.

The middle years of Edward's reign were a period of uneasy truce between King and barons. Thomas of Lancaster, leader of the opposition, had supervised the capture and execution of Piers Gaveston in 1312. He maintained a kind of surly enforcement of the ordinances. In 1314 the King went off to Scotland with an army raised by county muster and therefore not dependent on the barons for consent. In the Battle of Bannockburn, the Scots were victorious with an army consisting of pikemen and bowmen, giving the English a lesson they did not forget in the French war. The Scottish war continued in somewhat desultory fashion until 1323, when a truce was arranged. In 1315–17 there were torrential rains that destroyed the crops. In the ensuing famine, the gov-

ernment could think of no better remedy than trying to enforce maximum prices of wheat without any apparatus for enforcement.

In 1321 conflict again erupted between King and the opposition barons. The King's ablest ministers, Hugh Despenser, father and son, were banished in 1321 by act of Parliament. Civil war ensued in which the King was victorious. He got his revenge against Thomas of Lancaster by executing him after a pretended trial. Popular sympathy was with Lancaster, who was spontaneously canonized, though he had been anything but saintly in his life. In 1322 at York, Parliament repealed the ordinances and got from the king a promise

The Statute of York

> that matters which are to be determined with regard to the estate of our lord the king and of his heirs or with regard to the estate of the kingdom and of the people shall be considered, granted, and established in parliament by our lord the king with the consent of the prelates, earls, and barons, and of the community of the kingdom, as has been accustomed in times past.

The meaning of this Statute of York has been much debated by historians, the main problem being whether to give to the term parliament its later meaning of lords and representatives of the community of the realm, or to give it the narrower meaning of earlier times. However it is interpreted, there was clearly some notion of limiting the king's powers.

The final period of the reign was one in which the Despensers, restored to power, carried out various administrative reforms, ably assisted by Walter Stapledon, the treasurer. The reign ended with a renewal of conflict. Isabella, the king's French wife, with the assistance of Roger Mortimer, earl of March, landed in England with a force of only 700 men and, with popular support, especially in London, overthrew the government. The Despensers were tried and hanged, and the King was imprisoned. Parliament was called in his name, Edward II was charged with breaking his coronation oath and was persuaded to abdicate in favour of his son, Edward III. After two conspiracies to release him, the King was killed and his body was exhibited publicly to avoid further attempts on his behalf.

Edward's deposition

EDWARD III (1327–77)

Outbreak of the Hundred Years' War. Edward III's long reign was relatively uneventful in terms of political and constitutional crises. He was crowned at 14 and overthrew his mother's and Mortimer's dominance when he was 17. Mortimer was tried and condemned by the Lords in Parliament. Edward's mother was retired to her estates; she later repented her sins and died a sister of the Poor Clares. Her son began his fortunate military career by winning the Battle of Halidon Hill against the Scots (1333). From then until 1337, it was just a matter of time until Edward took up war against his French overlord, Philip IV, beginning over a century of Anglo-French warfare known as the Hundred Years' War. The causes of the war were several. Friction over allegiances in Gascony had been chronic since 1294. Both sides had built *bastides*, or new fortified towns, to try to keep one another at bay. English and French seamen had long engaged in acts of piracy along the coasts. The Count of Flanders was a vassal of the French king, but the livelihood of his state depended on wool from England, as the livelihood of England did on selling the wool in Flanders. The rulership of Brittany was in dispute, and both the English and French kings had their candidates. Finally, there was the matter of the French throne itself. Edward, through his mother, was closer in blood to the last of the Capetians than was Philip of Valois. Edward did not present his claim to the French throne in dead seriousness, but he used to the full its propaganda value. The French complained that he had not done liege homage to Philip for his possessions in Gascony in accordance with the agreement of Saint-Germain-en-Laye (1331). War began in somewhat desultory fashion in 1337 (see also HUNDRED YEARS' WAR).

Edward's claim to the French throne

Domestic achievements. In the domestic history of Edward III's reign there is little of interest except for a crisis in 1341–43 over the King's finances in the conduct of the war and a critical period at the end of the reign, when Edward was in his dotage. Edward received generous grants for the war in the years from 1336 to 1340, but he found himself short in 1340 because of his grants and promises of grants to his allies. He seized the wool exports and had recourse to reckless borrowing from Italian merchants in anticipation of future parliamentary grants. In 1341 he returned from France and charged John Stratford, archbishop of Canterbury, with working against him and delaying the grant and collection of subsidies. In the Parliament of April–May 1341, various statutes were passed that were reminiscent of the kind of restraints put on earlier and less popular kings. Officers of state and the king's household were to be appointed and sworn in Parliament. Commissioners were to be sworn in Parliament to audit the king's accounts. Peers of the realm were to be arraigned and tried only before their peers in Parliament. Breaches of the charters were to be reported in Parliament and tried there. Stratford was summoned before a committee of two bishops and four earls who were to hear the charges against him, but the charges were dropped, and in 1343 the record of the case was annulled. Also in 1343, the King repudiated the statutes. Only the Commons protested, and they did not persist. The chief lesson of the crisis was that it illustrated the king's dependence on Parliament and, particularly the Commons, for supply.

Later legislation

The later legislation of Edward III's reign had to do with matters that had for some time needed remedy or were related to the social and economic crisis that followed in the wake of the Black Death. The Statute of Treasons (1352) had as its object the clear definition of great treason, that is, treason against the king involving forfeiture of land and goods, as against petty treason against a lesser lord, in which case forfeiture to the crown was not involved. The Statute of Provisors gave statutory authority to measures already in use to prevent papal provisors from usurping the right of Englishmen to present to church offices in England. The Statute of Praemunire (1353) introduced better procedures for checking appeals to the papal courts in cases involving rights of Englishmen to present candidates to church offices. These acts were accepted by the King only with reservations on his side about enforcement. Many of his ministers and clerks were clerics, and it was often to his advantage to negotiate with the pope concerning appointments. The Statute of Labourers (1351) attempted to fix wages during the labour shortage following the devastation of the Black Death. In 1362 Parliament passed an act to make English rather than French the official language of pleadings in the law courts. This measure failed because of resistance of the lawyers, who complained that they could not state their cases properly in English. In parliamentary rolls and statutes on the other hand, the English language made its way slowly, so that English ultimately became the official language.

The crises of Edward's later reign. The last ten years of Edward III's reign were a time of suppressed crisis. The king was in his dotage and, since the death of his wife, Philippa, in 1369, in the clutches of Alice Perrers, the rather unscrupulous wife of a London citizen. Edward, the Black Prince, heir to the throne, was ill and dying. Lionel, duke of Clarence, the next eldest son, died in 1368, leaving a daughter, Phillippa, as heiress. Her husband, Edmund Mortimer, would not arrive at his majority until 1373. John of Gaunt, the fourth son, was occupied with his claims to Castile, his inheritance from his second wife, Constance of Castile, whom he had married in 1371. Edmund of Langley, the fifth son, earl of Cambridge, later duke of York, was a man of no ability and had nothing to offer toward establishing good and responsible government. Thomas of Woodstock, the King's youngest son, was not yet of age. John of Gaunt was the only real leader among the King's sons, and after 1373 he was under a cloud because of an ineffectual and fruitless campaign in France. A parliament met in 1371 and dismissed William of Wykeham, the chancellor, a notorious curialist and pluralist, and demanded the ap-

The rise of John of Gaunt

pointment of laymen to state offices. This proved to be a not very practical manoeuvre. It mainly illustrates the anticlericalism of the times, a spirit already illustrated by the Statutes of Provisors and Praemunire.

No parliaments were held in 1374 or 1375, and by the time the Good Parliament of 1376 was elected there was an accumulation of grievances to be dealt with. Petitions and protests included a demand for annual parliaments, for the election of sheriffs and knights of the shire by the better people of the county, reform of local government, measures to deal with "rogues, vagabonds, and sturdy beggars," a check to the peculations of royal officers (Gaunt's following especially), reform of the navy, and improvement in the protection of the borders of the realm. As in previous crises, a committee consisting of four bishops, four earls, and four barons was set up to take the responsibility for the reforms. Then, under the leadership of the speaker, Peter de la Mare, steward in the household of the Earl of March, the Commons stumbled onto a new procedure. They impeached Alice Perrers and the royal officers who profited personally from administration of the royal finances. The Commons took the role of prosecutors before the Lords as judges.

The achievement of the Good Parliament was ephemeral. John of Gaunt soon recovered his power in the government. Peter de la Mare was jailed in Nottingham. William of Wykeham was attacked for alleged peculations as chancellor, and Alice Perrers was restored to court. The Parliament of 1377 reversed all the important acts of the Good Parliament. But Richard, son of Edward, the Black Prince, was created prince of Wales, duke of Cornwall, and earl of Chester, allaying suspicions that John of Gaunt aimed at the throne. Richard was asked to make peace between John and the citizens of London. So the reign ended in truce if not peace.

RICHARD II (1377–99)

Richard II's reign was fraught with crises—economic, social, political, and constitutional. Richard was ten years old when his grandfather died, and the first problem that had to be dealt with was the King's minority. A "continual council" was set up to "govern the king and his kingdom." John of Gaunt was still clearly the dominant figure in the royal family, but neither he nor his brothers were included in the council.

The Peasants' Revolt (1381). Immediately the matter of finances for the war in France came up. In the last Parliament of Edward III's reign, a poll tax of fourpence per head had been introduced. It had not been a great success. The 1379 Parliament introduced a graduated tax based on rank in society. This, too, was a failure, and crown jewels had to be sold to meet expenses. In 1380 the tax was set up at one shilling per head with the proviso that the rich should help the poor in paying it. This was obviously an inequitable and impractical tax, and trouble developed rapidly when the government tried to speed up its collection in the spring of 1381. By May the whole of southeast England was on the verge of rebellion. The poll tax was the immediate cause of unrest, but the deeper origins of the so-called Peasants' Revolt of 1381 go back to earlier developments, particularly to the demographic crisis caused by the Black Death in 1348 and 1349.

Imposition of the poll tax

This outbreak of bubonic and pneumonic plague had carried off from one-third to one-half of the population and had been particularly severe among the lower social levels. The result was a labour crisis. Hired labourers, being fewer, asked for higher wages and better food, and peasant tenants, also fewer, asked for better conditions of tenure when they took up land. Some landlords, in trying to come to terms with the new conditions, attempted to reassert labour services where they had been commuted. They ran into strong opposition from the peasants. An Ordinance of Labourers (1349) and a Statute of Labourers (1351) had tried to set maximum wages at the levels of the years before the Black Death, but strict enforcement was impossible. Still the friction and the frustration provided by the acts persisted, and the peasants resented the efforts to prevent them from making the most of their new opportunities. Meanwhile, popular poor preachers were spreading subversive ideas about relations among the ranks of English society. A popular slogan asked:

When Adam delved and Eve span
Who was then the gentleman?

Sharper than the attacks on the gentlemen were the attacks on the clergy. A proposal widely accepted was that all the lands held by the clergy be confiscated and distributed among the peasantry.

Government policies that added coal to the fire were the fostering of the expanding powers of the justices of the peace at the expense of local courts and manorial courts and the attempts at levying the poll tax. Attempts at levying back taxes in Essex and Kent were the immediate signal for revolt. A royal justice on a special commission in Essex was seized and forced to swear not to hold further sessions of his court. The appearance of a tax collector in Kent was the signal for revolt there. Widespread outbreaks occurred in the southeastern part of the country: attacks on landlords and their manor houses and the destruction of documentary evidence of villein status, assaults on royal officers trying to collect taxes, and attacks on lawyers because of their association with the landed classes. Attacks on religious houses were particularly severe, perhaps because they had been the most conservative among the landlords about commuting labour services.

Meanwhile, men of Essex and men of Kent were moving on London to attack the King's evil councillors and to demand from him redress for their grievances. In this curiously spontaneous revolt, the men of Essex and the men of Kent arrived outside London at approximately the same time. By June 11 the men of Essex were assembled outside the northeast gates of the city. The Kentishmen gathered at Blackheath on June 13 and attacked the Marshalsea Prison and Lambeth Palace, both on the south side of the Thames. The rebels were let into London by sympathizers among the citizenry and attacked the Fleetstreet Prison and the town house of John of Gaunt, duke of Lancaster. On June 14 the young King rode out to Mile End to meet the rebels and, in default of sufficient available force to turn them back, promised them charters of liberation from serfdom. Meanwhile, rebels broke into the Tower and killed Sudbury, the chancellor, Hales, the treasurer, and two other ministers of the King. On the next day, Richard met the rebels at Smithfield. The rebel leader Wat Tyler presented the rebels' demands in the presence of the royal party and his own followers drawn up in battle array. During a parley with the King's forces Tyler was attacked and fatally wounded by the Mayor of London and a follower. The young King rode forward to reassure Tyler's men, who had not clearly seen the murder, and asked them to follow him to Clerkenwell. This proved to be the turning point of the rebellion. Having exhausted their supplies and got promises regarding their grievances, the rebels began to make their way home. Disorders in the countryside continued, although retaliatory measures were taken by the government. On June 23 the King and Sir Robert Tresilian began a tour of the eastern counties and trial of the ringleaders. When challenged about his promises at Mile End, the King replied: "Villeins ye are and villeins ye shall remain." Special commissions continued to act until August 30, when the King ordered all further arrest and executions to cease. In November a Parliament confirmed the King's revocation of charters but demanded amnesty except for a few special offenders.

The attack on London

The results of the uprising, though not spectacular, were important. The government never again attempted to collect a poll tax. The landlord class learned to fear the peasants. The London uprising would probably not have succeeded to the extent that it did if it had not been for the support of London citizens, but the march on London was bound to fail in the end because the peasants had no practical program to present to the King, in whom they placed their entire trust for the improvement of their condition. Richard seems to have derived a rather exalted idea of his own powers and prerogatives from the appeal to him and his success in meeting the peasants

at Smithfield. But the very real improvement in the position of the peasants—the abandonment of labour services and the leasing out of the demesne lands to them—seems to have occurred not so much as a consequence of the revolt as of changes in the economy that would have occurred anyhow.

John Wycliffe. Religious unrest was another subversive factor in the reign of Richard II. John Wycliffe, a priest and an Oxford scholar, began his career as a religious reformer with two treatises on divine and civil *dominium* in 1375–76. According to him, *dominium*, that is, the power of possession and of government, was a gift of God to those who were in his grace, that is, those who served him faithfully. He conceived *dominium* in feudal terms as power and possession granted in return for service, not in the hierarchical terms of contemporary feudalism. *Dominium* was exercised not mediately through kings or popes but immediately by anyone who was in God's grace. Everyone standing in God's grace has all the gifts of God. And, contrariwise, no one who is not in the grace of God has any sort of *dominium*. Priests, therefore, have no power to administer the sacraments unless they are in a state of grace. The pope himself has no power except through grace.

This doctrine brought Wycliffe into direct conflict with the church hierarchy. In the next years he was twice summoned before an assembly of bishops, first at St. Paul's (February 1377), then at Lambeth (March 1378). Both times, the trial was effectively interrupted by an outbreak of hostility between the London citizens and the retinue of John of Gaunt, Wycliffe's patron and protector. The beginnings of the Great Schism in 1378 gave Wycliffe further opportunities for attack on the papacy. And in 1379, in a treatise on the Eucharist, he espoused heresy. Christ, he said, was present in the bread and wine, not literally as the result of a miracle performed by the priest, but spiritually as the result of the faith of the believer. The miracle is God's miracle, not that of some sinful priest.

Wycliffe's denial of transubstantiation

Wycliffe was tried twice again and, after the second trial, was banished from Oxford. He retired to his parish at Lutterworth, in Leicestershire, which became the centre of the so-called Lollard movement. Two of Wycliffe's followers translated the Bible into English and others went out as missionaries in London and Leicestershire and in the West Country. Wycliffe died in 1384, but the movement continued to expand despite the loss of the founder and despite the government's attempts to destroy it.

Political struggles and Richard's deposition. Richard's reign is of great interest from the political and constitutional point of view as well as for economic and social developments. Soon after his success in putting down the peasant rebels, the King began to build up a court party. He used the signet for warranty of royal actions as against the Privy Seal and the Great Seal. He got control of the treasurership, the keepership of the Privy Seal, the subchamberlainship, the chamberlainship, and, eventually, the chancellorship itself. There was ground for thinking that these measures were in part directed against the King's uncle, John of Gaunt. But even the Londoners who hated Gaunt withdrew their support from Richard when he appointed the young and inexperienced Robert de Vere, earl of Oxford, as lieutenant of Ireland. A crisis was precipitated in 1386, when Parliament was asked for a subsidy to finance an expedition to France. Parliament demanded dismissal of the King's favourites, and the King withdrew to Eltham. Richard defied Parliament, threatened to enlist the King of France in his cause, and said that he would not dismiss so much as a scullion in his kitchen at the request of Parliament. In the end, however, he was forced by the impeachment of his ministers to agree to the appointment of a council to reform the King and the kingdom. He withdrew from London and made an appeal to the country. He also called the judges before him at Shrewsbury and asked them to pronounce the illegality of Parliament's actions. The King's appeal to the people and the judges failed, and a pitched battle at Radcot Bridge was needed to settle the matter of ascendancy. In the "Merciless Parliament" of 1388 five lords accused the King's friends of treason under a very expansive definition of the crime.

"The Merciless Parliament"

Richard was chastened. He pardoned those lords who had made the accusations and proceeded to rule with moderation for the few years until 1394, when Anne of Bohemia, his queen, died. He put down a rebellion in Ireland and was, for a time, almost popular. Then, after Anne's death, he began to implement his personal policy and to rebuild a royal party. He made a 25-year peace with France and married the seven-year-old daughter of the French king as security for the treaty. He built up a household of faithful servants, including the notorious Sir John Bussy, Sir William Bagot, and Sir Henry Green. He enlisted household troops wearing his personal badge, the white hart.

In January 1397 a Parliament met. Thomas Haxey, a clerical proctor, submitted a long bill of complaints concerning maladministration, extravagance in the royal household, and the inadequate defense of the Scottish border. Haxey was arrested and adjudged in Parliament a traitor, thus extending the definition of treason even beyond the scope adopted in the Merciless Parliament. The lords apellant, who had accused the King's friends in 1388, were taken into custody—that is, those who could be found. A second Parliament in September 1397 repealed the pardons of the lords who had accused the King's friends in 1388. Three of them were now accused. One was beheaded on Tower Hill; one was exiled; the third was secretly murdered. Parliament annulled all the acts of the Parliament of 1388, granted the customs on wool for the King's life, and delegated the powers of Parliament to a committee that was to continue to sit and finish the business after the Parliament was dissolved. After this other events followed quickly. The Duke of Norfolk and Henry, son of John of Gaunt, duke of Hereford, quarrelled, accusing each other of treason. They were both banished, the former for life and the latter for ten years. Following this, John of Gaunt, duke of Lancaster, died and Richard confiscated his estates instead of allowing his son, Henry, to return to claim them. Richard went off to Ireland seemingly secure.

Richard was unduly confident. Henry landed at Ravenspur in Yorkshire, as he said, to claim his father's estates and the hereditary stewardship. The Percys, the chief lords of the north, welcomed him and promised their aid. Popular support was far more than Henry had expected. Richard returned from Ireland to negotiate first with Archbishop Arundel at Conway, then with Henry at Flint. According to Lancastrian history, he abdicated at Flint. Other evidence is that he tried to keep his estate and his life and that Henry demanded only his father's lands and the stewardship. The historian is at a disadvantage in reconstructing events because the official records were altered and even the chroniclers were given an official version after the fact. The end was swift. A Parliament was called for September 30 in Richard's name. Before this body had fully assembled, its members, the "estates of the realm," and the *populus* of London were presented with Richard's alleged abdication and Henry's claim as legitimate descendant of Henry III and by right of conquest. Thirty-three articles of deposition were set forth against Richard, accusing him of misgovernment. The abdication and deposition were accepted, and Henry sent out writs for Parliament to meet on October 6.

Richard's deposition

Richard made a last futile appeal based on the sacred character of the power conferred on him. He was taken from the Tower and transferred to Pontefract Castle, where he either died of self-starvation or was murdered by smothering. Thus ended the last attempt of a medieval king to assert arbitrary power. Whether Richard had been motivated by an ideal of medieval monarchy or, as his accusers said, by new ideas about monarchy, he failed in the practical measures necessary to sustain his power.

VI. Lancaster and York (1399–1485)

HENRY IV (1399–1413)

Henry of Lancaster seemed to promise better rapport with his people. He was a warrior of great renown. He

had travelled to Jerusalem and had fought in Prussia against infidels. He had a reputation for affability and for statesmanlike self-control. But he had won his crown with the support of "the estates of the realm." It did not matter much whether that meant Parliament or something more vague and symbolic. His parliaments, from the first, expected him to govern with the advice and consent of his council and to listen in Parliament with respect to requests for money to carry on his government. And Henry himself, in order to demonstrate his superiority to Richard, emphasized his desire to govern with council and Parliament.

The rebellions. Henry's immediate task after his acceptance as king was to put down a rebellion threatening to restore Richard. The earls of Rutland, Kent, and Huntingdon, degraded from their former dukedoms but nonetheless members of the new king's council, supported by the former bishop of Carlisle, planned an attack on the King and his son at Windsor. Warned by Rutland's confession of the details to his father, the Duke of York, Henry went up to London, successfully raised an army there, and defeated the rebels near Cirencester. This event was followed by Richard's death at Pontefract. But though Richard's body was exhibited publicly in London and elsewhere, sentiment in his favour continued to crop up until well into Henry V's reign.

Owen Glendower's rebellion

A more serious rebellion was levied by Owen Glendower in 1402. He was the descendant of Welsh princes and a man of statesmanlike abilities. He sought an alliance with the French king and received some small contingents of raiders. He captured Edmund Mortimer, uncle of another Edmund, who was the only legitimate heir to Richard. He also won the valuable support of the northern barons of England including, first and foremost, the Percys of Northumberland. They had enormous prestige in the north and were connected to most of the other baronial families. Henry defeated the coalition at Shrewsbury in July 1403, and the younger Henry Percy ("Hotspur") was killed in battle. The elder Percy was pardoned on condition of surrendering his castles.

Owen Glendower meanwhile seized castles in Wales, renewed the alliance with the elder Percy, and got the support of Richard Scrope, archbishop of York. This new alliance had to be broken up in 1405. Henry won a victory at Shipton Moor and executed Scrope in a barley field without trial and over the protests of the Archbishop of Canterbury. He then defeated the elder Percy at Bramham Moor. The traitor's head was displayed on London Bridge, and his body was quartered, pickled, and sent for public exhibition to various parts of England. The war in Wales continued for some time because Henry had not enough resources to support the garrisons in the Welsh castles. But Glendower was pushed into the mountains of North Wales, and Henry was vastly more secure after 1408, although Glendower was never captured.

Henry and Parliament. Henry's relations with his Parliaments were uneasy. The main problem, of course, was money. Henry, as duke of Lancaster, was a wealthy man, wealthier than any private landlord in England. But, as king, he had forfeited some of his income by repudiating Richard's tactics. Richard had had an annual income of over £115,000, whereas Henry had only £90,000, and his income was diminished by his gifts of royal lands and revenues to his supporters. But his needs were as great as or greater than Richard's. He was threatened by rebellion at home and war from France. He borrowed as heavily as Richard but was slower in paying back. His first Parliament began the attack on royal extravagance.

They asked that he submit to the council the grants he had made to his supporters. They also asked for resumption of lands granted since 1327. Henry agreed to be advised concerning these matters but would not agree to a general resumption. On the other hand, issue was clearly joined, and the slogan that the "king should live of his own" had been introduced.

In Henry's second Parliament (1401), the Commons fired a salvo at the beginning, asking for redress of grievances before grant of supply. The King promised to confer with the Lords but in the end turned down the proposition as "unprecedented." Nonetheless, the grant of funds in the form of tenths and fifteenths and of customs is recorded in the Parliament roll as of March 10, the last day of the session. In this Parliament also, King, Lords, and Commons cooperated in a bill that required secular officers to assist ecclesiastical authorities in wiping out the Lollard heresy.

Henry called ten Parliaments in his 13 years as king. The main issues between him and these Parliaments were the demand for the resumption of crown lands so that the king might "live of his own," the demand for supervision of grants of crown lands and of expenditure generally, and finally the organization and personnel of the king's and queen's household.

The Parliament of 1406

The critical year in Henry's relations with Parliament was 1406. The Parliament of that year, the longest of the medieval period, met for 159 days and lasted from March to December. The grant of a subsidy was discussed early in the session but was promised only on condition that grants should be expended with the advice of "Lords and officers named and elected in the present parliament for defense of the realm and safeguard of the seas," except for £6,000 to be spent "as the king wishes." A grant of tonnage and poundage for safeguard of the seas was made to the merchants, but when they asked for an advance of £4,000 to deal with immediate problems, the King's reply was "Il n'y a de quoi" ("There is no money"). The second session of the Parliament demanded nomination of the King's council in Parliament. The King agreed but in no spirit of allowing interference with his choices of men to serve on the council. It was also agreed that warrants for payments from the subsidy after the safeguard of the seas had been provided for should be endorsed and made by the advice of the council. Audit of account was agreed to on the last day of the session. The third and final session of the Parliament dealt with household matters. A subsidy was granted as had been promised at the beginning of Parliament, and the Parliament broke up for Christmas on December 22.

The later Parliaments of Henry brought up no new issues, but Henry became less active in government as he was more and more incapacitated by illness. Archbishop Arundel and Henry, the King's eldest son, conducted the government until 1411, when young Henry was dismissed because of his father's suspicions concerning his loyalty. These uneasy relations between the Prince and his father lasted for the rest of the reign and kept young Henry from taking part in a campaign in France. Henry IV died on March 20, 1413. There was no question about Prince Henry's succession despite the fact of his father's usurpation.

HENRY V (1413–22)

Henry V's brief reign is important mainly for the glorious victories in the war with France, which visited on his infant son the enormous and not so glorious burden of governing both France and England. Two rebellions troubled the security of the realm in the first two years of the reign. The first was organized by Sir John Oldcastle, a Lollard and a former confidant of the new king. Oldcastle was tried by the archbishop's court and condemned to excommunication for heresy. He was handed over to the secular authorities and imprisoned in the Tower of London. He escaped with the help of two London citizens and formulated a plot against the life of the King and his brothers to take place during the Christmas celebrations in 1413–14. Some 38 of his supporters were caught and sentenced to execution. Oldcastle himself escaped arrest until 1417. Another plot against Henry's life gathered around Richard, earl of Cambridge, a younger brother of the Duke of York. Richard had married Anne Mortimer, daughter of Roger Mortimer and sister to Edmund Mortimer, the nearest legitimate claimant to the throne by descent from Lionel, duke of Clarence, second son to Edward III. Edmund gave the plot away, and the leading conspirators were tried and executed on the eve of the King's departure for France.

Sir John Oldcastle

In general, after these early disorders, the reign was internally a peaceful one. The King appointed a council to

carry on the government in his absence but kept the seals in his own hands abroad. The Parliaments of the reign granted the subsidies requested.

The Treaty of Troyes

The Treaty of Troyes marks the high point of Henry's greatest achievement; that is, his conquest of northern France. Under its terms, Henry was to marry Catherine, daughter of Charles VI. He was to be heir to the French throne, and that throne was to descend to his heirs in perpetuity. Charles VI's son, the Dauphin, was not party to the treaty, and so the war continued. Henry tried to make his possessions in France pay for their own upkeep, but he still needed money for the war. Reluctant to ask for subsidies at a time when he needed all the support he could get for the treaty, he asked for loans. That they were forthcoming as readily as they were is an indication of his popularity. Meanwhile, he contracted dysentery at the siege of Meaux on the Marne and died on August 31, 1422, just six weeks before the death of his father-in-law, Charles VI. He left as his heir a son less than a year old. There could be no immediate question of the accession of that infant to the French throne. On the other hand, no question was raised about the infant's title to the English throne even though the dynasty was of dubious legitimacy and was relatively new to tenure of the throne. Under the terms of Henry V's will a council of nine was set up in which Humphrey, duke of Gloucester and second brother to Henry V, was to be the protector and defender of the realm and the Church of England, and John Plantagenet, duke of Bedford, Henry's third brother, was to take over the rule of Normandy and of France also if the Duke of Burgundy would not accept the latter responsibility.

HENRY VI (1422–61 AND 1470–71)

Henry VI, whose long reign lasted from 1422 to 1461 with a brief revival of his power in 1470–71, was never a ruler in his own person. Until 1437 he was a child under the regency of a council of nobles dominated by his uncles of Lancaster and his Beaufort kin. When he was declared of age in 1437, John, duke of Bedford, had died, and the Beauforts were the real rulers of England. In 1445, through the initiative of the Duke of Suffolk, he married Margaret of Anjou, who with Suffolk dominated the King. Finally, in the period from 1450 to 1461, he suffered two bouts of mental illness. During these crises Richard, duke of York, ruled the kingdom as protector.

Domestic rivalries and the loss of France. In the first period of the reign, the Duke of Bedford proved to be as able a commander in the French war as his brother, Henry. He pushed the French back everywhere south of the Loire except at Orléans. Then, in 1429, Joan of Arc appeared and revitalized French resistance. Orléans was relieved, and Joan persuaded the Dauphin to go deep into Anglo-Burgundian country, to Reims (the traditional city for French coronations) to be crowned. Joan's brief career as charismatic leader of the French army ended in May 1430, when she was captured by the Burgundians and sold to the English. She was tried as a heretic and a witch by an Inquisition court and burned at the stake in May 1431. John, duke of Bedford, died in 1435, and the Congress of Arras, an effort at general peace settlement, failed. Philip of Burgundy deserted the English alliance and came to terms with Charles VII. From then on the war was one of attrition until the English had lost all their possessions save Calais.

Joan of Arc

At home there were no great political issues. The main problem was the financing of the war. The country was ruled by a council of magnates with the increasingly reluctant financial support of the Parliament. Humphrey, duke of Gloucester, and Henry Beaufort, bishop of Winchester (cardinal from 1426), were the main figures in the government. The Bishop was supported by his nephew John, duke of Somerset. He was enormously wealthy and effectively increased his wealth by lending money to the king and getting control of the customs for repayment. Gloucester was completely unscrupulous and irresponsible where his own interests were engaged.

In 1447 both the Cardinal and the Duke died, the latter under circumstances that suggested the possibility of murder by poison. The Duke of Suffolk, who had arranged the King's marriage with Margaret of Anjou, was in the ascendant. He was the leader of the so-called peace party, but his peace lasted only two years, from 1444 to 1446. Margaret proved to be a high-spirited, determined, and ambitious young woman of 16 who dominated King Henry throughout the rest of his reign and fought for her son's right long after the Lancastrian cause was lost.

Though the Duke of Suffolk was in the ascendant, he was blamed for the failure of the French peace and held accountable for rumours that Maine and Anjou had been surrendered. He was impeached in the Parliament of March 1450. The King tried to save him by exiling him for five years. But when he took ship for France, the ship "Nicholas de la Tour" waylaid him. "And thanne a knave of Yrlong smot of his hed" with six strokes of a rusty sword. Suffolk was succeeded by Edmund, duke of Somerset, as the leader of the court party.

Cade's rebellion. Less than three months later, in the southeast of England, Jack Cade, who sometimes styled himself as Mortimer, presumably to associate himself with the Yorkist claimant to the throne, led a rebellion against the government. Unlike the rising of 1381, this was not a peasant movement; Cade's followers were mainly middle class, from the rank of knight down, and their complaints were mainly about the want of governance rather than of economic repression. The rebels protested feigned indictments under forest law, failure of justice, excessive bail, those who endeavoured to teach the King that he was above the law, and rigged elections to Parliament. The remedies they proposed were political: they advocated reclamation of the King's land so that he might live off his own, the removal of his corrupt councillors, and improved methods of collecting taxes. Lord Saye and Sele, the treasurer, and Crowmer, sheriff of Kent, were singled out for special attack and were captured and executed after a military victory by Cade's forces near Sevenoaks. At the end of June the rebels brutally murdered Bishop Ayscogh of Salisbury, a friend of Suffolk. The revolt was put down in early July by troops under Lord Scales. He seized London Bridge from the rebels, and with the capture at Rochester of Cade, mortally wounded, the rebellion was over.

The beginning of the Wars of the Roses. Cade's rebellion was the signal for the beginning of the so-called Wars of the Roses—the struggle between the Lancastrian and the Yorkist descendants of Edward III for control of the crown and of local government. Richard, duke of York and heir apparent, claimed under two lines of descent. His mother was great-granddaughter of Lionel, duke of Clarence, second son of Edward III. His father was son of Edmund of Langley, duke of York, fourth son of Edward III. According to feudal principle he had a better hereditary right than anyone of the Lancastrian line. Henry VI was great-grandson to John of Gaunt, duke of Lancaster, third son of Edward III.

The Duke of York's claim to the throne

Richard returned from Ireland with 4,000 men in 1450 to assert his right to participate in the King's council and to counter the machinations of the court party, especially Edmund, duke of Somerset. Somerset was recalled from France to meet Richard's charges. In the Parliament of 1450 Richard supported a measure for rigorous reclamation of the King's grants, and Thomas Young, member of the Commons from Bristol, urged the recognition of Richard as heir apparent. Young was committed to the Tower, and Richard was not called to the council until 1453. That August the King fell into insanity. The Queen and the court party attempted to conceal this, but in March 1454 Richard was made protector; he represented himself as leader of a reform faction. Early in 1455 Henry recovered his wits. During Henry's illness, on October 13, 1454, there had been born to him a son, Edward; this changed the balance of politics because Richard of York was no longer the heir apparent.

Richard went north to gather his forces, alleging that he could not safely attend a council summoned to meet at Leicester without the support of his troops. He met the King near St. Albans and first tried to prefer his charges against Somerset. But the King would neither listen nor

Battle of St. Albans

have those whom Richard designated as traitors arrested. A brief battle followed, and York's forces, larger than the King's, won a decisive victory. As a result, a Yorkist regime was set up with York as constable of England and the Earl of Warwick, emerging as the strong support of the Yorkist cause, as captain of Calais. Somerset was killed in the battle and was succeeded in the title by his son, Henry. The King fell ill again in the autumn of 1455, and York was again protector for a brief period; the King recovered early in 1456.

Hostilities were renewed in 1459. The Yorkists were defeated at Ludford Bridge, giving the Lancastrians an opportunity to recover their influence. The latter failed to meet the challenge. Demands for money, purveyances, and commissions of array increased the burdens but not the benefits of Lancastrian rule. A brief battle at Northampton on July 10, 1460, went overwhelmingly for the Yorkists, and the King was captured. Parliament was summoned to meet at Westminster on October 7. There Richard showed unwarranted self-confidence; he put his hand on the cushion of the empty throne as if he intended to sit there. When the Archbishop asked if he wanted to see the King, Richard replied with a claim to the realm of England as heir to Richard II. The Commons and judges refused to consider a matter so high, leaving it to the Lord's decision. During the fortnight of debate, the Lancastrians had an opportunity to re-form their forces. When Richard finally met them at Wakefield (December 30) in Yorkshire, he was defeated and killed.

The death of York

The Yorkist cause would have been lost if not for Richard's son, Edward, earl of March, who defeated the Lancastrian forces at Mortimer's Cross (February 3, 1461) and marched on to an enthusiastic reception in London. The Lancastrians retreated northward. At Towton Moor on March 29, Edward won a victory that put the Lancastrians decisively to flight into Scotland. Edward was crowned king on June 28, but he dated his reign from March 4, the day the London citizens and soldiers recognized his title as king.

EDWARD IV (1461–70 AND 1471–83)

During the early years of his reign, from 1461 to 1470, Edward was chiefly concerned with putting down the opposition to his rule. He was occupied with trying to keep order and defeating Lancastrian plots against him. He was also involved with France and with Burgundy because Margaret of Anjou's chief hope of recovering Lancastrian fortunes lay in the support of the French king; but Louis XI was miserly in his aid to Margaret. Edward's main internal problem lay in his relations with Warwick, who had been his chief supporter in 1461.

Warwick, the "Kingmaker"

Richard Neville, earl of Warwick and Salisbury, called the "Kingmaker," was cousin to the King and was related to much of the English nobility. But Edward refused to let himself be dominated, particularly with respect to his marriage. When the crucial moment came in Warwick's negotiations for the French king's sister-in-law, Edward disclosed his secret marriage in 1464 to Elizabeth Woodville, a commoner. In addition, Edward conducted his own negotiations for the marriage of his sister, Margaret, to Charles the Bold of Burgundy in 1467. Warwick now allied himself with the Duke of Clarence, Edward's younger brother, basing the alliance in part on the marriage to Clarence of Warwick's daughter, Isabel; but he seemed to have no clear objective except to re-establish his authority with Edward. Ultimately, through the machinations of Louis XI, Warwick joined forces with Margaret of Anjou, deposed Edward in October 1470, and brought back Henry VI. The old king was from time to time exhibited to the London citizens in worn and unregal clothing, while Warwick conducted the government. Edward went into a brief exile in the Netherlands, but with the help of his brother-in-law, Charles, duke of Burgundy, he recovered his throne in the spring of 1471. Henry VI was put to death in the Tower, and his son was killed in battle.

The second half of Edward's reign, 1471–83, was a period of relative order, peace, and security. A council with extensive judicial and military powers was set up to govern the marches of Wales on behalf of the Prince of Wales; and Edward's brother, Richard of Gloucester, ruled ably in the north, presiding over a council that became the model for the Tudor Council of the North. Edward was popular. He levied few subsidies; in fact, he called Parliament only six times during his 25-year reign, and Parliament made only four grants of direct taxes. Early in his reign Edward had agreed to acts of resumption of royal estates, and he had also invested his personal fortune in trade; he thus had a considerable personal income, which allowed him more independence of parliamentary grants than his predecessors. Nonetheless, he levied benevolences, or supposedly voluntary gifts, from his subjects. In 1475 he took an army to France, but he accepted a pension from the King of France for not fighting. This increased Edward's financial independence and enabled him to leave a sizable fortune to his son. "False, fleeting, perjured Clarence," his eldest living brother, was attainted in Parliament in 1478 for involvement in a plot to depose Edward (Louis XI had planned for Clarence to marry Mary of Burgundy, the greatest hieress in Christendom, to stir up enmity between the two brothers). Clarence died in the Tower in 1478, reportedly executed by drowning in his bath.

Edward died in 1483, at age 40, worn out, it was said, by his sexual excesses. He left two sons, Edward and Richard, to the protection of his brother Richard, duke of Gloucester, although young Edward was actually at Ludlow with Earl Rivers, his maternal grandfather. After a series of skirmishes with the Queen's party, the Duke domiciled both young princes in the Tower. The Queen took sanctuary in Westminster Abbey; her father and a brother were arrested and later killed. Young Edward's coronation was set for June 24. Meanwhile, Richard eliminated those who opposed his function as protector and defender of the realm and guardian to the young King. Eventually, even William, Lord Hastings, who had sent Richard word of Edward IV's death and had warned him against the Queen's party, was accused of treachery and summarily executed. Then on the day after the date originally set for Edward V's coronation, Lords and Commons summoned to Parliament unanimously adopted a petition requesting Richard to take over the crown and royal dignity. Richard accepted and rode to Westminster to sit on the royal throne in the King's Bench. Richard was crowned on July 6, taking the oath in English.

