Population. The dearth of reliable demographic and economic statistics for 18th-century England contrasts with the abundance of contemporary writings on "political arithmetic." A lexicographer in 1710 described its content as the extent and value of land, population, public revenues, commerce, and manufactures, or whatever related to the strength and riches of a nation. Concern with the well-being of the state thus showed a mercantilist bias. The earliest official national census (1801) produced the first dependable population statistics for England, Wales, and Scotland. For the first two the population was 8,893,000 and for Scotland 1,608,000. In 1811 the numbers were 10,164,000 and 1,806,000—a remarkable growth. Just over a century earlier, the statistician Gregory King estimated the population of England and Wales as 5,500,000. Attempts to explain the near doubling of the population during the century produced disputes about numbers and statistical methodology. The population grew slowly, if at all, until the 1740s, rapidly after 1780.

Demographers and economic historians disagree on the reasons for population growth and its effect upon economic growth. The declining death rate, increasing birthrate, improved medical science, and a rise in the standard of living, all offered as explanation, have been challenged. None by itself explains the growth but taken together they mean multiple causation for a complex phenomenon. Statistical evidence is impeachable, contemporary opinions were impressionistic, yet together they suggest a rise in general well-being, whatever the hardships of life.

Equally complex is the relationship between economic and population growth. To say that the latter caused the other oversimplifies and hardly explains increased output per person. Population growth helps account for increased labour supply and consumer demand. Expansion of overseas trade stimulated demand and production. The overall impression is of a growing population and expanding economy buoyed by a confident spirit.

The Industrial Revolution. The word revolution is used to describe economic changes of the past two centuries. Though a few historians place the beginnings in the mid-16th century, most hold that the "takeoff," or the dramatic upturn, of industrial growth began about 1780, with the social impact coming later.

During the 18th century, English society was preindustrial, an agricultural and commercial rural society with one metropolis, London. After 1780 migration to cities increased as manufacturing acquired a factory, power-driven character, especially in the cotton-textile industry. This industry was the bellwether of the Industrial Revolution; by 1815 exports of cotton cloth exceeded woollen by three times. Yet the population, 85 percent in the country or in communities under 5,000 persons during the century, remained officially rural until the census of 1851. In the 18th century the structure of society and distribution of population among classes remained preindustrial. Contrary to older views, the enclosure of common lands to increase efficiency did not depopulate

Urbanization

the countryside. Population growth supplied the surplus from rural areas for the factory system. Migration was toward the towns and industry; in the midlands and north of England, new industry attracted people to once thinly populated areas. Not until the 19th century did the industrial–urban complex exist, emphasizing textiles, iron, and coal. Besides London, the population of which nearly doubled from 1700 to 1801 to a total of 1,000,000 persons, the considerable towns (though none exceeded 80,000) were Liverpool, Birmingham, Sheffield, Norwich, Bristol, and Glasgow. Birmingham doubled between 1770 and 1801.

Much of the rural population engaged in domestic manufactures of textiles or in supplying agricultural, mining, or building needs. Occupational classification was therefore difficult; the census of 1841 was the first to attempt it. Gregory King's groupings were socio-occupational. He thought 70 percent of the population was primarily agricultural, with the family the unit of production. King distinguished between families (511,586) who "increas[ed] to the Wealth of the Kingdom" and the majority (849,000) who decreas[ed] the Wealth of the Kingdom because the cost of living exceeded their incomes. Supplements deriving ultimately from the productive minority made up the difference, for England had an annual economic surplus and more than fed itself.

In King's groupings, the margins of the upper and middle classes and of the lower middle class and the lower class overlapped. Some great traders were wealthier than some peers and most gentlemen. Rich merchants often owned land and almost always aspired to it because land conferred status. Ownership of land was an eligibility requirement for the House of Commons. Below the nobility and gentry, King listed officeholders, merchants, clergy, professional men, freeholders, and farmers. Shopkeepers and artisans occupied the borderland above the lower class. The lower orders—common soldiers and sailors, labourers and servants, cottagers, paupers, and vagrants—constituted the majority who "diminished the wealth of the kingdom." Contemporaries nevertheless considered England a rich nation whose people were better off than any Europeans except the Dutch. Estimates of per capita income—£9 at the beginning of the century, £13 at midcentury, and £22 at the end—suggest a level comparable to that in the wealthier underdeveloped countries in mid-20th century.

Agricultural revolution

By 1815 English agriculture had changed in important ways within a nation becoming an urban and industrial community. Increasing consumer demand stimulated the agricultural revolution and an increasing supply of capital assisted improvement. New techniques of cultivation and of land usage and management as well as new crops not only made land more productive but brought new land into tillage. Between 1700 and 1760, some 300,000 acres were enclosed, and ten times that amount between 1760 and 1800. Under the General Act of 1801, which eliminated the need for private enclosure acts, the transformation to closed fields was nearly complete by 1820. Enclosure facilitated more effective use of arable land and encouraged improvement of breeding by the segregation of livestock. The social effects of enclosure have been debated vigorously and emotionally. Recent studies show that enclosure did not depopulate rural districts. The need for agricultural labour did not decline. The citywide migration was that of the rural surplus. Nor did enclosure eliminate the smallholders. If enclosure costs forced out some, compensation for surrender of ancient common rights often enabled cottagers to acquire small holdings. The post-1815 agricultural depression hurt the smallholders severely. The agricultural revolution, important in itself, sustained and encouraged the Industrial Revolution, providing food for the growing nonagricultural population and supplying some of the capital for industrial expansion.

Commercial revolution

The term commercial revolution usually refers to the two preceding centuries, but important changes occurred in the 18th century. Commerce became securely interlocked with agricultural and industrial expansion. The volume of trade, which increased sevenfold during the century and doubled between 1750 and 1800, also shifted regionally. Domestic exports to Europe declined from 85 to 30 percent of Britain's total, while those to North America increased from 6 to 30 percent and to the West Indies from 5 to 25 percent, all between the opening and the end of the century. Meanwhile imports from Europe declined from 66 to 43 percent of a total of which the West Indies and the East Indies each sent 25 percent. Europe took 85 percent of England's re-exports both at the beginning and the end of the century, but the total was much larger at the end. England was the primary supplier of colonial products to Europe. The monetary gains of the re-export trade were great because British merchants made a profit on the average of about 15 percent on the value of the goods traded. Commerce aided English manufacturing by stimulating domestic and foreign demand, assisting other countries to buy English goods, bringing raw materials to British industry, and contributing to the stock of investment capital.

The Industrial Revolution of the 18th and early 19th centuries was a British phenomenon. Manufacturing increased in Europe but the use of power-driven machinery concentrated in factories was strikingly particular to Britain and especially to the cotton and iron industries. If the history of the cotton industry is not quite the history of the Industrial Revolution from about 1780 to 1840, it is illustrative. The traditional textile industry was woollen; cotton manufacturing became important in the last third of the 18th century. In 1815 England exported £22,000,000 worth of cotton cloth, three times as much as woollen cloth, and over 100 times the value of cotton cloth exports in the early 1760s. This was the result of a sequence of technological innovations in spinning and weaving, beginning in the 1730s. The most sophisticated machine, Edmund Cartwright's power loom (1787), did not come into general use until after 1815. The cotton industry, new and unrestrained by tradition, became the example par excellence of machine work in the factory.

The iron industry was also amenable to technological change. Use of coke for smelting, shown to be practicable by Abraham Darby in 1709, was widespread by midcentury. Henry Cort's puddling process for making bar iron, patented in 1783, increased the supply of wrought iron. James Watt's improvement of the steam engine in 1775 marked the beginning of the machine age. The iron industry was as productive in the reign of Charles I as in 1760. Then came Watt and Cort and the "takeoff." In 1800 England produced 1,000,000 tons of pig iron, of which 60,000 were exported. The export figure alone was twice the total production of 1760. The statistics of coal production, so closely related, are 6,000,000 tons in 1770 and 15,000,000 in 1815.

Growth of transport

Inland transport responded to economic necessity and stimulated industrial growth. The canal age began in 1759, when Francis Egerton, 3rd duke of Bridgwater, linked his Worsley coal mines by canal with Manchester. By the 1820s local capital organized corporately, and ingenious engineers, such as the canal builder James Brindley and the highway builders Thomas Telford and John MacAdam, laced England with canals and improved roads. The history of the Wedgwood potteries, a striking story of entrepreneurial genius, reveals the dependence of manufacturing growth upon safer, cheaper, and faster transportation. New manufacturing techniques increased production, salesmanship and promotion spread the demand for Wedgwood ware, and improved transport brought raw materials to the potteries and carried the ware to consumers. When the age of canal building ended, England had invested £20,000,000 in a system of navigation vital especially to heavy industries but inadequate for the future needs of industry. The railways were to meet the need in the next age.

Effects of industrialization. To the usual list of physical, social, and political causes of the economic revolution should be added a psychological one. England in the 18th and early 19th centuries was as buoyant and confident as Holland in the 17th century or the United

States after the American Civil War. Englishmen responded to challenges, risking loss of capital should an invention prove impracticable, an enterprise be mismanaged, or any number of unforeseen calamities occur. This happened despite the fact that the principle of unlimited liability prevailed, whereby all shareholders were held responsible for any debts incurred by the company. Often the people who suffered worst when a joint-stock enterprise collapsed were small investors, and many were the unhappy partners in failing enterprises. The first 75 years of the Industrial Revolution were years when the spirit of adventure was keen.

The standard of living

The growth of wealth suggests the potential for amelioration of life in this period. Judgments have been influenced by emotional involvement and political opinions. No one denies the existence of poverty and hardship, but some historians stress improvement throughout the period. Economic growth helped the worker directly and made possible greater indirect aid from private and group philanthropy. Parish officials and the magistrates were responsible for enforcement of the Poor Laws, which was spotty in the absence of central supervision; a zealous local official, however, might send the poor to the workhouse, where paupers, sick or well, young or old, were thrown together indiscriminately. The Poor Laws also forbade the destitute to settle outside their own parishes, but these laws were not rigorously enforced, permitting mobility of labour. Economic growth and increased concern for the poor existed together; whether there was merely heightened awareness or an actual increase of poverty, the statistics show a sixfold growth in the amount of poor-rate collections between 1775 and 1825. Part of the increased expenditures went for wage supplements to bring incomes among the poor up to a minimum cost of living. The practice, called the Speenhamland system, spread widely after 1795, when a group of Berkshire magistrates adopted it. To attribute the apparently growing magnitude of the problem of the poor to industrialization and urbanization is to oversimplify the problem and to slight the problem of the poor in preindustrial England. The population trebled between 1700 and 1821, and the urban poor made the problem more visible.

The growth of industry and towns created a serious psychological problem. The pattern of life governed by the seasons, the sun and moon, and the weather gave way to the discipline of the clock and the rhythms of the machines. Neither the laws of nature nor of Parliament, but the laws of the marketplace, determined the times for operating machines. Workers had no preparation for the new industrial discipline. In addition to physical adjustment, they had to make within two generations a radical mental and moral adjustment to a new way of life.

Religion. Religion probably offered less consolation to the labouring poor and the paupers than some might like to think. The churches and organized religion did not deal adequately with problems arising from new urban and industrializing trends. But the churches were not meeting social problems in preindustrial England, and the poor often shirked churchgoing. Statistics are lacking except in scattered localities. Contemporary literature shows the churches as the preserves of the upper and middle classes. Among Protestant Dissenters, the Baptists were thought of as the poorer sort. Quakers, not strictly Dissenters, were in the middle ranks of society, along with Presbyterians, Independents, and Unitarians. The Roman Catholics, a small minority, cut across all ranks of the social structure, as did the Established Church of England.

Methodism

One of the traditional explanations for the rise of Methodism is that it filled a gap in religious life. This was particularly true in Wales, despite the prominence there of Protestant Dissent. Neither Dissent nor the Church of England reached certain areas and groups in England and Wales. Dissent was notoriously intellectual and held "enthusiasm" (which in the 18th century connoted fanaticism) in disfavour as much as did the Established Church. Launched by the brothers Charles and John Wesley and by George Whitefield in 1739, Methodism sought out the neglected and underprivileged. Emotionally and enthusiastically, itinerant preachers offered "the glad tidings of salvation," as John Wesley put it, often in the open air. Edmund Gibson, bishop of London, called Methodists "Rabble." Methodism was not a socially revolutionary force, except by the implication of equality in its teachings about salvation, but it felt the disapproval of the religious establishment. Separation from the Church of England did not come until just after John Wesley's death in 1791, and then on technical grounds. But in spirit and form Methodism was nonconformist long before the separation.

Methodism influenced some earnest Anglicans, the Evangelicals, who deplored the decline of manners in society and the religious lethargy in the Church of England. The Evangelicals promoted social but not political reforms; they worked for the abolition of the slave trade and of slavery; and as social superiors they desired the amelioration of the hard lot of the poor and the oppressed. But Evangelicalism did not try to abolish deference among the lower orders. Sunday schools would teach people to read the Bible and Hannah More's popular tracts that offered patience in this world and the expectation of rewards in Heaven. Literacy was not for absorbing the doctrines of Thomas Paine's *Rights of Man* or his *Age of Reason*.

Dissenters were prominent out of proportion to their numbers in the political-reform movements. The Test and Corporation acts (1673 and 1661) limited the civil rights of non-Anglicans, and Dissenters, often well-educated and prosperous, resented the discrimination. They disliked the preference for land in determining political qualifications, and they abhorred restrictions imposed upon them merely because they were Dissenters. They desired to open careers to men of talent, but they thought especially of opportunities for the middle class. Their campaign for repeal of the Test and Corporation acts lasted a century before it succeeded in the 1820s. It joined that for parliamentary reform to form an important chapter in the history of political and constitutional change in modern England.

The Church of England remained secure in its position of establishment, less torpid than tradition has it, but less vital intellectually than in the 17th century. Its legal position guaranteed involvement of the clergy in politics, if nothing more than in patronage. Deism did not become a strong influence in England, in part because, in its benevolently placid faith in reason, it was not far removed from the Latitudinarianism so prominent in the church.

The Enlightenment. Faith in the power of human reason has been emphasized into a cliché suggesting a monolithic character for 18th-century thought. Recent writings on the Enlightenment qualify this exaggeration. René Descartes, Sir Isaac Newton, and John Locke bequeathed a conception of man's capacity to discover the laws governing the universe and similarly his capacity to understand and apply the laws governing the social order. England enjoyed a reputation, spread by Voltaire and Montesquieu, for having devised a political order that was the envy of Europeans. Englishmen were proud that their "happy constitution" combined freedom with good order, protected property, and responded to the country's needs. It was a unique political system; the great powers of Europe knew only monarchical absolutism even in the later period of Enlightened Despotism.

The Philosophes desired freedom above all, for it was fundamental to human improvement or any concept of perfectibility. They did not seek a particular organization for society, nor were they uniformly optimistic about the powers of human reason to create a perfect social order. English writers, already enjoying freedom, had less at stake than continental Philosophes. England's two most important contributors to the Enlightenment were George Berkeley and the Scot David Hume, whose writings, by demonstrating the limitation of human reason, ironically did much to undermine the Rationalism upon which the Enlightenment was built. There were other

anti-Rationalist elements in 18th-century England. The novels of Samuel Richardson contributed to a "cult of sensibility." Edmund Burke wrote on the sublime in an anti-Rationalist approach to aesthetics and art and directly attacked Rationalism in other writings. Burke's emphasis upon history and experience in the development of society, law, and government placed him among the precursors of Romanticism. Jeremy Bentham denied the existence of natural law so prominent in Enlightenment thought and replaced it with utility (the principle of the greatest good for the greatest number) as the guiding principle of the legislator. Thus England contributed to the Enlightenment and exemplified the freedom it desired but at the same time prepared the way for Romanticism and Utilitarianism.

SCOTLAND AND WALES: 1714–1815

The union of England and Scotland in 1707 came exactly a century after Parliament rebuffed James I (James VI) on the issue. The ease with which Scotland accommodated itself to the union contrasts with the difficulties of achieving it. The Jacobite troubles and pro-Stuart feelings lost political force by midcentury. Political realism and economic opportunity attracted Scottish interests to England and the empire. Some facts about Glasgow concentrate the story. A town of 12,000 at the time of union, Glasgow was a commercial centre and becoming an industrial city by 1800, when it reached a population of 70,000 (as large as Liverpool's). Glasgow took eager advantage of opportunities in the imperial commercial system. Old dislikes between Scots and Englishmen lingered, but political and economic self-interest kept them properly subordinated.

History and the Act of Union operated to mesh the political systems in form and function. The Scottish electoral structure resembled England's and also lent itself to management. The office of secretary of state for Scotland was so unnecessary that it was vacant between 1746 and 1885. The best known managers, the 2nd and 3rd dukes of Argyll during the reigns of the first two Georges and Henry Dundas during the first administration of Pitt the Younger, dispensed patronage, influenced elections, and controlled the Scottish votes in Parliament. Normally, the Scottish contingent supported the government.

Areas unaffected by the Act of Union

The union did not dissolve particularities in three important areas—the law, the church, and education. The Scottish legal system was based on Roman law. In substance and form it provided justice admirably under such men as Duncan Forbes of Culloden, lord president of the Court of Session (1737–47). The Presbyterian Church remained the established church, with an influence upon Scottish life much greater than that of the church in England. Though nominally democratic by virtue of the electoral process that brought laymen to its governing bodies, the kirk was authoritarian in its supervision of the morals and the education of the community. About midcentury intolerance lessened, and the outlook of the clergy broadened, but this was a relative matter, subject to important local exceptions when parish clergymen had large moral influence. Yet this could work another way. The revival of patronage in appointment of ministers after 1712—so that some 90 percent of the benefices were filled by appointment by the crown, the nobility, and the gentry—strengthened the influence of patrons' views, generally more enlightened and tolerant than parishioners'. Because, however, congregations retained a formal right to reject nominees, tensions and disputes arose. The secessions of 1740 over personal and doctrinal matters produced four new Presbyterian churches.

The 18th century was a great age in Scottish educational and intellectual history. The church took seriously the duty to provide elementary education, after acquiring it in the time of John Knox. A beneficial result of the Forty-five Rebellion was that the Highlands were opened to the spread of educational facilities, by the church, by supplemental efforts of the Society for Promoting Christian Knowledge, and by some governmental assistance with money from forfeited estates. The English language became the language of instruction in the schools. The Scottish universities won admiring recognition in England, in the colonies, and in Europe. A flourishing intellectual, scientific, and literary life existed in the universities and in Edinburgh. At no time in its history have the names of Scotland's scholars and writers been so prominent in such proportionately large numbers as in the last half of the 18th century and the early 19th century. To name Adam Smith, David Hume, William Robertson, Lord Kames, Francis Hutcheson, and Thomas Reid is to suggest the quality of intellectual leaders of Scotland's golden age. The founding of *The Edinburgh Review* in 1802 by a new generation promised that the intellectual light would continue to glow as the new century opened.

The economic growth of Scotland is directly attributable to the union. Article VI of the Act of Union opened the imperial commercial system to Scots. The progress of Scottish agriculture was less spectacular than the expansion of trade. The most important agricultural development was the growth of livestock and dairy interests, and the benefits came in the next century. Union immediately opened commercial opportunities. The story is properly the history of the merchant class and of energetic individuals. If Glasgow virtually stole the tobacco trade from Bristol and Liverpool, it was the "tobacco lords" who did it. Union offered encouragements for the traditional industries—fishing, linen, and woollens. Later, cotton manufacturing in Scotland shared in the expansion of that new industry in the United Kingdom. An important consequence of the union, and then of the Forty-five Rebellion, was the participation of Scots with great effect in the military–imperial life of the British people. As soldiers, explorers, settlers, and administrators, Scots went with and ahead of the Union Jack. The history of the British Empire after the mid-18th century owes more to Scots than their relative numbers would suggest.

The work of a ruler part Welshman, Henry VIII, accounts for some differences between the histories of Wales and Scotland in the 18th century. Because Henry VIII completed the extension of the English system of law and local government to Wales and enlarged its representation in the House of Commons, there was no later problem of absorbing alien institutions into the English system as in 1707 with Scotland. Wales was a part of the English system when the Reformation occurred, and the religious history of Wales moved along with that of England. Welsh political history in the 18th century was either a part of national history or, as in the English counties, local history. Wales felt the same influences as England in that period, most notably in religion and in economic life. Nonconformity of the Dissenting and then the Methodist variety played a more important part in the intellectual and social life of Wales than of England. In the 19th century it was a strong political influence upon the Liberal and later the Labour parties. Along with England, Wales participated in the agricultural and industrial revolutions. The Welsh terrain and mineral endowments made the raising of livestock, the woollen industries, and later the production of coal and iron of first importance. The history of Wales in the 18th century can be written in the histories of religion and of the economic revolution more meaningfully than as an attempt at separate national political history, so long as proper attention is given to local differences. (C.B.Co.)

XIII. Great Britain: 1815–1914

BRITAIN AFTER THE WARS

The end of the long wars against Napoleon did not usher in a period of peace and contentment. Although both agricultural and industrial production had greatly, if unevenly, increased during the wars, the total national debt had nearly quadrupled since 1793. Of the total annual public revenue after 1815, more than half had to be employed to pay interest on this debt. The abolition of Pitt's income tax in 1816 meant that the debt burden fell on consumers—many of them with low incomes—and on industrialists. The archaic and regressive nature of the

national taxation system, associated as it was with a mounting scale of locally levied poor-law rates, provoked widespread anxiety and criticism.

The postwar economy and society. The peace was followed, indeed, by open social conflicts, most of them exacerbated by a postwar slump. As the long-run process of industrialization continued, with a rising population and a cyclical pattern of relative prosperity and depression, many social conflicts centred on questions of what contemporaries called "corn and currency." Others were directly related to the growth of factories and towns and to the parallel development of middle class and working class consciousness.

The Corn Law of 1815

The agriculturalists, who were predominant in Parliament, attempted to safeguard their wartime economic position by securing, in 1815, a new Corn Law designed to keep up grain prices and rents by taxing imported grain. Their political power enabled them to acquire economic protection. Yet many of them suffered, particularly after 1819, from a serious fall of agricultural prices. Debts contracted during the wars became more onerous as prices fell. There were many complaints of agricultural distress during the early 1820s.

Many of the industrialists, an increasingly vociferous group outside Parliament, resented the passing of the Corn Law. Others objected to the return of gold, agreed to by Parliament in 1819 and put into effect in 1821. Whatever their outlook, industrialists were beginning to demand a voice in Parliament. The term middle class began to be used more frequently in social and political debate.

Town and village labourers were also unrepresented in Parliament, and it was they who bore the main brunt of the postwar difficulties. Bad harvests and high food prices left them hungry and discontented, and in the worst years, when bad harvests and industrial unemployment coincided, discontent assumed a political shape. The creation of the sense of a working class followed the emergence of a steam-driven factory system with new rhythms of work and new disciplines of control, a breakdown in traditional family relationships, and the growth of towns with structures of communication quite different from those of villages or preindustrial urban communities. There were radical riots in 1816, 1817, and particularly in 1819, the year of the Peterloo Massacre, when there was a clash in Manchester between workers and troops of the yeomanry, or local citizenry.

Local magistrates, with no adequate police forces at their disposal, were often unsure how to deal either with secret "conspiracy" or with open challenges to authority, while Lord Liverpool's government, with only rudimentary administrative machinery at its disposal, tended to follow a policy of repression. The Six Acts of 1819, associated with Viscount Sidmouth, the home secretary, were designed to reduce disturbances and to check the extension of radical propaganda and organization. They provoked sharp criticism from Whigs as well as from radicals, and they did not dispel the fear and suspicion that were threatening the stability of the whole social order.

There was a revival of confidence after 1821, as economic conditions improved and the government itself embarked on a program of economic reform. Sidmouth retired, to be succeeded by Sir Robert Peel; and Viscount Castlereagh, the foreign secretary, committed suicide. Even the king, George IV (1820–30), who had been drawn into the heart of politics when his discarded queen, Caroline, returned to England in 1820 and for a time became a radical heroine, ceased to be the target for continual radical abuse. Liverpool was a sufficiently able and sensible prime minister to work with new men and to move in new directions. Between 1821 and 1825, duties on raw material imports were reduced and tariff schedules were simplified; and in 1828, one year after Liverpool resigned, the fixed Corn Law of 1815 was replaced with a sliding scale. During this same period, Peel was reforming the law. Even after the collapse of the economic boom of 1824–25, no attempt was made to return to negative policies of repression.

Foreign policy. There was a change of tone if not of principle in foreign policy, as in home affairs, after Castlereagh's suicide. Castlereagh himself, who had represented Britain at the Congress of Vienna in 1815, had refused to follow up the peace settlement he had signed by converting the Quadruple Alliance of the victorious wartime allies into an instrument of police action to suppress liberalism and nationalism anywhere in Europe. His policy was one of nonintervention. His successor at the Foreign Office, George Canning, propounded the British viewpoint in more colourful language and with a strong appeal to British public opinion and emphasized differences between British viewpoints and those of the European great powers as much as their common interests. In 1824 he recognized the independence of Spain's American colonies, declaring in a famous phrase that he was calling "the New World into existence to redress the balance of the Old." In 1826 he used British force to defend constitutional government in Portugal, while, in the tension-ridden area of the eastern Mediterranean, he supported the cause of Greek independence. Although he died in 1827, before the new Greek state came into existence, after having served for a few months as Lord Liverpool's successor as prime minister, his policies and styles were reasserted by Palmerston, who became foreign minister in 1830.

The beginning of political reform. Between the death of Canning and Palmerston's acceptance of office in a government presided over by the aristocratic Whig leader Earl Grey, there had been a major shift in British politics. Canning's weak successor as prime minister, Viscount Goderich, who had been a successful chancellor of the exchequer under Liverpool, was unable to deal adequately with the increasingly complicated tangle of Tory and Whig factions, and he was soon replaced by Wellington, the military hero of the Napoleonic Wars. It was the Wellington ministry that introduced the new Corn Law of 1828 and presented Peel, the Prime Minister's chief henchman, with the renewed opportunity of reforming the law and, in 1829, with the chance of creating a new model police force for London. Yet Wellington, more soldier than politician, had to tackle two very difficult tasks—coping with Irish disorders and holding together in the same government Tories who had supported and opposed Canning.

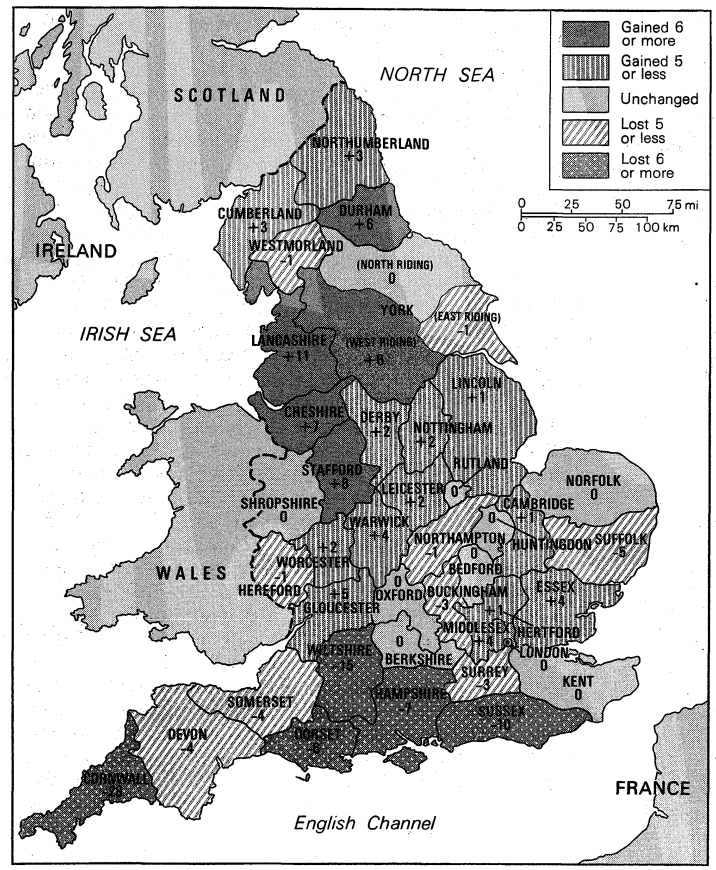
The issue of Catholic emancipation

Irish disorders centred, as they had since 1801, on the issue of Catholic emancipation, a favourite cause of the Whigs, who had been out of power since 1807. During the 18th century, Catholics in England had achieved a large measure of unofficial toleration, but, in Ireland, restrictions against Catholics' holding office were still rigorously enforced. In 1823 Daniel O'Connell, a Dublin Roman-Catholic lawyer, had founded the Catholic Association, the object of which was to give Roman Catholics in Ireland the same political and civil freedoms as Protestants. Employing impressive techniques of organization, he galvanized opinion in Ireland while at the same time mobilizing all his allies in England. In 1828 he won an election in County Clare, Ireland, so convincingly that Wellington, who—like the king—had always opposed Catholic emancipation, came to the conclusion that the government would have to push a measure for emancipation, which Canning had supported, through a Tory-dominated British Parliament. With difficulty he persuaded Peel, who had been tempted to resign, and the king, who had to be bullied, that an emancipation act was necessary and inevitable. Yet 128 "ultra-Tories" voted against the 1829 measure. Tory divisions left an opening for the Whigs, who were themselves divided on tactics if not on objectives. Some of them had joined the Canning ministry, but others had stayed aloof, biding their time. They had considerable support from financial interests and from religious dissenters, whose civil rights were recognized in 1828.

The death of George IV, in June 1830, speeded up events. After the accession of William IV (1830–37) and an inconclusive general election, Wellington, beset by many enemies, was defeated in November on a relatively unimportant motion on royal expenditure. In a year of

renewed economic distress and of revolution in France, when the political reform issue was being raised again at public meetings in different parts of the country, Wellington had not made matters easier for himself by expressing complete confidence in the constitution as it stood. He decided, therefore, to resign, and the king went on to send for Earl Grey, who had been *persona non grata* with George IV, to ask him to form a new ministry. The government Grey assembled was predominantly aristocratic—and it included Canningites as well as Whigs—but the new Prime Minister, like most of his colleagues, was committed to introducing a measure of parliamentary reform. For this reason, 1830 marked a real parting of the ways. At last there was a break in the continuity of regime that led back to Pitt's victory over Fox in the 1780s and that had only temporarily been interrupted in 1806–07. Moreover, the new government, aristocratic or not, was the parent of most of the Whig–Liberal administrations of the next 35 years.

The year 1830 was also one of economic and social grievances, with religion still being thrown into the melee. In many parts of the southern countryside, village labourers, backed, if not instigated, by the popular radical leader William Cobbett, were engaged in acts of violence against landlords and property (the "Captain Swing" disturbances), while in the midland and northern towns and cities, political reform movements were winning the support of the crowds. The Whigs were as afraid of rural riot as the Tories and almost as suspicious of new urban radical leaders in cities like Birmingham. Corn laws, currency laws, poor laws, and game laws were all being attacked, while, in the industrial north, the demand was growing for new laws to protect factory labour. It was in such an atmosphere that the new Whig-led government prepared its promised reform bill.



Membership change, by county, in the House of Commons as a result of the Reform Bill of 1832 (England only).

THE POLITICS OF REFORM

Three approaches to reform

Whig interest in parliamentary reform went back to the 18th century, and Grey himself provided a link between two separate periods of public agitation. Yet, in the country as a whole, there were at least three approaches to the reform question. Middle class "reformers" were anxious to secure representation for commercial and industrial interests and for towns and cities, like Birmingham and Manchester, that had no direct voice in Parliament. "Popular radicals," middle class or working class, were concerned with asserting rights as well as with relieving distress. "Philosophic radicals," the followers of the utilitarian philosophy of Jeremy Bentham, were strong ideological protagonists of parliamentary reform but deeply hostile both to the arguments and the tactics of the popular radicals, unless they felt that they were in a position to deploy or control them. It was agitation in the country that kept the reform question on the boil between 1830 and 1832, while Grey, aloof from all forms of agitation, faced unprecedented constitutional difficulties with both the King and Parliament.

The Reform Bill of 1832. A Whig reform bill was introduced in March 1831 and was carried, in its first form in the Commons, by one vote. In mid-April, however, after an opposition amendment had been successfully pressed, Grey induced a reluctant King to dissolve Parliament. At the ensuing general election, the government won a clear majority on the single cry "the bill, the whole bill and nothing but the bill." A second reform bill passed the Commons with no difficulty but was defeated in October in the Lords. Immediately there was a public outcry, with mass meetings of "political unions" and, in some cities, riots. A third bill was then passed by the Commons, only to be thrown out again—on an amendment—in the Lords in May 1832. William refused Grey's request to create a number of new peers who would carry the bill in the Lords, and, in consequence, Grey resigned and Wellington was called in. Such was the public mood, however, that he could not form a ministry, and Grey had to be reappointed, this time with a royal pledge that peers would be created if necessary. The threat was sufficient, and the bill passed, receiving the royal assent on June 7.

Achievement of the Reform Bill

The Reform Bill was in no sense a democratic measure. It was concerned with giving the middle classes a stake in responsible government rather than with changing the basis of government. Yet it entailed a substantial redistribution of constituencies and a change in the conditions of the franchise. The total electorate was increased by 217,000, but the artisans, the working classes, and some sections of the lower middle classes still remained outside "the pale of the constitution." No radical demands were met, even if the manner of the passing of the bill had demonstrated the force of organized opinion in the country. Those Tories who had prophesied that it would mean revolution were wrong, since the composition of the new House of Commons differed little from the old. It continued, indeed, for many years to reflect property rather than population, and landed interests remained by far the largest interests represented there. The Tories were nonetheless right in arguing that in the long run there would be a change of system. The Whigs, for their part, were wise in recognizing that if a reform bill were not passed, there might well be real pressure for revolution but unrealistic in arguing that it would satisfy reformers as a final measure.

Further Whig reforms. In fact, the Whigs, returned with a huge majority at the general election of December 1832, carried out a number of other important reforms. A statute in 1833 ended slavery in the British colonies; in the same year the East India Company lost its monopoly of the China trade and became a purely governing body with no commercial functions. In 1834 a new Poor Law, recommended by a royal commission appointed in 1832, was passed; this law grouped parishes into unions and placed the unions under the control of elected boards of guardians, with a national Poor Law Board in London. In 1835 the Municipal Corporations Act was passed, which swept away old oligarchies in local government. Elected councils were to appoint town clerks and treasurers, and many unincorporated industrial communities were to be granted their first governmental powers. In some towns, religious dissenters became the new govern-

ing class, though the Whigs did not satisfy their demands nationally.

The end of slavery was the final act in a long campaign in which a number of Tories had always played an important part, and the other reforming Whig measures owed much to the ideas of the philosophic radicals. The new Poor Law turned out to be an unpopular measure in the country and led to outbreaks of disturbance. Its basic principle—that outdoor poor relief should cease and that conditions in workhouses should be "less eligible" than the worst conditions in the labour market outside—was attacked by writers like Thomas Carlyle and Charles Dickens as much as by workingmen themselves. In fact, procedures of inquiry and inspection, associated with this and later reform measures, marked a change in the conduct of government at least as significant in the long run as the political reform of 1832. Public servants like Sir Edwin Chadwick, a disciple of Bentham, played an increasingly important, if controversial, part in administration, turning naturally from questions of poor relief to public health, education, and social reform. Inspired less by philanthropy than by belief in efficiency and economy, they extended the preoccupations of government at the very time when businessmen were demanding freer trade and seeking to demolish obsolete apparatus of economic control. Much administrative change in the 19th century was to have a cumulative momentum of its own, but its origins are to be found in new forms of social awareness in an increasingly industrialized society.

The new Poor Law

The Whigs were not at ease in this changing context. Nor were they united in dealing with the problems either of England or of Ireland. Indeed, Grey's successor, Viscount Melbourne, was for a time pushed out of office in 1834, to return in 1835. He was adept in his dealings with the young Queen Victoria, who came to the throne in 1837, but incapable of finding effective answers to any of the pressing financial, economic, and social questions of the day. All of these questions multiplied after 1836, when a financial crisis ushered in a period of economic depression accompanied by a series of bad harvests. Social conflicts, never far from the surface, became more open and dramatic. Early Victorian England was turbulent and excited, and if it had not been for Robert Peel, who succeeded Melbourne as prime minister after the general election of 1841 had returned to power the "Conservatives" (as Peel liked to think of his party), there might well have been even greater disorder. The achievements of his Conservative ministry must be considered both within the context of the immediate social and political disturbance and within the perspectives of 19th-century British history as a whole.

SOCIAL CLEAVAGE AND SOCIAL CONTROL IN THE EARLY VICTORIAN YEARS

Chartism and the Anti-Corn Law League. As the economic skies darkened after 1836 and prophets like Carlyle anticipated cataclysmic upheaval, the two most disgruntled groups in society were the industrial workers and their employers. Each group developed new forms of organization and each turned from local to national extraparliamentary action. The two most important organizations were the Chartists and the Anti-Corn Law League. Chartism drew on a multiplicity of working class grievances, extending working class consciousness as it grew; the Anti-Corn Law League, founded as a national organization in Manchester in 1839, was the spearhead of middle class energies, and it enjoyed the advantage not only of lavish funds but also of a single-point program—the repeal of the Corn Laws.

Chartism, which aimed at parliamentary reform, took its name from the People's Charter published in London in May 1838, containing six points, all of them political and all with a radical pedigree—annual parliaments; universal male suffrage; the ballot; no property qualifications for members of Parliament; payment of members; and equal electoral districts. Behind the political demands, however, was a fierce social discontent and a desire to establish working class political power. The new Poor Law of 1834 was a main source of grievance in the provinces; so, too, in Lancashire and Yorkshire, were long working hours in the factories. Earlier localized agitations centring on such grievances were subsumed in Chartism. In addition, the failure to create effective trade unions during the early 1830s directed efforts toward national political action. The Chartists failed to secure any of the six points during the course of their mostly uncoordinated agitation that continued with fluctuating fortunes until the early 1850s. Problems of organization, local differences, disagreements about tactics (including the use of force), arguments about leadership (particularly about the leadership of Feargus O'Connor), and an improvement in economic conditions—first between 1844 and 1846 and then after 1848—dictated the details of the story. One of the few violent incidents was the small "rising" at Newport on the Welsh border in November 1839, like many of the other demonstrations, a demonstration that got out of hand before it failed. In Scotland "moral force" Chartism was particularly strong. In discontented Ireland, which might have provided support for Chartism, it was only after O'Connell's death in 1847 that the Chartists found allies.

Disagreement among Chartists

The middle class Anti-Corn Law League, led by Richard Cobden and John Bright, attempted to secure the repeal of the duties on imported grain, which were believed to raise the price of food for the workingman and benefit only the landowning classes. The League also had its difficulties, particularly at the outset, but it employed every device of propaganda, including the use of new media of communication, such as the penny post, introduced in 1840. The formula of the League was a simple one, designed to secure working class as well as middle class support. Repeal of the Corn Laws, it was argued, would settle the two great issues that faced Britain in the "hungry forties"—securing the prosperity of industry and guaranteeing the livelihood of the poor. The only barrier to salvation was the landlord. Most Chartists were unconvinced by this logic, but, in a landed Parliament, a few Anti-Corn Law Leaguers, led by Richard Cobden, told Peel firmly that he would be "a criminal and a poltroon" if he did not repeal what they regarded as an immoral as well as an economically restrictive piece of legislation.

Peel and the Peelite heritage. Much depended on the nature of Peel's response to the problems of the time. Between 1832 and 1841 he had built up a disciplined party, most members of which accepted 1832 as a *fait accompli*. He himself, though brought up as a Tory, was a child of the Lancashire cotton industry and accepted industrialization as beneficial as well as inevitable. Afraid of violence, he sought, with a strong sense of public duty, to discover practical solutions to the complex issues of an industrializing society. He was the presiding genius of a powerful administration, strictly supervising the business of each separate branch of government, some of which were managed by very able lieutenants. From the start Peel attached top priority to financial reform. Beginning with his budget of 1842, he set about simplifying and reducing tariff restrictions on trade and in the same year he reintroduced income tax. In 1844 his Bank Charter Act laid the foundations of a sound national banking and credit system centred on the Bank of England. Finally, in 1846 he repealed the Corn Laws.

Peel's reforms

In this sequence of changes he alienated many of his followers, and repeal brought all the conflicts within his party to a head. The squirearchy rebelled, roused by the brilliant speeches of an exotic young politician, Benjamin Disraeli, who in his writings had already approached the "condition of England question" in a totally different style from that of Peel. During the crisis, Peel put his sense of duty to his sovereign, to posterity, and to his own conscience first and his obligations to his party second.

The results of repeal were important politically as well as economically. Party boundaries remained blurred until 1859, with the "Peelites" retaining a sense of identity even after Peel's premature death following a riding accident in 1850. Some of them, particularly Gladstone, eventually became leaders of the late-19th-century Lib-

eral Party, which emerged from the midcentury confusion. The protectionists, most of whom abandoned protection after 1852, formed the nucleus (around the Earl of Derby and Disraeli) of the later Conservative Party, but they were unable to secure a majority at any election until 1874. The minority governments they formed in 1852, 1858, and 1866 lacked any secure sense of authority. The Whigs, themselves divided into factions, returned to office in 1847 and held it for most of the midcentury years, but they were often dependent on radical and Irish support. Leadership in these years rested with strong or persuasive personalities, of whom Viscount Palmerston was the most prominent.

There was no time between 1846 and 1866, however, when extraparliamentary agitation assumed the dimensions it had done between 1838 and 1846; and, when revolutions spread throughout Europe in 1848, Britain remained almost immune. Only a fierce outburst of Chartism, this time Chartism with an injection of socialism and of Irish nationalism, disturbed the year. Ireland, positively or negatively, played an important part in the politics of crisis, for it was the failure of the Irish potato crop in 1845–46 and the threat of famine in Ireland that helped sway Peel to repeal the Corn Laws. Unfortunately, disaster was not averted in Ireland itself, and in the course of a few terrible famine years, about 500,000 Irish died and 1,000,000 Irish emigrated. Peel's Whig successor, Lord Russell, had no command over this situation, which challenged all the economic, administrative, and political assumptions of the time.

Irish famine

Social legislation and social control. In Britain, by contrast, steps were taken before and after Peel to assume an increasing measure of social control. The question of public health, raised in the late 18th century and given a high degree of urgency during the 1830s, was the subject of several widely discussed reports before the passing of the first national Public Health Act in 1848. Chadwick was the leading spokesman of "the sanitary idea," which was canvassed vigorously by the novelists Charles Dickens and Charles Kingsley and which was to inspire George Eliot. Industrial questions also figured prominently in the social novels of the 1840s, including those of Disraeli; and statisticians, treated warily by most novelists, provided a different form of ammunition in the social debate. A report on conditions in the mines was followed by legislation, in 1842, forbidding the employment underground of children under ten and of all women. Meanwhile, the reports of factory inspectors, appointed under an act of 1833, were attracting widespread interest; and in 1847, after earlier attempts had proved abortive, a Factory Act was passed, limiting the hours of work of children in textile factories to ten: it was the first of many acts amending abuses and extending the principle of intervention.

Developments in education

In education there were significant new departures, limited in scope by the rivalry between churchmen and dissenters. In 1833 the first government grants had been made to the two main voluntary organizations sponsoring primary education, and in 1839 the first school inspectors had been appointed. J.P. Kay (later Sir James Kay-Shuttleworth), secretary of the Committee of Council on Education, did everything he could to make the most of an admittedly inadequate system of provision, which was extended further with the first grants for teacher training and salaries in 1846. Kay's main object was to encourage the use of education as a means of introducing a measure of order and discipline into the working class population, when older and more traditional methods of wielding authority through subordination had broken down. Yet just as the operation of the deterrent Poor Law directed attention in the long run to the need for more complex welfare policies, so the extension of educational provision, limited and belated though it was, involved the interplay of more varied motives and purposes. That there was no revolution in Britain in 1848, as there was in most countries in Europe, was owing to the character of Britain's social structure. Yet the contemporary prophets of revolution, whether for or against, tended to overlook the effort, local as well as national, to influence conditions of life through conscious policies.

The evolution of such policies was difficult for a number of reasons: first, there were entrenched vested interests, particularly obvious in questions of public health; second, there was a shortage of professional expertise, particularly in engineering and medicine; third, most radicals were highly suspicious of all forms of state intervention, particularly if they involved spending large sums of money or interfering with local freedoms; fourth, the orthodox economic policies of the day stressed the need for private rather than for public initiative. Yet there were aspects of the social structure that encouraged social action. Industrialists were sometimes especially sensitive to the problems of the workers in the countryside, particularly during the heyday of the Anti-Corn Law League, when the Leaguers were attacking "feudalism"; and some landlords, notably the evangelical philanthropist Lord Ashley, were especially sensitive throughout the 1830s and '40s to the problems of town workers. In such circumstances, it was difficult to rest content with things as they were. In the words of one of Disraeli's characters, this was a "high-pressure" age. For the statistician G.R. Porter, whose *Progress of the Nation* (1836–43) went through many editions, all "the elements of improvement" in the country were "working with incessant and increasing energy." He added that in his own lifetime he had seen "the greatest advances in civilisation that can be found recorded in the annals of mankind."

The pace of economic change. Not all of Porter's contemporaries would have agreed about the phrase "the greatest advances in civilisation," for some of them criticized the quality of life in the new society, and others pointed to the social contrasts reflected, for example, in the unequal distribution of incomes. There was a debate between "optimists" and "pessimists," the latter suggesting that the condition of the working classes was actually deteriorating as national wealth increased. Most people were concerned, too, about the rise in population. At the first (defective) census of 1801, the population of England and Wales was around 9,000,000 and that of Scotland around 1,500,000. By 1851 the comparable figures were 18,000,000 and 3,000,000. At its peak between 1811 and 1821, the growth rate for Britain as a whole was 17 percent for the decade. It took time to realize that the fears expressed so eloquently by Malthus that population would outrun subsistence were exaggerated and that, as population grew, national production would grow also.

"Optimists" and "pessimists"

Indeed, national income at constant prices increased nearly threefold between 1801 and 1851, substantially more than the increase in population, and the share of manufacturing, mining, and building in the national accounts of wealth increased sharply, as compared with the share of agriculture. In 1801 agriculture accounted for 34 percent and manufacturing, mining, and building for 28 percent. The comparable figures for 1851 were 21 percent and 40 percent. Cotton textiles remained the dominant new industry, with the cotton factory being thought of by one of its contemporary admirers, Edward Baines, as "the most striking example of the dominion obtained by human science over the powers of nature of which modern times can boast." There were 1,800 cotton factories in 1851. Raw cotton imports had increased unevenly from 101,000,000 pounds in 1815 to 757,000,000 pounds in 1851 and exports of manufactured cotton piece goods from 253,000,000 yards in 1815 to 1,543,000,000 yards in 1851. Similar steam-driven technology accounted for the expansion of the woollen textiles industry over the same period, with Australia, which provided no raw wool for Britain in 1815, providing 30,000,000 pounds in 1851. It was the textiles industry more than any other that illustrated Britain's dependence on international trade, a trade that it commanded not only through the size of the import bill or of manufacturing output but through the strength of its banking and other financial institutions and the extent of its shipping industry. Despite the advance of steam (registered steamship tonnage in 1815, 1,000, and in 1851, 187,000), the tonnage of sail-

ing ships also increased. There was no problem comparable to that of the displaced handloom weavers, the victims of technological progress.