Accession of Richard III

RICHARD III (1483–85)

Richard was readily accepted no doubt because of his reputed ability and because people feared the insecurity of a long minority. The tide began to turn against him, however, in October 1483, when it began to be rumoured that he had murdered or connived at the murder of his nephews. Whether this was true or not mattered less than that it was thought to be true and that it obscured the King's able governance during his brief tenure of the royal estate. Legislation against benevolences and protection for English merchants and craftsmen did little to counteract his reputation as a treacherous friend and a wicked uncle; and in the summer of 1485, when Henry Tudor, Lancastrian claimant to the throne, landed at Milford Haven, Richard's supporters widely deserted him and he was defeated and killed at the Battle of Bosworth Field.

ENGLAND IN THE LATE MIDDLE AGES

Bosworth Field has traditionally been taken as the date of the end of the Middle Ages in English history. Recently, however, a strong case has been made for setting the division between medieval and modern at 1536 or 1540. Henry Tudor did not bring to England any unique concept of monarchy, nor did he bring new order and peace to the country until toward the end of his reign. Yet he was the first of a dynasty under which, in the course of a century, English society and culture took on the peculiarly national characteristics that account for England's place in the modern world.

The emergence of the English nationality

The outstanding change in late medieval England was the emergence of an English nationality, largely because of the adoption of English as the language not only of everyday speech but also of documents and literature. An attempt as early as 1362 to legislate English into use in the law courts failed because the lawyers contended that they could not accurately plead in English. But in spite of this failure, English began to creep into public documents and records, including a City of London proclamation in 1384, Henry of Lancaster's claiming of the throne in 1399, royal letters of Henry V, some parliamentary petitions, and some 15th-century chronicles. Chaucer wrote his great work in English, and 15th-century writers followed his example, even though there was as yet no standard form of the language. The printer William Caxton set up his press in 1476 to publish English works for the growing reading public.

Sir Thomas More estimated, perhaps optimistically, that in his time (the early 16th century) more than half the people of England could read. The 15th century was a great period in the foundation of song schools, English reading schools, grammar schools, and colleges. Some schools were set up as adjuncts to chantries, some by guilds or by collegiate churches. Henry VI founded Eton College in 1440 and King's College in the University of Cambridge in 1441. His wife founded Queens' College in 1448. St. Catharine's was founded in 1473. By midcentury Lincoln, All Souls, and Magdalen had all been founded at Oxford.

The academies of English law (*i.e.*, the Inns of Court) expanded their membership and systematized their teaching of the law in this period. Many gentlemen's sons became members of the inns though not necessarily lawyers; many attended to learn the rudiments of the law in order to be able to defend and extend their estates. Two lawyers—Sir John Fortescue and Sir Thomas Littleton—wrote treatises on law and government that are studied down to the present day. Fortescue, a Lancastrian supporter, wrote while in exile a book in Latin in praise of English law; later, returning to England, he wrote in English a book titled *The Governance of England*. Littleton wrote in law French a learned treatise on tenures.

Change in the economy

Basic to all social change in the 15th century was change in the economy. Though England remained a predominantly agrarian society, it had begun to manufacture woollen cloth, which by the end of the 15th century had become an important source of wealth and a major export. As early as the 13th century the woollen industry had begun moving from the guild-ridden towns to the country, where waterpower could be harnessed. This movement had by the 15th century reduced the population of many formerly prosperous towns and contributed to the growth of new villages and towns. Oxford, Winchester, and Lincoln, for example, declined; Halifax and Leeds grew at the expense of York, and the West Riding at the expense of the eastern parts of Yorkshire; Suffolk and the Cotswolds region became important in the national economy.

In England's agrarian society, towns remained intricately involved with the countryside surrounding them. Land was still the most conspicuous form of wealth, and even money gained by trade or by plunder and rich ransons in war was invested in land. But land ceased to be the main basis of feudal relationships. Money fiefs, in the form of annual stipends, increasingly took the place of landed fiefs in interconnections among the ruling classes. A great lord's power was no longer judged by the number of landed vassals who owed him service but by the number of liveried retainers he could call out to accompany him on important journeys. Contracted by indenture, a great man's retinue could be used to intimidate sheriffs or other local officers, to "labour" juries (to use prestige or force to persuade a jury to a verdict), and to assert rights of possession over land. This late medieval feudalism in England has been called bastard feudalism, because instead of acting as a substitute for public power in maintaining order it became on the part of the powerful lord a means of subverting it. When public power was weak, as it was in the latter part of Henry VI's reign, great lords implemented their rivalries in struggles for control of land and local offices.

On the lower social levels, villein labour service largely disappeared and serfdom or villeinage declined. Many serfs had taken up holdings deserted by victims of the Black Death at advantageous terms; others had escaped into the agrarian wage-labour force or taken refuge in towns. By the end of the 14th century many landlords had begun to see their best interest in letting out demesne lands formerly cultivated by villein or wage labour to tenants who would pay them a settled rent. Copyhold tenure (tenure by copy of the record of the manorial court) replaced villein tenure. In a time of falling prices, leaseholders were not necessarily better off financially than they had been as villeins, but they probably had more food. There was an active land market among peasants, some of whom managed to rise above their neighbours and began to constitute a class called yeomen. By the end of the 15th century villein status had ceased to have any importance.

Scholars disagree about what happened to the level of population in the century after the Black Death. An increase in the level of wages in a time of declining prices, extending well into the 15th century, can best be explained by a decline in population. But population figures for particular regions raise questions about this generalization. Part of the difficulty arises because there was in some areas a change in land use. Many landlords solved the problem of labour shortage and decline of food prices by converting their holdings to sheep pasture; this often involved displacement of peasant agriculturists. Some peasant cultivators also converted their lands to pasture. More land was enclosed for sheep pasture in the north, and there was a shift of population density to the southwest and southeast.

The main development in England's trade in the late Middle Ages was the increasing participation of Englishmen and the shift from trade in raw wool to trade in woollens. Edward III ruined the Italian bankers by failing to repay loans for conduct of the war. He then gave English merchants a monopoly of the wool export in return for their support. Many of these merchants were also ruined, but families like the de la Poles of Hull made lasting fortunes and eventually joined the ranks of the nobility. The Merchants of the Staple, who held a monopoly on raw wool exports, were more or less permanently established at Calais from the mid-14th century. As the cloth trade grew, a new association, the Merchant Adventurers, grew in power and wealth. Their chief export was cloth, and their chief market was the Netherlands, where they had their headquarters. In spite of xenophobia in England, which led to outbreaks in London against foreign merchants, the Italians reached their zenith of prosperity in Yorkist England, and Edward IV had to make important concessions to the Hanseatic merchants who helped him regain his throne in 1471.

Art and architecture in the 15th century

Culturally, in the 15th century monastic chronicles came to an end and the writing of history declined. Thomas Walsingham (died 1422) was the last of the St. Albans chroniclers. There were some English chronicles written by citizens of London, and two lives of Henry V, but no great work of history came until later. Neither were there great works of philosophy or theology, although Reginald Pecock wrote an English treatise against the Lollards and various other works emphasizing the rational element in the Christian faith; he was judged guilty of heresy for his pains. No great poets succeeded to Chaucer, perhaps partly because there was no standard English language in which to express thought. The influence of the Italian Renaissance scarcely affected England before 1485. The full impact of the new learning was not felt until the 16th century.

In architecture alone, England showed originality. The 15th century was a great period of building of parish churches. Especially in the areas where the woollen industry had produced wealth, large churches were built in the peculiarly English Perpendicular style. The tomb of Richard Beauchamp at Warwick and King's College Chapel in Cambridge show what heights could be

reached in English architecture and sculpture in the period.

England in the 15th century presents a confused picture politically and socially, and the economy is still something of an enigma. But as more work is done to elucidate their mysteries, these "scrambling and unquiet times" seem to promise a rich period to come. (M.Has.)

VII. England under the Tudors, 1485–1603

HENRY VII (1485–1509)

When the Lancastrian Henry Tudor, earl of Richmond, seized the throne on August 22, 1485, leaving the Yorkist Richard III dead upon the field of battle, few Englishmen would have predicted that 118 years of Tudor rule had begun. Eight sovereigns had come and gone, and at least 15 major battles had been fought between rival contenders to the throne since that moment in 1399 when the divinity that "doth hedge a king" was violated and Richard II was forced to abdicate. Simple arithmetic forecast that Henry VII would last no more than a decade. Bosworth Field appeared to be nothing more than another of the erratic swings of the military pendulum in the struggle between the houses of York and Lancaster, and further evidence that the English crown had become a political football to be kicked about by overmighty magnates who captained semimercenary armies financed largely by foreign sources. What gave Henry Tudor victory in 1485 was not so much personal charisma as the fact that key noblemen deserted Richard III at the moment of his greatest need, that Thomas Stanley, 2nd Baron Stanley (later 1st earl of Derby), and his brother, Sir William, stood aside during most of the battle in order to be on the winning team, and that Louis XI of France supplied the Lancastrian forces with 1,000 mercenary troops.

The weakness of Henry's claim to the throne

The desperateness of the new monarch's gamble was equalled only by the doubtfulness of his claim. Henry VII's Plantagenet blood was tainted by bastardy, for he was descended on his mother's side from the Beaufort family, the offspring of John of Gaunt and his mistress Catherine Swynford, and though their children had been legitimized by act of Parliament, they had been specifically barred from the succession. His father's genealogy was equally suspect: Edmund Tudor, earl of Richmond, was born to Catherine of Valois, widowed queen of Henry V, by her clerk of the wardrobe, Owen Tudor; and the precise marital status of their relationship has never been established. Had quality of Plantagenet blood, not military conquest, been the essential condition of monarchy, Edward, earl of Warwick, the ten-year-old nephew of Edward IV, would have sat upon the throne. Might, not soiled right, had won out on the high ground at Bosworth Field, and Henry VII claimed his title by conquest. The new king, however, wisely sought to fortify his doubtful genealogical pretension first by parliamentary acclamation and then by royal marriage. The Parliament of November 1485 did not confer regal power on the first Tudor monarch—victory in war had already done that; but it did acknowledge Henry as "our new sovereign lord." Then on January 18, 1486, Henry of Lancaster married Elizabeth of York, the eldest daughter of Edward IV, thereby uniting "the white rose and the red" and launching England upon a century of "smooth-fac'd peace with smiling plenty and fair prosperous days."

"God's fair ordinance," which Shakespeare and later generations so clearly observed in the events of 1485–86, was not limited to military victory, parliamentary sanction, and a fruitful marriage; the hidden hand of economic, social, and intellectual change was also on Henry's side. The day was coming when the successful prince would be more praised than the heroic monarch and the solvent sovereign more admired than the pious one. Henry Tudor was probably no better or worse than the first Lancastrian, Henry IV; they both worked diligently at their royal craft and had to fight hard to keep their crowns; but the seventh Henry achieved what the fourth had not—a secure and permanent dynasty—because England in 1485 was moving into a period of unprecedented economic growth and social change.

Economy and society. Long before 1485 the kingdom had begun to recover from the demographic catastrophe of the Black Death and the agricultural depression of the late 14th century; but as the 15th century came to a close, the rate of revival increased. The population in 1400 may have dropped as low as 2,500,000; by 1500 it was back up to at least 3,000,000, and a century later it was over 4,000,000. More people meant more mouths to feed, more backs to cover, and more vanity to satisfy. In response, yeoman farmers, gentleman sheep growers, urban cloth manufacturers, and merchant adventurers produced a social and economic revolution. With extraordinary speed the export of raw wool gave way to the export of woollen cloth manufactured at home, and the wool clothier or entrepreneur was soon buying fleece from sheep raisers, transporting the wool to cottagers for spinning and weaving, paying the farmer's wife and children by the piece, and collecting the finished article for shipment to Bristol, London, and eventually Europe. By the time Henry VII seized the throne, the Merchant Adventurers, an association of London wool exporters, were controlling the London–Antwerp market, replacing in economic importance the Staplers who dealt in raw wool. By 1496 they were a chartered organization with a legal monopoly of the woollen cloth trade, and largely as a consequence of their political and international importance, Henry successfully negotiated the Intercursus Magnus, a highly favourable commercial treaty between England and the Low Countries.

Revolution in the wool industry

As landlords increased the size of their flocks to the point that ruminants outnumbered human beings three to one, and as clothiers such as John Winchcombe (better known as Jack of Newbury) grew so rich that they could afford to entertain kings, inflation injected new life into the economy. England was caught up in a vast European spiral of rising prices, declining real wages, and cheap money. Inflation was largely the result of the growing abundance of gold and silver that flooded in upon the European economy from the New World and drove down the value and purchasing power of the traditional coinage, forcing up the cost of services and supplies. Between 1500 and 1540 prices in England doubled, and they doubled again in the next generation. In 1450 the cost of wheat had been what it was in 1300; by 1550 it had tripled.

Inflation and the wool trade together created an economic and social upheval. Land plenty, labour shortage, low rents, and high wages, which had prevailed throughout the early 15th century as a consequence of economic depression and reduced population, were replaced by land shortage, labour surplus, high rents, and declining wages. The landlord, who a century before could find neither tenants nor labourers for his land and had left his fields fallow, could now convert his meadows into sheep runs. His rents and profits soared; his need for labour declined, for one shepherd and his dog could do the work of half a dozen men who had previously tilled the same field. Slowly the medieval system of land tenure and communal farming broke down. The common land of the manor was divided up and fenced in, and the peasant farmer who held his tenure either by copy (a document recorded in the manor court) or by unwritten custom was evicted. The total extent of enclosure and eviction is difficult to assess, but between 1455 and 1607 in 34 counties 516,573 acres (208,954 hectares), or 2.76 percent of the total, were enclosed, and some 50,000 persons were forced off the land. Statistics, however, are deceptive both as to emotional impact and extent of change. The most disturbing aspect of the land revolution was not the emergence of a vagrant and unemployable labour force for whom society felt no social responsibility but an unprecedented increase in what men feared most—change. Farming techniques were transformed, the gap between rich and poor increased, the timeless quality of village life was upset, and on all levels of society old families were being replaced by new.

Enclosures

The beneficiaries of change, as always, were the most grasping, the most ruthless, and the best educated segments of the population: the landed country gentlemen

and their socially inferior cousins, the merchants and lawyers. By 1500 the essential economic basis for the landed country gentleman's future political and social ascendancy was taking shape—the 15th-century knight of the shire was changing from a desperate and irresponsible land proprietor, ready to support the baronial feuding of the Wars of the Roses, into a respectable landowner desiring strong, practical government and the rule of law. The gentry did not care whether Henry VII's royal pedigree could bear close inspection; their own lineage was not above suspicion, and they were willing to serve the prince "in parliament, in council, in commission and other offices of the commonwealth."

Dynastic threats. It is no longer fashionable to call Henry VII a "new monarch," and indeed if the first Tudor had a model for reconstructing the monarchy it was the example of the great medieval kings. Newness, however, should not be totally denied Henry Tudor; his royal blood was very "new," and the extraordinary efficiency of his regime introduced a spirit into government that had rarely been present in the medieval past. It was, in fact, "newness" that governed the early policy of the reign, for the Tudor dynasty had to be secured and all those with a better or older claim to the throne liquidated. Elizabeth of York was deftly handled by marriage; the sons of Edward IV had already been removed from the list, presumably murdered by their uncle Richard III; the Earl of Warwick was promptly imprisoned; but the descendants of Edward IV's sister and daughters remained a threat to the new government. Equally dangerous was the persistent myth that the younger of the two princes murdered in the Tower had escaped his assassin and that the Earl of Warwick had escaped his jailers. The existence of pretenders acted as a catalyst for further baronial discontent and Yorkist aspirations, and in 1487 John de la Pole, a nephew of Edward IV by his sister Elizabeth, with the support of 2,000 mercenary troops paid for with Burgundian gold, landed in England to support the pretensions of Lambert Simnel, who passed himself off as the authentic Earl of Warwick. Again Henry Tudor was triumphant in war; at the Battle of Stoke, de la Pole was killed and Simnel captured and demoted to a scullery boy in the royal kitchen. Ten years later Henry had to do it all over again, this time with a handsome Flemish lad named Perkin Warbeck, who for six years was accepted in Yorkist circles in Europe as the real Richard IV, brother of the murdered Edward V. Warbeck tried to take advantage of Cornish anger against heavy royal taxation and increased government efficiency and sought to lead a Cornish army of social malcontents against the Tudor throne. It was a measure of the new vigour and popularity of the Tudor monarchy, as well as the support of the gentry, that social revolution and further dynastic war were total failures, and Warbeck found himself in the Tower along with the Earl of Warwick. In the end both men proved too dangerous to live, even in captivity, and in 1499 they were executed.

The threats of pretenders

The policy of dynastic extermination did not cease with the new century. Under Henry VIII, the Duke of Buckingham was destroyed in 1521; the Earl of Warwick's sister, the Countess of Salisbury, was beheaded in 1541 and her descendants harried out of the land; and in 1546 the poet Henry Howard, earl of Surrey, the grandson of Buckingham, was put to death. By the end of Henry VIII's reign the job had been so well done that the curse of Edward III's fecundity had been replaced by the opposite problem—the Tudor line proved to be infertile when it came to producing healthy male heirs. Henry VII sired Arthur, who died in 1502, and Henry VIII in turn produced only one legitimate son, Edward VI, who died at the age of 16, thereby ending the direct male descent.

Financial policy. It was not enough for Henry VII to secure his dynasty; he also had to re-establish the financial credit of his crown and reassert the authority of royal law. Feudal kings had traditionally lived off four sources of nonparliamentary income: rents from the royal estates, revenues from import and export taxes, fees from the administration of justice, and moneys extracted on the basis of a vassal's duty to his overlord. The first Tudor was no different from his Yorkist or medieval predecessors; he was simply more ruthless and successful in demanding every penny that was owed him. Henry's first move was to confiscate all the estates of Yorkist adherents and to restore all property over which the crown had lost control since 1455 (in some cases as far back as 1377). To these essentially statutory steps he added efficiency of rent collection. In 1485 income from crown lands had totalled £29,000; by 1509 land revenues had risen to £42,000 and the profits from the Duchy of Lancaster had jumped from £650 to £6,500. At the same time, the Tudors profited from the growing economic prosperity of the realm, and custom receipts rose from over £20,000 to an average of £40,000 by the time Henry died.

Henry's sources of revenue

The increase in custom and land revenues was applauded, for it meant fewer parliamentary subsidies and fitted the medieval formula that kings should live on their own, not parliamentary, income. But the collection of revenues from feudal sources and from the administration of justice caused great discontent and earned for Henry his reputation as a miser and extortionist. Generally, Henry demanded no more than his due as the highest feudal overlord, and a year after he became sovereign he established a commission to look into land tenure to discover who held property by knight's fee—that is, by obligation to perform military services. Occasionally he overstepped the bounds of feudal decency and abused his rights. In 1504, for instance, he levied a feudal aid (tax) to pay for the knighting of his son—who had been knighted 15 years before and had been dead for two. Henry VIII continued his father's policy of fiscal feudalism, forcing through Parliament in 1536 the Statute of Uses to prevent landowners from escaping "relief" and wardship (feudal inheritance taxes) by legal trickery and establishing the Court of Wards and Liveries in 1540 to handle the profits of feudal wardship. The howl of protest was so great that in 1540 Henry VIII had to compromise, and by the Statute of Wills a subject who held his property by knight's fee was permitted to bequeath two-thirds of his land without feudal obligation.

To fiscal feudalism Henry VII added rigorous administration of justice. As law became more effective it also became more profitable, and the policy of levying heavy fines as punishment upon those who dared break the king's peace proved to be a useful whip over the mighty magnate and a welcome addition to the King's exchequer. Even war and diplomacy were sources of revenue, and one of the major reasons why Henry VII wanted his second son, Henry, to marry his brother's widow was that the King was reluctant to return the dowry of 200,000 crowns that Ferdinand and Isabella of Spain had given for the marriage of their daughter, Catherine of Aragon. Generally Henry believed in a good neighbour policy—alliance with Spain by the marriage of Arthur and Catherine in 1501 and peace with Scotland by the marriage of his daughter Margaret to James IV in 1503—on the grounds that peace was cheap and trade profitable. In 1489, however, he was faced with the threat of the union of the Duchy of Brittany with the French crown; and England, Spain, the empire, and Burgundy went to war to stop it. Nevertheless, as soon as it became clear that nothing could prevent France from absorbing the duchy, Henry negotiated the unheroic but financially rewarding Treaty of Étaples in 1492, whereby he disclaimed all historic rights to French territory (except Calais) in return for an indemnity of £159,000. By fair means or foul, when the first Tudor died, his total nonparliamentary annual income had risen at least twofold and stood in the neighbourhood of £113,000 (some estimates are as high as £142,000). From land alone the King received £42,000, while the greatest landlord in the realm had to make do with less than £5,000; economically speaking, there were no longer any overmighty magnates.

Income from the law courts and from marriage arrangements

The administration of justice. Money could buy power, but really successful kings, be they medieval or Tudor, had to earn the respect of their subjects by enforcing and administering the law. The problem for Henry VII

was not to replace an old system of government with a new—no Tudor was consciously a revolutionary—but to make the ancient system work tolerably well. He had to tame but not destroy the nobility, develop organs of administration directly under his control, and wipe out provincialism and privilege wherever they appeared. In the task of curbing the old nobility, the King was immeasurably helped by the high aristocratic death rate during the Wars of the Roses; but where war left off, policy took over. Within three years of Bosworth Field, Thomas Howard, earl of Surrey, who had fought for Richard III, was liberated from the Tower of London and his estates restored; six years later Sir William Stanley, whose betrayal of Richard had helped Henry win his crown, was executed for high treason. The former was willing to become a devoted Tudor workhorse; the latter persisted in the anachronistic code of the divine right of nobility. Commissions of Array composed of local notables were appointed by the crown for each county in order to make use of the power of the aristocracy in raising troops but to prevent them from maintaining private armies (livery) with which to intimidate justice (maintenance) or threaten the throne.

Previous monarchs had sought to enforce the laws against livery and maintenance, but the first two Tudors, though they never totally abolished such evils, built up a reasonably efficient machine for enforcing the law, based on the historic premise that the king in the midst of his council was the fountain of justice. Traditionally the royal council had heard all sorts of cases, and very rapidly its members began to specialize. The Court of Chancery had for years dealt with civil offenses, the Court of Star Chamber evolved to handle criminal cases, the Court of Requests for poor men's suits, and the Court of Admiralty to cope with piracy. The process by which the conciliar courts developed was largely accidental, and the Court of Star Chamber acquired its name from the star-painted ceiling of the room in which the councillors sat, not from the statute of 1487 that simply recognized its existence. Conciliar justice was popular because the ordinary courts where common law prevailed were slow, cumbersome, favoured the rich and mighty, and tended to break down when asked to deal with riot, maintenance, livery, perjury, and fraud. The same search for efficiency applied to matters of finance. The traditional fiscal agency of the crown, the exchequer, was burdened down with archaic procedures and restrictions, and Henry VII turned to the more intimate and flexible departments of his personal household—specifically to the treasurer of the chamber, whom he could supervise directly—as the central tax-raising, rent-collecting, and money-disbursing segment of government.

Conciliar government

The Tudors sought to enforce law in every corner of their kingdom, and step by step the blurred medieval profile of a realm shattered by semi-autonomous franchises, in which local law and custom were obeyed more than the king's law, was transformed into the clear outline of a single state filled with loyal subjects obeying the king's decrees. By 1500 royal government had been extended into the northern counties and Wales by the creation of a Council of the North and a Council for the Welsh Marches. The Welsh principalities had always been difficult to control, and it was not until 1536 that Henry VIII brought royal law directly into Wales and incorporated the 136 self-governing lordships into a greater England with five new shires.

If the term "new monarchy" was inappropriate in 1485, the same cannot be said for the year of Henry VII's death, for when he died in 1509, after 24 years of reign, he bequeathed to his son something quite new in English history: a safe throne, a full treasury, a solvent government, a prosperous land, and a united kingdom. Only one vital aspect of the past remained untouched, the independent Catholic Church, and it was left to the second Tudor to destroy this remaining vestige of medievalism.

Henry VII's achievements

HENRY VIII (1509–47)

Cardinal Wolsey. A prince of 18 inherited his father's throne, but the son of an Ipswich butcher carried on the first Tudor's administrative policies. While the young sovereign enjoyed his inheritance, Thomas Wolsey collected titles—archbishop of York in 1514, lord chancellor and cardinal legate in 1515, and papal legate for life in 1524. He exercised a degree of power never before wielded by king or minister, for as lord chancellor and cardinal legate he united in his portly person the authority of church and state. He sought to tame both the lords temporal and spiritual, administering to the nobility the "new law of the Star Chamber," protecting the rights of the underprivileged in the poor men's Court of Requests, and teaching the abbots and bishops that they were subjects as well as ecclesiastical princes. Long before Henry assumed full power over his subjects' souls as well as their bodies, his servant had marked the way. The cardinal's administration, however, was stronger on promise than performance, and for all his fine qualities and many talents he exposed himself to the accusation that he prostituted policy for pecuniary gain and personal pride. Together, the King and Cardinal plunged the kingdom into international politics and war and helped make England one of the centres of Renaissance learning and brilliance; had Henry VIII died before 1529 he would have had to share the accolades with his chief minister. The King, however, lived on for 17 crucial years, and three interrelated factors brought Wolsey's career to an end—England's weakness as an international power, Henry's "Great Matter," and the growth of heresy.

Foreign policy

Both the sovereign and his chief servant overestimated England's international position in the continental struggle between Francis I of France and the emperor Charles V. Militarily, the kingdom was of the same magnitude as the papacy—the English king had about the same revenues and could field about the same size army—and, as one contemporary noted, England with its back door constantly exposed to Scotland and with its economy dependent upon the Flanders wool trade was a mere "morsel among those choppers" of Europe. Nevertheless, Wolsey's diplomacy was based on the expectation that England could swing the balance of power either to France or to the empire and by holding that position could maintain the peace of Europe. The hollowness of the cardinal's policy was revealed in 1525 when Charles disastrously defeated and captured Francis at the Battle of Pavia. Italy was overrun with the Emperor's troops, the Pope became an imperial chaplain, all of Europe bowed before the conqueror, and England sank from being the fulcrum of continental diplomacy to the level of a second-rate power just at the moment when Henry had decided to rid himself of his wife, the 42-year-old Catherine of Aragon.

The divorce question. It is still a subject of debate whether Henry's decision to seek an annulment of his marriage and wed Anne Boleyn was a matter of state, of love, or of conscience. Quite possibly all three operated; Catherine was fat, seven years her husband's senior, incapable of bearing further children, and Anne was everything that the Queen was not—pretty, vivacious, and fruitful. Catherine had produced only one child and that was a girl, Princess Mary, and it semed ironic indeed that the first Tudor should have solved the question of the succession only to expose the kingdom to an even greater peril in the second generation: a female ruler. The need for a male heir was paramount, for the last queen of England, Matilda, in the 12th century, had been a disaster, and there was no reason to believe that another would be any better. Finally, there was the question of the King's conscience. Henry had married his brother's widow, and though the Pope had granted a dispensation, the fact of the matter remained that every male child born to Henry and Catherine had died, and it was clearly written in Leviticus: "If a man takes his brother's wife, it is impurity; he has uncovered his brother's nakedness, they shall be childless" (20:21).

Unfortunately, Henry's divorce was not destined to stand or fall upon the theological issue of whether a papal dispensation could set aside such a prohibition, for Catherine was not simply the King's wife, she was also the aunt of the emperor Charles V, the most powerful

sovereign in Europe. Both Henry and his cardinal knew that the divorce would never be granted unless the Emperor's power in Italy could be overthrown by an Anglo-French military alliance and the Pope rescued from imperial domination, and for three years Wolsey worked desperately to achieve this diplomatic and military end. Caught between an all-powerful emperor and a truculent English king, Clement VII procrastinated and offered all sorts of doubtful solutions short of divorce, including the marriage of Princess Mary and the King's illegitimate son, Henry Fitzroy, duke of Richmond; the legitimizing of all children begotten of Anne Boleyn; and the suggestion that Catherine go into a nunnery so that the King could be given permission to remarry. Wolsey's purpose was to have the divorce trial held in London, but in 1529, despite the arrival of Cardinal Lorenzo Campeggio to set up the machinery for a hearing, Wolsey's plans exploded. In July the Pope ordered Campeggio to transfer the case to Rome, where a decision against the King was a foregone conclusion; and in August Francis and the Emperor made peace at the Treaty of Cambrai. Wolsey's policies were a failure, and he was dismissed from office in October 1529. He died on November 29, just in time to escape trial for treason.

The fall of Wolsey

The Reformation background. Henry now began groping for new means to achieve his purpose. At first he contemplated little more than blackmail to frighten the Pope into submission; but slowly, reluctantly, and not realizing the full consequences of his actions, he moved step by step to open defiance and a total break with Rome. Wolsey in his person and his policies had represented the past. He was the last of the great ecclesiastical statesmen who had been as much at home in the cosmopolitan world of European Christendom, with its spiritual centre in Rome, as in a provincial capital such as London. By the time of Henry's divorce, Christendom was dissolving. Not only were feudal kingdoms assuming the character of independent nation-states but the spiritual unity of Christ's seamless cloak was also being torn apart by heresy. Possibly Henry would never have won his divorce had there not existed in England men who desired a break with Rome, not because it was dynastically expedient but because they regarded the Pope as the "whore of Babylon."

The medieval church had become an anachronism out of touch with the 16th-century reality of changing economic practices, governmental structure, and social values. More and more, God was French or German or English, and his representative in Rome was having ever greater difficulty in speaking so many languages and in persuading his international flock that he was the spiritual leader of all Christians and not simply a petty Italian potentate motivated by family ambition and political aggrandizement. The church was also withering from within. Historically, it was a state within a state—an independent clerical body possessed of special rights and privileges because of the fundamental division of man into body and soul. In the eyes of many, however, the church's duties in matters spiritual had been superseded by matters temporal. Absenteeism and pluralism were rife, and by 1520 in Oxfordshire alone 58 percent of the county's 192 parish priests were absentees. Bishops and high ecclesiastics were meant to tend to the cure of souls, but in fact they were engrossed in worldly affairs. Wolsey himself, as the greatest and richest clerical statesman, seemed to epitomize the worst aspects of that worldliness and corruption. Men continued to go to church, but it was increasingly difficult, especially for the landed gentleman and the wealthy merchant, to respect the old church. A sure sign that zeal for the ancient structure was flagging was the economic decline of the monasteries: in Norfolk, Yorkshire, and Buckinghamshire the capital wealth of the religious foundations rose only 1.13 percent between 1480 and 1540, which was not enough to offset normal depreciation, let alone keep up with inflation. More and more surplus wealth was being directed into other than religious channels; in the 15th century, the wool merchant Thomas Paycocke of Coggeshall had used the proceeds of trade to found a chantry to sing masses for his soul; a century later, William Sanderson of London invested the profits of fishmongering into two small ships to carry Capt. John Davis over the top of the world in search of the Northwest Passage to Cathay.

Abuses within the church

As the old church lived on in a fossilized condition, Christians looked elsewhere for inner contentment, and all over Europe men like Martin Luther, the German monk in Saxony, and Thomas Bilney, the Cambridge scholar in England, sought spiritual meaning and relief from ritualism, worldliness, and religious apathy. Luther in his monastery and Bilney in his college turned to the Bible, and each stumbled across the knowledge that even in the midst of despair, faith in God's mercy could save sinners. The new religious ideas flowed into England largely in the form of Lutheran doctrines, but they found a receptive audience not only because there were upper-class individuals who could find no spiritual satisfaction in the old religious formulas and who were looking for exactly what Luther and Bilney had to offer but also because there existed in England a religious subculture in the form of Lollardy. Its existence was always officially denied by the established church, but the ideas of John Wycliffe (died 1384) had never been exterminated. They lived on just below the surface, and by the time of the Reformation Lollardy was once again becoming respectable. Though Henry himself was never a Protestant, and during the first 20 years of his reign was a zealous persecutor of religious nonconformity, be it Lutheran or Lollard, the King would never have been able to push through the break with Rome simply on the basis of anticlericalism or apathy within the existing church. If his headship of an independent English church was to live in "the hearts of his subjects" and not "post alone hidden in acts of parliament," he had to call upon the support of the "zely people" (Protestant zealots) who viewed the political and constitutional steps by which Henry's divorce was legalized as being the prelude to a thorough spiritual reformation.

Lollardy

The break with Rome. With Wolsey and his papal authority gone, Henry turned to the authority of the state to obtain his divorce, and the so-called Reformation Parliament that first met in November 1529 was unprecedented—it lasted seven years, enacted 137 statutes (32 of which were of vital importance), and legislated in areas that no feudal Parliament had ever dreamed of entering. "King in Parliament" became the revolutionary instrument by which the medieval church was destroyed. The first step was to intimidate the church, and in 1531 Convocation was forced under threat of praemunire (a statute prohibiting the legal and financial jurisdiction of the pope without royal consent) to grant the sovereign a gift of £119,000 and to acknowledge him supreme head of the church "as far as the law of Christ allows." Then the government struck at the papacy, threatening to cut off its revenues; the Annate's Statute of 1532 empowered Henry, if he saw fit, to abolish payment to Rome of the first year's income of all newly installed bishops. The implied threat had little effect on the Pope; and time was running out, for by December 1532 Anne Boleyn was pregnant, and on January 25, 1533, she was secretly married to Henry. If the King was to be saved from bigamy and his child born in wedlock, he had less than eight months to get rid of Catherine of Aragon. Archbishop William Warham conveniently died in August 1532, and in March 1533 a demoralized and frightened pontiff sanctioned the installation of Thomas Cranmer as primate of the English church. Cranmer was a friend of the divorce, but before he could oblige his sovereign the Queen's right of appeal from the archbishop's court to Rome had to be destroyed; and this could be done only by cutting the constitutional cords holding England to the papacy. Consequently, in April 1533 the crucial statute was enacted; the Act of Restraint of Appeals boldly decreed that "this realm of England is an empire." A month later an obliging archbishop heard the divorce case and adjudged the King's marriage to be null and void. On June 1 Anne was crowned rightful queen of England, and three months and a week later, on September 7, 1533, the royal child was born. To "the great shame and con-

Thomas Cranmer and the divorce

fusion" of astrologers, it turned out to be Elizabeth Tudor.

Henry was mortified; he had risked his soul and his crown for yet another girl, but Anne had proved her fertility and it was hoped that a male heir would shortly follow. In the meantime it was necessary to complete the break with Rome and rebuild the Church of England. By the Act of Succession of March 1534, subjects were ordered to accept the King's marriage to Anne as "undoubted, true, sincere and perfect." A second Annate's Statute severed most of the financial ties with Rome, and in November the constitutional revolution was solemnized in the Act of Supremacy, which announced that Henry Tudor was and always had been "Supreme Head of the Church of England"; not even the qualifying phrase "as far as the law of Christ allows" was retained.

The consolidation of the Reformation. The medieval tenet that church and state were separate entities with divine law standing higher than human law had been legislated out of existence; the new English Church was in effect a department of the Tudor state. The destruction of the Catholic Church led inevitably to the dissolution of the monasteries. As monastic religious fervour and economic resources began to dry up, it was easy enough for the government to build a case that monasteries were centres of vice and corruption. In the end, however, what destroyed them was neither apathy nor abuse but the fact that they were contradictions within a national church, for religious foundations by definition were international, supranational organizations that traditionally supported papal authority. Though they bowed to the royal supremacy, the government continued to view them with suspicion, arguing that they had obeyed only out of fear, and their destruction got underway early in 1536. In the name of fiscal reform and efficiency, foundations with endowments of under £200 a year (nearly 400 of them) were dissolved on the grounds that they were too small to do their job effectively. By late 1536 confiscation had become state policy, for the Pilgrimage of Grace Catholic-inspired uprising in the north seemed to be clear evidence that all monasteries were potential nests of traitors. By 1539 the foundations, both great and small, were gone, and property worth possibly £2,000,000 was nationalized and incorporated into the crown lands, thereby almost doubling the government's normal peacetime, nonparliamentary income. Had those estates remained in the possession of the crown, English history might have been very different, for the kings of England would have been able to rule without calling upon Parliament, and the constitutional authority that evolved out of the crown's fiscal dependence on Parliament would never have developed. For better or for worse, Henry and his descendants had to sell the profits of the Reformation; and by 1603 three-fourths of the monastic loot had passed into the hands of the landed gentry. The legend of a "golden shower" is false. Monastic property was never given away at bargain prices, nor was it consciously presented to the kingdom in order to win the support of the ruling elite. Instead, most of the land was sold at its fair market value to pay for Henry's wars and foreign policy. The effect, however, was crucial—the most powerful elements within Tudor society now had a vested interest in protecting their property against papal Catholicism.

The dissolution of the monasteries

The divorce, the break with Rome, and even the destruction of the monasteries went through with surprisingly little opposition. It had been foreseen that the royal supremacy might have to be enacted in blood, and the Act of Supremacy (March 1534) and the Act of Treason (December) were designed to root out and liquidate the dissent. The former was a loyalty test requiring subjects to take an oath swearing to accept not only the matrimonial results of the break with Rome but also the principles on which it stood; the latter extended the meaning of treason to include all those who did "maliciously wish, will or desire, by words or writing or by craft imagine" the King's death or slander his marriage. Sir Thomas More (who had succeeded Wolsey as lord chancellor), Bishop John Fisher (who almost alone among the episcopate had defended Catherine during her trial), and a handful of monks suffered death for their refusal to accept the concept of a national church. Even the Pilgrimage of Grace of 1536–37 was a short-lived eruption. The uprisings in Lincolnshire in October and in Yorkshire during the winter were without doubt religiously motivated, but they were also as much feudal and social rebellions as revolts in support of Rome. Peasants, landed country gentlemen, and feudal barons could unite in defense of the monasteries and the old religion, and for a moment the rebels seemed on the verge of toppling the Tudor state. The nobility were angered that they had been excluded from the King's government by men of inferior social status, and they resented the encroachment of bureaucracy into the northern shires. The gentry were concerned by rising taxes and the peasants by threatened enclosure; but the three elements had little in common outside religion, and the uprisings fell apart from within. The rebels were soon crushed and their leaders—including Robert Aske, one of the most pleasing figures of the century—brutally executed.

The acts of Supremacy and Treason

Henry's last years. Henry was so securely seated upon his throne that the French Ambassador announced that he was more an idol to be worshipped than a king to be obeyed, and the King successfully survived four more matrimonial experiments, the enmity of every major power in Europe, and an international war. On May 19, 1536, Anne Boleyn's career was terminated by the executioner's ax. She had failed in her promise to produce further children to secure the succession. The King's love had turned to hatred, but what sealed the Queen's fate was the death of her rival, Catherine of Aragon, on January 8, 1536. From that moment it was clear that should Henry again marry, whoever was his wife, the children she might bear would be legitimate in the eyes of Catholics and Protestants alike. How much policy, how much repulsion for Anne, how much attraction for Jane Seymour played in the final tragedy is beyond analysis, but 11 days after Anne's execution Henry married Jane. Sixteen months later the future Edward VI was born. The mother died as a consequence, but the father finally had what it had taken a revolution to achieve, a legitimate male heir.

Birth of Edward VI

Henry married thrice more, once for reasons of diplomacy, once for love, and once for peace and quiet. Anne of Cleves, his fourth wife, was the product of Reformation international politics. For a time in 1539 it looked as if Charles V and Francis would come to terms and unite against the schismatic King of England, and the only allies Henry possessed were the Lutheran princes of Germany. In something close to panic, he was stampeded into marriage with Anne of Cleves, but the following year, the moment the diplomatic scene changed, he dropped both his wife and the man who had engineered the marriage, his vicar general in matters spiritual, Thomas Cromwell. Anne was divorced July 12, Cromwell was executed July 28, and Henry married Catherine Howard the same day. The second Catherine did not do as well as her cousin, the first Anne; she lasted only 18 months. Catherine proved to be neither a virgin before her wedding nor a particularly faithful damsel after her marriage. With the execution of his fifth wife, Henry turned into a sick old man, and he took as his last spouse Catherine Parr, who was as much a nursemaid as a wife. During those final years, the King's interests turned to international affairs. Henry's last war (1543–46) was fought not to defend his church against resurgent European Catholicism but to renew a much older policy of military conquest in France. Though he enlarged the English Pale at Calais by seizing the small French port of Boulogne, the war had no lasting diplomatic or international effects except to assure that the monastic lands would pass into the hands of the gentry.

The achievements of Henry VIII

By the time Henry died (January 28, 1547) medievalism had nearly vanished. The crown stood at the pinnacle of its power, able to demand and receive a degree of obedience from both great and small that no feudal monarch had been able to achieve. The measure of that authority was threefold: (1) the extent to which Henry had been

able to thrust a very unpopular divorce and supremacy legislation down the throat of Parliament; (2) his success in raising unprecedented sums of money through taxation; and (3) his ability to establish a new church on the ashes of the old. It is difficult to say whether these feats were the work of the King or his chief minister, Thomas Cromwell. The will was probably Henry's, the parliamentary means his minister's, but whoever was responsible, by 1547 England was a long way along the road of Reformation. The crown had assumed the authority of the papacy without as yet fundamentally changing the old creed, but the ancient structure was severely shaken. Throughout England men were arguing that because the pontiff had been proved false, the entire Catholic creed was suspect; and the cry went up to "get rid of the poison with the author." It was not long before every aspect of Catholicism was under attack—the miracle of the mass whereby the bread and wine were converted into the body and blood of Christ, the doctrine of purgatory, the efficacy of saints and images, the concept of an ordained priesthood with miraculous powers, and the doctrine of the celibacy of the clergy. The time had come for Parliament and the supreme head to decide what constituted the "true" faith for Englishmen. Henry never worked out a consistent religious policy: the Ten Articles of 1536 and the *Bishop's Book* of the following year tended to be somewhat Lutheran in tone; the Six Articles of 1539, or the Act for Abolishing Diversity of Opinion, and the *King's Book* of 1543 were mildly Catholic. Whatever the religious colouring, Henry's ecclesiastical *via media* was based on obedience to an authoritarian old king and on subjects who were expected to live "soberly, justly and devoutly." Unfortunately for the religious, social, and political peace of the kingdom, both these conditions disappeared the moment Henry died and a nine-year-old boy sat upon the throne.

EDWARD VI (1547–53)

Seymour's protectorate

Henry was legally succeeded by his son Edward VI, but power passed to his brother-in-law, Edward Seymour, earl of Hertford, who became duke of Somerset and lord protector shortly after the new reign began. Seymour ruled *in loco parentis;* the divinity of the crown resided in the boy king, but authority was exercised by an uncle who proved himself to be more merciful than tactful, more idealistic than practical. Sweet reason and tolerance were substituted for the old King's brutal laws. The treason and heresy acts were repealed or modified, and the result came close to destroying the Tudor state. The moment idle tongues could speak with impunity, the kingdom broke into a chorus of religious and social discord. To stem religious dissent, the Lord Protector introduced the Prayer Book of 1549 and an act of uniformity to enforce it. Written by Thomas Cranmer, the Prayer Book was a literary masterpiece but a political flop, for it failed in its purpose. It sought to bring into a single Protestant fold all varieties of middle-of-the-road religious beliefs by deliberately obscuring the central issue of the exact nature of the mass—whether it was a miraculous sacrament or a commemorative service. The Prayer Book succeeded only in antagonizing Protestants and Catholics alike.

Somerset was no more successful in solving the economic and social difficulties of the reign. Rising prices, debasement of the currency, and the cost of war had produced an inflationary crisis in which prices doubled between 1547 and 1549. A false prosperity ensued in which the wool trade boomed, but so also did enclosurers with all their explosive potential. The result was social revolution. Whether Somerset deserved his title of "the good duke" is a matter of opinion. Certainly the peasants thought that he favoured the element in the House of Commons that was anxious to tax sheep raisers and curb enclosures and that section of the clergy that was lashing out at economic inequality. In the summer of 1549 the peasantry in Cornwall and Devonshire revolted against the Prayer Book in the name of the good old religious days under Henry VIII, and almost simultaneously the humble folk in Norfolk rose up against the economic and social injustices of the century. At the same time that domestic rebellion was stirring, the protector had to face a political and international crisis, and he proved himself to be neither a far-sighted statesman nor a shrewd politician. He embroiled the country in war with Scotland that soon involved France and ended in total defeat, and he earned the enmity and disrespect of the members of his own council. In the eyes of the ruling elite, he was responsible for governmental ineptitude and social and religious revolution. The result was inevitable: a palace revolution in October 1549 ensued in which Seymour was arrested and deprived of office, and two and a half years later he was executed on trumped-up charges of treason.

The fall of Seymour

The protector's successor and the man largely responsible for his fall was John Dudley, earl of Warwick, who became duke of Northumberland. The Duke was a man of action who represented most of the acquisitive aspects of the landed elements in society and who allied himself with the extreme section of the Protestant reformers. Under Northumberland, England pulled out of Scotland and in 1550 returned Boulogne to France; social order was ruthlessly re-established in the countryside, the more conservative of the Henrician bishops were imprisoned, the wealth of the church was systematically looted, and uncompromising Protestantism was officially sanctioned. The Ordinal of 1550 transformed the divinely ordained priest into a governmental appointee, the new Prayer Book of 1552 was avowedly Protestant, altars were turned into tables, clerical vestments gave way to plain surplices, and religious orthodoxy was enforced by a new and more stringent Act of Uniformity. How long a kingdom still attached to the outward trappings of Catholicism would have tolerated doctrinal radicalism and the plundering of chantry lands and episcopal revenues under Somerset and Northumberland is difficult to say, but in 1553 the ground upon which Northumberland had built his power crumbled: Edward was dying of consumption. To save himself from Catholic Mary, who was Edward's legal heir as established both by Parliament and her father's will, the Duke tried his hand at kingmaking. He persuaded Edward to declare his sister illegitimate and to bequeath his throne to Lady Jane Grey, the granddaughter of Henry VIII's sister (Mary, duchess of Suffolk), and incidentally Northumberland's daughter-in-law. The gamble failed, for when Edward died on July 6, 1533, the kingdom rallied to the daughter of Catherine of Aragon. Whatever their religious inclinations, Englishmen preferred a Tudor on the throne to a kingmaker ruling behind a puppet queen; in nine days the interlude was over, and Northumberland and his daughter-in-law were in the Tower.

Lady Jane Grey

MARY I (1553–58)

The new Catholic Queen had many fine qualities, and contemporaries announced that she was "a prince of heart and courage more than commonly is in womanhood"; but she was hopelessly outdated. She envisioned the return of a Catholic Church that had long since ceased to exist anywhere in Europe. The worldly and pliable church of pre-Reformation days had been destroyed by the fire of religious war and extremism, and both Catholic and Protestant now denied the tolerant humanistic principle that "men who live according to equity and justice shall be saved" no matter what their creed. By 1553 salvation was strictly a matter of right belief. For Mary it was a sacred obligation to return England to the Catholic fold, and it was almost as great a duty to marry Philip of Spain, her Habsburg cousin and the son of Charles V, the man who had defended her mother's marital rights. She married Philip on July 25, 1554, and six months later, after the landed elements had been assured that their monastic property would not be taken from them, Parliament repealed the Act of Supremacy, reinstated the heresy laws, and petitioned for reunion with Rome. In the end both achievements proved sterile. Her marriage was without love or children, and by associating Catholicism in the popular mind with Spanish arrogance, it triggered a rebellion that almost overthrew the Tudor throne. In January 1554, under the

leadership of Sir Thomas Wyat, the peasants of Kent rose up against the Queen's Catholic and Spanish policies, and 3,000 men marched on London. The rebellion was crushed, but it revealed to Mary and her chief minister, Cardinal Reginald Pole, that the kingdom was filled with disloyal hearts who placed Protestantism and nationalism higher than their obedience to the throne.

The Smithfield martyrs

The tragedy of Mary's reign was the belief not only that the old church of her mother's day could be restored but also that it could be best served by fire and blood. Some 300 men and women were martyred in the Smithfield Fires during the last three years of her reign; compared to the Continent, the numbers were not large, but the emotional impact was great. Among the first half-dozen martyrs were the Protestant leaders Cranmer, Ridley, Latimer, and Hooper, and they were burned to strike terror into the hearts of lesser men. Their deaths, however, had the opposite effect; their bravery encouraged others to withstand the flames, and the Smithfield Fires continued to burn because nobody could think of what to do with heretics except to put them to death. The law required it, the prisons were overflowing, and the martyrs themselves offered the government no way out except to enforce the grisly laws.

Mary's reign was a study in failure. Her husband, who was ten years her junior, remained in England as little as possible; the war between France and the Habsburg Empire, into which her Spanish marriage had dragged the kingdom, was a disaster and resulted in the loss of England's last continental outpost, Calais; her subjects learned to call her "bloody," and Englishmen greeted the news of her death and the succession of her sister Elizabeth on November 17, 1558, with ringing bells and bonfires.

ELIZABETH I (1558–1603)

No one in 1558, any more than in 1485, would have predicted that despite the social discord, political floundering, and international humiliation of the past decade, the kingdom again stood on the threshold of an extraordinary reign. Elizabeth had much in common with her grandfather; in both cases their pedigrees were suspect and the political omens unfavourable, and to make matters worse the new monarch was the wrong sex. Englishmen knew that it was unholy and unnatural that "a woman should reign and have empire above men." At 25, however, Elizabeth was better prepared than most women to have empire over men. She had survived the palace revolutions of her brother's reign and the Catholicism of her sister's; she was the product of a fine Renaissance education, and she had learned the need for strong secular leadership devoid of religious bigotry. Moreover, she possessed her father's magnetism without his egotism or ruthlessness. She was also her mother's daughter, and the offspring of Anne Boleyn had no choice but to re-establish the royal supremacy and once again sever the ties with Rome. Elizabeth herself would have preferred a variety of her father's Catholicism without the pope, but she needed the support of the "zely people" and had to take her religious stand well to the left of centre. Her religious settlement was based on the Protestant Prayer Book of 1552. Many of the ceremonial trappings of Catholicism, however, were retained, and the tone of the document was softened to allow the communion service to become a mass for those Catholics who were looking for a way of conforming with the new settlement. The compromise worked largely because the Queen and her advisers correctly argued that Catholics were better losers than Protestants and that the structure of the new religious establishment should be large, comfortable, and popular, with authority stemming from the royal prerogative. The ecclesiastical history of Elizabeth's reign was, in fact, a long debate with the radicals over the source of divine power—whether it was hierarchical and ultimately emanated from the crown itself or whether it was democratic and was centred in the congregation of all believers.

Religious policy

The Tudor ideal of government. The religious settlement was part of a larger social arrangement that was authoritarian to its core. Elizabeth was determined to be queen in fact as well as in name. She tamed the House of Commons with tact combined with firmness, and she carried on a love affair with her kingdom in which womanhood, instead of being a disadvantage, became her greatest asset. The men she appointed to help her run and stage-manage the government were *politiques* like herself: William Cecil (later Lord Burghley), her principal secretary and in 1572 her lord treasurer; Matthew Parker, her archbishop of Canterbury; and a small group of other moderate and secular men.

In setting her house in order, the Queen followed the hierarchical assumptions of her day. All creation was presumed to be a Great Chain of Being, running from the tiniest insect to the godhead itself, and the universe was seen as an organic whole in which each part played a divinely prescribed role. In politics every element was expected to obey "one head, one governor, one law" in exactly the same way as all parts of the human body obeyed the brain. The crown was divine and gave leadership, but it did not exist alone, nor could it claim a monopoly of divinity, for all parts of the body politic had been created by God. The organ that spoke for the entire kingdom was not the king alone, but "King in Parliament," and when Elizabeth sat in the midst of her Lords and Commons it was said that "every Englishman is intended to be there present from the prince to the lowest person in England." The Tudors needed no standing army in "the French fashion" because God's will and the monarch's decrees were enshrined in acts of Parliament, and this was society's greatest defense against rebellion. The controlling mind within this mystical union of crown and Parliament belonged to the Queen. The Privy Council, acting as the spokesman of royalty, planned and initiated all legislation, and Parliament was expected to turn that legislation into law. Inside and outside Parliament the goal of Tudor government was benevolent paternalism in which the strong hand of authoritarianism was masked by the careful shaping of public opinion, the artistry of pomp and ceremony, and the deliberate effort to tie the ruling elite to the crown by catering to the financial and social aspirations of the landed country gentleman. Every aspect of government was intimate because it was small and rested on the support of probably no more than 5,000 key persons. The bureaucracy consisted of a handful of privy councillors at the top and at the bottom possibly 500 paid civil servants—the 15 members of the secretariat, the 265 clerks and custom officials of the treasury, a staff of 50 in the judiciary, and approximately 150 more scattered in other departments. Tudor government was not predominantly professional. Most of the work was done by unpaid amateurs: the sheriffs of the shires, the lord lieutenants of the counties, and above all the Tudor maids-of-all-work—the 1,500 or so justices of the peace.

Benevolent paternalism

Smallness did not mean lack of government, for the 16th-century state was conceived of as an organic totality in which the possession of land carried with it duties of leadership and service to the throne, and inferior social position bore the obligation to accept the decisions of elders and betters. The Tudors were essentially medieval in their economic and social philosophy. The usurer and capitalist were considered as dangerous to the commonweal as the overmighty magnate. The aim of government was to curb competition and regulate life so as to attain an ordered and stable society in which all could share according to status. The Statute of Apprentices of 1563 embodied this concept, for it assumed the moral obligation of all men to work, the existence of divinely ordered social distinctions, and the need for the state to define and control all occupations in terms of their utility to society. The same assumption operated in the famous Elizabethan Poor Law of 1601—the need to assure a minimum standard of living to all men within an organic and noncompetitive society. By 1600 poverty, unemployment, and vagrancy had become too widespread for the church to handle, and the state had to take over, instructing each parish to levy taxes to pay for poor relief, and to provide work for the able-bodied, punishment for the indolent, and charity for the sick, the aged, and the disabled. The

The Elizabethan Poor Law

Tudor social ideal was to achieve a static class structure by guaranteeing a fixed labour supply, restricting social mobility, curbing economic freedom, and creating a kingdom in which subjects could fulfill their ultimate purpose in life—spiritual salvation, not material well-being.

Elizabethan society. Social reality, at least for the poor and powerless, was probably a far cry from the ideal, but for a few years Elizabethan England seemed to possess an extraordinary internal balance and external dynamism. In part the Queen herself was responsible. She demanded no windows into men's souls, and she charmed both great and small with her artistry and tact. In part, however, the Elizabethan age was a success because men had at their disposal new and exciting areas into which to channel their energy. From a kingdom that had once been known for its "sluggish security," Englishmen suddenly turned to the sea and the world that was opening up around them. The first hesitant steps had been taken under Henry VII when John Cabot in 1497 sailed in search of a Northwest Passage to China and as a consequence discovered Cape Breton Island. The search for Cathay became an economic necessity in 1550 when the wool trade collapsed and merchants had to find new markets for their cloth. In response, the Muscovy Company was established to trade with Russia, and by 1588 a hundred vessels a year were visiting the Baltic. Martin Frobisher during the 1570s made a series of voyages to northern Canada in the hope of finding gold and a shortcut to the Orient; John Hawkins encroached upon Spanish and Portuguese preserves and sailed in 1562 for Africa in quest of slaves to sell to West Indian plantation owners; and Sir Francis Drake circumnavigated the globe (December 13, 1577–September 26, 1580) in search not only of the riches of the East Indies but also of Terra Australis, the great southern continent, and new worlds to open up to English trade and colonization. Suddenly Englishmen were on the move: Sir Humphrey Gilbert and his band of settlers set forth for Newfoundland (1583); Sir Walter Raleigh organized the equally ill-fated "lost colony" at Roanoke (1587–91); John Davis in his two small ships, the "Moonshine" and the "Sunshine," reached 72° north, the farthest north any Englishman had ever been (1585–87); and the honourable East India Company was founded to organize the silk and spice trade with the Orient on a permanent basis. The outpouring was certainly inspired by the urge for riches, but it was also religious—the desire to labour in the Lord's vineyard and to found in the wilderness a new and better nation. As it was said, Englishmen went forth "to seek new worlds for gold, for praise, for glory." The same dynamism was manifest in art and culture. Elizabeth's reign was the age of Shakespeare, Marlowe, Spenser, Raleigh, Sidney, Bacon, Donne, and a host of lesser literary lights. It was also the century of stately homes, when the houses of the great were no longer fortresses to defend a man's retainers and dependents but were unprotected residences open to the sunshine. They were designed to reflect man's rational control over nature and were built by gentlemen with enormous confidence in England's future as well as their own. Even the dangers of the reign—the precariousness of Elizabeth's throne and the struggle with Catholic Spain—somehow contrived to generate a self-confidence that had been lacking under "the little Tudors."

The English explorers

Mary, Queen of Scots. The first decade of Elizabeth's reign was relatively quiet, but after 1568 three interrelated matters set the stage for the crisis of the century: the Queen's refusal to marry, the various plots to replace her with Mary of Scotland, and the religious and economic clash with Spain. Elizabeth Tudor's virginity was the cause of great international discussion, for every bachelor prince of Europe hoped to win a throne through marriage with Gloriana, and the source of even greater domestic concern, for everyone except the Queen herself was convinced that Elizabeth should marry and produce heirs. The issue was the cause of her first major confrontation with the House of Commons, which was informed that royal matrimony was not a subject for commoners to discuss. Elizabeth preferred maidenhood; it was politically safer and her most useful diplomatic weapon, but it gave poignancy to the intrigues of her cousin Mary, Queen of Scots. Mary had been an unwanted visitor-prisoner in England ever since 1568, after she had been forced to abdicate her Scottish throne in favour of her 13-month-old son, James VI. She was Henry VIII's grandniece and, in the eyes of many Catholics and a number of political malcontents, the rightful ruler of England, for Mary of Scotland was a Catholic. As the religious hysteria mounted, there was steady pressure put on Elizabeth to rid England of this dangerous threat, but the Queen delayed a final decision for almost 19 years. In the end, however, she had little choice. Jesuit priests were entering the kingdom to harden the hearts of the Queen's subjects against her, forcing the government to introduce harsher and harsher recusancy laws (the fine for failure to attend Anglican service on Sundays was raised from one shilling a week to £20 a month). Puritans were thundering for even stiffer penalties, and Mary played into the hands of her religious and political enemies by involving herself in a series of schemes to unseat her cousin. One plot helped to trigger the rebellion of the northern earls in 1569. Another, the Ridolfi plot of 1571, called for an invasion by Spanish troops stationed in the Netherlands and resulted in the execution in 1572 of the Duke of Norfolk, the ranking peer of the realm. Yet another, the Babington plot of 1586, was in fact a carefully arranged government trap to gain sufficient evidence to have Mary tried and executed for high treason.

The question of the Queen's marriage

Plots on Mary's behalf

The clash with Spain. Mary was executed on February 8, 1587; by then England had moved from cold war to open war against Spain. Philip II was the colossus of Europe and leader of resurgent Catholicism. His kingdom was strong; Spanish troops were the best in Europe, Spain itself had been carved out of territory held by the infidel and still retained its crusading zeal, and the wealth of the New World poured into the treasury at Madrid. Spanish pre-eminence was directly related to the weakness of France, which ever since the accidental death of Henry II in 1559 had been torn by factional strife and civil and religious war. In response to this diplomatic and military imbalance, English foreign policy underwent a fundamental change. By the Treaty of Blois in 1572 England gave up its historic enmity with France, accepting by implication that Spain was the greater danger. It is difficult to say at what point a showdown between Elizabeth and her former brother-in-law became unavoidable—there were so many areas of disagreement—but the two chief points were the refusal of English merchants-cum-buccaneers to recognize Philip's claims to a monopoly of trade wherever the Spanish flag flew throughout the world, and the military and financial support given by the English to Philip's rebellious and heretical subjects in the Netherlands.

The most blatant act of English poaching in Spanish imperial waters was Drake's circumnavigation of the earth, during which Spanish shipping was looted, Spanish claims to California ignored, and Spanish world dominion proved to be a paper empire. But the encounter that really poisoned Anglo-Iberian relations was the Battle of San Juan de Ulúa in September 1568. It concerned John Hawkins' third and final slaving expedition to the Caribbean. After a highly successful voyage in which he exchanged African slaves for West Indian sugar, gold, and hides in defiance of Spanish commercial regulations, Hawkins' fleet of ten vessels put in for repairs at San Juan de Ulúa on the Mexican coast. The next day the Spanish Caribbean fleet appeared, and on the Spanish commander's written statement of peaceful intentions, Hawkins made room in the crowded harbour. No sooner were the Spanish anchored than they launched a surprise attack; only Hawkins in the "Minion" and Drake in the "Judith" escaped. The English cried foul treachery, the Spanish dismissed the action as sensible tactics when dealing with pirates. Drake and Hawkins never forgot or forgave, and it was Hawkins who, as treasurer of the navy, began to build the revolutionary ships that destroyed the old-fashioned galleons of the Spanish Armada.

The harassment of Spain at sea

If the English never forgave Philip's treachery at San Juan de Ulúa, the Spanish never forgot Elizabeth's interference in the Netherlands, where Dutch Protestants were in full revolt. At first, aid had been limited to money and the harbouring of Dutch ships in English ports; but after the assassination of the Protestant leader, William of Orange, in 1584, the position of the rebels became so desperate that Elizabeth in August 1585 sent over an army of 6,000 under the command of the Earl of Leicester. Reluctantly, Philip decided on war against England as the only way of exterminating heresy and disciplining his subjects in the Netherlands. Methodically, he began to build a fleet of 130 vessels, 31,000 men, and 2,431 cannons to hold naval supremacy in the Channel long enough for the Duke of Parma's army, stationed at Dunkirk, to cross over to England. Nothing Elizabeth could do seemed to be able to stop the *Armada Catholica*. She sent Drake to Spain in April 1587 in a spectacular strike at that portion of the fleet forming at Cádiz, but it succeeded only in delaying the sailing date. That delay, however, was important, for Philip's Admiral of the Ocean Seas, the veteran Marqués de Santa Cruz, died, and the job of sailing the Armada was given to the Duque de Medina-Sidonia, who was invariably seasick and confessed that he knew more about gardening than war. What ensued was not the new commander's fault. He did the best he could in an impossible situation, for Philip's Armada was invincible in name only. It was technologically and numerically outclassed by an English fleet of close to 200. Worse, its strategic purpose was grounded on a fallacy: that Parma's troops could be conveyed to England; for the Spanish controlled no deep-water port in the Netherlands in which the Armada's great galleons and Parma's light troop-carrying barges could rendezvous. Even the deity seemed to be more English than Spanish, and in the end the fleet, buffeted by gales, was dashed to pieces as it sought to escape home via the northern route around Scotland and Ireland. Of the 130 ships that left Spain, only 76 crept home; 10 had been captured, sunk, or driven aground by English guns, 24 were sacrificed to wind and storm, and 20 others were "lost, fate unknown."

Defeat of the Armada

Internal discontent. When the Armada died during the first weeks of August 1588, the crisis of Elizabeth's reign was reached and successfully passed. The last years were an anticlimax, for the moment the international danger was surmounted, domestic strife ensued. There were moments of great heroism and success—as when Essex, Raleigh, and Howard made a second descent on Cádiz in 1596, seized the city, and burned the entire West Indian treasure fleet—but the war so gloriously begun deteriorated into a costly campaign in the Netherlands and France and an endless guerrilla action in Ireland, where Philip discovered he could do to Elizabeth what she had been doing to him in the Low Countries. Even on the high seas, the days of fabulous victories were over, for the King of Spain soon learned to defend his empire and his treasure fleets. Both Drake and Hawkins died in 1596 on the same ill-conceived expedition into Spanish Caribbean waters—symbolic proof that the good old days of buccaneering were gone forever. At home the cost of almost two decades of war (£4,000,000) raised havoc with the Queen's finances. It forced her to sell her capital (about £800,000, or roughly one-fourth of all crown lands) and increased her dependence upon parliamentary sources of income, which rose from an annual average of £35,000 to over £112,000 a year.

Elizabeth's financial difficulties were a symptom of a mounting political crisis which under her successors would destroy the entire Tudor system of government. The 1590s were years of depression—bad harvests, soaring prices, peasant unrest, high taxes, and increasing parliamentary criticism of the Queen's economic policies and political leadership. Imperceptibly, the House of Commons was becoming the instrument through which the will of the landed classes could be heard and not an obliging organ of royal control. In Tudor political theory this was a distortion of the proper function of Parliament, which was meant to beseech and petition, never to command or initiate. Three things, however, forced theory to make way for reality. First was the government's financial dependence on Commons, for the organ that paid the royal piper eventually demanded that it also call the governmental tune. Second, under the Tudors, Parliament had been summoned so often and forced to legislate on such crucial matters of church and state—legitimizing and bastardizing monarchs, breaking with Rome, proclaiming the supreme headship (governorship under Elizabeth), establishing the royal succession, and legislating in areas that no Parliament had ever dared enter before—that Commons got into the habit of being consulted. Inevitably a different constitutional question emerged: if Parliament is asked to give authority to the crown, can it also take away that authority? Finally, there was the growth of a vocal, politically conscious, and economically dominant gentry; and the increase in the size of the House of Commons reflected the activity and importance of that class. In Henry VIII's first Parliament there were 74 knights who sat for 37 shires, and 224 burgesses who represented the chartered boroughs of the kingdom. By the end of Elizabeth's reign, borough representation had been increased by 135 seats. Commons was replacing the Lords in importance because the social element it represented had become economically and politically more important than the nobility. Should the crown's leadership falter, there existed by the end of the century an organization that was quite capable of seizing the political initiative, for as one disgruntled contemporary noted: "the foot taketh upon him the part of the head and commons is become a king." Elizabeth had sense enough to avoid a showdown with Commons, and she retreated under parliamentary attack on the issue of her prerogative rights to grant monopolies regulating and licensing the economic life of the kingdom, but on the subject of her religious settlement she refused to budge.

Elizabeth and Parliament

By the last decade of the reign, Puritanism was on the increase. During the 1570s and '80s "cells" had sprung up to spread God's word and rejuvenate the land, and Puritan strength was centred in exactly that segment of society that had the economic and social means to control the realm—the gentry and merchant classes. What set a Puritan off from other Protestants was the literalness with which he held to his creed, the discipline with which he watched his soul's health, the militancy of his faith, and the sense that he was somehow apart from the rest of corrupt humanity. This disciplined spiritual elite clashed with the Queen over the purification of the church and the stamping out of the last vestiges of Catholicism. The controversy went to the root of society: was the purpose of life spiritual or political, was the role of the church to serve God or the crown? In 1576 two brothers, Paul and Peter Wentworth, led the Puritan attack in Commons, criticizing the Queen for her refusal to allow Parliament to debate religious issues. The crisis came to a head in 1586, when Puritans called for legislation to abolish the episcopacy and the Anglican Prayer Book. Elizabeth ordered the bills to be withdrawn, and when Peter Wentworth raised the issue of freedom of speech in Commons, she answered by clapping him in the Tower of London. There was emerging in England a group of religious idealists who derived their spiritual authority from a source that stood higher than the crown and who thereby violated the concept of the organic society and endangered the very existence of the Tudor paternalistic monarchy. As early as 1573 the threat had been recognized:

The growth of Puritanism

> At the beginning it was but a cap, a surplice, and a tippet [over which Puritans complained]; now, it is grown to bishops, archbishops, and cathedral churches, to the overthrow of the established order, and to the Queen's authority in causes ecclesiastical.

James I later reduced the problem to one of his usual *bon mots*—"no bishop, no king." Elizabeth's answer was less catchy but more effective; she appointed as archbishop John Whitgift, who was determined to destroy Puritanism as a politically organized sect. Whitgift was only partially successful, but the Queen was correct: the

moment the international crisis was over and a premium was no longer placed on loyalty, Puritans were potential security risks.

The final years of Gloriana's life were difficult both for the theory of Tudor kingship and for Elizabeth herself. She began to lose hold over the imaginations of her subjects, and she faced the only palace revolution of her reign when her favourite, Robert Devereux, earl of Essex, sought to touch her crown. There was still fight in the old Queen, and Essex ended on the scaffold in 1601, but his angry demand could not be ignored:

> What! Cannot princes err? Cannot subjects receive wrong? Is an earthly power or authority infinite? Pardon me, pardon me, my good Lord, I can never subscribe to these principles.

When the old Queen died on March 24, 1603, it was as if the critics of her style of rule and her concept of government had been waiting patiently for her to step down. It was almost with relief that men looked forward to the problems of a new reign, a new dynasty, and a new century. (La.B.S.)

VIII. Wales to c. 1540

WALES BEFORE THE NORMAN CONQUEST

The Roman influence. The early history of Wales (Cymru, Gwalia, Cambria) is largely gleaned from what is known of the withdrawal of Roman authority from the land by the end of the 4th century AD. Wales in the Roman period had shared broadly the experience of the other parts of highland Britain, and the Welsh evidence can often be better understood by analogy with that of other areas. The Latin element in the Welsh language and some features of the literary tradition, such as the legends associated with the Roman emperor Magnus Maximus (Maxen Wledig in Welsh legend), suggest that the Celtic, and largely Brythonic, population of Wales assimilated some aspects of Roman culture and that the memory of imperial governance was cherished. Brythonic refers to one of the two major divisions of Celtic languages (*q.v.*), the other being Goidelic. The former comprises Welsh, Cornish, and Breton; the latter, Irish, Scots Gaelic, and Manx.

The extent of Roman influence on political and social organization is difficult to assess. Roman authors provide the names of some of the "tribes" that occupied parts of Wales, such as the Silures in the southeast and the Demetae in the southwest, but the precise boundaries of these "tribal" territories and their relationship to the political entities that emerged in the following centuries present problems not easily resolved. With others—tribes such as the Ordovices, located roughly in central and northwest Wales—the difficulties are even more pronounced. Archaeological evidence suggests that the civilizing influence of Rome, best exemplified in the Roman town of Caerwent, was most potent along the eastern borderland and the southeast. There is certainly a marked contrast between the Roman villas of the southeast and the enclosed homesteads of the northwest. But even in those areas in which the military aspects of imperial governance are predominant, the evidence indicates increasingly that a more general infusion of Roman culture had been at work. The question of the extent of Roman influence is complicated, however, by the effects both of late migrations into Wales and the processes by which Christianity was established in the land.

Cunedda Wledig's migration

The *Historia Brittonum* of Nennius, a compilation of historical and geographical lore dating from about AD 800, records a tradition that a certain Cunedda Wledig and his sons migrated to northwest Wales from Manaw, a small province round the head of the Firth of Forth in the land of Gododdin, one of the Brythonic kingdoms of north Britain, in order to expel the Irish who had occupied the area. The tradition, which may be authentic in its essentials, points to a movement about AD 400 by an aristocratic group drawn from an area of strong Romano-British traditions. It would seem that Cunedda brought stability to the area that was later to be known as Gwynedd and that he was the founder of its royal dynasty. His descendants were to rule as kings, the assumption of a royal estate being inferred from the inscribed stone at Llangadwaladr, Anglesey, which commemorates his 7th-century descendant Catamanus Rex (Cadfan the King). The ostensible reason for Cunedda's intervention in Wales was the presence of an Irish population, and independent evidence does indicate the existence of Goidelic features in the northwest. In southwest Wales the Irish influences were particularly marked; this was due to an immigration of Goidelic people from the land of the Deisi in southern Ireland, probably in the late 4th and 5th centuries. The royal dynasty that emerged in the southwestern kingdom of Dyfed was distinctly Irish in origin, but the adoption of some Romano-British characteristics is suggested in the inscribed stone commemorating a 6th-century ruler styled "Voteporix the Protector." Irish connections are discernible, too, in the dynasty of the inland kingdom of Brycheiniog. In the southeast, where the Roman *civitas*, or urban community, had perhaps been most firmly established, the consolidation of stable kingdoms was probably accomplished later than elsewhere. Here the territories of Glywysing and Gwent emerged to be united, though not permanently, in the 7th century and called Morgannwg. Finally, among the major divisions, an area in north-central Wales was stabilized to form the kingdom of Powys (Powis), the name being derived from the *paganses*, or country people, of the *civitas* of the Cornovii upon the Welsh borderland. It was this once large kingdom, centred at Pengwern upon the Severn, that bore the brunt of Anglo-Saxon penetration of Wales.

Early Christianity. The extent of the Romano-British inheritance is again problematical in considering the origins of the Christian Church in Wales, for direct literary and archaeological evidence is slight. Traces of Romano-British Christian influence have been detected in the southeast, the area in closest cultural contact with romanized southern Britain. But Wales as a whole was undoubtedly affected by a western reorientation of trade and cultural connections that occurred in the 5th century. Wales and Ireland participated in renewed trade with the Mediterranean and reopened traditional culture routes that had exercised a powerful influence in prehistoric times. The early Christian stone inscriptions point to the strength of the Christian influences derived from Gaul and transmitted along the western seaways. Epigraphic studies reveal, in the script and in the formulas employed upon the stones, a fusion of Gallic Christian and Celtic influences. The stones, especially numerous in southwest Wales, which bear inscriptions in the ogham script (an alphabet comprised of notches), reflect the mingling of Christian with what were essentially Goidelic influences. In its forms, the church revealed a monastic character due both to its Gallic origins and to the needs of a Celtic society that did not possess important urban centres. Major monasteries were established in Wales by the 6th century, associated with figures such as St. Illtud at Llantwit Major or St. Cadog at Llancarfan. The founding of these centres was probably followed by a secondary movement, characterized by intense activity within the church, associated particularly with the names of St. David in south Wales and St. Beuno in north Wales. An examination of the distribution of the dedications of the churches and of the evidence of place-names in which the *llan* element (signifying a sacred enclosure) is often coupled with a personal name has served to suggest the spheres of influence of the Christian missionaries, or "saints," and to illustrate the close contacts with other Celtic lands that were maintained by means of the western seaways in this creative period. During the 6th century, in fact, the characteristics of the pre-Norman church were well established. Church organization was based upon a monastic church, or *clas*, akin to a minster, with which lesser churches were associated.

Westward orientation

Relations with the Anglo-Saxons. The settlement of Anglo-Saxon peoples along the Welsh borderland separated the Brythonic people of Wales from their compatriots in the north and southwest of Britain, and the name Cymry ("compatriots"; *i.e.*, the Welsh) dates from this period. The campaign waged by Cadwallon, king of

Gwynedd, in Northumbria early in the 7th century represents a late involvement of a Welsh king in the conflict between the Brythonic kingdoms of northern Britain and the English. That conflict in the north had already provided the subject matter of the earliest poetry in the Welsh language, the work of Taliesin and Aneirin. The conflict upon the Welsh border itself is echoed in the Llywarch Hen poems, which, though probably dating from the 9th century, have their setting two centuries earlier in the contest between Powys and Mercia. The gradual colonization of the approaches to Wales by English peoples, a process marked by short dikes still visible upon the landscape, led to a final demarcation of the line of Mercian penetration with the construction in the time of King Offa (died 796) of the great linear earthwork known as Offa's Dyke.

Attempts at unity

Attempts during the next two centuries to bring the Welsh kingdoms west of the dike into a political unity proved to be only partially successful and impermanent. Rhodri Mawr ("the Great"; died 878), the king of Gwynedd who provided stern resistance to the Viking attacks, brought Powys within his dominion and then briefly extended his sway over two areas in the southwest (lying north and east of Dyfed), namely Ceredigion and Ystrad Tywi, which had previously been united to form the kingdom of Seisyllwg. The period following Rhodri's death proved to be of far-reaching significance. The outlying kingdoms of Wales—Dyfed, Brycheiniog, Glywysing, and Gwent—being subjected to pressure exerted by Rhodri's sons or by Mercia, turned to the kingdom of Wessex and by a formal commendation entered into that allegiance, ultimately expressed in homage and fealty, which each of the kings of Wales owed, individually and directly, to the English monarchy. Anarawd (died 916), a son of Rhodri, and his brothers, who shared the governance of their father's lands, subsequently submitted to Alfred (died 899) and completed the theoretical subjection of the Welsh kingdoms to the English sovereign. Rhodri's grandson, Hywel ap Cadell (Hywel Dda, "the Good"; died 950), starting from a patrimony in Seisyllwg, secured Dyfed by marriage, thereby creating the kingdom of Deheubarth. Eventually Gwynedd and Powys also came under his rule. Hywel accepted the position of a *sub-regulus*, or under-king, of the king of Wessex and seems to have endeavoured to emulate the advanced institutions of the contemporary West Saxon kingdom. Hywel's appeasement of Athelstan of Wessex (died 939) provoked a reaction expressed in the poem *Armes Prydein*, which envisages the formation of an alliance of Celtic peoples to oppose the Anglo-Saxon *mechdeyrn*, or overlord.

The conflicting impulses that were to be a feature of Welsh medieval political history were already discernible by the 10th century. Before its close, Maredudd ap Owain (died 999), a grandson of Hywel Dda, brought the northern and western kingdoms once more into a transitory unity. But his death opened a period of prolonged turmoil in which internal conflicts were complicated and intensified by Anglo-Saxon and Norse intervention. The established dynasties were challenged by men who asserted themselves within the kingdoms and exercised ephemeral supremacies. Of these, the most successful

Temporary unity under Gruffudd

was Gruffudd ap Llywelyn (died 1063), who brought Gwynedd, then Deheubarth, and finally (though briefly) the whole of Wales under his dominion. The devastation wrought upon the English borderland, still not erased at the time of the making of Domesday Book (1086), was probably in large measure due to him. His death in 1063 meant that the most powerful ruler of independent Wales was destroyed only a few years before the coming of Norman forces to the Anglo-Welsh frontier.

Early Welsh society. The endeavours of the dynasties in the 9th and 10th centuries, though only partially successful with regard to the problem of Welsh unification, had important and lasting consequences. Scholarly activity such as that represented in the *Historia Brittonum* and in annals and genealogies, material relating both to north Britain and to Wales, may well reflect the attempt of the descendants of Rhodri Mawr to consolidate their position and enhance their prestige. In creative literature it is likely that the origins of some texts preserved in medieval manuscripts, including some material in triad form (triple groupings of legal, literary, historical, and other materials), may be traced back to this period. The earliest Welsh law texts, though they date from the late 12th century onward, attribute the original codification of law to Hywel Dda; and the possibility that a significant development in Welsh jurisprudence took place under the aegis of that ruler is not improbable. The presence not only of a stratum of early indigenous law but of Anglo-Saxon influences (reflected, for instance, in the use of the term *edling* for the heir to the throne) points to a conscious adoption by the Welsh kings of some Anglo-Saxon concepts and procedures. These indications accord well with others, including that of the late inscribed stones, which point to an eastward reorientation of Welsh culture in this period.