The new technology rested on coal, iron, and steam; it reached its peak in the age of the railway and the steamship. Coal production, about 13,000,000 tons in 1815, increased five times during the next 50 years, and, by 1850, Britain was producing over 2,000,000 tons of pig iron, half the world's output. Both coal and iron exports increased dramatically, with coal exports amounting to 3,300,000 tons in 1851, as against less than 250,000 tons at the end of the French wars. Coal mining was scattered in the coal-producing districts, with few large towns and with miners living a distinctive life with their own patterns of work and leisure. Iron production was associated with larger plants and considerable urbanization. In South Wales, for example, one of the areas of industrial expansion, the Dowlais works were employing 6,000 people and turning out 20,000 tons of pig iron each year during the 1840s. Birmingham, Britain's second largest city, was the centre of a broad range of metallurgical industries, mainly organized in small workshops, very different in character from the huge textile mills of Lancashire and Yorkshire.

Impact of the railroads

Industrialization preceded the coming of the railway, but the railway did much to lower transport costs, to consume raw materials, to stimulate investment through an extended capital market, and to influence the location of industry. The railway age may be said to have begun in 1830, when the line from Liverpool to Manchester was opened, and to have gone through its most hectic phases during the 1840s, when contemporaries talked of a "railway mania." By 1851, 6,800 miles of railway were open, some of them involving engineering feats of great complexity. There was as much argument among contemporaries about the impact of railways as there was about the impact of steam engines in factories, but there was general agreement about the fact that the coming of the railway marked a great divide in British social history. The novelist William Thackeray put it succinctly, when he compared the last years of the stagecoach with the railway age. "Your railroad starts the new era, and we of a certain age belong to the new time and the old one." It was not until the 1870s and '80s that steamships brought this "new time" to its full realization, and by then British engineers and workmen had been responsible for building railways in all parts of the world. By 1890 Britain had more registered shipping tonnage than the rest of the world put together.

The Great Exhibition of 1851. By 1890 it had become apparent that the British industrial revolution, far from being unique, was merely the first in a sequence of industrial revolutions and that Britain's early lead was becoming something of a handicap. In 1851, however, Britain was not only the workshop of the world but the main influence on the industrialization of other nations as well as its own. The Great Exhibition of 1851, in London, symbolized this economic supremacy. The exhibition was housed in a huge glass and iron building called —with a touch of romance—"the Crystal Palace." Here, people from all parts of the world could examine machines of every kind, which Thackeray, once again catching the mood for posterity, described as "England's arms of conquest . . . the trophies of her bloodless war." Part of the success of the exhibition was political as much as economic. Many of the visitors who flocked to London came from European cities that had been racked with revolution only three years before.

Victoria and Albert

The exhibition was a triumph not only for the economy but also for Victoria and her German husband, Albert, whom she had married in 1840. "In England," wrote a continental observer, "loyalty is a passion." Despite outbursts of opposition to Albert, particularly in 1855, the family life of the Victorian court began to be considered increasingly as a model for the whole country. The fact that Albert had appreciated the significance of Peel's achievement and that he put his trust in the advancement of industry and science was as important as the fact that Victoria herself established monarchy on respectable foundations of family life. It was during the 1850s that the word "Victorian" began to be employed to express a new self-consciousness, both in relation to the nation and to the period through which it was passing. The death of Albert in 1861 and the subsequent withdrawal of the Queen from public life led to a decline in the popularity of the court, but in time the Queen's subjects, both at home and overseas, came once again to consider both her developed virtues and her obvious limitations as the very essence of "Victorianism" itself.

MID-VICTORIAN SOCIETY, RELIGION, AND CULTURE

After the excitements of the 1830s and 1840s, mid-Victorian England was relatively quiet, with the family being regarded by most mid-Victorians as the central institution in society. In national social life, a kind of balance was struck between the busy industrial north and midlands and the sleepy countryside described in the novels of Anthony Trollope. A kind of balance was also struck between the traditional ideal of "the gentleman" and the new ideal of the hero of "self-help," with a place being left both for deference and dependence, on the one hand, and for individual advancement and acquisitiveness, on the other. There was far more talk during this period of self-help than there was of class conflict; indeed, the most comfortable social theory of the period rested on the assumption that class dividing lines could and should stay, provided that individuals in each class could move. Social discipline was strong, counting for more, perhaps, than the extension of the local police forces by an act of 1856.

Effects of economic prosperity

Victorian attitudes. All kinds of balance rested, however, on economic as well as on psychological and sociological factors. From the early 1850s to the early 1870s, with occasional years of high unemployment and business failure (bad harvests counted for less as food imports increased), almost all sections of the population seemed to be benefitting from relative prosperity. Profits rose, as did wages and incomes from land. Indeed, those supporters of protection who had argued in the 1840s that free trade would ruin British agriculture were mocked by the mid-Victorian prosperity of agriculture in a golden age of high arable farming. There seemed to be little need in such a society for strong government, and it was only during the Crimean War (1854–56), when even many radicals looked for enemies abroad rather than at home and when the war itself was managed with obvious inefficiency, that either society or government seemed to be under great strain.

Self-criticism and doubt

It was during these years, when great individual creative power was tapped, that Victorianism, perhaps the only "ism" in history attached to the name of a sovereign, came to represent a cluster of restraining moral attributes —earnestness, respectable comportment and behaviour, "character," "duty," hard work, and thrift. All these were virtues extolled and related to each other in the many books of Samuel Smiles, author of the best seller *Self-Help* (1859). Later in the century, they were to be taken apart and criticized, even lampooned, one by one in the course of a late-Victorian revolt. It is too simple, however, to dismiss them as bourgeois virtues, since many of them were shaped more by religion than by class, and all of them made an appeal, for a time at least, to non-middle-class sections of the population, aristocratic or trade unionist. All of them, moreover, were subjected to contemporary criticism. In the same year as Smiles's *Self-Help*, there appeared John Stuart Mill's essay, *On Liberty*, a powerful attack on conformity and a classic liberal statement of freedom of discussion. Charles Dickens frequently made fun of the Victorian smugness and unwillingness to face unpleasant facts, as represented by Mr. Podsnap in *Our Mutual Friend;* the critics Matthew Arnold and John Ruskin, each arguing from a different point of departure, questioned many of the accepted beliefs and prejudices of the age. Minority communicators in the widely read reviews were often extremely critical, and even Smiles himself, writing for a bigger public, thought that none of the virtues he was extolling came to men naturally nor could any of them

be taken for granted in the middle of the 19th century. There was always a Victorian underworld. Belief in the family was accompanied by a high incidence of prostitution, and in every large city there were districts where every Victorian virtue was ignored or flouted. Mill's London was also the London of Henry Mayhew, whose *London Labour and the London Poor* was published in book form in 1862.

Religion. The critical sense of many of the great Victorians—at least as far as opinions were concerned—inevitably involved questions of religion as much as of society or politics, and Victorian doubt was as much an acknowledged theme of the period as Victorian belief. During the year of the Great Exhibition, the poet Tennyson's *In Memoriam* considered the triumphs of 50 years of economic advance against the background of the whole story of man and of the earth. Geology and biology continued to challenge all accepted views of religion handed down from the past. Darwin's *Origin of Species* was another of the great books of the remarkable year 1859. A year later *Essays and Reviews* was published; a lively appraisal of fundamental religious questions by a number of liberal-minded religious thinkers, it provoked the sharpest religious controversy of the century.

Yet, behind such controversies, there were many signs of a confident belief on all sides that inquiry itself, if freely and honestly pursued, would do nothing to dissolve the ideals of conduct that were generally shared. Even those writers who were "agnostic" sought the "religion of humanity" or tried to be good "for good's sake, not God's." There was also a dutiful acceptance of the importance of standards in institutional as well as in private life. These were years when the extension of the civil service involved the development of a remarkable code of institutional morality. Following a report by Sir Charles Trevelyan and Sir Stafford Northcote in 1853–54, a civil service commission was set up. Recruitment and promotion in most parts of the service were to depend on competitive examination. An order-in-council of 1870 made this system mandatory, except for the Foreign Office. The extended civil service that took shape owed little to political patronage and was almost completely free from corruption.

Emphasis on conduct was, of course, related to religion. The English religious spectrum was of many colours. The Church of England was flanked on one side by Rome and on the other by religious dissent. Both were active forces to be reckoned with. The Roman Catholic Church was growing in importance not only in the Irish sections of the industrial cities but also among university students and teachers. Dissent had a grip on the whole culture of large sections of the middle classes, dismissed too abruptly by Arnold as "mutilated and incomplete men." Sometimes the local battle between Church of England and Dissent was bitterly contested, with Nonconformists acting as a militant group, opposing church rates (taxes), challenging closed foundations, and preaching total abstinence and educational reform. A whole network of local voluntary bodies, led either by Anglicans or Dissenters, usually in rivalry, came into existence, a tribute to the energies of the age and to its fear of state intervention.

The Oxford Movement

The Church of England itself was a divided family, with different groups contending for positions of influence. The High Church movement (which emphasized the "Catholic" side of Anglicanism) was given a distinctive character, first by the Oxford Movement, or Tractarianism, which had grown up in the 1830s as a reaction against the new liberal theology, and then by the often provocative and always controversial ritualist agitation of the 1850s and '60s (see ANGLICAN COMMUNION: *19th and 20th centuries*). The fact that prominent members of the Church of England flirted with "Romanism" and even crossed the Rubicon often raised the popular Protestant cry of the "church in danger." Peel's conversion to free trade in 1846 scarcely created any more excitement than John Henry Newman's conversion to Rome the previous year, while, in 1850, Lord John Russell, Peel's successor as prime minister, tried to capitalize politically on violent antipapal feelings stimulated by the Pope's decision to create Roman Catholic dioceses in England.

The Evangelicals, in many ways the most influential as well as the most distinctively English religious group, were suspicious both of ritual and of appeals to any authority other than that of the Bible. Their concern with individual conduct was a force making for social conformity during the middle years of the century rather than for that depth of individual religious experience that the first advocates of "vital religion" had preached in the 18th century. Yet leaders like Ashley were prepared to probe some of the difficult questions of the social order and to stir men's consciences, even if their preoccupation was with saving souls, and their missionary zeal influenced overseas as well as domestic development. There were some members of the church, usually not evangelicals, who urged the cause of what they called "Christian Socialism." Their intellectual leader was the outstanding Anglican theologian Frederick Denison Maurice.

Beyond the influence of both church and chapel there were thousands of people in mid-Victorian England who were ignorant of, or indifferent toward, the message of Christianity, a fact demonstrated by England's one religious census in 1851. Although movements like the Salvation Army, founded by William Booth in 1865, attempted to rally the poor of the great cities, there were many signs of apathy or even hostility. There was also a small but active secularist organization. The great religious controversies of mid-Victorian England were not so much settled as shelved.

The Church of Scotland

In Scotland, where the Church of Scotland had been fashioned by the people against the crown, there was a revival of Presbyterianism in the 1820s and '30s. A complex and protracted controversy, centring on the right of congregations to exclude candidates for the ministry whom they thought unsuitable, ended in schism. In 1843, 474 ministers left the Church of Scotland and established a free church. Within four years they had raised over £1,250,000 and built 654 churches. This was a remarkable effort, even in a great age of church and chapel building. It left Scotland with a religious pattern even more different from that of England and Wales than it had been in 1815. Yet many of the most influential voices in mid-Victorian Britain, including Thomas Carlyle and Samuel Smiles, were Scottish voices, and the conception of the gospel of work, in particular, owed much in content and tone, even if often indirectly, to Scottish Calvinism.

MID-VICTORIAN POLITICS

Religious questions helped divide the limited electorate, with the dissenters encouraging, from their local bases, the development of liberalism, and churchmen often—but by no means universally—supporting the Conservative Party. Party divisions were based on customary allegiance as much as on careful scrutiny of issues, and there was still considerable scope for bribery at election times. The civil service might be pure, but the electors often were not. The Corrupt Practices Act of 1854 provided a more exact definition of bribery than there had been before, but it was not until a further act of 1883 that election expenses were rigorously controlled. During the mid-Victorian years, the way to Parliament often led through the pigsty.

The prestige of the individual member of Parliament was high, and the fragmentation of parties after 1846 allowed him considerable independence. Groups of members supporting particular economic interests, especially the railways, could often determine parliamentary strategies. Contemporaries feared such interests less than they feared what was often called the most dangerous of all interests, executive government. Powerful government and large-scale "organic" reform were considered dangerous, and even those radicals who supported organic reform, like Cobden and Bright, were suspicious of powerful government. For most politicians, politics was identified not with theories or even programs but with pragmatic leadership.

In his interesting analysis of the English constitution (1867), Walter Bagehot considered the cabinet as "a board of control chosen by the legislature, out of persons whom it trusts and knows, to rule the nation." Its primary task was to administer, not to legislate. There was little legislation dealing with public health or trade unions or Irish agrarian problems until the late 1860s, although the Company Act of 1862 consolidated limited liability legislation passed during the 1850s. A judge told a number of men who were convicted of illegal activities during a strike of 1867,

> Everybody knows that the total aggregate happiness of mankind is increased by every man being left to the unbiased, unfettered determination of his own will and judgement as to how he will employ his industry and other means of getting on in the world.

Palmerston. Palmerston, an aristocrat born in 1784, stood out as the dominant political personality in mid-Victorian Britain, precisely because he was opposed to dramatic change and because he knew through long experience how to manoeuvre politics within the half-reformed constitution. In a period when it was difficult to collect parliamentary majorities, he often forced decisions, as at the general election of 1857, on the simple question, "are you for or against me?" He was skillful also in using the growing power of the press in order to reinforce his influence. At a time of party confusion, when the Queen might well have played a key part in politics, Palmerston found the answer to royal opposition in popular prestige, carefully stage-managed. His chief preoccupation was with foreign affairs, and his approach was diametrically opposed to that of the court on several occasions.

There was no contradiction between his views on domestic and foreign policy. He preferred the English system of constitutional government, resting on secure social foundations, to continental absolutism, but, like Canning before him, he was anxious above all else to advance the interests of England as he saw them. The supremacy of British sea power, British economic ascendancy, and political divisions inside each of the main countries of Europe before and after the revolutions of 1848 gave him his opportunity. He liked to appear active. In 1850 he sent a blockading squadron to Greece to enforce payments of debts due to Don Pacifico, a Gibraltar-born British subject, and restated the doctrine of *civis Romanus sum* ("I am a Roman citizen," by which an ancient Roman could proclaim his rights throughout the empire) in a Victorian setting. In 1852, when he helped overturn Russell's shaky government, he had his revenge on Russell, who had dismissed him from his post as foreign secretary in December 1851 for welcoming Napoleon III's coup d'etat in France. In January 1855, after Lord Aberdeen, a Peelite, had shown his incompetence as a war leader during the Crimean War, Palmerston was made prime minister for the first time. His interventions were not confined to Europe. In 1840–41 he forced the China ports open to foreign trade and, by the Treaty of Nanking (1842), acquired Hong Kong for Britain. In 1857 he went to war in China again and, when defeated in Parliament, appealed triumphantly to the country. Although his government was defeated in 1858, he was back again as prime minister, for the last time, a year later.

The Don Pacifico affair

During the remarkable ministry of 1859–65, which included Russell as foreign secretary and the Peelite Gladstone as chancellor of the exchequer, it was impossible for Britain to dominate the international scene as effectively as in previous periods of Palmerstonian power. With efficient military power at his disposal, the Prussian prime minister, Otto von Bismarck, proved more than a match for him. The union of modern Italy, which Palmerston supported; the American Civil War, in which his sympathies were with the South; and the rise of Bismarck's Germany, which he did not understand, were reshaping the world in which he had been able to achieve so much by forceful opportunism. When he died, in October 1865, it was clear that, in foreign relations as well as in home politics, there would have to be what Gladstone described as "a new commencement."

In home politics it had been only the continued influence of Palmerston as prime minister that had delayed overdue reforms. In the large urban constituencies, the demand for a new and active liberalism was gaining ground, and at Westminster itself Gladstone was beginning to identify himself not only with the continued advance of free trade but with the demand for parliamentary reform. In 1864 he forecast new directions in politics when he stated that the burden of proof concerning the case for reform rested not with the reformers but with their opponents. A year later he lost his seat at Oxford University and was returned "unmuzzled" as representative for a populous Lancashire constituency. The death of Palmerston was followed by the reopening of the question of parliamentary reform and by the passing of the Second Reform Bill in 1867.

The Reform Bill of 1867. Yet it was Disraeli and not Gladstone who claimed the credit for the act of 1867. On Palmerston's death, Russell and Gladstone had introduced a modest and colourless bill that was severely mauled both by Conservatives and reform Liberals. The government resigned, and Derby and Disraeli took office. It was difficult to shelve the demand for reform, and the government decided to "dish the Whigs" and "take a leap in the dark." Agitation in the country was more vociferous on the issue than it had been since the days of the Chartists, and organizations, notably the Reform League, were engaged in stirring the public, alongside prominent individuals, notably John Bright. In a Parliament where Disraeli was in a minority, his only chance lay in accepting amendments, however radical, to the bill that he had introduced and in claiming them as his own. All reserves and safeguards were dropped, and, although he lost some of his own supporters, he eventually carried a bill very different from the one he had introduced. It added 938,000 new names to the register, almost a doubling of the electorate, and gave the vote to many workingmen in the towns and cities. The county franchise was not substantially changed, but 45 new seats were created by taking one member from existing borough constituencies with a population of less than 10,000. Disraeli hoped that, in return for passing this measure, urban workingmen would vote for him—he believed rightly that many of them were Conservatives already by instinct and allegiance—but, at the first general election under the new system, it was Gladstone who was returned as prime minister.

The "leap in the dark"

GLADSTONE AND DISRAELI

The choice between Gladstone and Disraeli was the first of many similar choices offered to an extended electorate —the choice between two men who were completely different in temperament and political outlook. Gladstone had made his mark first and lived on far longer (1898) than did his rival (1881). He saw politics in terms of moral principles and, in his ministry of 1868–74, introduced some of the most important Liberal legislation of the 19th century. Disraeli, who combined opportunism and political imagination, carried through an impressive program of social reform and embarked upon an active foreign policy both in Europe and overseas. Yet much of the Liberal legislation was the product of compromise rather than of principle, and much of the significant social legislation of the Conservatives was considered sufficiently politically unimportant by them, at the time, for them to neglect it when they appealed to the electorate in 1880. In both parties, there were new forces stirring at the local level and energetic efforts to organize the electorate and the political parties along new lines. With the development of central party machinery and local organization, the role of the crown was reduced during this period to that of merely ratifying the result of general elections. Although the Queen greatly preferred Disraeli to Gladstone, she could not keep Gladstone out. Her obvious partisanship made some of her acts look unconstitutional, but they would not have been deemed unconstitutional in any previous period of history. The public during this period was more interested in the political leaders than in the Queen, who lived in retirement and was sharply criticized in sections of the press.

Administrative reforms

Gladstone's first administration. The achievements of Gladstone's first administration were several: the disestablishment and partial disendowment of the Irish Church, accomplished in 1869 in face of the opposition of the House of Lords; the Irish Land Act of 1870, providing some safeguards to Irish tenant farmers; William Edward Forster's Education Act of the same year, the first national act dealing with primary education; the Trade-Union Act of 1871, legalizing unions and giving them the protection of the courts; and the Ballot Act of 1872, introducing secret voting. There were many other important reforms, most of which were designed to broaden the span of individual opportunity or to reform cumbersome administrative machinery. In 1871, for example, the universities of Oxford and Cambridge were opened to Dissenters, while between 1868 and 1873 the cumbrous military machine was renovated by Gladstone's secretary for war, Edward Cardwell. The system of dual responsibility of commander in chief and secretary at war was abolished, and the subordination of the former to the latter was asserted. In 1873 the Judicature Act, amended in 1876, simplified the tangle of legal institutions and procedures.

Many of these reforms did not satisfy affected interests. The Irish Church Disestablishment Act failed to placate the Irish and alarmed many English churchmen, while the Education Act was passed only in face of bitter Nonconformist opposition. The Dissenters objected that Forster's system did not break the power of the church over primary education, and, although the act was extended in 1880 when primary education was made compulsory and in 1891 when it became free, there were often noisy struggles between churchmen and Dissenters in the new school boards set up locally under the Forster Act. If the Education Act alienated many Dissenters, the Licensing Bills of 1871 and 1872 alienated their enemies, the brewers. At the general election of 1874, therefore, months after Disraeli had described the Liberal leaders in one of his many memorable phrases as a "range of exhausted volcanoes," the brewers threw all their influence behind the Conservatives. "We have been borne down in a torrent of gin and beer," Gladstone complained.

Disraeli's second administration. Disraeli's ministry embarked upon a sizable program of social legislation. Gladstone, throughout his life, preferred free and cheap government to expensive and socially committed government. He was anxious, indeed, in 1873 to abolish income tax, on which the public finances of the future were to depend. Disraeli had always been interested in "the condition of England question" and, with the assistance of men like Richard Cross, the home secretary, justified at last his reputation as a social reformer. By the Employers and Workmen Act of 1875, "masters" and "men" were put on an equal footing as regards breaches of contract, while by a Trade-Union Act of 1875 that went much further than the Liberal act of 1871, trade unionists were allowed to engage in peaceful picketing and to do whatever would not be criminal if done by an individual. The Public Health Act of 1875, a consolidating piece of legislation, created a public health authority in every area; the Artizans' and Labourers' Dwellings Improvement Act of the same year enabled local authorities to embark upon schemes of slum clearance; a factory act of 1878 fixed a 56-hour week; while further legislation dealt with Friendly Societies (private societies for mutual-health and old-age insurance), the protection of seamen, land improvements carried out by tenants, and the adulteration of food. There was no similar burst of social legislation until after 1906.

Foreign policy. If there were significant, if not fully acknowledged, differences between the records of the two governments on domestic issues, there were open, even strident differences on questions of foreign policy. Gladstone had never been a Palmerstonian. He was always anxious to avoid the resort to force, and he put his trust not in national prejudices but in an enlightened public opinion in Europe as well as England. His object was justice rather than power. In practice, however, he often gave the impression of a man who vacillated and could not act firmly. Disraeli was willing to take risks to enhance British prestige and to seek to profit from, rather than to moralize about, foreign dissensions. His first ventures in "imperialism"—a speech at the Crystal Palace in 1872, the purchase of the Suez Canal shares in 1875, and the proclamation of the Queen as "Empress of India"—showed that he had abandoned the view, popular during the middle years of the century, that colonies were millstones around the mother country's neck. But these moves did not involve him in any European entanglements, nor did the costly if brilliantly led campaigns of Major General Roberts in Afghanistan (1878–80) and the annexation of the Transvaal in South Africa in 1877.

Disraeli's "imperialism"

It was the Near Eastern crisis of 1875–78 that produced the liveliest 19th-century debate on foreign policy issues. In May 1876, Disraeli rejected overtures made by Russia, Austria-Hungary, and Germany to deal jointly with the Turks, who were faced with revolt in Serbia. His pro-Turkish sympathies irritated many Liberals, and, after the Turks had gone on to suppress with great violence a revolt in Bulgaria in 1876, the Liberal conscience was stirred and mass meetings were held in many parts of the country. Gladstone, who had gone into retirement as Liberal leader in 1875, was slower to respond to the issue than many of his followers, but, once roused, he emerged from retirement, wrote an immensely influential pamphlet on the atrocities, and led a public campaign on the platform and in the press. For him the Turks were "inhuman and despotic," and, whatever the national interests involved, Britain, in his view, should do nothing to support them. Disraeli's calculations concerned strategic and imperial necessities rather than ideals of conduct, and his suspicions were justified when the Russians attacked Turkey in April 1877. Opinion swung back to his side, and in 1878 Disraeli sent a British fleet to the Dardanelles. There was a war fever in London—the term jingoism was used to describe it—that was intensified when news reached London that a peace treaty had been signed at San Stefano whereby the Turks accepted maximum Russian demands. Reservists were mobilized in Britain, and Indian troops were sent to the Mediterranean. Disraeli's Foreign Minister, who disapproved of such action, resigned, to be succeeded by Lord Salisbury, who was eventually to serve as prime minister in the last Conservative administrations of the 19th century. The immediate crisis passed, and, at an international conference held in Berlin in June and July 1878, which Disraeli attended, the inroads into Turkish territory were reduced, Russia was kept well away from Constantinople, and Britain acquired Cyprus. Disraeli brought back "peace with honour." But the swings of public opinion continued, and in 1879 Gladstone, starting at Midlothian in Scotland, fought a nationwide political campaign of unprecedented excitement and drama. At the general election of April 1880, the Liberals returned to power triumphantly, with a majority of 137 over the Conservatives. Disraeli, who had moved to the House of Lords in 1876, died in 1881.

LATE VICTORIAN POLITICS

Gladstone and Chamberlain. Yet the second Gladstone administration (1880–85) did not live up to the promise of the election victory. The Cabinet that Gladstone assembled was neither compact nor united. Eight of the members were Whigs, but, of the other three, one—Joseph Chamberlain—was representative of a new and aggressive urban radicalism, less interested in orthodox statements of liberal individualism than in the uncertain aspirations and strivings of the different elements in the mass electorate. Already, as mayor of Birmingham (1873–76), he had embarked upon large-scale schemes of civic improvement, which he did not scruple to call "municipal socialism." At the opposite end of the spectrum, the Whigs were the largest group in the Cabinet, but the smallest in the country. Many of them were already abandoning the Liberal Party; all of them were nervous about the kind of radical program that Chamberlain and the newly founded National Liberal Federation (1877) were advocating and about the kind of caucus-based or-

ganization that Chamberlain favoured locally and nationally. In terms of political logic, it seemed likely in 1880 that the Gladstonian Liberal Party would eventually split into Whig and radical components, the latter led by Chamberlain. For the moment, however, Gladstone was the man of the hour, and Chamberlain himself conceded that he was indispensable.

Third Reform Bill

The government carried a number of important reforms culminating in the Third Reform Bill of 1884, which continued the trend toward universal male suffrage by giving the vote to agricultural labourers, thereby tripling the electorate, and the Redistribution Act of 1885, which robbed 79 towns with populations under 15,000 of their separate representation. For the first time, the franchise reforms ignored the claims of the traditional influences of property and wealth and rested firmly on the democratic principle that the vote ought to be given to people as a matter of right and not of expediency.

The most difficult problems continued to arise in relation to foreign affairs and, above all, to Ireland. When, in 1881, the Boers defeated the British at Majuba Hill and Gladstone abandoned the attempt to hold the Transvaal, there was considerable public criticism. And in the same year, when he agreed to the bombardment of Alexandria in a successful effort to break a nationalist revolt in Egypt, he lost the support of the aged radical, Bright. In 1882 Egypt was occupied, thereby adding, against Gladstone's own inclinations, to British imperial commitments. A rebellion in the Sudan, which led to the sending out of British troops in 1883, was the occasion of one of the most terrible tragedies of the decade. Gen. Charles Gordon, who was dispatched to Khartoum, was killed in 1885, two days before the arrival of a mission to relieve him. Large numbers of Englishmen held Gladstone personally responsible, and, in June 1885, he resigned after a defeat on an amendment to the budget.

The Irish Question. The Irish question had loomed ominously as soon as Parliament had assembled in 1880, for there was now an Irish nationalist group of more than 60 members led by Charles Stewart Parnell, most of them committed to Irish Home Rule; in Ireland itself, the Land League, founded in 1879, was struggling to destroy the power of the landlord. Parnell himself embarked on a program of agrarian agitation in 1881, at the same time that his followers at Westminster were engaged in various kinds of parliamentary obstructionism. Gladstone's response was an Irish Land Act, based on guaranteeing "three *fs*"—fair rents, fixity of tenure, and free sale—and a tightening up of the rules of closure in parliamentary debate. The Land Act did not go far enough to satisfy Parnell, who continued to make speeches couched in violent language; a coercion act was passed by Parliament against Irish agitators and Parnell was arrested. He was released, however, in April 1882 after an understanding had been reached that he would abandon the land war and the government would abandon coercion.

The Phoenix Park Murders

Lord Frederick Charles Cavendish, a close friend of Gladstone and brother of the Whig leader, Lord Hartington, was sent to Dublin as chief secretary on a mission of peace, but the whole policy was undermined when Cavendish, along with the permanent undersecretary, was murdered in Phoenix Park, Dublin, within a few hours of landing in Ireland.

Between 1881 and 1885, Gladstone coupled a somewhat stiffer policy in Ireland with minor measures of reform, but in 1885, when the Conservatives returned to power under Salisbury, the Irish question forced itself to the forefront again. Lord Carnarvon, the new lord lieutenant of Ireland, was a convert to Home Rule and followed a more liberal policy than his predecessor. At the general election of November 1885, Parnell secured every Irish seat but one outside Ulster and urged Irish voters in British constituencies—a large group mostly concentrated in a limited number of places like Lancashire and Clydeside in Scotland—to vote Conservative. The result of the election was a Liberal majority of 86 over the Conservatives, almost exactly balanced by the Irish group, who thus controlled the balance of power in Parliament. The Conservatives stayed in office, but when, in December 1885, the newspapers reported a confidential interview with Gladstone's son, in which he had stated (rightly) that his father had been converted to Home Rule, Salisbury made it clear that he himself was not a convert, and Carnarvon resigned. All Conservative contacts with Parnell ceased, and a few weeks later, in January 1886, after the Conservatives had been defeated in Parliament on a radical amendment for agrarian reform, Salisbury resigned, and Gladstone returned to power.

Split of the Liberal Party. Gladstone's conversion had been gradual but profound, and it had more far-reaching political consequences for Britain than for Ireland. It immediately alienated him further from most of the Whigs and from a considerable number of radicals led by Joseph Chamberlain. He had hoped at first that Home Rule would be carried by an agreement between the parties, but Salisbury had no intention of imitating Peel. Gladstone made his intentions clear by appointing John Morley, a Home Rule advocate as Irish secretary, and in April 1886 he introduced a Home Rule bill. The Liberals remained divided, and 93 of them united with the Conservatives to defeat the measure. Gladstone appealed to the country and was decisively beaten at the general election, in which 316 Conservatives were returned to Westminster along with 78 Liberal Unionists, the new name chosen by those Liberals who refused to back Home Rule. The Liberals mustered only 191, and there were 85 Irish nationalists. Whigs and radicals, who had often seemed likely to split Gladstone's 1880 government on left–right lines, were now united against the Gladstonians, and all attempts at Liberal reunion failed.

Chamberlain, the astute radical leader, like many others of his class and generation, ceased to regard social reform as a top priority and worked in harness with Hartington, his Whig counterpart. In 1895 they both joined a Salisbury government. The Liberals were, in effect, pushed into the wilderness, although they held office briefly and unhappily from 1892 to 1895. Gladstone, 82 years old when he formed his last government, actually succeeded in carrying a Home Rule bill in the Commons in 1893, with the help of Irish votes (Parnell's power had been broken as a result of a divorce case in 1890, and he died in 1891), but the bill was thrown out by the Lords. He resigned in 1894, to be succeeded by Lord Rosebery, who further split the party; at the general election of 1895, the Conservatives could claim that they were the genuinely popular party, backed by the urban as well as the rural electorate. Although Salisbury always stressed the defensive aspects of Conservatism, both at home and abroad, Chamberlain and his supporters were able to mobilize considerable working class as well as middle class support for a policy of crusading imperialism.

Rise of the Conservatives

THE EXPANSION OF EMPIRE

The word imperialism was the key word of the 1890s, just as Home Rule had been in the critical decade of the 1880s, and the cause of empire was associated not merely with the economic interests of businessmen, looking for materials and markets, and the enthusiasm of crowds, excited by the adventure of empire, but with the traditional lustre of the crown. Disraeli had emphasized the last of these associations, just as Chamberlain emphasized the first. When Chamberlain deliberately chose to take over the Colonial Office in 1895, he was acknowledging the opportunities, both economic and political, afforded by a vast "undeveloped estate." The same radical energies that he had once devoted to civic improvement were now directed toward imperial problems, with every effort being made at the same time to make the empire meaningful and attractive to children at school and to the newspaper-reading mass electorate.

In fact, however, it was difficult to pull the empire together politically or constitutionally, certainly to move toward federation, since the interests of different parts were already diverging, and in the last resort only British power—above all, sea power—held it together. The processes of imperial expansion were always complex, and there was neither one dominant theory of empire nor one single explanation of why it grew. White colo-

nies, like Canada or New Zealand and the states of Australia, had been given substantial powers of self-government since the Durham Report of 1839 and the Canada Union Act of 1840. Yet India, "the brightest jewel in the British crown," was held not by consent but by conquest. The Indian "mutiny" of 1857 was suppressed, and a year later the East India Company was abolished; thereafter, given the strategic importance of India to the military establishment, attempts were made to justify British rule in terms of benefits of law and order said to accrue to Indians. "The white man's burden," as the poet Rudyard Kipling saw it, was a burden of responsibility.

It was difficult for the British voter to understand or to appreciate this network of motives and interests. Chamberlain himself was always far less interested in India than the white "kith-and-kin dominions" and in the new tropical empire that was greatly extended in area between 1884 and 1896, when 2,500,000 square miles of territory fell under British control. Even he did not fully understand either the rival aspirations of different dominions or relationship between economic development in the "formal" empire and trade and investment in the "informal" empire where the British flag did not fly.

Victoria's jubilees in 1887 and 1897 involved both imperial pageantry and imperial conferences, but, between 1896 and 1902, public interest in problems of empire was intensified not so much by pageantry as by crisis. British–Boer relations in South Africa, always tense, were further worsened after the Jameson raid of December 1895, and, in October 1899, war began. The early stages of the struggle were favourable to the Boers, and it was not until spring 1900 that superior British equipment began to count. British troops entered Pretoria in June 1900 and Paul Kruger, the Boer president, fled to Europe, where most governments had given him moral support against the British. Thereafter the Boers followed guerrilla tactics, and the war did not end until May 1902. It was the most expensive of all the 19th-century "little wars," with the British employing 450,000 troops, of whom 22,000 never returned. Just as the Crimean War had focussed attention on "mismanagement," so the South African (Boer) War led to demands not only for greater "efficiency" but for more enlightened social policies in relation to health and education.

The South African War

While the war lasted, it emphasized the political differences within the Liberal Party and consolidated Conservative–Unionist strength. Rosebery's Liberal imperialism was totally uncongenial to young pro-Boer Liberals like Lloyd George. A middle group of Liberals emerged, but it was not until after 1903 that party rifts were healed. The Unionists won the "khaki election" of 1900 and secured a new lease of power for nearly six years, but their unity also was threatened after the Peace of Vereeniging in May 1902. Salisbury retired in 1902, to be succeeded by his nephew, Arthur Balfour, a brilliant man but a tortuous and insecure politician. There had been an even bigger break in January 1901 when the Queen died, after a brief illness, in her 82nd year. She had ruled for 64 years and her death seemed to mark not so much the end of a reign as the end of an age.

LATE VICTORIAN AND EDWARDIAN BRITAIN

Her successor, Edward VII, 59 years old, had never been on good terms with his mother, whose ways of life were sharply different from his. He, too, gave his name to an age: flamboyant, ostentatious, at times vulgar and strident, with picturesque contrasts of fortune and circumstance. Yet the sharpness of the contrast between "Edwardian" and "late Victorian" should not be exaggerated. The last decade of the 19th century and the first decade of the 20th century had much in common, and there had been bigger breaks in mood and preoccupation between the high-Victorian years and the 1890s.

Darwin's disciple, Thomas Huxley, an influential popularizer of science, had noted during the 1870s that everything was in question—opinions, institutions, and conventions—and the questioning thereafter never stopped. "The disintegration of opinion is so rapid," one writer put it in the 1880s, "that wise men and foolish are equally ignorant where the close of this waning century will find us." The writers of the last decades of the 19th century included iconoclasts like George Bernard Shaw and deviants like Oscar Wilde; for both, as for many others like them, all that was established was now suspect. Some commentators wrote of "a general revolt" against the accepted canons of the midcentury, a revolt influenced by thinkers outside Britain and challenging not only political or social assumptions (for example, about law and will or self-help and respectability) but also 19th-century culture as a whole, the culture of an industrialized society transformed through individual enterprise.

The economy. Changes in economic conditions during the last decades of the century were obviously of crucial importance. Mid-Victorian prosperity had reached its peak in a boom that collapsed in 1873. Thereafter, although national income continued to increase (nearly four times at constant prices between 1851 and 1911), there was a persistent pressure on profit margins, with a price fall that lasted until the mid-1890s. Contemporaries talked misleadingly of a "great depression," but however misleading the phrase was as a description of the movement of economic indexes, the period as a whole was one of doubt and tension. There was anxious concern about both markets and materials, and the fact that there was a retardation in the national rate of growth to below 2 percent per annum was even harder to bear when the growth rates of competitors were rising, sometimes in spectacular fashion.

Slowing of growth rate

The interests of different sections of the community diverged between 1870 and 1900 as they had diverged before the mid-Victorian period of equipoise. In particular, arable and meat-producing farmers felt the full weight of foreign competition in cereals, and many, though not all, industrialists felt the growing pressure of foreign competition both in old and new industries. As a result of improved transport, including storage and refrigeration facilities, and the application of improved agricultural machinery, overseas cereal producers fully penetrated the British market. In 1877 the price of English wheat stood at 56s. 9d. a quarter (1846: 54s. 6d); for the rest of the century it never again came within 10s. of that figure. During the 1890s, therefore, there was a sharp fall of rents, a shift in land ownership, and a challenge to the large estate in the cereal-growing and meat-producing areas of the country. The fact that dairy and fruit farmers flourished did not relieve the pessimism of most spokesmen of the threatened landed interests.

In industry, where there were new forms of power and a trend toward bigger plants and more impersonal organization, there were also moves throughout the period to increase cartels and amalgamations. Britain was never as strong or as innovatory in the age of steel as in the earlier age of iron—by 1896 British steel output was less than that of either the United States or Germany—while the textile industry was declining absolutely. Exports fell between 1880 and 1900 from £105,000,000 to £95,000,000. There were many explanations of what was happening, psychological as well as economic, but none of them was encouraging. Yet the country's economic position would have been completely different, had it not been for Britain's international economic strength as banker and financier. During years of economic challenge at home, capital exports greatly increased, until they reached a figure of almost £200,000,000 per annum before 1914, and investment income poured in to rectify adverse balances on visible trade accounts. During the last 20 years of peace before 1914, when Britain's role as *rentier* was at its height, international prices began to rise again, continuing to rise, with fluctuations, until after the end of World War I.

The rise of labour. Meanwhile, whether prices were falling or rising, labour in Britain was increasingly discontented, more articulate, and more highly organized. Throughout the period, national income per head grew faster than the continuing population growth (which stayed at above 10 percent per decade until 1911, although the birth rate fell sharply after 1900), but neither the growth of income nor the falling level of retail prices

until the mid-1890s made for industrial peace. By the end of the century, when pressure on real wages was once again increasing, there were 2,000,000 trade unionists in unskilled unions as well as in skilled unions of the midcentury type, and by 1914 the figure had doubled.

Labour and politics

There were also significant political changes. Some of the new union leaders were confessed socialists, anxious to use political as well as economic power to secure their objectives, and a number of socialist organizations emerged between 1880 and 1900—all conscious, at least intermittently, that, whatever their differences, they were part of a "labour movement." The Social Democratic Federation, influenced by Marxism, was founded in 1884; it was never more than a tiny and increasingly sectarian organization. The Independent Labour Party, founded in Bradford in 1893, had a more general appeal, while the Fabian Society, founded in 1883–84, included intellectuals who were to play a big part in 20th-century labour politics. In February 1900 a labour representation conference was held in London at which trade unionists and socialists agreed to found a committee, with Ramsay MacDonald as first secretary, to promote the return of Labour members to Parliament. This conference marked the beginning of the 20th-century Labour Party, which, with Liberal support, won 29 seats at the general election of 1906. Although until 1914 the party at Westminster for the most part supported the Liberals, in 1909 it secured the allegiance of the "Lib-Lab" miners' members. Financially backed by the trade unions, it was eventually to take the place of the Liberal Party as the second party in the state.

THE RETURN OF THE LIBERALS (1905–14)

The Liberals returned to power in December 1905 after Balfour had resigned. Between the end of the South African War and this date, they had become more united as the Conservatives had disintegrated. In 1903 Chamberlain had taken up the cause of protection, thereby disturbing an already uneasy balance within Balfour's cabinet. He failed to win large-scale middle class or working class support outside Parliament as he had hoped, and the main effect of his propaganda was to draw rival groups of Liberals together to protect free trade. At the general election of 1906 the Liberals won 377 seats, which gave them an enormous majority of 84 over all other parties combined. Their leader was Sir Henry Campbell-Bannerman, a cautious Scot, who had stayed clear of the extreme factions during the South African War. He formed an able cabinet that included radicals and Liberal imperialists, and when he retired in 1908, H.H. Asquith moved from the Home Office to become prime minister.

Social legislation. Social reform had not been the chief cry at the general election, which was fought mainly on the old issues of free trade, temperance reform, and education. In many constituencies there was evidence of Nonconformist grievances against a Balfour education act of 1902 that abolished the school boards, transferred educational responsibilities to the all-purpose local authorities, and laid the foundations of a national system of secondary education. Yet local and national inquiries, official and unofficial, into the incidence of poverty had pointed to the need for public action to relieve distress, and, from the start, the new Liberal government embarked upon a program of social legislation. In 1906 free school meals were made available to poor children; in 1907 a school medical service was founded; in 1908 a Children's Act was passed, along with an Old Age Pensions Act granting pensions under prescribed conditions to people over 70; in 1908 the miners were given a statutory working day of eight hours; and in 1909 trade boards were set up to fix wages in designated industries where there was little or no trade-union strength, and labour exchanges were created to try to reduce unemployment (a subject that was also being investigated locally and nationally) and to increase mobility. The vigour of these reforms owed much to a partnership between Winston Churchill at the Board of Trade and Lloyd George, chancellor of the exchequer.

Lloyd George's budget of 1909 set out deliberately to raise money to "wage implacable warfare against poverty and squalidness." The money was to come in part from supertax on high incomes and from capital gains on land sales. The budget so enraged Conservative opinion, inside and outside Parliament, that the Lords, already hostile to the trend of Liberal legislation, rejected it, thereby turning a political debate into a constitutional one. Passions were as strong as they had been in 1831, yet, at the ensuing general election of January 1910, the Liberal majority was greatly reduced and the balance of power in Parliament was now held by Labour and Irish Nationalist members. The death of Edward in May 1910 and the succession of the politically inexperienced George V added to the confusion, and it proved impossible to reach agreement between the parties on the outlines of a Parliament bill to define or to curb the powers of the House of Lords. After a Liberal Parliament bill had been defeated, a second general election in December 1910 produced similar political results to those earlier in the year, and it was not until August 1911 that the peers eventually passed the Parliament Act by 131 votes to 114. The act provided that money bills could become law without the assent of the Lords and that other bills would also become law if they passed in the Commons and failed in the Lords three times within two years. The act was finally passed only after the Conservative leadership had repudiated the "diehard peers" who refused to be intimidated by a threat to create more peers.

The Parliament Act of 1911

In the course of the struggle over the Parliament bill, strong, even violent, feelings had been roused among lords who had seldom bothered hitherto to attend their house. Their intransigence provided a keynote to four years of equally fierce struggle on many other issues in the country, with different sectional groups turning to noisy direct action. The Liberals remained in power, carrying important new legislation, but they faced so much opposition from extremists, who cared little either about conventional political behaviour or the rule of law, that these years have been called by the American historian, George Dangerfield, "the strange death of Liberal England." The most important legislation was once more associated with Lloyd George—the National Insurance Act of 1911, which provided, on a contributory basis, for limited unemployment and health insurance for large sections of the population.

Liberal difficulties. The National Insurance Act, which Parliament accepted without difficulty, was the subject of much hostile criticism in the press and was bitterly opposed by doctors and duchesses. Nor did it win unanimous support from labour. The parliamentary Labour Party itself mattered less during these years, however, than extraparliamentary trade-union protests, some of them violent in character—"a great upsurge of elemental forces." There was a wave of strikes in 1911 and 1912, some of them tinged with syndicalist ideology, all of them asserting, in difficult economic circumstances for the workingman, claims that had never been made before. Old-fashioned trade unionists were almost as unpopular with the rank and file as capitalists. In June 1914, less than two months before the outbreak of World War I, a "triple alliance" of transport workers, miners, and railwaymen was formed to buttress labour solidarity. In parallel to labour agitation, the suffragettes, fighting for women's rights, resorted to militant tactics that not only embarrassed Asquith's government but tested the whole local and national machinery for maintaining order. The Women's Social and Political Union, founded in 1903, was prepared to encourage illegal acts, including bombing and arson, which led to sharp police retaliation, severe sentences, harsh and controversial treatment in prison, and even martyrdom.

Irish difficulties

The issue that created the greatest difficulties, however, was one of the oldest: Ireland. In April 1912, armed with the new powers of the Parliament Act, Asquith introduced a new Home Rule bill. Conservative opposition to it was reinforced on this occasion by a popular Protestant movement in Ulster; and the new Conservative leader Bonar Law, who had replaced Balfour in 1911,

gave his covert support to army mutineers in Ulster. No compromises were acceptable, and the struggle to settle the fate of Ireland was still in full spate when war broke out in August 1914. Most ominously for the Liberals, the Irish Home Rule supporters at Westminster were losing ground in southern Ireland, where in 1913 a militant working class movement entered into close alliance with the nationalist forces of Sinn Féin. Ireland was obviously on the brink of civil war.

The international crisis. The seeds of international war, sown long before 1900, were nourished between the resignation of Salisbury and August 1914. Two intricate systems of agreements and alliances—the Triple Alliance of Germany, Austria-Hungary, and Italy, and the Triple Entente of France, Russia, and Britain—faced each other in 1914. Both were backed by military and naval apparatus (Britain had been building a large fleet, and Richard Haldane had been reforming the army), and both could appeal to half-informed or uninformed public opinion. The result was that a war that was to break the continuities of history started as a popular war cheered by the crowds.

The Liberal government under Asquith faced a number of diplomatic crises from 1908 onward. Throughout a period of recurring tension, its foreign minister, Sir Edward Grey, often making decisions that were not discussed by the Cabinet as a whole, strengthened the understanding with France that had been initiated by his Conservative predecessor in 1903. An alliance had already been signed with Japan in 1902, and in 1907 agreements were reached with Russia. Meanwhile, naval rivalry with Germany familiarized Englishmen with the notion that if war came, it would be with Germany. The 1914 crisis began in the Balkans, an old storm centre, where the heir to the Austro-Hungarian throne was assassinated in June 1914. Soon Austria, backed by Germany, and Russia, supported by France, were arrayed against each other. The British Cabinet was divided, but after the Germans invaded Belgium on August 4, thereby violating a neutrality that Britain was committed by treaty to support, Britain and Germany went to war. Bonar Law pledged full support, as did John Redmond, the Irish leader at Westminster; only a few pacifists, radicals, and socialists stood on one side. Few foresaw a war of attrition or had any intimation of the profound economic, social, and political changes that lay in store. (As.B.)

XIV. Britain since 1914

THE PERIOD OF THE WORLD WARS

World War I. In the political and constitutional areas, the war witnessed many significant modifications in parliamentary and administrative practices required for transforming democratic processes designed for peace into an efficient machine for waging war. Thus, to avoid partisan division on war issues, no elections were held during the war—the general election, provided by law at the latest in 1915, was postponed by parliamentary resolution. There were, nevertheless, shifts in power. The first formal change came in May 1915, when the Liberal government under Asquith, weakened by criticism of the War Office and the munitions shortage and suffering from controversy over strategy between Churchill at the Admiralty and John Fisher, the first sea lord, was reorganized as a "Coalition" government, including Conservatives and one Labourite. But continued discontent in Parliament over the conduct of the war, distrust of Asquith's capacity as a war leader, and the weakening of his control over the Cabinet forced his hand in December 1916, and he was replaced as prime minister by David Lloyd George. Political power became largely concentrated in the War Cabinet of five, with parliamentary support taken for granted. As political processes, these changes were hardly revolutionary—well before 1914, party organization controlling the electorate and tighter discipline within parliamentary parties were elevating the roles of prime minister and Cabinet.