The law texts, studied in association with other materials, reveal an early society ruled by kings (*brenhinoedd*) of independent kingdoms who possessed an authority, notably a recognized function in the public enforcement of legal obligations, that stood in contrast to traditional Celtic custom. The kingdoms were normally divided for purposes of royal administration into *cantrefs*. These in turn consisted of groups of *maenors* occupied by the bond or free elements of which Welsh society was composed. The bond population, which was probably larger than was at one time thought and which was concentrated in fairly compact *maenors* in lowland areas favourable to an agrarian economy, was organized on conventional manorial principles. In the economy of the upland areas the emphasis was upon a pastoral economy practiced by free communities, which were accorded more extensive *maenors*. The *maenor* organization as a whole represents a stage in the economic organization of Welsh society that was to be gradually superseded as a result of changes, quickened considerably in the 12th century, designed to ensure a more intensive exploitation of the soil. A smaller unit, the *tref*, or township, then replaced the *maenor*. In the sphere of royal administration the *cantref*, by a process probably well advanced on the eve of the first Norman invasions, was largely replaced by a small unit, the *commote*, which was to remain, under Welsh and alien lords, the basic unit of administration and jurisdiction throughout the medieval period.

Organization of the kingdoms

WALES FROM THE 11TH TO THE 16TH CENTURY

Norman infiltration. The Norman conquest of England saw the establishment upon the Welsh border of the three earldoms of Chester, Shrewsbury, and Hereford, and from each of these strongpoints advances were made into Wales. Norman progress in southern Wales in the reign of William I (1066–87) was limited to the colonization of Gwent in the southeast. Domesday Book contains evidence suggesting that King William and Rhys ap Tewdwr, king of Deheubarth (died 1093), made a compact that recognized the Welsh ruler's authority in his own kingdom and perhaps also his influence in those other areas of southern Wales outside Deheubarth, particularly Morgannwg and Brycheiniog, that still lay outside Norman control. Meanwhile, from Chester and Shrewsbury, the Normans had penetrated more deeply into Wales, so that at Domesday, though the area colonized was limited, Norman lordship had been asserted over numerous *cantrefs* and *commotes* that had previously formed portions of the kingdoms of Gwynedd and Powys. The political situations in the northern and southern parts of the country were reversed during a period of renewed conflict in the reign (1087–1100) of William II who invaded Wales three times, unsuccessfully. The death of Rhys ap Tewdwr in 1093, opposing the Norman advance into Brycheiniog, was quickly followed by the invasion of virtually the whole of southern Wales. Advances from several bases along the Welsh border enabled Norman lords to establish the major lordships of Cardigan, Pembroke, Brecon, and Glamorgan. This advance constituted the decisive stage in the creation of the March of Wales (that portion of Wales under the author-

Creation of the March

ity of the English Crown). In each lordship of the March, the Norman lord, who was himself responsible for the conquest of the land, assumed the wide range of powers previously exercised there by the Welsh kings. These indigenous rights, enlarged and given definition during the course of the following centuries, formed the basis of the Custom of the March. This was a regality that enabled the lords to exercise extensive jurisdictional powers over the largely Welsh communities of their lordships and afforded them an extraordinary degree of autonomy in their relations with the English monarchy.

Gwynedd, Powys, and Deheubarth. The crucial years after 1093 saw also the initiation in northern Wales of a period of conflict by which the area was gradually recovered from Norman rule and the kingdoms of Gwynedd and Powys reconstituted as major political entities. Gwynedd, first under Gruffudd ap Cynan (died 1137) and then under his son Owain Gwynedd (died 1170), gained a firm governance that enabled the younger ruler, controlling a kingdom extending from the Dyfi to the Dee, to withstand foreign pressure, which was particularly severe during the reign (1154–89) of Henry II. In Powys the rule of Madog ap Maredudd (died 1160) likewise proved to be a period of stability and of expansion eastward beyond Offa's Dyke into lands that had been subjected to alien settlement in both the Anglo-Saxon and Norman periods. In southwest Wales, too, representatives of the dynasty of Deheubarth for over 30 years waged a campaign that finally enabled Rhys ap Gruffudd (died 1197), a grandson of Rhys ap Tewdwr, to win from Henry II a recognition of his position. Rhys ruled a land that was not as extensive as the ancient kingdom, for Norman control of the lordship of Pembroke and of other lordships along the southern coastline was conceded, but it nevertheless constituted a considerable dominion. The three kingdoms of Gwynedd, Powys, and Deheubarth formed by the third quarter of the 12th century a well-defined sphere of Welsh political influence (Wallia, or Pura Wallia) in contradistinction to the sphere of Norman influence (Marchia Wallie). Throughout the remainder of the period of Welsh independence there remained a memory that Wales, outside the March, had consisted historically of three kingdoms ruled from the three principal seats of Aberffraw in Gwynedd, Mathrafal in Powys, and Dinefwr in Deheubarth. The evidence, especially that of Welsh jurisprudence as revealed in texts dating from the late 12th century onward, reflects an endeavour on the part of these rulers to formulate a concept of Welsh kingship in which indigenous elements were blended with the new influences at work in the feudal monarchies. Each ruler, still known as a king (*rex*, *brenin*) but later to be styled prince (*princeps*, *tywysog*) or lord (*dominus*, *arglwydd*), governed an autonomous kingdom. The kings' relationship with the English monarchy was formalized in the homage and fealty that was done by each ruler in respect of his patrimony.

Welsh kings outside the March

The stability provided by these rulers enabled their territories to recover from the depredations suffered during the conflicts of the Norman period. There are strong indications that the kings effected changes in social organization designed to increase the resources of the royal demesne, or crown land, and to promote generally a more intensive exploitation of the agrarian resources of their territories. The rulers deployed, especially on the coastal lowlands, communities characterized by personal servitude and the obligation to provide labour services. The organization of the large bond element in the population was in some areas adjusted to provide more favourable tenurial conditions as an incentive to the colonization of marginal lands. The agrarian changes also involved the settlement upon the soil of kindred groups of freemen. Stemming from a primary settlement of a single family in a shareland, the combined effect of successive divisions—the result of partible inheritance and of the expansion of the cultivated area—produced a pattern of dispersed settlement, in contrast to the nucleated (clustered) settlement of the bond communities. The endowment of some privileged free proprietors with substantial estates facilitated the growth of a class of landowners, who, linked to the royal lineages by ties of service, supplied the Welsh rulers with the personnel of their increasingly sophisticated administration. A renewed cultural vitality is revealed in Latin scholarship and in a flowering of the literary tradition.

Ecclesiastical affairs in the Norman period

In ecclesiastical affairs, the early Norman period saw the inauguration of a process by which the *clas* organization was replaced by arrangements consonant with the practice of the reformed church. The four territorial dioceses of Bangor, St. David's, Llandaff, and St. Asaph were created, and a parochial organization was gradually established. The church structure was a creation of the Normans, and the bishops appointed to Welsh sees owed a profession of obedience to Canterbury. Even so, Bernard, bishop of St. David's in 1115–48, claimed the status of an archbishop and, in furthering his campaign, appealed to the historical legacy of an early independent Welsh church. His bid was revived at the end of the century by Giraldus Cambrensis, but more significant was the resistance of the clergy of Bangor, who, acting under the protection of Owain Gwynedd at a time of national resistance toward the end of his reign, steadfastly refused to meet the demands of Thomas Becket, archbishop of Canterbury, that the newly elected bishop should swear fealty to Canterbury. The lay powers found adherents in the Cistercian Order. Houses such as Margam and Tintern, situated in the March, had close associations with their marcher patrons. The offshoots of the Cistercian monastery of Whitland, notably Strata Florida and Aberconway, were handsomely endowed by the Welsh rulers, who in return were supported in their political endeavours.

Llywelyn ap Iorwerth. In each of the three kingdoms of Gwynedd, Powys, and Deheubarth, the death of its powerful ruler was followed by a contested succession. The resulting conflicts portended a furthering of the fractionization characteristic of Welsh political history. In Powys and Deheubarth the unity of the kingdom was never restored; but with the emergence to power in the late 12th century of Llywelyn ap Iorwerth (died 1240), a grandson of Owain Gwynedd, Gwynedd was united once more under the strong hand of a single ruler. Llywelyn's aggression against neighbouring territories incurred resistance, which King John turned to his advantage in a campaign in 1211 whereby the Prince of Gwynedd was subjected to humiliating terms. But availing himself of a general Welsh reaction to John's measures for the permanent subjugation of the country, Llywelyn directed a sustained campaign in which his former adversaries participated. Llywelyn achieved a dominant position among the princes, which, while the contest with John persisted, augured the forging of a Welsh polity by bonds of homage and fealty to himself. But though he remained a powerful influence over the other Welsh princes and thereby minimized the crown's involvement in the affairs of Wales, Llywelyn was unable to secure a formal royal recognition of the territorial and conceptual achievements of the period of conflict. Llywelyn's aspirations for a wider Welsh principality based upon the supremacy of Gwynedd then centred upon David (later David II), his son by Joan, daughter of King John. David was designated as Llywelyn's heir in preference to his elder but bastard son, Gruffudd, and the Welsh dynasty looked to the English monarchy to ensure an unchallenged succession. In the event, the crown was able to use the dissension between the two sons and the disparate ambitions of the other Welsh princes to restrict David's power to Gwynedd alone. During the war of 1244–46 David contended for a broader influence, but his promising endeavour was cut short by his early death in 1246, without heir.

In the following year his nephews Owain and Llywelyn, two of the four sons of Gruffudd, entered into a treaty obligation by which the crown decreed the partition of a truncated Gwynedd into two parts, with the prospect of further division to provide for the younger brothers. But between 1255 and 1258 Llywelyn ap Gruffudd (died 1282), one of the four brothers, asserted his supremacy first in Gwynedd and then farther afield. Helped by the

preoccupation of the English crown with the baronial conflict, the Prince secured a hegemony formally acknowledged by Henry III in 1267 by the Treaty of Montgomery, when Llywelyn's style, "prince of Wales," first assumed in 1258, and his right to the homage and fealty of the Welsh lords of Wales were recognized. Llywelyn had thereby brought into being a Principality of Wales comprised of the lands that had formed the 12th-century kingdoms of Gwynedd, Powys, and Deheubarth as well as parts of the March. Historically, this meant the reversal of a situation, for which there were several centuries of precedent, whereby the increasingly fragmented territories under Welsh rule had been fiefs held directly from the king of England. The opportunity to consolidate the governance of the principality proved to be brief. Friction between Llywelyn and Edward I led in 1277 to a war in which the Prince, isolated by the withdrawal of his vassals' fealty and confronted with the great resources and superior organization of England, was forced to accept terms that restricted his power to Gwynedd west of the Conway. By 1282 a deterioration in relations between Edward and a number of Welsh princes resulted in renewed conflict, which, widespread and vigorous, became a true war of Welsh independence. Although sustained even after the death of Llywelyn in December 1282, the resistance finally collapsed in the summer of the following year.

War with Edward I

The Edwardian settlement. Edward I provided for the security of his conquests by means of a program of castle building, initiated after the war of 1277 and subsequently extended to include the great structures of Conway, Caernarfon, Harlech, and, later, Beaumaris. Each castle sheltered a borough where English colonists were settled. The king's arrangements for the governance of Llywelyn's former lands in northwest Wales were embodied in the Statute of Wales (1284). Three counties—Anglesey, Caernarfon, and Merioneth—were created and placed under the custody of a justice of North Wales. In northeast Wales a fourth county, Flint, was attached to the earldom of Chester. In southwest Wales the counties of Cardigan and Carmarthen, under the custody of the justice of West Wales, were formed out of lands over which royal power had been gradually extended by a process completed upon the failure, in 1287, of the revolt of Rhŷs ap Maredudd, the last of the princes of the dynasty of Deheubarth. Structurally, the shires that formed the Principality of Wales were similar to those of England, and certain common-law procedures were introduced into their courts, but the shires remained outside the jurisdiction of the central courts of Westminster, and they did not elect representatives to Parliament. The March of Wales was extended through the creation by royal charters, out of parts of Gwynedd and Powys, of the lordships of Denbigh, Ruthin, Bromfield and Yale, and Chirk. In his relations with two of the major barons of the older March, Gilbert de Clare of Glamorgan and Humphrey de Bohun of Brecon, Edward showed a determination to assert the sovereignty of the crown over the March and to eradicate abuses of the Custom of the March such as the claim, defiantly expressed by Gilbert, to the right to wage war in the March. But neither Edward nor his successors attempted any far-reaching changes in the organization of the March, and political fractionization persisted over the next two centuries.

Rebellion and annexation. Both the crown and the marcher lords employed in the administration of their lands Welshmen drawn from an administrative class that had been fostered by the princes themselves. Those of the principality revealed a particular loyalty to Edward II in the political crises of his reign, and their continued attachment to his cause even after his deposition created a tense situation in 1327. During the 14th century there were occasional variances, but the identity of interest established between the crown and the leading Welshmen proved durable. Even so, the community endured both the economic difficulties encountered over wide areas of Europe at this time and the specifically Welsh problems created by the fact that an important phase in the transition from early medieval social arrangements coincided with the pressures exerted by an alien and fiscally extractive administration. At the very end of the century, the deposition of Richard II, who had influential Welshmen among his partisans, released from allegiance to the monarchy a group that, associated with Owain Glyndŵr (Owen Glendower), raised a great rebellion that drew its strength from the community as a whole. In the period 1400–07 the royal government lost control of the greater part of Wales, and in some areas the insurrection remained unextinguished several years later.

The rebellion, however, quickened certain processes that were to lead ultimately to the enfranchisement provided by Tudor legislation. In northern Wales particularly, the availability of civil actions by English law led to an early but unrequited demand for English land law. After the rebellion the disabilities incurred by reason of Welsh nationality were underlined. Though often expressed in literature in militant terms and, during the years of dynastic conflict, manipulated by the protagonists of York and Lancaster, the aspirations of the community were focussed in a demand for English denizenship. First individual petitioners looked for enfranchisement and then whole communities in northern Wales secured from Henry VII, by negotiation and payment, charters conferring upon them English land law and other advantages. A realization by the crown of its inability to reverse a decline in the financial yield of its Welsh lands, an experience shared by the marcher lords, contributed to Henry VII's policy, and it may also have influenced Henry VIII's advisers in formulating the union legislation. The acts of 1536 and 1543, opening Wales to parliamentary taxation, extended to all of Wales practices already at work in the Principality of North Wales and introduced new features. The March was finally eradicated, and Wales was now divided into 13 counties. English common law was made applicable, and justice was to be administered by justices of the peace in quarter sessions and, in 12 counties (other arrangements being made for Monmouthshire), by the judges upon the four circuits of the Great Sessions. Wales was given a jurisdiction that remained separate from the Westminster courts, though each of its shires was represented at the Westminster Parliament. (J.B.Sm.)

The union of 1536

IX. Scotland to 1603

EARLY HISTORY

Evidence of human settlement in the area later known as Scotland dates from the 3rd millennium BC. The earliest people, Mesolithic (Middle Stone Age) hunters and fishermen, were to be found on the west coast, near Oban, and as far south as Kirkcudbright, where their settlements are marked by large deposits of discarded mollusk shells. There were also settlements in the Forth estuary, where, in the area of Stirling, they obtained meat from stranded whales. These were followed, early in the 2nd millennium BC by Neolithic (New Stone Age) farmers who knew the use of cereals and of cattle and sheep. They made settlements on the west coast and as far north as Shetland. Many built collective chamber tombs, that at Maeshowe in Orkney being the finest in Britain. A settlement of such people at Skara Brae in Orkney consists of a cluster of seven self-contained huts connected by covered galleries or alleys. The "Beaker folk," so called from the shape of their drinking vessels, came to east Scotland from northern Europe, probably from about 1800 BC on. They buried their dead individually and were pioneers in bronze working. The most impressive monuments of Bronze Age Scotland are the stone circles, presumably for religious ceremonies, like those at Callanish in Lewis and Brodgar in Orkney, the latter being over 300 feet (91 metres) in diameter.

From about 700 BC onward there was a distinct final period in Scottish prehistory. This period is the subject of current archaeological controversy, with somewhat less stress than in the past being placed on the importance of the introduction of iron using or on the impact of large new groups of iron-using settlers. One key development in the middle of the 1st millennium was the change from a relatively warm and dry climate to one that was cooler

and wetter. Another was the appearance of hill forts, having stone ramparts with an internal frame of timber: a good example is at Abernethy near the Tay. Some of these forts have recently been dated to the 7th and 6th centuries BC, and this might suggest that they were adopted by already established tribes rather than introduced by incomers, whose presence at this early date has yet to be proved. Massive decorated bronze armlets with Celtic ornamentation, found in northeastern Scotland and dated to the period AD 50–150, suggest that chieftains from outside may have come to these tribes at this period, displaced from farther south by fresh settlers from the Continent and then by the advent of the Romans in AD 43. From 100 BC the "brochs" appeared in the extreme north of Scotland and the northern isles. These were high, round towers, that at Mousa in Shetland standing almost 50 feet (15 metres) in height. The broch dwellers may have carried on intermittent warfare with the fort builders of farther south. On the other hand, the two types of structures may not represent two wholly distinct cultures, and the two peoples may have together comprised the ancestors of the people later known as the Picts.

The "brochs"

The houses of this people were circular, sometimes standing alone, sometimes in groups of 15 or more, as at Hayhope Knowe in the Cheviot Hills on the border between modern Scotland and England. Some single steadings, set in bogs or on lakesides, are called crannogs. Corn growing was probably of minor importance in the economy; the people were pastoralists and food-gatherers. They were ruled by a warrior aristocracy whose bronze and iron parade equipment has, in a few instances, survived.

Roman penetration and the Dark Age peoples. Gnaeus Julius Agricola, the Roman governor of Britain (AD 77–84), was the first Roman general to operate extensively in Scotland. He defeated the natives at Mons Graupius, possibly in Banffshire, probably in AD 84. In the following year he was recalled, and his policy of containing the hostile tribes within the Highland zone, which he had marked by building a legionary fortress at Inchtuthil in Strathmore, was not continued. His tactics were logical, if Scotland was to be subdued, but probably required the commitment of more troops than the overall strategy of the Roman Empire could afford. The only other period that a forward policy was attempted was between about 144 and about 190, when a turf wall, the Antonine Wall (named after the emperor Antoninus Pius), was manned between the Forth and the Clyde.

The still-impressive stone structure known as Hadrian's Wall had been built between the Tyne and Solway Firth in the years 122–128, and it was to be the permanent northern frontier of Roman Britain. After a northern rising, the emperor Severus supervised the restoring of the Hadrianic line in the years 209–211, and thereafter southeast Scotland seems to have enjoyed almost a century of peace. In the 4th century there were successive raids from north of the Wall and periodic withdrawals of Roman troops to the Continent. Despite increasing use of native buffer-states in front of the Wall, the Romans found their frontier indefensible by the end of the 4th century.

At Housesteads, at about the midpoint of Hadrian's Wall, archaeologists have uncovered a market where northern natives exchanged cattle and hides for Roman products: in this way some Roman wares, and possibly more general cultural influences, found their way north, but the scale of this was probably small. Roman civilization, typified by the towns and villas, or country houses, of southern Britain, was unknown in Scotland. Thus Scotland as a whole was never dominated by the Romans, nor even strongly influenced by them.

From about AD 400 there was a long period for which written evidence is scanty. Four peoples—the Picts, the Scots, the Britons, and the Angles—were eventually to merge and thus form the kingdom of Scots.

The peoples of early Scotland

The Picts occupied Scotland north of the Forth. Their identity has been much debated, but they possessed a distinctive culture, seen particularly in their carved symbol stones. Their original language, presumably non-Indo-European, has disappeared: some Picts probably spoke a Brythonic Celtic language. Pictish unity may have been impaired by their custom of succession to the throne, which is thought to have been matrilinear.

The Scots, from Dalriada in northern Ireland, colonized the Argyll area, probably in the late 5th century. Their continuing connection with Ireland was a source of strength to them, and Scots and Irish Gaelic (Goidelic Celtic languages) did not become distinct from one another until the late Middle Ages. Scottish Dalriada soon extended its cultural as well as its military sway east and south, though one of its greatest kings, Aidan, was, in 603, defeated by the Angles at Degsastan near the later Scottish border.

The Britons, speaking a Brythonic Celtic language, colonized Scotland from farther south, probably from the first century BC onward. They lost control of southeastern Scotland to the Angles in the early 7th century AD. The British heroic poem *Gododdin* describes a stage in this process. The British kingdom of Strathclyde in southwestern Scotland remained, with its capital at Dumbarton.

The Angles were Teutonic-speaking invaders from across the North Sea. Settling from the 5th century, they had by the early 7th century created the kingdom of Northumbria, stretching from the Humber to the Forth. A decisive check to their northward advance was administered in 685 by the Picts at the Battle of Nechtansmere in Angus.

Christianity. Christianity was introduced to Scotland in late Roman times, and traditions of St. Ninian's evangelizing in the southwest have survived. He is a shadowy figure, and it is doubtful if his work extended very far north.

Christianity was firmly established throughout Scotland by the Celtic clergy, coming with the Scots settlers from Ireland, and possibly giving the Scots a decisive cultural advantage in the early unification of Scotland. The Celtic Church lacked a territorial organization of parishes and dioceses and a division between secular and regular clergy: its communities of missionary monks were ideal agents of conversion. The best known figure, possibly the greatest, is St. Columba who founded his monastery at Iona, an island of the Inner Hebrides, in 565: his life was written by Adamnan, abbot of Iona, within a century of his death. Columba is believed to have been influential in converting the Picts, and he certainly did much to support the Scots king Aidan politically.

St. Columba

St. Aidan brought the Celtic Church to Northumbria in the 630s, establishing his monastery at Lindisfarne. At the Synod of Whitby in 664 the king of Northumbria had to decide between the Celtic and the Roman styles of Christianity: he chose the latter. There had been differences over such observances as the dating of Easter, but there was no question of the Celtic monks being regarded as schismatics. The *Ecclesiastical History of the English People*, by Bede, a monk of Jarrow in Northumbria (died 735) is a first-rate source for the history of Dark Age Scotland and shows remarkable sympathy with the Celtic clergy, though Bede was a Roman monk.

In the early 8th century the church among the Picts and Scots accepted Roman usages on such questions as Easter. Nevertheless, the church in Scotland remained Celtic in many ways until the 11th century: still dominated by its communities of clergy (who were called Célidé or Culdees), it clearly corresponded well to the tribal nature of society.

The Norse influence. Viking raids on the coasts of Britain began at the end of the 8th century, Lindisfarne and Iona being pillaged in the 790s. By the mid-9th century, Norse settlement of the western and northern isles and of Caithness and Sutherland had begun: the main cause was probably overpopulation on the west coast of Norway. During the 10th century, Orkney and Shetland were ruled by Norse earls nominally subject to Norway. In 1098 Magnus II Barefoot, king of Norway, successfully asserted his authority in the northern and western isles and made an agreement with the king of Scots on

their respective spheres of influence. A mid-12th-century earl of Orkney, Ragnvald, built the great cathedral at Kirkwall in honour of his martyred uncle St. Magnus.

The Norse legacy to Scotland was long lasting. In the mid-12th century there was a rising against the Norse in the west under a native leader, Somerled, who drove them from the greater part of mainland Argyll. A Norwegian expedition of 1263 under King Haakon IV failed to maintain the Norse presence in the Hebrides, and three years later they were ceded to Scotland by the Treaty of Perth. In 1468–69 the northern isles of Orkney and Shetland were pawned to Scotland as part of a marriage settlement with the crown of Denmark-Norway. A Scandinavian language, the Norn, was spoken in these Viking possessions, and some Norse linguistic influence is discernible in Shetland to the present day.

THE UNIFICATION OF THE KINGDOM

In 843 Kenneth I MacAlpin, king of Scots, also became king of the Picts and crushed resistance to his assuming the throne. Kenneth may have had a claim on the Pictish throne through the matrilinear law of succession: probably the Picts, too, had been weakened by Norse attacks. The Norse threat helped to weld together the new kingdom of Alba and to cause its heartlands to be located in eastern Scotland, the former Pictland, with Dunkeld becoming its religious capital. But within Alba it was the Scots who established a cultural and linguistic supremacy, no doubt merely confirming a tendency seen before 843.

Ascendancy of the Scots

As the English kingdom was consolidated, its kings, in the face of Norse attacks, found it useful to have an understanding with Alba. In 945 Edmund of England is said to have leased to Malcolm I of Alba the whole of Cumbria, probably an area including land on both sides of the western half of the later Anglo-Scottish border. In the late 10th century a similar arrangement seems to have been made for Lothian, the corresponding territory to the east. The Scots confirmed their hold on Lothian, from the Forth to the Tweed, when, about 1016, Malcolm II defeated a Northumbrian army at Carham. About the same time, Malcolm II placed his grandson Duncan I upon the throne of the British kingdom of Strathclyde. Duncan succeeded Malcolm in 1034 and brought Strathclyde into the kingdom of Scots. During the next two centuries the Scots kings pushed their effective power north and west—William I was successful in the north and Alexander II in the west—until mainland Scotland became one political unit. Less discernible but as important was the way the various peoples grew together, though significant linguistic and other differences remained.

According to the Celtic system of succession, known as tanistry, a king could be succeeded by any male member of the *derbfine*, a family group of four generations: members of collateral branches seem to have been preferred to descendants, and the successor, or tanist, might be named in his predecessor's lifetime. This system, in practice, led to many successions by the killing of one's predecessor. Thus Duncan I was killed by his cousin Macbeth in 1040, and Macbeth was killed by Malcolm III Canmore, Duncan I's son, in 1057. Shakespeare freely adapted the story of Macbeth, who historically seems to have been a successful king and who may have gone on pilgrimage to Rome.

Up to the 11th century the unification was the work of a Scots Gaelic-speaking dynasty, and there is place-name evidence of the penetration of Gaelic south of the Forth. But from then on, the Teutonic English speech that had come to Scotland from the kingdom of Northumbria began to attain mastery, and Gaelic began its slow retreat north and west. This is not obscured by the fact that, from the 12th century onward, Anglo-Norman was for a time the speech of the leaders of society in England and Scotland alike. By the later Middle Ages, Old English had evolved into two separate languages, Middle English and Middle Scots, the latter with the court of the Stewart (Stuart) kings of Scots as its focus. After 1603, the increasing political and cultural assimilation of Scotland to England checked the further development of Scots as a separate language.

The persistence of distinctively Celtic institutions in post-12th-century Scotland is a more complex question, as will be seen from the way in which primogeniture replaced tanistry as the system of royal succession. It can be argued, however, that a Celtic stress on the family bond in society persisted throughout the Middle Ages and beyond—and not only in the Highlands, with its clan organization of society.

The royal succession

The development of the monarchy. Malcolm III Canmore (1058–93) came to the throne by disposing of his rivals and thereafter sought, in five unsuccessful raids, to extend his kingdom into northern England. Whereas his first wife, Ingibjorg, was the daughter of a Norse earl of Orkney, his second, Margaret, came from the Saxon royal house of England. With Margaret and her sons, Scotland entered a phase of being particularly receptive to cultural influence from the south. Margaret was a great patroness of the church but without altering its organization as her sons were to do.

On the death of Malcolm III on his last English raid, sustained attempts were made to prevent the application of the southern custom of succession by primogeniture. Both Malcolm's brother and Malcolm's son by his first marriage held the throne for short periods: but it was the three sons of Malcolm and Margaret who eventually established themselves—Edgar (1097–1107), Alexander I (1107–24), and David I (1124–53). The descendants of Malcolm III's first marriage continued to trouble the ruling dynasty until the early 13th century, but the descendants of his second retained the throne. It happened that until the late 13th century, the heir to the throne by primogeniture was always the obvious candidate. It is noteworthy that in charters of about 1145, David I's son Henry (who was to die before his father) is described as *rex designatus*, very much like the tanist of the Celtic system. It is thus very hard to date precisely the acceptance of southern custom as exemplified by primogeniture.

Such was the force of Celtic reaction against southern influence that Edgar and Alexander I could be said to owe their thrones solely to English aid and were feudally subject to the English king.

David I. David I was by marriage a leading landowner in England and was well-known at the English court: he was, nevertheless, an independent monarch, making Scotland strong by drawing on English cultural and organizational influences. Under him and his successors many Anglo-Norman families came to Scotland, and their members were rewarded with lands and offices. Among the most important were the Bruces in Annandale, the de Morvilles in Ayrshire and Lauderdale, and the Fitzalans, who became hereditary High Stewards and who, as the Stewart dynasty, were to inherit the throne, in Renfrewshire. (After the 16th century the Stewart dynasty was known by its French spelling, "Stuart," the French language having no "w.") Such men were often given large estates in outlying areas to bolster the king's authority where it was weak.

Anglo-Norman settlement in Scotland

The decentralized form of government and society that resulted was one of the many variants of what is known as "feudalism," with tenants in chief holding lands, with jurisdiction over their inhabitants, from the king, in return for the performance of military and other services. An essentially new element in Scottish society was the written charter, setting out the rights and obligations involved in landholding. But the way in which the Anglo-Norman families, in their position as tenants in chief, were successfully grafted onto the existing society suggests that the Celtic and feudal social systems, although one stressed family bonds and the other legal contracts, were by no means mutually incompatible. The clan system of Highland Scotland became tinged with feudal influences, whereas Lowland Scottish feudalism retained a strong emphasis on the family.

David began to spread direct royal influence through the kingdom by the creation of the office of sheriff (*vicecomes*), a royal judge and administrator ruling an area of the kingdom from one of the royal castles. Centrally, a nucleus of government officials, such as the chancellor, the chamberlain, and the justiciar, was created by David

and his successors: these officials, with other tenants in chief called to give advice, made up the royal court (Curis Regis). This body became formalized in various ways: by the mid-13th century it might meet as the king's council to discuss various types of business; and before the Wars of Independence (see below) the royal court in its capacity as the Supreme Court of Law was already being described as a Parliament. The almost total loss of all of the Scottish governmental records from before the early 14th century should not lead one to underestimate the efficiency of the Scots kings' government in this period; historians in recent years have done much to assemble the surviving royal documents from scattered sources.

From David's time onward, the burghs, or incorporated towns, were created as centres of trade and small-scale manufacture in an overwhelmingly agrarian economy. At first, all burghs probably had equal rights. Later, however, royal burghs had, by their charters, the exclusive right of overseas trade, though tenants in chief could create burghs with local trade privileges. Burghs evolved their own law to govern trading transactions, and disputes could be referred to the Court of the Four Burghs (originally Berwick, Edinburgh, Roxburgh, and Stirling). Many of the original townspeople, or burgesses, were newcomers to Scotland. At Berwick, the great trading town of the 13th century, exporting the wool of the border monasteries, Flemish merchants had their own Red Hall, which they defended to the death against English attack in 1296. Besides commercial contacts with England, there is evidence of Scottish trading with the Low Countries and with Norway in the period before the Wars of Independence.

David's reorganization of the church

The church was decisively remodelled by David I and his successors. A clear division emerged between secular and regular clergy according to the normal western European pattern. A complete system of parishes and dioceses was established. But the system of "appropriating" the revenue of parish churches to central religious institutions meant that the top-heaviness in wealth and resources of the church in Scotland was a built-in feature of its existence until the Reformation. Kings and other great men vied in setting up monasteries. Alexander I had founded houses of Augustinian canons at Scone and Inchcolm, while among David's foundations were the Cistercian houses of Melrose and Newbattle and the Augustinian houses of Cambuskenneth and Holyrood. Augustinian canons might also serve as the clergy of a cathedral, as they did at St. Andrews. Prominent foundations by the magnates included Walter Fitzalan's Cluniac house at Paisley, and Hugh de Morville's Premonstratensian house at Dryburgh. Later royal foundations included that of the Benedictine house at Arbroath, established by William I.

From the standpoint of a later age, when the monasteries had lost their spiritual force, the piety of David I especially seemed a misapplication of royal resources. But the original monasteries, with their supply of trained manpower for royal service, their hospitality, and their learning, epitomized that stability which it was royal policy to achieve.

From at least 1072, the English Church, particularly the Archbishop of York, sought some control over the Scottish Church: the Scottish Church was weakened in face of such a threat through having no metropolitan see. But, probably in 1192, the Pope by the bull *Cum Universi* declared the Scottish Church to be subject only to Rome; and in 1225 the bull *Quidam Vestrum* permitted the Scottish Church, lacking a metropolitan see, to hold provincial councils by authority of Rome. Such councils, which might have served to check abuses, were, however, seldom held.

It has been argued that the cultural developments encouraged by the church in pre-Reformation Scotland were not as great as might be expected, but this may be a false impression created because the manuscript evidence has failed to survive. The monasteries of Melrose and Holyrood had each a chronicle, and Adam of Dryburgh was an able theologian of the late 12th century. Surviving Romanesque churches show that Scotland partook of the common European architectural tradition of the time: good small examples are at Dalmeny, near Edinburgh, and at Leuchars, in Fife. Glasgow and Elgin cathedrals are noteworthy, and St. Andrews Cathedral is impressive even in its ruined state. There are also distinguished examples of castle architecture, such as Bothwell in Lanarkshire; and the castles of Argyll may reflect a distinctive mixture of influences, including Norse ones.

David's successors

Malcolm IV (1153–65) was a fairly successful king, defeating Somerled when the latter, who had been triumphant over the Scandinavians in Argyll, turned against the kingdom of Scots. Malcolm's brother, William I the Lion (1165–1214) subdued much of the north, and established royal castles there. After his capture on a raid into England, he was forced to become feudally subject to the English king by the Treaty of Falaise (1174); he was able, however, to buy back his kingdom's independence by the Quitclaim of Canterbury in 1189, though it should be emphasized that this document disposed of the Treaty of Falaise and not of the less precise claims of superiority over Scotland that English kings had put forward over the previous century. William's son, Alexander II (1214–49), subdued Argyll and was about to proceed against the Hebrides at the time of his death. His son, Alexander III (1249–86), brought these islands within the Scottish kingdom in 1266, adroitly fended off English claims to overlordship, and brought to Scotland the peace and prosperity typified by the commercial growth of Berwick. In the perspective of the subsequent Wars of Independence, it was inevitable that men should look back on his reign as a golden age.

THE WARS OF INDEPENDENCE

Competition for the throne. With the death, in 1286, of Alexander III and of his young granddaughter Margaret, the "Maid of Norway," four years later, almost two centuries of relatively amicable Anglo-Scottish relations came to an end. A complete uncertainty as to the proper succession to the throne provided Edward I of England and his successors with a chance to intervene in and then to assimilate Scotland. Though the two countries were feudal monarchies of a largely similar type, the English attempt was, in practice, too tactless to have any hope of success. Besides, the struggle for independence disclosed that a marked degree of national unity had arisen among the different peoples of Scotland. The Anglo-Scottish conflict thus begun gave Scotland a basic tendency—to seek self-sufficiency and at the same time to look to continental Europe for alliances and inspiration—that persisted at least until 1560.

The "Maid of Norway"

Before the death of the Maid of Norway, the Scottish interim government of "guardians" had agreed (by the Treaty of Birgham, 1290) that she should marry the heir of Edward I of England, though Scotland was to be preserved as a separate kingdom. After her death, 13 claimants for the Scottish crown emerged, most of them Scottish magnates. The Scots had initially no reason to suspect the motives of Edward I in undertaking to judge the various claims. It emerged, however, that Edward saw himself not as an outside arbitrator but as the feudal superior of the Scots monarch and, therefore, able to dispose of Scotland as a fief. That Edward's interpretation was disingenuous is suggested by the fact that he had not invoked the old and vague English claims to superiority over Scotland while the Maid of Norway was still alive and had made a treaty with Scotland on a basis of equality, not as a feudal superior claiming rights of wardship and marriage over the Maid.

The leading competitors, who had much to lose by antagonizing Edward, agreed to acknowledge his superior lordship over Scotland. But a different answer to his claim to lordship was given by the "community of the realm" (the important laymen and churchmen of Scotland as a group), who declined to commit whoever was to be king of Scots on this issue and thus displayed a sophisticated sense of national unity.

Bruce and Balliol

Robert Bruce and John Balliol, descendants of a younger brother of Malcolm IV and William, emerged as the

leading competitors, and in 1292 Edward I named the latter as king. When Edward sought to exert his overlordship by taking law cases on appeal from Scotland and by summoning Balliol to do military service for him in France, the Scots determined to resist. In 1295 they concluded an alliance with France, and in 1296 Edward's army marched north, sacking Berwick on its way.

Edward forced the submission of Balliol and of Scotland with ease. National resistance to English government of Scotland grew slowly thereafter and was led by William Wallace, a knight's son, in the absence of a lead from the magnates: Wallace defeated the English at Stirling Bridge in 1297 but lost at Falkirk the next year. He was executed in London in 1305, having shown that heroic leadership without sufficient social status was not enough. When Robert Bruce, grandson of the competitor, rose in revolt in 1306 and had himself crowned Robert I, he supplied the focus necessary for the considerable potential of national resistance.

In several years of mixed fortunes thereafter, Robert had both the English and his opponents within Scotland to contend with. Edward I's death, in 1307, and the dissension in England under Edward II were assets that Bruce took full advantage of. He excelled as a statesman and as a military leader specializing in harrying tactics: it is ironic that he should be remembered best for the atypical set-piece battle that he incurred and won at Bannockburn in 1314. The Declaration of Arbroath of 1320 is perhaps more informative about his methods. Ostensibly a letter from the magnates of Scotland to the Pope, pledging their support for King Robert, it seems in reality to have been framed by Bernard de Linton, Robert's chancellor. In committing Robert to see the independence struggle through, it likewise committed those who set their seals to it. Some of them were waverers in the national cause, whether or not Robert had proof of this at the time, and his hand was now strengthened against them.

Robert I secured from England a recognition of Scotland's independence by the Treaty of Northampton in 1328; 1329 saw the Pope's granting to the independent kings of Scots the right to be anointed with holy oil, but it also saw the death of Bruce. By the appropriate standards of medieval kingship his success had been total; but by the nature of medieval kingship, his successor was left with the same struggle to wage all over again.

David II. Robert I's son, David II (1329–71), has perhaps received unfair treatment from historians through having been contrasted with his illustrious father. Just over five years of age at his accession, he was soon confronted with a renewal of the Anglo-Scottish war, exacerbated by the ambitions of those Scots who had been deprived of their property by Robert I or otherwise disaffected. In the 1330s Edward Balliol, pursuing the claim to the throne of his father John, overran southern Scotland. In return for English help, he gave away to England southern lands and strongpoints not recaptured fully by the Scots for a century. After the Scots defeat at Halidon Hill near Berwick in 1333, David was forced to flee to France in the following year. Berwick itself fell to the English and was never again in Scots hands except in the period 1461–82.

Battle of Halidon Hill

The Scots gradually regained the initiative, and in 1341 David was able to return to Scotland. But in 1346 David II himself was captured at the Battle of Neville's Cross near Durham. He was released in 1357 for a ransom of 100,000 merks. This ransom, if paid (and three-quarters of it eventually was), would constitute a serious burden on Scotland, and there is evidence of Parliament's using this national emergency to establish some checks on the actions of the crown. In addition, the representatives of the royal burghs, which were important as an accessible source of finance, established a continuing right to sit in Parliament with the magnates and churchmen from the 1360s on, thus constituting the third of the "Three Estates."

Complex evidence relating to these transactions has been uniformly interpreted in a way discreditable to David. Another interpretation is possible. That he collected revenues more assiduously than he made ransom payments may indicate a reasoned attempt to strengthen the crown financially; and his negotiations, especially of 1363, whereby a member of the English royal house was to succeed him on the Scottish throne, may have been a diplomatic charade. Whatever his faults, David left Scotland with both its economy and its independence intact.

The long wars with England necessarily took their toll, retarding Scotland's economy and weakening the authority of her government. The buildings that have survived from this era are inferior to earlier work, much of which, of course, suffered damage at this time. War was increasingly expensive, and taxation was increased drastically to pay David II's ransom. But again, a rosier alternative picture can be painted, suggesting that the burgesses were able to meet the increased taxation because of increased prosperity through the still-continuing trade with England.

SCOTLAND IN THE 15TH CENTURY

The early Stewart kings. David was succeeded by Robert II (1371–90), previously the high steward and son of Robert I's daughter Marjory. The next king was Robert II's son John, restyled Robert III (1390–1406). It may be that Robert II's conduct was responsible for dissension in Scotland during David II's reign, particularly during his captivity in England. At any rate, neither Robert II nor his son Robert III were strong kings and some nobles regarded both as upstarts, and the latter as of doubtful legitimacy. There thus began a long period of monarchical weakness in Scotland, accentuated by a series of royal minorities in the 15th and 16th centuries. Historians have made much of the turbulence of these times, but there were comparable periods of governmental weakness in contemporary England and France: and "bonds of manrent" and other alliances made by the magnates with each other and with their social inferiors should be seen as much as attempts to secure political stability in their own localities as threats to the overall peace of the kingdom.

Robert III's younger brother, Robert Stewart, 1st duke of Albany, more than once was given powers to rule in his brother's name, and Robert's son James may have been sent to France in 1406 in order to keep him out of Albany's clutches. But James was captured at sea by the English, and shortly afterward Robert III died. Albany (died 1420) and then his son Murdac misgoverned the realm until 1424, when James I, then 29, was ransomed.

The Douglas family was becoming particularly powerful at this time. They had been rewarded with the gift of the royal forest of Selkirk and other lands in south and southwest Scotland for loyal service to Robert I. But the growing power of the Douglases in this vital border area posed by the end of the 14th century a growing threat to the crown, no longer able to count on the direct personal loyalty of the Douglas family. At the same time the Lords of the Isles had attained a stature in the western Highlands that overtopped that of the kings of Scots.

One notable event was the founding of Scotland's first university at St. Andrews. The Wars of Independence led Scots students to go to Paris rather than to Oxford or Cambridge. But universities were the training grounds of the clergy, and when, in the period 1408–18, Scotland recognized the anti-Pope Benedict XIII after he had been abandoned by France, it became expedient for Scotland to have its own university. The bulls of foundation from Benedict XIII reached St. Andrews in 1414.

James I (1406–37) was an active and able king, keen to make the crown wealthy and powerful again. Perhaps he was overimpatient to make up for time lost in his captivity, and thus he prompted the opposition to him that led to his death. New posts, those of the comptroller and treasurer, were created to gather royal revenues more efficiently. Murdac, 2nd duke of Albany, was executed in 1425, and other powerful men were overawed, even in the far north. The laws were to be revised, and in 1426 a court for civil cases was set up, presaging the later Court of Session.

The reign of James I

Possibly to balance the power of the magnates, it was

enacted in 1426 that all tenants in chief should attend Parliament in person. More realistically, they were, from 1428, permitted to send representatives from each shire. Even this system did not operate until the late 16th century. If James had been inspired during his captivity by the English House of Commons, he was unable to transplant that institution to Scotland. The Scots Parliament, like that of many other European countries, remained throughout the medieval period the feudal court of the kings of Scots: not undergoing the distinctive development of the English Parliament, it did not differ essentially in kind from the feudal court of any great magnate. Despite, or perhaps because of, his innovative vigour, James made enemies for himself. His murder in 1437 was part of an attempt to seize the throne for Walter Stewart, earl of Atholl, but the conspirators were executed and James's young son succeeded him.

James II (1437–60) was six at the time of his accession. His minority was marked by struggles between the Crichton and Livingstone families. During this minority and that of James III, James Kennedy, bishop of St. Andrews, played a statesmanlike part in seeking to preserve peace. James II took a violent line against overmighty subjects. In 1452 he stabbed William Douglas, 8th earl of Douglas to death, and in 1455 James Douglas, 9th earl, was attainted. The main line of the Douglas family never regained its position, though a younger, or cadet, branch of the family, the earls of Angus, was important in the late 15th century. James II, like his father, thus sought manfully to reassert royal authority, and Scotland lost an able king when he was killed by the bursting of a cannon at the siege of Roxburgh Castle, one of the last Scottish strongpoints in English hands. Roxburgh was subsequently captured by the Scots. Among the cultural advances of the reign was the founding, in 1451, by Bishop William Turnbull of the University of Glasgow, Scotland's second university.

James III (1460–88), James's son, was eight years old at his accession. During his minority he was for a time the pawn of the Boyd family. The so-called Treaty of Westminster-Ardtornish of 1462 showed that John, Lord of the Isles, and the exiled Douglas were prepared to try to carve Scotland into two vassal states of England for themselves. The alliance came to nothing, but the Lords of the Isles were a threat to the territorial integrity of Scotland until their final forfeiture in 1493. On the other hand, the power vacuum left by their removal was responsible for much of the unrest in the western Highlands thereafter. It was in James III's reign that the territory of Scotland attained its fullest extent with the acquisition of Orkney and Shetland in 1468–69.

Character of James III

As James III came of age, he seems to have given grave offense to his nobles by shunning their company for that of artistic people. It has been suggested that his fine sensibility did him credit, but this is probably an anachronistic view. When it is seen what political disorder could follow from the absence of an adult male ruler in later medieval Scotland, it may be thought correspondingly important that such a ruler, when present, should have cultivated the nobles who were his natural companions and political associates and who tended to support a ruler who combined tact with good government. So serious was James's lack of authority that Berwick fell in 1482, when the nobles, led by Archibald Douglas, 5th earl of Angus, chose—rather than defend it against the English—to seize their opportunity to hang some of James's favourites. In 1488 James was murdered while fleeing from a battle against his opponents at Sauchieburn, though it seems that the death of the king was not intended, and he was succeeded without trouble by his son.

Fifteenth-century society. There is evidence of economic recovery in Scotland in this period, despite the continuing war and unrest. Castle-building and the extending of monasteries and cathedrals were widespread: work was done on the royal residences at Linlithgow and Stirling. The building of collegiate churches and of fine burgh churches is additional evidence of prosperity. Royal burghs with their share in international trade and baronial burghs with their rights in their own locality were alike flourishing. The craftsmen threatened to rival the merchants in the running of burgh affairs, but an act of 1469 gave the merchants the majority on the town councils: this allowed self-perpetuating cliques to misapply the assets of the burghs, an abuse not remedied until the 19th century. Accompanying the prosperity general in Scotland at this time was a tendency to inflation, and a debasement of the coinage added to the troubles of James III's reign.

Cultural life

From the late 14th century onward, interesting Scottish writing, both in the vernacular and in Latin, has survived. John Barbour (1316?–95) wrote a verse life of Robert I in Scots. A Latin history of Scotland was compiled by John of Fordun and continued by Walter Bower, abbot of Inchcolm, in his *Scotichronicon*. Andrew of Wyntoun wrote a history of Scotland in Scots verse.

Little is left of the corpus of medieval writings in Scottish Gaelic. But the sophistication of the west Highland stone carvings of the later Middle Ages suggests that a strong literary culture, too, was associated with the courts of the Lords of the Isles and other chiefs. The *Book of Deer*, containing the Gospels, has in its margins an 11th-century Gaelic account of Columba's foundation of the monastery of Deer in Aberdeenshire, and a series of *notitiae*, or lists of church rights, which provide clues to the nature of Celtic society. The early-16th-century *Book of the Dean of Lismore* (the seat of the Bishop of Argyll) contains over 60 Gaelic poems. From the quality of the architecture that has survived from the 15th century, one can infer the existence of paintings and other objects, such as church furnishings, that have largely disappeared. An outstandingly intricate collegiate church is that at Roslin near Edinburgh, founded by Sir William Sinclair, 3rd earl of Orkney, about 1450. There are fine burgh churches, such as St. John's in Perth and the Church of the Holy Rood in Stirling. Perhaps the outstanding piece of evidence of royal patronage of the arts is the altarpiece for James III's Trinity College Church in Edinburgh: the altarpiece is almost certainly the work of the great Flemish painter Hugo van der Goes.

The church

In the 14th century the papacy had built up its claims to appoint to the higher offices in the church and in Scotland had established a system of "provisions," or papal appointments, to vacant offices. This cut not merely across the rights of rulers who used the church to provide their loyal bureaucrats with a living and the rights of other local patrons; it also meant a drain to Rome of money in the form of the tax payable by a cleric "provided" to a vacant post by the pope. James I resisted these developments, and at the same time, in the Council of Basel (1431–49), the "conciliarists" were seeking to curb papal power in the church: a distinguished member of the Council of Basel was the Scot Thomas Livingston, one of the first St. Andrews graduates.

James also sought to revive the monastic ideal in its early purity and established a house of the strict Carthusians at Perth. A compromise between James I and the Pope was probably pending when James was murdered, and his successors tended to let the popes collect their money as long as they "provided" to church offices along lines acceptable to the monarchy. In 1487 James III was granted the concession that the Pope would delay promotions to the higher offices for eight months so that the king could propose his nominee.

St. Andrews was made the seat of an archbishopric in 1472, in itself a desirable step. But the first archbishop of St. Andrews secured the honour by supporting the papacy against the king, and there was, as a result, no welcome for it in Scotland. Glasgow also became an archbishopric in 1492.

SCOTLAND IN THE 16TH CENTURY

James IV and James V. James IV (1488–1513) was well equipped for kingship, being physically impressive, cultured, generous, and active in politics and war alike. He eliminated a potential rival by carrying out the forfeiture of the last Lord of the Isles, in 1493, and dealt

severely with unrest on the English border and elsewhere. James and Bishop William Elphinstone of Aberdeen founded King's College, Scotland's third university, in Aberdeen in 1495. This was the great age of Scots poetry, and while one of the leading "makars," or poets, Robert Henryson (1430?–1506?), author of the *Testament of Cresseid*, was a burgh schoolmaster, the others were members of the court circle: Gavin Douglas (1474–1522), bishop of Dunkeld and kinsman to the earls of Angus, translated Virgil's *Aeneid* splendidly into Scots, and William Dunbar (1460?–1520), a technically brilliant poet, showed the versatility of which Scots was capable.

After initial disharmony with England, James concluded a "treaty of perpetual peace" with Henry VII in 1502 and married Margaret, Henry's daughter, in 1503. But Henry VIII of England became involved in the anti-French schemes of Pope Julius II, and in 1512 France and Scotland renewed their "auld alliance" as a counterbalance. In 1513 Henry VIII invaded France: James IV, consequently, invaded England; there he died, along with thousands of his army, in the rashly fought and calamitous Battle of Flodden.

Battle of Flodden

James's efficiency at home was thus offset by his excessive international ambitions. And both had cost money—for artillery; for a navy whose greatest ship, the "Michael," cost £30,000; for embassies. The crown granted lands in feu-ferme tenure, which gave heritable possession in return for a substantial down payment and an unchangeable annual rent thereafter. In the great European price rise of the 16th century, this policy in the long term weakened the crown.

James V (1513–42) was in his second year at his accession. The factional struggles of his minority were given shape by the division between those who adhered to Scotland's pro-French alignment, and those who were determined that the price Scotland paid at Flodden should not be repeated. John Stewart, duke of Albany, was regent until 1524, and favoured France: Archibald Douglas, 6th earl of Angus, then maintained a pro-English policy until 1528 when James began his personal rule. James now found Scotland's support in international politics being sought on all sides. In the 1530s he obtained papal financial help in establishing a College of Justice, and he concluded two successive French marriages, each bringing a substantial dowry: his second wife was Mary, daughter of the duc de Guise and mother of Mary, Queen of Scots. James's support for the papacy and France alienated some of his subjects, however, and his rule was not simply strict and financially vigorous but rather avaricious and vindictive. Lack of noble support seems to have caused the rout at Solway Moss in November 1542 of a force invading England. This, and the deaths of his infant sons, led to the death of James, probably from nervous prostration, in December, a week after the birth of his daughter Mary.

Mary and the Scottish Reformation. The church in 16th-century Scotland may not have had more ignorant or immoral priests than in previous generations, but restiveness at their shortcomings was becoming more widespread. And the power structure of the church seemed to preclude the possibility of reform without revolution. The church made a poor showing at the parish level, since by 1560 the bulk of the revenues of nearly nine parishes in every ten was appropriated to monasteries and other central institutions. The papacy, in return for receiving its share of this wealth, abandoned spiritual direction of the Scottish Church: from 1487, royal control over appointments to the higher church offices grew steadily. All this, at a time when the church's annual revenue—reckoned at £400,000 in 1560—was ten times that of the crown, readily explains the attraction of church office for unspiritual career-seeking nobles. Church lands were feued to laymen, who also became collectors of church revenues and were given abbeys as benefices. Church property, particularly monastic property, was effectively being secularized, and if Protestantism offered to the nobles and lairds of Scotland a more spiritually alive church—and one with lay participation—it probably also appealed to them as a system under which they would not have to hand back what they had grabbed.

Particular laymen were as pious as ever, endowing collegiate churches as they had once endowed monasteries, and trenchant criticism of church abuses was expressed in the play *Ane Pleasant Satyre of the Thrie Estaitis* by Sir David Lyndsay (*c.* 1490–*c.* 1555). But reform from within was probably almost impossible: Archbishop John Hamilton, for instance, a would-be reformer who gave his name to a vernacular catechism (1552), belonged to the family who had most to lose if the careerists were curbed.

Mary, Queen of Scots

Mary (1542–67) began her reign as another Stewart child ruler in the hands of factions: the pro-French party upheld the old church, while the pro-English desired reform. By the Treaties of Greenwich (1543), Mary was to marry Edward, Henry VIII's heir. Cardinal David Beaton and Mary of Guise, the queen mother, had this policy rescinded, and the murder of Beaton (1546) and English punitive raids culminating in the Scots defeat at Pinkie (1547) did not cause Scotland to love England more. France helped Scotland to expel the English but only in return for such a hold over the country that by the time of young Mary's marriage to the Dauphin in 1558 it was France that appeared to be about to absorb Scotland.

Anti-French feeling combined with Protestant preaching to bring about revolt. In 1559 the reformers took up arms to forestall Mary of Guise's action against them. Despite the preaching of John Knox and others and the plundering of the monasteries, the decisive issues were political and military: Queen Elizabeth of England sent troops to check French plans in Scotland. Mary of Guise died in June 1560, and by the Treaty of Edinburgh in July, both France and England undertook to withdraw their troops. With Scotland thus neutralized, England had the important advantage over France of relative nearness.

The Scots Parliament in August 1560 abolished papal authority and adopted a reformed Confession of Faith, but Mary, still in France, did not ratify this legislation. Still, the organization of local congregations, which had been going on for some years, continued, and the General Assembly emerged as the central legislative body for the church. In the *First Book of Discipline* (1560), John Knox and other ministers proposed for the church a striking social program, providing education and poor relief. But laymen had not despoiled the old church to enrich the new, and, as an interim settlement secured by Mary's government in 1562, the church and crown were together to share but one-third of the old church's revenue.

John Knox

Mary's husband died in 1560, and in 1561 she returned to Scotland. As a Catholic in a Protestant land and as nearest heir, by descent from Henry VII's daughter, to Elizabeth of England, she had many enemies. Her personal reign was brief and dramatic—she married her cousin Darnley (1565); their son James was born (1566); Darnley was murdered (1567); Mary married the adventurer James Hepburn, 4th earl of Bothwell; was imprisoned and forced to abdicate (1567); escaped and fled to England (1568). Her task as a ruler was hard, and the harder for her own errors of judgment, but she essayed it bravely and was a truly tragic rather than a pathetic figure.

James VI (1567–1625). James lived through the usual disrupted minority to become one of Scotland's most successful kings. In a civil war between his and his mother's followers, laird (landed proprietor) and merchant support for James may have been decisive in his eventual victory. Elizabeth detained Mary in England and assisted James Douglas, 4th earl of Morton, regent from 1572, to achieve stability in Scotland.

James's government ratified the reformed church settlement, and more permanent measures of church endowment were taken. The Concordat of Leith (1572) allowed the crown to appoint bishops with the church's approval. As in Mary's reign, the crown was intervening to prevent the wealth of the old church from being entirely laicized. And if the bishopric revenues were saved from going the

same way as the monastic wealth, the crown expected a share in them for its services.

A new presbyterian party in the church, whose members wanted parity of all ministers and freedom from state control, rejected this compromise. Led by Andrew Melville, a rigid academic theorist, they demanded, in the *Second Book of Discipline* (1578), that the new church should receive all the wealth of the old, that it be run by a hierarchy of courts, not one of bishops, and that the state should leave the church alone but be prepared to take advice from it. Many historians have seen these demands, as James undoubtedly did, as an attempt to achieve full-blown theocracy. James was not strong enough for out-and-out resistance immediately, and he sometimes made concessions, as in the Golden Act of 1592, which gave parliamentary sanction to the system of presbyterian courts. But he gradually showed his determination to run the church his own way, through the agency of his bishops, who were brought into Parliament in 1600. From 1606 Melville was detained in London and later banished. By 1610 the civil and ecclesiastical status of the bishops was secure. The continued existence of church courts—kirk sessions, presbyteries, synods, and the General Assembly—show James's readiness for compromise; and he showed a wise cautiousness toward liturgical reform after encountering hostility over his Five Articles of Perth (1618), which imposed kneeling at communion, observance of holy days, confirmation, infant Baptism, and other practices.

In the 1580s James, as he became personally responsible for royal policy, faced the need to control unruly subjects at home, nobles and kirkmen alike, and to win friends abroad. He concluded a league with England in 1586, and when Elizabeth executed his mother in the following year, he acquiesced in what he could not prevent. He thus inherited his mother's claim to the English throne, and his efforts thereafter to keep in the good graces of Elizabeth and her minister William Cecil were successful. He succeeded peacefully to the English throne in 1603, though his two monarchies, despite his own personal inclinations, remained distinct from one another.

Accession to English throne

His policy was one of overall insurance: he avoided giving offense to Catholic continental rulers, and, while he dealt effectively with lawbreakers on the border and elsewhere, he showed marked leniency to his Catholic nobles, even when the discovery of letters and blank documents (the "Spanish Blanks" affair, 1592) showed that several of them were in treasonable conspiracy with a foreign power. Neither a heroic king, like James IV, nor the pedantic and cowardly buffoon depicted in Sir Walter Scott's *The Fortunes of Nigel*, James VI was a supple and able politician. His theories of Divine Right monarchy were a scholar-king's response to an age when the practice and theory of regicide were fashionable. Except perhaps at the very end of his life, James was too realistic to let his theories entirely govern his conduct.

James excelled in picking good servants from among the lairds and burgesses: they were his judges and privy councillors, and sat on the Committee of Articles, with which he dominated Parliament. After 1603 they governed Scotland smoothly in his absence. From 1587 Parliament was made more representative by the admission of shire commissioners to speak for the lairds, thus realizing the program of James I. The privy council had judicial as well as legislative and administrative functions: there were, in addition, the Court of Session for civil cases (it had evolved from the council in the early 16th century and, as the College of Justice, had been endowed with church funds in the 1530s) and justice courts for criminal cases. Local justice and administration continued, however, despite James VI's efforts, to be largely the prerogative of the landowners.

Scotland still had a subsistence economy, exporting raw materials and importing finished goods, including luxuries. But such luxury imports showed that the greater landowners and merchants were gaining in prosperity. Despite the absence of adequate endowment, the reformed church began to create a network of parish schools and there was advance in the universities: Andrew Melville brought discipline and the latest scholarship to Glasgow and St. Andrews in turn, and there were new foundations at Edinburgh (the Town's College, 1582) and Aberdeen (Marischal College, 1593).

Scotland and England were drawing closer together, as the period of continual strife between them receded in time. Though the two national churches were not identical in structure, they shared a common desire to protect and preserve the Reformation. James VI's accession to the English throne in 1603 as James I encouraged further cultural and economic assimilation. It was far from guaranteeing further political assimilation, but a century of the barely workable personal union of the crowns was continually to sharpen for the Scots the dilemma of choosing between complete union and complete separation. (J.M.S.)

X. The early Stuarts and the Commonwealth (1603–60)

THE CONDITION OF ENGLAND IN 1603

In 1603 England was a nation of some 4,000,000–4,500,000 people, mostly living in the south and east, who were divided into social classes based, as Shakespeare observed in *Troilus and Cressida* (1609), upon "degree, priority, and place." At the top of the social hierarchy was the Stuart royal family, headed by King James I (1603–25), whose hereditary claim to the English throne came from his mother, Mary, Queen of Scots. Also, as James VI of Scotland, the King represented a personal union between the two kingdoms. Advising the King were his privy councillors, men of lesser political stature than those who had served under Elizabeth and, consequently, far less successful in managing the houses of Parliament. The ablest of them was Robert Cecil, 1st earl of Salisbury, son of Elizabeth's great minister Lord Burghley. After Salisbury's death in 1612, two young men captured James's affections: Robert Carr, earl of Somerset, who fell from power after his lovely young wife caused a court scandal by poisoning her detractor, Sir Thomas Overbury; and George Villiers, who rose from a gentleman of the bedchamber to become the 1st duke of Buckingham (1623). The King's fondness for young men can be seen in his statement to the Privy Council in 1617: "I love the Earl of Buckingham more than anyone else. . . . Christ had his John, and I have my George."

Social classes

Below the royal family came some 60 hereditary members of the nobility or aristocracy, ranging in descending order from dukes, marquesses, earls, viscounts, and barons who, together with 26 nonhereditary bishops, sat in the House of Lords. The doubling of the number of lay nobles as a result of "bargain and sale" by Buckingham not only brought the monarchy into disrepute but also brought a loss of prestige to the nobility. This crisis of confidence in the nobility, aggravated by its conspicuous consumption and the slow decay of its military power, greatly weakened the effectiveness of the Lords as a mediating body between the King and the House of Commons. The decline in the prestige of the nobility had been preceded by a financial crisis among the aristocracy from about 1590 to 1610 as a result of the shrinkage of their landed wealth. A member of the nobility claimed in 1628 that the Commons, which was made up mostly of gentry, could buy up the Lords three times over. By 1640 the aristocracy had probably recovered from its financial crisis.

Below the nobility came the gentry, who numbered less than 5 percent of the population. They were technically those large landowners to whom the College of Arms had granted the right of gentility—*i.e.*, the right to bear a coat of arms—but a small number of them held nonhereditary titles (either baronetcies or knighthoods), which, like the titles of the nobility, were sold by the crown or its ministers. Nearly 1,000 knights were created in James's first year on the throne. A fairly high turnover in the ownership of land, because of the inflation of prices, resulted in some changes in the composition of the gentry: some new families rose to the top (a few becoming peers), whereas some older families either died

out or declined, sometimes falling into the social category of yeomen, or chief farmers, who were only one step above the husbandmen, or petty farmers. Some members of both the gentry and the nobility engaged in careful estate management in order to meet the price squeeze, and a number of these improving landlords sought positions at court. These officeholders were part of the Court Party in the House of Commons. At the local county level, the justices of the peace—unpaid administrative officers of the crown—tended to be Country, or opposition, gentry, whereas the lords lieutenant—the unpaid military officers of the crown—frequently were Court, or government, peers. The conflict between the Court and Country parties was one of the long-range causes of the English Civil War later in the century, but it would be a mistake to assume that the difference, either at the national or local level, was as simple as an affluent rising Court Party and a poverty-stricken declining Country Party.

The economy

Although the economy of England was predominantly tied to land, there was a commercial society of financiers, manufacturers, merchants, shopkeepers, tradesmen, and artisans who lived in the cities and towns, the largest of which was London, with a population of about 250,000; Norwich, Norfolk, with 15,000, was the second largest. There were four times as many borough seats in the Commons as County seats, but the merchants comprised only a small fraction of the Commons. Many successful merchants acquired landed estates and married their daughters into the gentry and aristocracy. Conversely, the younger sons of gentry families who could not succeed to the family estate under the law of primogeniture frequently turned to trade and commerce in order to make their livings. As a result, there was a horizontal social mobility between town and country in addition to the vertical mobility within the town and country hierarchies that gave a certain vigour and freedom of opportunity to English society that tended to offset its rigid social structure.

JAMES I (1603–25)

Religious policy. When James travelled south from Edinburgh in April 1603 to take up his duties at Westminster, he was presented with the Millenary Petition (so called because it was allegedly supported by 1,000 ministers) calling for reforms of the Anglican Church.

The King, though a Calvinist in his theology, was an Erastian in church government, advocating state supremacy in ecclesiastical affairs; he responded to the Millenary Petition by calling a conference at Hampton Court in London to which he invited moderate Puritan divines and Anglican bishops. The Puritans presented their case for recasting the Thirty-Nine Articles along more Calvinist lines, for revitalizing popular preaching, and for excluding the "relics of popery" from the Anglican prayer book. The Puritans also proposed that religious questions should be settled by episcopal synods made up of a bishop and a presbytery (or a group of elders) rather than by the bishops alone. But James erroneously assumed that the Puritan proposal for a "reduced episcopacy" was in fact a proposal for a "Scottish presbytery," which, as he knew from personal experience in Scotland, tried to subordinate the state to the church. After all, it had been in reaction to this hierocratic view that the King had exhumed the medieval notion of divine-right monarchy in order to counteract the clerical demands of both Scottish Presbyterians and Roman Catholics. As James had written in his *Trew Law of Free Monarchies* (1598), "Kings are called Gods . . . because they sit upon GOD his Throne in the earth, and have the count of their administration to give unto [H]im." The King regarded any diminution of episcopal power as having the same effect, as stated in his often-quoted political aphorism: "no bishop, no king." The bishops were instrumental in getting the Convocation of the clergy to pass the Canons of 1604, which provided for the excommunication of anyone who impugned the royal supremacy, the Anglican prayer book, or the Thirty-nine Articles. Shortly afterward a group of Puritan Separatists—separatists because they no longer felt a binding tie with the Anglican Church—were forced to leave England, settling in Holland until their transatlantic crossing as Pilgrims to Plymouth Rock in 1620. Perhaps some of them were attracted by stories they had heard about an earlier English settlement at Jamestown, Virginia, in 1607. The only significant Puritan accomplishment to come out of the Hampton Court conference was the authorization for a new translation of the Bible—the King James Version used by all English-speaking Protestants until well into the 20th century. The King's experience with English Catholics was about as bad as it had been with Scottish Catholics, especially when a group of them, including Guy Fawkes, was caught in an abortive plot on November 5, 1605, to blow up the houses of Parliament. The Gunpowder Plot, which provoked Parliament to require an oath of allegiance to the King from Catholic recusants, jeopardized the Catholic cause for a number of years.

The Gunpowder Plot

James and Parliament. The first session of James's first Parliament in 1604 was primarily concerned with several questions of parliamentary privilege, which set the tone for the constitutional struggle with the crown. In a disputed parliamentary election case (*Goodwin* v. *Fortescue*), it was decided that in the future the Commons, rather than the Court of Chancery, was the proper judge of election returns. In a dispute over the parliamentary privilege of freedom from arrest, it was decided that a member of Parliament, Sir Thomas Shirley, who had been imprisoned for a private debt, should not be molested while Parliament was in session. Both of these privileges, together with that of freedom of speech (especially in matters of religion), were eloquently set forth at the end of the session by some of the members in *The Form of Apology and Satisfaction*. The *Apology* was a lecture to a foreign king on how parliamentary privileges were "our right and due inheritance," not something bestowed by the grace of the crown. Although the extremist language of the *Apology*—"the voice of the people, in the things of their knowledge, is said to be as the voice of God"—kept it from coming to a vote in the Commons and although James probably never received the intended instruction, it was a shadow of things to come.

The most important difference between the King and his parliaments arose over the question of money. James's conventional sources of revenue were several: the income from crown lands, feudal dues (especially wardship, or the right to collect income from estates left to minors), purveyance (buying at less than the market price), monopolies, and customs duties called tonnage and poundage on imported wine and exported wool. Since all of these fiscal sources were inadequate to handle the extravagance of the court, the rising costs, and the debt from the recently concluded war with Spain, the crown decided to levy impositions (additional customs duties). The legality of impositions had been upheld in 1606 in the trial of John Bate, a merchant who had refused to pay an imposition on currants. Chief Baron Thomas Fleming had ruled that impositions fell under the king's "absolute power," which, unlike his "ordinary power," could not be changed by Parliament. The new Book of Rates of 1608 increased impositions, but in the parliamentary session of 1610, when James had forbidden the members to discuss that subject, once again the Commons claimed the privilege of free speech. Salisbury's proposal in that session for a Great Contract (1610)—by which the King would give up his feudal dues and purveyance in exchange for an annual parliamentary grant of £200,000—was never completed because of the King's dissolution of Parliament. The short-lived "Addled" Parliament of 1614 was no more successful in solving the crown's financial problems. In that same year a syndicate formed by a London alderman, William Cockayne, tried to increase James's revenue by substituting the export of finished woollen cloth (with its higher duties) for the export of undyed woollen cloth previously handled by the monopoly company of the Merchant Adventurers. But the Dutch boycotted the new product,

The Great Contract

and, as a result, the woollen-cloth industry, the largest after agriculture, suffered severe dislocation, drastically reducing the King's revenue from customs.

According to Attorney General Francis Bacon, the king's judges were supposed to be "lions *under* the throne," but Chief Justice Edward Coke, who disagreed with the decision in the Bate case, thought that the judges, as interpreters of the common law, should be mediators between the prerogative of the king and the rights of Parliament. In the case of Dr. Thomas Bonham (1606), Coke stated: "when an act of Parliament is against common right and reason, or repugnant, or impossible to be performed, the common law will control it, and judge such an act to be void." American scholars in particular have regarded the "higher law background" of this case as an important precedent for the American doctrine of judicial review, whereby a supreme court may annul legislation or executive acts as contrary to a constitution. In the matter of prohibitions, whereby the common-law courts would take over proceedings in the Anglican Church courts dealing with the collection of tithes, Coke told James, much to the joy of the Puritans, that matters of property were not to be decided by "natural reason," which the king and the bishops admittedly possessed, but by "artificial reason," which only common lawyers possessed. In a dispute between the King and Parliament over the use, or abuse, of royal proclamations in 1610, Coke and his colleagues told James that the king had no prerogative except that which the law allowed him. The final showdown between James and Coke came in the case of *Commendams* (1616), when Bacon requested the 12 judges to delay their decision until the King—who said that, in cases involving the prerogative, he was a party to the suit—had spoken with them, but Coke alone, while lying prostrate before the throne, contended for the independence of the judiciary. Coke was dismissed as a judge but later joined the Country opposition in Parliament. Bacon became lord chancellor, only to be impeached by Parliament for bribery the year after he published his scientific treatise, *Novum Organum* (1620).

The Spanish marriage

Foreign policy. In matters of foreign policy, James was anxious to marry his surviving son, Charles, to the Spanish princess Donna Maria (in order to obtain a large dowry) and to become a peacemaker for Europe. But, at the same time, the German Catholic League, which Spain supported, toppled James's son-in-law, Frederick of the Palatinate, from his newly acquired kingdom of Bohemia and invaded the Upper Palatinate in what were to be the opening moves of the Thirty Years' War. Said James: "I like not to marry my son with my daughter's tears." The King reluctantly called his third Parliament in 1621 for funds to aid Frederick. The Commons continued to encroach upon the Stuart royal prerogative by criticizing the Spanish marriage and by urging a naval war with Spain, but James ordered them to desist from such "deep matters of State." At once the Commons issued the Protestation stating that foreign policy was a proper subject for the exercise of free speech in Parliament; the King, in turn, promptly tore the Protestation out of the journal of the House of Commons and dissolved Parliament. Even though the Rhenish Palatinate was occupied by Spanish troops in 1622, Prince Charles and Buckingham journeyed to Madrid the following year in an attempt to sweep the Princess off her feet. But they were so humiliated by their treatment there—Charles's leap over a wall to see the Princess was a fiasco—that they returned to England calling for war against Spain and the impeachment in Parliament of the pro-Spanish privy councillor, Sir Lionel Cranfield. At this, James told Buckingham that he was "making a rod with which you will be scourged yourself." England went to war with Spain in 1624, and negotiations were opened with France for a marriage between Charles and the French Catholic princess Henrietta Maria.

The economy. One of the results of the Thirty Years' War was a severe slump in the woollen-cloth trade in 1620, just after Cranfield had been successful in bringing about a temporary recovery following the disastrous Cockayne project. The most important cause of the slump was a devaluation of currencies in Germany and eastern Europe that made it difficult for the Merchant Adventurers and the Eastland Company to export cloth profitably. The ensuing unemployment and poverty in the West Country and Suffolk, the home of the Old Draperies, or broadcloths, together with bad harvests beginning in 1621 that sent food prices spiralling, produced the worst depression of the first half of the century. The parish register of Ashton-under-Lyne, Lancashire, indicates a possible famine condition during the bad harvest year of 1623–24, when burials were up 250 percent and births fell 43 percent from the previous year. The development of New Draperies, or worsted cloths, in East Anglia, which were sold in Spain and the semitropical climates by the Levant Company, did not offset the loss from the older markets. The King, who insisted that the regulation of economic affairs (not in any mercantile sense but as a part of his concern for public order and economic stability) was part of the royal prerogative, appointed a Commission of Trade, the precursor of the Board of Trade, to look into the whole matter. On its recommendation the Parliament of 1624 was able to get the Privy Council to loosen the grip of the Merchant Adventurers on trade to the Low Countries and Germany by allowing any merchant to join the export trade in the cheaper varieties of the Old Draperies and in the New Draperies. But Sir Edward Coke drew up a bill that prevented the granting of monopolies to individuals by the crown on the grounds that these monopolies constituted only a different form of taxation. Even though specific exemptions were made for charters of trading companies and town corporations and for patents on inventions, the Monopolies Act was a clear blow to the royal prerogative. By 1625 the stabilization of the foreign currencies permitted the cloth trade to return almost to normal, but the problem of Dutch competition remained, as was indicated by the massacre of East India Company traders in 1623 by the Dutch at Amboina in the Dutch East Indies.

Economic depression of 1620s

CHARLES I (1625–49)

Charles and Parliament. Unlike his father, Charles I (1625–49) was shy and nervous but handsome and dignified, as can be seen in portraits by Van Dyck, whom, with Rubens, he brought to England. Like James, Charles was an advocate of divine right, and, as James had warned, he was to have his "bellyfull of Parliament." Charles's immediate problem was to get Parliament to pay for the war against Spain. His first Parliament, in 1625, refused to grant him tonnage and poundage duties for life, so he dissolved this Parliament without getting any money to fight the war. From the King's rapidly dwindling resources, Buckingham was able to finance an expedition to attack the Spanish port of Cádiz. The venture failed disastrously, and Charles was again forced to turn to Parliament for funds. Charles's second Parliament, under the leadership of Sir John Eliot, demanded (as James had predicted) the impeachment of Buckingham. Charles again dissolved Parliament, still without money, because of the attack on his favourite. Instead, Charles and Buckingham resorted to the collection of forced loans and began to billet troops under martial law in private homes. Moreover, they foolishly went to war with the Catholic monarchy in France in addition to the ongoing war with Spain. The militant Puritans in Parliament were delighted with the opportunity to aid the rebelling French Calvinists (Huguenots), but Buckingham's military operations at La Rochelle in their behalf ended in failure, as at Cádiz. Five knights from the Country gentry, who were imprisoned for refusing to pay forced loans in 1627, obtained a writ of habeas corpus, but Chief Justice Nicholas Hyde ruled that their arrest, which had been at the special command of the King, was for "matters of state." In Charles's third Parliament of 1628 (the fifth Parliament in eight years), Coke, Eliot, and Sir Thomas Wentworth, somewhat incorrectly claiming the precedent of Magna Carta, drew up a petition asking the King not to levy taxes without the consent of

The Petition of Right

Parliament, not to imprison his subjects without due cause being shown, not to billet soldiers in private homes, and not to put civilians under martial law. Charles reluctantly agreed to the Petition of Right, thereby receiving the money he needed to fight Spain and France. Within a few months, however, Buckingham was dead from an assassin's knife.

In addition to the problems of finance and constitutional privilege, Charles's first three Parliaments also were greatly concerned with the growth of Arminianism within the Anglican Church. Beginning in the 17th century, many followers of the Dutch theologian Jacobus Arminius modified the Calvinist doctrine of predestination and election. The Arminians moved in the direction of free will and good works for the salvation of all men, not merely a few elect. An international synod was held at Dort (Dordrecht, in the Netherlands) in 1618–19, at which the orthodox followers of Calvin refused to alter their position. Nevertheless, several Anglican churchmen opted for Arminianism. Among them was the archdeacon of Hereford, Herefordshire, Richard Montagu, whose book *Appello Caesarem* (1625) won him a bishopric from the King. Another Arminian was William Laud, bishop of London (1628), who introduced innovations in the church service—for example, placing the communion table "altar-wise" at the east end of the chancel—and who stressed the divine right of bishops, a view that tended to erode the royal supremacy. Laud shared the anti-Calvinist theology but not the Erastianism of the Dutch Arminians, since he believed, as did many Puritans, that the king should be merely a member, not the supreme governor (a tenet to which he only paid lip service), of the church. Because these innovations in theology, liturgy, and episcopacy were so close to Roman Catholicism, the Arminians, as high churchmen, were in effect Anglo-Catholics. In an eloquent speech before the Commons in 1629, the Puritan Francis Rous called Arminianism "an Error that makes the Grace of God Lackey it after the will of man," a "Trojan Horse . . . ready to open the Gates to *Romish* Tyranny, and Spanish Monarchy." Apparently other members agreed with Rous, for the Commons passed Eliot's three resolutions against Arminianism and tonnage and poundage duties, with the Speaker held in his chair to prevent adjournment. (The King had continued to collect the duties because he believed they were not included in the Petition of Right.) In this instance, at least, the Puritan and Country opposition were united against Anglo-Catholicism and the court.

The years of personal rule. By 1629 Charles had had enough of Parliament, and for the next 11 years he conducted a policy of personal rule, sometimes with the aid of the "Thorough" policy of Laud and Wentworth, the latter having defected from the Country opposition. Thorough is the name applied to the governmental policies of these two ministers, who called for strong and efficient central government under the King. In order to cut down on his expenses, Charles terminated the wars with France (1629) and with Spain (1630), but the immediate advantages to the nation's economy from the return to peace were offset by a temporary slump in the cloth trade, especially the New Draperies of East Anglia, plus two consecutive harvest failures. The Privy Council's attempt to meet the crisis, particularly with a rigorous enforcement of the Elizabethan Poor Law, or Statute of Poor Relief (1601), was to give rise to a limited policy of state paternalism. Some paternalistic projects, such as the monopoly of pin making, were designed to inaugurate new industries, but others, such as the London Society of Soap Boilers, had the effect of an embryonic excise tax. The King attempted to raise revenue from the commercial classes by obtaining long-term loans from London financiers who managed the traditional customs revenue (though he did add some impositions), but he milked the gentry through the absurd revival of obsolete feudal dues (fines on forest lands once owned by the crown and fines on those who refused to buy knighthoods) and Ship Money. As late as 1626 writs for Ship Money, in the form of either ships or cash, had been temporarily levied on all of the commercial ports in order to raise a navy to protect commerce from pirates or to provide for the national defense. When the King, against the advice of Laud and Wentworth, extended the writs to the whole country, thereby making it a regular assessment like the future land tax, John Hampden, a Puritan gentleman from an inland county, refused to pay. In the Hampden Ship Money case (1637), Attorney General John Bankes, arguing for the King's "absolute power" as promulgated in Bate's case, stated that there was no such "King-yoking" policy requiring parliamentary consent. A bare majority of the common-law judges found Hampden guilty, a decision that alienated many Country gentry.