Wartime government

While intervention of the state in economic and social questions had been increasing since the late Victorian era and accelerated after 1906, during 1914–18 governmental controls were greatly expanded in marshalling resources for the war effort. DORA (Defence of the Realm Acts), though usually administered with caution and discretion, authorized regulations "for public safety and defence," control of armament plants, the requisitioning of factories, and the control of production and distribution. But authority was exercised through advisory commissions and was usually limited to establishing priorities. In munitions, coal, and railroads, controls came closest to outright government ownership. Various measures encouraged home food production and regulated prices and wages, but rationing of foodstuffs came only in 1918, and to a limited degree.

The prolongation of the war beyond all initial expectations complicated these problems and added to them. When voluntary enlistment proved insufficient to replace the thinning ranks of the armed forces, after long debate, in May 1916, came military conscription of all males between 18 and 41—the first such in English history. Labour unrest, at a peak at the outbreak of the war and further aroused by fears of the consequences of a war economy, was a constant concern, with serious strikes and stoppages in 1917 and 1918, but government and industry managed to maintain, without compulsion, a fairly satisfactory degree of order. In all ranks of society the tragedy of long casualty lists (of 6,000,000 in uniform from the United Kingdom some 750,000 lost their lives and 1,700,000 others were wounded) made heavy inroads on national morale. With the Lloyd George government a policy of "war to the finish" terminated any prospects for an early end to the war by negotiation, and in some circles, particularly the literary and the intellectual, patriotic support of the war effort turned to one of horror and despair at man's inhumanity to man.

Deterioration of morale

Public morale, however, was periodically fortified by talk of reconstruction, social reform, "a better world." There were indeed winds of change during the war. What peace had not secured for women, the war did: women's suffrage in 1918, and inevitably so because of their role in the war—in the auxiliaries of the armed forces, in the nurses corps, and particularly in industry—in offices, in shops, on the farms, on trams and buses. Because of the heavy reliance on home production of foodstuffs, the status of the farmer and the agricultural labourer attained a respectability unknown for two generations. In general, class lines, so pronounced in Victorian and Edwardian days, were becoming blurred, particularly in matters of dress. Economic inequalities were lessened. There was a sharp decline in servant keeping. A salaried and professional "middle class" grew apace, and the traditional cleavage between landowners and men of commerce disappeared for good. Nonetheless, distinct class lines remained in education, in accent, in class consciousness, and in life style generally.

Lloyd George, always sensitive to public opinion, took the lead in establishing by statute the Ministry of Reconstruction in 1917; investigations of industry, public health, transport, and housing were soon underway. An education act set the school-leaving age at 14, envisioned raising it to 15, and provided for part-time schooling until 16.

The power structure that waged and won the war began as a Liberal government in 1914 and ended as a Coalition dominated by Conservatives, though still under the leadership of a Liberal, Lloyd George. The split in 1916 between those Liberals supporting Asquith and those supporting Lloyd George was widened in May 1918 by Asquith's motion for a committee of inquiry in the Commons to investigate divergent statements of the Prime Minister and the director of military operations in the War Office over the strength of the army. Asquith's motion was defeated, with 100 Liberals voting for his motion and 71 against. But even more important, the composition of the constituencies of the major parties was uncertain, as well as the issues that would divide them after the war.

One matter became increasingly clear. The Labour Party under the leadership of J. Ramsay MacDonald and

Growth of the Labour Party

Arthur Henderson, though still small in numbers in the Commons, was becoming a stronger voice for social democracy. Labour, though somewhat divided by issues of war and peace, managed to maintain its solidarity as a parliamentary party, while moving to the left in social and economic matters. By 1918 Labour had established unity on certain essentials: (1) reorganization of its structure to provide for active membership through individuals, as well as through trade unions and socialist societies; (2) a restatement of purpose in socialist terms—"a new social order based . . . on deliberately planned cooperation in production and distribution for the benefit of all who participate by hand or brain"; (3) a decision to leave the Coalition at the end of the war and contest the next general election as an independent party.

Aftermath of the war (1918–24). World War I ended November 11, 1918. England's mood was one of profound relief and a sense of triumph but also one of optimism for the future. It was perhaps unfortunate that the general election came so promptly (polling day was December 14)—unfortunate in its revival of party bitterness, revelation of personal animosities, and demands for revenge against Germany. But an immediate election was essential; the existing Parliament had been elected in 1910. In the campaign the significant factor was Lloyd George's decision to maintain the Coalition with both Conservative and Liberal support and the arrangement that no Conservative candidate would oppose a Liberal pledged to the Coalition. This divided the Liberal vote, rendering it unlikely that anything approaching proportional representation would result. The main issue was this: should Lloyd George and the Coalition continue? The result was their stunning triumph with some 478 seats out of 707, though the popular vote for their candidates was slightly in excess of their opponents. Asquith Liberals were crushed and Labour emerged, with 59 seats, as the official opposition.

The Coalition continued in power until October 1922. Its tasks and those of the British people were formidable: to negotiate a durable peace mindful of British interests; to restore a peacetime economy favourable to British production and world trade; to absorb the returning armed forces in a changing economy and society; and to solve the problem of Irish national aspirations. These problems were compounded by a conflict of generations (especially between those returning from the trenches and the high seas, and their elders), by an almost irrational desire to forget the war and return to "normalcy," and, thus, by a breakdown of morale.

So it was that the peace treaty negotiated at Versailles was debated in England in a partisan spirit and increased the difficulty of the government in clarifying and achieving policies in the national interest: limited disarmament designed to slow down the arms race; diplomacy by negotiation to relieve international tension; general rehabilitation of Germany. In these years, in spite of some 23 international conferences, questions of disarmament and German reparations seemed without solution.

The postwar economy

As to the economy, no one seemed prepared for the situation that developed. A brief postwar boom rather encouraged the business world in its inclination to return to prewar policies and methods: free trade abroad and laissez-faire at home; restoration of the gold standard, which had been temporarily suspended in 1919; reduction of wages and other costs of production, if necessary to meet foreign competition. But when European markets were opened to the expanding economies of the United States and Asia, Britain suffered a decided decline in production and foreign trade relative to its prewar status. The chief consequence was an alarming rise in unemployment—reaching, in July 1921, 22.4 percent of all insured workers (who comprised nearly the entire work force).

Politics, influenced by uncertainties at home and abroad, tended to become motivated by fear—fear of the other side—and to polarize political groups. A new "Right" sought to erase the old distinction between Liberal and Conservative and to advocate a limited role of the state in society and the economy, to stabilize Europe as a British market, to keep a safe distance from Russia, and to strengthen imperial ties. The "Left," composed of Labour and dissident Liberals, urged nationalization of key industries and government housing, supported collective security and disarmament, encouraged ties with Russia, and was increasingly skeptical about the empire.

Resignation of Lloyd George

The Lloyd George government met the crisis in the coal industry with temporary subsidies, extended unemployment insurance, and established the Irish Free State. But the Coalition steadily weakened; in October 1922 Conservatives voted their independence and Lloyd George resigned. There followed three governments in three years. The first, a Conservative government under Bonar Law, sought to capitalize on the cry for "tranquility"; Law's serious illness soon brought about his replacement (May 1923) not by Lord Curzon, his logical successor, but by Stanley Baldwin, a member of the cabinet only since 1921. He successfully reunited the Conservative Party but failed in his attempt to get party and national support for a protective tariff. As a result of the general election of December 1923, Labour, with 191 seats in the Commons, formed with Liberal support the first Labour government in British history. In its short rule of ten months the only significant change in domestic policy was in legislation establishing new procedures for government housing. MacDonald, foreign minister as well as prime minister, was more active abroad, where he helped set in motion the Dawes Plan for German reparations, which brought evacuation of the Ruhr. Soviet Russia was recognized. But it was its policy toward Russia, including matters of trade, that lost Labour Liberal support; and in the general election of October 1924 Stanley Baldwin and the Conservatives returned to office with 48 percent of the popular poll and 419 seats in the Commons. Labour more than held its own in the popular vote, but the Liberals collapsed, polling but 18 percent of the vote.

Stanley Baldwin as prime minister

Stability and crisis (1924–31). It was perhaps logical that Stanley Baldwin was prime minister, 1924–29. He was fairly typical of Britishers of the 1920s—plain-spoken, rather modest in manner, honest, patient. He did not profess to know all the answers and was committed to no policy. But he did seek stability, tranquility, peace of mind, good will among men; in such an atmosphere, he insisted, problems would find solutions. So it was, to a degree. By mutual consent among parties British armaments were drastically reduced. Austen Chamberlain, foreign secretary, received good marks for his part in deliberations leading to the Pact of Locarno (1925), providing for arbitration of disputes in western Europe. There was little dissent to the creation of the British Broadcasting Corporation as a monopoly in 1926. National health insurance, unemployment insurance—these, in principle, ceased to divide the nation. Under Neville Chamberlain at the Ministry of Health, more social legislation was enacted than by either the Labour government that had preceded or the one that followed. This included implementation of Chamberlain's Housing Act of 1923, with over 400,000 new dwellings, and the Local Government Act of 1929, which abolished the Boards of Guardians.

In the economy, production went beyond prewar figures and unemployment levelled off at 10 percent. But such favourable signs were illusory; the significant fact was that Britain lagged behind the rest of the industrial world —by 1929 the volume of exports was still below the 1913 figure, and the annual value of exports declined after the return to the gold standard in 1925. That problems of production and of labour were out of control was evident in the General Strike of 1926. This came from the crisis in coal—the largest single industry—where royal commissions produced but temporary measures to deal with rising costs of production. An end to governmental subsidies supplementing wages led to the owners' insistence on wage reductions. Rejection of the new wage scale by the Miners' Federation of Great Britain brought lockout notices, closing down the mines on May 1, 1926. An overwhelming vote of unions affiliated with the national Trades Union Congress (TUC) approved a general strike in support of the miners. In actuality, the General Strike affected about 70 percent of union members and has been

The General Strike of 1926

aptly described as "a strike under wraps." Most of the strikers had served in the armed forces during the war, and few of them had revolutionary intent. The strike was conducted with little violence and no loss of life. The government's attitude, however, was one of firmness; it declared the strike "unconstitutional" and "illegal" and soon persuaded the general council of the TUC to accept revision of the wage scale after reorganization of the industry. The strike ended May 12, and Baldwin broadcast a message calling for a general reconciliation. It was his greatest hour.

The aftermath of the strike was less successful. The government took no action to bring about reorganization of the coal industry and passed in 1927 a statute that declared sympathetic strikes illegal. Furthermore, the Baldwin government produced no program for dealing with general unemployment and did nothing to revitalize other basic industries such as steel and textiles or to assist agriculture, again in difficulties. Treasury economies stalled advances in secondary education. In foreign policy nothing was done to implement the spirit of Locarno. In imperial affairs, largely due to L.S. Amery at the Colonial Office, policy was more progressive. The Imperial Conference of 1926 adopted Balfour's report calling for abrogation of all British legislative control in the dominions—this became the Statute of Westminster in 1931. In 1927 was created the Simon Commission to review the political situation in India since 1919, when dyarchy had been adopted.

In the general election of May 1929, Labour profited by the inaction of the Baldwin government in many areas and emerged with a plurality in Parliament. The Liberals, now under Lloyd George, who had replaced Asquith as party leader in 1926, made a gigantic effort in support of state action to solve the problems of the economy and finished respectably with 23 percent of the popular vote and 59 seats. Nevertheless, they came in a poor third.

MacDonald's government

MacDonald formed a moderate Labour Cabinet the major accomplishments of which were again in foreign affairs. Philip Snowden, chancellor of the exchequer, helped implement the Young Plan for German payment of reparations; Arthur Henderson, foreign secretary, presided over the commission at The Hague that brought allied evacuation from the Rhineland. Thanks in large part to MacDonald himself, progress was made on naval reduction at the London Naval Conference in 1930. The Round Table Conference was a step toward a federated India. But the record in domestic affairs was found "meagre" by the usually objective British periodical *The Economist*. The Great Depression compounded all of England's problems. Escalating unemployment (23 percent of the insured workers by mid-1931) brought such demands on the Unemployment Insurance Fund that a budgetary and financial crisis threatened the country's international credit. Proposals for drastic cuts in unemployment insurance and other social services divided the Cabinet, and MacDonald resigned in August 1931. Neither Baldwin nor Sir Herbert Samuel (now Liberal leader) were anxious to assume responsibility alone, and MacDonald was persuaded to form a coalition, the so-called National Government (August 24).

The National Government: crisis and recovery (1931–39). The necessary financial credits were secured abroad, and the National Government, formed to deal with an emergency, was overwhelmingly confirmed in office in the general election in October 1931. The Parliamentary Labour Party had, however, repudiated MacDonald and fought the election independently; the result was disastrous—every former cabinet member save one was defeated, and only 52 Labourites were returned. In the election, the National Government made a virtue of the division of opinion in its ranks—voters were merely asked to support "Safety and the Union Jack." Whether diversity of opinion could produce action was soon tested. To meet the problems of finance and trade, the government pushed through a general protective tariff—the Liberal and Labour free traders in the Cabinet were allowed to "differ" both in the debate and in the poll. But the extension of the tariff to imperial preference brought resignation of the free traders.

Continued effects of depression

As to economic matters in general, the Depression continued until 1933 (the drop in production from 1929 to 1932 was 16 percent), with substantial recovery thereafter (by 1937 production was 50 percent above that of 1932). British industry turned to the home market with housing (average annual construction of 270,000 houses) and new industries—automobiles, electrical applicances, industrial chemistry. Recovery, however, was only in relation to the 1920s, for the United Kingdom's share in world trade continued to decline. Unemployment, though reduced, was concentrated in certain areas and trades. The very significant Unemployment Act of 1934 reorganized the system of relief, and for the working classes life was, in general, somewhat better in the 1930s than in the 1920s.

In June 1935 Baldwin replaced MacDonald as prime minister. And a few months later a general election confirmed the National Government, but with considerable gains for Labour. George Lansbury, Labour leader since 1931, but now at odds with his party on foreign policy, resigned; Clement Attlee, who had proved himself as a parliamentarian, became Labour leader. In domestic affairs the most important episode for Baldwin was the abdication crisis. The death of George V in January 1936 led to the succession of Edward VIII. For many months, few outside official circles knew of his friendship with an American-born lady, Mrs. Simpson, already twice married and once divorced. Her second divorce was granted in October. The government, with Labour support, opposed her marriage to the King and held firm against a "King's Party" forming around a strange nucleus including Winston Churchill, Sir Oswald Mosley, and George Bernard Shaw. In a message to Parliament (December 10), Edward VIII abdicated and his brother was proclaimed King George VI. But it soon became clear that the institution of monarchy had not suffered.

Abdication of Edward VIII

After the coronation of George VI in May 1937, Baldwin was replaced as prime minister by Neville Chamberlain, whose administration was largely concerned with meeting the social and economic problems of the late 1930s. The 1930s as a whole were preoccupied with "planning." PEP (Political and Economic Planning) was a nonpartisan agency for research—beginning in 1933 a series of significant reports dealt with iron and steel, cotton, coal, international trade, public health, housing, the press, and other areas of public concern. *Plan or No Plan* (1934), by Barbara Wootton of London University, urged a planned economy. *Reconstruction: A Plan for a National Policy* (1933) and *The Middle Way* (1938), by Harold Macmillan, a Conservative and a future prime minister, urged a minimum wage and partial nationalization of industry. B. Seebohm Rowntree, studying poverty in the city of York, found that 19 percent of the population was existing on a substandard diet. The distribution of national income came in for careful study and led to scholarly studies of unemployment and "the depressed areas." Implementation of some of the ideas did not have to wait. Some 120 railway companies were amalgamated into four systems. The Central Electricity Board purchased current and distributed it through "a grid"—of incalculable importance when war came. With the creation of the Exchange Equalization Fund (1932), the Bank of England was all but nationalized, and the nationalization of coal royalties in 1938 was a long step toward nationalization of that industry. As to steel, a committee from the industry and a committee from the government determined prices and controlled production. Altogether, "nationalization" was well under way before World War II.

Beginning of nationalization

Foreign policy and appeasement (1931–39). In July 1931 each of the party leaders paid pious tribute to the League of Nations, to disarmament, and to the renunciation of war. But statesmanship did not bridge the gap between piety and circumstance. The carefully prepared World Disarmament Conference that convened at Geneva in February 1932 proved a disappointment. Any decisive action to break the deadlock of French and Ger-

man demands depended on a military commitment that Britain refused to give. On questions of war and peace, the climate of thought in England was negative. A vague pacifism did not consider how peace was to be maintained. Collective security through the League of Nations was generally supported—as long as no obligations were incurred. This seemed to be the purport of the so-called Peace Ballot of 1934, a house-to-house canvass organized by the League of Nations Union, in which 40 percent of those polled favoured disarmament.

In his successful election campaign of 1935, Baldwin advocated collective action by the League in the border dispute between Italy and Abyssinia but added that war was not anticipated. But while government spokesmen were endorsing the League, Sir Samuel Hoare and Pierre Laval, foreign ministers for England and France, were drafting in private the proposal to settle the dispute by handing over half of Abyssinia to Italy. Its disclosure (December 9) brought a flood of protest in the press, the pulpit, and the electorate that forced the government to repudiate the agreement. Hoare resigned, to be succeeded by Anthony Eden. But there was still no will to impose sanctions on Italy, which completed without interference the conquest of Abyssinia.

The Spanish Civil War

The year 1936 was one of crisis. There was the abdication at home, and abroad the unfolding of Nazi policy in Europe and the outbreak of the Spanish Civil War. The usually placid *Annual Register* described British policy as hesitant, indecisive, apologetic, content to drift. The German military occupation of the Rhineland (March 1936) in violation of Versailles was accepted by the British government, with little dissent from Labour, as a *fait accompli;* few favoured sanctions against Germany and many thought Germany was justified. This was the beginning of appeasement.

British policy toward Spain in the civil war between the Loyalists to the Republic and the "nationalist rebels" led by Francisco Franco was hardly more forthright. Britain was the chief sponsor of "nonintervention" by the powers, which was something of a farce since Fascist Italy and Nazi Germany sent military aid to the rebels, and the Soviet Union the same, on smaller scale, to the Republic. In actuality, Britain did take sides—the government sympathized with the rebels, the Labour opposition with the Loyalists. But in public opinion generally, cleavage cut across party lines. In general, the Spanish Civil War marked the end of pacifism as a fashionable attitude.

Neville Chamberlain, as prime minister, dominated foreign policy from May 1937; the subordinate role assigned the Foreign Office contributed to Eden's resignation early in 1938. Policy, determined by Chamberlain and a few advisers, put little faith in collective security and sought direct negotiation with Hitler and Mussolini —compromise and appeasement where necessary—to reduce tensions that might lead to war. In an important interview in November 1937 Lord Halifax told Hitler that Britain would not oppose boundary changes in central Europe if they came by "peaceful evolution." But Chamberlain was not without a strategy of his own: he would settle differences with Mussolini and thus strengthen his hand against Hitler.

But in the event, negotiation tempered by appeasement merely brought a succession of crises. In March 1938

Munich conference

Austria was absorbed into the German *Reich*. In August 1938 the "Runciman mission" failed in its attempt to mediate between Germany and Czechoslovakia over the status of German-speaking Sudetenland, a part of Czechoslovakia. In September, at Munich, Chamberlain, along with the French premier Édouard Daladier, Mussolini, and Hitler, agreed to the cession of the Sudetenland to Germany but accompanied with a guarantee of the integrity of the remainder of Czechoslovakia. When Chamberlain returned to London he proclaimed that the agreement meant "peace for our time." Six months later, however, the Nazis invaded Czechoslovakia and seized control. Now at last Chamberlain denounced Hitler; rearmament was stepped up and policy reversed. Guarantees of support were given to Poland, Romania, and Greece, but Chamberlain's patient efforts to include the Soviet Union in the security system ended abruptly with the signing (August 23) of the German-Soviet Nonaggression Pact. Germany invaded Poland on September 1, and when an ultimatum to Germany calling for a cessation of hostilities went unanswered, Chamberlain broadcast to the nation, Sunday morning, September 3, that Britain was at war.

World War II. World War II was "total war" and, as such, was in many ways a conflict in which the civilian and the man in uniform shared dangers and hardships in common. Air raid warnings began the Battle of London on the first day of the war. Two days before, on September 1, began the evacuation from danger zones, and in three days 1,473,000 persons were relocated. Two million others had already removed themselves privately, some to the country, some to the dominions, others to the United States. Schooling for a time was demoralized, and it is estimated that by the following January 1,000,000 children had not yet been placed in classrooms. Construction began at once on a program of 2,500,000 outdoor household steel shelters designed to protect 10,000,000 persons against air attack. They sold for £5 but were distributed free to low-income families.

Chamberlain broadened his government to include Winston Churchill at his old post in the Admiralty and also Anthony Eden. Hitler's Polish campaign quickly over in September, there followed six months of the "Phony War," with land operations almost at a standstill and national morale in Britain diminished. The British consoled themselves with the conviction that if it were to be an endurance contest control of the seas and blockade of Germany would eventually bring victory. But any complacency was suddenly jolted in April 1940 by the German invasion of Denmark and Norway; the collapse of Norway led to an angry Commons' debate in which some 100 Conservatives refused continued support of Chamberlain, who forthwith resigned (May 10). King George was inclined to Halifax as prime minister, but on Chamberlain's advice he sent for Churchill, who formed a coalition government, with a five-member war cabinet including the Labour leader, Attlee, who became in effect leader of the Commons. Another key appointment was that of Ernest Bevin, a trade union official, as minister of labour and national service.

The wartime government

An inspired Churchill led the country in the "miracle of Dunkirk"; at the end of May, 338,000 Allied troops were evacuated to Britain after the Germans had smashed their way to the French coast. But this episode was soon overshadowed by the Battle of Britain in August and September 1940—the most critical period of the war. Germany threatened invasion, and for that to succeed it must first cripple British defenses—air fields, radar stations, London docks—and attain air supremacy. But the Royal Air Force stood up against all attacks and by September 15 was having the better of it. Some of the most stirring narratives of the war relate the experience of "the Blitz." For a time in the metropolitan area one out of every seven was sleeping in a public shelter—a basement, a railway arch, a "tube" station. From July to December 1940 civilian casualties in air raids numbered 23,000 dead—more than in the armed forces.

The war at home remained grim in the spring of 1941 with aerial attacks on Plymouth (600 killed in five days), in Liverpool (death toll of 1,900 in a week), in London (1,400 deaths in two days and the destruction of the chamber of the Commons), and elsewhere. But 1941 was also the year in which Britain found the answer to the manpower problem in the Registration for Employment Order, which eventually mobilized into the services or into industry 94 percent of all males between the ages of 14 and 64. And in 1941 came "lend-lease" for war supplies from the United States, the Nazi invasion of the Soviet Union, and the Japanese attack on Pearl Harbor. The Grand Alliance was formed, and by the end of 1942—with allied landings in North Africa, the rout of the Germans in Libya, and the counterattack against the Germans in Russia—Churchill could speak of "the end of the beginning."

By 1943 it was clear that the war was bringing change at home. World War II was undoubtedly the most socially levelling experience in modern English history—in the risks of war, in food and shelter, in clothing and amusement, and to a degree in taxation. "Planning," in vogue in the 1930s, now became more systematically applied, for war, of course, but also for peace. Commissions drafted proposals for the use of land in town and country. And the Beveridge Report, December 1942 (Sir William Beveridge was chairman of an interdepartmental committee), outlined a program of social insurance embracing in theory all persons but in application classified according to need, with a "national minimum" of income guaranteed to all. Impressive as it was, the report was merely "welcomed" and not endorsed by the Commons and had to await the end of the war for serious consideration. The most significant piece of legislation not directly associated with the war effort was the Education Act of 1944—for the most part the work of R.A. Butler—which created the Ministry of Education with effective power for developing a national educational policy, raised the school-leaving age (after the war) to 15, and provided for a full range of educational services—primary, secondary, and "further" without fees.

The Beveridge Report

Even as the war was approaching its end, civilians still confronted grave danger. In June 1944, soon after the Allied invasion of Normandy, the first of the "flying bombs"—the V-1s—fell on England; there were nearly 5,500 dead from this weapon by September. And then came the rockets, the V-2s. When the conflict ended September 2, 1945, one day short of six years, civilian casualties numbered about 60,000. Of the armed forces of the United Kingdom, 300,000 lost their lives. And Britain lost one-fourth of its national wealth.

Commonwealth and empire. World War II gave a new direction to Commonwealth affairs. Unlike World War I, the entrance of the dominions in the war in 1939 was their own action; Ireland remained officially neutral. During the course of the war it was clear that equality of status (implicit in the Statute of Westminster of 1931) was being replaced by equality of function. The dominions controlled the employment of their own forces and were usually consulted in matters of strategy. The war strengthened both the bonds of the Commonwealth in a world that seemed destined to be dominated by the United States and the Soviet Union and the conviction of the dominions that as independent nations they were approaching the status of "great powers."

But the growth of this notion of equality within the Commonwealth tended to differentiate more sharply the dominions from India, Burma, and Ceylon, on behalf of which the United Kingdom declared war in 1939. For them the significance of the war lay in its impact upon their future. For India the chief result was internal—the war greatly strengthened Muslim nationalism, which, through the Muslim League lead by Jinnah Mohammad Ali, came into violent conflict with the Indian National Congress led by Jawaharlal Nehru.

BRITAIN SINCE WORLD WAR II

Labour and the welfare state (1945–51). World War II, like World War I, was followed immediately by a general election; and Churchill, like Lloyd George, sought to perpetuate the wartime coalition. But here the parallel ends. In 1945 all parties contested the election independently. During the war, Labour maintained its organization. In 1941 it had issued "Labour in Government: A Record of Social Legislation in War Time," and in 1942, "The Old World and the New Society," a statement of postwar policy. In contrast, the Conservatives had not redefined their policies.

The European war was at an end May 8. Angry with Labour for breaking away from the Coalition, Churchill would not await the end of the Japanese war and resigned May 23. Polling day was set for July 5. The heart of the campaign was a series of evening broadcasts. The British Broadcasting Corporation estimated that on the average 45 percent of the adult population listened, with Churchill's audiences only slightly larger than the others.

The postwar election

In his opening broadcast Churchill sought to associate Labour with Socialism and thereby show it to be dangerous. Attlee refused to take this seriously, for Socialism as an ideology was hardly an issue. Nor was the achievement of the war coalition, despite its emphasis by the Conservatives. The important question seemed to be: What of the future? Labour had a comprehensive program; the Conservatives did not. The outcome was a stunning victory for Labour, beyond all prediction, with 393 members of Parliament, a clear majority of 146 over all other parties. Attlee formed a strong cabinet with Bevin at the Foreign Office, Hugh Dalton at the Exchequer, and Herbert Morrison as leader of the Commons.

Labour promptly implemented its program. First came nationalization of the Bank of England, of coal, of electrical power, and of inland transport (railroads, road transport, inland waterways, docks and harbours). Only transport was seriously contested. No private interest was confiscated, and management usually remained in the hands of those who directed the industry when privately owned. As to agriculture, war legislation guaranteeing prices and markets was continued, rendering farming a respected occupation and one that provided a good livelihood. Labour created "the welfare state," or, more accurately, extended in dramatic fashion social services by the state. Legislation provided insurance against unemployment, sickness, industrial injury, old age; supplementary grants were provided for emergencies—pregnancy and maternity care, widowhood, burial. The National Assistance Act provided a weekly benefit for minimum needs. The National Health Service Act (1946)—which did not go into effect until July 1948—provided medical care for all, regardless of ability to pay; as such the act was the outcome of 35 years of piecemeal social legislation. Though all assumed that some kind of national health service was required, the problem was to enact legislation that would satisfy the medical profession without their active participation in its formulation. In the controversy, the medical profession was rent asunder. But by 1950 it was clear that Britain's health service was there to stay—95 percent of the population were enrolled on lists of doctors in the service, who numbered 88 percent of all medical practitioners.

National Health Service

In order to implement the Education Act of 1944, the government by 1951 had trained 35,000 new teachers (one-sixth of those in service), had established 6,300 temporary school rooms and constructed 1,000 new buildings, had extended the school-leaving age to 15 (1947), had expanded part-time technical training schools to nearly 300,000 workers, and had underwritten higher education (73 percent of students in universities were receiving grants-in-aid).

In the economy, Britain's task was clear: to restore and if possible to improve upon its prewar standard of living; to achieve a rate of production that would satisfy consumer demands at home and provide a surplus for export to pay for imported foodstuffs and raw materials; to bolster up sterling. Labour sought to achieve these goals by maintaining controls and powers exercised by the government during the war. While there was full employment, production was unimpressive. And in 1947, partly because the severe winter of 1946–47 interfered with production and transportation, but more especially because of slowdowns in mines and factories from discontented labour, there came a severe economic crisis, British exports falling sharply and the stability of sterling challenged.

But economic policy can hardly be separated from foreign policy, for it became apparent soon after the end of the war that Britain would depend on the United States for economic aid. It was agreed that on the lend-lease war account, Britain incurred no obligation for American aid actually consumed during the war; and, more importantly, outright financial aid through the Marshall Plan began in 1948. But before the end of 1945 it was just as clear that British and Soviet interests in Europe were irreconcilable. From the Baltic to the Adriatic, said Churchill at Fulton, Missouri, March 5, 1946, "an iron curtain has descended across the continent." Eastern Eu-

ropean states, including East Germany, became Soviet satellites, and by 1947–48 a state of "cold war" existed between the Soviet Union and the West. In its search for economic recovery and national security, Britain apparently had to choose between Commonwealth or imperial ties or European cooperation. It moved cautiously toward Europe. The Dunkirk Treaty of Alliance (1947) allied Britain and France against a possible revival of German militarism, and with them were associated Belgium, The Netherlands, and Luxembourg in the Brussels Treaty (1948). The crowning event, for security in "the free world" and for containing the Soviet Union, came with the North Atlantic Treaty Organization (NATO) in April 1949, which bound the signatories at Brussels with Canada and the United States in a military alliance.

NATO

In Commonwealth affairs there began a veritable revolution. Labour had long pledged self-determination to India. Delayed and complicated almost beyond human understanding, independence came, but with it partition. In August 1947 India and Pakistan, as independent dominions within the Commonwealth, came into being. In 1949 Ireland proclaimed itself a republic and left the Commonwealth. In 1946 Britain terminated its mandate over Transjordan, and in 1948, over Palestine. In Egypt, native nationalism forced British policy into the withdrawal of all military forces, save in the Suez, by March 1947.

At the end of 1949, Labour was confronted with a general election. The party's limited success at nationalization and other controls to strengthen the economy and an "austerity" program limiting consumption had somewhat broken Labour's hold on the electorate. Further, there was disaffection in Labour's ranks, particularly against policy at the Foreign Office. The Conservatives had, meanwhile, effectively reorganized. In the poll of February 1950, with 84 percent of the electorate voting, Labour's vote was cut sharply by the still active Liberals, and the Labour majority in the Commons was reduced to a mere six—hardly a mandate. Parliamentary government became a sparring engagement. The steel industry was nationalized, but its methods of operation remained much as before. The economy improved somewhat. United Nations support for South Korea brought modest rearmament, but this further alienated leftists in the Labour party. Britishers found a brief diversion from their problems in the summer of 1951 in the Festival of Britain on the south bank of the Thames. Reality returned in autumn, when, to no one's surprise, Attlee announced a general election. The Conservatives, in Churchill's words, made "one more heave," which brought them a majority of 17, a modest victory, but significant in ending the postwar rule of Labour.

The Conservative response to postwar change (1951–64). The Conservative comeback proved genuine, the party winning three elections in succession (1951, 1955, 1959), each with a larger majority. Leadership of the party changed, first in April 1955 in the shift from Churchill, then 80 years old, to Anthony Eden and then in January 1957 from Eden to Harold Macmillan. At Buckingham Palace there was also a change—King George VI died in February 1952. Elizabeth II was proclaimed in June 1953 with coronation ceremonies in Westminster Abbey that were televised all over the world.

Coronation of Elizabeth

The Conservatives dominated the 1950s primarily because their domestic program proved more dynamic than that of Labour, which was slow to appreciate the need for new goals and new slogans to replace "full employment," "fair shares," and "nationalization," nearly all of which, as defined by Labour, had been achieved by 1951. Furthermore, on foreign policy Labour was seriously divided, with Aneurin Bevan and Harold Wilson leading a strong minority opposed to rearmament.

But at first the Churchill government, with its slender control in the Commons, moved slowly, tampering little with Labour legislation, save for denationalizing steel and road transport. But R.A. Butler at the Exchequer produced measures designed to reverse the unfavourable balance of international payments—curtailing imports, raising the bank rate for borrowing, and cutting tourist allowances abroad 50 percent. With these measures and favourable conditions abroad, the dollar account in foreign trade by 1953 was on even terms for the first time since the war, the volume of exports steadily increased and domestic consumption advanced—an increase between 1951 and 1954 of 12 percent, especially noticeable in automobiles and television sets. A matter of great popular interest was the creation of the Independent Television Authority (until 1955 television had been a British Broadcasting Corporation monopoly). On the strength of this record, the Conservatives in the election of 1955 increased their majority in the Commons to 58.

The economy

There was now talk of an "affluent society." But actual growth remained modest. A threat of inflation of prices and wages caused the government to turn again in 1957 to fiscal control—raising the bank rate to 7 percent, increasing purchase taxes, reducing food subsidies, and restricting installment buying. The economy accordingly improved; 1959 was an impressive year, with industrial production up 13 percent from 1954 and with exports doubling in volume those of 1938. By 1960 the rate of growth in production was about 3 percent annually. The advances in the 1950s came, not in the nationalized industries, which under public ownership were only a little more prosperous than under private, but rather in new industries—especially automobile and aircraft production but also chemicals, scientific instruments, and electrical equipment. During the decade, real wages rose 40 percent, and the average family could possess an automobile, a refrigerator, and a television set. By 1959, 70 percent of British households had television sets. The Conservatives again scored at the polls, in 1959 polling 50 percent of the electorate against Labour's 44 percent and achieving a majority in the Commons of 100.

In the 1950s, in external affairs, decisions even more momentous than those of the immediate postwar years were forced upon Britain. A great task and a great achievement was the liquidation of the empire—accomplished without violence and, with few exceptions, the newly independent states choosing to remain in the Commonwealth. After India and Pakistan came the Anglo-Egyptian Sudan, the Somali Republic, the Federation of Malaya, Malta, a host of states in Africa. Only in Rhodesia was the movement for independence marred by intransigence—this over the status of the vast African majority. But the same issue—that of white supremacy—along with national consciousness caused South Africa to proclaim itself a republic and to sever ties with the Commonwealth.

Foreign policy in the 1950s

While World War II had once more made clear that Britain was not a part of Europe, interests of national security had persuaded the country to abandon its traditional policy of temporary international agreements for immediate ends and to associate in permanent military union with those who shared its dangers. In Europe, NATO, with the admission of the Federal Republic of Germany in 1955, became the Western European Union. And in 1954 in the Far East, Britain associated itself with SEATO (Southeast Asia Treaty Organization) to resist aggression in the Southwest Pacific.

Such arrangements were made with dignity. It was otherwise in the Middle East, where Britain did not have sufficient power to implement policy in its own interests. This it was slow in realizing. As in Palestine so in Suez British policy failed. According to Eden, an Anglo-Egyptian treaty of 1954, by which British troops were to be evacuated in stages, was to create close military cooperation with Egypt. In 1956 Britain as well as the United States hoped through loans for the construction of the Aswān High Dam to counter influence of the Communist bloc with the Egyptian leader, Gamal Abdel Nasser. But Nasser's recognition of the People's Republic of China and his encouragement of a Soviet proposal to finance the dam caused the United States and Britain to withdraw their offers. Nasser's answer (July 26) was immediate nationalization of the Suez Canal. An Israeli attack across the Egyptian border brought Anglo-French intervention (perhaps by French collusion with Israel) in force. Opinion in the United Nations and throughout the

world was so generally hostile to the Anglo-French action that they soon halted operations. This abortive intervention made Nasser an Arab hero and cost Britain what remained of Arab confidence. And in the next few years it was evident that the Middle East had ceased to be a British "sphere of influence."

In domestic affairs, the early 1960s stand in some contrast to the 1950s. The economy, which had been growing, if somewhat unsteadily, came to a standstill. From 1960 to 1962 three chancellors of the exchequer sought to stimulate the economy by old measures (higher bank rates and higher taxes) and new ("a pay pause"; *i.e.*, restraints in wages and salaries, and an "incomes policy"). These measures were neither popular nor successful. While British production lagged behind that of other industrial countries, wages and prices rose. For many the future looked brighter when Britain in October 1961 formally applied for membership in the European Economic Community (the Common Market). There was, to be sure, opposition in Britain, from agricultural interests and from concern over the Commonwealth as well as from an important section of the Labour Party. But negotiations were actually ended (January 1963) by France, or more exactly by Gen. Charles de Gaulle, who declared that Britain's geography, economy, and trade made it impossible, at least for the present, for Britain to join the Common Market.

The year 1963 brought other surprises, and some tragedies. First came the sudden and untimely death in January of Hugh Gaitskell, the leader of the Labour Party since 1955—a person very much respected in all political circles. His successor was Harold Wilson, another academic, around whom leftists in the party had gathered, but no extremist himself. After failure with the Common Market the Conservative government turned to the National Economic Development Council and to the National Incomes Commission for guidance in a planned economy that would stimulate production and control inflation. Progress in both directions was limited. And the Beeching Report on British railways, calling for the discontinuance of service on one-third of the route miles, while rational, was unpopular.

The "Profumo Affair"

Macmillan and the Conservatives also suffered in public esteem in the "Profumo Affair." John Profumo, war secretary, was involved in an unsavory situation that included a call girl and a naval attaché at the Soviet embassy. A judicial inquiry found no breach of security but censured the government for failing to make prompt and adequate investigation. Macmillan suffered acute embarrassment in the Commons (June) but made a good comeback in his contributions to the Nuclear Test-Ban Treaty (July). In October, however, after being hospitalized for a major operation, he resigned. His exit left the Conservatives divided. On his advice, Lord Home, foreign secretary, who had revealed surprising strength as a second choice, was chosen by the Queen.

The Peerage Act, just enacted (July 1963), permitted Home to renounce his peerage, and as Sir Alec Douglas-Home he won a vacant seat in Scotland and took his place in the Commons. Of Cabinet rank only since 1957, he soon demonstrated that he was well able to govern. But in 1964 current events were in any case overshadowed by the prospect of a general election called for by law.

Contemporary affairs. But that election, long expected, did not come until October; thus there was a long preelection campaign. Douglas-Home's task was to make himself known, while that of Wilson was to overcome complacency within his party, which expected an easy victory. But though Labour's popularity was waning, the feeling of "time for a change" prevailed with enough voters to give Labour a majority of four in the Commons. Wilson formed the first Labour Cabinet since 1951.

Despite its slender majority, it started vigorously with an emergency budget but was considerably embarrassed when the foreign-secretary designate, Patrick Gordon Walker, was defeated in a by-election in January 1965. Also in that month came the death of Sir Winston Churchill, aged 90, a solemn moment for Britain and much of the world.

Labour made a determined effort through the National Board for Prices and Incomes to control inflation and in September 1965 unveiled a master plan for attaining a 25 percent increase in production by 1970. With by-elections favourable to Labour, Wilson, in an effort to enlarge his majority, called for a general election in March 1966. Edward Heath, the new (since July 1965) leader of the Conservatives, declared that his party would "lead England into Europe" and through free enterprise would restore the economy. In a low poll, Labour emerged with a solid majority of 97. One factor was certainly Heath's unknown and uncertain quality.

Election of 1966

In the years 1966–69 Labour's economic and financial policy was energetic and often bold—with severe budgets, a six-month freeze on wages in 1966 and restraints thereafter, a 14.3 percent devaluation of sterling in November 1967, a firm tone toward labour unions, and proposals for shifting from the principle of universality in welfare to that of selectivity. But it was a policy that achieved little success and that alienated the trade unions and much of Labour's working-class following.

The 1960s proved to be an important decade in education. The school-leaving age was scheduled to rise to 16 in 1970–71, and the "comprehensive school," offering all types of secondary education, was expanding. Goals set by the Robbins Report (1963)—60 universities by 1973–74 as against 32 in 1963, and 390,000 student places in higher education—were being pursued. And, prodded by the Franks Report (1966), Oxford and Cambridge, bulwarks of tradition, were undergoing change.

By the end of the decade the Labour government was not winning high marks for its success in dealing with the economy. On the other hand, Heath had hardly made himself credible as a future prime minister. For him a major problem was Enoch Powell, a former Conservative Cabinet member, who thrust the racial issue into politics in 1968 with a demand for a halt to nonwhite immigration from Commonwealth lands. Powell was dismissed from the shadow Cabinet, but his popularity grew.

By 1969 industrial stability seemed threatened by a series of wildcat strikes, democratic processes were being questioned, and student demonstrations illustrated a general social discontent. Wilson's government was forced to abandon two major measures on its agenda: reform of the House of Lords and reform of trade unions. But an unforeseen improvement in the nation's foreign trade, and modest gains by Labour in by-elections and in public opinion polls led Wilson to call for a general election in June 1970. With only 72 percent of the electorate voting, the lowest since 1945, it is likely that many normally Labour voters stayed away from the polls. The result was an unexpected victory for the Conservatives, with a popular swing to its ranks of 4.6 percent and a majority of 30 in the Commons. (A.F.H.)

The new Heath government had to deal with the highest unemployment since 1939 and a series of crippling strikes. Meanwhile, unrest continued in Northern Ireland and violence increased (see below *The history of Ireland: Northern Ireland after 1921*). Prime Minister Heath temporarily balanced his difficulties with dramatic success when Britain formally entered the European Economic Community (EEC) on January 1, 1973, but the debate over this step was by no means over.

Common Market entrance

Economic problems continued to trouble Britain—low growth rate, record trade deficits, the oil crisis, demands for higher wages, rising prices (the rate of inflation reached 25 percent in 1975)—despite strong measures by the Heath (and later the Wilson) government, which included, in 1973, the declaration of a state of emergency, the imposition of a three-day workweek, and an emergency budget. Lack of confidence in the government was reflected by Conservative Party losses in the local elections of that year, and the Prime Minister called for a general election on February 28, 1974. This gave Labour five more seats in Parliament than the Conservatives, and Harold Wilson (whose party had pledged to renegotiate the terms of British membership in the EEC) was again asked to form a government on March 4. The state of emergency was ended and the five-day workweek re-

sumed. Because Labour's lead in Parliament was so flimsy, another general election was held on October 10. Though it again failed to produce a clear majority for Labour, it did give the party 43 more seats than the Conservatives.

Still striving to cope with the recurrent economic crises, the government in December announced plans to cut defense spending by reducing military manpower, ending new programs, and bringing overseas forces home. In a national referendum on June 5, 1975, the British voted 2:1 to remain in the EEC, ending a debate that had raged for more than two decades. In March 1976 Wilson resigned and was succeeded in April by the foreign secretary, James Callaghan.

North Sea petroleum

In the mid-1960s petroleum deposits began to be discovered in the North Sea, from which natural gas was already being recovered. Though their size could not be determined accurately, by 1975 it was estimated that they amounted to about 2 percent of the world's total petroleum reserves and that recoverable reserves in the British sector amounted to about 7,300,000,000 barrels. It was expected that by 1980 Britain would be self-sufficient in petroleum and would become a petroleum exporter, relieving the very serious balance of payments position.

(Ed.)

SCOTLAND AND WALES IN THE 20TH CENTURY

Scotland and Wales, though integral parts of the British community, by virtue of their history, language, and local institutions, still preserve something of their individuality. In Scotland, national consciousness has tended to be political rather than cultural. The Scots have long had their own national church, and language has almost ceased to be a national symbol. The universities are not zealous for a cultural revival, and the Edinburgh Festival is international.

On the other hand, Scottish legal and school systems and local institutions have survived into the 20th century. To preserve them as such and to seek particular remedies for particular economic problems have inspired in many a revival of nationalism. Around the turn of the century, the idea of "Home Rule All Round" spread from Ireland to Scotland and to Wales, and for a time something like dominion status seemed possible for Scotland. But after World War I this notion was moribund. Scottish demands for a dignified relation with Westminster led to the establishment of a secretary of state for Scotland, with Cabinet status later, based in Edinburgh. But this was insufficient for the nationalists, who, while seldom favouring outright independence, did seek an autonomous Scottish parliament. They formed the Scottish National Party (SNP) in 1934, which achieved considerable success in local elections. In parliamentary politics, where the established parties dominate, the SNP was victorious only in by-elections in 1945 and 1967. But it kept Westminster aware of the Scottish problem. In 1966 a White Paper outlined long-range plans, and in 1968 the government announced a select committee to consider the possibility of a Scottish assembly. Since Aberdeen was one of the major British ports for reception of petroleum from the North Sea fields (see above), Scotland hoped to derive great economic benefit from the exploitation of these fields; this was reflected in a resurgence of the SNP, which in the elections of October 1974 gained 11 seats in Parliament.

Welsh Radicalism

In Wales, Welsh Radicalism—its great objective, that of the disestablishment of the Church of England, having been achieved—virtually came to an end with World War I. Enthusiastic support for one of their own, David Lloyd George, as prime minister, continued after the war. The idea of a Welsh state revived with the formation in 1925 of the Welsh Nationalist Party, later called Plaid Cymru (Party of Wales). By the 1950s it had some 210 local branches, and in 1966 amid much excitement, in a by-election in Carmarthenshire, returned to Parliament the party president, Gwynfor Evans (in October 1974 three Welsh nationalists gained seats). Indeed, in the 1960s issues of devolution and federation were much discussed. In 1968 a poll indicated that 59 percent favoured some kind of Welsh parliament. These developments did not go unnoticed at Westminster—the minister for Welsh affairs, appointed in 1951, became a secretary of state in 1964, and in 1960 a Welsh grand committee was established in the Commons.

The Welsh have been interested in cultural revival, though, with strong differences between the rural north and the industrial south, this concern has not always been unifying. The University of Wales has stimulated Celtic scholarship. Welsh poets use their native tongue. The annual festival, the Eisteddfod, held alternately in North Wales and South, stimulates interest in Welsh poetry and choral singing. But the use of the Welsh language continues to decline—the census of 1971 revealed that only one-fifth of the population could use it.

The attention of much of the world focussed on Wales on July 1, 1969, with the investiture of Prince Charles as prince of Wales by his mother, the Queen, in bilingual ceremonies at Caernarvon (Caernarfon) Castle. The Prince gave his pledge "to associate myself in word and deed with as much of the life of the principality as possible."

(A.F.H.)