The "Thorough" policy

Although there was an appearance of a Catholic revival in England during the mid-1630s—Laud himself was twice offered a cardinal's hat but refused "til Rome were other than it is"—the period is better characterized as the Laudian counterreformation. With the appointment of Laud as archbishop of Canterbury (1633) and Bishop William Juxon as lord treasurer (1636), it was the highest point of clerical influence since the days of Cardinal Wolsey. As Laud said: "a bishop may preach the Gospel more publicly, and to far greater edification, in a court of judicature, or at a council table." The persecution of the Puritans now began in the Courts of High Commission and Star Chamber. When Charles reissued James's Book of Sports (1618), permitting lawful recreations on Sundays, a Puritan lawyer named William Prynne published his *Histrio-Mastix* (1633), an attack upon stage plays, mixed dancing, lewd pictures, face makeup, and long hair, among other things. An index entry listed women actors, which the Queen aspired to be, as "notorious whores." Prynne was found guilty of seditious libel in the Court of Star Chamber, a royal prerogative court made up of Laudian bishops. His sentence consisted of imprisonment for life, expulsion from the law profession, a fine of £5,000, a session in the pillory, and the hacking off of both ears (the stumps of which he could cover, ironically, only by growing long hair). In prison Prynne was joined by a Puritan clergyman, Henry Burton, and a Puritan physician, John Bastwick, and all of them busied themselves by writing vitriolic pamphlets attacking the bishops for their Arminianism. All three were brought before Star Chamber for libel and given the usual severe punishments, Prynne being specially branded on both cheeks with an *SL* (seditious libeler). From Ireland, where he was serving as lord deputy, Wentworth (now earl of Strafford) wrote to Laud: "these men do but begin with the Church, that they might have freer access to the State." Laud's harassment of the Puritans, with an assist from the depressed cloth industry in East Anglia, contributed greatly to that exodus of Puritans to New England in the 1630s that is sometimes called the Great Migration.

Persecution of Puritans

Religious reform in Scotland. With the nation at peace, trade recovering, a revenue coming into the crown, and the bishops seemingly in control of the Puritans, Charles conceivably could have carried on for some time, if not indefinitely, without calling Parliament into session. A turning point in the fortunes of the monarchy, however, was reached when the King and the Archbishop decided to bring the Scottish Presbyterian Church, or Kirk, into closer accord with the Anglican Church. Accordingly, a new prayer book was prepared by the Scottish bishops, who had been reinstituted by James I (1610). When the new liturgy was first read in Edinburgh (1637), rioting broke out against what many Scots considered popery. Large numbers of Scots drew up the National Covenant (1638), a civil compact to resist all of the innovations in worship. The General Assembly of the Scottish Kirk quickly rejected the new prayer book and the Scottish episcopacy. Faced by such defiance to the royal prerogative, Charles made his fateful decision to send an army into Scotland. The English troops, lacking money and discipline, ended the First Bishops' War (1639) without fighting by signing a truce. At the advice of Laud and Strafford, in 1640 Charles summoned his first Parliament in 11 years, with its concomitant Convocation of the clergy. Although the proposed agreement in this Short Parliament for the King to abandon Ship

The Bishops' Wars

Money in exchange for 12 subsidies fell through, Convocation did give him six benevolences (gifts of money) plus a new set of canons defining the church liturgy. The Canons of 1640 were severely criticized by the Puritans in Parliament for enshrining Arminian practices as well as requiring of all clergy and selected laymen the Etcetera Oath never to alter the Anglican hierarchy of archbishops, bishops, etc. Without having learned the obvious lesson from these events, Charles opened the Second Bishops' War (1640), but this time the Scottish Covenanters encamped on English soil with a large army, charging Charles £850 per day for its upkeep until their demands were met. The King could not tolerate such ignominy, and, since loans were not forthcoming from the London financiers, a new Parliament, the most eventful in all of English history, had to be called, this time to sit for 13 years.

The meeting of the Long Parliament. The first session of the Long Parliament met from November 1640 to September 1641 with the support of the Scottish army. The new Parliament, under the leadership of John Pym, immediately set about redressing its grievances against what it considered the arbitrary authority of the royal government. The first order of business was to release the political prisoners—including Prynne, Burton, and Bastwick—and to impeach both Laud and Strafford for treason, the latter allegedly having advised Charles that he had an army in Ireland with which he could overawe Parliament. When impeachment proceedings by Pym against Strafford looked doubtful, both Houses passed a Bill of Attainder—*i.e.*, an arbitrary political sentence of death without trial. The King, fearful for the Queen's life from a London mob, reluctantly signed the bill. Laud remained imprisoned in the Tower of London until his execution in 1645. Action was next taken to guarantee Parliament's own existence against future periods of "personal rule"; the Triennial Act stated that there should be no more than three years between Parliaments, and another act—in many ways the most significant of all—stated that the present Parliament could not be adjourned without its own consent. The constitutional revolution continued with statutes abolishing the courts of Star Chamber and High Commission and abolishing Ship Money, forest and knighthood fines, and tonnage and poundage duties, except with parliamentary consent. On the matter of religious reform, all agreed that the Canons of 1640 were invalid, but it was soon apparent that there was considerable division of thought among the Country opposition. Some radical Puritans in the Commons, such as Henry Vane the Younger, thought that the Anglican form of church government should be destroyed "root and branch"; some moderate Puritans and Low Church Anglicans, such as Edward Hyde, only wished to trim branches by removing the bishops and clergy from all secular offices. A bill containing the moderate proposal passed the Commons overwhelmingly, but it was rejected by the Lords. In the Lords the Calvinist archbishop James Ussher advocated a reduced episcopacy, as advanced at Hampton Court, conjoining episcopal and presbyterian church government. The only agreement came in a protestation by the Lords and Commons, reminiscent of the Scottish National Covenant, to defend the "*true reformed Protestant Religion . . . against all Popery and Popish innovations.*" Just before a six weeks' autumn recess, both houses voted sufficient funds to send the Scottish army back home since it was no longer useful or necessary.

Laud's fall

The outbreak of rebellion in Ireland during the autumn recess (with the attendant question as to who should control the army needed to quell it) only added to the differences about religion already existing within the Country opposition. These differences became even more apparent in November with the slim 11-vote majority given to the Grand Remonstrance, creating new royalist and parliamentary parties in place of the old parties. The Grand Remonstrance, which demanded that the King should appoint only advisors approved by Parliament and that an international synod of divines should be called to resolve the religious question, contained a long list of political and religious grievances that later became a model for Jefferson's Declaration of Independence. Had the Remonstrance not passed, Oliver Cromwell is supposed to have said that he would leave England—perhaps for Massachusetts. At Christmastime the Commons impeached, and the Lords sequestered, 12 bishops who had the audacity to claim that Parliament was "not free" after they had been jostled by a London mob while en route to the House of Lords. Charles panicked at the mob and at the Lords' about-face on the bishops; yet, in an uncharacteristically bold but ill-advised counterrevolutionary act, he attempted to arrest five members of Parliament, including Pym and Hampden, on January 4, 1642. Shortly before the King's arrival in the Commons' chamber with troops, the five members sought refuge in the City of London, the new government of which was sympathetic to them. When Charles asked where they had gone, the Speaker of the House boldly spoke: "I have neither eyes to see nor tongue to speak . . . but as this house is pleased to direct me." The Speaker's independence from the crown dates from this occasion. The King's violent breach of parliamentary privilege against arrest, as established in Shirley's case, had so backfired that he and the Queen left Westminster on January 10, he not to return for seven years and she for 18.

The Grand Remonstrance

From mid-January through mid-August, Charles and Parliament seemed to be playing out the last few scenes of a tragic drama the climax of which had already taken place. The Lords, with their numbers now decimated by royalist defections, gave their assent to the Bishops' Exclusion Bill, which prevented all clergymen from holding secular office and all bishops from sitting in the Lords. On February 5 the King reluctantly signed the bill, either to save the bishops from a worse fate or, more likely, to gain time for effective military resistance. The final break came with the passage of the Militia Ordinance without Charles's signature. From that moment until 1660 all parliamentary legislation was technically illegal. The Militia Ordinance, which seemed directed more toward Parliament's self-preservation than toward the reconquest of Ireland, gave control over the militia to lords lieutenant appointed by Parliament rather than by the king. Some members of Parliament now claimed that the person of the king should be distinguished from the office and that the office could be better administered by them. In June 1642, Parliament issued its Nineteen Propositions, terms for Charles's surrender that called for acceptance of the Militia Ordinance and a church synod, as well as approval by Parliament of the King's ministers and the education and marriage of his children. Charles of course refused, but his response, written by the moderate Lord Falkland, surprisingly set forth a "mixed" theory of government by king, Lords, and Commons. The events of the preceding year and a half had clearly shown that the Parliamentary Party had become just as arbitrary as Charles, if not more so. But on August 22 at the small county town of Nottingham, the King, in a rebel-like action, raised his military standard against Parliament. Ireland was practically forgotten for ten years.

The Militia Ordinance

THE CIVIL WAR

The causes. The various reasons that historians have given for the cause(s) of the English Civil War indicate that there is no simple explanation. Some contemporaries, such as Richard Baxter, observed that the nobility, gentry, and the "poorest of the people" followed the King, whereas tradesmen, freeholders, and the "middle sort of men" followed Parliament. Recent research, however, indicates that there were no important economic or social differences within the leadership of the two parties; about two-thirds of the nobles became royalists; almost three-fifths of the gentry became parliamentarians. The gentry of some northern and western counties, such as Yorkshire and Cheshire (agricultural areas of traditional royal power), were predominantly royalist, whereas the gentry of some eastern and southeastern counties, cloth-making areas accessible to European trade, were predominantly parliamentarian. Cities such as London, Bristol, and Norwich tended to be parliamentarian, but oth-

er cities, such as Newcastle upon Tyne and Chester had a majority of royalists. Textile areas such as East Anglia and the West Riding of Yorkshire also tended to be centres of Puritanism, partly because these areas had once been the home of the Lollard heresy, partly because of the Calvinist ethic of work (emphasizing public service but not profit-making acquisitiveness), and partly, perhaps, because of the relief provided by the Calvinist doctrine of election from the anxiety that characterized an urban and commercial milieu such as London. Although the religious issue had been divisive in the summer of 1641, the parliamentary leaders had kept it to a minimum in the debate over the Grand Remonstrance, and, with the Bishops' Exclusion Act, it temporarily lost some of its importance. Nevertheless, religion was a determining factor in the selection of sides, because the men who stayed at Westminster at the outbreak of hostilities were mostly Puritan in sympathy. The decisive issue—one that had been building up for several decades and reached its peak with the impeachment of Strafford, the Grand Remonstrance, the attempted arrest of the five members, and, above all, in the Militia Ordinance—was constitutional in nature: who should have the sovereign power in the kingdom? Only a civil war would determine the answer to that question.

Parliamentary victory. The Civil War began on August 22, 1642, when Charles, like the feudal barons of old, erected his standard before only a few hundred followers and onlookers at Nottingham, an unimportant county town. The King controlled most of the north and west of England, including Wales, and had the advantage of a well-trained cavalry led by his nephew, Prince Rupert of the Palatinate. Parliament, on the other hand, possessed London and most of the east and southeastern England and had the advantage of more regular sources of revenue and manpower. The inconclusive outcome of the Battle of Edgehill (1642) accentuated the political divisions within the Parliamentary Party. In the Commons a war group wanted the unconditional surrender of the King before negotiations; a middle group, led by Pym, wanted to negotiate only from a position of strength; a peace group wanted immediate negotiations, which shortly resulted in the Oxford Propositions, a document more conciliatory on constitutional matters than the Nineteen Propositions, although demanding ("root and branch") on religion. But Charles rejected them. Some royalist victories in the summer of 1643 forced Pym to obtain military assistance from the Scots, but the price—Scotland's revenge for Laud's imposition of the prayer book—was agreement to the Solemn League and Covenant, which called for the complete reformation of the Anglican Church "according to the Word of God [Vane's phrase] and the example of the best reformed churches," obviously meaning Scottish Presbyterianism. At long last the synod of Puritan divines called for in the Grand Remonstrance met at Westminster. The Scottish and English divines of the Westminster Assembly drew up a Calvinistic confession of faith and agreed to substitute the Scottish Directory for Public Worship for the Anglican prayer book. The adoption by Parliament of the Directory, plus the victory by an East Anglian cavalry leader, Oliver Cromwell, over Prince Rupert at Marston Moor (1644), produced the stronger Uxbridge Propositions to the King in 1645, constitutional proposals similar to the Nineteen Propositions but, in addition, requiring agreement to the Solemn League and Covenant. Again Charles refused. On matters of church government and church discipline in the Assembly, the Presbyterian majority called for a compulsory national church with a hierarchy of church courts that would suspend scandalous members from the Sacrament, but a group of "dissenting brethren" called Independents advocated voluntary congregational churches, independent of any higher ecclesiastical authority, the visible saints of which covenanted together on the basis of a conversion experience. By 1645 the members of the peace group in Parliament were called the Presbyterian Party because they sometimes overlapped with that kind of Puritanism, and for a similar reason the members of the war group were called the Independent Party. The middle group tended

England during the Civil War.

to ally with the Independent Party. The religious Presbyterians in Parliament were successful in replacing the bishops of the Anglican Church with a Presbyterian form of church government, but the Scottish Presbyterians in the assembly called it a "lame Erastian Presbytery" since the Erastians from all parliamentary groups or parties had made sure that Parliament rather than the church would have control over religious affairs. Lieutenant General Cromwell, an Independent in religion and a radical member of the middle group in Parliament, was able, with a corps of Independent chaplains, to establish his religious imprint on the parliamentary forces, which, under the leadership of Sir Thomas Fairfax (later 3rd Baron Fairfax of Cameron), the commander in chief, was remodelled into a well-disciplined fighting unit. The New Model Army—with the motto "If God be for us, who can be against us?"—defeated the King's forces at Naseby (1645). With the King's flight to the Scots in May and the surrender of Oxford to the New Model Army in June 1646, the first phase of the Civil War came to an end.

Naseby

The King, the army, and Parliament. The Scots, Parliament, and the army made successive attempts during the next two years to come to terms with an evasive King determined to play off one suitor against the others. After the failure of negotiations between Charles and the Scots, they turned him over to Parliament. Parliament presented the King with the Newcastle Propositions (very similar to the Uxbridge Propositions), and on May 31 he finally agreed to accept Presbyterianism for a period of three years and to surrender control of the militia to Parliament for ten years. The agreement did not come into effect because the New Model Army seized Charles on June 4. On the following day, disturbed at Parliament's desire to reduce its numbers and send a force to Ireland, the New Model Army issued its Solemn Engagement not to disband until its grievances, including pay in arrears, were redressed. While the quarrel between Parliament and the army progressed, some army officers, especially Cromwell's son-in-law, Commissary General Henry Ireton, made some new proposals to Charles on August 1. The officers' Heads of the Proposals called for a council of state and biennial Parliaments that would control the militia for ten years and a limited toleration as a defense against Presbyterianism. Charles liked the Heads better than the Newcastle Propositions because of the implied admission of episcopacy, but he finally rejected them. Within the New Model Army's rank and file were the Agitators, who drew up an Agreement of the People based upon the views of the Leveller Party leaders: men such as John Lilburne, William Walwyn, and Richard Overton. Lilburne was influenced by the fundamental law of Coke, whereas Walwyn and Overton stemmed from a Christian Humanist tradition. The Agreement set forth ideas that were to be realized in the U.S. Constitution: legislative power as a trusteeship from the people (who are sovereign) and civil and religious rights, based upon natural laws, reserved by the people from the legislature. Although some Levellers, such as Lilburne, wanted to limit voting privileges only to freemen (excluding servants and alms takers), other Levellers, such as Col. Thomas Rainborow, wished to include everyone. For instance, at the army debates over the Agreement at Putney (October 1647), Rainborow said: "The poorest hee that is in England hath a life to live as the greatest hee." To this, Ireton (no Leveller) responded that no one should vote except those with "a permanent fixed interest in the kingdom." However much Puritan Independency may have provided a training ground for Leveller ideas through the election of ministers, the church covenant, and the equality of the saints, the chaplains of the New Model Army preached an Antinomianism (the complete assurance of salvation for God's elect solely through the free gift of the Holy Spirit), which stressed a millennial holy commonwealth ruled over by the lay saints.

The Agreement of the People

Flight of Charles

While the army was debating the Agreement, Charles fled from its custody to the Isle of Wight, where on December 26 he signed the secret Treaty of Newport with the Scots that was to lead to his undoing. In the treaty the King agreed to eradicate Independency and to establish Presbyterianism for three years, and the Scots agreed to send an army to England to settle a lasting peace should the King, Parliament, and themselves fail to do so. The treaty virtually made a second civil war a certainty. In a huge prayer meeting at New Windsor, Berkshire, the army agreed to bring Charles Stuart, "that man of blood," to account. This took place just before the army defeated the Scots at Preston in mid-August. "Surely," wrote Cromwell, "this is nothing but the hand of God." After Preston the Commons passed the final ordinance establishing the Erastian Presbyterianism. When it appeared that the King and Parliament at long last would sign a peace treaty, Col. Thomas Pride arrested or imprisoned 231 M.P.'s from the Presbyterian Party and the moderate majority of the middle group that previously had been tied to the Independent Party. Pride's Purge left a small Rump Parliament made up of the Independent Party and the radical minority of the middle group, some of whom were religious Presbyterians. The Rump Parliament proceeded to create a wholly unprecedented High Court of Justice to bring Charles to trial for high treason and other crimes. High treason, according to the law, was a crime performed against, not by, the king, but something of a case could be made that Charles had levied war against his subjects. The army, having reached the point where it no longer trusted the King, was determined to show that kings had to be responsible to their subjects. At his trial in late January, Charles refused to recognize the jurisdiction of the court, but he did say, without his usual stammer: "if Power without Law may make Lawes . . . I do not know what subject he is in England, that can be sure of his life or any thing that he calls his own." The King's guilt was a foregone conclusion. On January 30 at Whitehall, Charles Stuart—unlike Edward II, Richard II, and Henry VI, who were deposed before they were killed—was executed as a reigning king. Cromwell attributed the Court's action to "Providence and necessity."

Trial of the King

THE COMMONWEALTH (1649–60)

With the abolition of the office of monarchy and the House of Lords in 1649, the Rump proclaimed the "Commonwealth and Free-State," a republican form of government to be directed by the Council of State for the next four years. As Latin secretary for the Council, it was the task of John Milton, the poet, to defend the regicide to the rest of Europe. With Cromwell as commander in chief, the army, after suppressing a Leveller mutiny, weakened the Presbyterian Church settlement by defeating the Scots at Dunbar, East Lothian (1650), and at Worcester (1651). Also, it finally ended the Irish revolt by slaughtering the survivors (including women and children) of the besieged garrisons of Drogheda and Wexford in accordance with contemporary practice. As a result Scotland and England achieved a temporary political union, as James I had wished, and many English landowners acquired property in Ireland, a situation somewhat related to the confiscation and sale of sizable church, crown, and royalist lands in England. The Commonwealth's navy took command of the English Channel in the first of three trade wars fought with the Dutch in the mid-17th century. On matters of religion, the Rump produced no major ecclesiastical changes, but a spate of legislation, including the Blasphemy Act of 1650, dealt with moral and doctrinal laxity, especially in such Puritan sects as the Ranters, Diggers, Muggletonians, and Quakers. The Rump delayed enacting the army's program to abolish tithes, to reform the law, and to hold free elections, so Cromwell entered St. Stephen's Chapel with troops, as Charles I had done, and dissolved the remnant of the Long Parliament (1653). At the advice of Maj. Gen. Thomas Harrison, who was sympathetic to the political millennialism of another Puritan sect known as the Fifth Monarchy Men, Cromwell convoked a small Parliament of 140 Puritan saints chosen by the army with nominations by some Independent churches. The radical millenarians of this Barebones Parliament (named after a member, Praise-God Barbon) abolished the Court of Chancery and planned to abolish ecclesiastical patronage

and tithes, so Cromwell, always a conservative in social reform, got the moderate Independents to dissolve the experiment in saintly rule after six months.

The Instrument of Government

The Protectorate. For the next few years the form of government was to be called a Protectorate, as provided by the Instrument of Government (1653), a written constitution (England's first) drawn up by Maj. Gen. John Lambert from Ireton's Heads of Proposals. In addition to making Cromwell the lord protector (an office subsequently to be elective) and commander in chief of the army, the Instrument provided for a council and a single-chamber, triennial Parliament, the redrawn constituencies of which contained a much larger percentage of county seats held by Country gentry. The Instrument designated Christianity as the "public profession" of the nation, but religious toleration was to be extended only to such Puritan groups as the Independents, Presbyterians, Baptists, and some Puritan sectarians (not to Catholics, Anglicans, and licentious people). Cromwell, who allowed the Jews to return to England, was somewhat more tolerant than his two Parliaments, which prosecuted the Socinian (Unitarian) John Biddle for heresy and the Quaker James Nayler for blasphemy. The Protector's preference for Independency was revealed in his personal ordinances to regulate the ministry: a central committee of Triers to admit new ministers and county committees of Ejectors to remove scandalous ministers. Peace with Holland (1654) and a war with Spain (1655), which resulted in the capture of Jamaica, suited the Protector's notion of a Protestant crusade, but he did make an alliance with the France of Cardinal Mazarin. Cromwell also differed with his Parliaments, both of which he purged, over the control and payment of the army, even though taxes, including the excise begun in the 1640s and a new assessment levied directly on property, were higher than they had been under Charles I. In response to a royalist uprising in 1655, the Protector instituted the Rule of the Major Generals, a scheme dividing England into 11 military districts to keep down plots and to enforce the Commonwealth's repressive blue laws. The resentment inspired by the major generals caused Parliament to issue a modified version of the Instrument known as the Humble Petition and Advice (1657). This new constitution would have made Cromwell a king, but, under heavy republican pressure from the army, which he had hoped to reduce in size, he refused the crown while accepting its other provisions providing for the restoration of the "Other House" (*i.e.*, an upper chamber), a hereditary protectorate, and further restrictions on liberty of conscience. On September 3, 1658, Cromwell died, and with him went all hope for a permanent Puritan commonwealth. He had been a brilliant commander of troops, but he had never been able to find a lasting settlement for church and state. "I am as much for government by consent as any man," he once said, "but where will you find that consent?"

The return of the monarchy. The next two years brought about the restoration of the monarchy through a continuation of the steps, in reverse order, by which it had been dismantled. In January 1659 Richard Cromwell, who succeeded his father as lord protector, called his only Parliament, elected by the pre-Instrument constituencies, but in April he dissolved it under pressure from ambitious army officers whose allegiance his inexperience and indecision could not command. Richard resigned as protector, and the army, in need of some legitimate authority, decided to restore the surviving members of the Rump Parliament whom they had expelled in 1653. The Protectorate had come to an end. Despite the appearance of a large number of tracts by Milton, James Harrington, and others in behalf of the "good old cause" of republicanism, an alliance between royalists and Presbyterians was formed. Lambert, acting on behalf of the republicans in the army, dismissed the Rump Parliament in October, but Gen. George Monck, commander of the army in Scotland, decided to intervene. Meanwhile, the Rump, which had been expelled twice, was restored in December for the second time. Lambert's troops were unable to stop Monck's entrance into London in February 1660, whereupon Monck enlarged the Rump Parliament to include all of those surviving members who had been purged by Colonel Pride. This restored Long Parliament, with its Presbyterian party majority, proceeded to implement Presbyterianism and to reaffirm the Treaty of Newport of 1647 as the basis for peace with the crown. After 20 years it finally voted to dissolve itself, as the law prescribed, in favour of a Convention Parliament that called for the return of the Stuarts in the person of Charles II, the son of the executed king. The Convention Parliament accepted without any conditions Charles II's Declaration of Breda (April 4), promising his consent to parliamentary bills relating to land purchases and army arrears in pay, a general pardon to all except those specified by Parliament, and liberty of conscience for all men unless there was a disturbance to the peace of the kingdom. There was something in the declaration for everyone. Because of Richard Cromwell's weakness, because of the differences between the various Parliaments and the army, and because of the divisions within Parliament (at first between republicans and Cromwellians and later between republicans and Presbyterians), Charles II (ruled 1660–85) could safely return to England on May 25, never to embark on his travels again.

The Declaration of Breda

XI. The later Stuarts (1660–1714)

CHARLES II (1660–85)

The Restoration settlement. Charles II quickly addressed himself to the promises in the Declaration of Breda: the crown, the Anglican Church (including bishops in England and Scotland), and some royalist lands in England were restored; a large part of the army was demobilized with full pay in arrears; and only a handful of Independent and sectarian regicides, including Vane and Harrison, were executed. But the liberty of conscience did not come into effect despite the King's efforts. The Sion House Proposals of some leading Presbyterians, including Richard Baxter, for a comprehensive church through Ussher's 1641 plan for a reduced episcopacy were firmly rejected by the 11 surviving Anglican bishops. Charles's Worcester House Declaration, drafted by Edward Hyde (soon to be earl of Clarendon), called for suffragan bishops and Presbyters plus the calling of a national synod on the Anglican prayer book. But these concessions, the most generous ever offered by Anglicans to Puritans, were rejected by the Convention Parliament, some Independent members voting with the majority. The only salve for the Presbyterians was the King's call for a conference to be held at the Savoy (in London) between Presbyterian and Anglican divines, but, before any agreement was reached, the Convention Parliament was superseded by the Cavalier Parliament (1661–79), which was overwhelmingly Anglican. The failure of the Presbyterians at the Savoy Conference was similar to that of their forefathers at Hampton Court.

Religious policies

The Cavalier Parliament set the tone for forthcoming legislation by welcoming the bishops back to the House of Lords with the repeal of the Bishops' Exclusion Act of 1642. This repeal was followed by the passage of the Corporation Act (1661) restricting local political office to Anglicans. Meanwhile, the Convocation of the clergy, after taking over from the Savoy Conference, drafted a new prayer book making slight concessions to the Savoy Presbyterians and to the Laudian Anglicans that became the basis for a new Act of Uniformity (1662). The Caroline Uniformity Act required subscription by the clergy to the new prayer book, the Thirty-nine Articles, the oaths of supremacy and allegiance, and a new oath of nonresistance to the crown. The expulsion of nearly 2,000 ministers (about 20 percent) from their livings meant the end of comprehension, or the policy of including diverse religious groups within the Anglican Church. In the Conventicle Act (1664) the Nonconformists, or Dissenters, as the Puritan community was now called, were prevented, largely out of fear of subversion, from assembling in groups of five or more persons. In the Five Mile Act (1665) they were forbidden from coming within five miles of where they had once preached. The Great Fire of London (1666) destroyed Dissenter meeting

houses and Anglican churches, and from the ruins of the city, Inigo Jones developed the Palladian style of church architecture, which ultimately found its way into Christopher Wren's St. Paul's Cathedral.

The foregoing pieces of legislation, inaccurately referred to as the Clarendon Code, had one important consequence: together with the Test Acts of the 1670s, they cut off Dissenters from all avenues of professional advancement—church, politics, education, and the professions—except for business. It may well be that the affinity between Dissent and the business world, so characteristic of the age of the Industrial Revolution, can be explained more by this exclusion than by the Calvinist ethic of Puritan theology. Nor does there seem to have been much affinity between Puritan theology and the "new science," as some historians have claimed, in the founding of the Bacon-inspired Royal Society by Charles II in 1662. Such scientists as William Harvey, Robert Boyle, Isaac Newton, and John Wilkins were latitudinarian in their religious views, tending to gravitate toward the natural theology of the Cambridge Platonists, who reacted strongly against the Puritan doctrines of predestination and election.

Economic policies

The policies of the government in economic affairs at the Restoration were an acceleration, rather than a reversal (as in religious affairs) of those underway during the Interregnum. On the question of the king's revenue, for example, Charles agreed to give up purveyance and the feudal dues, abolished during the Interregnum, in exchange for Parliament's retention of the excise started by Pym and continued by Cromwell. A new hearth tax and the traditional tonnage and poundage duties for life did not bring the King up to the proposed annual income of £1,200,000 per year, and he was constantly in debt, as his father had been. Charles II, therefore, was not able to resist Parliament as strongly as he might have wished. In matters of overseas trade, including that with Scotland and Ireland, the government's policy of protectionism was reflected in the Corn Laws, which were to protect producers—instead of consumers, as under earlier acts—through import duties on grain from abroad during bad harvests and by means of bounties on exports to foreign countries during good harvests. Thomas Mun's book *England's Treasure by Forraign Trade* (written earlier but published in 1664), in which he said that the rule is "to sell more to strangers yearly than we consume of theirs in value," reflected the mercantilist idea of the Navigation Acts (1660–63). Patterned after the Cromwellian ordinance of 1651, the Navigation Acts provided for the transportation of all goods to and from the colonies in English or English colonial ships. The exceptions to this principle were (1) certain colonial enumerated commodities that were first to be shipped directly to England and (2) all commodities produced in Europe for the colonies, which were first to be shipped to England, either in ships of England, her colonies, or the originating European country. The Navigation Acts, designed to give the mother country a favourable balance of trade with the colonies, stood for the triumph of the national interest over the special interests of the trading companies. They were also designed to damage the Dutch carrying trade by giving shipping a monopoly, and they contributed heavily to the commercial rivalry, especially in the New Draperies, that was a basic cause of the second Dutch war in 1665. The capture and burning of English naval ships by the Dutch in the Thames in 1667 terminated the war but not before the English capture of New Amsterdam (renamed New York). It also led to the fall of Charles's chief minister, the Earl of Clarendon.

The Cabal. After the fall of Clarendon in 1667, government power passed into the hands of a group of five men, all non-Anglicans, whose initial letters formed the word cabal. Although a Triple Alliance had been signed with Holland and Sweden in 1668, Charles was more interested in a treaty with the France of Louis XIV, whom he admired. Accordingly, the Treaty of Dover was signed in 1670, in which Charles promised to support France in a war with Holland in exchange for a subsidy during the war. But a secret provision, known only to the Cabal's Catholic sympathizers, Thomas Clifford and Lord Arlington, provided for the King, in exchange for another subsidy and troops if necessary, to declare himself a Roman Catholic—a step his brother James, duke of York, had taken the preceding year. A Stop of the Exchequer in 1672, by which the government halted payment to its banker creditors, indicated that the royal treasury was almost bankrupt, so Charles declared war on Holland, gaining the annual subsidy from Louis XIV. Charles did not announce any conversion to Catholicism, but he did resume his attempts at religious toleration with the issuance of a Declaration of Indulgence (1672). As a result the Dissenter John Bunyan was freed from Bedford jail, where he had written most, if not all, of *Pilgrim's Progress* (1678). The Indulgence suspended the penal laws, including the Clarendon Code, in ecclesiastical matters, but it was greeted with reservations by some Dissenters, partly because they questioned this extension of the royal prerogative and partly because they feared that the King's ultimate goal was the advancement of popery. The Cavalier Parliament strongly opposed the Indulgence, largely for the same reasons, so Charles, anxious to get a subsidy from Parliament, cancelled the Indulgence on the advice of a Cabal Dissenter (Lord Ashley, by then earl of Shaftesbury). Not content to stop there, Parliament passed a Test Act (1673) requiring any civil or military officeholder at the national level to take the Anglican holy sacrament and to denounce the Roman Catholic doctrine of transubstantiation. The latter excluded all Catholics, and the former excluded all Dissenters. The King reluctantly signed the bill, and the Duke of York resigned as lord high admiral. The Test Act began the breakup of the Cabal that was completed with the appointment of the Earl of Danby as chief minister (1674).

Treaty of Dover

The Popish Plot. Danby represented a change from the Cabal, for he was pro-Dutch and pro-Anglican in his sympathies. Although he brought the war with Holland to a close and although he was able to arrange the marriage of Mary, the Duke of York's elder Protestant daughter, to William (later King William III of England), the Protestant stadtholder of the United Provinces of the Netherlands, he was obliged to conduct a pro-French foreign policy, including the handling of the French subsidy, in order to remain in office. In the summer of 1678 Titus Oates, a habitual liar, "informed" the Privy Council of an alleged Popish Plot to kill the King and to replace him with his brother, the Duke of York. In September Oates made depositions to this effect before a popular London magistrate, Sir Edmund Godfrey, who in turn revealed them to Edward Coleman, the secretary to the Duchess of York. The arrest of Coleman, who had had a long correspondence of a treasonable nature with the Jesuit confessor to Louis XIV, gave some credence to the plot, but it was raised to near panic proportions with the discovery of Godfrey's body on Primrose Hill in Hampstead. His death still remains a mystery. On the day after Coleman was found guilty of treason (November 28), Oates accused Catherine, Charles's Catholic queen, of treason before the bar of the House of Lords; but Charles, who had sired numerous children by several mistresses throughout his entire marriage, remained cool throughout the whole proceedings and stood loyally behind the Queen. Meanwhile, Parliament passed a second Test Act (1678) requiring all members of either house of Parliament, the Duke of York excepted, to be members of the Anglican Church. In December, Danby was impeached by the House of Commons for arranging a French subsidy for Charles, but the King responded by dissolving the Cavalier Parliament in 1679, 18 years after it had begun.

The Exclusion Controversy. The anti-Catholic atmosphere of the Popish Plot led directly into the Exclusion Controversy. Three short Parliaments during the years 1679–81 were primarily occupied with the efforts of Shaftesbury to exclude the Duke of York from succeeding Charles on the throne. The issue, which caused men to form embryonic political parties, was quite simple: should the future supreme governor of the church and state be a Roman Catholic? The exclusionist supporters

Political parties

of Shaftesbury, who were Dissenter (and frequently Low Anglican) critics of the royal prerogative, were called Whigs. The anti-exclusionist supporters of the Duke of York, who were Anglican, especially High Church (but not Catholic) backers of the royal prerogative, were known as Tories. Even though the situation was by no means as serious as 1641, Charles II, unlike his father when confronted by a Country opposition, made some conciliatory moves: he took Shaftesbury into the government as part of a new Court group, and he offered to place limitations on James. The Whigs, however, would settle only for exclusion in the Parliament of 1679, so the King dissolved it after signing a bill that strengthened procedures in the use of writs of habeas corpus, which safeguarded Englishmen from arbitrary arrest and imprisonment. In the Parliament of 1680, the Whig candidate for the succession was Charles's illegitimate son, the Duke of Monmouth—"that Absalom, ambitious of the Crown" in John Dryden's biblical allegory—but the Whigs failed again with their exclusion bill, mostly because of the opposition in the Lords. The Parliament of 1681 at Oxford, where the King had posted troops, was dissolved within a week, but there was no repetition of the events of January 1642. It was just after the Exclusion Controversy that the philosopher John Locke wrote his book *Two Treatises of Government* (published in 1690), stating that a government could be changed if it no longer represented the interests of the people; Locke's work was later used to justify the overthrow of James II in 1688. For his unflinching support of James and the Catholic succession, Charles was able to obtain another subsidy from Louis XIV, making it unnecessary for him to call any more Parliaments during the remaining four years of his reign, even though this action violated the Triennial Act of 1664, based upon that of 1641. On his deathbed Charles received the last rites of the Catholic Church, at long last fulfilling his promise in the secret Treaty of Dover.

JAMES II (1685–88) AND THE GLORIOUS REVOLUTION

When the Duke of York succeeded his brother Charles as James II (1685–88), he promised both the Privy Council and his only Parliament to preserve the church and state "as it is now by law established," but it was soon apparent that he wanted to re-establish the Catholic religion. An attempt by Monmouth to raise a rebellion in the southwest was crushed a few months later, and Chief Justice George Jeffreys exacted a fearful retribution from Monmouth's Protestant supporters in the "Bloody Assizes." Monmouth himself was put to death. James, determined not to be without Catholic officers in the future, could not get Parliament to repeal the Test Act of 1673. In a court test of the issue in 1686 (*Godden* v. *Hales*), the judges upheld the royal dispensing power for army commissions, clearing the path for James to appoint Catholics elsewhere. Although he did not appoint any Catholics to the episcopal bench, James did create a Commission for Ecclesiastical Causes (somewhat different from the old Court of High Commission), which suspended Bishop Henry Compton, among other clergymen, for disobedience. At the instigation of William Penn, who had introduced religious toleration to the colony of Pennsylvania, James pardoned 1,200 Quakers, and he issued, as Charles II had done, a Declaration of Indulgence (1687). In the preface, James frankly admitted: "We cannot but heartily wish, as it will be easily believed, that all the people of our dominions were members of the Catholic Church." The Earl of Halifax spoke for most Dissenters: "You are therefore to be hugged now, only that you may be squeezed at another time." James's success in appointing Catholics as president and fellows of Magdalen College, Oxford, may have offset any support he may have gained from the Indulgence.

The "Bloody Assizes"

The negative response the King got from county justices of the peace and prominent gentry to questions posed by the lords lieutenant, asking if they would vote to repeal the penal laws and Test Acts if elected to a new Parliament, was the first of several defeats. James issued a second Declaration of Indulgence (April 1688), but this time he required the bishops to have it read in all churches. Seven bishops stated their "averseness" to the Indulgence in a petition to the King because they believed the suspending power was illegal. James brought them to trial for seditious libel. The bishops finally had abandoned nonresistance and passive obedience. During the course of their trial, the Queen gave birth to a male heir, which assured the continuance of a Roman Catholic monarchy. On the same day that the seven bishops were acquitted, seven Whig and Tory peers, including Bishop Compton and Lord Danby, invited William of Orange to assume the throne of England. Some last minute concessions by James came too late. Aided by the so-called Protestant wind, William landed at Torbay (the modern Tor Bay) on November 5, while Louis XIV, hopeful of another long English civil war, sent troops to his eastern border. Unlike the time of Monmouth's invasion, James's army experienced wholesale desertions. Even his old comrade-in-arms, John Churchill (later 1st duke of Marlborough and ancestor of the 20th century's Winston Churchill), deserted his post as lieutenant general of the army for William because, as he put it, "our religion and country were in danger of being destroyed." On December 11 James burned the writs for a new Parliament (already overdue) and fled to France. Although captured, James was allowed to escape, since William had no intention of making James the martyr his father had become. For the second time in 40 years, a king had been toppled from the throne; this time, however, the Church of England had been saved rather than destroyed.