XV. The history of Ireland

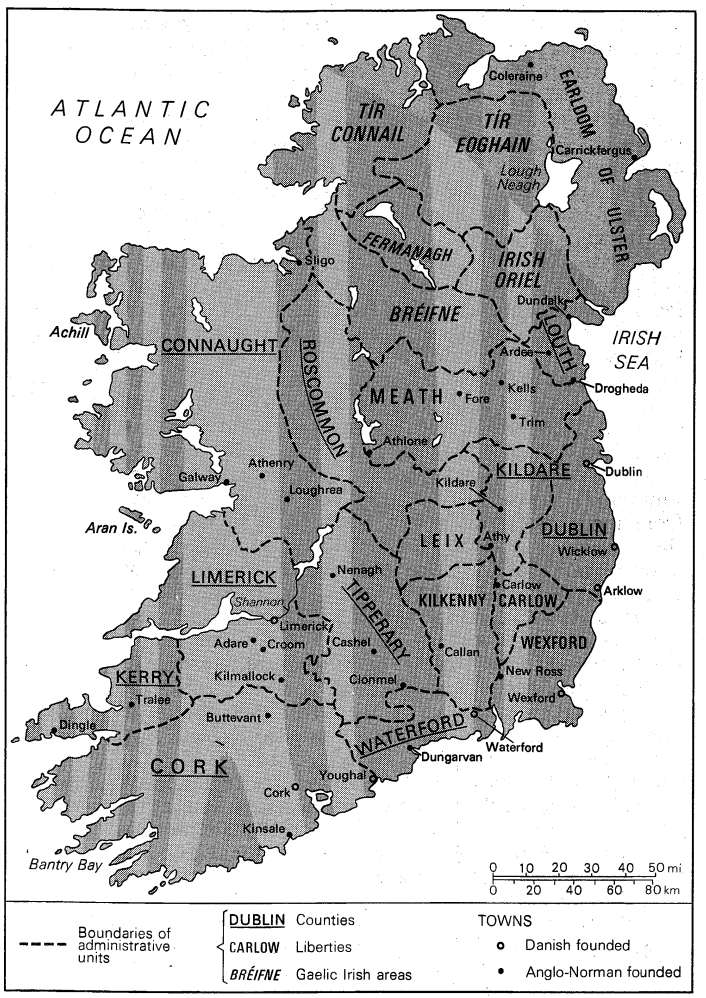
Ireland, lying to the west of Britain, has always been to some extent cut off by it from direct contact with other European countries, especially the area between Sweden and the Rhine. Approach from France, Spain, and Portugal, and even from Norway and Iceland, has been more possible. Internally, the four ecclesiastical provinces into which Ireland was divided in the 12th century realistically denoted the main natural divisions of the country. Of these, the north had in the earliest times been culturally connected with Scotland, the east with Roman Britain and Wales, the south with Wales and France, and the southwest and west with France and Spain. In later times, despite political changes, these associations tended to continue in greater or lesser degree.

The position of Ireland, geographically peripheral to western Europe, became central and thus potentially more important once Europe's horizons expanded, in the 15th and 16th centuries, to include the New World. But paradoxically it was in the earlier period that Ireland won especial fame as a notable and respected centre of Christianity, scholarship, and the arts. After the Middle Ages, subjugation to Britain stultified, or the struggle for freedom absorbed, much of Ireland's native energy. But its influence was always exercised as much through its emigrants as in its achievements as a nation. During the centuries of British occupation the successors of the great missionaries and scholars who, from the 7th to the 9th century, fostered Christianity and learning among the Germanic peoples of the Continent were those who formed a considerable element in the armies and clergy of Roman Catholic countries and had an incalculable influence on the later development of the United States. In British history innumerable great men of Anglo-Irish origin or nurture have, as statesmen or soldiers, played vital parts; the influence of Ireland itself on Britain has been constant and profound.

Ireland's influence

EARLY IRELAND

The human occupation of Ireland did not begin until a late stage in the prehistory of Europe. It has generally been held that the first arrivals were Mesolithic hunter-fisher people, represented largely by flintwork found mainly in ancient beaches in Antrim, Down, Louth, and Dublin. These artifacts have been named Larnian after the type site at Larne, County Antrim; dates from 6000 BC onward have been assigned to them. More recent work, however, casts considerable doubt on the antiquity and affinities of the people who were responsible for the Larnian industry; association with Neolithic remains suggests that they should be considered not as a Mesolithic people but rather as groups contemporary with the Neolithic farmers. The Larnian could then be interpreted as a specialized aspect of contemporary Neolithic culture. Lake and riverside finds, especially along the River Bann, show a comparable tradition. A single radioactive carbon date of 5725 ± 110 BC from Toome



Medieval Ireland.
From A. Orme, *Ireland*

Bay, north of Lough Neagh, for woodworking and flint has been cited in support of a Mesolithic phase in Ireland, but such a single date cannot be relied on.

The Irish Neolithic. The general pattern of radioactive-carbon determinations suggests that the Neolithic period in Ireland began about 3000 BC. As in Britain, the most widespread evidence of early farming communities is long-barrow burial. The main Irish long-barrow series consists of Megalithic tombs called court tombs because an oval or semicircular open space, or court, inset into the end of the long barrow, precedes the burial chamber. These court tombs number well over 300. They occupy the northern half of Ireland, and the distribution is bounded on the south by the lowlands of the central plain. The development of the design of the tombs and the great densities west of the River Erne indicate a general spread of tomb builders from centres in Sligo and Mayo, across central Ulster, and beyond to western Scotland and the Isle of Man. Timber-built rectangular houses belonging to the court-tomb builders have recently been discovered at Ballynagilly, County Tyrone, and at Ballyglass, County Mayo.

Megalithic tombs

The court tombs are intimately related to the British long-barrow series of the Severn-Cotswold and chalk regions and probably derive from more or less common prototypes in northwest France.

In Ireland a second type of Megalithic long barrow—the so-called portal tomb—developed from the court tomb. There are over 150 examples. They spread across the court tomb area in the northern half of Ireland and extend into Leinster and Waterford and also to west Wales and Cornwall.

A notable feature of the Irish Neolithic is the passage tomb. This Megalithic tomb, unlike the long-barrow types, is set in a round mound, sited usually on hilltops and grouped in cemeteries. The rich grave goods of these tombs include beads, pendants, and bone pins. Many of the stones of the tombs are elaborately decorated with engraved designs. The main axis of the distribution lies along a series of great cemeteries from the River Boyne to Sligo (Boyne and Loughcrew in County Meath, Carrowkeel and Carrowmore in County Sligo). Smaller groups and single tombs occur largely in the northern half of the country and in Leinster—for example, there is a group on the headlands around Fair Head in Antrim and another on the fringe of the Dublin–Wicklow mountains. A specialized group of later, indeed advanced, Bronze Age date, near Tramore, County Waterford, are quite closely akin to a large group on the Scilly Islands and Cornwall. The great Irish passage tombs include some of the most magnificent Megalithic tombs in all Europe—for example, Newgrange and Knowth. While the passage tombs represent the arrival of the Megalithic tradition in its fullest and most sophisticated form, the exact relation between the builders of these tombs and the more or less contemporary long-barrow builders is not clear. The passage tombs suggest rather more clearly integrated communities than do the long barrows.

From the final stages of the Neolithic, single burials are found in Leinster—for example, at Rath, County Wicklow, and Linkardstown, County Carlow. These, while preserving certain of the Neolithic traditions, seem to represent a new influence that presages the Bronze Age single-burial mode. To this final stage of the Neolithic probably belong the rich house sites of both rectangular and circular form at Lough Gur, County Limerick. The pottery shows a strong connection with the tradition of the long barrow (court tomb and portal tomb).

The Irish Bronze Age. Two great incursions establish the early Bronze Age in Ireland. One represented by approximately 400 Megalithic tombs of the wedge-tomb variety, is associated with beaker pottery. This group is dominant in the western half of the country. Similar tombs also associated with beaker finds are common in Brittany, and the origin of the Irish series is clearly from this region. In Ireland the distribution indicates that these tomb builders sought well-drained grazing land, such as the Burren limestones in Clare, and also copper deposits, such as those on the Cork-Kerry coast and around the Silvermines area of Tipperary.

In contrast, in the eastern half of the country a people in the single-burial tradition dominate. Their burial modes and distinctive pottery, known as food vessels, have strong roots in the beaker tradition that dominates in many areas of western Europe. They may have reached Ireland via Britain from the lowland areas around the Rhine or farther north.

Throughout the early Bronze Age Ireland had a flourishing metal industry, and bronze, copper, and gold objects were exported widely to Britain and the Continent. In the middle Bronze Age (around 1500 BC) new influences brought urn burial into eastern Ireland.

From about 1200 BC elements of a late Bronze Age appear, and by about 800 BC a great late Bronze Age industry was established. A very considerable wealth of bronze and gold is present, an example of which is the great Clare gold hoard. Nordic connections have been noted in much of this metalwork. Unfortunately, as a result of the paucity of habitation and burial sites, many aspects of the culture of these fine metalworkers remain obscure.

The Irish Iron Age. The period of the transition from the Bronze Age to the Iron Age in Ireland is fraught with uncertainties. There is little sign of a continental-like Hallstatt Iron Age in Ireland. La Tène, which may date in Ireland from 300 BC or earlier, is represented in metalwork and some stone sculpture, mainly in the northern half of the country. Connections with northern England are apparent. Hillfort building seems also characteristic of the Iron Age. The problem of identifying archaeological remains with language grouping is notoriously difficult, but it seems on the whole likely that the principal Celtic arrivals occurred in the Iron Age. Irish sagas,

which probably reflect the pagan Irish Iron Age, reflect conditions in many respects similar to the descriptions of the ancient classical authors, such as Poseidonius and Julius Caesar.

Early Celtic Ireland. *Political and social organization.* Politically, Ireland was organized into a number of petty kingdoms or *tuatha*, each of which was quite independent under its elected king. Groups of *tuatha* tended to combine, but the king who claimed overlordship in each group had a primacy of honour rather than of jurisdiction. Not until the 10th century AD was there a king of all Ireland (*árd rí Éireann*). A division of the country into five groups of *tuatha*, known as the Five Fifths (Cuíg Cuígí), occurred about the beginning of the Christian era. These were Ulster (Ulaid), Meath (Midhe), Leinster (Laigin), Munster (Muma), and Connaught (Connacht).

The Five Fifths

Surrounding a king was an aristocracy (*airi aicme*, the upper class), whose land and property rights were clearly defined by law and whose main wealth was in cattle. Greater landowners were supported by *céilí*, clients. These and other grades of society, minutely classified and described by legal writers, tilled the soil and tended the cattle. Individual families were the real units of society and exercised collectively powers of ownership over their farms and territory. At law the family (*fine*) did not merely act corporatively but was, by one of the oldest customs, held responsible for the observance of the law by its kindred, serfs, and slaves.

Rural economy and living conditions. There were no urban centres, and the economic basis of society was cattle rearing and agriculture. The principal crops were wheat, barley, oats, flax, and hay. The land was tilled with plows drawn by oxen. Sheep appear to have been bred principally for their wool, and the only animal reared specifically for slaughter was the pig. Fishing, hunting, fowling, and trapping provided further food. Transport of goods by land was by packhorse, for wheeled vehicles appear to have been few. Sea transport was by currach, a wicker-framed boat covered with hides; the normal freshwater craft was the dugout.

The dwellings of the time were built on the post-and-wattle technique, and some, at least, were situated within the protected sites called by archaeologists ring forts. Excavations have shown that some of these may have existed even in the Bronze Age and that they remained a normal place of habitation down to medieval times. Advantage was also taken of the relative security of islands in rivers or lakes as dwelling places; and artificial islands, called crannogs, were also extensively made.

The Irish laws point to a large development of rural industry in the period in which they were first written down, shortly before the Norse invasions beginning at the end of the 8th century. They deal minutely not only with the management of land and animal rearing but with innumerable further details of husbandry, including milling, dyeing, dairying, malting, meat curing, and spinning and weaving. Wool was spun with a wooden spindle weighted with a whorl of bone or stone; and it was woven on a loom. The outer garment worn by both men and women was a large woollen cloak (*brat*), fastened on shoulder or breast with a pin or brooch. The inner garment was a long linen tunic (*léine*), girded at the waist with a belt. Shoes of rawhide or tanned leather were worn, at least by the upper classes and the higher professional ranks. A large amount of metalwork reveals the adaptation by Irish craftsmen of many techniques originating in Britain or on the continent. An instinct for design, added to the skillful use of these techniques, enabled them to produce many superb objects, of which the Tara brooch, dating from about the mid-8th century, is an outstanding example. The chief musical instrument of the period was the harp.

Early political history. The documentary history of Ireland really begins only in the 7th century, which saw the production both in Latin and Irish of sufficiently rich and numerous records of all sorts. For events before that time historians have to rely on literary sources such as the sagas, many of whose characters may represent only poetic imagination and in which the social or political circumstances portrayed reflect the fantasies of their authors rather than historical reality. Nevertheless, the traditions seem to indicate, during the early centuries of the Christian era, a process of political cohesion in Ireland through which the *tuatha* ultimately became grouped into the Five Fifths. Among these, Ulster seems at first to have been dominant; but by the time of Niall of the Nine Hostages (died early 5th century), hegemony had passed to his midland kingdom of Meath, which was then temporarily associated with Connaught. In the 6th century, descendants of Niall, ruling at Tara in northern Leinster, were claiming to be overkings of three provinces, Ulster, Connaught, and Meath. Later, they claimed to be kings of all Ireland, although their power rarely extended over Munster or the greater part of Leinster. Two branches of Niall's descendants, the Cenél nEogain, of the northern Uí Néill, and the Clan Cholmáin, of the southern Uí Néill, alternated as kings of Ireland from 734 to 1002, a fact that suggests a formal arrangement between the two septs. Inevitably, claims to a high kingship came to be contested by the rulers of Munster, who, from their capital at Cashel, had gradually increased their strength, depriving Connaught of the region that later became County Clare. But not until the reign of Brian Boru in the 11th century was Munster sufficiently strong to secure a real high kingship over all Ireland.

The Irish kingship

Irish raids and migrations. From about the middle of the 3rd century Latin writings make frequent reference to raiding expeditions carried out by the Irish, who were now given the new name, Scotti, rather than the older one, Hiberni. Native Irish traditions also suggest that such attacks took place. In the second half of the 4th century, when Roman power in Britain was beginning to crumble seriously, the raids became incessant, and settlements were made along the west coast of Britain and extensively in Wales and Scotland. From the early 5th century the rulers of Dalriada in northern Antrim extended their power over the Irish already settled in Argyll and the neighbouring islands. Ultimately the Scottish kingdom of Dalriada became separated from the Irish; and when, in the 9th century, it overcame the Picts, it gave its name, Scotland, to the whole area.

Early Christianity. *Conversion.* Little is known of the first impact of Christianity upon Ireland. Traditions in the south and southeast refer to early saints who allegedly preceded St. Patrick, and their missions may well have come through trading relations with the Roman Empire. The earliest firm date is AD 431, when St. Germanus, bishop of Auxerre in Gaul, proposed, with the approval of Pope Celestine I, to send a certain Palladius to "the Scots believing in Christ." Subsequent missionary history in Ireland is dominated by the figure of St. Patrick, whose 7th-century biographers, Tirechán and Muirchú, credited him with converting all the Irish to Christianity, and won for him the status of national apostle.

A 9th-century record, the *Book of Armagh*, includes a work by Patrick himself, the *Confessio* ("Confession," a reply to charges made by British ecclesiastics), in which he describes his life at a Roman villa in Britain, his capture by Irish raiders, and his seven years of slavery in Ireland. Recovering his freedom, he was educated and ordained to the priesthood and eventually managed to be sent as a missionary to Ireland. He concentrated on the north and west of the country, achieving remarkable success; he did not himself claim to have converted all Ireland. Confusion exists regarding the chronology of Patrick's life, and it is seriously contended that tradition came to merge the experience of two men, the continental Palladius and the Patrick of the *Confessio*. No sufficient evidence supports the traditional date (AD 432) for the beginning of Patrick's mission, while of the rival dates (AD 461/462 and AD 492/493) given for his death in annals and biographies, the latter is now preferred.

St. Patrick

Irish monasticism. Though monks and monasteries were to be found in Ireland at the time of Patrick, their place was then altogether secondary. But in the course of the 6th and 7th centuries a comprehensive monastic system developed in Ireland, partly through the influence of Celtic monasteries in Britain, such as Candida Casa at

Whithorn in Galloway and Llangarvan in Wales. Early attempts to organize the Irish Church on the usual Roman system—by which each bishop and his clergy exercised exclusive jurisdiction within a diocese—seem to have given way to one in which groups of Christian settlements were loosely linked together, usually under the auspices of some one or other of the great saints. Careful study of the lives of the early saints reveals the manner in which their reputations developed in proportion to the power of the political dynasties that became connected with them.

By the end of the 6th century, enthusiasm for Christianity was leading Irishmen to devote themselves to a most austere existence as monks, as hermits, and as missionaries to pagan tribes of Scotland, in the north of England, and in a great area of west central Europe, particularly between the Rivers Rhine, Loire, and Rhône. St. Columba's foundation (*c.* 563) of the monastery of Iona off the northwest Scottish coast provided the best known base for the Celtic Christianization of Scotland; and its offshoot, Lindisfarne, lying off the coast of the Anglo-Saxon kingdom of Northumbria, was responsible for the conversion of that area. Of the continental missionaries, the best known is St. Columban (died 615), whose monastic foundations at Luxeuil near Annegray in the Vosges and at Bobbio in northern Italy became important centres of learning. Columban, however, by his individualism and austere puritanism, came into conflict not only with the Merovingian rulers of Gaul but also with the local ecclesiastical administration; his limitations exemplify those of the Irish monastic system as a whole and explain why, in the end, it was supplanted by the ordinary administrative system of the Church.

Learning and art. Both at home and abroad the saints were succeeded by scholars, whose work in sacred and classical studies and particularly in elaborating an Irish Christian mythology and literature was to have profound effects upon the Irish language and was to be a major factor in its survival. The Irish monasteries became notable centres of learning; in Ireland itself those of Clonmacnoise (in County Offaly) and Clonard (in County Meath) were among the most famous. Christianity had brought to Ireland the Latin tongue and command of the Latin authors; not only Church Fathers but classical writers were read and studied. Irish scribes produced manuscripts written in the clear hand known as Insular; this usage spread from Ireland to Anglo-Saxon England and to the continental Irish monasteries. Initial letters in the manuscripts were illuminated, usually with very intricate ribbon and zoomorphic designs. The most famous of the Irish manuscripts is the *Book of Kells,* a copy of the Four Gospels dating from about the 8th or 9th century. The earliest surviving illuminated manuscript, the *Book of Durrow*, was probably made about a century earlier.

Illuminated manuscripts

The adoption of Christianity made it necessary to relate the chronology of Irish tradition, history, and genealogies to the events recorded in the Bible. The *Book of Invasions* (*Leabhar Gabhála*), in which Irish history was linked with events in the Old Testament, was a notable example of this process. In this way Latin civilization in Ireland became linked to the Gaelic; and the association became closer under the impact of the Viking wars. Gradually the Latin products of the Christian schools became replaced by Irish works; Latin lives of the saints, for example, are almost always earlier in date than those written in Irish. Recurring bouts of puritanism and reforming movements in the church tended to remove secular literature from monastic control; ultimately, a class of professional families developed, who were its custodians from the 12th to the 17th centuries. The medieval secular writers, employing a degenerate form of Old Irish usually known as Middle Irish, were responsible for a large proportion of Irish literary achievement; their historical works, the annals, and the great genealogies, supplemented by the law collections, have enabled historians to reconstruct early Irish social history.

The Norse invasions and their aftermath. The first appearance of the Norsemen on the Irish coast is recorded in 795. Thereafter the Norsemen made frequent plundering raids, sometimes far inland. They seized and fortified two ports, Annagassan and Dublin, in 838; and the 840s saw a series of large-scale invasions in the north of the country. These invaders were driven out by Aed Finnliath, high king from 862 to 879, but meanwhile the Norse rulers of Dublin were reaching the zenith of their power. They took Waterford in 914 and Limerick in 920. Gradually, without quite abandoning piracy, the Vikings became traders in close association with the Irish and their commercial towns became a new element in the life of the country. The decline of Norse power in the south began when they lost Limerick in 968 and was finally effected when the Scandinavian allies of the king of Dublin were defeated by High King Brian Boru at the Battle of Clontarf in 1014.

Though the Battle of Clontarf removed the prospect of Norse domination, it brought a period of political unsettlement. High kings ruled in Ireland but almost always "with opposition," meaning that they were not acknowledged by a minority of provincial kings. The Viking invasions had, in fact, shown the strength and the weakness of the Irish position. The fact that power had been preserved at a local level in Ireland enabled a maximum of resistance to be made; and although the invaders established maritime strongholds, they never achieved any domination comparable to their control of eastern England or northwest France. After Clontarf they remained largely in control of Ireland's commerce but came increasingly under the influence of neighbouring Irish kings.

In the 11th and 12th centuries the ecclesiastical reform movement of western Europe was extended into Ireland. And as the kings of Munster and Connaught, Leinster and Ulster struggled each to secure the dominant position that had once been held by Brian Boru, they came to realize the value to them of alliance with the forces of church reform. Thus, with the aid of provincial rulers, the reformers were able to set up in Ireland a system of dioceses, whose boundaries were coterminous with those of the chief petty kingdoms. At the head of this hierarchy was established the archbishopric of Armagh, in association with the province of Ulster dominated by the royal family of Uí Néill. But the victory of the reformers was not complete, for the parochial system was not introduced until after the Anglo-Norman Conquest. Moreover, the reformers sought to influence Irish conduct as well as church organization. The enormities of Irish moral behaviour were colourfully described by St. Bernard of Clairvaux in his life of his contemporary St. Malachy, the reforming bishop who introduced the Cistercian monks into Ireland. The reforming popes Adrian IV and Alexander III encouraged Henry II's invasion of Ireland, believing that it would further church reform in that country. In a remarkable account of the conquest, Gerald of Wales provided a lurid description of the archaic Irish civilization that the invaders encountered. The recognition of Henry II as lord of Ireland and the linking of the church to a foreign administration terminated the independence of Gaelic Ireland and reduced the country to a position of subordination for centuries to come.

Church reform

FIRST CENTURIES OF ENGLISH RULE (C. 1166–C. 1600)

The Anglo-Norman invasion. Before the arrival of Henry II in Ireland (October 1171), Anglo-Norman adventurers, including Richard de Clare, earl of Pembroke, subsequently known as "Strongbow," invited by Dermot MacMurrough, a king of Leinster who had been expelled by the high king, Rory O'Connor (Roderic), had conquered a substantial part of eastern Ireland, including the kingdom of Leinster, the towns of Waterford, Wexford, and Dublin, and part of the kingdom of Meath. Partly to avert any chance of Ireland's becoming a rival Norman state, Henry took action to impose his rule there. He granted Leinster to de Clare and Meath to Hugh de Lacy, who had gone to Ireland in the King's army; but he kept the chief towns in his own hands, exacted forms of submission from the Irish kings, and secured from a church synod recognition of his overlordship. During subsequent

years the Anglo-Norman sphere in Ireland was extended; and while all the Irish kings, except in the northwest, agreed to recognize his supremacy, Henry was obliged to acquiesce in the establishment of new Norman lordships in Ulster under John de Courci and in Munster under de Cogan, de Braose, and others. By the Treaty of Windsor (1175), O'Connor, the high king, accepted Henry as his overlord and restricted his own style to that of king of Connaught. But he was permitted to exercise some vague authority over the other Irish kings and was charged with collecting from them tribute to be paid to Henry. This arrangement was unsuccessful, for thereafter O'Connor encountered opposition even in his own province, and he was ultimately obliged to abdicate.

King John, who visited Ireland in 1210, established there a civil government independent of the feudal lords, and during the 13th century it became more fully organized. An Irish exchequer had been set up in 1200, and a chancery followed in 1232. The country was divided into counties for administrative purposes, English law was introduced, and serious attempts were made to reduce the feudal liberties of the Anglo-Norman baronage. Parliament started in Ireland, as in England; in 1297 the peers and prelates were joined by representatives of counties, and in 1300 the towns also sent members. But these represented the Anglo-Irish only; the native Irish, to some extent resurgent in Ulster under the O'Neills and O'Donnells, and in southwest Munster under the MacCarthys, were aloof and unrepresented.

The medieval Irish Parliament

The 14th and 15th centuries. A brief threat to English control of Ireland, made by Edward Bruce, brother of King Robert I of Scotland, ended when Bruce was killed in battle at Faughart near Dundalk (1318). English control was reasserted and strengthened by the creation of three new Anglo-Irish earldoms, that of Kildare, given to the head of the Leinster Fitzgeralds; that of Desmond, given to the head of the Munster Fitzgeralds; and that of Ormonde, given to the head of the Butlers, who held lands around Tipperary. But the increased power and lands of the Anglo-Irish brought an inevitable reaction; and the remainder of the 14th century saw a remarkable revival of Irish political power, matched by a flowering of Irish language, law, and civilization. The Gaels recovered large parts of Ulster, the midlands, Connaught, and Leinster, while the Anglo-Irish became increasingly Irish, marrying Irish wives and often adopting Gaelic customs.

The English government, which in any case, because of its aim to curtail feudal privileges, was always to some extent opposed by the Anglo-Norman aristocracy, made an effort to restore control but achieved little more than a definition of the status quo. Edward III's son, Lionel, duke of Clarence, as viceroy from 1361 to 1367, passed in the Irish Parliament the Statutes of Kilkenny (1366), which listed the "obedient" (English-controlled) lands as Louth, Meath, Trim, Dublin, Carlow, Kildare, Kilkenny, Wexford, Waterford, and Tipperary. Intermarriage or alliances with the Irish were forbidden. Although the king's sovereignty over the whole country was not renounced, the independent Irish outside the Pale (the area of English control) were regarded as enemies and were assumed to possess their lands only by usurpation. In practice they were feared, and their attacks were often bought off by almost regular payments. Visits by King Richard II in 1394–95 and 1399 achieved nothing. During the first half of the 15th century Ireland was, in effect, ruled by the three great earls, of Desmond, Ormonde, and Kildare, who combined to dominate the Dublin government. Desmond had sway in Counties Limerick, Cork, Kerry, and Waterford; Ormonde in Tipperary and Kilkenny; and Kildare in Leinster. Although both the Gaels and the Anglo-Irish had supported the Yorkist side in the Wars of the Roses, the Yorkist king Edward IV found them no less easy to subjugate than had his Lancastrian predecessors. Succeeding (1468) in bringing about the attainder and execution for treason of Thomas, earl of Desmond, he was, nevertheless, obliged to yield to aristocratic power in Ireland. The earls of Kildare, who thereafter bore the title of lord deputy (for the English princes who were lords lieutenant), were, in effect, the actual rulers of Ireland until well into the 16th century.

The Kildare ascendancy. The substitution (1485) of Tudor for Yorkist rule in England had no apparent effect in Ireland, where the ascendancy of the Fitzgerald earls of Kildare, established when Thomas, 7th earl, was created lord deputy in 1471, had passed (1477) to his son Garret More (Great Gerald). The fiction of the king's power was preserved by appointing an absentee lieutenant, from whom Kildare held as deputy; in practice, any real power was exercised largely through dynastic alliances with the chief Gaelic and Anglo-Irish lords. Opposition to Kildare was negligible so long as the king was unable to maintain a permanent power to which his opponents might turn; an attempt to displace him was made when Kildare gave support (1487) to Lambert Simnel, a pretender to the English throne. After the advent of a more dangerous pretender, Perkin Warbeck, it was decided (1494) to remove Kildare and rule through an Englishman, Sir Edward Poynings. Poynings subdued Kildare, but he could not reconquer the northern Gaelic Irish. At Drogheda (1494–95) he induced a Parliament to pass an act that came to be known as "Poynings' Law"; it subjected the meetings and legislative drafts of the Irish Parliament to the control of the English king and council. But his administrative expenses were too great, and Henry VII decided in 1496 to restore Kildare.

Sir Edward Poynings

On Kildare's death (1513), the deputyship passed to his son Garret Oge (Young Gerald), 9th earl of Kildare, who continued, though less impressively, to dominate the country. But James, 10th earl of Desmond, intrigued with the emperor Charles V; and Henry VIII became convinced that Kildare had lost the power to keep Ireland neutral. Therefore, when the divorce (1533) of Catherine of Aragon made the danger of imperial intervention particularly acute, the King summoned Kildare to England (1534). There were, thereafter, no Irish-born viceroys for more than a century.

The Reformation period. Rumours that Kildare had been executed precipitated the rebellion of Kildare's son, Lord Thomas Fitzgerald, called Silken Thomas. The rebellion facilitated the transition to the new system. Silken Thomas had opposed Henry VIII's breach with Rome; his execution (1537) caused a revival of the power of the Butlers of Ormonde; Piers Butler, earl of Ossory, helped to secure the enactment of the royal (instead of papal) ecclesiastical supremacy by the Dublin Parliament of 1536–37. As a further step in getting rid of the Pope, in 1541 a complaisant Parliament recognized Henry VIII as king of Ireland (his predecessors had held the title of lord of Ireland). Confiscation of monastic property, as well as the lands of the rebels, met most of the costs of the expanded administration. This loss of land inevitably drove the religious orders and the Anglo-Irish into the arms of the Gaelic Irish, thus weakening the old racial rivalries of medieval Ireland.

Sir Anthony St. Leger, lord deputy in 1540–48 and again in 1550–56, then began a conciliatory policy by which outstanding lords were persuaded, in order to gain new titles and grants of lands, to renounce the Pope and recognize the King's ecclesiastical supremacy. This policy, however, required a steady series of efficient governors and disciplined administrators; in fact, neither in Tudor nor in Stuart times did the English succeed in converting elective chiefs into hereditary nobles holding offices delegated by the crown. Moreover, even those who had recently submitted were often condemned for religious conservatism and deprived of their lands. St. Leger's personal success was all the more remarkable because the first Jesuit mission to Ireland arrived in the north in 1542.

Under Edward VI (1547–53), the Dublin authorities carried out a forward policy in religion as well as in politics, but Protestantism got no support except from English officials. The official restoration of Catholicism under Queen Mary (1553–58) revealed the strength of resentment in Ireland against Protestantism. As in England, the papal jurisdiction was restored, but otherwise the Tudor regulations of authority were observed. The Pope was induced to recognize the conversion of the Tudor Irish

lordship into a kingdom. Finally, Mary gave statutory approval for the plantation of Leix, Offaly, and other Irish lordships of the central plain. Her viceroy was Thomas Radcliffe, earl of Sussex, lord deputy (1556–59), who was soon, as lord lieutenant (1559–66) for Elizabeth I, to restore the state's authority over the church.

Ireland under Elizabeth I. The Acts of Supremacy and Uniformity, enforcing the Anglican Church settlement, were passed in Ireland in 1560, but fear of driving the inhabitants of the Pale into alliance with the Gaelic Irish and perhaps with the Spanish made the government lenient in enforcing the terms of the Acts. Political affairs continued to preoccupy the administrators, so that the new Protestant church was unequipped to resist the forces of the Counter-Reformation. This was inevitable in an Ireland only superficially conformed to royal obedience; but the seriousness of the situation was shown by the three great rebellions of the reign, those of Shane O'Neill (1559), of the Fitzgeralds of Desmond (1568–83), and of O'Neill (Tyrone) and O'Donnell (1594–1603).

The rebellion of Shane O'Neill

The first of these rebellions, that of Shane O'Neill, fully exposed the weakness and later the folly of the government. O'Neill's father, Con Bacach (the Lame), who as the "O'Neill" was head of a whole network of clans, had been made earl of Tyrone in 1541, the succession rights of his illegitimate son Feardorchadh (Matthew) being recognized. Shane, younger but the eldest legitimate son, was, nevertheless, elected O'Neill on his father's death (1559), and soon afterward Feardorchadh was killed. O'Neill then took the field against the Dublin government, demanding recognition according to the laws of primogeniture, and he insisted that neither of Feardorchadh's sons, Brian and Hugh, had claims to the earldom. Elizabeth invited O'Neill to London to negotiate, but the opportunity for a statesmanlike settlement was lost. O'Neill was to be "captain of Tyrone" and was encouraged to expel from Antrim the MacDonnell (MacDonald or MacConnell) migrants from Scotland. Returning to Ireland in May 1562, O'Neill routed the MacDonnells as well as the loyal O'Donnells of the northwest, and attempted to secure support from Scotland and France. Eventually the government was saved from a serious situation only through the defeat of O'Neill by the O'Donnells and his murder in 1567 by the MacDonnells.

The lands of the O'Neills and even of loyal Gaelic lords were declared forfeit in 1569, and in a wave of enthusiasm for colonization, various questionable adventurers were permitted to attempt substantial plantations in Munster, Leinster, and Ulster. The folly of this policy was seen when the government, despite its having declared the position of "O'Neill" extinguished, yet allowed the O'Neills to elect Shane's cousin, Turloch Luineach, as their chief. Butlers and Munster Fitzgeralds also combined forcibly to resist the plantations. The only gleam of statesmanship shown in these years by Henry Sidney, lord deputy (1565–71, 1575–78), was that he managed to avoid a major combination against the government's religious policy. The Butlers were induced to submit, the planters were given only limited support, and a head-on collision with Turloch Luineach was averted. When the Ulster plantation plans could not be carried out against Irish resistance, the Queen wisely decided they should be dropped. The pardon of the Butlers pacified Leinster, and although in Munster the earl of Desmond's cousin James Fitzgerald, called "Fitzmaurice," attempted to make the war one of religion, he too was eventually pardoned.

The Desmond wars

Despite his pardon, Fitzmaurice in 1575 fled to the Continent, returning to Ireland in 1579 with papal approval for a Catholic crusade against Queen Elizabeth. Although neither France nor Spain supported it, and Fitzmaurice was surprised and killed in August 1579, the government was extremely apprehensive. Gerald Fitzgerald, 14th earl of Desmond, then assumed direction of the enterprise. As a military commander he was wholly deficient, and his mediocrity may well have kept outstanding figures in the north and west out of the movement. The rebels were defeated, and in November 1580 a force of Italians and Spaniards was massacred at Dún an Óir ("Golden Fort"), Smerwick Harbour, County Kerry.

The end of the Desmond rebellion gave the government the opportunity to confiscate more than 300,000 acres (100,000 hectares) in Munster and initiate more stringent proceedings against Catholics. But the plantation was not a success. A more statesmanlike attitude was displayed in regard to Connaught land titles. When Sir John Perrot was lord deputy (1584–88), a number of agreements were made with individual landowners and chieftains, by which their titles were officially recognized in return for fixed regular payments. This was a step in the process of converting a great part of the country to English tenures. Perrot was less successful in handling the 1585–86 Parliament, in which the government's anti-Catholic program was defeated by the opposition.

The Tyrone war

The origins of the third rebellion, the O'Neill (Tyrone) war, remain in doubt. Both Hugh Roe O'Donnell and Hugh, younger son of Feardorchadh O'Neill, for whom the earldom of Tyrone had been revived in 1585 and who had had himself elected O'Neill on Turloch Luineach's death in 1595, certainly resented the extension of the royal administration, but the religious issue was probably more important. For a generation exiled Catholics had been trained as missionaries in the continental colleges of the Counter-Reformation, and the majority of those who returned to Ireland concluded that Catholicism could only survive there if Elizabeth were defeated. The outbreak of hostilities in Ulster in 1594 was at first confined to the northwest, where O'Donnell and Maguire, lord of Fermanagh, tried to drive out the English troops. The intervention of Hugh O'Neill was expected, if not inevitable. His participation with his brother-in-law O'Donnell proved decisive in the north and west, and the English were defeated both in Ulster and in Connaught. A more intimidating combination thus threatened Dublin than even in Shane O'Neill's time. Even in the Pale, arbitrary exactions and exclusion from offices won Hugh much sympathy, and it was said that he knew of Dublin Castle decisions before they were known in the city. Resentful of O'Neill's alleged ingratitude, Elizabeth became impatient of negotiations with him and finally sent Robert Devereux, earl of Essex, to Ireland (1599) to subdue him. But Essex lost his reputation by his inglorious progress through the country and by the speed with which he returned to England after a private conversation with O'Neill. Before Charles Blount, Lord Mountjoy, arrived (1600) to replace Essex, the Irish leaders had gained the qualified support of Pope Clement VIII and of King Philip III of Spain. But Philip could afford to send only a minimal force to aid the Irish rebels. Its leader Juan del Aguila occupied Kinsale and was besieged (1601) by Mountjoy. O'Neill marched south to relieve Aguila, but a rash attempt to surprise the English lines by night proved disastrous (December 24, 1601); the Irish were defeated and the Spaniards surrounded. O'Neill held out in Ulster for over a year but finally submitted a few days after the Queen's death (March 1603).

Viewed generally, Elizabeth's Irish policy had the distinction of having reduced the country to obedience for the first time since the invasion of Henry II. But the cost was a serious one. The loyalty of the Irish was perennially strained over the religious issue, so that further rebellion was almost inevitable and virtually predictable in 1640 when the English government was embarrassed by the Second Bishops' War with Scotland. Economically, the towns and the countryside were needlessly exploited by the new administrators and planters, while the Queen's expenditure was substantially increased. Commitments in Ireland were at least partly responsible for the poverty of the crown, which was to become a serious factor in precipitating its 17th-century conflict with Parliament.

MODERN IRELAND

The 17th century. *James I (1603–25).* James VI of Scotland, who also became King James I of England and Ireland in 1603, might have pursued an Irish policy more enlightened than that of Elizabeth, who had been committed to war against the papacy and against Spain. He did make peace with Spain, but his policy of guarded religious toleration was nullified by the intransigence of

From A. Orme, *Ireland*

the established Anglican Church and of the papacy. Unfortunately, James allowed Irish policy to be dominated by the interests of the English governing class and also sought to provide in Ireland opportunities for his countrymen. He thereby virtually continued Elizabethan policy, and as a result the steady exodus of Irish soldiers and churchmen to Catholic countries on the continent was unabated. On a short-term basis, their absence contributed to peace; but their influence abroad made the Irish question an international one. In Ireland, the overwhelming majority of the Gaelic Irish and of the old Anglo-Irish remained detached from government in attitude as well as in way of life.

Plantation in Ulster

As soon as James's policy became clear, the earls of Tyrone and of Tyrconnel and other Ulster Gaelic lords joined the flight from Ireland. Their departure opened the way for the plantation of Ulster by a new landowning class, which included Scots as well as Englishmen. This proved the most successful British settlement made in Ireland, mainly because British tenantry and labourers were introduced as well as landlords. The newcomers were mainly from the Scottish Lowlands, and at first the English feared them almost more than they feared the Irish. In an attempt to counter their influence, the city of London was involved in the Ulster plantation, its name being combined with that of the historic ecclesiastical settlement of Derry to provide the name of a plantation. The Presbyterianism of the Scottish immigrants was successfully kept at bay until the time of the English Civil War; the Anglican bishoprics in Ireland were well endowed and powerful, and it was not until 1643 that the first presbytery was established in Belfast.

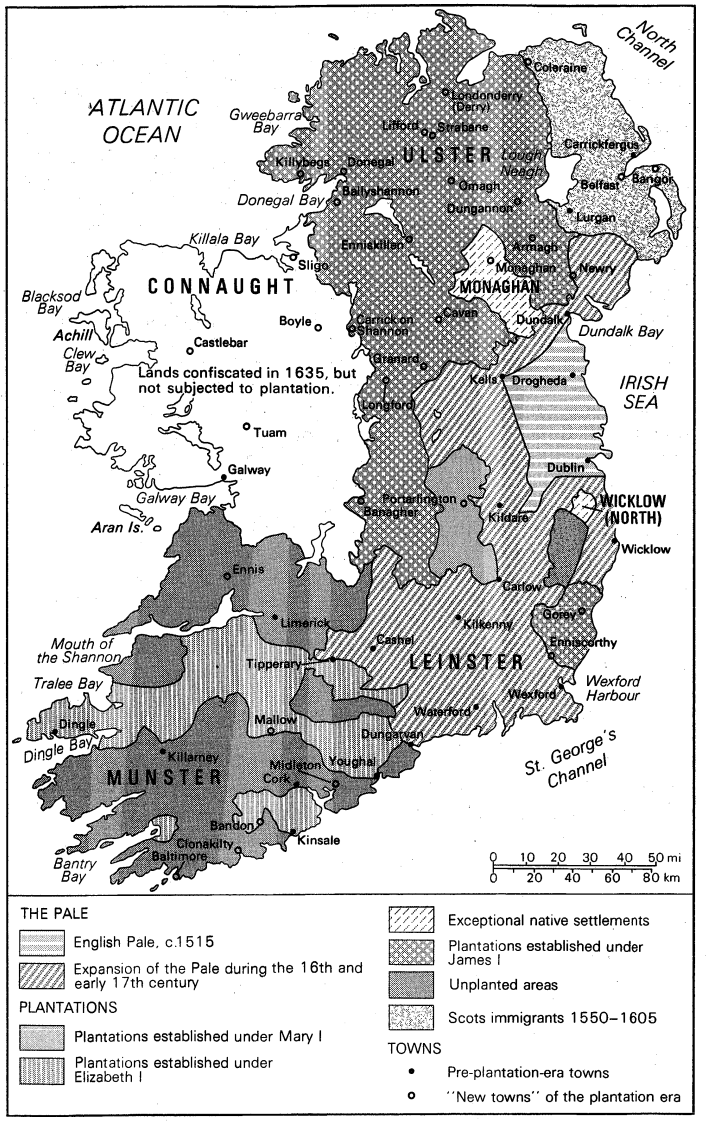
In the Parliament of 1613–15, summoned to ratify the Ulster plantation, a small Protestant majority was achieved because many new boroughs had been created in the newly planted areas. But government was concerned more with the appearance than the reality of consent, and no Parliament was called again until 1633. In the last years of James's reign, pressure from his Spanish and French allies caused him to concede toleration to the Catholics; and from 1618 a Catholic hierarchy was in residence in Ireland.

Charles I (1625–49) and the Commonwealth (1649–60). Charles I conceived the idea of raising armies and money in Ireland, in return for religious concessions known as "the graces" by which Catholics were allowed to engage in various public activities. But this policy was abandoned by Thomas Wentworth, later earl of Strafford, lord deputy from 1633 to 1640. He set himself to break the power of the great and of trade monopolists, both Irish and English, including the London city companies. He induced the Catholic members of the Irish House of Commons to join in voting large subsidies in the hope of obtaining further concessions but then abolished most of the existing "graces." He thus seriously weakened the loyalty to the crown of the old landowning classes; and later all his enemies in Ireland joined with those in England in bringing about his execution (1641). His Irish Army was disbanded, and control of the Irish government passed to Puritan lords justices.

Ireland during the English Civil War and its aftermath

A general rising of the Irish in Ulster was almost inevitable. It took place in October 1641, and thousands of colonists were murdered or fled. A Catholic confederacy was formed at Kilkenny in 1642, but it did not succeed in welding together the various groups of which it was composed. During the period of the English Civil War there were Irish confederate armies in Ulster and in Leinster; English parliamentary armies operated in the north and south; and Dublin was held by James, duke of Ormonde, commanding an army of Protestant royalists. Negotiations for peace between Ormonde and the confederates were difficult and protracted; and in 1646, when it was clear that Charles I's cause was lost, Ormonde surrendered Dublin to a parliamentary commander. The confederates in isolation could offer little resistance (1649–50) to Oliver Cromwell. By 1652 all Irish resistance was over.

During the Commonwealth and Protectorate, authority in Ireland was exercised by parliamentary commissioners and chief governors. A union of the three kingdoms of England, Scotland, and Ireland, effected in 1653, resulted in Irish representatives attending Parliaments held in London in 1654, 1656, and 1659. By an Act of Settlement, Ireland, regarded as conquered territory, was parcelled out among soldiers and creditors of the Commonwealth, and only those Irish landowners able to prove their constant support of the Parliamentary cause escaped having their estates confiscated. Of these, those who were Catholics were still obliged to exchange land owned to the northeast or south of the River Shannon for land in Connaught. Catholics and Anglicans were forbidden to practice their religion, but the campaign against Irish Cathol-



The English plantation of Ireland in the 16th and 17th centuries.

icism was not successful. After the Restoration (1660) Charles II personally favoured complete religious toleration, but the forces of militant Protestantism sometimes proved too strong for him. The Commonwealth parliamentary union was, after 1660, treated as null and void.

The Restoration period and the Jacobite war. Most significant of the events of the Restoration was the second Act of Settlement (1662), which enabled Protestant loyalists to recover their estates. The Act of Explanation (1665) obliged the Cromwellian settlers to surrender one-third of their grants, providing a reserve of land from which Catholics were partially compensated for losses under the Commonwealth. This satisfied neither group. Catholics were prevented from residing in towns, and local power, in both borough and county, became appropriated to the Protestant interest. But Protestantism itself became permanently split; as in England, the Presbyterians refused to conform to Episcopalian order and practice and, in association with the Presbyterians of Scotland, organized as a separate church.

Under James II, advantage was taken of the King's Catholicism to reverse the tendencies of the preceding reign. After his flight from England to France (1688), James crossed to Ireland, where, in a Parliament, the Acts of Settlement and Explanation were repealed and provision was made for the restoration of expropriated Catholics. When William III landed in Ireland to oppose James, the country divided denominationally, but the real issue was not religion but the land. After his defeat at the Battle of the Boyne (1690) James fled to France, but his Catholic supporters continued in arms until defeated at Aughrim and obliged to surrender (1691) at Limerick. Here, however, they secured either the right to go overseas or, if they accepted William's regime, immunity from discriminatory laws. But civil articles to secure toleration for the Catholics were not ratified, thus enabling later Irish leaders to denounce the "broken treaty" of Limerick. Immediately after Limerick, the Protestant position was secured by acts of the English Parliament declaring illegal the acts of King James's Parliament in Ireland and restricting to Protestants membership of future Irish Parliaments. The sale of the lands forfeited by James and some of his supporters further reduced the Catholic landownership in the country; by 1703 it was less than 10 percent. On this foundation was established the Protestant Ascendancy.

The Protestant Ascendancy

The 18th century. The Protestant Ascendancy was a supremacy of that proportion of the population, about one-tenth, which alone belonged to the established Protestant Episcopalian Church. They celebrated their position as a ruling class by annual recollections of their victories over their hated popish enemies. Not only the Catholic majority but also the Presbyterians and other Nonconformists, whose combined numbers exceeded these of the church establishment, were excluded from full political rights, notably by the Test Act of 1704, which made tenure of office dependent upon willingness to receive communion according to the Protestant Episcopalian (Church of Ireland) rite. Owing to their banishment from public life, the history of the Catholic Irish in the 18th century is concerned almost exclusively with the activities of exiled soldiers and priests, many of whom distinguished themselves in the service of continental monarchs. Details of the lives of the unrecorded Catholic majority in rural Ireland can be glimpsed only from ephemeral literature in English and from the Gaelic poetry of the four provinces.

The Protestant Ascendancy of 18th-century Ireland began in subordination to that of England but ended in asserting its independence. In the 1690s commercial jealousy compelled the Irish Parliament to destroy the Irish woollen export trade, and in 1720 the Declaratory Act affirmed the right of the British Parliament to legislate for Ireland and transferred to the British House of Lords the powers of a supreme court in Irish law cases. By the end of the first quarter of the 18th century, resentment at this subordination had grown sufficiently to enable the celebrated pamphleteer Jonathan Swift to whip up a storm of protest over the affair of "Wood's halfpence." Wood, an English manufacturer, had been authorized to mint coins for Ireland; the outcry against alleged exploitation of the lesser country by arbitrary creation of a monopoly became so violent that it could be terminated only by withdrawing the concession from Wood.

Nevertheless, it was another 30 years before a similar protest was made. In 1751 a group of patriots organized themselves to defeat government resolutions in the Irish Parliament appropriating a financial surplus as the English administrators rather than the Irish legislators saw fit. Although in 1768 the Irish Parliament was made more sensitive to public opinion by provision for fresh elections every eight years instead of merely at the beginning of a new reign, it remained sufficiently controlled by government to pass sympathetic resolutions on the revolt of the American colonies.

The American Revolution greatly influenced Irish politics, not least because it removed government troops from Ireland, and the Protestant Irish volunteer corps, spontaneously formed to defend the country against possible French attack, exercised a coercive influence for reform. A patriotic opposition, led by Henry Flood and Henry Grattan, began an agitation that led in 1782 to the repeal of the Declaratory Act of 1720, and to an amendment of Poynings' Law to give legislative initiative to the Irish Parliament. In this period many of the disabilities suffered by Catholics in Ireland were abolished, and in 1793 the British government, seeking to win Catholic loyalty on the outbreak of war against Revolu-

tionary France, gave them the franchise and admission to most civil offices. The government further attempted to conciliate Catholic opinion in 1795 by founding the seminary of Maynooth to provide education for the Catholic clergy. But the Protestant Ascendancy had become concerned about its position and resisted efforts to make the Irish Parliament more representative. The outbreak of the French Revolution had effected a temporary alliance between an intellectual elite among the Presbyterians and leading middle class Catholics; these, under the inspiration of Theobald Wolfe Tone, founded societies of United Irishmen, a series of radical political clubs. After the outbreak of war, the societies, reinforced by agrarian malcontents, were driven underground. In despair they sought the military support of Revolutionary France, which, between 1796 and 1798, dispatched a series of abortive naval expeditions to Ireland. The United Irishmen were preparing for rebellion; it broke out in May 1798 but was widespread only in Ulster and in Wexford in the south. Although the rebellion was unsuccessful, it brought the Irish question forcibly to the attention of the British Cabinet, and the prime minister William Pitt planned and carried through an amalgamation of the British and Irish Parliaments, merging the kingdoms of Great Britain and Ireland into the United Kingdom. Despite substantial opposition in the Irish Parliament, the measure passed into law, having effect from January 1, 1801. To Grattan and his supporters the Union seemed the end of the Irish nation; the last protest of the United Irishmen was made in Robert Emmet's abortive rebellion of 1803.

The Union with Great Britain

Social, economic, and cultural life in the 17th and 18th centuries. Although the late 16th century saw the destruction of Gaelic civilization in the upper levels of society, it was preserved for more than the next two centuries among the ordinary people of the northwest, west, and southwest, who continued to speak Irish and who maintained a way of life remote from that of the new landlord class.

The 17th-century confiscations made Ireland a land of great estates and, except for Dublin, of small towns decaying under the impact of British restrictions on trade. Except on the Ulster plantations, the tenantry was relatively poor in comparison with that of England and employed inferior agricultural methods. Over large parts of the east and south, tillage farming had given way to pasturage. In the north of Ireland, a somewhat similar tendency, creating a decline in the demand for labour, led in the early 18th century to the migration of substantial numbers of Ulster Scots to North America. In Ulster there gradually emerged a tenantry who compelled their landlords to maintain them in their farms against the claims and bids of Catholic competitors now once again legally entitled to hold land. This purpose immensely strengthened the Orange Order, founded in 1795 in defense of the Protestant Ascendancy. Increasingly it linked the Protestant gentry and farmers, while excluding Catholics from breaking into this privileged ring. Tillage farming was maintained in Ulster more extensively than in the south and west, where there developed on the poorer lands a system of subdivision apparently necessitated by population increase. Little is known of the lives of the ordinary people and even for those of the gentry the evidence, apart from that of estate records, is rarely extensive.

Little need be said of the culture of the Anglo-Irish in the same period, as it followed so closely the traditions of Britain and, very occasionally, those of the rest of Europe. Gradually, during the 18th century, the new landowning class developed some appreciation of the visual arts. But the really original achievement of the period was in literature, particularly in drama, where the rhetorical gifts of the people secured an audience. In this period there was a strong connection between rhetoric and the arts, as between oratory, themes of social decay, and the consoling power of language and form. Such works as Oliver Goldsmith's *Deserted Village* and *Traveller*, Edmund Burke's speeches, and the speeches and plays of Richard Brinsley Sheridan are manifestations of a rhetorical tradition central to Irish feelings.

The 19th and early 20th centuries. By the Act of Union it was provided that Ireland would have in the United Kingdom about one-fifth of the representation of Great Britain, with 100 members in the House of Commons. The union of the churches of England and Ireland as the established denominations of their respective countries was also effected, and the pre-eminent position in Ireland of Protestant Episcopalianism was further secured by the continuation of the British Test Act, which virtually excluded Nonconformists (both Catholic and Protestant) from Parliament and from membership of municipal corporations. Not until 1828–29 did the repeal of the Test Act and the concession of Catholic emancipation provide political equality for most purposes. It was also provided in the Union that there should be free trade between the two countries and that Irish merchandise would be admitted to British colonies on the same terms as British merchandise. But these advantages were not enough to offset the disastrous effect upon Ireland of exposure to the full impact of Britain's industrial revolution. Within half a century agricultural produce dropped in value, estate rentals declined, while the rural population increased substantially. When the potato, the staple food of rural Ireland, rotted in the ground through the onset of blight in the mid-1840s, thousands died of starvation and fever in the Great Famine that ensued, and thousands more fled abroad.

At first, and perhaps for more than one-third of the 19th century, the auguries of success for the Union were favourable. After the defeat of Napoleon at Waterloo (1815), political discontent increased but became concentrated, so far as the Catholics were concerned, on securing their emancipation. Until this was achieved there had not clearly emerged any notable difference in outlook between the Catholics and Presbyterians; but the dramatic manner in which the Catholic Daniel O'Connell was elected for County Clare (1828), subsequently sweeping the emancipation movement into victory, provoked a panic among timid Protestants and led to an alliance between the Presbyterians and their old oppressors, the Protestant Episcopalians. After emancipation, the middle class Catholics and Protestants drifted apart, the latter increasingly clinging to the Union, the former more slowly but at last decisively coming to seek its repeal.

Emergence of Daniel O'Connell

O'Connell's adherence to the cause of repeal did not prevent him from participating actively in British politics. Lord Melbourne, the Whig prime minister, by a bargain known as the Lichfield House Compact (1835), secured O'Connell's support in return for a promise of "justice for Ireland." But meanwhile the Tories, led by Sir Robert Peel, exercised through their control of the House of Lords an effective restriction on promised social and economic reforms for Ireland, and when Peel returned to power in the early 1840s O'Connell, despairing of further concessions, began a massive campaign outside Parliament for repeal of the Union, notably by organizing large popular demonstrations. A climax was reached in October 1843 when troops and artillery were called out to suppress the mass meeting arranged at Clontarf outside Dublin. O'Connell's method of popular agitation within the law proved unavailing, however, and his influence thereafter rapidly declined.

Associated with O'Connell's repeal agitation was the Young Ireland movement, a group connected with a repeal weekly newspaper, *The Nation*, and led by its editor Charles Gavan Duffy, its chief contributor Thomas Osborne Davis, and its special land correspondent John Blake Dillon. But they became increasingly restless at O'Connell's cautious policy after Clontarf and in 1848 became involved in an abortive rising. Its failure, and the deportation or escape from Ireland of most of the Young Ireland leaders, destroyed the repeal movement.

For about 20 years after the Great Famine, political agitation was subdued, while emigration continued to reduce the population every year. The landowners had also suffered severely from inability to collect rents, and there was a wholesale transfer of estates to new owners. Evic-

tions were widespread, and cottages were demolished at once by the landlords to prevent other impoverished tenants from occupying them. The flow of emigrants to the United States was encouraged by invitations from Irishmen already there. And in England, also, the new industrial cities and shipping centres attracted large settlements of hopeless and embittered exiles from Ireland.

Rise of Fenianism. Among the exiles both in the United States and in England, the Fenian movement spread widely. A secret revolutionary society named after the Fianna, the Irish armed force in legendary times, it aimed at securing Ireland's political freedom by exploiting every opportunity to injure English interests.

Imprisonment of Fenian leaders

In Ireland, Fenian ideals were propagated in the newspaper *The Irish People;* and in 1865 four Fenian leaders, Charles Kickham, John O'Leary, Thomas Clarke Luby, and Jeremiah O'Donovan Rossa were sentenced to long-term imprisonment for treasonable writing in it. Gradually, during the next two years plans developed for a projected nationwide rising, financed largely by funds collected in the United States. It took place in March 1867 but was easily crushed and its leaders imprisoned. The prime minister, W.E. Gladstone, at last recognized the necessity for drastic Irish reforms, disestablishing the Protestant Church in Ireland in 1869 and in 1870 introducing the first Irish Land Act, which conceded the principles of secure tenure and compensation for improvements made to property. He may also have been concerned at the cleavage between English and Irish public opinion caused by the execution at Manchester of W.P. Allen, Michael Larkin, and Michael O'Brien for involvement in a Fenian prisoner-rescue operation that resulted in the shooting of a British police sergeant. To most Englishmen the "Manchester murderers" richly deserved their fate; to most Irishmen they were the "Manchester martyrs," celebrated in ballad and legend.

The Home Rule movement and the Land League. Soon afterward, in 1870, a constitutional movement, the Home Government Association (Home Rule League), was founded by Isaac Butt, a prominent Unionist lawyer interested in land reform. In the election of 1874 it returned about 60 members to Parliament. The movement was tolerated rather than encouraged by the various groups of Irish nationalists, and it was not fully supported by the Catholic clergy until the 1880s.

A return of bad harvests in 1879 brought new fears of famine, and Michael Davitt founded the Irish Land League, seeking to achieve for tenants security of tenure, fair rents, and freedom to sell property. A formidable agrarian agitation developed when Davitt was joined by Charles Stewart Parnell, a young landowner and member of Parliament in the Home Rule Party, which soon elected him as its leader in place of Butt. Parnell undertook a tour of North America to raise funds for the Land League; there he was influenced by two Irish Americans, John Devoy, a leading member of Clan na Gael, an effective American Fenian organization, and Pat Ford, whose New York paper *The Irish World* preached militant Socialism and hatred of England. At Westminster Parnell adopted a policy of persistent obstruction, which compelled attention to Irish needs by bringing parliamentary business to a standstill. Gladstone was forced to introduce his Land Act of 1881, conceding fixity of tenure, fair rents, and free sale of the tenant's interest.

Parnell's success was not achieved without serious difficulties, including the ultimate proscription of the Land League by the government and the imprisonment of its leaders. As a result, Parnell used his parliamentary party, then increased to 86, to defeat and thus dismiss from office Gladstone's Liberal government, already unpopular in England as a result of its failure to relieve General Gordon at Khartoum in 1884. For a while Conservatives and Liberals both negotiated with Parnell, but ultimately

Gladstone's Home Rule bill

Gladstone became converted to Home Rule, introducing a bill to bring it into effect after he returned to office in 1886. The bill, however, was defeated by a combination of Conservative Unionists influenced by Irish Orangemen and splinter groups from the Liberal Party. There followed 20 years during which Irish Nationalist ambitions seemed frustrated, partly because Conservative-Unionists were mainly in power and partly because bitter internal rivalries discredited the Irish Nationalist Party after Parnell's involvement (1889) in a divorce suit. Meanwhile, Gladstone's second Home Rule Bill (1893) was rejected in the House of Lords. Only in 1900 was a Parnellite, John Redmond, able to reunite the Nationalists. In the last years of the century, partly in reaction to political frustrations, a cultural nationalist movement developed, led by Douglas Hyde and Eoin MacNeill. Through the Gaelic League much was done to revive interest in the speaking and study of Irish. These cultural movements were reinforced by others, such as that of the Sinn Féin ("Ourselves") movement led by Arthur Griffith, who preached a doctrine of political self-help. It subsequently emerged that a Fenian organization, the Irish Republican Brotherhood, had revived and was secretly recruiting membership through various cultural societies and through the Gaelic Athletic Association, founded to promote specifically Irish sports.

Around the close of the century the Conservatives initiated a policy designed to "kill Home Rule by kindness" by introducing constructive reforms in Ireland. Their most important achievement in this field was the Wyndham Land Purchase Act of 1903. This, by providing generous inducements to landlords to sell their estates, effected by government mediation the transfer of land ownership to the occupying tenants.

The 20th-century crisis. After the great Liberal victory of 1906, Redmond decided to force the Liberals to revive Home Rule, and when Lloyd George's radical budget provoked a collision with the House of Lords in 1909, he seized his opportunity. He agreed to support the campaign of the prime minister, H.H. Asquith, against the Lords in return for the promise of a Home Rule bill. The reduction of the power of the Lords by the 1911 Parliament Act seemed to promise success for the third Home Rule bill, introduced in 1912. But in the meantime the Irish Unionists, under their colourful leader Sir Edward Carson, had mounted an effective countermovement, backed by most of the British Unionists. Thousands of Ulstermen signed the Ulster Covenant of resistance to Home Rule (1912), and Carson announced that a provisional government would be formed there. At first planning to reject Home Rule for all Ireland, the Unionists gradually fell back on a demand for Ulster to be excluded from its scope. Redmond's claim that there was "no Ulster question," implying that even among the Ulster members of Parliament there was a majority for Home Rule, hardened the Protestant and Unionist resistance in the areas around Belfast. Down, Antrim, Armagh, and Derry all contained large Unionist majorities; Donegal, Cavan, and Monaghan had strong Home Rule majorities; and Tyrone and Fermanagh had small Home Rule majorities. The Ulster Volunteer Force was organized and boasted of active sympathy among army officers; their boasts became formidable when all the officers in the cavalry brigade at the Curragh suddenly announced (March 1914) that they would resign if ordered to move into Ulster. Meanwhile, to counter the Ulster Volunteers, a nationalist force, the Irish Volunteers, had been launched in Dublin in November 1913. Both forces gathered arms, and Ireland was on the verge of civil war when World War I broke out. Assured of Redmond's support in recruiting for the army, Asquith enacted Home Rule but followed this with a Suspensory Act, delaying implementation until the return of peace.

Meanwhile in Ireland, the revolutionary element gained support from those alienated by Redmond's pro-British attitude. Before the end of 1914 the Irish Republican Brotherhood had made full plans for a revolutionary outbreak. Sir Roger Casement went to Germany to solicit help; but he obtained only obsolete arms and was himself arrested on his return to Ireland on April 21, 1916. When the rising took place three days later, on Easter Monday, only about 2,000 of the small force available were actually engaged. A provisional Republic government was proclaimed. The General Post Office and other parts of Dublin were seized; street fighting continued for about a week

The Easter Rising

until Patrick Pearse and other Republican leaders were forced to surrender. Their subsequent execution aroused Irish public opinion and led to the defeat and virtual extinction of Redmond's constitutional party at Westminster in the general election of December 1918. Their successful opponents, calling themselves Sinn Féin but supporting the Republican program announced in 1916, were led by Eamon De Valera, a surviving leader of the Rising. Again the Republicans set up their provisional government, elected by the Irish members of Parliament at a meeting in Dublin called Dáil Éireann, the "Irish Assembly." This provided a constitutional facade when British government was rapidly breaking down except in the northeastern counties. Simultaneously, the Irish Republican Army (IRA) was organized to resist British Administration and to secure recognition for the Republican government. Its members soon engaged in widespread ambushes and attacks on barracks, while the government retaliated with ruthless reprisals. A large proportion of the Irish police resigned and were replaced by English recruits, known from their temporary uniforms as the Black and Tans.

In this condition of virtual civil war Britain gradually alienated Irish public opinion and was forced, partly under American influence, to pass the Government of Ireland Act (1920). By this measure Ireland was divided into two self-governing areas, Northern Ireland and Southern Ireland. Both were to enjoy, within the United Kingdom, limited powers of self-government. After a general election in Ireland, King George V opened the Parliament of Northern Ireland in Belfast (1921) and in his speech appealed for an end to fratricidal strife. The King's initiative forced the British prime minister Lloyd George to open negotiations with De Valera, but for some time progress proved impossible, because neither side would admit the other's legality. Ultimately, on December 6, 1921 a treaty was signed on behalf of Great Britain by Lloyd George and leading members of his cabinet and on behalf of Ireland by Arthur Griffith, Michael Collins, and other members of the Republican Cabinet.

THE IRISH FREE STATE AND THE REPUBLIC OF IRELAND

Establishment of the Irish Free State. The Anglo-Irish treaty, signed on December 6, 1921, provided that Ireland should in future have the "same constitutional status in the Community of Nations known as the British Empire" as had the dominions of Canada, Australia, New Zealand, and South Africa, "with a Parliament having powers to make laws for the peace, order and good government of Ireland and an Executive responsible to that Parliament." The new dominion was to be known as the Irish Free State. This peace agreement, ratified by the British Parliament, became operative when it had also been passed (January 1922) by a meeting of the Dáil. The new state comprised only 26 of the 32 counties, the northeastern area, known as Northern Ireland, remaining separate.

But the terms of the treaty had been accepted by the Irish signatories only because Lloyd George had threatened war on Ireland if they were rejected. Particularly obnoxious were a prescribed oath of allegiance to the British crown and the provisions allowing Northern Ireland to remain outside the new State. De Valera and the Republicans immediately repudiated the treaty, and after its passage in the Dáil, De Valera resigned the presidency. Michael Collins, chairman of the provisional government set up according to the terms of the treaty, and Arthur Griffith, the new president, desired an immediate general election to obtain a verdict on the treaty; in deteriorating conditions he eventually made with De Valera an agreement known as the Pact (May 20, 1922), in which it was settled that government and Republican candidates would not oppose each other and that De Valera would consider resuming office. But the Pact naturally could not bind other parties, and at the election (June 16) Republicans were ousted in favour of members of a labour party and a farmers' party and by independents, thus reducing the anti-treaty vote to a small minority. Before the Dáil could meet, civil war had broken out between the government and the Republicans, who were allegedly accessories to the assassination (June 22) in London of Field Marshal Sir Henry Wilson soon after his acceptance of the position of military adviser to the government of Northern Ireland. The Republicans in Dublin had occupied the Four Courts (central courts of justice) and eventually, under pressure from Britain, which also provided military equipment, Collins ordered them to retire. Serious fighting ensued for a week, until the Courts were blown up, and Rory O'Connor, the Dublin Republican leader, surrendered. Meanwhile, De Valera, who had escaped to the southwest, was openly supporting the Republicans. Griffith and Collins decided that no further compromise was possible, and military operations were begun. The strain had told so heavily on Griffith that he died suddenly on August 12, while Collins, inspecting the military operations, was killed in an ambush on August 22.

Repudiation of the treaty by the Republicans

The provisional government had thus lost two of its most prominent leaders, and surviving ministers could not appear openly without armed protection. Moreover, there was urgency in that, by the terms of the treaty, the newly elected Dáil was required to frame its constitution before December 6, 1922. It was therefore summoned to meet on September 9, elected as the new president William Thomas Cosgrave, and, in the absence of the Republican deputies, quickly passed the clauses of the constitution defining the relations of the Free State with the British crown and outlining arrangements for imperial defense. Timothy Michael Healy, a veteran follower of Parnell who had later supported Sinn Féin, was then appointed governor general, and Cosgrave became president of the executive council. The new constitution was also ratified at Westminster.

The Cosgrave ministries. Both before and after the ratification of the constitution the government resorted to strong measures to quell disorder and violence. Its decision to execute those found in unauthorized possession of firearms embittered Irish politics for years afterward. Numerous Republican insurgents were also imprisoned, and 77 were executed. Although Republican opposition was at first more bitter than ever, it eventually became less well organized, and by May 1923, on De Valera's recommendation, armed resistance ended.

The fourth Dáil

At the end of August 1923 the fourth Dáil was elected, on a basis of adult suffrage for men and women. De Valera retained his personal following, and his party won 44 seats out of 128. Cosgrave's party won less than half the total number of seats, but as the Republicans refused to sit in the new Dáil, he had a majority among those who did attend. The absence of any effective opposition party greatly strengthened the power of the new government to carry measures quickly, and in the following years it displayed great energy. Despite initial economic difficulties, it pursued an efficient farming policy and carried through important hydroelectric schemes. Government was increasingly centralized, with the elimination of various corrupt borough corporations; Kevin O'Higgins, as minister for justice, carried through many judical reforms, and an efficient civil service was organized, in which competence in the Irish language became an essential qualification for promotion.

The Anglo-Irish Treaty of 1921 had provided that, if Northern Ireland did not enter the Free State, a boundary commission must establish the frontier between the two countries. Two of the six excluded counties, Tyrone and Fermanagh, contained clear, though small, Nationalist majorities, and the southern portions of both Down and Armagh had for years returned Nationalist members. Despite Northern Ireland's reluctance, a commission was established and sat in secret session during 1925. But it only recommended minor changes, which all three governments rejected as less satisfactory than maintaining the status quo.

In the general election of June 1927 Cosgrave's support in the Dáil was further reduced, but he nevertheless formed a new ministry, in which O'Higgins became vice president of the Executive Council. O'Higgins' assassination on July 10 suddenly revived old feuds, and Cosgrave

passed a Public Safety Act, declaring all revolutionary societies treasonable. He forced the Republicans to acknowledge allegiance to the crown before being seated in the Dáil, though De Valera decried the oath as an "empty political formula." Shortly thereafter the Republicans, allied with the Labour Party and the National League, almost defeated Cosgrave, who thereupon dissolved the Dáil. In new elections Cosgrave won 61 seats as compared to Fianna Fáil's 57 and again formed a ministry. In the depression of the early 1930s, unemployment and general discontent with the government led to its defeat in February 1932. Fianna Fáil won enough seats for De Valera, with Labour Party support, to be able to form a new government.

De Valera's governments (1932–48). De Valera entered office with a policy of encouraging industry and improving the social services. He abolished the oath of allegiance to the crown and also stopped payment to Britain of interest on the capital advanced under the Land Purchase Acts of the late 19th and early 20th centuries. This refusal led to a tariff war with Britain. A conflict with the governor general, James MacNeill, enabled De Valera to engineer MacNeill's retirement (September 1932) and replacement by De Valera's nominee. The country endorsed his policies in January 1933 by returning him to the Dáil with 77 seats and the support of the Labour Party.

De Valera invoked the Public Safety Act against the Blue Shirts, a quasi-Fascist body organized (by Cosgrave's militant supporters) allegedly to protect Treatyites from Republican extremists at public meetings.

De Valera introduced proposals for a new constitution in 1937, taking advantage of British weakness during the crisis over the abdication of Edward VIII. The power of the crown was ended, and the office of governor general was replaced by that of a president elected by national suffrage. The first president was Douglas Hyde, a Celtic scholar who had been associated with the Gaelic revival since 1890. The new constitution did not proclaim an independent republic, but it replaced the title of the Irish Free State with the word Eire (Ireland). The new constitution was ratified by a plebiscite at the 1937 general election (in which De Valera was again victorious) and became operative on December 29, 1937.

Establishment of Eire

An agreement in April 1938 ended British occupation of naval bases at Cork and Berehaven in southwest Ireland and Lough Swilly in the north, which had been left in British hands by the Anglo-Irish Treaty of 1921. The dispute over the land-purchase annuities was settled, and the economic warfare was abated. In this period government relations with the radical Republicans deteriorated; members of the IRA suspected of complicity in shootings were imprisoned, and some were executed.

At the outbreak of World War II, De Valera renewed his statement, made in 1938, that Ireland would not become a base for attacks on Great Britain. His government, re-elected in 1943 and 1944, remained strictly neutral, despite German air raids on Dublin in 1941 and, after the United States entered the war in December 1941, pressure from U.S. president Franklin D. Roosevelt.

Postwar developments. In the general election of 1948 Fianna Fáil won 68 of the 147 seats comprising the Dáil, but De Valera refused to enter a coalition. John A. Costello emerged as the leader of a bloc composed of his own party, Fine Gael, and several smaller groups. Out of office, De Valera toured the world advocating the unification and independence of Ireland. Fearful of De Valera's prestige, Costello introduced in the Dáil the Republic of Ireland Act, which ended the fiction of Commonwealth membership that had been maintained since 1937. Britain recognized the status of Ireland in 1949 but declared that cession of the six counties could not occur without consent of the Parliament of Northern Ireland. Economic difficulties and a controversy between the ministry and the Catholic hierarchy over the Public Health Act weakened Costello's government, and after the general election of 1951, De Valera again became prime minister. His ministry aroused sufficient discontent for Costello to be returned to power in 1954, but economic troubles enabled Fianna Fáil to win a majority in 1957. The aging De Valera was elected president in 1959 and was succeeded as prime minister by Sean Lemass (1959–66) and Jack Lynch (1966–73). From the mid-1950s until 1962, the government tried to restrain IRA members who were raiding British army posts on the Ulster border; from the late 1960s the worsening situation in Northern Ireland increasingly preoccupied the Irish government. In 1973 a Fine Gael-Labour coalition won control of the Dáil, and Liam Cosgrave (son of William Cosgrave) became prime minister.

Ireland, like Britain, suffered setbacks in the 1960s in attempting to join the European Economic Community, but both nations formally entered the EEC on January 1, 1973. Since World War II, the international role played by Ireland has included the contribution of troops for United Nations peace-keeping efforts, notably in the Congo and Cyprus.

De Valera's second term as president expired in 1973, and he was succeeded by Erskine Childers, who, however, died in 1974; the office passed to Cearbhall O Dalaigh. The death of De Valera at the age of 92 in August 1975 ended an era; the establishment of the autonomy of the Irish republic was predominantly the result of his influence.

NORTHERN IRELAND AFTER 1921

Under successive prime ministers—Sir James Craig, later Viscount Craigavon (1921–40); John Miller Andrews (1940–43); Sir Basil Brooke, later Viscount Brookeborough (1943–63); Capt. Terence O'Neill, later Lord O'Neill of the Maine (1963–69); Maj. James Chichester-Clark, later Lord Moyola of Castledawson (1969–71); and Brian Faulkner (1971–72)—the Unionist Party ruled the six counties. During that time the two main political factions became identified with the religious affiliations of their adherents. Unionist support had come from two Protestant groups, the Presbyterians (who make up 30 percent of the population) and members of the Church of Ireland (25 percent); opposition had centred in the Roman Catholics (35 percent), most of whom are Irish Nationalists resentful of the partition of Ireland and of their second-class social and economic status.

From the early 1960s more active opposition arose among the younger Catholics, and successive British governments urged Ulster to endorse equality in housing, public employment, and opportunities in general. A militant Protestant group, proclaiming the dangers of popery, secured a strong following among the poorer elements. Upon the launching of a civil-rights campaign in 1968, violence erupted in Belfast and Londonderry. At first, British troops contained the strife, but later they seemed to aggravate it. Bitterness was increased in August 1971 by the internment without trial of several members of the IRA who were suspected of playing leading roles in the uprising. Bombings and shootings increased in frequency for the rest of the year, and in January 1972, after British soldiers shot 13 demonstrators in Londonderry, an angry crowd burned the British embassy in Dublin. In March the British prime minister, Edward Heath, suspended the constitution and replaced the provincial government by appointing William Whitelaw secretary of state for Northern Ireland. Tension relaxed somewhat: internees were released, and the IRA declared a cease-fire; but by late 1972, more than 600 persons had died in the violence.

In March 1973 a British White Paper called for a new assembly with increased representation for Catholics and for "cooperation and consultation" between Northern Ireland and the republic. After elections in June, limited self-government resumed under a moderate Catholic-Unionist coalition. Faulkner became chief of an 11-member executive body, and Gerard (Gerry) Fitt of the Social Democratic and Labour Party became deputy chief executive; Whitelaw resigned and was replaced by Francis Pym. Representatives of Britain, Northern Ireland, and the republic met at Sunningdale, Berkshire, in December 1973, but the Ulster Unionist Council rejected Faulkner's recommendation to endorse the discussions, and he re-

signed from the party. A general strike by the Unionist workers paralyzed the province in May 1974, and the executive body collapsed. Pym had been replaced by Merlyn Rees in March, after Harold Wilson became British prime minister; in July a new White Paper proposed a constitutional convention to be elected by proportional representation. Elections took place in May 1975, and the convention held its first meeting; but the Unionists continued to resist the sharing of power.

(R.W.D.E./Ed.)

BIBLIOGRAPHY

General works: The 15 volumes of the *Oxford History of England*, under the editorship of SIR G.N. CLARK (3rd–4th ed., 1934–65), provide a comprehensive survey, with excellent bibliographies. Other multivolume histories include the "Pelican History of England" series, 8 vol., particularly valuable for social history; *The Political History of England*, 12 vol. (1905–10), somewhat antiquated but informative; and CHRISTOPHER BROOKE and D.M. SMITH (eds.), *A History of England*, 8 vol. (1960–). GEORGE MACAULAY TREVELYAN, *History of England*, 2nd ed. (1937; reprinted with minor corrections, 1966), is a beautifully written but highly patriotic survey. A.B. ERICKSON and M.J. HAVRAN, *England: Prehistory to the Present* (1968), is a good one-volume textbook.

The Anglo-Saxon period: (Sources): BEDE, *Historia ecclesiastica; Anglo-Saxon Chronicle.* For a translation of and commentary on essential record and narrative material, see DOROTHY WHITELOCK (ed.), *English Historical Documents*, vol. 1 (1955). *(General histories)*: F.M. STENTON, *Anglo-Saxon England*, 3rd ed. (1971); P. HUNTER BLAIR, *An Introduction to Anglo-Saxon England*, 2nd ed. (1956); R.H. HODGKIN, *A History of the Anglo-Saxons*, 3rd ed. (1952); H.R. LOYN, *Anglo-Saxon England and the Norman Conquest* (1962); R.I. PAGE, *Life in Anglo-Saxon England* (1970); DOROTHY WHITELOCK, *The Beginnings of English Society*, rev. ed. (1966). *(Works on specific topics)*: T.D. KENDRICK, *A History of the Vikings* (1930, reprinted 1968); L.M. LARSON, *Canute the Great* (1912); W.R.W. STEPHENS and W. HUNT (eds.), *A History of the English Church*, vol. 1 (1899); WILHELM LEVISON, *England and the Continent in the Eighth Century* (1946); DAVID KNOWLES, *The Monastic Order in England*, 2nd ed. (1963); J. ARMITAGE ROBINSON, *The Times of Saint Dunstan* (1923); FRANK BARLOW, *The English Church, 1000–1066* (1963); JAMES TAIT, *The Medieval English Borough* (1936, reprinted 1968); R.H.M. DOLLEY (ed.), *Anglo-Saxon Coins* (1961) and *Anglo-Saxon Pennies* (1964); C.S. and C.S. ORWIN, *The Open Fields*, 3rd ed. (1967); C.T. CHEVALLIER and DOROTHY WHITELOCK *et al.*, *The Norman Conquest: Its Setting and Impact* (1966).

England from 1066 to 1485: (Sources): CARL STEPHENSON and F.G. MARCHAM (eds.), *Sources of English Constitutional History* (1937), devotes about a third of its coverage to the medieval period. In the new "English Historical Documents Series," see D.C. DOUGLAS and G.W. GREENAWAY (eds.), *English Historical Documents, 1042–1189* (1953); and A.R. MYERS (ed.), *English Historical Documents, 1327–1485* (1969). BERTIE WILKINSON, *The Constitutional History of England, 1216–1399*, 3 vol. (1948–58) and his *Constitutional History of England in the Fifteenth Century, 1399–1485* (1964), are anthologies of documents with extensive commentary by the author. *(General works)*: HELEN M. CAM, *England Before Elizabeth*, 2nd rev. ed. (1960); CHRISTOPHER BROOKE, *From Alfred to Henry III, 871–1272* (1961); GEORGE HOLMES, *The Later Middle Ages, 1272–1485* (1962); F.M. STENTON, *English Society in the Early Middle Ages (1066–1307)* (1952), and A.R. MYERS, *England in the Late Middle Ages* (1952), two works that emphasize social history; A.L. POOLE, *From Domesday Book to Magna Carta, 1087–1216*, 2nd ed. (1955); F.M. POWICKE, *The Thirteenth Century, 1216–1307* (1953); MAY MCKISACK, *The Fourteenth Century, 1307–1399* (1959); E.F. JACOB, *The Fifteenth Century, 1399–1485* (1961). *(Special topics)*: J.H. CLAPHAM, *A Concise Economic History of Britain, from Earliest Times to 1750* (1949); *The Cambridge Economic History of Europe*, ed. by J.H. CLAPHAM *et al.*, 3 vol. (1941–63; 2nd ed., 1966–); H.C. DARBY (ed.), *An Historical Geography of England Before A.D. 1800* (1936), includes several essays on the medieval period; DAVID KNOWLES, *The Religious Orders in England*, 3 vol. (1948–59), a comprehensive and definitive account; C.H. LAWRENCE (ed.), *The English Church and the Papacy in the Middle Ages* (1965), a volume of essays by specialists; WILLIAM STUBBS, *The Constitutional History of England*, 6th ed. (1897, reprinted 1967), not altogether superseded by modern works such as BRYCE D. LYONS, *A Constitutional and Legal History of Medieval England* (1960). *(1066–1307)*: FRANK BARLOW, *The Feudal Kingdom of England, 1042–1216*, 2nd ed. (1961); R. ALLEN BROWN, *The Normans and the Norman Conquest* (1968); C.R. CHENEY, *From Becket to Langton: English Church Government, 1170–1213* (1956); H.W.C. DAVIS, *England Under the Normans and Angevins, 1066–1272* (1905), an old but not completely superseded work; R.H.C. DAVIS, *King Stephen, 1135–1154* (1967), sheds new light on the period of the anarchy; D.C. DOUGLAS, *William the Conqueror* (1964), the best single source on the conquest of England by the Normans; V.H. GALBRAITH, *The Making of Domesday Book* (1961), discusses the Conquest in an analytical statement about the survey of 1086; J.C. HOLT, *Magna Carta* (1965), the latest and most readable scholarly book on the Great Charter; J.E.A. JOLLIFFE, *Angevin Kingship*, 2nd ed. (1963), a challenging thesis that England might have developed into an absolute state in the medieval period if it had not been for the barons who fought John; REGINALD LENNARD, *Rural England, 1086–1135* (1959); H.R. LOYN, *The Norman Conquest* (1965), gives special emphasis to the social and economic impact of the Conquest; F.W. MAITLAND, *Domesday Book and Beyond* (1897), a seminal classic by a great historian; F.M. POWICKE, *King Henry III and the Lord Edward*, 2 vol. (1947); SIR FRANK STENTON, *The First Century of English Feudalism, 1066–1166*, 2nd ed. (1961), not superseded despite a great deal of discussion of the subject in later work; G.O. SAYLES, *The Medieval Foundations of England*, 2nd rev. ed. (1950), an excellent introduction to the history and the primary sources to the time of Edward I. *(The 14th and 15th centuries)*: A.R. BRIDBURY, *Economic Growth: England in the Later Middle Ages* (1962); F.R.H. DU BOULAY, *An Age of Ambition* (1970); V.H.H. GREEN, *The Later Plantagenets* (1955), a useful general textbook; P.M. KENDALL, *Richard the Third* (1955) and *Warwick the Kingmaker* (1957); E.F. JACOB, *Henry V and the Invasion of France* (1947), a critical modern treatment; GEORGE MACAULAY TREVELYAN, *England in the Age of Wycliffe*, new ed. (1909), a social and political history of Richard II's reign; R.L. STOREY, *The End of the House of Lancaster* (1966), the best book on the Wars of the Roses.

The 16th century: Standard bibliographies for 16th-century England are CONYERS READ (ed.), *Bibliography of British History: Tudor Period, 1485–1603*, 2nd ed. (1959); and MORTIMER LEVINE'S shorter compilation, *Tudor England 1485–1603* (1968). The best political and social surveys are S.T. BINDOFF, *Tudor England* (1950); and G.R. ELTON, *England Under the Tudors* (1955). For the personalities of the sovereigns, see CHRISTOPHER MORRIS, *The Tudors* (1955); and for the European setting, L.B. SMITH, *The Elizabethan World* (1966). Constitutional and institutional development can be studied in CHRISTOPHER MORRIS' short but brilliant *Political Thought in England: Tyndale to Hooker* (1953); JOHN NEALE'S classic works on Parliament, *Elizabeth I and Her Parliaments*, 2 vol. (1953–57), and *The Elizabethan House of Commons* (1949); and G.R. ELTON'S controversial *The Tudor Revolution in Government* (1953). Social and intellectual change is best sampled in four provocative but important works: W.K. JORDAN, *Philanthropy in England, 1480–1660* (1959); LAWRENCE STONE, *The Crisis of the Aristocracy, 1558–1641* (1965); R.H. TAWNEY, *Religion and the Rise of Capitalism* (1926, reprinted 1962); and E.M.W. TILLYARD, *The Elizabethan World Picture* (1943). The religious crisis of the century is neatly summarized in A.G. DICKENS, *The English Reformation*, rev. ed. (1967); and treated in greater length from a Catholic point of view by PHILIP HUGHES, *The Reformation in England*, rev. 5th ed., 3 vol. (1963). The best works on the Elizabethan period are PATRICK COLLINSON, *The Elizabethan Puritan Movement* (1967); and W.R. TRIMBLE, *The Catholic Laity in Elizabethan England, 1558–1603* (1964), whereas a fine book on religion in pre-Reformation England is HERBERT MAYNARD SMITH, *Pre-Reformation England* (1938). Foreign policy is surveyed by R.B. WERNHAM in *Before the Armada: The Growth of English Foreign Policy, 1458–1588* (1966). Overseas expansion is handled in A.L. ROWSE, *The Expansion of Elizabethan England* (1955).

The 17th century: The starting points for a detailed study of Stuart England from 1603 to 1656 and from 1685 to 1702 are still, for all their Whiggish faults, the respective multivolume studies of two great 19th-century historians, SAMUEL RAWSON GARDINER (continued to 1660 by CHARLES H. FIRTH and GODFREY DAVIES) and T.B. MACAULAY. The best one-volume surveys of the 17th century are GEOFFREY AYLMER, *The Struggle for the Constitution, 1603–1689*, 2nd ed. (1968); CHRISTOPHER HILL, *The Century of Revolution, 1603–1714* (1961); MAURICE ASHLEY, *England in the Seventeenth Century*, 3rd ed. (1961); and JOHN P. KENYON, *The Stuarts* (1958). The best one-volume study of the causes of the English Civil War is PEREZ ZAGORIN, *The Court and the Country* (1969); and of the interregnum, IVAN ROOTS, *The Great Rebellion: 1642–1666* (1966). There are several good three-volume studies: C.V. WEDGWOOD for the reign of Charles I from 1637 to 1649 (1956–66); DAVID OGG for the later Stuarts from 1660 to 1702 (1955); and GEORGE

MACAULAY TREVELYAN (1930–34) for the reign of Queen Anne. There are fine biographies: DAVID HARRIS WILLSON, *King James VI and I* (1956); CATHERINE DRINKER BOWEN, *The Lion and the Throne: The Life and Times of Sir Edward Coke* (1957) and *Francis Bacon* (1963); HUGH R. TREVOR-ROPER, *Archbishop Laud, 1573–1645*, 2nd ed. (1962); and C.V. WEDGWOOD, *Strafford, 1593–1641* (1935). There have been several important historiographical controversies on the Stuart period in recent years. The Max Weber thesis on the relationship between Puritanism and economic matters was recast by R.H. TAWNEY in *Religion and the Rise of Capitalism* (1926, reprinted 1962), but it has been challenged in two articles in *Church History* by WINTHROP S. HUDSON (1949) and CHARLES H. GEORGE (1958). For the controversy over the rise of the gentry, see R.H. TAWNEY, *Economic History Review*, 11:1–38 (1941); HUGH R. TREVOR-ROPER, *Economic History Review Supplement* (1953); and JACK H. HEXTER, "Storm over the Gentry," *Encounter*, 10:22–34 (1958); LAWRENCE STONE has analyzed *The Crisis of the Aristocracy, 1588–1641* (1965); and PETER LASLETT has examined the lower orders of society in *The World We Have Lost* (1965). The relationship between Puritanism and democracy has been set forth by WILLIAM HALLER, *The Rise of Puritanism* (1938) and *Liberty and Reformation in the Puritan Revolution* (1955); and A.S.P. WOODHOUSE (ed.), *Puritanism and Liberty*, 2nd ed. (1951), but some of their conclusions have been questioned by MICHAEL WALZER, *The Revolution of the Saints* (1965); and LEO F. SOLT, *Saints in Arms* (1959). The relationship between Puritanism and the New Science was first developed by ROBERT K. MERTON, *Science, Technology and Society in Seventeenth Century England* (1938); and more recently by J.E.C. HILL, *The Intellectual Origins of the English Revolution* (1965), but they have come under attack in articles by HUGH F. KEARNEY and THEODORE K. RABB in *Past and Present* (1964–66) and by the latter in the *Journal of World History*, 7:46–67 (1962). The traditional interpretation of a two-party system in Queen Anne's reign given by WILLIAM T. MORGAN, *English Political Parties and Leaders in the Reign of Queen Anne, 1702–1710* (1920); KEITH FEILING, *A History of the Tory Party, 1640–1714* (1924); and Trevelyan were challenged by the biographical studies of ROBERT WALCOTT, *English Politics in the Early Eighteenth Century* (1956), but the earlier view has been stressed by J.H. PLUMB, *The Growth of Political Stability in England: 1675–1725* (1967); and GEOFFREY S. HOLMES, *British Politics in the Age of Anne* (1967).

1714–1815: T.S. ASHTON, *An Economic History of England: The Eighteenth Century* (1955), a readable introduction for the general reader, and *The Industrial Revolution, 1760–1830* (1948), a classic brief overview; JOHN M. BEATTIE, *The English Court in the Reign of George I* (1967), combines administrative with political history—aids understanding of later Hanoverian reigns; LEWIS B. NAMIER, *The Structure of Politics at the Accession of George III*, 2 vol. (1929; 2nd ed., 1 vol., 1957), an analytical study that destroyed traditional views on 18th-century political history—the starting point for all modern studies of 18th-century politics; JOHN BROOKE, *The Chatham Administration, 1766–1768* (1956), a detailed political history in the Namierite manner; HERBERT BUTTERFIELD, *George III and the Historians*, rev. ed. (1959), historiographical study with extended criticism of Namierite treatment of politics; IAN CHRISTIE, *The End of North's Ministry, 1780–1782* (1958); CARL B. CONE, *Burke and the Nature of Politics*, 2 vol. (1957–64), political biography based on recently available corpus of Burke papers; *The English Jacobins* (1968), narrative account of parliamentary reform before and during the French Revolution; PHYLLIS DEANE, *The First Industrial Revolution* (1965), topically organized work stressing the concept of economic growth; JOHN EHRMAN, *The Younger Pitt* (1969), standard biography; A.S. FOORD, *His Majesty's Opposition, 1714–1830* (1964), on the growth and acceptance of the idea and practice of a formed parliamentary opposition; DEREK JARRETT, *Britain, 1688–1815* (1965), the best short history, mainly political; D.L. KEIR, *The Constitutional History of Modern Britain Since 1485*, 9th ed. (1968), a balanced narrative treatment of this period; W.E.H. LECKY, *A History of England in the Eighteenth Century*, 7 vol. (1899–1901), good on social history but outdated in many respects; DOROTHY MARSHALL, *English People in the Eighteenth Century* (1956), emphasis on social history; RICHARD PARES, *King George III and the Politicians* (1953), a highly regarded analysis that modifies some Namierite interpretations; J.H. PLUMB, *The Growth of Political Stability in England, 1675–1725* (1967), a conceptual study showing how and why stability replaced instability; *Sir Robert Walpole*, 2 vol. (1956–61; vol. 3 in prep.), the definitive biography; NORMAN SYKES, *Church and State in England in the Eighteenth Century* (1934), corrects older views of torpor and inadequacy of the church; J.S. WATSON, *The Reign of George III, 1760–1815* (1960); R.J. WHITE, *The Age of George III* (1968), readable, brief, interpretative, and comprehensive in its coverage; BASIL WILLIAMS, *The Whig Supremacy, 1714–1760*, 2nd ed. (1962); E.N. WILLIAMS (ed.), *The Eighteenth Century Constitution, 1688–1815* (1960), a collection of well-selected documents.

1815–1914: ELIE HALEVY, *Histoire du peuple anglais au XIX^e siècle*, 5 vol. (1912–32; Eng. trans., *A History of the English People in the Nineteenth Century*, 2nd ed., 6 vol., 1949–52), is the best general account, although the second half of the century is only partially and sketchily covered. G.M. YOUNG, *Victorian England: Portrait of an Age*, 2nd ed. (1960), is a brilliant essay, as is GEOFFREY BEST, *Mid-Victorian Britain, 1851–1875*, (1971). E.L. WOODWARD, *The Age of Reform, 1815–1870*, 2nd ed. (1962); see also his *Victorian People* (1954) and *Victorian Cities* (1963). R.C.K. ENSOR, *England, 1870–1914* (1936), is a good standard study. ASA BRIGGS, *The Age of Improvement* (1959), is the fullest account of the period from the Industrial Revolution to the Second Reform Bill in all its aspects; and R.K. WEBB, *Modern England: From the 18th Century to the Present* (1969), is the most valuable recent textbook; but also of interest is WALTER HOUGHTON, *The Victorian Frame of Mind, 1830–1870* (1957). There is much that cannot be found elsewhere in *Edwardian England, 1901–1914*, ed. by SIMON H. NOWELL-SMITH (1964). Among a large number of studies of economic history, W.H.B. COURT, *A Concise Economic History of Britain, from 1750 to Recent Times* (1954), provides the most useful introduction, while for Britain's overseas relationships, R.W. SETON-WATSON, *Britain in Europe, 1789–1914* (1937, reprinted 1968); and C.E. CARRINGTON, *The British Overseas*, 2nd ed. (1968), deal with both continental and imperial relationships. On World War I, see ARTHUR MARWICK, *The Deluge* (1965).

Great Britain since 1914: Several works deal in a fairly comprehensive manner with British history since 1914: W.N. MEDLICOTT, *Contemporary England, 1914–1964* (1967); T.O. LLOYD, *Empire to Welfare State: English History 1906–1967* (1970); ALFRED F. HAVIGHURST, *Twentieth-Century Britain*, 2nd ed. (1966). Medlicott emphasizes political and diplomatic history, while the other two are somewhat broader in scope. More detailed is A.J.P. TAYLOR, *English History, 1914–45* (1965), at times extraordinarily perceptive and provocative. The best work on the interwar years is CHARLES LOCH MOWAT, *Britain Between the Wars, 1918–1940* (1955). SIDNEY POLLARD, *The Development of the British Economy, 1914–1967*, 2nd ed. rev. (1969), is reliable; and F.S. NORTHEDGE, *The Troubled Giant: Britain Among the Great Powers, 1916–1939* (1966) and *British Foreign Policy: The Process of Readjustment, 1945–1961* (1962), provide consecutive treatment of diplomatic history. The period may be approached in an interesting manner through diaries and memoirs—*e.g.*, three volumes by HAROLD MACMILLAN: *Winds of Change, 1914–1939* (1966), *The Blast of War 1939–1945* (1968), and *Tides of Fortune, 1945–1955* (1969). Excellent biographies include: HAROLD NICOLSON, *King George the Fifth: His Life and Reign* (1952); ALAN BULLOCK, *The Life and Times of Ernest Bevin*, 2 vol. (1960–67); RANDOLPH CHURCHILL, *Life of Winston S. Churchill*, 2 vol. (1966–67), vol. 3 by MARTIN GILBERT (1971). *The Annual Register of World Events* provides a useful and reliable summary of British and Commonwealth affairs. As a reference book, D.E. BUTLER and JENNIE FREEMAN, *British Political Facts, 1900–1967* (1968), is the best of its kind.