Landing of William and flight of James

WILLIAM III (1689–1702) AND MARY II (1689–94)

The revolutionary settlement. From the various plans put forward for the settlement of the kingdom by Whigs and Tories, the one adopted for political affairs was the moderate Whig plan. The throne was declared vacant because of the King's abdication, and a Convention Parliament offered the throne to William III and Mary II as joint sovereigns subject to certain conditions set forth in a Bill of Rights. A hereditary succession was replaced by a parliamentary succession. With the exception of a few articles guaranteeing individual rights against royal power, the Bill's main provisions were directed toward the king and Parliament. The Bill affirmed free speech, free elections, and frequent meetings of Parliament; it prohibited the levying of taxes or the keeping of a standing army except with the consent of Parliament; and it proscribed ecclesiastical commissions, or courts, and the royal suspending and dispensing power. Subsequent legislation, some of which was sponsored by a new Country Party made up of Old Whigs and New Tories, enlarged upon this essentially conservative settlement by ensuring Parliament's control over the army with a system of courts-martial (1689), regularizing the election of Parliament triennially (1694), permitting a freer press through the lapse of the Licensing Act (1695), providing for the testimony of two witnesses in all treason trials (1696), and creating from the excise tax a fixed Civil List for both the crown's household and administrative expenditures (1698), the latter an enlargement upon the Long Parliament's distinction between the private man and the public office. When the Bill of Rights was enacted into law (1689), Parliament added a provision requiring oaths of fidelity and true allegiance (replacing the old oaths of supremacy and allegiance) to William and Mary, which several bishops (including, ironically, five of the "seditious" seven) refused to take. It also added a provision preventing the sovereign from being a Catholic. Even the new coronation oath required the sovereign to uphold the "protestant reformed religion established by law." A large group of Tory members agreed to support a religious toleration bill when the Whigs agreed to drop a comprehension bill to unite Anglicans and Dissenters in one church. The decline of rigid Calvinism, the weariness with religious strife, and the desire to reward Dissenters for their obedience to the law produced the Toleration Act (1689), which permitted everyone except Catholics, Jews, and Unitarians to worship as he pleased. In 1690 the Scottish Parliament removed the bishops

The Bill of Rights

from the Kirk, ratified the Westminster Confession, and set up the Presbyterian form of church government once again.

The revolutionary settlement brought an end to innovative attempts by Charles II and James II to rule without Parliament and to reintroduce the Catholic religion by religious toleration. In short, it was a vindication of the old Whig policy of exclusion. The Bill of Rights made it obligatory for the king to rule with the assistance of Parliament, and the Toleration Act outlawed Catholicism for all Englishmen. Monumental as the Toleration Act was, it did not repeal the Test and Corporation Acts, which would have allowed Dissenters access to the political and professional life of the nation. The Bill of Rights was neither a forward-looking guarantee of individual rights against the power of a legislative body nor a statement of the natural rights of man, as in the United States and France, respectively, 100 years later. Rather, it had much in common with the medieval charters that set out the rights and privileges of a particular group in society. As Magna Carta had guaranteed the rights of the barons against the crown, so did the Bill of Rights guarantee the rights of the nobility and gentry against the crown. By his interference with voting privileges, army commissions, church benefices, and university fellowships, James II had not only restricted the freedom of the upper orders in English society, but he had also tampered with their freeholds, the privileged social position they regarded as a property right like the ownership of land. Free elections and free speech meant free from influence by the king and the lower orders of society but not free from influence by the nobility or the gentry. Although the revolutionary settlement reasserted that the king was under the law, as Magna Carta had done, by preventing the suspending and dispensing power, it would be a mistake to assume that it effectively transferred sovereign power from the king to Parliament. While it did make Parliament a partner on the important questions of revenue and the army, other aspects of the royal prerogative remained, for the most part, untouched: the waging of war and the making of peace, the conduct of foreign policy, and, above all, the appointment and dismissal of the crown's ministers. The increasing costs of postrevolutionary warfare would increasingly bring even these aspects into the orbit of Parliament's concern.

Effect of the revolutionary settlement on Parliament

William's campaign against France. William's central purpose in assuming the throne of England was to use its men and resources in his life's work of defending Holland against the aggrandizement of France under Louis XIV. As carried out, it meant a sharp reversal in the traditional pro-French and anti-Dutch foreign policy. William's forces, including some 70,000 English troops, lost border fortresses, such as Namur in the Spanish Netherlands, to France during the early years of the War of the League of Augsburg (1689–97), but in Ireland they were successful at the Battle of the Boyne (1690), crushing James II's last hope of regaining his throne. The scale of such operations could not be financed from the tonnage and poundage duties that William's second Parliament (1690–95) had granted for four years. The hearth tax was repealed and replaced by a general land tax, but even that was insufficient. In 1693–94 the Junto group of Court Whigs joined the Cabinet Council (also called the Lords of the Committee when the monarch was absent). The Cabinet Council, or Cabinet, which was smaller than the ungainly Privy Council and designed to handle the daily business of the war, took steps to handle the growing debt—about £14,000,000 from 1688 to 1702. Investors were able to place their money not only with trading companies, which were engaged in war profiteering and speculation, but also with the government. The means to do the latter was the newly chartered Bank of England (1694), a Whig joint-stock company. The Bank raised £1,200,000 in 12 days from the public and loaned it to the government (not the King) at 8 percent interest in exchange for the right to issue bank notes and to discount bills. The loan did not have to be repaid as long as the interest, about £100,000 annually, was raised by import duties. Here was the origin of a funded national debt.

Establishment of the Bank of England

The debt precluded future Stops of the Exchequer, as in 1672, and the Bank's loan paid for the recapture of Namur in 1695. The Bank's issuance of notes in excess of deposits, however, led to an inflation that, combined with a depreciated currency through the clipping of silver coins and the need to pay the troops in the Spanish Netherlands, led to a financial crisis in 1696 almost as severe as that of the early 1620s. Some 60 or 70 joint-stock companies, including the Scots' Darién Scheme in Spanish Central America, collapsed. The bank survived through the wealth of its directors; a huge pamphlet debate on monetary policy led to recoinage, rather than devaluation, under the Warden of the Mint, Isaac Newton; the Board of Trade was re-created (1696), after brief starts in 1660 and 1670, to regulate overseas trade; and the war with France was terminated by the Treaty of Rijswijk in 1697. The economy snapped back because it was more diversified and broadly based than in the 1620s, but William was only waiting for the opportunity to form an alliance once more against France.

The last few years of William's life were absorbed with the problem of the succession to the throne of Spain and, to a lesser extent, with the succession to the throne of England. When the new Country Party, together with the Tories, forced out the Whig Junto after the election of 1698, the King's armed forces were drastically reduced; even his Dutch guards were dismissed. William, disgusted with an ungrateful people, threatened to abandon England. His main concern was that the Spanish Netherlands might fall to France upon the death of the childless Spanish king, Charles II the Sufferer. The dying Spanish king's last will provided that his throne and empire should go to Louis's second grandson (Philip V) if the crowns of France and Spain would remain separate. Louis at once accepted the will. In September 1701 the French king's prohibition of imports to France and Spain from England, plus his recognition of the 13-year-old pretender, James III, upon the death of James II, as king of England, swung public opinion behind William's new Grand Alliance against France (1701).

The Spanish succession

The Act of Settlement. Meanwhile, the last surviving child of Princess Anne, the younger daughter of James II, also had died, leaving the English throne—except for Anne—without a successor, since William and Mary had had no children. After the first of two elections in 1701, both won by Tories, including Robert Harley (who had made the passage from Old Whig to New Tory), Parliament passed the Act of Settlement (1701). The act designated the granddaughter of James I, the electress Sophia of Hanover, as Anne's heir and required all future sovereigns to be members of the Anglican Church. Other clauses, which were as much New Tory and Country Party criticism of William as they were to be restrictions upon the Hanoverians, stated that foreign-born kings should not defend their continental possessions without parliamentary consent; that no king should leave the country without parliamentary consent; that all governmental transactions should be handled only in the Privy Council and signed by all who consented (repealed in 1706, thereby continuing the life of the Cabinet); that foreigners could not sit in Parliament and the Privy Council or hold civil or military office; that officeholders could not sit in the Commons (modified in 1706 so that members of the Commons, when appointed to high office, must resign but could be re-elected); that no king could pardon men impeached by the Commons; and that judges held their commissions solely on good behaviour. The last provision gave judges independence from the crown, but it did not give them the right to declare parliamentary legislation unconstitutional. When William died in 1702, the Tory party leaders had assumed the mantle of the Old Whigs as the chief critics of the royal prerogative, whereas the Whig leaders (to a lesser extent with the Junto) had assumed the mantle of the Old Tories as the chief proponents of the royal prerogative.

QUEEN ANNE (1702–14)

The dull, dowdy, and devout princess Anne succeeded William as sovereign, but John Churchill (now earl of

Marlborough), whose witty, beautiful, and free-thinking wife, Sarah, was an intimate friend of the new queen, succeeded William as military commander of the English and Dutch forces in the Grand Alliance. After the parliamentary election of July 1702, Marlborough and Sidney (Lord Godolphin) formed a Tory Cabinet. This election was the third in 20 months and the fifth of nine held between 1695 and 1713. While these frequent and strongly contested elections may have given a certain instability to the English political process, they also provided a healthy polarization of the two parties over issues of the royal prerogative, the war, and the church. As a High Anglican, the Queen supported the efforts of the high Tories, including the Earl of Nottingham and her uncle the Earl of Rochester to pass an Occasional Conformity Bill. Such an act would have prevented Dissenters from qualifying for political office by their occasional attendance at Anglican communion services. Some Latitudinarian bishops regarded occasional conformity as a "healing custom"—a substitute for comprehension, although Daniel Defoe thought it hypocrisy—"playing bopeep with God Almighty." But Anne's support was withdrawn when they tried unsuccessfully to win over moderate Tories to their bill by tacking it on to the land tax measure, Lord Treasurer Godolphin's means to support the European campaigns of Marlborough. The high Tories subsequently were defeated in the election of 1705. Even though the Tories still outnumbered the Whigs by 30 votes in the new Commons, Godolphin wanted the Queen to bring more Whigs into the Cabinet, since they gave stronger support than the Tories to the war, at least in the Spanish Netherlands. The Whigs, together with 100 Queen's Servants—courtiers holding pensions and placemen holding offices—formed the war majority in the Commons. Against the advice of the Tory Harley, who had joined the Cabinet, the Queen reluctantly appointed a few Whigs to her Cabinet because she did not wish to jeopardize the military successes against France. Gibraltar had been captured in 1704, and Marlborough had won two brilliant victories: at Blenheim in 1704, which saved the Grand Alliance, and at Ramillies in 1706, which removed the French from the Spanish Netherlands. For the first time since the Hundred Years' War, England was a triumphant military power in Europe.

Marlborough's victories

The Act of Union. Godolphin also called on the Whigs to help him carry through Parliament an incorporating union with Scotland that William had recommended on his deathbed. The Scottish Parliament had passed an Act of Security (1703) providing for a Protestant Stuart succession, upon Anne's death, unless the Scottish government was freed from "English or any foreign influence." The English Parliament retaliated with an Aliens Act (1705) prohibiting all Scottish imports to England unless the Scots accepted the Hanoverian succession. In 1706 agreement was reached to an Act of Union passed by both Parliaments the following year. The Scots gained the advantage of free trade within the new British common market of some 7,000,000 people; the English gained increased security, because Scotland could no longer be used by European powers as a base for an attack on England. The Scots were allowed to keep their legal system and the Presbyterian Kirk, but they gave up their Parliament. In return, they received 45 seats in the English House of Commons and could elect 16 lords to the English House of Lords. The Act of Union provided a constitutional means whereby the crown's influence in Parliament could be strengthened through a distribution of patronage to the Scots.

Whigs and Tories. The strong backing of the Whigs for the Act of Union gave them an even stronger claim for additional appointments to the Cabinet. A kinswoman of Harley (and of the Duchess of Marlborough), Abigail Hill, a lady of the bedchamber for Queen Anne, gave the Tory leader some influence over the Queen, but Harley's attempt in February 1708 to oust Marlborough and Godolphin, who in effect had become Whigs, only resulted in his own resignation from the Cabinet. An invasion scare in March, through Scotland, helped the Whigs in their May election victory even though many people were tiring of the war. In July at Oudenarde, Marlborough defeated a French army, which was saved from annihilation only by darkness, and the navy seized Minorca. The death in October of the prince consort, George of Denmark, opened up additional offices to the Whigs. By the beginning of 1709 the war against France had been won, but the peninsular war against Spain had only endeared Philip V to his subjects. The Whigs entered into peace negotiations with Louis on the slogan "No peace without Spain," but when Louis agreed to all of the Allies' terms except removing Philip V from the throne by force, the English broke off the negotiations. In September Marlborough won the last of his important battles at Malplaquet, but it was with such a heavy loss of life that the French spirit was restored. On November 5 Henry Sacheverell, a High Anglican who had no use for the increasing rationalism in religion, preached an inflammatory sermon against Godolphin, the Whigs, and the settlement of 1689. The Whig leaders of the Commons impeached Sacheverell for high crimes and misdemeanours, but it was a Pyrrhic victory, like Malplaquet, since the Lords convicted him only by 17 votes and gave him a light sentence. With the cry of "Sacheverell and Peace," the Tories won the election of October 1710, but Godolphin had been dismissed from the Cabinet the previous August without any thanks from the Queen, and the Duchess of Marlborough had left the Queen's service in a burst of hysterics the previous April. Only Marlborough, who had been denied his request to be captain general for life, remained at his post.

Whig ascendancy

The efforts of the Tory Cabinet under Harley and Henry St. John were concentrated on a peace settlement. Because the Tories believed, with some truth, that the war's high tax on land was depleting the landed interest, which was predominantly Tory, and that wartime investments were enriching the moneyed interest, which was predominantly Whig, they passed a Parliamentary Property Qualification Act requiring possession of land worth £600 for county members and £300 for borough members. In October, St. John, much to the disgust of George of Hanover (the future George I), negotiated with French diplomats the preliminaries for a separate peace settlement that would leave Philip V on the Spanish throne, give Gibraltar, Minorca, Hudson Bay, Newfoundland, and Nova Scotia to Britain, and provide Britain with certain trading rights with the Spanish colonies in the Americas. While the Whig views on the peace found an outlet in the coffee shops through the journalistic efforts of Joseph Addison (*The Spectator*) and Richard Steele (*The Tatler*), the Tory leaders engaged an Irish Anglican churchman, Jonathan Swift, who defended a "Peace without Spain" in his *Conduct of the Allies* (1711). In the Lords the High Tory, Nottingham, agreed to support an amendment opposing "Peace without Spain" if the Whigs agreed to an Occasional Conformity bill. The Whigs sacrificed the Dissenters in order to overthrow the government, the bill becoming law and the amendment carrying by eight votes. This blow to the Tory government by the Whig lords was overcome by Anne's appointment of 12 Tory peers. The dismissal of Marlborough and the withdrawal of English troops from the field finally brought their Dutch allies to the conference table at Utrecht in 1713. At Utrecht the preliminaries were adopted, plus a line of barrier fortresses for Holland and a guarantee from Louis that the thrones of France and Spain would not be united.

Problem of succession

Although the Tories were able to present a united front to win the election of 1713, on the matter of the succession to the throne there had been growing division, especially between the lord treasurer, Harley (now earl of Oxford) and the secretary of state, St. John (now Viscount Bolingbroke), who became bitter rivals for power in the Tory Party. The serious illness of the Queen in December caused both men to make overtures to the Pretender, the more serious commitment being made by Bolingbroke, but by March it was clear that the Pretender would not give up his Catholicism. In

April suspicious of the policies of their party leaders, a group known as the Hanover, or "Whimsical," Tories, voted with the Whigs against a governmental motion that the Hanoverian succession was not in danger, a sure sign that the Tories were in trouble. With the death of Sophia, her son George became the heir to the throne, and Oxford, now favouring the Hanoverian succession, made a speech in favour of a large reward for the capture of the Pretender. In an effort to embarrass Oxford, who had a Dissenter's background, Bolingbroke brought forward a Schism Bill designed to put an end to all Dissenting academies, the nesting area for future Whigs. The Schism Bill passed the Commons by more than a 100-vote majority, but in the Lords, where Oxford could not bring himself to oppose it, it passed by only five votes. Oxford failed in an attempt to bring corruption charges against Bolingbroke, and on July 27 the Queen dismissed Oxford as lord treasurer, but Bolingbroke did not get the coveted post. When the Queen died on August 1, the bitter struggle for power in the Tory Party was dangerous but far from hopeless.

The achievement of the Stuarts. Queen Anne's death followed by two years that of the Earl of Rochester, whose father, the Earl of Clarendon, had been born six years after James I came to the throne. The two men had witnessed (as had Oliver Cromwell, who was born in 1599, and his son Richard, who died in 1712) the whole succession of Stuart rulers. What were the main outlines of the struggles they had seen? Political and constitutional matters took on a fairly recognizable pattern of development. The struggle for control of the state by the king and Parliament, neither of which had a concern for anything resembling manhood suffrage, was characterized by the increasing claims of both the royal prerogative and parliamentary rights (the latter more than the former) until the 1640s when the office, as well as the holder, of the crown was eliminated and Parliament became the sovereign power in the realm. The reestablishment of the monarchy at the Restoration, foreshadowed in the Cromwellian Protectorate, was not altogether different from what it had been under James I, but the absolutist tendencies of Charles II and particularly James II brought limitations upon the crown through the revolutionary settlement, which laid the basis for the "mixed" government of the 18th century. A somewhat similar pattern can be found in religious matters. The struggle for control of the church by Puritans and Anglicans, both of which had extremists who wanted to put down the royal supremacy, was characterized by Calvinist and Arminian modifications (the former perhaps more than the latter) upon the Elizabethan church settlement until the 1640s, when the Anglican Church was abolished and the Puritans came to power—at first under a state-controlled Presbyterianism and, later, under Cromwell's theocratic establishment. The revival of the Anglican Church at the Restoration, largely along the non-Arminian and Erastian lines of Elizabeth's day, was reinforced by the monopoly of political privileges given only to Anglicans, but the move toward Catholicism under Charles II and James II, together with the enforced separation of the Dissenters from the Anglican Communion, culminated in 1689 in a policy of religious toleration (but not political privileges) for Dissenters that was to remain until the 19th century.

In social and economic matters the pattern is broken. There was no struggle between the various classes in English society at the time of the Civil War; instead, there were divisions to varying degrees within the aristocracy, gentry, and merchants, when it came to choosing sides. Although many aristocrats and some gentry lost political and economic influence during the Interregnum, partly because of the composition of Parliament and the confiscation of lands, after the Restoration they regained their earlier privileged positions. Also, there is some evidence that these social classes were not as strongly represented among the Dissenters as they had been among their Puritan predecessors; conversely, Dissent became more associated with trade and finance. Finally, there is some evidence that the bankers and the merchants after 1689 were to be found more in the Whig Party, which embraced many Dissenters, than in the Tory Party, which embraced the High Anglicans.

(L.F.S.)

XII. Great Britain: 1714–1815

THE FIRST HANOVERIANS (1714–60)

When Queen Anne died, George Louis, elector of Hanover, became George I of Great Britain and Ireland under the Act of Settlement. The Revolution of 1688 gave legitimacy to the Hanoverian succession. The Jacobite Party—a few thousand country squires, High Anglicans, and Roman Catholics—were committed to the Stuarts under the doctrine of indefeasible hereditary succession discredited by the Revolution of 1688. Most politicians and place seekers showed acceptance of George I by courting Baron Johann Caspar von Bothmer, the Hanoverian envoy. Immediately upon Anne's death, Caspar revealed to the Privy Council the list of regents; 14 of the 18 were known as Whigs. The liveliest question was not who would oppose the new king but whom he would prefer as his ministers.

The old order crumbled before the King's arrival from Hanover in September. George I had already dismissed the Tory leaders Henry St. John, 1st Viscount Bolingbroke, and James Butler, duke of Ormonde, and had excluded John Churchill, duke of Marlborough, from the regency. Preferring known loyalty, the King sought it among Whigs. Only Charles Howard, 1st earl of Nottingham, and George Talbot, duke of Shrewsbury, represented the ideal of a "mixed ministry" of Whigs and Tories. Charles Viscount Townshend and James Stanhope, 1st Earl Stanhope, secretaries of state, headed the ministry. Passing time and royal decisions virtually eliminated the leaders of the revolutionary generation of both parties.

The changeover went smoothly. The King enjoyed the prerogative right of appointment and dismissal; the only grounds for challenging his appointments were political. The Whigs, led by such men as Charles Spencer, 3rd earl of Sunderland, James Stanhope (after 1717, Earl Stanhope), Lord Townshend, and Robert Walpole, 1st earl of Orford, identified themselves with the security of the Hanoverian succession; and the election of 1715 gave the Whigs a majority of about 150 in the House of Commons. Because Bolingbroke obligingly fled to France, the government did not proceed beyond a resolution of impeachment against former ministeries responsible for the unpopular Treaty of Utrecht ending English participation in the War of the Spanish Succession. Ormonde followed Bolingbroke into exile a few months later; the Earl of Oxford remained in the Tower of London; the Tory minority was leaderless. In France, Bolingbroke became secretary of state to James II's son, James III, the Stuart pretender who was preparing an invasion of Great Britain. The Jacobite Rebellion of 1715–16 (the "Fifteen") and the Whig success in identifying the Tories with it frustrated Tory hopes of recovery. The romantics who surrounded the Pretender in France persuaded him to undertake an invasion that his able half brother Marshal Berwick and Bolingbroke opposed. Stanhope and Townshend were prepared when John Erskine, earl of Mar, led a premature rising in Scotland and an invasion of England. Mar was in retreat even before the Pretender arrived in Scotland in December. A month later they left for France, where the regency encouraged James to go on to Italy. The "Fifteen" was Mar's rebellion, mixed with Scottish politics and religious antipathies, as much as it was a Jacobite rising.

The Whig leaders

The establishment of Whig supremacy. The rising blasted Tory ambitions. The government treated actual rebels with moderation but took political vengeance upon politicians of doubtful loyalty, and, by the spring of 1716, the ministry was purely Whig. Robert Walpole, formerly paymaster of the forces, became first lord of the treasury and chancellor of the exchequer. The Septennial Act of 1716 extended the life of "this present Parliament" four years, postponed the unsettling effects of an early election, and, by providing legal lives of seven years

for subsequent Parliaments, gave winners more time to consolidate victories. All politicians would enjoy the benefit of fewer elections and economies in election expenses. The act did not abolish the king's prerogative of dissolution, but it did inaugurate the septennial convention, which during the 18th century was clearly violated only once, in the election of 1784.

Whig factionalism succeeded a long generation of Whig–Tory warfare. After a decade of doubt, scholars again believe that the last two Stuart reigns knew a two-party system based on significant distinctions between the parties. Under the Whig supremacy after 1715, the differences among Whig politicians did not go to the bedrock of English life as had earlier Whig–Tory ones. Between the Townshend–Walpole and Stanhope–Sunderland factions, personal rivalries as well as disagreements over foreign policy created ill feeling, leading to Townshend's demotion and Walpole's resignation in April 1717. In foreign affairs, Stanhope pursued a vigorous continental policy. In 1717 he concluded a Triple Alliance with France and the Dutch that minimized foreign support for the Jacobites and gained for England the valuable diplomatic influence and organization of France in northern Europe. Stanhope's treaty with France was a constant of British policy for 15 years. His forward policy in the Baltic area exposed the controversial question of England's responsibilities toward Hanover, unavoidable in any case. Russia's presence in Europe after its victory over Sweden in the Great Northern War (1700–21) was less threatening to England than to Hanover; England and Russia were able to resolve commercial problems.

Peace with France

During his three years of office, Walpole engaged in factious opposition. In particular, he and Townshend courted the Prince of Wales. During the 18th century, the Hanoverian kings were nearly always at odds with the heir apparent, who constituted a "reversionary interest": unemployed politicians might cluster around the Prince of Wales, especially if the king was old. The game, however, was risky, as the Georges looked suspiciously at the reversionary principle. In 1719 Walpole helped defeat the Peerage Bill, which aimed at restricting the prerogative power to create new peers. The King himself favoured the bill because, if he died, it would prevent his successor from using the prerogative against Stanhope, whom he liked.

By 1720 Stanhope reached the height of his power. He had converted the Elector of Hanover into the king of Great Britain by winning for English ministers that part of the King's confidence formerly given to Hanoverian advisers. The King and the Prince of Wales were reconciled, and Walpole and Townshend accepted Stanhope's foreign policy. By April 1720 an era of good feeling prevailed among Whigs, marked by Walpole's return to the paymastership and Townshend's acceptance of the lord presidency of the council. All of this occurred on the eve of Walpole's accession to leadership. He had political luck as well as ability.

No sooner was Walpole back in office than the government was embroiled in a frenzy of speculation associated with the South Sea Company. Sunderland, first lord of the treasury, sponsored a plan whereby the company took over three-fifths of the national debt in return for trading privileges and a payment to the government of £7,000,000. Anticipations of profits inflated imaginations, and by September 1720 the boom in company shares collapsed. An indignant public opinion and ruined speculators blamed the company and the government. Walpole, however, who had not sponsored the scheme, escaped criticism. In December his plan of salvation, endorsed by the Bank of England and the company, revived public confidence and raised Walpole's prestige. Sunderland and John Aislabie, chancellor of the exchequer, had to resign. Then Stanhope's death in February 1721 vacated the northern secretaryship of the state. The successions were predictable. Walpole, with Townshend, did not acquire full control, however, until Sunderland died a year later and until John, Lord Carteret, the other secretary of state, resigned in 1724 after offending the King's mistress, the Duchess of Kendal. (The office of secretary of state was divided between the northern and southern departments until 1782, when the southern department became the Home Office and the northern department became the Foreign Office.) With Townshend and Thomas Pelham-Holles, 1st duke of Newcastle, as secretaries of state, with disaffected Whigs such as William Pulteney, 1st earl of Bath, and John Carteret (later Earl Granville) powerless, with the Tories in the wilderness, with the ministry united and strong in Parliament and enjoying the King's favour, Walpole by 1725 inaugurated the age of political stability.

The South Sea bubble

Political stability in the 18th century. The English historian J.H. Plumb has defined this stability as "the acceptance by society of its political institutions, and of those classes of men or officials who control them." Three conditions making for stability prevailed by 1725: single-party government; executive control of the legislature; and a sense of identity among those people who possessed social, economic, and political power. The completeness of the Whig monopoly was unprecedented. Besides losing parliamentary seats, Tories suffered purges from local offices and governmental services. Family allegiances became Whig. That politics was a Whig preserve was clear in 1733 when Walpole created a furor of popular protest by his attempt to impose an excise tax on wine and tobacco. But despite the unpopularity of the measure, a Tory government was not a conceivable alternative to Walpole's. At his fall in 1742, the Whigs continued in power; the aristocrats were nearly all Whig, and the hard-core Tories, mainly gentry and squires, numbered only 150 in Parliament. Until the 1780s and the beginning of a new two-party system, the Whigs predominated; ministerial changes were mere Whig reshufflings.

The three conditions of stability

Control of the legislature. Walpole was the first minister to control the legislature with a one-party executive. His steadfast supporters were government officeholders and placeholders whose influence joined with his own, with the King's, and with others', such as the powerful and wealthy Duke of Newcastle, to manage the electoral system. Walpole, Henry Pelham, and Frederick North, Lord North, who had the longest tenures as heads of ministries until the younger William Pitt—21, 11, and 12 years, respectively—had time to perfect this kind of management, which in turn prolonged their tenures of office.

In the 18th century, a ministry needed the king's support. With the exceptions of Charles James Fox and Edmund Burke, who in the political turmoil of 1783–84 were 50 years ahead of their time in asserting the primacy of the House of Commons, politicians accepted the king's prerogative power of appointment and dismissal. Kings, like politicians, distinguished between constitutional and political precepts, conceding the importance of political realities when considering the makeup of ministries. Besides his ultimate powers, the king's patronage power and influence were available to a ministry he favoured. Good relations between ministers and courtiers who could influence the king were also important to ministerial security. George II's queen, Caroline of Ansbach, gave powerful aid, for example, to Walpole. Yet Carteret exaggerated in saying that the crown alone could keep a minister in power. Henry Pelham said more correctly that, in single instances, the king's support could get what a minister wanted; steady control required the support of both king and Parliament.

The king sometimes farmed out his patronage powers to others, such as the Duke of Newcastle, who became known as the "ecclesiastical minister" because of his control over church appointments. Under George II, however, no one mistook the fount of patronage: government, as it had always been, was the king's. The delegation of local administrative work to parish officials and justices of the peace did not lessen the numbers of royal officials. Wars being more costly, more people were needed to collect and manage the growing revenues. Besides money for the debt service (the interest payment on the national debt) and the armed services, Parliament

provided the civil list, or the annual payment to the crown, increasing it for George II from £700,000 a year to £800,000. It came in a lump sum, and with it the king paid the costs of the civil side of government, pensions, household support, and the secret service. The political use of the civil list was not so great, however, as gossip had it.

Influence and patronage did not necessarily bribe members of Parliament. Generally, placeholders as well as independent country gentlemen recognized an obligation to support the government in office because it was the king's. In any given House of Commons, two-thirds of the 200 placemen were holdovers free of obligation to the ministry in office. The total consisted of some 40 ministers and administrative officials, 50 court and household officials, 60 officers in the armed service, and the remainder sinecurists and pensioners. The king had 26 ecclesiastical appointments to the House of Lords. Political considerations entered into them, and generally the incumbents supported the government.

The electoral system. Management of the electoral system was the other requisite for control of Parliament. The peers sat in the House of Lords by hereditary right, bishops by virtue of their offices; Scotland was represented in the House of Lords by 16 members elected by their own Scottish peers. The first two Georges used sparingly their prerogative power of creating peers. The House of Lords remained at about 220 members until the 1780s, when George III tried to offset the reduction of his patronage by increasing the appointment to peerages. Some peers were active politicians, and 18th-century cabinets were predominantly aristocratic.

Management of elections

Parliament had taken control of the ancient electoral system in the late 17th century. The politicians preferred to manage the system rather than to tamper with it. The list of borough constituencies and franchise qualifications remained virtually unchanged until the Reform Bill of 1832 (see below). The property-based franchise was fixed by statute in 1430 for the counties and by local custom or charter in the boroughs. The electorate numbered about 400,000 voters distributed unevenly among some 300 constituencies. In only 19 boroughs besides Westminster, London, and Bristol did the electorate exceed 1,000. Yet the management of elections was neither easy nor cheap. Each borough and county had a unique character, history, and personality. Management also meant arrangements for avoiding electoral contests. A general election was a varying number of contests, normally on local issues or personalities, and not a national electorate's judgment on national issues. In the last half of the 18th century, the largest number of contested counties in any election was 11. The absence of contests, as much as electoral victories, attested to good management.

After 1770, radicals increasingly stirred the question of parliamentary reform. They desired a Parliament more representative of the number and distribution of voters, and they hoped to achieve this by more frequent elections, by the redistribution of seats in accord with population, and by adding personal (*i.e.*, not landed) property to the electoral qualifications. The basic complaint was against the preponderance of land in the electoral structure.

Land was only one of the several interests deserving representation. In 1770 Edmund Burke in his *Thoughts on the Causes of the Present Discontents* identified other interests—commercial, official, professional, military, and naval. Actually, close-knit family and political relationships guaranteed representation of the other interests in themselves and through land. The propertyless—the poor, the wage labourers, the people who lacked free agency—were thought to deserve no voice in public affairs. The national consensus on the connection between property and political participation underlay the political stability of the 18th century. In the "balanced" constitution mixing democracy, aristocracy, and monarchy, and resting upon a property base, England enjoyed a closer union of political, constitutional, and social systems than perhaps any other European nation.

The growth of the Cabinet. Stability after 1725, however, was not synonymous with dullness or predictability in politics. The life of every government depended upon good working relations among king, ministers, and Parliament. The appearance of the institution of the Cabinet after the Revolution of 1688 did not solve the problem. Politicians were uncertain of the status or even the name of the executive group that took over the work of the Privy Council, which by 1715 had been reduced to honorary status. A committee of the Privy Council, the Cabinet or Cabinet Council met with the sovereign in its early days. Responsible individually to the king for the business of their offices, ministers only slowly developed a sense of corporate responsibility.

The Cabinet's membership fluctuated and was often too large for effectiveness. It included upward of 20 household and state officers, heads of administrative departments, and prominent persons such as the archbishop of Canterbury. This "nominal" Cabinet lasted into the 1760s. Walpole preferred to work with an inner cabinet made up of the two secretaries of state, the lord chancellor, the lord privy seal, the lord president of the council, and himself as first lord of the treasury and chancellor of the exchequer. But instead of creating the cabinet system, Walpole might have checked its growth had his preference prevailed. His opponents accused him of concentrating authority too narrowly, and later first ministers learned from his experience. After 1762 the "nominal" Cabinet yielded to the "effective" Cabinet, the membership of which, made up out of the Privy Council, for practical and political reasons stabilized at about nine until the 1790s, when it grew to some 12. The composition also became more fixed. By the 1780s the household officers were gone, and the Cabinet consisted of the three great officers of state and heads of administrative departments.

Yet uncertainties remained. The Cabinet had no legal status, but it was politically important and soon became a part of the working constitution. After 1718, George I, who did not speak English, ceased to attend its meetings; the next two kings followed his precedent almost without exception and did not thereby diminish the Cabinet's growing constitutional authority. Historians are cautious against dogmatism on details of Cabinet development and practice, because the sources are sometimes contradictory and seldom full.

The role of the prime minister

The lack of a clearly defined party structure and the uncertain status of the Cabinet left unclear the role of the first, or prime, minister. Politicians said they feared the rise of an all-powerful subject. After the eclipse of the Tories and the prevalence of Whig factionalism, no one person was head of the Whig Party and thus the indubitable first minister. Yet the head of the government was usually identifiable. From Walpole onward he was normally the first lord of the treasury or, if in the House of Commons, chancellor of the exchequer. The term prime minister gradually took hold. The important thing was the substance, not the name, and Walpole provided an example of strong leadership of a relatively well knit government. No 18th-century head of a ministry could be a prime minister in the modern sense, because there was not a disciplined party opposition whose leader was the alternative prime minister. Nevertheless, the difference between Walpole's government after 1724 and its predecessors was striking. The contrast encouraged exaggerations of the maturity of Cabinet, party, and prime ministership and tempted historians in the 19th century to see George III trying to subvert a developed parliamentary government. None could have existed until the 19th century.

Walpole's ministry. *Domestic affairs.* Walpole became first minister after 20 years in Parliament. A proud House of Commons man who mastered its ways, he understood the prejudices and sensitivities of its members. During the first decade of his administration, he concentrated upon domestic matters, leaving foreign affairs to Townshend. Some substance and much political opportunism informed his harassment of Jacobites. Bolingbroke returned from exile in France in 1723 more inter-

ested in politics (though excluded from the House of Lords) than in the Pretender. Gathering about him disaffected politicians, notably William Pulteney and the old Tory Sir William Wyndham, and speaking through the newspaper *The Craftsman*, Bolingbroke attacked Walpole. Just as vocal were the "Patriots"—an ironic name given to a group of Whigs whom Walpole had alienated, among them Carteret, Lord Chesterfield (Philip Dormer Stanhope), Lord Cobham (Richard Temple), William Pitt, and Archibald Campbell, 3rd duke of Argyll. Soon after the accession of George II in 1727, the opposition swarmed around Frederick Louis, Prince of Wales, on the reversionary principle. His establishment, Leicester House, was also—in addition to being a centre of political opposition to Walpole—the centre of fashion, and attracted such leading authors as Jonathan Swift, Alexander Pope, John Gay, and Henry Fielding, along with important ladies, including Carteret's mother, Lady Granville.

Opposition to Walpole

The opposition was a varied, interesting group, but Walpole had the votes. The parliamentary elections of 1727 and 1734 were his victories. His parliamentary strength had a core of about 150 men, some of them placeholders, who faithfully attended sessions of Parliament. There were times of stress, like the storm over "Wood's Halfpence" in 1723–25, when an English ironmaster, William Wood, was granted a patent to mint a debased coinage for Ireland. The Irish complained that they had not been consulted and also feared that the new coins would drive out good currency. Swift's "Drapier's Letters" powerfully attacked the deal. Walpole revoked the patent in 1725. The main effect was upon Ireland, where the furor contributed to a political awakening.

The fiasco revealed two of Walpole's weaknessess—stubbornness, as contrasted with persistence, and secretiveness. His conduct over the excise in 1733 also showed these traits. Walpole desired to convert certain customs duties into excises, payable after the sale of goods released from bonded warehouses. Before he revealed his plan, the opposition and *The Craftsman* spread rumours of a general excise the merits of which were not as self-evident as Walpole thought. When he finally introduced a plan for a tobacco excise, the opposition had already misled the public. Though the government retained a majority in the House of Commons, Walpole gave up the scheme in April. "Coerced by clamor and opinion," he retreated, not because he had lost his majority but because he feared he might. But electoral success in 1734 showed that the storm had done no fatal damage.

Walpole's financial achievements

These two episodes are better known than Walpole's solid accomplishments in national finance and commercial policy. Politicians accepted the principles underlying the protectionist commercial system; but Walpole improved its workings. He lowered many import duties, notably on raw materials, in the interest of British manufacturing and exports. Walpole's work on national finances was technical and administrative. He diverted the sinking fund to uses other than debt retirement, thus keeping down taxes. The national debt in 1739, when war began with Spain, was £46,000,000, reflecting a reduction of only £8,000,000 since 1714. But he halved the annual debt service charge by reducing the interest rate. Had he retired the debt, many holders of securities would have been unhappy. Walpole taught England that it could live and prosper with a national debt; he made it a permanent part of the nation's financial structure and of the domestic economy of many private citizens.

Foreign policy. Townshend continued Stanhope's policy of friendship with France against the empire. An alliance in 1725 between Austria and Spain justified distrust of Austria. Fearful for the European balance of power and for British interests in the Mediterranean, Townshend tried unsuccessfully to supplement the old Triple Alliance by new arrangements with Prussia and the northern countries. Walpole's desire for agreement with Austria, however, caused Townshend to resign in 1730 and meant the abandonment of the Stanhope policy. The Treaty of Vienna (1731) was a return to cooperation with the emperor and implied conflict of English–French interests. Commercial, colonial issues between them were growing more tense. The Treaty of Vienna proved immediately useful for Walpole, who found in it an excuse for staying out of the War of the Polish Succession, which erupted in Europe in 1733.

In the 1730s, when England had no staunch continental ally, relations with Spain deteriorated. Both sides complained of violations of trade treaties. English merchants poached upon Spain's protectionist system in the West Indies, and English opinion supported them. In 1739 Capt. Robert Jenkins, who had earlier had his ear cut off by the Spanish coastal patrol, exhibited his severed ear to Parliament. Against his will Walpole had to agree to war against Spain because Parliament, the merchants, and the nation wanted it. The Anglo-Spanish War (the so-called War of Jenkins' Ear) soon blended with the War of the Austrian Succession, a wider European war that broke out after the death of Emperor Charles VI. As a guarantor of the Pragmatic Sanction intended to safeguard the Habsburg patrimony of Charles's daughter Maria Theresa, England granted a subsidy to Austria. Walpole survived the election of 1741 with a reduced majority. He was becoming an anachronism. When he resigned in February 1742, he left the nation in good economic condition, but with military and naval establishments unprepared for war.

The War of Jenkins' Ear

The attacks of the "Patriots" during the preceding decade were against Walpole personally and the concentration of authority in himself, rather than against the ministry. Neither the King nor the opposition expected or desired a clean sweeping. The new ministry was a reshuffling of Whig politicians. The opposition leader, Pulteney, tried to bring the King and Leicester House together and promoted Spencer Compton, earl of Wilmington, for first lordship of the treasury. The King and Newcastle brought in Carteret as secretary of state but kept out Pitt, Chesterfield, and the Grenvilles. "Patriot" stock fell even further when the King and the Prince of Wales made peace. The new government was strong enough to stall attempts to inquire into Walpole's conduct as minister.