History of Wales: Two standard surveys are DAVID WILLIAMS, *A History of Modern Wales* (1950; reprint, 1965); and WILLIAM REES, *An Historical Atlas of Wales from Early to Modern Times*, new ed. (1959). J.E. LLOYD, *A History of Wales from the Earliest Times to the Edwardian Conquest*, 3rd ed., 2 vol. (1939), remains a valuable survey of the history of Wales to 1282. The results of more recent investigations into the early history of Wales are reflected in I.L. FOSTER and G. DANIEL (eds.), *Prehistoric and Early Wales* (1965); N.K. CHADWICK (ed.), *Studies in Early British History* (1954) and *Studies in the Early British Church* (1958). V.E. NASH-WILLIAMS, *The Roman Frontier in Wales*, rev. ed. by M.G. JARRETT (1969), and *The Early Christian Monuments of Wales* (1950); and E.G. BOWEN, *Saints, Seaways and Settlements in the Celtic Lands* (1969), are major studies. J.G. EDWARDS, "The Normans and the Welsh March," *Proceedings of the British Academy*, 42:155–177 (1956), is of fundamental importance for an understanding of the effect of the Norman invasion. The narrative account of the age of the princes in Lloyd's *History of Wales* has not been superseded; but J.G. EDWARDS, *Littere Wallie* (1940); THOMAS JONES, *Brut y Tywysogyon; or, the Chronicle of the Princes, Peniarth MS. 20 Version* (1955); and H.D. EMANUEL (ed.), *The Latin Texts of the Welsh Laws* (1967), provide key source materials and important critical studies. Chapters relating to Wales are included in F.M. PO-

WICKE, *King Henry III and the Lord Edward*, 2 vol. (1947) and *The Thirteenth Century, 1216–1307* (1953). T. JONES PIERCE, *Medieval Welsh Society: Selected Essays* (1972); or WILLIAM REES, *South Wales and the March, 1284–1415* (1924), are indispensable studies of social and agrarian history. J. CONWAY DAVIES, *Episcopal Acts Relating to Welsh Dioceses*, 2 vol. (1948–53); and GLANMOR WILLIAMS, *The Welsh Church from Conquest to Reformation* (1962), cover ecclesiastical history. J.E. LLOYD, *Owen Glendower* (1931), describes the early-15th-century rebellion; and GLYN ROBERTS, *Aspects of Welsh History* (1969), includes essays dealing with the later Middle Ages. KENNETH O. MORGAN, *Wales in British Politics, 1868–1922*, rev. ed. (1970), treats the principality in its United Kingdom context. *The Dictionary of Welsh Biography down to 1940* (1959) is valuable. *A Bibliography of the History of Wales* (1958; 2nd ed., 1962), with supplements in *The Bulletin of the Board of Celtic Studies*, vol. 20, 22, 23, provides a comprehensive guide to primary and secondary sources, including numerous important essays whose conclusions are not as yet reflected in general works.

History of Scotland: The best general histories are W.C. DICKINSON, *Scotland from the Earliest Times to 1603*, 2nd rev. ed. (1965); and ROSALIND MITCHISON, *A History of Scotland* (1970), which also contain bibliographies. (*Prehistoric and Roman times*): STUART PIGGOTT, *Scotland Before History* (1958), is a good introduction. I.A. RICHMOND (ed.), *Roman and Native in North Britain* (1958), is helpful. (*Dark Age peoples*): ISABEL HENDERSON, *The Picts* (1967), is authoritative. (*Unification and the development of the monarchy*): A.O. ANDERSON, *Early Sources of Scottish History*, 2 vol. (1922), supplies the sources; see also the Scottish chapters in G.W.S. BARROW, *Feudal Britain* (1956). (*The Wars of Independence*): G.W.S. BARROW, *Robert Bruce and the Community of the Realm of Scotland* (1965), is balanced and important. (*The Reformation and the 16th century*): GORDON DONALDSON, *The Scottish Reformation* (1960); and the early chapters of T.C. SMOUT, *A History of the Scottish People, 1560–1830* (1969).

History of Ireland: T.W. MOODY and F.X. MARTIN (eds.), *The Course of Irish history* (1967), a collection of essays by various scholars that provides a good introduction to Irish history, with bibliographies, illustrations, and a useful chronological table; A.J. OTWAY-RUTHVEN, *A History of Medieval Ireland* (1968), essential for the study of medieval Ireland prior to 1496; J.C. BECKETT, *The Making of Modern Ireland, 1603–1923* (1966), a standard textbook for this period, with an excellent critical bibliography, including books on local history; J.F. KENNEY, *Sources for the Early History of Ireland: An Introduction and Guide* (1929 and 1967); R.J. HAYES (ed.), *Manuscript Sources for the History of Irish Civilization*, 11 vol. (1966), an extensive index of manuscript sources on Irish history from the 5th to the 20th century, with a list of microfilms in the National Library of Ireland; SEAN O'RIORDIAN, *Antiquities of the Irish Countryside*, 4th ed. (1964), a good introduction and bibliography; KATHLEEN HUGHES, *The Church in Early Irish Society* (1966), an account of the development of the Irish Church to the 11th century, including bibliography and illustrations; MYLES DILLON (ed.), *Early Irish Society* (1959), an authoritative collection, originally a broadcast discussion; JOHN MACNEILL, *Early Irish Laws and Institutions* (1935) and *Celtic Ireland* (1921); F.X. MARTIN in *Irish Historical Studies* (1948), for a listing of MacNeill's other writings; MAIRE and LIAM DE PAOR, *Early Christian Ireland*, 3rd ed. (1961), a detailed illustrated work; FRANCOIS HENRY, *Irish Art in the Early Christian Period to 800 A.D.*, rev. ed. (1965), a discussion of the art of this period against its historical background, with bibliography and illustrations; LUDWIG BIELER, *Ireland, Harbinger of the Middle Ages* (1963), a study of Irish missions and their influence in Europe; G.H. ORPEN, *Ireland Under the Normans, 1169–1333*, 4 vol. (1911–20, reprinted 1968), remains indispensable for this period; H.G. RICHARDSON and G.O. SAYLES, *The Administration of Ireland, 1172–1377* (1963) and *The Irish Parliament in the Middle Ages* (1952), an important work on the early history of the Irish parliament; RICHARD BAGWELL, *Ireland Under the Tudors*, 3 vol. (1885–90, reprinted 1963), and *Ireland Under the Stuarts and During the Interregnum*, 3 vol. (1909–16, reprinted 1963); and R. DUDLEY EDWARDS, *Church and State in Tudor Ireland* (1935, reprinted 1972), all standard works; L.W. HANSON, *Contemporary Printed Sources for British and Irish Economic History, 1701–1750* (1963), especially valuable because little has been written in this area; K.H. CONNELL, *The Population of Ireland, 1750–1845* (1950), a scholarly account; see also Connell's "Land and Population in Ireland 1780–1845," in D.V. GLASS and D.E.C. EVERSLEY (eds.), *Population in History* (1965); R.B. MCDOWELL, *Public Opinion and Government Policy in Ireland, 1801–46* (1952), a continuation of *Irish Public Opinion, 1750–1800*, with good bibliography; *The Irish Administration, 1801–1914* (1964), a detailed reference work on 19th-century administration; P.S. O'HEGARTY, *A History of Ireland Under the Union, 1801–1922* (1952), an extremely interesting but not wholly objective history of this period; K.B. NOWLAN, *The Politics of Repeal* (1965), an examination of Great Britain–Ireland relations, 1841–50; ANGUS D. MACINTYRE, *The Liberator: Daniel O'Connell and the Irish Party, 1830–1847* (1965), a recent study of O'Connell, with new material added on aspects of Anglo-Irish politics in the 1830s and 1840s; R.D. EDWARDS and T.D. WILLIAMS (eds.), *The Great Famine* (1956), an important compilation by Irish scholars; NICHOLAS MANSERGH, *The Irish Question, 1840–1921* (1965), a revision of *Ireland in the Age of Reform and Revolution* (1940), an interpretation of the effects of various political and social forces on Anglo-Irish relations; J.L. HAMMOND, *Gladstone and the Irish Nation* (1938, reprinted 1964), a standard work on Gladstone's Irish policy, 1869–93; C. CRUISE O'BRIEN (ed.), *The Shaping of Modern Ireland* (1960), a collection of biographical essays on prominent Irish personalities; *Parnell and His Party 1880–90*, rev. ed. (1964), the standard work on Parnell; BASIL CHUBB (ed.), *A Source Book of Irish Government* (1964), a collection of illustrative documents on the nature and background of the Republic of Ireland; T.P. COOGAN, *Ireland Since the Rising* (1966), presents the republican view of Irish history since 1916; F.S.L. LYONS, *Ireland Since the Famine* (1971); and R. DUDLEY EDWARDS, *A New History of Ireland* (1972), two recent interpretative works.

(D.W./M.Has./La.B.S./L.F.S./C.B.Co./As.B./A.F.H./J.B.Sm./J.M.S./R.W.D.E.)

British Columbia

One of the last regions of the North American continent to be explored and settled, British Columbia has become within recent decades one of the major provinces of Canada in population, economic wealth, and overall potentiality. Its 366,255 square miles (948,596 square kilometres) create a diversity of climate and scenery unparalleled in the nation, from the island-studded and fjord-indented coast to the great peaks of the western continental cordilleras with their large interior plateaus. The province is bounded on the west by the Pacific Ocean and the Panhandle of Alaska, on the north by the Yukon and Northwest territories, on the east by Alberta, and on the south by Montana, Idaho, and Washington.

Although the impetus for settlement of the province was the fur trade and the gold that lay in its mountains, British Columbia in the 1970s had a prosperous, modern economy balanced between the forest and mineral wealth of its interior, the hydroelectric production of its rivers, the agriculture of its plateaus and river valleys, the attraction of dramatic and varied scenery for the tourist, and the industry and shipping of its coastal cities. The cities include Vancouver, largest port of Canada and of western North America, and Victoria, the provincial capital, located on the southeastern tip of Vancouver Island. British Columbia, with Alberta and Ontario, was one of Canada's "have" provinces, contributing far more to federal coffers than they received back in grants. The 2,200,000 British Columbians enjoyed a per capita income second only to that of the citizens of Ontario.

Canada's prairie provinces and the Yukon constitute an added factor in British Columbia's prosperity, for they ship a large part of their grain, potash, sulfur, and phosphates from British Columbia's ports. The potential of the Yukon hinterland has been seriously developed only in recent decades. Although British Columbia lies far from the heartland of Canada and is overshadowed in the federal Parliament by the larger representations of Ontario and Quebec, the province has become a major force in the nation's economic, political, and social life. (For information on related topics, see the articles CANADA; CANADA, HISTORY OF; NORTH AMERICA; ROCKY MOUNTAINS; FRASER RIVER; and PACIFIC COAST RANGES.)

THE HISTORY OF BRITISH COLUMBIA

At the time of initial contact with white explorers, Indians in present-day British Columbia numbered about 80,000. The coast was dominated by Coast Salish, Nootkas, Kwakiutls, Bella Coolas, Tsimshians, and Haidas, whose economy was largely based on the prod-

ucts of the sea and on the huge coastal cedars. Expert fishermen, they utilized traps, nets, hooks, spears, and even an ingenious toggling harpoon for hunting down whales. Their clothing was made of skins and cedar bark covered by beautifully patterned blankets woven from the wool of mountain goats. Indian dwellings were large square or rectangular buildings of cedar beams and planks, divided into compartments for families. Houses were located in clusters along beaches suitable for canoe landings and just above the high-water mark. These pre-white Indians were already enterprising traders in copper, blankets, elk hides, furs, shells, candlefish oil, and slaves along the intertribal routes that ran north–south into California and east–west into the interior. They also enjoyed a rich social life in this land of the potlatch. Rival families competed with each other to distribute blankets, food, jewelry, and other favours to guests, often invited from hundreds of miles away, to mark the birth, adolescence, marriage, or death of an important member of the tribe.

Explorations and trading posts. The area that was to become British Columbia first caught the attention of European nations in the late 18th century. Spanish ships visited the coast in 1774, followed by Capt. James Cook, who was searching for the Northwest Passage. The latter's account of the fur wealth of the area stimulated the interest of British and American traders, who soon arrived to trade with the Indians for the highly prized sea otter pelts. The growing interest of Great Britain in the area was indicated by the dispatch of Capt. George Vancouver, who circumnavigated Vancouver Island and charted the mainland's intricate coastline.

Simultaneously, other British fur traders penetrated the region from the east, thereby strengthening Britain's claim to the area. Alexander Mackenzie of the North West Company of Montreal entered the region through its winding waterways; he completed the first overland journey across the entire continent when he arrived at Bella Coola, at the mouth of Dean Channel, in 1793. A fur trade based on fixed posts in the interior followed the establishment, by Simon Fraser in 1805, of the first trading post at McLeod Lake. Three years later he descended the Fraser River to its mouth, the site of present-day Vancouver.

Early dominance of the fur trade

After the southern boundary was fixed at the 49th parallel, Vancouver Island was recognized as solely British territory, following years of near-conflict with the United States. Ft. Victoria became the western headquarters of the Hudson's Bay Company. In 1849 Vancouver Island was made a crown colony by the imperial government, which expected that an orderly settlement in this distant outpost of empire would follow. Settlement, however, ran counter to the best interest of Gov. James Douglas and the fur company, which controlled local policy, and they discouraged it so successfully that in 1855 the total population of European origin in the colony was only 774, most of them involved in the pursuit of the fur trade.

Gold rush and permanent settlements. The gold strike of 1858 and the gold outpourings of the next five years made Ft. Victoria into a city, opened the mainland to settlement, and transformed an unpeopled frontier into a prosperous and dynamic society that was proclaimed the Colony of British Columbia in 1858. Hordes of gold seekers from California, Australia, and other parts of the Pacific community joined with Britishers and Canadians to work the alluvial gold deposits of the Lower Fraser and by 1862 the Cariboo gold country on the Upper Fraser.

By 1865 the gold days were over, and most of the miners had departed with the larger part of nearly $25,000,000 in gold dust. But the palmy days of the rush had attracted an army of ranchers, farmers, hotel operators, storekeepers, and civil servants who, although diminished in numbers, formed a nucleus for an ongoing, settled society. Left behind also was a fairly well-established transportation and communications network. Steamships linked Victoria and points on the Fraser River, and a 400-mile coach road connected Ft. Hope, on the Lower Fraser, with Barkerville, in the Cariboo gold country. The two colonies solved their problem in 1871 by joining Canada as the Province of British Columbia.

The arrival of the Canadian Pacific Railway at Port Moody in 1885 opened a new era. Permanent railroad and lumbering settlements sprang up along the railroad route. The extension of the lines into Vancouver in 1886 brought about the incorporation of that city in the same year. The establishment of a steamship line connecting it with the Orient, in 1891, assured its future as a port.

Stimulus of the railroads

Once the construction of the Panama Canal was assured, British Columbia experienced its first boom since the heady days of the gold rush, a boom based upon the assumption of investors that the province's raw resources would soon be able to compete in the markets of the Atlantic nations. Forest tracts were allotted by the thousands to eager American, British, German, and Canadian investors by a funds-starved provincial government eager to make an impressive fiscal showing and ensure its perpetual re-election. A similar situation prevailed in the mining industry, with the initial prizes going to British investors. Simultaneous with the opening up of these resource industries, the belated but now rapid settlement of the treeless prairies occurred, with its demand for lumber and other supplies best filled from British Columbia. With a revitalized economy the population increased from less than 180,000 to nearly 400,000 between 1901 and 1911, and Vancouver emerged as the leading city, with more than 111,000.

Economic cycles. Postwar dislocation after 1918, a continued shortage of shipping, strikes, and sporadic unemployment fed the flames of anti-Oriental feeling, always strong in Vancouver. Politicians, union leaders, and the *Vancouver Daily World* (now defunct) eagerly laid the blame for lack of prosperity on Oriental workers. Exclusionist legislation was passed by an obliging provincial legislature in 1923 and remained in force until the late 1940s, when Orientals were enfranchised.

But, scarcely recovered from the war years, the province found its newly acquired markets swept away by the economic depression of the 1930s. Recovery was delayed until war once again was declared in 1939. This time, military demands were extensive enough to reach across the continent into the shipbuilding yards, the lumbering communities, and the mines of British Columbia, ensuring the continued prosperity of the province's industry even beyond the war years.

Postwar political consolidation. With postwar economic prosperity came political change. To meet the political threat of the Depression-born Cooperative Commonwealth Federation (CCF), a moderate Socialist party, Conservatives and Liberals combined forces to form a coalition government during the war years. Growing disenchantment with the party in power, however, made inevitable the appearance of a new party as an alternative to the CCF. The Social Credit Party, which won the election of 1952, was formed by dissidents of both old-line parties but chiefly by conservatives, who adopted the name but not the philosophical principles of a highly successful conservative party in power in Alberta. The Social Credit government remained in power until 1972, when it lost the provincial election to the New Democratic Party (reformist successor to the CCF) which increased its standing from 12 to 38 seats in the 55-seat legislature.

THE LANDSCAPE

The natural environment. *Surface features.* The vast territory of British Columbia lies almost entirely within the great mountain system, or cordillera, that stretches along the western edge of the Americas from above the Arctic Circle to Cape Horn, at the southernmost extremity of South America. Its hundreds of rugged, coast-hugging islands—the largest of which are Vancouver Island and the Queen Charlotte Islands—offer a protected waterway along the coastline, which is indented by myriads of narrow fjords that twist inland about the bases of towering mountains. The broad Fraser Delta, behind Vancouver, is the largest of the limited coastal lowlands, while in the interior many of the wide plateaus are cut

The mountains, the sea, and the islands

by deep canyons and entirely surrounded by seemingly endless ranges of mountains.

About 60 percent of the land area is forested, while another one-third consists of barren alpine tundra, snowfields, and glaciers. More than three-quarters of the province is above 3,000 feet in altitude, beyond the limits of agriculture and often useful only for grazing. The Peace River country in the far north, outside the cordillera, contains the only vast areas suitable for large-scale farming, but its high latitudes make the growing season short.

Rivers and lakes. The province contains three main river systems: the Peace in the far north; the Fraser, which drains nearly all of the interior plateau; and the Columbia in the southeastern and south central regions. Lesser rivers, such as the Skeena, Nass, Iskut, and Stikine, drain the northwestern region into the Pacific, while the Laird system drains the northeastern section into the Arctic Ocean.

The Fraser, the only major river that lies entirely within the province, rises in the Rockies near the Yellowhead Pass, flows north along the Rocky Mountain Trench, and then southwestward to Prince George. There it receives the Nechako and turns almost due south for 300 miles, flowing through plateau and mountain valley to Hope, then westward through the lush farmlands of the Lower Fraser to the sea south of Vancouver. The Columbia follows the Rocky Mountain Trench northward, receiving the flow off the Columbia Icefield and the Selkirk glaciers, bends around the northern end of the Selkirk Mountains, and turns south to flow into the Arrow Lakes and then heads southward into Washington and Oregon, where it finds an outlet to the sea.

The Peace also becomes a formidable stream within the Rocky Mountain Trench, but it cuts eastward through the Rockies and into the plains area of Alberta, where it loses itself in the complex Mackenzie River system flowing to the Arctic.

Exploitation of the lakes

Most of the thousands of lakes are small, but they are important for the water they store in an age when hydroelectric power has become a prized resource. The larger lakes are made long and narrow by the north–south mountain ranges that confine them in the deep and narrow valleys in all parts of the province. Atlin and Teslin in the northwest extend into the Yukon. Babine, Stuart, Shuswap, Quesnel, and François, which range from 90 to 200 square miles (230 to 520 square kilometres) in area, are important salmon-spawning lakes. The Arrow Lakes are important storage reservoirs for the Columbia hydroelectric projects downstream while Kootenay Lake fulfills the same function for the generating plants on the Kootenay River.

Climate. Because of the Kuroshio, or Japanese, Current, which warms the coast, and the mountain ranges that make up its topography, British Columbia experiences a widely diverse range of climates. Climatologists claim that, in its temperature, humidity, and variability, the southwestern corner of the province has one of the most favourable climates for man, plants, and animals. There the climate resembles that of European nations in the same latitude, but it is tempered by the warm Kuroshio Current. The prevailing winds from the Pacific, flowing over succeeding mountain ranges, cause a wide variety of precipitation and temperature across the province, but along the coast such variation is negligible. Summers are comfortably cool, while winters are not severe, and 0° F (−18° C) is seldom recorded. In the Okanagan and Cariboo regions to the east, wider ranges are recorded; summers are hot and winters are colder. Still farther east, up against the Rockies, similar temperature ranges prevail but with considerably heavier snowfalls. In the northern interior and Peace River country very cold winters and very hot summers are normal.

British Columbia is well supplied with water, but its distribution is far from ideal. Some coastal towns have average annual rainfalls of 160 inches (4,100 millimetres) or more (perhaps the wettest region on the continent), while Ashcroft and Merritt, only 125 miles from the coast, register only seven and nine inches (180 and 230 millimetres), respectively. Victoria, sheltered by Vancouver Island mountains, receives only 27 inches, but Vancouver, 72 miles across the Strait of Georgia, receives 60 inches, picked up by the winds crossing that body of water.

Human uses of the land. The mountains and waters that surround them have made the British Columbians a race of valley dwellers. Valleys have assumed enormous importance for transportation and communications as well as for settlement, especially in the southern part of the province, where three-quarters of its population lives.

The mountains of Vancouver Island are separated from the Coast Mountains on the mainland by the Strait of Georgia, a saltwater valley along whose rocky slopes, on both sides, are located the province's largest and most important cities: Vancouver, Victoria, New Westminster, Nanaimo, and the pulp and paper centre of Powell River. East of that valley is located the valley and canyon of the Fraser, with such service centres as Hope, Boston Bar, Lytton and Lillooet, while still farther east lie the irrigated fruitlands of the Okanagan Valley and the cities of Salmon Arm, Enderby, Vernon, Kelowna, and Penticton. Beyond and pressing against the Rockies are the parallel mining and lumbering valleys of the West and East Kootenays, with the communities of Rossland, Trail, Nelson, and Fernie.

For the most part, trails, roads, railroads, oil and gas pipelines, and, to a less extent, electric power lines follow the routes of the rivers. Often they lie within yards of each other, so restricted are the narrow passes in much of the province's topography.

THE PEOPLE OF BRITISH COLUMBIA

British Columbia is the most urbanized province of Canada, with more than 80 percent of its citizens living in incorporated municipalities. It is also one of the most racially diverse.

Composition of the populace. The English, Scots, and Northern Irish played the major role in founding the province, and, to this day, they form the controlling elite. Scots dominated the fur-trade settlements before 1858, but, with the arrival of more than 20,000 Americans from California by 1864, the imperial government dispatched large numbers of Northern Irish to serve as the political and administrative arms of the province. With the return of most Americans to California in the mid-1860s, British Columbia became essentially British and remained so until the 1940s, in spite of notable minorities of Chinese, Japanese, Swedes, Norwegians, Italians, and Americans.

The ethnic mix

Since World War II the pattern has been modified somewhat by the arrival of large numbers of Europeans, especially Dutch farmers, attracted to the Fraser Delta lands, Germans, to the cities of the lower mainland, and Italians, to the railroads and construction industry. By the 1970s the people of the province were considerably less than 50 percent British in origin.

The native Indian population of 47,000 has more significant problems than any other minority group. It has been estimated that they numbered about 80,000 in the early 1800s, before tuberculosis, diphtheria, smallpox, and other "white man's diseases" reduced their ranks to 23,600 by 1934. Improved health measures, inaugurated since then, have stemmed their decimation, but they still live in greater poverty and have a much higher mortality rate than the white population. Scores of reservations dot the province's landscape, chiefly in rural areas. The pressure of an increasing population combined with great poverty and a lack of opportunity began driving Indians from reservations into the cities, in which about 30 percent of them lived in the early 1970s. Without education or skills valued by white society, they were relegated, with few exceptions, to permanent unemployment. In 1969 only 34 Indians were enrolled in the province's four universities.

The French-Canadian minority of 80,000 is scattered so thinly throughout the province that only the community of Coquitlam, near Vancouver, has the bilingual school program that prevails throughout much of Canada. Significant numbers of this minority are also

found in the forest-industry centres of Terrace, Prince George, Powell River, and Port Alberni. In spite of the pleas of their leaders, French-Canadians in this province most distant from Quebec are singularly unmilitant about the bilingual and bicultural crusade that has so moved French-Canadians in other parts of the nation in recent years.

Although Americans constitute a small minority, they are an influential factor in the industrial life of the province—in manufacturing, mining, ranching, and forestry. During the education boom of the mid-1960s, they became a very important part of the teaching, administration, and research staffs of the universities and colleges.

About 2,500 blacks make up one of the smallest minorities. Most live in the Vancouver area, although a notable pioneer group, originating in a pre-Civil War exodus from the United States, reside in the Gulf Islands near Victoria.

Contemporary migratory patterns. Interprovincial migration, a noteworthy feature of Canadian life, holds particular significance in the rapid growth of British Columbia. During the 1960s it gained about 200,000 inhabitants from elsewhere in the nation, more than twice the number gained by the next-largest magnet, Ontario. Its relative prosperity, high rate of personal income, and mild climate are special enticements for residents of the prairie provinces. The Victoria, Vancouver, and Okanagan areas attract large numbers of older persons, bent on retirement amid a gentler climate and abundant amenities, from the prairies.

Recent influx of people

By contrast, central and northern British Columbia attract a preponderance of young people from the south, as well as from the prairies and eastern Canada. They are able to cope with the rigours of the more severe climate, the lack of good housing, and the absence of many services taken for granted in the south. In return, the north offers them higher wages and the opportunity to establish themselves in a still largely virginal territory, an appealing prospect in a period in which populations increasingly show signs of deserting the crowded and polluted urban centres.

THE PROVINCE'S ECONOMY

Areas of public ownership. The economy of British Columbia is a mixture of public and private enterprise. Two of the three major railroads serving the province are publicly owned. The provincially owned British Columbia Railway (BCR) contributes significantly to the economic viability of the central and northern regions, which are served poorly or not at all by the two national roads. It operates some 1,100 miles of mainline track between North Vancouver and its northern terminal at Fort Nelson; 420 additional miles of track, under construction in the early 1970s, will take it to Dease Lake, about 100 miles from the Yukon border.

The second important public corporation is British Columbia Hydro and Power Authority, which generates, transmits, and distributes electricity in areas containing 90 percent of the province's population and distributes natural gas in the Vancouver and Lower Fraser Valley areas. It also operates transit systems in greater Vancouver and greater Victoria and interurban bus systems between Fraser Valley points and Vancouver and between Vancouver, Victoria, and Nanaimo. On the Peace River the corporation undertook construction of the W.A.C. Bennett Dam, one of the largest in the world, and several others on the Columbia River. By 1973 the Peace River power project, located west of Fort St. John, was to supply 1,800,000 kilowatts of power to Vancouver and southern British Columbia. The Mica, Hugh Keenleyside, and Duncan dams in the Columbia system aided in flood control in the downstream sections of the river in U.S. territory.

The private sector. Of chief interest in the private sphere are forest industries, mining, tourism, shipping, and agriculture. The forests of British Columbia make up more than half of the total Canadian forest resource. The forest industry is dominated by several giant multinational corporations, which usually hold forest-management licenses from the provincial government for sustained-yield forestry, a continuous replanting that is practiced in more than 85 percent of the province's forest area. These companies have integrated the production of timber, lumber, chips, shingles, plywood, and pulp and paper under single corporate organizations for maximum utilization. The chief areas of forest activity are the Georgia Strait area, between Campbell River and Vancouver, where pulp and paper production is particularly important; and the Prince George area, where pine production and pulp and paper predominate. In 1969 the forest industry contributed more than $1,200,000,000 to the province's economy.

Minerals, petroleum, and natural gas worth nearly $520,000,000 were produced in British Columbia in 1971, but the production of petroleum, natural gas, and coal were still in their infancy, with rapid expansion likely in the decade of the 1970s. The most valuable mined products are copper, crude oil, molybdenum, zinc, lead, and natural gas.

The ports of Vancouver, Victoria, Chemainus, Powell River, New Westminster, and Prince Rupert are the chief ones through which the resources of British Columbia and other provinces are exported to the United States, Japan, and other world markets. Most of Vancouver's shipping is carried out from the inner harbour, but Roberts Bank "superport" handles increasingly large shipments of coal and other bulk cargoes, especially for the Japanese market. The National Harbours Board of Canada is responsible for the construction of Roberts Bank, Canada's first superport, located just south of Vancouver at the mouth of the Fraser. Facilities capable of loading thousands of tons an hour have been erected, and berths capable of servicing the world's largest cargo carriers have been set up.

Transportation. Although an elementary system of transportation was established in gold-rush days and most of its routes are still followed, no concerted effort was made to tie the isolated areas of the province together by roads, ferries, and railroads until after World War II. Highways are exceedingly important in a province having the highest number of passenger cars per capita in Canada. This crucial fact was recognized and exploited by the infant Social Credit Party, which adopted an ambitious and controversial program of road building, bridge building, and ferry services as the chief plank of its highly successful political platform. In the 15-year period after 1955, over $1,500,000,000 was spent constructing and repairing over 7,800 miles of highway and building 528 bridges, including such structures as the Alexandra North Arch in the Fraser Canyon, the Port Mann Bridge near New Westminster, the Okanagan Bridge at Kelowna, and the unique four-lane, 2,100-foot Deas Island Tunnel under the Fraser River near Vancouver.

Highway expansion

British Columbia's convoluted landscape makes it a bridge country, with more than 3,000 crossings, and places construction costs of roads in many areas at more than $1,000,000 per mile, apart from the bridges. The Fraser Canyon, north of Hope, includes seven highway tunnels up to 2,000 feet long.

Vancouver Island, with one-sixth of the province's population, represents a special transportation problem. This has been met by the development of one of the world's largest ferry fleets. Most of the ferries connecting Vancouver with Victoria and Nanaimo carry 1,000 passengers and from 140 to 200 cars each.

The province is served by three railroads. The Canadian Pacific Railway (CPR) connects Vancouver with eastern Canada via a mail line through the Crowsnest Pass and maintains a network of branches serving the mining, forest, and agricultural industries throughout southern British Columbia. The Canadian National Railway, like the BCR, is publicly owned. It serves the south and the north with terminals at Vancouver and Prince Rupert. The British Columbia Railway was discussed above.

The vastness of the province combined with difficult terrain and variable weather conditions have offered

particular encouragement to the development of air travel. Vancouver International Airport is headquarters for Canadian Pacific Air and Pacific Western Airlines Ltd., Canada's second- and third-largest carriers.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. Parliamentary government in British Columbia dates from the inauguration of the first legislature of the Colony of Vancouver Island, August 12, 1856, but responsible government was not achieved until confederation.

Provincial level. The lieutenant governor, appointed by the government in Ottawa, ostensibly represents the British crown, but in the real sense he represents the federal government. The lieutenant governor calls upon the recognized leader of the majority party in the provincial Legislative Assembly to form a government, with that leader as premier. The premier and his Cabinet, whom he selects from the elected members of the legislature, comprise the Executive Council. The Cabinet is responsible to the Legislative Assembly for the operation of the day-to-day business of the government. The unicameral assembly has 55 members representing 42 electoral districts.

Local government. More than 80 percent of the population resides in municipalities governed by elected mayors and councils. These local governments are the children of the provincial government, which creates them and supervises their activities. Because the senior government has greater access to revenue sources, especially new forms of taxation, funds-starved municipalities are growing more receptive to the requests of the minister of municipal affairs for greater cooperation among them in such areas as education, hospital services, transportation, and even local government. Since the provincial government meets a large part of the municipal budgets outside of the large cities, the minister receives considerable cooperation even in his demands for outright amalgamation of contiguous municipalities.

Justice and law enforcement. The attorney general of the province is responsible for the administration of justice, for the enforcement of the law, and for the administration of the provincial Court of Appeal, Supreme Court, and county courts (except judicial appointment) under terms of the British North America Act. There are two Courts of Appeal registries, in Vancouver and Victoria, and 40 Supreme Court and county registries throughout the province. In addition, at the lower court level, the attorney general controls the appointment of magistrates, family-court judges, coroners, and justices of the peace, all of whose duties are defined by federal and provincial statutes.

By agreement, the Royal Canadian Mounted Police (RCMP) act as the provincial police force under the control of the attorney general. Most cities and district municipalities are responsible for law enforcement within their own boundaries. Most elect to have this function contracted out to the RCMP, but Vancouver, Victoria, and New Westminster maintain independent forces. The RCMP is responsible for all unorganized areas. Legal aid, administered by the British Columbia Law Society on a limited basis to the poor, is paid for chiefly by the attorney general from provincial funds.

The social milieu. *Health and welfare.* The British Columbia Overall Medical Services Plan is available to all residents of the province on a voluntary subscription basis at low, uniform rates. It provides comprehensive medical care coverage, including specified services of physicians, surgeons, certain dental surgeons, the Red Cross, nurses, chiropractors, osteopathic physicians, and others. Hospital care at $1.00 per day is also available under the British Columbia Hospital Insurance Service (BCHIS). Medical care for the aged meets the standards of the Medical Care Act of Canada and receives contributions from the federal government. About 98 percent of the province's population is covered by the plan and by BCHIS. Ninety-four general hospitals operate under BCHIS in addition to eight Red Cross outpost hospitals, five federal hospitals, and 22 special hospitals.

Provincial involvement in medical services

Narcotics addiction is a special medical problem of enormous significance to British Columbia, which has in the past accounted for more than half of Canada's narcotics addicts. Prior to 1908, when narcotics were made illegal, Vancouver legally produced refined opium of high quality. Though supplies now come illegally from Europe rather than China, the problem of addiction has remained serious. The Narcotic Addiction Foundation of British Columbia, located in Vancouver, offers methadone treatment and psychotherapy free of charge, but no unified system of addiction treatment has been established in the province.

Environmental pollution. Environmental health and pollution control are of enormous concern to British Columbians, especially as they affect the Fraser River, the Gulf and Strait of Georgia, and the lakes of the Okanagan and Kootenay regions. Of the 42 communities within the Fraser River watershed, only a handful have adequate waste-disposal units. Consequently, the river is polluted to the point where the important salmon runs are endangered and the usefulness of the river for recreation purposes is being rapidly circumscribed. The only tertiary treatment plant in British Columbia is located in Kelowna, where the plant removes a high percentage of phosphates from sewage effluent dumped into that endangered lake.

The rapid expansion of the raw-resources industries, especially in pulp, paper, and mining since 1960, has produced a problem of mammoth proportions. Each pulp mill releases millions of gallons of toxic effluents into rivers and coastal waters daily and tons of obnoxious air pollutants. Strip-mining of coalfields in the Kootenay Range, to feed the blast furnaces of Japan, are laying waste miles of mountainside, and scores of mines (nine in the Fraser watershed alone) release staggering quantities of toxic substances from mining processes into the tributaries of the Fraser, the Columbia, and other streams.

British Columbia has been slow to enforce pollution control, partly because of the cost and partly out of fear of slowing down investment in the industries responsible for the pollution. Ecologists consider existing control legislation inadequate and government supervision of offending industries lax.

Education. The provincial government spends about 30 percent of its budget on the rapidly expanding education industry of the province. Public school education is free and compulsory to the age of 15. High schools can be found in every part of the province, while two-year junior colleges, operated by local school boards, are located in ten communities. Vocational schools are operated in most districts, and the local school board operates the Vancouver School of Art.

The University of British Columbia, in Vancouver, offers a wide range of advanced studies to upward of 20,000 students. Of special interest are the schools of medicine, forestry, dentistry, oceanography, agriculture, architecture, and Asian studies. A library of nearly 2,000,000 books, manuscripts, and microforms is especially strong in periodical literature, Canadiana, English literature of the 19th and early 20th centuries, and Chinese literature and history. Simon Fraser University, in adjacent Burnaby, has an enrollment of 5,000, as does the University of Victoria. Notre Dame University of Nelson is a small Roman Catholic institution.

CULTURAL LIFE AND INSTITUTIONS

Cultural dominance of the frontier

The majority of cultural activities in British Columbia tend to reflect the pioneer background of the province, the great distances between pockets of population, and the various economic backgrounds of areas still oriented to resource industries and to the outdoors. The Williams Lake Stampede is the great annual event of the white and the Indian populations of the ranching country of the Central Interior. The Kelowna Regatta attracts thousands to that watersports and tourist centre. Even the annual Pacific National Exhibition in Vancouver is largely oriented to the agricultural communities of the Lower Fraser Valley rather than to the urban interest of Van-

couver. Other centres hold annual loggers-day festivals, salmon contests, and pioneer events related to outdoor industry and pursuits.

Cultural activities of the larger cities are in a transitional stage, neither frontier nor unabashedly big city. Spectator sports based on monster stadiums and imported professional players made their debut with the building of the Empire Stadium in Vancouver and the establishment of the British Columbia Lions professional football team, later supplemented by the Vancouver Canucks of professional hockey. Vancouver's opera association, both respectable and ambitious, mounts productions featuring artists imported from the world's great opera houses, while its symphony society receives enthusiastic support from a loyal following of citizens. Smaller but important organizations, such as the Vancouver Institute, with its presentation of important speakers of international repute, and the Vancouver History Society, with its growing list of publications on provincial history, are finding increasing support as the city leaves the frontier behind.

Local industrialists have done much to support the recent upsurge in cultural activities through their financial support of such distributing agencies as the Vancouver Foundation and the Koerner Foundation. Private funds are channelled through them into the theatres, orchestras, university libraries, art galleries, and museums, as well as to private artists and scholars.

Cultural activities were given a sharp impetus by the three centennial celebrations of 1958, 1967, and 1971, when millions of dollars were provided by all three levels of government and by foundations and private companies to mark the establishment of the province, the founding of the nation, and the entry of British Columbia into confederation. The centennials fortunately occurred in a period of economic prosperity that found the public and private enterprise in a mood to support the expenditure of large sums on theatres, libraries, museums, planetariums, public squares and fountains, the restoration of historic sites, and similar expressions of unappeased cultural hunger. Among the most noteworthy constructions in Vancouver were the Centennial Museum, Maritime Museum, and H.R. MacMillan Planetarium, the Bloedel Conservatory, the Queen Elizabeth Theatre complex, the Court House square and fountain. In Victoria the McPherson Playhouse–City Hall complex is outstanding, as is the British Columbia Provincial Museum.

In a special place is the continuing restoration of Barkerville, once the thriving centre of the Cariboo gold rush of the 1860s. There the provincial government has rebuilt scores of old buildings to re-create the old gold town as it appeared over a century ago. A noncommercial project, it is probably the most historically faithful restoration of a complete town in the North American West.

The restoration of historic buildings of Victoria is also a notable consequence of a rebirth of interest in the province's cultural heritage. Scores of derelict buildings of historic interest have been restored to their original appearance and rented to merchants. Squares have been opened, and whole streets have been revitalized without recourse to bulldozers or slum clearance. Old buildings have been blended in with new in one of the most expansive and imaginative programs of its kind on the North American continent. Victoria, always a history-conscious city, has demonstrated that the architectural and cultural heritage of the province can be preserved and at the same time be made to serve a day-to-day useful purpose.

PROSPECTS

It is possible to look hopefully at future possibilities for British Columbia because of the ironic juxtaposition within the province of the untamed and the settled, of the promise that lies ahead and the rewards for the past. Urban British Columbia is, in every sense, economically vital and fully a part of western Canada's economy. Close at hand lie frontier and wilderness areas that provide not only spectacular recreational and nonurban-living opportunities but also potentialities for a continued economic development. Environmental damage is perhaps the most serious problem threatening at least a part of the province, unhappily but inevitably the most populated portion. Finally, it remains a question as to how long the province's economy, without pursuing new avenues of innovation, can continue to absorb the influx from other parts of the nation.

BIBLIOGRAPHY. RODERICK HAIG-BROWN, *The Living Land: An Account of the Natural Resources of British Columbia* (1961), a first-rate comprehensive inventory of the natural resources of the province, with a useful outsize map in folder pocket; MARGARET A. ORMSBY, *British Columbia: A History* (1958), a scholarly yet eminently readable account of the historical development of the province, especially rich in the pre–1935 period; REGINALD E. WATTERS (ed.), *British Columbia: A Centennial Anthology* (1958), a literary treatment of the province's many-sided development drawing upon hundreds of diverse sources; *British Columbia Historical Quarterly* (1937–58), a rich source on British Columbia history; *B.C. Studies*, a quarterly periodical presenting scholarly papers about the province's history, geography, archaeology, and economics; HARRY B. HAWTHORNE (ed.), *A Survey of the Contemporary Indians of Canada: Economic, Political, Educational Needs and Policies*, 2 vol. (1966–69), a comprehensive account of one of the most pressing human problems in Canada today; *Canadian Literature*, a scholarly quarterly periodical devoted to the study of Canadian literature (offers excellent coverage of British Columbia's literature); IRENE HOWARD, *Vancouver's Svenskar: A History of the Swedish Community in Vancouver* (1970), a noteworthy first publication of the Vancouver History Society's series on the ethnic groups of British Columbia; E.O.S. SCHOLEFIELD and F.W. HOWAY, *British Columbia from the Earliest Times to the Present*, 4 vol. (1914), full treatment of the province's history up to 1914—dated but valuable (two of four volumes are biographical); GEORGE WOODCOCK and IVAN AVAKUMOVIC, *The Doukhobors* (1968), a scholarly account of an unusual people; *Transactions of the Ninth British Columbia Natural Resources Conference* (1956), the most comprehensive account of the province's resources compiled by government departments.

(J.C.L.)

British Empire and Commonwealth

The development of the British Empire and Commonwealth was long and complicated. Not only did Britain win and lose a number of territories through conquest and cession (*e.g.*, Manila was British from 1762 to 1764; Java, from 1811 to 1816) but the degree of sovereignty Britain possessed over particular territories varied (*e.g.*, there was never any actual sovereignty over Egypt, in spite of British administration for half a century; and in a number of other cases British sovereignty was indirect, being derived from treaties or the proclamation of a protectorate).

The growth of independence by territories of the empire led to a new kind of political organization—the (British) Commonwealth of Nations; and, while later members of this body became independent only after a clear renunciation of sovereignty by Britain, the older members (such as Canada, Australia, and New Zealand) were, between the two World Wars, thought of as still in the British Empire, of which the British Commonwealth of Nations, consisting of self-governing territories, was regarded as part.

THE GROWTH OF THE BRITISH EMPIRE

Beginnings of the empire

British voyages of discovery and profit. The beginnings of the British Empire are usually located in the 16th century, when an urge toward overseas trade and settlement developed out of the pioneering voyages of Elizabethan seamen. A succession of voyages followed John Cabot's discovery of Newfoundland in 1497 and the establishment of a flourishing fishing trade there. At first the objects were trade and plunder; settlement had to wait until the beginning of the 17th century, although there were earlier abortive attempts to settle Newfoundland and Virginia. The expansion of Britain's maritime strength, however, paved the way for the establishment of settlements in North America and the West Indies.

In later centuries, exploration again stimulated imperial expansion, notably through the discoveries of Capt. James Cook in the South Pacific in the latter part of the 18th century and those of David Livingstone, Richard Burton, John Hanning Speke, and other travellers in Africa in the 19th. Apart from these notable cases, however, the 18th- and 19th-century development of the empire was due much more to conquest, international rivalry, and the search for favourable trading opportunities than to direct discovery.

Origins of British expansion. British expansion in the Americas, India, and Africa began in earnest in the 17th century. North America and the Caribbean were the scenes of what is sometimes called "the first British Empire," terminating in the loss of the colonies that became the United States. In nearly all cases, the early settlements arose from the enterprise of particular companies and magnates rather than from any effort on the part of the crown.

In the first half of the 17th century, when Virginia, Maryland, and the colonies of New England were set up, there were also settlements in Nova Scotia, Barbados, the Bermudas, Honduras, Antigua, and certain other West Indian islands. Jamaica was obtained by conquest in 1655. The Hudson's Bay Company established itself in what became northwestern Canada from the 1670s onward. The hold of the crown over these colonies, obtained through the issue of a charter, was slight but greater than that of the British Parliament. As late as 1732, the parliamentary leader Robert Walpole objected to the discussion by Parliament of the charter for Georgia, since it was regarded as part of the royal prerogative.

The crown exercised some rights of appointment and supervision, but the colonies were essentially self-managing, the form of their management depending on the character of those who had established them. No attempt was made to establish a uniform administration, although it was usual for the colonies to have some sort of local legislature and to reproduce the English legal system.

India. In India the beginnings of British influence were similar, though they did not involve settlement. The East India Company, granted its charter in 1600, was content for a long time to establish trading posts without controlling territory. Not until the authority of the Mogul Empire began to disintegrate at the beginning of the 18th century and other European powers, especially France, began actively to look for gains in India did the company set about the series of treaties and conquests that led to the consolidation of the Indian Empire. The Straits Settlements (Penang, Singapore, Malacca, and Labuan) became British through an extension of the East India Company's activities (see INDIAN SUBCONTINENT, HISTORY OF THE: *India and European expansion, c. 1500–1858*).

Africa. The British became involved in Africa later than in the Americas and India, though the first permanent British settlement on the African continent was established on James Island in the Gambia River as early as 1661. Sierra Leone was the scene of Sir John Hawkins' successful slave-trading ventures in 1562, but it did not become a British possession until 1787, after which it was used to resettle slaves from other British colonies. The Gold Coast (later Ghana) was a further example of 17th-century British trading effort, but it did not develop into an administered territory until the 19th century, when Nigeria, by various stages, also became British.

Whereas the main British interest in these western African territories was in trade, in the southern tip of Africa it was in settlement, following the acquisition of the Cape in 1806; the interior was opened up by Boer and British pioneers, ultimately under British control. British administration of what are now Kenya and Uganda, on the eastern coast, did not begin until the 1880s.

Thus the motives that led to British control of great areas far from Britain itself were various. The commercial motive was undoubtedly the strongest at the start, and it remained important; but as time went on, it was augmented by missionary influence and by strategic considerations. It is important to emphasize, however, how unorganized was the extension of the empire. Only rarely was there strong sentiment in Britain in favour of the acquisition of territory as such (the last two decades of the 19th century were one such period). The British tradition was of piecemeal acquisition, each case being treated on its merits, sometimes with the British government being the least willing partner in the enterprise.

Relations between England and the empire

The empire of outposts, to 1763. The sphere in which the crown exercised most control over the colonies in the 17th and 18th centuries was trade and shipping.

Trade in goods. In accordance with the mercantilist philosophy of the time—also adhered to by other European colonial powers—the colonies were regarded as a source of necessary supplies for England and were granted monopolies for their products, such as tobacco and sugar, in the British market. In return, they were expected to conduct all their trade by means of English ships. The Navigation Act of 1651 and further acts after the Restoration provided that no other country could carry goods to or from the colonies, that the main colonial products could be exported only to England, and that only those foreign products that had been brought to England first could be imported into the colonies. This closed economic system caused objections from some of the colonies but guaranteed others that their distinctive products would find a sheltered market in Britain and not be subject to competition from other powers' sugar colonies, especially those of Spain. This arrangement lasted until the combined effects of the Scottish economist Adam Smith's *Wealth of Nations* (1776), the loss of the American colonies, and the growth of a free-trade movement in Britain slowly brought it to an end; but the last Navigation Act was not repealed until 1849.

The slave trade. In the 18th century, most of the colonial economic systems in the Americas rested on the Navigation Acts, on the one hand, and slavery, on the other. The slave trade, begun by Hawkins, had become an economic necessity for the Caribbean colonies and the southern parts of what later became the United States. It was not confined to these British colonies but was common to those of France and Spain, with which the British colonists were in competition. Movements for the ending of the slave trade and of slavery itself had begun in Britain before the loss of the colonies on the eastern American seaboard; they came to fruition in British possessions long before the similar movement in the United States. The trade was abolished in 1807, slavery in 1833. It left behind it, however, many people of African stock who still form the bulk of the populations of the independent states of Jamaica, Trinidad, Barbados, and other Caribbean islands that remain British dependencies.

British sea power. In the 18th century, the Caribbean colonies were important to Britain not only as suppliers of sugar and buyers of slaves but also as strategic possessions in deciding the issue of naval supremacy between Britain, France, and Spain. The admirals George Rodney and Horatio Nelson were as familiar with the waters of the Indies as with those of Europe. Indeed, as hostility continued between Britain and France, colonial possessions became not only bases but also prizes. In the process, Britain gained two of the most important parts of its empire—Canada and India.

British conquests. Fighting between the French and British colonies in North America was endemic in the first half of the 18th century. It was especially fierce during the Seven Years' War (1756–63), which was ended by the Peace of Paris in 1763, whereby British control of Canada became undisputed, with expansion into the west and northwest no longer threatened by a chain of French forts stretching southward from Quebec to Louisiana. Control of a large population of French descent, language, and culture in Quebec was a new experience for Britain, but this did not prevent an eventual consolidation of Canada.

In India, the East India Company was confronted by the French Compagnie des Indes. Under the governor general Joseph-François Dupleix, French influence and conquest flourished while British influence diminished. The

balance was redressed in favour of the British by the military genius of Robert Clive and by a change in French policy, which recalled Dupleix. Clive and Eyre Coote went on to further victories against the French and against the rulers of Bengal, thus providing the East India Company with its first massive accession of territory and ensuring that no other European power would challenge British supremacy in India.

Clive's victory at Plassey in India was in 1757; James Wolfe's at Quebec, in 1759. By this time Britain was, of necessity, showing more governmental concern for the colonies. Although the New England colonists in America and the East India Company in India might fight the French on local ground, their doing so was part of the larger struggle between Britain and France and had to be taken into account—sometimes assisted, sometimes muted—by the government in London. For strategic reasons, the government displayed a great interest in acquiring territory at the Treaty of Aix-la-Chapelle in 1748 and the Treaty of Paris in 1763. Yet it could not be said that any great colonial design was manifest in the British demands; the fact that Lord Bute's Cabinet in 1763 discussed whether it would be better to retain the conquered sugar island of Guadeloupe than to keep the French out of Canada indicates the short-term considerations that often governed policy.

Changes in the empire

Losses and gains, 1763–1815. Despite the loss of its colonies in what is now the United States, the empire continued to grow during the late 18th and early 19th centuries.

The loss of the American colonies. Britain lost the 13 colonies in North America because it attempted to interfere in their affairs but lacked the military skill and organization to bring them to heel when they revolted. The war in America dragged on from 1775 until 1783 and was enlarged by the entry of France, Spain, and Holland against Britain. Apart from the loss of the colonies in revolt, some Caribbean islands were lost temporarily to France, and Tobago and Minorca were no longer British after the peace settlement. The blow to British pride was considerable; but the British Empire was soon to show further vitality through the spectacular growth of Upper Canada after the emigration there of loyalists from what had become the United States and through the establishment of new colonies of settlement in the South Pacific.

The first settlements in Australia. In 1770 Capt. James Cook sailed along the previously unknown eastern coast of Australia and around New Zealand, bringing back reports that formed the basis of later settlement. New Zealand did not come under formal British control until 1840; but the settlement of Australia began in New South Wales in 1788, in part due to the loss of the American colonies, which were no longer available as a repository for some of Britain's convicts. Australia's period of transportation lasted only about 60 years, however, and the main mass of the population was derived from free settlement. Tasmania (1803) and Queensland (1824) were convict settlements, and Western Australia, after its inception as a freemen's colony, took convicts for labour from 1849 until 1868; but Victoria (1834) and South Australia (1836) were never convict colonies.

Conquests during the Napoleonic Wars. The Napoleonic Wars (1799–1815) provided further additions of territory to the empire, although only one acquisition—the Cape of Good Hope—became an area of substantial British settlement. By the Treaty of Amiens in 1802 Britain gained Trinidad and Ceylon. By the first Treaty of Paris in 1814 gains included Tobago, Mauritius, St. Lucia, and Malta—each of which had strategic value. At the Cape, however, Britain made its most fateful acquisition. The Dutch had been settling there since 1652, reinforced by French Huguenots. The Boer farmers had developed a distinctive society and an ethos of their own. Britain's interest in retaining the Cape was at first a naval one because of the route to India, but this was soon augmented by the wish to anglicize the Boers through the use of the English language and through added immigration from Britain. Many of the Boers proved recalcitrant.

Certain other additions, made early in the 19th century, were of great future importance. They included Malacca, which came into British hands in 1795, and Singapore—a mudbank with few inhabitants when Sir Thomas Stamford Raffles took it over for the East India Company in 1819, but later a trading port of growing importance. The future shape of Canada was being determined with the settlement of Alberta, Manitoba, and British Columbia. These, like Australia, New Zealand, and the Cape, were fertile and comparatively empty; they were to become areas of substantial British migration. The War of 1812 with the United States provided an impetus to Canadian unity and strengthened Canadian disinclination to become part of the U.S.

In India, the period of the Napoleonic Wars was notable—not for fighting with France but for local wars against French influence and for the acquisition by the East India Company, through conquest and treaty, of the United Provinces of Agra and Oudh and the Central Provinces; East Bengal and Assam were to follow before long.

Further spread of British influence

Expansion in the 19th century. The Crimean War (1854–56) made little or no difference to the British Empire, and Britain had no other wars with European powers between 1815 and 1914. During this long period, British wars were either in India or in the colonial empire—notably in pacification programs in Africa—but also against the Maoris in New Zealand. The most serious conflicts were with the Boers (in 1881 and 1899–1902) and with the Mahdi (*q.v.;* 1884) in the Sudan. For the most part, 19th-century development was a matter of consolidating existing colonies and of extending into new areas, especially in Africa.

Colonial administration and policy. Administration and policy changed during the century from the haphazard arrangements inherited from the 17th and 18th centuries to the relatively sophisticated system characteristic of Joseph Chamberlain's tenure in the Colonial Office (1895–1900). That office, the distinct existence of which can be traced from 1801, was first an appendage of the Home Office and Board of Trade, and then linked with the secretary for war. By the 1850s, it had become a separate department with an increasing staff and something of a continuing policy; it was the means by which discipline and pressure were exerted on the colonial governments (though not upon the East India Company) when such action was considered necessary.

In the main, however, colonial governments were left largely to themselves. In the areas of new settlement in North America, South Africa, and the Pacific, local self-government was soon granted to the settlers. In the Caribbean, however, an opposite movement took place; the powers of most of the long-established legislative bodies were reduced and those of the governors increased so that these became "crown colonies," subject to direct rule. The reason for this was the condition of the islands after the repeal of slavery in 1833. Emancipation, combined with the effects of the withdrawal of the sugar monopoly in Britain after the triumph of Free Trade, made government in the interests of the tiny minority of planters no longer acceptable. When expansion took place in Africa and the Pacific, the crown colony system was again applied.

New Zealand and Oceania. In the Pacific, New Zealand became officially British in 1840, following pressure from the missionaries who were alarmed at the impact on the Christianized Maoris of the small collection of white rogues and vagabonds who had established themselves there. Systematic colonization followed rapidly. Land disputes between the settlers and the Maoris led to the Maori Wars of the 1840s and 1860s; but the eventual settlement satisfied both sides, and British troops were withdrawn. Late in the century British control was extended to other islands in the Pacific—often again because of missionary pressure and sometimes because of international rivalry. Fiji was ceded in 1874. A British High Commission for the Western Pacific Islands was established in 1877. A protectorate was declared over Papua in 1884, following pressure from Queensland, and

over Tonga in 1900. Other groups of islands were also taken over. Some of these acquisitions later became the responsibility of Australia and New Zealand.

Asia. The situation in 19th-century India was one of slow but constant extension, first of the East India Company's territory, and then, after the replacement of the company's authority by that of the crown following the Indian Mutiny (1857), of the Indian Empire. The greatest acquisition was that of Burma, completed in 1886; but the conquest of the Punjab (1849) and of British Baluchistan (1854–76) provided substantial territory in the Indian subcontinent itself. The importance of a new route to India, after the opening of the Suez Canal, was signified by the growth of Aden (originally captured by the East India Company in 1839), by a protectorate in Somaliland, and by the extension of British influence among the sheikhdoms of southern Arabia and the Persian Gulf. Cyprus—a link, like Gibraltar and Malta, in the chain of communication with India through the Mediterranean—was occupied by treaty with the Ottoman Empire in 1878.

British influence in the Far East expanded with the development of the Straits Settlements and the federated Malay states. In the 1880s Britain became established in Borneo, with a chartered company at work in British North Borneo and protectorates over Brunei and Sarawak. Hong Kong island became British in 1841, and adjacent territories on the Chinese mainland were acquired in 1860 and 1896. The British also obtained special rights in Shanghai, another great trading port through which Britain's "informal empire" in China operated; this was not a matter of sovereignty, however, and mention of it in the context of the British Empire, while realistic in a sense, is more doubtful in legal terms.

Africa. The greatest development of 19th-century British imperial power took place in Africa. In Egypt, Britain was the acknowledged ruling force from 1882 onward, following a naval bombardment of Alexandria; in The Sudan, formerly a nominal Egyptian province, British control was exercised under the guise of an Anglo-Egyptian joint administration established in 1899. The idea that British power might extend "from the Cape to Cairo" fascinated many people in Britain in the 1880s and '90s—a period of great enthusiasm for the empire, marked by Queen Victoria's two jubilees, by colonial conferences, by the re-establishment of chartered companies to seek out new areas of opportunity, and by mining discoveries and wars in South Africa. On the western coast the Royal Niger Company began the extension of British influence in Nigeria. The Imperial British East Africa Company operated in what are now Kenya and Uganda, and the British South Africa Company in the areas now called Rhodesia, Zambia, and Malawi. Again, missionary influence was strong in the eventual transfer of some of these territories to the crown.

After the South African War (Boer War, 1899–1902), British influence spread northward from the Cape. Natal had become British in 1843. The Orange Free State and the Transvaal swayed back and forth between independence and British suzerainty, but they were annexed after the South African War. Meanwhile, the activities of the British South Africa Company, north of the Transvaal, had ensured a British presence in Southern and Northern Rhodesia. South Africa was the principal source of argument between imperialists and anti-imperialists. To many, British policies there epitomized the misuse of imperial power.

For better or worse, the spread of the British Empire had been so great during the 19th century that it comprised nearly a quarter of the land surface and included more than a quarter of the population of the world. The term empire, however, was obviously used rather for convenience than in any sense equivalent to the older or despotic empires of history. This was due to the high degrees of self-government obtained by the white-dominated colonies.

THE COMMONWEALTH OF NATIONS

Growth of self-government. The beginnings of the self-government movement probably lie with Lord Durham's *Report on the Affairs of British North America* (1839). Following minor rebellions in both Upper Canada (Ontario) and Lower Canada (Quebec), Durham was sent out as governor general to investigate.

Responsible government. Durham's report recommended that responsible government (*i.e.*, the acceptance of the advice of local ministers by governors) be granted to the two Canadas, which should be merged in one. The merger took place immediately, but Durham's advice on responsible government was not accepted until put into effect by his son-in-law Lord Elgin, governor general in 1847. Thereafter, the pattern was applied to other Canadian provinces and to the Australian colonies. The British government's willingness to let the colonies of settlement manage their own affairs was very much in line with its contemporary disavowal of the mercantilist philosophy and with its withdrawal of colonial privileges in the British market.

New South Wales, Tasmania, South Australia, and Victoria had responsible government by the end of 1855, having been invited to draw up their own constitutions by the Australian Colonies Government Act of 1850. Queensland followed in 1859. Western Australia had to wait until 1890. In New Zealand and South Africa, the position of the local colonists was not so strong as in Canada and Australia because in both cases they were still dependent on British troops for protection against natives; moreover, the existence of large native populations in both was an argument used by the Colonial Office (often subject to humanitarian pressure in London) against a too rapid advance toward local autonomy. New Zealand obtained responsible government in all but native matters in 1856; by 1870, when the British troops went home after the Maori Wars, even these reservations had disappeared, and the local settlers were in full charge of the country's affairs. The Cape Colony achieved responsible government in 1872, and Natal in 1893.

Dominion status. Meanwhile, British North America experienced further development in self-government. The union of Upper and Lower Canada developed many stresses by the 1860s. In addition, the maritime colonies were seeking new forms of association with one another and with Upper and Lower Canada. The result, after local conferences, was the British North America Act of 1867, whereby Ontario, Quebec, New Brunswick, and Nova Scotia were brought together in a confederation known as the Dominion of Canada. Manitoba joined in 1870, British Columbia in 1871, and Prince Edward Island in 1873. The continuing development of the prairies brought in Alberta and Saskatchewan in 1905. Of the British North American colonies, this left only Newfoundland outside the confederation—a situation finally adjusted by Newfoundland's entrance in 1949.

The Australian colonies formed a federation in 1901. There was a union of the South African colonies in 1910. In the latter, the defeated Transvaal and Orange Free State were added to the Cape and Natal. By means of these arrangements, each of the three countries (including Canada) obtained a national government that operated in full control of its own affairs, as did that of New Zealand. Britain retained minor powers of veto, which amounted to very little. Its influence lay in its provision of naval defense and its position as a buyer of local products and an investor in local enterprises. In 1907 the countries' special position was recognized by their designation as "dominions," not colonies; by the creation of a special Dominions division in the Colonial Office; and by the regular institution of an Imperial Conference, which they, with Newfoundland, would attend.

Growth of national governments

In World War I, the contribution of the dominions was so substantial that they were given representation in an "imperial cabinet" that, while it did not survive the war, emphasized the degree of autonomy they had attained. At the peace settlement some of the dominions acquired mandatory responsibilities, and all became members of the League of Nations. In the 1920s Canada, South Africa, and the Irish Free State (which had been given the status of a dominion in 1921) applied pressure for a clearer definition of dominion status.

Independence. At the 1926 Imperial Conference this was met by an agreed statement that Great Britain and the dominions were "autonomous communities within the British Empire, equal in status, in no way subordinate one to another in any aspect of their external or domestic affairs, though united by a common allegiance to the Crown and freely associated as members of the British Commonwealth of Nations." Parliament passed the Statute of Westminster in 1931, which embodied this declaration in a self-denying ordinance, whereby legislation concerning the dominions would be enacted only with their consent.

The Commonwealth in operation. The 1926 definition of dominion status, while immediately satisfying to those who had pressed for it, left a number of questions unanswered: Could a dominion secede from the Commonwealth? Did "common allegiance" mean a single crown, or was the crown divisible? Could and should there be more than one foreign policy in the Commonwealth? Could one dominion be at peace while others were at war? These questions were much discussed in the 1930s; they were answered effectively in World War II, when Canada and South Africa made separate, delayed declarations of war, and Ireland remained neutral. As in World War I, there was considerable support for Britain's war effort from the belligerent dominions, though the dispersed nature of the war—especially its Pacific aspect—led to more active diplomacy by some of them. When the war ended, their independence was no longer in question.

Independence for Asian, African, Caribbean, and Oceanic nations

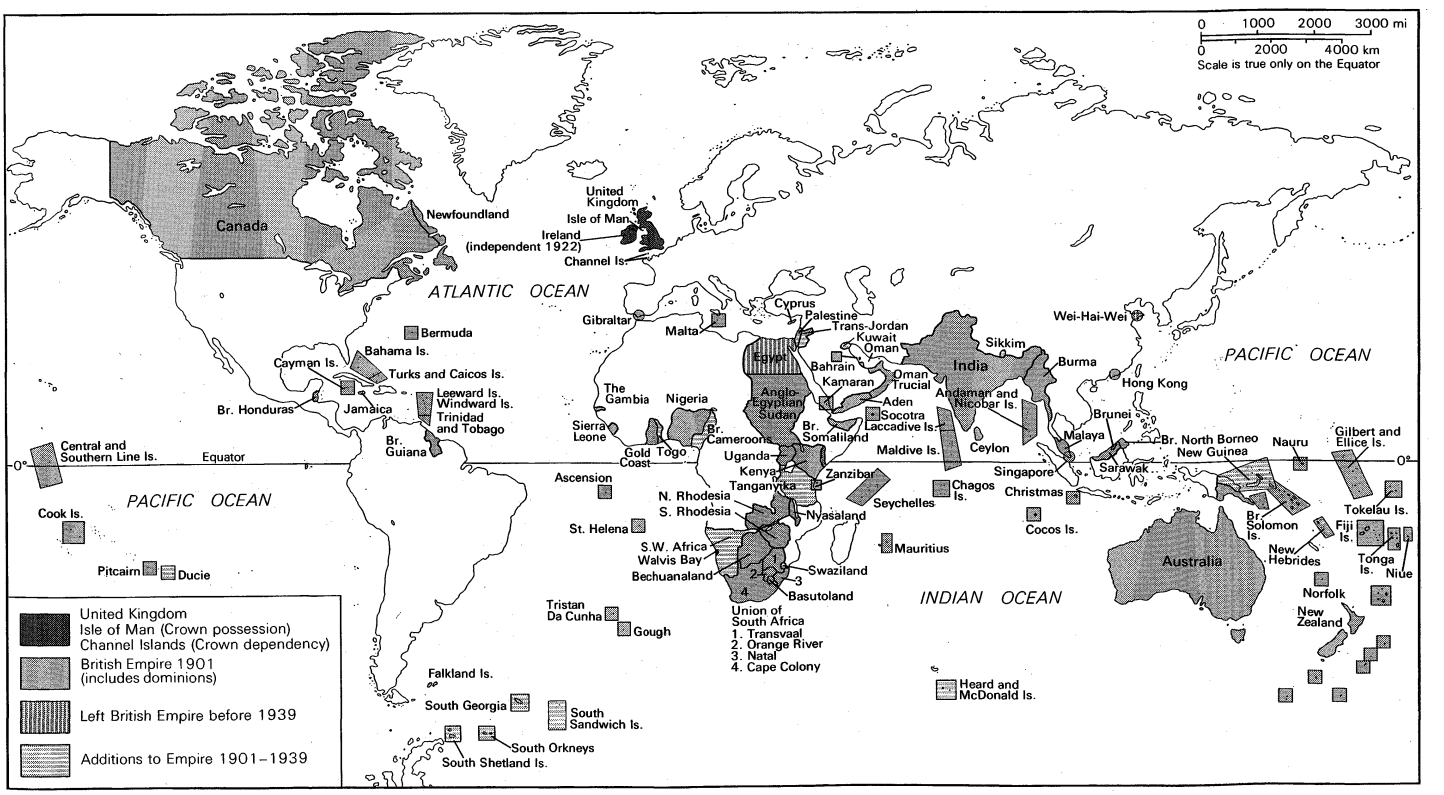
India's independence. At this stage (1945), dominion status still applied only to settler communities. For some time, however, the possibility of India's achieving dominion status had been actively canvassed. India was a special case within the British Empire; by title an empire in its own right, it had a viceroy, a separate secretary of state in London, its own army, and even, to a certain degree, its own foreign policy. Its size alone made it unique—the most notable of Britain's possessions. Since the beginning of the century, however, there had been agitation for greater local autonomy, even though India's communal divisions made this hard for many Englishmen to envisage.

Indian contributions in World War I had led to reforms in 1919, whereby British India was governed under a system called "dyarchy," which gave a good deal of experience to provincial legislatures but stopped far short of self-government. The viceroy still held the keys of power. In the 1920s and '30s, the Indian National Congress, led by Mahatma Gandhi and Jawaharlal Nehru, agitated for independence. The exigencies of World War II led to explicit British promises of dominion status; this entailed splitting the formerly undivided India into two dominions—India and Pakistan—when the move took place in 1947. Ceylon and Burma also obtained their independence at this time, but Burma chose independence outside the Commonwealth.

Changes in Commonwealth relations. The appearance of Asian dominions led to changes of tone and character in the Commonwealth of Nations. No longer was its British quality stressed; even the adjective British was tacitly dropped by British spokesmen when they referred to it. The large-scale Imperial Conferences of the interwar years, intended to display imperial unity, gave way to briefer and more intimate gatherings of prime ministers. The Dominions Office, which had been detached from the Colonial Office in 1925, was amalgamated with the India Office to form a Commonwealth Relations Office with its own secretary of state. The network of diplomatic posts within the Commonwealth grew rapidly, under high commissioners with the status of ambassadors; but the previous assumption of a common foreign policy disappeared. Consultation, not unity, was assumed to be the essence of the Commonwealth tie.

This loosening of the previous connections was taken a stage further in 1949, when India stated its wish to assume the status of a republic but to remain within the Commonwealth. The other members gave approval. The crown thus became an institution applicable to individual Commonwealth countries, which remained realms, but not to the Commonwealth as a whole. Instead, the British monarch, in his or her person, was recognized as "Head of the Commonwealth," a ceremonial position without functions.

The rush toward independence. In the 1950s the remaining British colonies in Africa, Asia, the Caribbean, and the Mediterranean moved at varying speeds toward further self-government. The process was at first hesitant, but it gained speed as international pressure mounted



The British Empire, 1901 and 1939.

(notably at the United Nations), as the notion of independence spread in the colonies themselves, and as the British public, no longer actively imperial in its sentiments, accepted the idea of independence as a foregone conclusion. The British political parties no longer argued about whether independence should be granted or not, but about its pace and structure. In some cases—such as Aden, Singapore, Cyprus, and Malta—strategic considerations made independence difficult to contemplate at first; but these concerns were overcome either by special arrangements after independence or by the abandonment of the strategic assumptions that had previously been held. In such other cases as The Gambia and the former High Commission territories of southern Africa (Basutoland, Bechuanaland, and Swaziland), smallness of size and poverty of resources seemed at first to prevent independence; but these considerations, too, were displaced. The experiences of other European colonial powers and the pressure of American opinion also hastened the policy of independence. In nearly all cases, except those in which the complex politics of the Middle East made it impossible (The Sudan, Somaliland, South Arabia, and Palestine), former colonies chose membership in the Commonwealth. Increasingly in the 1960s, they chose also the status of republics, not realms. By the late 1970s the number of Commonwealth members had grown to 36.

Problems within the Commonwealth

The process of colonial independence was not, however, altogether smooth. Kenya, Cyprus, British Guiana, and Malaya experienced violence beforehand. The white settlers of Africa, alarmed not only by the speed of British decolonization but also by the example of the Belgian Congo and French Algeria, saw the Commonwealth increasingly as a means whereby Britain was pushed into granting independence to peoples who were not ready for it, who would misuse it, and who might, through example and subversion, threaten others' privileged position. Such feelings by the settlers of Kenya were successfully overcome. But in Southern Rhodesia they became dominant when the former Federation of Rhodesia and Nyasaland—set up in 1953 and involving, in practice, domination by the Rhodesian settlers—was dissolved in 1963 because of African pressure. The government of Rhodesia made a unilateral declaration of independence in 1965, and in spite of British, Commonwealth, and UN opposition maintained its position. The independent black African states were powerless to displace the white Rhodesians, despite the Commonwealth's "multiracial" character.

Even more markedly, the white government of South Africa survived a long campaign against it by African and Asian states. South Africa left the Commonwealth in 1961, following what it regarded as interference in its racial policy from other members. (This was not the first withdrawal, or the last: Ireland had done the same in 1948, and Pakistan did in 1972.)

Members' influence on each other

It was clear that while the Commonwealth ostensibly rested upon the complete independence of its members and had no right of censure of any majority upon individual members, pressure could be exerted to try to make a member change its policies. Because Britain remained the most powerful state in the Commonwealth, with the most extensive range of policies likely to affect other members, it was natural that most pressure should be exerted upon it—as over the Suez crisis of 1956, the British decision to seek entry into the European Economic Community in 1961, and various British decisions to restrict the immigration of Commonwealth citizens into the United Kingdom after 1962.

Links with Britain. The achievement of independence by the members did not, in itself, change a number of their traditional and informal links with Britain, though these were subject to erosion by the forces of world change generally. British investment remained a significant factor in some members' economies, and British trade did in most (although the widespread but not universal system of preferential trade, set up at a conference in Ottawa in 1932, was greatly eroded by war and postwar changes); the wartime organization of the Sterling Area (countries with most of their exchange reserves in the Bank of England) continued in the 1950s but proved less important in the 1960s and '70s. Migration was considerable from Britain to Australia, New Zealand, and Canada and was matched by a flow into Britain from these countries and from India, Pakistan, and the West Indies in the 1950s and '60s. British educational, sporting, publishing, legal, and professional influence continued to be felt in countries that had been part of the empire.

Commonwealth organization. The formal organization of colonial and Commonwealth affairs changed under the pressure of accelerated independence. The Colonial Office, which had grown in the 1940s and '50s, as the colonies were provided with more elaborate assistance in development and welfare, shrank in the 1960s and was incorporated in the Commonwealth Relations Office (renamed the Commonwealth Office). The Commonwealth Office, in turn, was merged with the Foreign Office, a small section continuing to administer the affairs of the few remaining dependent territories, of which by the 1970s there were none in Africa, only Hong Kong and Brunei in Asia, Gibraltar in the Mediterranean, and certain islands in the Pacific, Indian, and Atlantic oceans, together with some islands in the Caribbean and British Honduras (Belize) in Central America.

Before 1965 there had been no executive for the Commonwealth as such. The British government normally arranged the meetings of Commonwealth prime ministers; otherwise, contacts were at the diplomatic level, with a network of ad hoc bodies in such spheres as scientific and educational cooperation. In 1965 a Commonwealth Secretariat was established in London, with a secretary general and a staff drawn from and supported by the member states. Its duties were the promotion of Commonwealth cooperation and the conduct of Commonwealth meetings, which continued to take place at various levels, from those of prime ministers to those of officials concerned with particular activities such as finance and the promotion of trade and tourism. There was also a certain amount of intra-Commonwealth economic aid, although most aid was bilateral between donors and recipients.

Commonwealth Secretariat

The Commonwealth is now only one of a growing band of international bodies to which its members belong. The British Empire, from which the Commonwealth grew, is a vestigial survival, further attenuated each year.

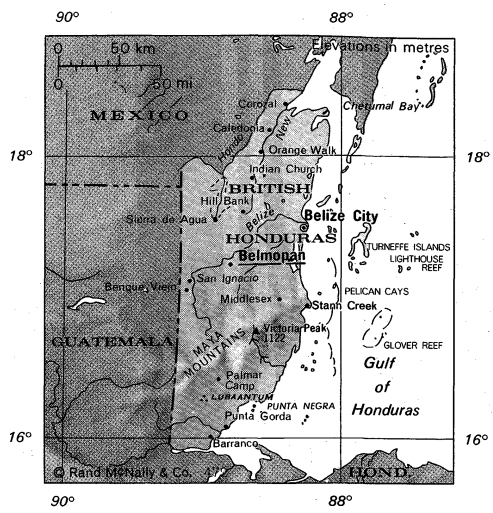
British Honduras (Belize)

British Honduras, since 1973 officially Belize (Belice to neighbouring countries), is a British crown colony on the east coast of Central America. The name Belize is derived from a Mayan word meaning "muddy water." After El Salvador it is the smallest political unit on the mainland of the Americas. It has an area of 8,866 square miles (22,963 square kilometres) and a population of 120,000. To the north and northwest it is bounded by Mexico, to the south and west by Guatemala, and to the east by the Caribbean Sea, on which it has a 200-mile (320-kilometre) coastline. The colony expected to attain independence in the 1970s.

The attainment of independence will confront the new state with two challenges: the problem of its relationship to neighbouring Guatemala, which claims sovereignty over the territory, and the problem of establishing the viability of its agricultural economy. In anticipation of independence, the capital of the territory was moved, in May 1970, from Belize City to Belmopan, a new city being built with a grant from the United Kingdom of U.S. $16,000,000. In the early 1970s negotiations were in progress for British Honduran membership in the



BRITISH HONDURAS

Caribbean Free Trade Association (Carifta) and the Central American Common Market (CACM). (For coverage of an associated physical feature, see CARIBBEAN SEA; for coverage of historical aspects, see CENTRAL AMERICAN STATES, HISTORY OF.)

Relief and drainage. Situated at the base of the Yucatán Peninsula, British Honduras is a land of mountains, swamps, and tropical jungle. The southern half of the country is dominated by the Maya Mountains, a plateau cut by erosion into hills and valleys that stretch across the frontier from Guatemala in a southwesterly to northeasterly direction. The Cockscomb Mountains, a spur of the Maya range, run toward the sea, culminating in Victoria Peak (3,681 feet [1,122 metres] high), the highest point in British Honduras. The northern half of the country consists of lowlands less than 200 feet (60 metres) above sea level, much of which are swamp. The lowlands are drained by the navigable Belize River (on which stands Belize City), the New River, and the Hondo River; the latter forms the northern frontier with Mexico. Both the New and the Hondo rivers drain into Chetumal Bay. South of Belize City the coastal plain skirts the highlands and is crossed by short river valleys. About 15 miles (24 kilometres) off the coast the second largest barrier reef in the world, underlain by a submarine escarpment, runs parallel to the coast. It is fringed by dozens of small islands, called cays.

Climate. The climate is subtropical, with a well-marked dry season from late February to May and a wet season from June to November. The mean temperature at Belize City is 74° F (23° C) in December and 85° F (29° C) in July. The mean annual rainfall increases sharply from 53 inches (1,350 millimetres) at Corozal on the northern frontier to 180 inches (4,575 millimetres) at Barranco on the southern frontier. At Belize City it is 69 inches (1,750 millimetres), but there, as elsewhere, there are considerable yearly variations. Trade winds blow onshore most of the year, but from September to December northerly winds bring cooler, drier air. Belize City was devastated by hurricanes in 1931 and in 1961, and Corozal was similarly ravaged in 1955.

Temperature and rainfall

Vegetation and animal life. About 50 percent of the country is best adapted to forestry. There are at least 50 different forest tree species, of which mahogany is the most important economically. Other woody plants are Santa Maria (an evergreen tree with shiny leathery leaves and white flowers), cedar, and ironwood. On the limestone soils of the north the forest is deciduous, and sapote (date plum) and mahogany predominate. In the south the forest is taller and is evergreen. Santa Maria, rather than mahogany, flourishes on the plateau. The rivers are largely bordered by swamp forests. Oak and pine grow on some of the plateau ridges. On the southern coastal plain and inland from Belize City, open savanna (grassland), with scattered oaks, pines, and palmetto palms, occurs. The coast is fringed with mangrove trees.

The abundant wildlife includes such animals as jaguar, puma, tapir (a hoofed quadruped, resembling a hog), deer, the American crocodile, and the manatee (an aquatic, herbivorous mammal), as well as many species of turtles, tortoises, birds, reptiles, insects, and fish.

The land under human settlement. Less than 10 percent of the land is being actively utilized; agricultural land amounts to about 3,000,000 acres. A shifting system of agriculture is practiced, with the land lying fallow for a period after use. About half the population practices agriculture, cultivating milpas (temporary forest clearings). The highlands are almost uninhabited.

Belize City, the former capital, which is located just above sea level and is crowded, is surrounded by a mangrove swamp. Its population is about 39,000. Its growth has been unplanned, and it forms a strange mixture of old colonial structures, wooden frame buildings, and new concrete blockhouses. Belmopan, the new capital, is situated 50 miles (80 kilometres) inland on a site not liable to flooding.

People and population. Much of the population is racially intermixed. Negroes and people of Negroid extraction predominate in the coastal regions, while Maya Indians predominate in the more sparsely inhabited interior, making up about one-seventh of the population. There are also a small number of Europeans and Asian Indians living in the coastal area.

English is the official language, but about one-third of the population also speaks Creole. About 8,000 Black Caribs (a mixture of Carib Indians and African stock) live in settlements on the southern coast. The Indians speak Spanish or one of the Indian languages. Some groups of Mennonites (members of a nonconformist Christian sect) who came from northern Mexico in 1957 have established themselves inland on the Belize River at San Ignacio (formerly El Cayo), and at Orange Walk on the New River in the north.

British Honduras, Area and Population

Forest and agricultural products

The national economy. The export of timber was for years the basis of the country's economy, but by 1960 the combined value of sugar and citrus exports exceeded that of timber, and since 1965 timber production has steadily declined. Mahogany cutting is most active in the northwest; chicle (used in the manufacture of chewing gum) is obtained from the sapodilla tree, and other commercial timbers, such as cedar and pine, are also exploited. Veneers are obtainable from about four species of hardwoods.

Sugar, which is grown in the Corozal and Orange Walk districts, is sold in Canada, Great Britain, and the United States. Rice is cultivated in the Orange Walk and Toledo districts. Citrus fruit is grown mainly in the Stann Creek area, south of Belize City. Most of the catch of coastal fishing is consumed locally, but lobsters are exported to the United States. Subsistence crops include maize, beans, and rice.

Industrial development is limited. There is a citrus-processing plant at Stann Creek, a sawmill at Belize City, and a sugar refinery at Corozal. The demand for labour, based upon agriculture and forestry activities, is seasonal, and underemployment persists.

Transport. Apart from one line used for logging, there are no railroads in the country. Agricultural and forest produce is usually transported by road, although rivers are still used. The road network extends to all the district capitals, west to the Guatemalan border, and north to the Mexican border. All-weather roads link Belize City with San Ignacio in the interior, Stann Creek farther south on the coast (via Hummingbird Highway), and with Corozal in the north. Much of the colony remains, however, inaccessible. Belize City, the main port, has no docks or deepwater quays; ships drawing more than five feet of water have to anchor in the harbour, and ships drawing more than 20 feet have to anchor a mile or more offshore. A regular motor-vessel service links Belize City with the southern settlements. The Belize City International Airport is about ten miles (16 kilometres) from Belize City; scheduled flights link it to the United States, Mexico, and Central America, and to the Caribbean through Jamaica. There are also domestic flights. Shipping services are irregular.

Administration and social conditions. The country is divided into six districts: Corozal, Orange Walk, Stann Creek, Toledo, Cayo, and Belize; all except Belize are administered by district commissioners. District town boards have authority over most municipal affairs; in some villages an alcalde (headman) is appointed with limited powers. The legal system is based upon the common law of England.

Under a constitution that came into force on January 1, 1964, British Honduras attained full internal self-government. The constitution provides for universal suffrage for those over the age of 21, for a bicameral National Assembly composed of an elected House of Representatives and an appointed Senate, and for a Cabinet with the premier as chairman. The governor of the colony, appointed by the British crown, is responsible for foreign affairs, defense, internal security, and the civil service.

Education

More than 90 percent of the population is literate. Primary schooling is compulsory between the ages of 6 and 14 and is often in the vernacular. Most schools are Roman Catholic, although some are Methodist or Anglican; all are partly government aided. There are several secondary schools, the Belize Technical College, and the Belize Teachers' College. Comparatively few pupils receive more than primary schooling, and there is a shortage of vocational training facilities. The Baron Bliss Institute in Belize City is the centre for cultural activity; it is devoted to the promotion of the arts and drama and houses a museum and a library. There are no free social, medical, or other health services. The colony is, however, relatively free from endemic diseases, and there is a government hospital in each district.

The cost of living is high, and there is an acute housing shortage in Belize City. The Belize radio broadcasts in Spanish and English; there are two daily newspapers.

Prospects for the future. Guatemala's claim to British Honduras on the grounds that it has inherited Spanish sovereignty over the territory and that British claims are void constitutes a stumbling block to the integration of the economy into that of the Central American region. Despite the rejection in 1968 by Guatemala of a United States draft treaty proposing a settlement of the dispute, diplomatic consultations between the British and Guatemalan governments are continuing. The association of the nascent state with the Commonwealth of Nations is expected to result in some economic advantages, as well as a measure of diplomatic support; an association with the Organization of American States (OAS) also has not been discounted. Meanwhile, public attention in British Honduras is focussed primarily on the imminent attainment of independence.

Broadcasting

Broadcasting is the transmission of radio and television programs intended for general public reception, as distinguished from private signals directed to specific receivers. In its most common form, broadcasting may be described as the systematic dissemination of entertainment, information, educational, and other features for simultaneous reception by a scattered audience, individually or in groups, with appropriate receiving apparatus. The subject matter may be either audible or visual, or a combination of both. Sound broadcasting in this sense may be said to have come into being about 1920, while television broadcasting began in the 1930s.

This article limits itself to coverage of the non-technical aspects of broadcasting, and covers the following subjects:

I. History
  Radiobroadcasting
    The United States
    The United Kingdom
    Radio developments in other countries
    International conferences
    International organizations
  Television broadcasting
II. Broadcasting systems

(For a history of the development of radio and a technical description of radio equipment, see RADIO. For similar information about television, see TELEVISION.)

I. History

RADIOBROADCASTING

The United States. The first known radio program in the United States was broadcast by Reginald Aubrey Fessenden from his experimental station at Brant Rock, Massachusetts, on Christmas Eve, 1906. Two musical selections, the reading of a poem, and a short talk apparently constituted the program, which was heard by ship wireless operators within a radius of several hundred miles. Following the relaxation of military restrictions on radio at the conclusion of World War I, many experimental radio stations—often equipped with homemade apparatus—were operated by amateurs. The range of such broadcasts was only a few miles, and the receiving apparatus necessary to hear them was mostly in the hands of other experimenters, who, like the broadcasters themselves, pursued radio as a hobby. Among the leading personalities of this early period was David Sarnoff, later of the Radio Corporation of America and the National Broadcasting Company, who first, in 1916, envisaged the possibility of a radio receiver in every home.

Growth of commercial radio. From this beginning the evolution of broadcasting was rapid; many persons who wanted to hear music from the air soon created a demand for receivers suitable for operation by the layman. The increase in the number of listeners in turn justified the establishment of stations especially for the purpose of broadcasting entertainment and information. The first commercial radio station was KDKA in Pittsburgh, which went on the air in the evening of November 2, 1920, with a broadcast of the returns of the Harding–Cox presidential election. The success of the KDKA broadcast and of the musical programs initiated thereafter motivated others to install similar stations; a total of eight were operating in the United States by the end of 1921.

First commercial radio station

The popularity of these early stations made evident two possible sources of financial support to offset the operating costs of broadcasting. First, there were possibilities for profit in the manufacture and sale of receiving equipment; and, second, the fame attained by the organizations operating the first broadcasting stations called attention to the value of broadcasting as an advertising medium, and advertising was eventually to become the chief means of support for broadcasting in the United States.

During the period 1921–22, the sale of radio receiving sets and of component parts for use in home construction of sets began a boom that was followed immediately by a large increase in transmitting stations. By November 1, 1922, 564 broadcasting stations had been licensed.

Interconnection of stations. The use of long-distance wire telephone lines in 1922 to interconnect a radio station in New York City and one in Chicago to broadcast a description of a football game introduced a new idea into radio broadcasting. In 1926 the National Broadcasting Company purchased WEAF in New York and, using it as the originating station, established a permanent network of radio stations to which it undertook to distribute daily programs. Some of these were sponsored by advertisers and furnished revenue to both the network and its associated stations, while others were supported by the network, with part of the time being set aside for public-service features.

Government regulation. Though the growth of radiobroadcasting in the United States was spectacularly swift, it was also chaotic, unplanned, and unregulated. Furthermore, business arrangements between the leading manufacturers of radio equipment and the leading broadcasters seemed to threaten monopoly. Congress responded by passing the Radio Act of 1927, which, though directed primarily against monopoly, also set up the agency now called the Federal Communications Commission to allocate wavelengths to broadcasters. The government's attack on monopoly resulted eventually in four radio networks—the National Broadcasting Company, Columbia Broadcasting System, Mutual Broadcasting System, and American Broadcasting Company—while the Federal Communications Commission permitted orderly growth and assured the survival of educational radio stations.

The United Kingdom. *Early development.* Radiobroadcasting in Britain eventually developed in quite a different way from the United States. The first initiatives after World War I were taken by commercial firms that thought of broadcasting primarily as a means of point-to-point communication. The first successful broadcasting of the human voice, from a transmitter in Ireland across the Atlantic in 1919, led to the erection of a six-kilowatt (6,000-watt) transmitter at Chelmsford, Essex. From this spot, two daily half-hour programs of speech and music, including a well-received broadcast by the opera singer Dame Nellie Melba, were broadcast for about a year between 1919 and 1920. Opposition from the armed services, fear of interference with essential communications, and a desire to avoid the "commercialization" of radio led, however, to a ban on the Chelmsford broadcasts, which the Post Office claimed the right to impose. Experimental broadcasts, the Post Office ruled, had each to be individually authorized. Nevertheless, 4,000 receiving-set licenses and 150 amateur transmitting licenses issued by the Post Office by March 1921 were evidence of growing interest. When these amateurs, grouped into 63 societies comprising about 3,000 members, petitioned for regular broadcasts, their request was granted in very limited form: the Marconi Company was authorized to broadcast about 15 minutes weekly.

First trans-atlantic broadcast

The first of these authorized broadcasts, from a hut at Writtle, close to Chelmsford, took place on February 14, 1922; the station call signal was 2MT. Shortly thereafter a new experimental station was authorized at Marconi House in London, whose first program went on the air May 11, 1922. Other stations were soon to follow.

Formation of the British Broadcasting Company. By this time, developments in the United States had demonstrated the commercial possibilities of radio but also suggested a need for order and control. The Post Office took the initiative in encouraging cooperation among manufacturers, and on October 18, 1922, the British Broadcasting Company, Ltd. was established as a private corporation. Only bona fide manufacturers could hold shares, and the directors of the firm, all representing manufacturing interests, met under an independent chairman. The company's revenue came from half the ten-shilling license fee for receivers and a 10 percent royalty on the sale of sets and equipment. Provincial stations were provided for, and all stations were to broadcast "news, information, concerts, lectures, educational matter, speeches, weather reports, theatrical entertainment. . . ."

BBC's revenue sources

Already several precedents had been established that were later followed in many other countries; of these the license revenue was the most important, but the royalty on sets and equipment was also adopted elsewhere, even after its abandonment in Britain. Because the British Broadcasting Company was a monopoly and because British radio as a result developed in a more orderly manner than elsewhere, such problems and issues of broadcasting as finance control, broadcasting of controversy, relations with government, network organization, and public-service broadcasting became apparent and began to find solutions in the United Kingdom earlier than elsewhere.

In 1925, upon recommendation of a parliamentary committee, the company was liquidated and replaced by a public corporation, the British Broadcasting Corporation, answerable ultimately to Parliament but with day-to-day control left to the judgment of a Board of Governors appointed on the basis of their standing and experience and not representing any sectional interests. A key figure, chief executive of the original company, and director general of the Corporation was John Reith (later Lord Reith), whose concept of public-service broadcasting prevailed in Britain and influenced broadcasting in many other countries. The BBC retained its monopoly until the creation of the Independent Television Authority in 1954. Its radio monopoly was finally broken by the government's decision to permit local commercial broadcasts starting in the 1970s.

Radio developments in other countries. Even before the pioneer station in Pittsburgh commenced operations, regular broadcasts began from The Hague, running from November 1919 until 1924. In Canada the first regular broadcasts from Montreal began in 1920, while in Australia a small station in Melbourne opened in 1921, though the official start occurred in Sydney in 1923. In New Zealand several low-powered stations were operating in 1921, though the Radio Broadcasting Company was not founded until 1927. In Denmark experimental amateur stations went on the air in 1921, and the official State Broadcasting System started in 1925. France began regular transmissions from the Eiffel Tower in 1922, and the first Soviet station commenced broadcasts from Moscow in the same year. By the end of 1923 there were radio stations also in Belgium, Czechoslovakia, Germany, and Spain. The list of countries lengthened rapidly, with Finland and Italy in 1924 and Norway, Poland, Mexico, and Japan in 1925. In India organized broadcasting first began in 1926; the Indian Broadcasting Company had stations in Bombay and Calcutta in 1927.

In most of these countries, the problem of control arose. In some, private enterprise was given free rein, subject to licensing by a government department or agency and to agreement upon the wavelengths or frequencies to be used. In others there was closer control (*e.g.*, France) or encouragement to cooperation between potentially conflicting interests (*e.g.*, Germany and Japan). Britain's example was followed in Denmark, Sweden, several British Commonwealth countries, and some British colonies. In Canada and France state and private enterprise operated side by side. Private stations were well established in Canada, for example, before the Canadian Broadcasting Commission was formed in 1936.

The problem of control

In France the Administration of Posts and Telegraphs handled early broadcasts; although a state monopoly was declared in 1923 and state broadcasting remained a department of the Administration of Posts and Telegraphs until World War II, some private stations were licensed, including Radio Normandy, which broadcast programs and advertising to the United Kingdom. Some of these commercial stations continued to broadcast under government control until 1945, when their licenses were withdrawn and radio became a complete state monopoly, independent of the Administration of Posts and Telegraphs but answerable to the government.

In Germany the Ministry of Posts retained control and ownership of all technical equipment, while private companies started programs in various cities. It was not long before the Reich Broadcasting Company acquired controlling interests in these companies; in 1932 all were nationalized.

International conferences. The wavelength problems that created so much confusion in the United States and provided one of the strongest arguments for monopoly in Britain arose also internationally, particularly in Europe, where the concentration of heavily populated and advanced sovereign nations compelled international agreement. Telegraphy had led to an early conference in Paris in 1865 that created what became later the International Telecommunications Union. This was followed by the Berlin conference of 1885 to discuss international telephone communications, two further conferences in Berlin in 1903 and 1906 on radiotelegraph, and still another in London in 1912 to cover the whole field of radio communications. An informal conference of ten countries held in London in 1925 created the Union Internationale de Radiophonie. Based in Geneva and with a BBC man as president and another as secretary general, this was the first international broadcasting organization. Inevitably the use of wavelengths, copyright problems, and international program exchanges were discussed and a plan drawn up.

Agreement on wavelength allocation, implemented in November 1926, was based on a formula involving area, population, and the extent of telephone and telegraph traffic. In spite of its dominating position, the BBC, which had been using 20 medium wavelengths, emerged with one long wavelength, ten medium wavelengths, and five further medium wavelengths shared with others but below the Post Office limit range for broadcasting of be-

tween 300 and 500 metres (one megahertz and 600 kilohertz). (Long waves range from 30 to 300 kilohertz; medium waves from 300 kilohertz to three megahertz; and shortwaves from three to 30 megahertz.) All the more advanced of the participating countries (which had grown to 16: Austria, Belgium, Czechoslovakia, Denmark, Finland, France, Germany, Hungary, Ireland, Italy, The Netherlands, Norway, Spain, Sweden, Switzerland, and the United Kingdom) had to make some sacrifices, and some, such as the United Kingdom, had to persuade their post offices to agree to the use of wavelengths outside the existing broadcasting range; but the principle of international agreement had been established. The Washington Conference of 1927 widened the area of cooperation in respect to radiotelegraph, broadcasting, and the international allocation of wavelengths or frequencies. It was followed by the Madrid Conference of 1932, which codified the rules and established the official international frequency list. This stabilized the situation until World War II, after which the European scene was substantially changed, and a new conference in Copenhagen in 1948 reallocated frequencies in the European Broadcasting Area. The Atlantic City Conference in 1947 had already created the International Frequency Registration Board. A conference in Buenos Aires in 1952 prepared the new text of the International Telecommunications Convention. The text was revised at Geneva in 1959, where the existing radio regulations were also revised. Geneva also saw the 1963 conference for the allocation of frequency bands for space and Earth–space communications.

International organizations. In the early 1970s the International Telecommunications Union, created in 1865, had worldwide membership; within the union are the International Frequency Registration Board, the International Telegraph and Telephone Consultative Committee, and the International Radio Consultative Committee. Apart from the International Telecommunications Union and Union Internationale de Radiophonie, a number of organizations have been established, primarily on a regional basis, since World War II. When tensions between East and West made the Union Internationale de Radiophonie almost unworkable, a strong organization, the European Broadcasting Union, was created by the nations of western Europe in 1950, and it now has a membership that includes not only all west European nations but also Cyprus, Greece, Iceland, Israel, Lebanon, Morocco, Tunisia, Turkey, and Yugoslavia; associate members include the United States, most British Commonwealth and former French colonial countries, as well as Japan, South Africa, and some Latin American countries. A parallel organization, also created in 1950, is the International Radio and Television Organization, which embraces nearly all Communist countries (excepting Yugoslavia), and, as an associate member, Algeria. The European Broadcasting Union is based in Geneva, while the International Radio and Television Organization has headquarters in Prague.