The Pelhams. The times at first favoured Carteret. Content to manage foreign affairs, he refused to be angry when, after the death of Wilmington in 1743, the King replaced the latter with Henry Pelham, the brother of Newcastle, instead of Pulteney (now earl of Bath). Carteret, a Europeanist, rejected the Patriots' emphasis upon the colonial–maritime war. His search for a German settlement appeared to the Patriots to be oriented toward Hanover, and Pitt protested vigorously. English aid to Austria helped it regain ascendancy in Italy, which displeased Frederick II of Prussia. His alliance with France shattered Carteret's diplomatic structure. Pelham and Newcastle thought him a political liability. The King's protection was not enough, and Carteret resigned in November 1744.

Pelham tried to make the ministry his own. He brought in some of the Patriots, but the King balked at Pitt, without whom Pelham had trouble controlling Parliament. In February 1746, when the King rejected Pelham's request to appoint Pitt to office, the ministry resigned. It says much for Pelham's success in monopolizing political talent that only Carteret (now Earl of Granville) and Bath were available to the King. When they failed to form a government, Pelham came back on his own terms. In one of his finer moments as king, George II agreed to give his confidence to Pelham and appointed Pitt as paymaster general. For the first time there was a "broad bottomed" Whig ministry, which included all factions.

The Jacobite Rebellion

The ministerial crisis of 1746 occurred against the background of the Jacobite Rebellion of 1745, not because of it. The Young Pretender, Charles Edward, hoped that success in Scotland would bring French reinforcements. The enterprise was hopeless in spite of the Stuart mystique. Charles landed in western Scotland with a few friends and gathered support as he moved eastward. In September 1745 he occupied Edinburgh. He invaded England, reaching Derby unopposed. But his officers, seeing signs of gathering English strength, forced him to

withdraw. The Duke of Cumberland's forces backed Charles into northern Scotland and, on April 16, 1746, destroyed his army at Culloden. Charles then wandered in the Highlands, a refugee, until he left for France in September, committing his cause to romance and dwindling Jacobite sentimentality.

Cumberland and his successor in Scotland, William Keppel, earl of Albemarle, enforced loyalty, or at least submission, to the Hanoverian succession in Scotland. The Lowlands were by now accommodated to the Act of Union of 1707 and the new dynasty. The Highlands had remained apart, dominated by a feudal regime. Clan chieftains enjoyed medieval judicial and military privileges that were frequently in conflict with sterner conceptions of public order. Upheld by acts of Parliament, the government now extended the royal system of shires and judges, as had been done centuries before in Wales. A statute abolished the chieftains' authority to require military service from tenants. Still, the chieftains did not suffer economically; they became landlords over estates formerly held in trust for their clans. The change in the basis of landholding worked a social revolution, to the detriment of the crofters, or tenant farmers. Scottish emigration to the empire increased greatly thereafter. Other statutes required oaths of allegiance from the Episcopalian clergy, forbade the wearing of kilts and tartans, and disarmed the Scots. After the Forty-five Rebellion, Highland Scotland became a part of the United Kingdom and knew peace.

English politics were not peaceful despite the Pelham–Newcastle victory in the 1747 election. Unable to accuse Pelham of acting like Walpole, the opposition instead criticized the excessive influence of the Pelhams and the great Whig families. The opposition took up the idea, advocated by Bolingbroke, of a "patriot king," who would rule above faction and party strife. Never reliable, Pitt courted the Prince of Wales at Leicester House, while Newcastle muttered about Cumberland's influence upon the King. As George II grew older, the reversionary interest became more intriguing. Ironically, however, the Prince of Wales died first, in 1751. Pitt returned to the safety of the ministry in time to support the Regency Act that checked the ascendancy of Cumberland and before Bolingbroke's death completed the discomfiture of Pelham's opponents.

Pelham's last years

Pelham's ministry accomplished a good deal. The Treaty of Aix-la-Chapelle in 1748 ended the war but left colonial issues unsettled. During Pelham's last six years (he died in March 1754), England was officially at peace, and Pelham, an able finance minister, reduced the annual budget from the wartime peak of £10,000,000 to just over £2,500,000. He further reduced the cost of debt service by converting most of the debt to "three per cents." The Gin Act of 1751 took distillers out of retailing. Contemporaries thought the consequent reduction in gin consumption caused a decline of drunkenness, disorder, and crime. Other legislative reforms included the adoption of the Gregorian calendar in 1752 and the Hardwicke Marriage Act of 1753, which checked the racket in secret marriages, whereby younger sons in the aristocracy could inveigle a young heiress into a quick marriage. Against these measures prejudiced and uninformed opinions protested, but never so effectively as in 1753, when, with an election pending (1754), the government repealed its own measure permitting naturalization of Jews.

More than the politicians, George II in his commonsense way had appreciated Pelham's abilities, and he feared political troubles when Pelham died. Newcastle, who overrated his own abilities as much as he underrated his brother's and who confused electioneering with statesmanship, went to the Treasury as head of the ministry. Refusing to pay the price (patronage control) demanded by Henry Fox, 1st Baron Holland, or to meet Pitt's insincere conditions, he entrusted leadership in the House of Commons to two second-rate men, Thomas Robinson, 1st Baron Grantham, and Henry Legge. In 1755, Newcastle brought in Fox as secretary of state, passing over Pitt, whose discomfiture was the greater because he disliked Newcastle's foreign policies. Pitt attacked the Newcastle–Fox combination and was dismissed from his post of paymaster general in 1755.

Pitt and the Seven Years' War. Like the King, Newcastle did not understand the importance of the imperial issue with France, and both were anti-Prussian and pro-Austrian. Anglo-French colonial rivalry came to a head in 1754 over conflicting claims to the Ohio Valley in North America. Already Pitt could point to Gen. Edward Braddock's defeat at Ft. Duquesne in July 1755, by French and Indian forces, as indicative of French strength. Yet Newcastle managed to arrange a system of treaties that was to serve as the base in Europe for Pitt's global strategy. After arranging subsidies for Bavaria, Saxony, and Hesse, Newcastle in September 1755 made a subsidy treaty with Russia. Frederick of Prussia felt the pressure and in January 1756 agreed with England to the Convention of Westminster, providing for mutual territorial guarantees. France completed this "diplomatic revolution" by accepting Austria's overtures. Russia, realizing the incompatibility between England's treaties with Prussia and itself, joined France and Austria. In May 1756, after a French attack on the British in Minorca, Great Britain declared war; within a year all of Europe was plunged into war (see also SEVEN YEARS' WAR).

The "diplomatic revolution"

Pitt saw the potentialities of these treaties more clearly than Newcastle. News of disasters in India, North America, and Minorca added substance to attacks upon the government, which he was freer to make after dismissal from office in November 1755. Fox resigned as secretary of state in October 1756, forcing Newcastle to tell the King that only Pitt could save the government. Pitt, who hated Newcastle, thought he could save England without Newcastle's help. The King yielded in November. The government, nominally headed by William Cavendish, 4th duke of Devonshire, had support in the nation, where Pitt, secretary of state, was popular; but it lacked the King's confidence and the support of the House of Commons. The King dismissed it in April 1757. The weakness of the patchwork ministry that replaced it made possible the obvious solution. Pitt contributed his own popularity and the support of Lord John Stuart Bute and Leicester House. Newcastle offered his patronage support, his personal influence, and his political skill. Fox contributed nothing, but as paymaster he could make a fortune, and the government need not worry about him. Pitt as secretary of state controlled the war effort; Newcastle at the Treasury devoted himself to political management.

When he took over Newcastle's treaty structure, Pitt redirected it from Hanoverian to global ends. Pitt was not unique in his theoretical understanding of the relation between the German war and the imperial conflict with France. But he was foremost in determination and ability to act according to his assessment of priorities. Sea power enabled the British navy to put France upon the defensive throughout the world, preparing the way for the victories that made 1759 the "year of miracles." French naval strength was great enough, however, to threaten invasion of England until the English victory of Quiberon Bay in November 1759. This was two months after the fall of Quebec and one month after the French fleet left India, where the English dominated Bengal and were winning in the Carnatic. These victories followed upon the capture of Guadeloupe and a British surge in the West Indies. English successes continued in 1760. Pitt had united the nation in the greatest war effort in its history. At the close of the war in 1763, Great Britain had become a major world power.

Quiberon Bay victory

George II died on October 25, 1760, in the middle of the war. His last were his best years, in that at crucial moments he subordinated personal preferences to national needs. Whether he chose freely or was a prisoner of the Whig politicians is a much debated question. The accession of his grandson, George III, who at age 22 was far from mature, made everyone ask whether a new king meant new men.

The answer was self-evident because the ministry was a patchwork of factions, and the King's opinions on

politics and the war were well-known. Newcastle and his Old Whigs, wearing the Pelham mantle, were the largest active faction, allied with the Court during the late years of George II. Pitt, supported at the moment by his wife's brothers, Richard Grenville-Temple, 1st Earl Temple, and George Grenville, was popular with the Country and in the city of London but lacked parliamentary strength. He had lately neglected Leicester House, where Lord Bute and the Princess Dowager dominated. Under the reversionary principle, both Newcastle and Pitt could expect unfriendly treatment. John Russell, 4th duke of Bedford, headed a growing faction that as a peace party would soon be at odds with Pitt. The hard-working civil servant types by definition were loyal to the King and were ready on the same principle to join with politicians who naturally gravitated toward the King and were known as King's Friends. The Duke of Cumberland, though Fox followed him, was not a factional leader but a political influence in his own right. The politicians feared most Lord Bute's capacity for intrigue and his influence upon the King. Together they represented the old cant of Leicester House, namely, throw the rascals out, eliminate factions, and establish a regime of purity and high-mindedness under a king who was devoted to the public good and an enemy of evil. The program of unemployed politicians was also the substance of the idea of a patriot king, and had Bolingbroke never written the book of that title, George III would have possessed the idea, having been under the moralizing tutelage of Bute.

There were also differences of opinion among the factions over the war. George III desired to end what he called "this bloody and expensive war"; Bute thought England should consolidate its gains before concluding peace; Pitt insisted upon continuing the war vigorously, though he consented to preliminary peace talks with France. Pitt found himself in the minority in favouring immediate war against Spain when its alliance with France became known. Not only the Bedford faction but also Newcastle and Lord George Anson, the talented first lord of the admiralty, opposed him. Pitt resigned. His successor, Lord Bute, as secretary of state with the responsibility for a Cabinet he could not control, had the powerful support of the King and the Princess Dowager. Though England declared war on Spain in January 1762, the government refused to renew the Prussian subsidy treaty and resumed peace talks with France. The Bedford peace party grew in influence as war weariness spread. Newcastle, old and tired, gave way to Bute, who formed a ministry in May 1762. In Paris, Bedford reached agreement on peace terms with France. Pitt opposed these terms violently in the House of Commons in November because he thought they threw away England's war gains. But he had the sense neither of the nation nor of Parliament. The opposition was adrift, and waverers supported the government in the absence of a reversionary interest. The government's victory (319–65) indicated not steady strength but, rather, the absence of a desirable alternative policy. Nonetheless, the nation did not think the less of Pitt for losing on the peace. Contemporaries gave him credit for leading England to heights it had never before attained, and posterity has agreed.

Treaty of Paris

THE REIGN OF GEORGE III TO 1789

Political instability, 1760–70. George III had support from country gentlemen and independent members, from placeholders, from ambitious young men who aspired to political careers and government service, and from factional leaders eager to replace the Old Whigs. Newcastle had no political future, and other Old Whigs such as Devonshire and Hardwicke soon died off. A corps of younger Old Whigs maintained some cohesion and by 1764 looked to the 34-year-old Charles Watson-Wentworth, 2nd marquess of Rockingham, as their leader. Though neither a dynamic personality nor a parliamentary speaker, Rockingham had patience and a character that inspired loyalty.

The national debt and taxes were the most pressing postwar problems. The debt of £114,000,000 continued to increase. The land tax met only one-half of the annual debt service. The government's excise tax on cider was a political blunder and, as a financial expedient, not worth a furor. Pitt and the Old Whigs feared for the liberties of the subject. Though the measure passed easily, Bute quailed. He was too thin-skinned for a front-rank politician. He resigned in April 1763; neither he nor the King saw political danger in a private advisory relationship. The King's alternatives reduced to one—Sir George Grenville, whom he personally disliked. Grenville saw his constitutional duty in serving the King and protecting him from political pressures. Though honest and an able lawyer, Grenville was rigid, dogmatic, and haughty—in short, a poor politician. Grenville's Cabinet, however, was an abler one than Bute's, if for no other reason than that Grenville replaced Bute as first lord of the treasury and the incompetent Sir Francis Dashwood as chancellor of the exchequer.

Miscalculation, bad luck, and his own poor judgment of people doomed Grenville. His measures, such as the Sugar Act of 1764 and the Stamp Act of 1765, to improve the customs service and revenue collections were fiscally sound but as politically explosive as the Proclamation of 1763, a well-intentioned, temporary arrangement for the territories in America newly acquired in the Seven Years' War. The most damaging effects of these measures beset Grenville's successors. Grenville was unlucky enough to be in office when the political agitator John Wilkes, who supported Pitt, burst into prominence. Wilkes, a London demagogue, gave virulent journalistic support to Pitt and the opposition in his newspaper the *North Briton*. Wilkes was given financial assistance by Richard Grenville-Temple, 1st Earl Temple, Grenville's brother, who was, however, hostile to the new ministry. Temple encouraged Wilkes to issue the famous "No. 45" (April 23, 1763) of the *North Briton*, which attacked the King's speech defending the Treaty of Paris. The government reacted by issuing a general warrant under which 48 persons, in addition to Wilkes, were arrested. Sir Charles Pratt, chief justice of common pleas and a friend of Pitt, checkmated the government's assault upon Wilkes by affirming his privilege as a member of Parliament. Later Pratt ruled illegal the "general warrant" under which the government first proceeded against Wilkes. In Parliament the government fared better. The House of Commons voted "No. 45" a seditious libel; the House of Lords declared Wilkes's "Essay on Woman" an obscenity. After Wilkes fled to Paris to escape proceedings under an indictment in the Court of King's Bench, that court outlawed him. The House of Commons expelled Wilkes and overruled Pratt's decision on general warrants. The Rockingham Whigs and Pitt again cried that liberty was in danger and nearly beat the government on the question of general warrants.

Agitation of John Wilkes

Grenville's financial and administrative measures began to take effect by 1765. Wartime finance gave way to peacetime finance. But Grenville embarrassed the King's mother by mishandling the Regency Bill (necessitated by the King's illness). Then Grenville asked the King to keep away from Bute. After dismissing Grenville and failing to enlist Pitt's help, the King had to turn to Rockingham. The Marquess accepted some "king's friends," but his major appointments were from a Rockingham party independent of Pitt's patriots, the Grenvilles, and the Bedford gang. Rockingham appointed Edmund Burke as his secretary, and Burke won election to Parliament in December 1765.

The Rockingham government early met reactions to the Stamp Act. American discontent mingled with English mercantile complaints of declining trade. Though from substantial people, these protests were extramural (*i.e.*, outside Parliament), and they added a new dimension to parliamentary politics. When Parliament assembled in January 1766, Pitt thundered for repeal of the Stamp Act, which he claimed violated the rights of Englishmen by taxing colonials without their consent. Grenville upheld Parliament's right to tax the colonies and demanded enforcement of it. The Rockingham compromise accepted something from each. It repealed the Stamp Act

as impolitic and passed the Declaratory Act of 1766 asserting Parliament's right to legislate "in all cases whatsoever." The principle of the Declaratory Act continued to frustrate the empire. Americans, who rejected the principle, eventually ceased to talk about their rights as Englishmen; in 1776 they based their claim to independence upon their rights as men. The British constitution, as most members of Parliament understood it, did not admit autonomy of subordinate assemblies in the empire. The debate on the Stamp Act showed that on questions of constitutional rights, English and American claims were antithetical.

Achievements of Rockingham's ministry

During its short life, the Rockingham ministry accomplished much. It repealed the Cider Act, declared general warrants illegal, and amended the Navigation Acts. Reduction of the levies on West Indian molasses helped the trade and produced a handsome revenue. But the King's open distaste for the ministry encouraged disaffection within it. The nation and some politicians continued to look to Pitt. The King surprised no one when he dismissed the ministry, and the nation learned joyously in midsummer of 1766 that Pitt had consented to save it. At his best, Pitt could not have imposed his reading of the constitution upon Parliament and would have met difficulties in conciliating American opinion. He was at his worst, physically and mentally, after a few months in office. He failed to provide the "patriotic," nonpartisan government the nation expected. Sitting in the House of Lords as the earl of Chatham, Pitt lost touch with the House of Commons. When he was in the country, ill and at times deranged, ministers went their several ways. Prussia and Russia repelled England's advances. Chatham's plan for asserting crown sovereignty over East India Company territories in India became a temporary arrangement whereby the company paid money to the government and continued to expand its responsibilities in India. The Americans found arguments against the quartering of troops in Massachusetts and New York.

The Townshend duties

The chancellor of the exchequer, Charles Townshend, persuaded Parliament in 1767 to levy duties on certain imports into America, which he asserted were palatable as commercial regulations. This casuistry provoked an American challenge to indirect taxation and made tea a symbol of the imperial tyranny.

By autumn 1768, when a pitiful Chatham resigned along with his discouraged secretary of state, the 2nd Earl of Shelburne, the ministry lost whatever Chathamite tinge had lasted beyond Townshend's death and the entry of the Bedfords—except for Augustus, 3rd duke of Grafton, who agreed to carry on the government. John Wilkes continued to embarrass the government. Wilkes had returned from France in March to win election for the county of Middlesex. The Court of King's Bench reversed his outlawry on a technicality, but Wilkes had to spend 22 months in the Tower on other charges. There he lived happily during the storm created by government's efforts to keep him out of the House of Commons. Middlesex re-elected him each time the House of Commons expelled him, until after the fourth election the House of Commons resolved that his opponent, Col. Henry Luttrell, ought to have won and seated him.

The Rockinghams, Grenvilles, and Chathamites supported a petitioning campaign asserting the rights of electors and asking redress of grievances. The King gave them, instead, a new prime minister in January 1770. This was Lord North, a charming man and a skillful parliamentarian but a man who lacked, as Burke said, the "spirit of command that the time required." But in 1770 this deficiency was not yet apparent. North had, at any rate, strong parliamentary support and the King's confidence. Though in time he acquired a following, he never welded into a party the factions that supported him. North did not control the government tightly; each department head had access to the King.

Radical movements and the loss of America. Until the election of 1774, which seated North's government firmly, the ministry survived a sequence of embarrassments. The petitioning movement was followed by a squabble over publication of parliamentary debates. Without conceding the right of publication, the government ceased to prosecute offenders. Wilkes became active in London politics, serving as lord mayor in 1774, the year he won the election to the House of Commons. He contributed to English political history the beginnings of extramural radicalism and the movement for parliamentary reform. When Burke's *Thoughts on the Causes of the Present Discontents* (1770) decried the court's influence over Parliament, it offered as remedy only the Rockingham party as "trustees" for the people. But the radicals, mostly middle class and strongly Protestant Dissenter in tone, preferred parliamentary reform. The Society for the Defence of the Bill of Rights, founded in 1769 to aid Wilkes, was the first in the long history of reform associations. The radicals disagreed on details; most of them connected property with political participation. In 1776 Maj. John Cartwright's pamphlet *Take Your Choice!* demanded universal manhood suffrage. James Burgh's *Political Disquisitions* (1774–75), advocating popular associations for reform, became a source book for radicals.

Agitation outside Parliament

The radicals, rather than the Rockingham Whigs, were the true friends of America in England. Between the Dissenters and the American Puritans was an especially close communion. Richard Price, a Dissenting clergyman, wrote a best selling pamphlet, *Observations on the Nature of Civil Liberty* (1776), linking freedom with autonomy. By that test America was not free. Neither the Rockingham Whigs nor the Chathamites could go so far. The Rockingham party, stuck with the Declaratory Act, hoped that men of goodwill might somehow adjust imperial differences. Burke made it seem that the tax on tea was the problem. Chatham denounced the right to tax but defended the imperial protectionist system. His ideas were out of date by the time the Americans declared their independence.

For the first six years the nation supported the war against America. After France entered the war in 1778 and Spain joined France in 1779, the war took on a new character. The opposition had to support it as a foreign war and could only criticize the government's conduct of it. When North fell in 1782, it was because England had lost the war, not because the country had gotten into it in the first place.

The East India Company

The British Empire in India was another of North's problems. The East India Company exercised sovereign powers in the country. Its financial crises inflamed bitter rivalries within the court of directors and invited parliamentry concern. Between 1770 and 1773 Parliament hardly mentioned American affairs, giving its attention to the Indian question. Two temporary acts passed in 1773. One granted a loan to the company, along with trade concessions that angered American merchants and led to the Boston Tea Party. The Regulating Act altered administrative arrangements in India. The statute's abiguities, as well as the personalities of the people who directed company affairs in India, produced contentions between the governor general, Warren Hastings, and members of the Bengal council, notably Sir Philip Francis.

By 1780 England's fortunes sank low. High taxes, a mounting debt, talk of financial mismanagement, and the dreary continuation of the war in America worried the country gentlemen whose support North needed. The parliamentary opposition and the radicals outside criticized bitterly. Ireland stirred as the "Volunteers," formed to defend the nation against invasion, changed into a political organization. Concessions to Roman Catholics and to Irish trade in 1778 encouraged demands for more, and in 1779 the government granted them. In April 1780 Henry Grattan in the Irish House of Commons demanded an independent legislature for Ireland. Men saw similarities between America and Ireland. In England the parliamentary reformers revived. In Yorkshire in December 1779, an Anglican clergyman, Christopher Wyvill, led a meeting to endorse a mild parliamentary reform and the idea of corresponding societies to agitate for it nationwide. Edmund Burke announced his plan to reform the king's household and the executive establishment to reduce expenditures and the political influence

of the crown. Burke's bill was defeated in March 1780, but on April 6 the House of Commons demanded reduction of the influence of the crown. In the metropolis the Westminster Committee asked for radical parliamentary reform. The Society for Constitutional Information began its effort to educate England to the need for reform to recover "lost rights." In the late spring of 1780, the anti-Catholic feeling mounted. The Protestant Association under Lord George Gordon protested to Parliament against concessions to Catholics. The demonstrations degenerated into mobs, and, during the first two weeks of June, men feared for the very existence of London. Before troops restored order, much property was destroyed.

The Gordon riots

The Gordon riots temporarily discredited extramural associations. Lord North therefore asked for an election. Without much altering the political status quo, it gave North's government a new lease on life.

The country remained troubled. Late in 1781 came news of Cornwallis' surrender at Yorktown. Independent members began to desert North. On March 15, 1782, his majority fell to nine votes, and a few days later he resigned. The angry King accused North of deserting him; in fact, an angry Parliament had overturned a ministry enjoying the King's confidence. Parliament forced upon the King a new ministry under Rockingham and a reform program he did not want. Rockingham held over only one man from North's Cabinet. George III salvaged something by using Shelburne, secretary of state for home and colonial affairs, as royal confidant. Few politicans trusted Shelburne, but Rockingham had to tolerate him because he led the Chathamites who had opposed North. Parliament passed Rockingham's reform program. Burke's economical reform marked an important stage in transferring control of the executive and all but the most intimate parts of the household to parliamentary supervision. Other reform measures disfranchised revenue officers, excluded holders of government contracts from Parliament, and changed the paymaster's office from a private sinecure to a public trust. The grant of legislative independence to Ireland did not terminate England's political control of the Irish administration or oligarchical management of the Irish Parliament.

The Fox–North coalition. Peace negotiations in Paris split the government. Shelburne hoped to hold America within the empire under a revised commercial system. Rockingham's death on July 1 gave George III an opening. Burke and Fox were alone in wanting to fight him for control of appointments to the new ministry. Rather than serve under Shelburne, the King's choice, some Rockingham ministers resigned. The possibility of a drastic change of the constitution disappeared. Shelburne, with his chancellor of the exchequer, the young William Pitt, extended the administrative reforms begun by Rockingham. Shelburne also reached peace terms with France and America, which Parliament rejected as overgenerous in February 1783. The Rockingham Whigs (now headed by William Bentinck, 3rd duke of Portland, and led in the House of Commons by Fox) and Lord North's party, after defeating the treaty, went on to form a government. Again the King had to surrender. The Old Whigs dominated the government headed by Portland, with Fox and North as secretaries of state. Contemporaries established a caricature of an unholy, unnatural coalition, which historians accepted. The coalition had substance. The American Revolution was now history; Fox and North agreed to act independently on parliamentary reform; they agreed on most other current issues; they were personal friends and both hated Shelburne. Among possible combinations, the Fox–North coalition was the most likely.

Reform movement

The coalition survived the embarrassment of passing a peace treaty like the one they had defeated to force Shelburne's resignation. But there was a difference. Shelburne hoped to supplement the treaty with generous trading concessions to the United States. The coalition, like England, revered the protectionist system.

Apart from American affairs, England was looking to the East, where the problem of India was paramount. It had been under study since the acts of 1773. The reports of Burke's Select Committee and the secret committee of Henry Dundas, 1st Viscount Melville, appeared in 1782–83 as mines of information and indictments of company administration. The coalition brought in two bills. The opposition saw the provisions for a board of commissioners, named in the bill and after four years to be appointed by the King, as a coalition effort to monopolize Indian patronage. The bill to tighten English supervision over the administration in India was called unworkable. Fought by the East India interest and the younger Pitt's followers, the bills passed the House of Commons only to meet defeat in the House of Lords on December 17, 1783. Ignoring the coalition's victory in the House of Commons, the King dismissed it and called upon Pitt.

Pitt's ministry. The King's action was irregular and dangerous, but events vindicated him. Pitt hung on throughout the winter as a minority minister, but the minority grew. On March 25, 1784, the King dissolved Parliament in disregard of the septennial convention. Pitt's victory was not that of a homogeneous party but of varied groups and hatred of the coalition. Pitt was not a party leader until 1789, though the Portland Whigs acted steadily in opposition along with a dwindling number of North's men.

Pitt dealt masterfully with accumulated business, aided by able men who had their first chance to lead. Pitt's India Act of 1784 created a Board of Control nominated by the King from among privy councillors. The extent of the board's domination over the company could not be specified, but under Dundas' presidency the board was vigorous. Burke and his opposition friends led the prosecution of Warren Hastings for alleged high crimes and misdemeanours in India. Pitt voted for one crucial charge as a matter for impeachment. Burke won his greatest parliamentary victory when the House of Commons voted for impeachment. In 1788 the trial opened before the House of Lords in Westminster Hall. It went on intermittently until 1795, when the House of Lords acquitted Hastings. If the evidence did not support a conviction, it supported the need for some kind of proceedings to settle doubts.

Pitt's India Act

Pitt pursued administrative and fiscal reform more vigorously than parliamentary reform. He owed an election debt to the parliamentary reformers and brought in a bill in 1785. Not a test of loyalty to him, the bill lost, 248 votes to 174; thereafter Pitt was done with the subject. His commercial reforms went as far as contemporary protectionist sentiment permitted. He carried a commercial treaty with France but failed to win lower duties on American and Irish trade. His customs reforms improved revenue collections and simplified customs administration. Advised by Richard Price, he altered methods of managing the national debt with a new sinking fund. The substantial increase of trade increased the annual revenue by one-half during Pitt's peacetime ministry. Had not war intervened in 1793, his sinking fund could have fulfilled its purpose of orderly debt retirement.

In foreign affairs Pitt raised England from the depths of the early 1780s. In 1788 he engineered a triple alliance with Holland and Prussia against France. Pitt took a strong line in two diplomatic crises. Under threat of war, Spain conceded British fishing and settlement rights on Vancouver Island and thus opened England's future interests in that region. Pitt could not force Russia in 1791 to give up Oczakov on the Black Sea. But this was so far removed that only Turkey was disturbed; in western Europe England's prestige was high. Just before the war of the French Revolution began, Pitt said England was secure and the future looked stable.

By 1789 the political future also appeared secure. The King's illness and mental derangement in the winter of 1788 (according to the latest studies, as the result of porphyria, a hereditary blood disorder) caused a crisis. As regent, the Prince of Wales might use the prerogative powers to replace Pitt with Fox. Pitt hoped by statute to restrict the regent's (not the royal) powers, but the King's recovery halted proceedings on the bill. The bitter partisanship of the debates thoroughly discredited the parlia-

mentary opposition. Pitt emerged a Galahad with a larger and more closely knit majority. The election of 1790 renewed his political strength.

England, celebrating the King's recovery, reacted initially with mixed feelings toward the French Revolution. Enthusiasts, including survivors of the earlier reform movement, welcomed the fall of the Bastille as heralding an era of freedom and brotherhood among men. Speaking to the Revolution Society commemorating the Revolution of 1688, Dr. Price called the French Revolution an example to England and a warning to fulfill the promise of 1688 by reforming Parliament. Few people openly opposed the Revolution. The government, officially neutral, thought France too beset with internal troubles to disturb the peace of Europe. Two months after Pitt recommended a reduction in army appropriations because the future promised peace, France, in April 1792, declared war on Austria, plunging Europe into war.

THE ERA OF THE FRENCH REVOLUTION (1789–1815)

The end of reform. By this time English opinion had become divided. Burke's *Reflections on the Revolution in France* (November 1790) condemned the English reformers and warned of the Revolution's threat to the Christian social order of Europe. Thomas Paine, whose *Rights of Man* (1791) was written in reply to Burke, represented to upholders of the established order the dangers from revived English radicalism and French Jacobinism. Burke and Paine were the extremists in the controversy over the related questions of reform, the Revolution, and war. Pitt and his foreign secretary, William Wyndham Grenville, Baron Grenville, found no English vital interest at stake in the continental war until the winter of 1792–93, when France executed its king, and its Revolutionary armies threatened the independence of the Low Countries and the European balance of power. France spared Pitt a decision by declaring war on England, February 1, 1793.

Fear of Jacobinism

The Revolution and the war strongly affected politics and the movement for parliamentary reform. The old reform societies were middle class and property conscious. The London Corresponding Society, however, founded in 1792 with the shoemaker Thomas Hardy its secretary, brought the lower middle class and the working class into politics. This society, with its affiliates throughout England and Scotland, had organization and a sense of public purpose to distinguish it from mobs of 18th-century England. The Corresponding Societies, unlike the Society for Constitutional Information, asked for universal manhood suffrage. The number of active reformers never numbered more than a few thousand; the established order retained its credit with the nation; it is doubtful that England was on the verge of revolution. But panic spread among some of the governing class and the propertied, encouraged by reformers' indiscretions and excesses of zeal. The Association for the Preservation of Liberty and Property, founded in the winter of 1792–93 in London, had affiliates throughout the country. Authorities broke up reform conventions in Scotland in 1792–93, and the courts sentenced a few of the leaders harshly. English radicals' talk of a convention, for purposes never made quite clear, stimulated the government to act. In May 1794 it seized 12 reform leaders. After the jury acquitted the first three to be tried for high treason, the remaining cases were dropped. Some prosecutions succeeded, but the number before magistrates has never been determined. Parliament enacted some repressive statutes. By 1795 the reform agitation virtually ended, to be revived toward the end of the Napoleonic Wars.

Wartime politics. Like England, the parliamentary opposition divided over reform and war. Fox led the liberal minority—the New Whigs—whom Burke accused of deserting the principles of 1688. The Old Whigs, fearful of splitting the Portland party, only slowly came to accept Burke's views. In 1794 they crossed over. Portland, William Wentworth, 2nd Earl Fitzwilliam, and Burke's disciple William Windham took Cabinet offices. The coalition of 1794 did not essentially change Pitt's policy. Relying on alliances and subsidies, he aimed to preserve the balance of power and England's vital interests rather than overthrow the Revolutionary government. Burke desired a Bourbon restoration in France. The abortive peace negotiations of 1796–97 showed Pitt's willingness to treat with the Revolutionary regime.

The Irish problem flared up in the 1790s. Legislative independence was a mockery when the Lord Lieutenant of Ireland and Pitt's Cabinet leagued with the Irish junto to block reforms, control patronage, and preserve the Protestant ascendancy. Although another extension of civil rights was granted to the Irish in 1793, Catholics were still forbidden to sit in Parliament. Catholic hopes rose late in 1794, when Earl Fitzwilliam became lord lieutenant. His hasty dismissal of junto politicians and his advocacy of Catholic emancipation so alarmed the government that Portland, his superior, recalled him. Ireland drifted toward civil war, as the recently formed Society of United Irishmen took a militant lead. The Rebellion of 1798 was not as dangerous as it was dramatic. French aid supported only a small effort in the northwest of Ireland, while elsewhere English forces quickly suppressed risings. Pitt saw the solution to the Irish problem in a legislative union combined with Catholic emancipation. Cornwallis, the lord lieutenant, agreed. Both parliaments enacted legislative union in 1801, adding 100 Irish seats to the House of Commons and 28 Irish peers and four bishops to the House of Lords at Westminster. The King broadcast his opposition to Catholic emancipation, and Pitt's Cabinet rejected it. For a month in February–March 1801, the King was again deranged. Pitt could not accept responsibility for both the government of the empire and the King's health. He resigned, promising never again to bring up emancipation.

The Irish Rebellion

Besides the Irish business, Pitt resigned because he was weary after 17 strenuous years in office. The contrast between his successes before the war and failures afterward encouraged the judgment that he was only a great peacetime minister. Yet he laid down the lines of war policy that England followed to the end.

Henry Addington (later 1st Viscount Sidmouth) formed a government in March 1801. Country gentlemen in Parliament and a nation anxious for peace supported him. Englishmen persuaded themselves that peace with Napoleon, who had recently come to power, was peace with a stable France. By the Treaty of Amiens (1802), England recognized the republican regime in France and restored all conquests except Trinidad and Ceylon. The election of 1802 registered satisfaction with both the Irish Union and the peace. But relations with France quickly deteriorated. When England declared war in May 1803, men looked to Pitt for leadership. Pitt recommended a nonpartisan ministry. George III detested Fox, but he could accept Grenville, who had deserted Pitt over Catholic emancipation. Pitt reconsidered, dropped Grenville, and formed a conservative government including only ministers personally desirable to the King. The second Pitt ministry, in May 1804, came largely from its immediate predecessor, excluding Addington. The parliamentary opposition was uncomfortably strong just when French invasion threatened and the Third Coalition was forming against Napoleon. When, in August 1805, Austria allied with England and Russia, the danger of invasion had passed, for Admiral Nelson had frustrated Napoleon's plans for controlling the Channel. Nelson's victory at Trafalgar in October 1805 gave England mastery of the seas. Napoleon, however, smashed the Third Coalition after invading Austria.

Battle of Trafalgar

Pitt's death on January 23, 1806, confused English politics. The Cabinet refusing to go on, George III was forced to accept the Fox–Grenville "Ministry of All the Talents," less comprehensive than the name suggests. It was mainly Foxite, if returned Whigs like Fitzwilliam and Windham are so considered, but hardly homogeneous with its inclusion of Addington (Lord Sidmouth) and Thomas Lord Erskine, counsel for the defendants in the treason trials of 1794. Before his death in September 1806, Fox failed to achieve the peace with France that he had always thought men of goodwill could make. Grenville carried on, strengthened by the election of October

1806. With strong radical support, the government abolished the slave trade in March 1807, ending a 20-year campaign that had worn down the opposition. The King, encouraged by Sidmouth, frustrated Grenville's desire to open army careers to Catholics by dismissing the government before Parliament seriously took up the bill. The Duke of Portland was called upon to form a ministry. There was no place in Portland's government for Sidmouth because George Canning would not serve with him. Portland's strong Cabinet included Canning, Spencer Perceval, Lord Hawkesbury (Robert Banks Jenkinson), and Viscount Castlereagh. But personal dislikes and disagreements over the conduct of the war betrayed the ideological harmony. After Canning and Castlereagh resigned, Portland yielded to Perceval in October 1809; the Whigs could only observe. Perceval carried on until an assassin's bullet killed him in May 1812.

Liverpool's ministry

Yet through this period cabinets were remarkably stable. Like Perceval, Lord Liverpool (Hawkesbury) as prime minister continued his predecessor's Cabinet. Canning and Castlereagh were the main problems. With Canning choosing to remain out of office, Castlereagh returned as foreign secretary before Perceval died and continued under Liverpool. Two other men contributed to the stability. The Prince of Wales, regent because of his father's incapacity, wisely gave his confidence to Liverpool. After his powers as regent were made permanent, he broke with his former Whig friends. The choice of Liverpool was a happy one. Considered a man of second-rate abilities in his own time and nearly ever since, Liverpool has recently been recognized for one great talent. He held his government together as a conciliator rather than as a powerful personality. Prime minister until 1827, he molded a party out of the elements that Pitt, Portland, and Perceval had gathered. More than Pitt, Liverpool left a party behind him, having identified with conservatism the Tory party he inherited.

The conduct of the war. The steady war effort also reveals the continuity of the period of 1807–15. The standoff between French land power and British sea power persuaded Napolean to try economic warfare against England. By his Continental System he aimed to exclude English goods from European markets. England, in turn, blockaded ports its ships could not enter. This warfare hurt England; the trade statistics show that in 1811 England exported to northern European ports goods of only one-sixth the value of exports in 1805. Unemployment grew. The increase in England's Latin American trade only partially made up for the decline in trade with Europe and the United States. The Americans boycotted British goods in retaliation against England's interference with their shipping and neutral rights. The War of 1812 with the United States followed; a central event in American history, the war is only peripherally treated in British history.

The Continental System

Europe also suffered from Napoleon's economic war, and in 1810 he replaced exclusion with high tariffs. His economic policy needed political–military support; Napoleon invaded Russia and the Iberian Peninsula in part to complete his economic system. But England found entry to the Continent in Portugal, where its forces landed in 1808 (see FRENCH REVOLUTIONARY AND NAPOLEONIC WARS). The Peninsular War culminated in Wellington's invasion of France over the Pyrenees in 1813–14. This occurred as the allies penetrated from the east. Never before had Napoleon faced such universal and united opposition. Stressing the need for unity to win victory and a peace settlement imposed by the great powers, Castlereagh avoided piecemeal treaties lacking the force of general agreement. The government and Parliament supported generously the subsidy policy undergirding Castlereagh's diplomacy. The Treaty of Chaumont (March 9, 1814), his great edifice, clarified allied war aims (including the expulsion of Napoleon), tightened allied unity, and promised a general European settlement under supervision of the great powers for 20 years. Napoleon's return from Elba, the Hundred Days ending at Waterloo, and his exile to St. Helena did not interrupt the peacemakers at Vienna or change England's policy.

The end of the wars

The Vienna Congress settlement of 1815 was the concrete manifestation of Castlereagh's definition of British policy: to assure the peaceful conduct of France by not mistreating her, while providing security against her for the Netherlands and northern Italy; to stabilize Germany by strengthening Prussian and Austrian influence in central Europe and the Rhineland; to check the extension of Russian influence westward; and to safeguard England's commercial and colonial interests.

The end of a long generation of war found in office a Tory government proud of England's contribution to war and the peace, secure in its parliamentary strength, but uncertain of its domestic course. A vastly different England than had entered the war in 1793 faced problems only partly to be understood as marking the transition from war to peace. They were also those of the first modern nation to experience the change from rural and agrarian to industrial and urban nationhood.

ECONOMIC, SOCIAL, AND CULTURAL HISTORY (1714–1815)