Asian and African organizations

The Asian Broadcasting Union, formally established in 1964 as a union of national broadcasting organizations in Asia and the Pacific, includes Japan, Australia, New Zealand, and the Philippines, as well as Iran, Turkey, Egypt, and most of the non-Communist countries of Asia; headquarters are in Tokyo. The Union of National Radio and Television Organizations of Africa, formed in 1962, includes most former French and British colonies. Based in Dakar, Senegal, it has its technical centre at Markala, Mali. The Arab States Broadcasting Union was formed in 1969 as an intergovernmental organization within the framework of the Arab League; the secretariat is in Cairo and the Engineering Center in Khartoum, The Sudan. The Asociación Interamericana de Radiodifusión covers North, Central, and South America, with a central office in Miami. The Commonwealth Broadcasting Conference, established in 1945 as a standing association of national public-service broadcasting organizations in the independent countries of the British Commonwealth, bases its secretariat in London.

There are other international broadcasting bodies, including the United Nations itself and the Radio and Visual Information Division and Mass Communication Department of the United Nations Educational, Scientific, and Cultural Organization (UNESCO). The International Broadcast Institute, a non-profit-making and nongovernmental association supported by charitable foundations, was created in 1968 with headquarters in Rome, with the purpose of fostering a free flow of communications for informational, cultural, and educational purposes. There exists also a substantial number of religious broadcasting bodies, some of regional and some of worldwide proportions; among the most important are the World Association for Christian Communications, set up in 1968 and based in London, and the Association Catholique Internationale pour la Radiodiffusion et la Télévision, based in Fribourg, Switzerland. There is finally Radio Free Europe, based in Vienna, financed by United States government funds, and engaged in broadcasting pro-Western propaganda to the Communist countries of east Europe.

TELEVISION BROADCASTING

Through a series of technical developments in Britain, continental Europe, the Soviet Union, and the United States, television reached a state of technical feasibility by 1931. (For a fuller history of television's development, see TELEVISION.) In that year a research group was set up in Britain under Isaac (later Sir Isaac) Shoenberg, a dynamic and farsighted man of long experience in radio transmission in the Soviet Union. He fostered the evolution of a complete and practical television-broadcast system based on a camera tube known as the Emitron and an improved cathode-ray tube for the receiver. Shoenberg saw the need to establish a system that would endure for many years, since any subsequent changes in basic standards could give rise to severe technical and economic problems. He therefore proposed a system that, though ambitious for its day, was fully justified by subsequent events. Shoenberg's electronic scanning proved far superior to the mechanical scanning method developed by the pioneer John Baird. The government authorized the British Broadcasting Corporation to adopt Shoenberg's standards (405 lines) for the world's first high-definition service, which was launched in London in 1936. So adequate were they that they formed the sole basis of the British service until 1962, when they were gradually superseded by the European continental standard of 625 lines. The first notable outside broadcast by the BBC was the procession of the coronation of King George VI from Hyde Park Corner in November 1937; a new portable transmitter mounted on a special vehicle made its first public appearance. Several thousand viewers saw the transmission.

First practical television system

Television developments were slower in the United States. It was not until April 30, 1939, at the opening of the New York World's Fair, that a public demonstration was made by the National Broadcasting Company, which announced in that year that it was ready to begin broadcasting for two hours per week. The Columbia Broadcasting System and the Dumont network began telecasting in 1939 and 1940. By mid-1940 there were 23 television stations in the United States. World War II, however, brought nearly all activity to an end, as electronics factories were converted to wartime production. The Federal Communications Commission had authorized only limited commercial operation (the first sponsored television broadcasts began in 1941), and gradually stations closed down; only six were left with limited programs to serve the owners of some 10,000 sets. When wartime restrictions governing the manufacture of receivers were removed in 1946, the stage was set in the United States for a rapid growth of the television-broadcasting industry. By 1949 there were 1,000,000 receivers in use; the 10,000,000 mark was passed in 1951 and the 50,000,000 mark eight years later. In England, the BBC's television service was resumed in June 1946; by 1949 there were 126,567 television licenses, and by 1950 there were 343,882, equal in proportion to 1,000,000 in the United States.

Other nations did not begin television broadcasting on a wide scale until the early 1950s, but by the early 1970s receivers in use throughout the world totalled about 250,000,000; about 84,600,000 were in the United States, 16,125,000 in the United Kingdom, and 7,100,000 in Canada. Japan had about 22,000,000 sets and, in 1972, the Soviet Union had an estimated 40,000,000 sets.

II. Broadcasting systems

THE BROADCASTER AND THE GOVERNMENT

Most observers recognize that no broadcast organization can be wholly independent of government, for all must be licensed in accordance with international agreements. Though broadcasters in democratic countries pride themselves on their freedom in respect to their governments, they are not always free of stockholder or advertiser pressure, nor are producers and editors truly independent if senior executives, under pressure from whatever source, interfere with editorial functions. Independence, therefore, is a relative term when applied to broadcasting.

In a monograph written for the European Broadcasting Union, broadcasting systems are classified under four headings: state operated, those that work under the establishment of a public corporation or authority, those whose systems are a partnership blend of public authorities and private interests, and those under private management. A brief summary of these systems provides an indication of the complex variations that have arisen.

State operation. Grouped under this heading are broadcasting systems that are operated by a government department, or delegated to an administration, perhaps with a legal personality and even possibly independent in financial and administrative matters, but subject to the government and not essentially autonomous. Under this heading is listed the Soviet Union, where a special committee, set up in 1957, is in charge of Soviet radio and television under the direct authority of the Ministry of Culture. Similar arrangements prevail in Czechoslovakia and Poland, save that the committees have a legal personality and do not work for the Ministry of Culture. Romania also delegates broadcasting to a committee attached to the Council of Ministers. In Sri Lanka (Ceylon) the Broadcasting Department is part of the Ministry of Education and Broadcasting. All-India Radio is a department of the Ministry of Information and Broadcasting. Similar arrangements prevail in most Communist countries and in most nations that were colonies but have gained their independence since World War II.

Establishment of a public corporation or authority. Both historically and in its present form, the BBC is the prototype of this kind of system. Provided it abides by the charter and terms of the license under which it operates, the BBC enjoys a maximum independence as regards the disposal of its funds (though its revenue is subject to governmental decision as to the cost of a license required for every television or radio receiver), the production and scheduling of programs, and, above all, in editorial control. Certain residual government powers are either hedged around with agreed provisos or never exercised. Its income, save for profits on the sale of programs abroad and the sale of various phonograph records and publications, is exclusively derived from licenses. External broadcasting (*i.e.*, broadcasting to areas outside national boundaries) is separately financed. The chairman and board of governors constitute the legal personality of the BBC; they are chosen by the government, not as representatives of sectional interests but on the basis of their experience and standing. Political parties in office have been careful to avoid political prejudice in these appointments.

Canadian Broadcasting Corporation

The Canadian Broadcasting Corporation—or Société Radio-Canada—also enjoys substantial independent powers as determined by the Broadcasting Act of 1958, though over the years producers have often been restive due to political pressures, and Canadian broadcasting has been affected by the problems arising from the aspirations of some French-speaking citizens. The Canadian Broadcasting Corporation is now dependent on an annual parliamentary grant for its finance, supplemented by an income derived from advertising that amounts to nearly a quarter of its annual revenue.

The Japan Broadcasting Corporation, like the BBC, enjoyed a monopoly but has since lost it. By a series of acts in 1950, however, the Nippon Hōsō Kyōkai is charged with the task of conducting "its broadcasting service for the public welfare in such a manner that its broadcasts may be received all over Japan." A Board of Governors is appointed by the prime minister with the consent of both houses of The Diet. The system is financed almost exclusively from the sale of licenses for receiving sets.

Under this heading is also included the Office de Radiodiffusion-Télévision Française (ORTF), although there are substantial differences. The French system has enjoyed a monopoly since 1945 and continues to do so, but it must contend, in the field of radio, with the so-called *postes périphériques*, which broadcast in French from just outside French frontiers. The ORTF system is described as a public administration attached directly to the presidency of the council or by delegation of the chief of the government to a minister or secretary of state, normally the minister responsible for information. It is, therefore, in its finances and its editorial policy under closer government control than, for example, its British counterpart. There is an administrative council presided over by a president, and the chief executive is the director general. The French system derived its revenue almost exclusively from the sale of receiving-set licenses until 1968, when this source began to be supplemented by advertising.

Though West German broadcasting is properly included in this category, the situation there is substantially different, for the basic radio and television services are not a matter for the Federal government but for the provinces. The nine provincial broadcasting organizations are also grouped together in a national organization to cooperate in the first television network. In each province (*Land*), though there are some variations, there is a broadcasting council appointed by the legislature or nominated by churches, universities, associations of employers or trade unions, political parties, or the press; an administrative council; and a director general. Their revenue comes from receiving-set licenses and sometimes also from advertising.

Belgian broadcasting

The broadcasting system in Belgium provides an interesting example of a device for coping with a two-language country. There are three public authorities: the first for French broadcasts; the second for Flemish; and a third that owns the property, owns and operates the technical equipment, and is responsible for the symphony orchestra, record library, and central reference library.

Partnership of public authorities and private interests. In many cases this partnership is nominal and historical rather than substantial and actual. The outstanding example is Radiotelevisione Italiana, originally founded in 1924. In 1927 an agreement was made with the government for a 25-year broadcasting concession. The charter was extended to cover television in 1952, and two years later control and over 75 percent of the shares were acquired by a government agency. A board of managers includes ten members elected by the shareholders at the general meeting and the remaining six appointed by government departments. Inevitably, therefore, the Radiotelevisione Italiana is subject to close government surveillance, but an ad hoc committee of 30, appointed from all political parties by the presidents of the two legislative chambers, is responsible for ensuring political independence and objective news reporting. The organization must also prepare an outline plan of programs on a quarterly basis for approval by the Ministry of Posts and Telecommunications, aided by an advisory committee concerned with cultural, artistic, and educational policies. A separate organization runs the broadcast advertising business, which, together with receiving-set licenses, provides the revenue of Radiotelevisione Italiana.

Ownership of Swedish radio

In Sweden the broadcasting monopoly is technically a privately owned corporation in which the state has no financial interest, thus emphasizing the independence

of Sveriges Radio from the government. The shares must be held by the press (40 percent), large noncommercial national bodies or movements (40 percent), and commerce and industry (20 percent). The board of governors is made up of a chairman and government nominees and an equal number elected by the shareholders. The government, however, reserves the right to determine the allocation of revenue from receiving-set licenses on an annual basis and thus controls both investment and the amount of broadcasting. On balance, though, Sveriges Radio enjoys a very substantial measure of freedom.

In Switzerland, too, there are elements of partnership between private interests and public authorities, but the federal constitution, the need to broadcast in three languages, and geographical factors have led to a system by which the Société Suisse de Radiodiffusion et Télévision is made up of nine regional societies based, respectively, in Geneva, Lausanne, Zürich, Bern, Basel, Lugano, Saint-Gall, Luzern, and Chur.

Private management. Most of the broadcasting organizations under this heading are commercial firms that derive their revenue from advertising, which takes the form of brief announcements scheduled at regular intervals throughout the day. In some cases an entire program, such as a sports event or concert, may be sponsored by one advertiser or group of advertisers. Methods and degree of government control vary, and no general characteristics may be isolated. Private enterprise radio predominates in the United States and Latin America.

Subject to similar controls in these nations are many non-profit-making educational stations, financed by universities, private subscriptions, and foundations. There now exists a public-service network in the United States.

Other methods of distributing sound and vision programs by wire and cable are not strictly broadcasting. In the main, wire-diffusion enterprises concentrate on giving efficient reception in densely populated areas, large blocks of buildings, and in hotels of programs that are being broadcast. A tall apartment building, for example, may have one television antenna on its roof to which residents may attach their receivers. Experiments with "pay TV," the provision of such programs as sports, special events, films, and theatrical performances via direct cable lines to subscribers, had not yet met with significant success in the early 1970s.

THE BROADCASTER AND THE PUBLIC

Nature of the broadcast audience. The disposition of a radio or television audience, which is composed principally of individuals in the privacy of their own homes, differs considerably from that of an audience in a theatre or lecture hall. There is none of the crowd atmosphere that prevails in a public assembly, and each listener is no more than casually aware that he is actually part of a large audience. This engenders a sense of intimacy that causes the listener to feel a close personal association with the speaker or performer. Furthermore, many people will not accept in their own homes many of the candid forms of expression that they readily condone or support on the stage or in literature.

Because it owes its license to operate to the state, if indeed it is not state operated, and because of its intimate relationship to its audience, broadcasting exists in a quasi-public domain, open in all its phases to public scrutiny. It is therefore held to be invested with a moral as well as a legal responsibility to serve the public interest and must remain more sensitive to public sentiment and political opinion than most other forms of public expression.

Audience measurement. For economic reasons, as well as those outlined above, evaluation of audience opinion and response is important to the broadcaster. Audience measurement presents difficult problems, because there is no box office by which to determine the exact number of listeners. Mail received comes principally from those who have the time and inclination to write and cannot be regarded as wholly representative. Audience measurement information may also be obtained by telephone-sampling methods, interviews in the home by market-research organizations, or by special recording devices attached to individual receiving sets. The latter, installed with the owner's consent, record the amount of time the set is used, when it is turned on and off, and the stations tuned in. These devices are expensive, however, do not necessarily indicate whether someone is actually watching or listening, and therefore are limited to small samples of the total audience. Whatever the method of rating, commercial broadcasters are quick to alter or discontinue any program that shows lack of audience appeal, and the listeners are thus influential in determining the nature of programs offered them. In commercial broadcasting, sponsored programs are also affected by their apparent success or failure in selling the goods advertised.

Audience-measuring devices

Educational broadcasting. It is difficult to give an account of educational broadcasting in those countries where broadcasting is largely or wholly a matter of private management and where the larger and more important stations and networks are private commercial enterprises. Nevertheless, considerable numbers of educational transmissions are made in the United States and Latin America by universities and colleges and sometimes by municipal or state-owned stations. The Public Broadcasting Service in the United States is increasing the amount of educational and generally more thought-provoking material available on the air, and in Latin America some countries not only make use of broadcasts to support the work of teachers in schools but also to combat illiteracy and to impart advice in matters of hygiene, agricultural methods, and other social and practical subjects to isolated rural populations. The Catholic Church has been in the forefront of the latter activity, operating, for example, the Rede Nacional de Emissôras Católicas in Brazil and the Acción Cultural Popular in Colombia. A similar use of broadcasting is made in most of the tropical nations of Africa and Asia.

Japan's educational broadcasting

Japan's Nippon Hōsō Kyōkai has the most ambitious educational-broadcasting output in the world. One each of its two television and AM radio services is devoted wholly to education, while general television services and FM radio also transmit material of this nature. Japan prepares programs for primary, secondary, and higher education, special offerings for the mentally and physically handicapped, and a wide range of transmissions under the general heading of "social education," which includes foreign languages, vocational and technical instruction, advice on agriculture, forestry, fisheries, and business management, plus special programs for children, adolescents, and women. About 80 percent of Japanese educational broadcasts are devoted to instruction, with the remainder given over to cultural programs and news.

In Europe the French state broadcasting service devotes over 18 percent of its radio output to school, university, and cultural broadcasts (excluding its general literary and dramatic offerings); and on television nearly 10 percent of its first network and 8 percent of its second are devoted to school broadcasts. Primary and secondary instruction is offered, as well as refresher courses for teachers and university-level courses.

Though Italian radio devotes less than 1 percent of its output specifically to educational programs for children, over 10 percent is given to cultural and allied offerings. Educational television began in Italy in 1958 with courses of a vocational nature, followed by transmissions aimed at secondary schools. In 1966 special programs were initiated for areas where there are no secondary schools. Today, over 9 percent of Italian television time is devoted to school broadcasts and 6 percent to adult education.

Swedish radio offers a comprehensive service of primary and secondary school broadcasting, though, unlike Italy, the output on radio is more than four times as great as on television. There is also a substantial output of adult education at the university level, and Sweden has concentrated on vocational training and refreshment for teachers. German broadcasting, by contrast, has been used much less for formal education. Though there are

transmissions aimed at primary schools, none are offered at the secondary or university levels. In The Netherlands two hours of school broadcasting are offered weekly during the school term; three and a half hours of educational television are also transmitted every week.

The British Broadcasting Corporation pioneered in education; its work, both in radio and television, has steadily expanded. The latest extension, in 1970, in both radio and television, consisted of programs especially designed for study in degree courses with the Open University, created and financed by the government with the broadcast teaching supplemented by publications and work by correspondence. In 1970, during scholastic terms, BBC broadcasts for schools totalled nearly ten hours weekly on television and over 11 hours on radio; adult education output (including preparatory courses for the Open University) was over eight hours on television and nearly nine hours on radio. In addition, the Independent Broadcasting Authority in the United Kingdom has required the commercial program companies to contribute educational material both for schools and for adults; in 1970 this amounted to ten hours weekly during periods totalling 28 weeks of the year.

In Australia there is a small educational output on the commercial stations, both radio and television, but by far the greater part of educational broadcasting is undertaken by the Australian Broadcasting Commission. Educational programming accounts for about 5 percent of radio time and 18 percent of television output, the greater part of which is broadcast to schools and kindergartens. The Canadian Broadcasting Corporation is required to provide educational programs both in English and French and does so on its AM and FM radio networks, as well as on television.

Broadcasts for external reception. International broadcasting—that is to say, the transmission of programs by a country expressly for audiences beyond its own frontiers—dates from the earliest days of broadcasting itself.

Radio propaganda

The Soviet Union began foreign-language transmissions for propaganda purposes in the 1920s. Fascist Italy and Nazi Germany made such broadcasts at a later date. France, Great Britain, and The Netherlands were next in the field among European countries, though their first use of shortwave broadcasting was aimed at French-, English-, or Dutch-speaking populations overseas. Great Britain began foreign-language broadcasting early in 1938 with a program in Arabic and transmissions in Spanish and Portuguese directed to Latin America. By August 1939 countries broadcasting in foreign languages included Albania, Bulgaria, China, France, Germany, Great Britain, Hungary, Italy, Japan, Romania, the Soviet Union, Spain, the United States, and Vatican City.

During World War II foreign-language broadcasting continued; the programs of the BBC in particular, because of their reliability and credibility, had an important effect in maintaining morale among countries under German occupation. The continuance of international tension after World War II led to remarkable growth of foreign-language services. In 1950, for example, though all the Communist countries of eastern Europe except East Germany had launched external services, these were on a small scale, and even the Soviet Union was transmitting a total of little more than 500 hours of broadcasts weekly in all foreign languages. The United Kingdom's output, which had once led the field, had been reduced to just over 600 hours a week and the Voice of America to less than 500 hours per week. By 1970 the situation had changed radically. The Soviet Union alone broadcast nearly 2,000 hours per week, and the output of all east European Communist countries totalled some 3,775 hours. The United Kingdom logged 719 hours in 1970, West Germany 724 hours, and the United States broadcast over the Voice of America, Radio Liberty, and Radio Free Europe 1,908 hours a week. The output of China had risen from 66 hours weekly in 1950 to 1,468 hours in 1970. The increase in Chinese broadcasts reflected in part the rising tension between China and the Soviet Union; significantly, the output of China's ally Albania rose from 26 to 480 hours weekly in the same period. In 1970, also, Japan transmitted for 256 hours, Australia for 359 hours, and Canada for 98 hours every week.

Monitoring and transcriptions. A logical development following from external broadcasting is the monitoring of foreign broadcasts and their analysis for intelligence purposes. The BBC in particular has a highly developed monitoring service; this activity often yields quite valuable information. Transcriptions (recordings) of programs produced either in the domestic or external services of one country can be acceptable for broadcast in others. Radiobroadcasts of an educational nature can be used in different countries speaking the same language. Though many radio transcriptions are supplied free, in television the situation is wholly different, and a substantial trade exists in television films (see below).

Pirate and offshore stations. In recent years, in some countries where broadcasting in general or radio only is a monopoly, radio has had to face for brief periods the competition of independent commercial stations mounted on ships anchored at sea, outside territorial waters. Sweden, Denmark, The Netherlands, and the United Kingdom have been the countries most affected by these stations, which have made use of unauthorized wavelengths, so endangering other radio communications, and have been wholly free of any copyright obligations in respect to any of their broadcast material. Gradually, government action has forced closure of such operations: in Sweden a new competitive service of popular music proved effective; and in Denmark naval police action (the international legality of which might be questioned), followed by confiscation and heavy penalties, brought an end to the pirate station. The United Kingdom combined legislation penalizing any who advertised or supplied such ships with the launching by the BBC of Radio 1, substantially a popular music service, to solve the problem.

The problem of *postes périphériques* in France

The French face a particular problem of competition from the so-called *postes périphériques*, which include Europe No. 1 in the Saar, Monte Carlo in Monaco, and Radio Andorra in the Pyrenees, not to mention the French-language broadcasts of Belgium, Luxembourg, and Switzerland. The strongest competition came from Europe No. 1, in which the French government finally purchased a controlling interest.

III. Broadcasting operations

TYPES OF PROGRAMS AND DEVELOPMENT OF STUDIOS

There are certain distinguishable types of programs, but as often as not these overlap in technique, subject matter, and style. Radio, for example, broadcasts speech and music, but in an endless number of combinations. Television adds the visual element, greatly increasing the number of possible program forms. Most sizable broadcast organizations, however, have certain categories for administrative convenience. But the definitions cannot be too precise, and lines of demarcation are vague.

Entertainment. Entertainment can include comedy, impossible wholly to differentiate from drama; quizzes, not always easily distinguished from relatively serious programs of information and education; popular music, in which the frontier with jazz and serious music is anything but rigid; and variety, or a series of unrelated acts, nearly always linked by a popular presenter or established performer.

From the early days of radio there was a tendency to make use of a variety format, and as this approach represented an extension of old music-hall traditions, success was achieved by many programs in this vein. From the music-hall–variety-type program grew the "gang show," in which a cast of performers remaining the same from week to week would make use of a series of humorous situations or catchphrases, gradually building up a familiar background against which the incongruities of the script could exploit humour to the full. A further development was the "situation comedy," in which a number of characters, such as the members of a family, remain in the same situation week after week but experience comic adventures. Though these laughter programs lost popularity on radio as television gained popular acceptance, they have become the mainstays of television.

Situation comedy

A phenomenon of recent years has been the comedy program involving substantial amounts of political and social satire. The situation comedy has also been influenced by this trend.

The many types of comedy entertainment programs produced around the world all have one common characteristic: not only have the performers needed the stimulus of a studio audience, but the listeners and viewers are stimulated by the laughter and applause of the audience. This had led to some abuses, such as the superimposition of laughter and applause on prerecorded programs, a practice now frowned upon but still practiced in the early 1970s. It has also meant that large studios are required to accommodate not only the performers, frequently including more than one music combination, but also the audience. In television there must be room for settings that have become increasingly ambitious and for dancers and choruses. Broadcasting organizations have generally been able to build studios of appropriate size, though radiobroadcasters in the early days preferred to purchase or rent small existing theatres.

In their form and structure, children's entertainment shows resemble those for adults. Animated cartoons, however, represent an exception to this rule; the Hungarians, Poles, and French have achieved genuine distinction in this area.

Drama. Radio and television drama is not best produced in a theatre; the nature of the studio is therefore different. Early radio drama was produced in a relatively small studio, often with a single microphone, just as early television plays were produced with a single camera. Radio engineers soon began to employ a control panel with inputs from more than one studio and sound effects ingeniously achieved; their counterparts in television expanded their use of cameras and sets from one to several. Mixing in radio from one studio to another and in television from one set to another, plus increasingly sophisticated sound effects and background music, have all become accepted techniques in drama production. Inevitably, television drama has borrowed substantially from the techniques of film production.

Feature films, usually originally made for the cinema, continue to form an accepted and important element in television schedules throughout the world. Both radio and television occasionally broadcast live stage plays from theatres, but there is a general feeling that such offerings do not adequately exploit the advantages of either medium. From the earliest days of radio and television, the studio-produced drama has been an important ingredient in program schedules; in television, as in films, it was not long before shooting on location also became an accepted practice. Offerings have included classical Greek drama, Shakespeare and other Elizabethan dramatists, the Spanish and French theatre, Russian and Scandinavian plays, plus modern works of living authors.

Serial presentations on television and radio have included adaptations of famous works of literature, such as the novels of Dickens, Balzac, and Tolstoy, the *Forsyte Saga* of John Galsworthy, historical costume dramas based on the lives of such figures as Henry VIII and Elizabeth I of England, and, of course, the romantic melodramas aimed largely at the daytime woman listener and sometimes known as "soap operas." Radio and television serials of fantasy and adventure are also produced for children.

Three other distinguishable types of drama program have achieved almost universal popularity: western adventures; gangster–crime–police; and medical–hospital.

Violence on television

Violent episodes in some crime and western adventure programs have drawn criticism from those who believe that they are harmful to children. In response, many broadcasting organizations have introduced codes of practice to minimize such scenes.

Western adventure programs, largely produced in the United States, have been popular with studios because of their relatively low production costs and ready salability abroad. Dramatic series of this type have been shown all over the world, often with dubbed sound tracks. Though these exported U.S. productions are often much less expensive than home-produced programs, Australia has been able to produce some western-type series, and Canada has exploited its legendary "Mounties." So many United States television programs have been exported, however, that broadcasting organizations in some nations, such as Japan and the United Kingdom, have taken steps to assure that home-produced dramas should have priority in terms of percentage of schedule hours and prime time (peak placing).

Spoken word. Spoken-word programs have included entertainment types, such as "This is Your Life" and many of the "talk shows," in which a personality interviewer questions famous people, sometimes with interludes of music or comedy or with serious discussions, documentaries, or lectures. A fear of controversy, the problem of maintaining an overall impartiality, and sometimes the belief that the mass audience would be alienated by programs demanding a conscious effort and concentration, combined, in the early days of radio, to limit the time given to serious spoken-word programs. It was not long, however, before many broadcasters developed a sense of pride and responsibility in their function and regarded it as their duty to provide information and opinion. Gradually, too, in those countries where broadcasting achieved a substantial measure of independence, some broadcasters became concerned not only with the exposition of fact and controversy but also with the task of exposing the ills and abuses of their society.

News broadcasts

News continues to be the most important element in spoken-word radio. Since it was inescapable that broadcast news would affect the industry, newspaper proprietors in the early days of radio made efforts either to restrict the sources of news and the times at which it could be broadcast or sought themselves to enter the new field. In areas where broadcasting was commercialized, the press was further concerned, because radio competed with it for advertising revenues and because radio could almost always get a story to the public before the newspapers did. Nevertheless, there is no evidence that radio news reduced the circulation of newspapers; some have even maintained that radio whetted the appetite of listeners for news and increased newspaper sales. It would seem, however, that television has adversely affected the daily press and, even more so, weekly or monthly magazines. Long before television outstripped radio, broadcasting organizations were employing reporters and special and foreign correspondents and were supplementing the service received from news agencies. Some broadcast reporters became public personalities in their own right.

Television news presented new production problems; the announcer at the microphone reading from a script or TelePrompTer was not satisfactory, and it was not long before the greater part of television news was appropriately accompanied by relevant pictures. The need for film shots and the cost and difficulty of obtaining them were, and to some extent remain, serious problems. In spite of substantial expenditure on the supply of such shots, television news is open to the criticism that news values and objectivity are distorted by the availability or nonavailability of pictures.

In general, however, broadcasting organizations have faced up to the much higher cost of television news. The syndication of film reports, the development of live networks on an international basis, such as Eurovision, and, more recently, satellite communications have substantially if not entirely overcome the problems of news reporting on television. On the other hand, it has become apparent that the psychological impact of film shots of war and civil disturbance, as of accidents and disasters, is far greater than that of the radio report. Television reports of, for example, the Vietnam War have done far more to influence public opinion than radio news bulletins could do. Radio has the advantage, however, of not requiring the same degree of attention; the trend has been toward frequently repeated short bulletins. In the United States there are radio stations that restrict themselves entirely to news, usually in a continuous magazine format, plus, of course, the advertising spots. The news magazine

Emotive effect of television news

or newsreel in radio was introduced even earlier on BBC. A series of brief reports, interviews, extracts from speeches, making use of many voices and exploiting the technique of frequent renewal of stimulus, proved to be a successful formula. This technique has spread into the news bulletins themselves and is increasingly used in the coverage of current affairs, both in radio and television. In all these programs of news and comment, one of the problems has been that of the anchor man, or presenter, and the degree to which he may be given freedom to project his personality or express his views. In the United States there have been fewer inhibitions in this area than in countries where broadcasting is or has been a monopoly and where the need for and tradition of impartiality have been dominant. In the case of the BBC, newsreaders were for long anonymous; but on television the identity of a newsreader, or of the presenter of a magazine of news or comment or both, cannot be concealed, and these inhibitions have now all broken down. Nevertheless, in western Europe and British Commonwealth countries the impartiality of broadcasting services remains an issue of greater importance than in the United States or Latin America. In Britain, when the Independent Television Authority was created, it was enjoined to see that in the coverage of controversial matters each program should be balanced in itself. The BBC, with greater freedom, makes no effort to ensure balance in any one program, provided that an overall balance in respect of any issue is achieved over a reasonable period of time.

In all advanced countries, elaborate programs are prepared to report the results of elections, though it is in the United States and the United Kingdom that these are most ambitious. In radio the straight talk persists in some countries, though there are fewer than in the heyday of the medium. Nevertheless, some successful lectures at much greater length have been scheduled occasionally on television and in some countries on radio. Straight talk of ten minutes or more does not lend itself to exciting television production, unless accompanied by filmed illustrations to the point where it all but becomes a documentary.

Another pattern popular in many countries involves a panel of distinguished figures under a chairman, answering questions of a topical nature from members of a studio audience. In some cases, a parabolic microphone is employed so that questions may be asked from any part of the studio or hall in which the program is mounted; others may call for written queries in advance so that questioners can be conveniently seated in the first row. Some radio panel programs also solicit queries from members of the listening audience who call them in on the telephone.

The documentary program

Development of the radio documentary stemmed from drama, as writers searched for new material especially appropriate to the medium. Not surprisingly, early documentary was in dramatic form, and a great deal of it was in fact based on famous historical events, of which the programs were in effect dramatic reconstructions. Production of radio documentaries was greatly simplified by the invention of magnetic recording tape that was far easier to edit and use on location than its predecessors, the wax-coated disc and the wire recorder. Ironically, just when these technical advances had made the best form of radio documentary possible, the television documentary on contemporary themes began to supplant its radio counterpart. Documentaries today are far more expositions of public (current) affairs concerned with international relations, domestic politics, and social problems than they were in the past, but they have not wholly abandoned the tradition of historical reconstruction and biography.

Religion. There have been, in the main, two types of religious program: devotional and information–discussion. The former comprise prayer, religious services, or hymn singing, either mounted in a studio or as outside broadcasts from a church, chapel, or hall. A third type is the dramatization of a religious theme, though the tendency in recent years has been to devote a good proportion of religious broadcasting time to documentaries, discussions, and interviews. Some sects have produced broadcasts that combined political and religious material. Missionary bodies, mostly under the control of one of the many international or regional religious broadcasting organizations, either buy time on commercial stations or themselves operate stations in many parts of the world, including Latin America, Africa, and Asia.

Outside broadcasts. Broadcasts under this heading do not constitute a distinct and definable form but, nevertheless, have been since the birth of radio the most popular and arresting of all material transmitted on either medium. Sport of every description and ceremonial and political events have exercised an unfailing appeal and, in general, attract the largest audiences. Outside broadcasts have stimulated the imagination and taxed the ingenuity of television-broadcasting engineers to such an extent that they have now accustomed the public to feats unimaginable to the pioneers of radio. The improvement of line communications, the development of mobile transmitters, and, above all, the use of satellite communications have given the outside broadcast an elasticity and an almost limitless range, as strikingly demonstrated by the 1969 telecast of astronauts walking on the moon.

Music. Radio has had two important effects on the musical life of the world: it has greatly widened the public for serious music and has made easier the development of new forms, such as electronic music. Music remains a staple ingredient of radio in its own right, whereas in television, though there are programs of music as such, it is more often an adjunct to something else, as, for example, dancing, or a small component of a mixed program. In the field of popular music, radio has immensely aided the rapid changes of fashion, which have coincided with technical advances in the making of records and their greatly increased popularity and sales. A recognition by record manufacturers of the enormous power of radio in popularizing a song or performer led to some abuses. In the United States "payola," or bribes, were given to prominent radio personalities by record companies in return for promotion of their songs.

The development of stereophonic sound techniques in recent years has revolutionized the record industry and has played an important role on radio, though mostly in the field of serious music. Frequency modulated (FM) radio broadcasts of serious music have been popular in many areas; some records are broadcast stereophonically but can be received on monophonic radios (see SOUND RECORDING AND REPRODUCING; RADIO).

Opera, too, has profited from broadcasting, and outside broadcasts from opera houses, as well as studio performances both on radio and television, have done much in all European and many other countries to bring this form of music to a large public. Music programs have presented more difficulties than most others in the matter of studios, partly because of the size of studio required for a full symphony orchestra and partly because of the delicate balancing of acoustics for proper reproduction of such performances.

RELATIONS WITH ARTISTS, SPEAKERS, AUTHORS, AND UNIONS

In the early days of radio, problems of fees, royalties, performing rights, copyright, and relations with unions were hardly thought of. Entertainers performed largely for publicity purposes. Only gradually did performers appreciate radio's real effect, first, as a threat to their theatre earnings and, second, as a highly lucrative substitute. To try to trace how a modus vivendi was reached in these matters in different countries would present a picture of baffling complexity in the light of the different prevailing laws and different union structures. Generally speaking, copyright issues have revolved around the rights of record manufacturers and fees for composers (see COPYRIGHT LAW). Rates and fees for reproducing recordings have often been the subject of disputes with the unions. Radiobroadcasters soon found that purchasing records or making their own recordings from live musical performances meant substantial economies; these, however, came at the expense of the musicians. Conse-

Copyright fees

quently, the musicians' unions sometimes attempted to prevent use of phonograph records or recording of live performances. In some countries, such as The Netherlands, the repeat problem has been solved by the performers receiving a fee for each repeat, the fee rising with each successive use of the recording until it ceases to represent an advantage to the broadcaster.

Relations of the broadcasting organizations with their staffs have also been complex. In Canada attempts to exercise a restrictive control have led to revolts and resignations, while in France editors and producers who have been unwilling to conform to government policy have been removed from their jobs, though often under other pretexts. The position of staff is particularly vulnerable in those countries where broadcasting is a state monopoly; an example is Czechoslovakia, where senior broadcasting officials were ousted after the fall in 1968 of Premier Alexander Dubček, who had attempted to liberalize the Communist regime there.

INTERNAL ORGANIZATION, ADMINISTRATION, AND POLICY CONTROL

The organization and administration of broadcasting bodies can, in the case of a small independent station, be relatively simple, and the policies can be implemented with ease. Sizable organizations, however, have a complex problem because it is not possible to determine success or failure purely on the basis of financial returns. Monopoly organizations, though in theory their sole purpose is public service, in practice, in many countries, must take into account the views of the government. In the case of nonprofit–public-service operations dependent upon license fees for revenue but with commercial competition, ratings cannot be completely ignored, and these organizations must compete for mass audiences to some extent in order to justify their existence at the expense of the listening and viewing public.

Functions of the broadcast administration

The broadcasting administration has two essential functions: first, programming—*i.e.*, allocation of funds and setting of schedules—and, second, production, the preparation of programs. The former is in effect a branch of direction, and those in charge of planning program schedules and allocating funds have a power that if not checked can be absolute. On the other hand, these planners are dependent on the goodwill of the production and supply departments.

One of the main policy problems arises in the treatment of controversial subjects in the field of current affairs. Where broadcasters are under no obligation to be impartial, as in The Netherlands, or where, as in totalitarian countries, only one point of view may be aired, the problem does not really exist. In democratic countries where the broadcaster enjoys independence and where there is a need to achieve an overall impartiality, the problem is a real one. Even though decisions may be reached by discussion and come as a result of a consensus of opinion, the responsibility usually has to be carried by one man. No broadcasting organization has been able to find a complete solution to the problem that does not involve rigid control and intrusion on the independence of the editorial and production staff.

Administration must also deal with routine matters, such as staff pay and conditions of service, recruitment, finance, accounting, negotiations with unions, procurement of equipment, and provision of office and studio space. In general, it has been found best to subordinate such routine management operations to the needs of those directly concerned with the principal function of broadcasting. Much the same may be said of engineering and technical staff, though their research work and technical advances influence the decisions of direction and development of broadcasting.

THE STATE OF BROADCASTING IN SELECTED COUNTRIES

Argentina. Broadcasting in Argentina is wholly controlled by the government but only partly operated by government agencies. Partly for historical reasons, the method of control is not clear-cut: all broadcasting is subject to the approval of the State Secretariat for Radio and Television, a body working under the State Secretary of Communications, though the Secretary of Information can and does intervene on behalf of the president of the republic. All political activities were suppressed between 1966 and 1971, and even after the government of General Lanusse lifted the ban the restored freedom was not reflected in broadcasting. Of the more than 100 radio stations in the country, about half are grouped into four large networks: an official cultural noncommercial network with 20 stations, some strategically placed in relation to broadcasts from other countries; and three government-controlled commercial networks. More than 50 private commercial stations exist; some are small and low powered. All television is commercial. LS82 Canal 7 in Buenos Aires is state owned; the other three stations in that city have separately owned provincial affiliates. Argentina has about 30 television stations.

Sources of Argentine programs

Early television in Argentina depended on United States-produced telefilms dubbed into Spanish, and, although U.S.-dubbed feature films are still used, Argentine-produced programs are in the majority today. Some material comes from Spain, Italy, and the United Kingdom. Argentine-produced programs can rarely be exported, because the Argentine accent in Spanish, particularly that of Buenos Aires, is not acceptable elsewhere in Latin America. There are more than 6,000,000 radio sets and over 3,000,000 television receivers.

Australia. Australian broadcasting is under the overall supervision of the Australian Broadcasting Control Board. The principal organization is the Australian Broadcasting Commission, which is financed by parliamentary appropriations, revenue from the sale of publications, profits from public concerts, and subsidies for symphony orchestras. Government derives considerable income from the sale of receiving-set licenses, of which in June 1970 there were 2,750,000 combined radio and television, nearly 400,000 for radio only, and some 250,000 for television only. The Australian Broadcasting Commission, as well as the commercial stations, enjoy a fair measure of freedom, though consultation with government and officials occurs frequently. The commission operates over 80 radio stations, two in each state capital are "metropolitan," four serve Papua and New Guinea, six are shortwave stations broadcasting to inland Australia, and the rest are "regional" provincial stations in all states including Tasmania and Northern Territory, save for the nine transmitters and three Darwin relay stations for the external services (Radio Australia). The domestic stations are grouped into three networks. The Australian Broadcasting Commission is required by law to broadcast all sessions of the Federal Parliament, which it does on its First network of seven stations. There are in addition 114 commercial radio stations, of which 25 are in state capitals and the remainder in the provinces. These are associated in the Federation of Australian Commercial Broadcasters, and many are grouped in various networks. The Australian Broadcasting Commission has a total of 41 television stations, six in state capitals. Nearly half their output is imported, and of the total almost 30% is drama, 22% news and "public interest" programs, nearly 10% sport, and about 7% cultural, excluding education. There are 45 members of the Federation of Australian Commercial Television Stations, 15 in state capitals and the remainder in provincial areas. Imported programs account for nearly 57% of the commercial output, and of the total 54% is drama, 14% news, information, and current affairs, and 23% light entertainment. There are an estimated 7,250,000 radio sets and nearly 3,000,000 television receivers in Australia.

Brazil. There are some 800 radio and over 50 television stations in Brazil; the great majority are commercial. In general they are under the authority of the Ministry of Communications. All broadcasting is subject to censorship, and any station that runs counter to the government's wishes can be closed. There are radio stations of the Ministry of Education in Rio de Janeiro and Brasília; some of the states have official radio outlets, and a few have television installations. There are

also some university radio stations and a few television, apart from the Catholic educational radio network described above. The remaining stations are private commercial enterprises, operating independently or linked to one of the networks, of which the best known are associated with large newspaper concerns, such as Diarios Associados or O Globo. The larger radio networks use shortwave broadcasting making possible simultaneous transmissions on medium-wave provincial stations. Provincial television stations prepare their newscasts, often in cooperation with a local newspaper and radio station. The others employ film, telefilm, and videotape to supplement local production. All radio stations must carry daily, between 7:00 and 8:00 PM, an hour of official news supplied by the official Agencia Nacional; also one-half hour daily of educational programs from Monday to Friday and one and a quarter hours on Saturdays and Sundays. Television stations may be called upon to broadcast programs produced by the Agencia Nacional, consisting mainly of government statements and ministerial and presidential speeches. Television entertainment consists substantially of Brazilian-produced serials, supplemented by U.S.-produced and dubbed films and telecine programs. The number of radio sets in Brazil is uncertain, but there is an estimated total of more than 6,000,000 television receivers.

Official news on Brazilian stations

Canada. The principal broadcasting organization is the Canadian Broadcasting Corporation, which has one main television network in French and another in English and one main AM radio network in each language. In addition there is a small FM network and some shortwave transmission. Several regional networks exist, including one for French television, five for English television, two for French radio, and eight for English radio. The Canadian Broadcasting Corporation has 27 principal radio stations and 183 low-power relay stations; in addition, 61 privately owned stations are affiliated with it and are paid for transmitting its output. For the French television service there are six principal stations, 15 relay stations, some of which are dependent on videotape material, and some 42 privately owned affiliates. The English television service has 12 principal stations, 83 Canadian Broadcasting Corporation-owned relay stations, and 153 privately owned affiliates. The corporation's output, apart from educational broadcasts, consists of information, including news, public affairs, and religion (23% on French, about 45% on English radio, and 16–20% on television in both languages); light entertainment, including light music and drama (37% on French radio, 27% on English radio, and 50–58% on television in both languages); cultural programs, including serious music and drama (18 to 20% on radio in both languages and 2 to 3% on television); and sport, accounting for the remainder. There are over 7,000,000 television receivers.

Two-language broadcasting in Canada

External services are smaller than in most comparable countries; there are broadcasts on shortwave to the Canadian armed forces overseas and an international service in English, French, German, Spanish, Portuguese, Czech, Slovak, Hungarian, Polish, Ukrainian, and Russian, for listeners in Europe and Latin America. Apart from the Canadian Broadcasting Corporation domestic-service stations and disregarding stations of less than 1,000-watt power, there are about 250 radio and 70 television stations, privately owned and commercial.

France. The broadcasting system in France has been outlined above. The Office de Radiodiffusion Télévision Française (ORTF) broadcasts on three national radio networks: (1) France-Inter, a 24-hour service of entertainment and news, integrated with Inter-Variétés on regional transmitters carrying programs produced by regional stations and France-Inter Paris, a morning program of popular music and news flashes for Paris and the surrounding area; (2) France-Culture contains information and public affairs along with cultural programs; and (3) France-Musique, whose name is a sufficient indication of its content. Regional television service began in 1938, was interrupted by World War II, and recommenced in 1945. Colour television was inaugurated in 1967.

Regional broadcasting is organized in 11 regions; these control 30 program production centres and 23 news offices. The purpose of the regional structure in France is to communicate the news and artistic and cultural developments in each region to its inhabitants, as well as integrate a reflection of the region in the national networks. Regional coordination and liaison are the responsibility of a special group working directly under the national office, which is also responsible for broadcasting in the overseas departments and territories of France.

French regional broadcasts

Although the largest contribution to the revenue of ORTF continues to be the proceeds of receiving-set licenses, it is active in promoting commercial activities, including the sale of publications, records, and films, and is authorized to derive revenue from advertising on a limited scale on both television networks and on the France-Inter radio network. The ORTF distinguishes between *publicité de marques* (advertising of named products) and *publicité collective* (advertising of types of products on behalf of manufacturers' associations or state monopolies); France-Inter may carry only the latter. Two committees, appointed for radio and television, advise the central Direction on programs, schedules, and the balance between the different categories of output and may be called upon to comment on future projects and make proposals. Approximate percentages of the total radio output devoted to the main program categories, excluding the educational, are as follows: news and public affairs, 16%; entertainment, 28%; popular music, 27%; drama and literary programs, 8%. There is only a small radio sports output, but the use of radio for traffic control on a national scale (Radio-guidage) is particularly effective during the late summer, when children travel home from school vacations. Television output in France is more difficult to classify, but about 30% is devoted to news, magazine programs, and documentaries; 9% to sport; 9% to variety; 4% to drama; and 5% to children's programs, excluding school broadcasts. Practically all homes have radios, and there are over 10,000,000 television receivers.

France's external services have a weekly output of some 322 hours, of which nearly half is in French. In foreign languages the largest output is in Arabic (33 hours weekly), followed by German (15) and Spanish for Spain and Latin America (14), the Russian and Polish output also being substantial.

Italy. The origin of RAI-Radiotelevisione Italiana and its development into the present structure is outlined above. Regular television broadcasts began in January 1954. RAI has three radio services on national networks on AM and FM: a First or National Program offering a balanced output, a Second Program essentially of entertainment, and a Third Program. In addition there is a substantial regional output. At the end of 1970 there were two television services: the first, on VHF (very high frequency), broadcasting 71 hours weekly, is the National Program; the Second Program transmits 25 hours weekly on UHF (ultrahigh frequency). There is limited regional television on special occasions only, except for a daily one and one-half hours in German for the German-speaking minority of the Trentino-Alto Adige region. RAI has five production centres and 14 regional offices. The Trieste and Bolzano offices are responsible, respectively, for 86 hours of radio output weekly in Slovene for the Friuli-Venezia Giulia region and, apart from the German television output, for a further 79 hours weekly in German and three hours in Ladin (Romansh) for the Trentino-Alto Adige region. RAI's revenue comes from a proportion, determined by the government, of the proceeds of the sale of radio- and television-receiving licenses and from advertising, which in 1970 represented 31% of the total revenue. Advertising is closely regulated and may not "prejudice the good quality of programs"; it is guided by a code, and the percentage of time given to it is limited. In 1970 Radiotelevisione Italiana devoted 25.9% of its radio output to "folk" and serious music and 29.3% to light music, 15% to news and public affairs, 8.9% to entertainment, 10.5% to cultural programs, 3.7% to drama, and 1.2% to sport. On television

Italy's advertising code

22.1% is news and public affairs, 20.8% is entertainment (including 5.8% drama), 11.6% is sport, 10.2% cultural, and 9.5% is programs for children, excluding education. There are about 10,000,000 television receivers in Italy. Italy's external services use medium wave for broadcasting to the Mediterranean basin in Arabic, French, English, and German and shortwave for services to Africa, the Americas, Australasia, Europe, and the Middle East in Italian and 26 foreign languages; the total output amounts to some 216 hours weekly.

Japan. The basic structure of Nippon Hōsō Kyōkai (NHK) is covered above. NHK has two television and three radio networks (two AM and one FM), of which one television and one AM network are almost entirely devoted to education. The General Television program gives a balanced service, as does the First (AM) Radio service, while the FM (VHF) service is concerned mainly with even more educational, as well as with cultural, local and stereophonic music programs. There is relatively little political broadcasting in Japan, and the first occasion on which candidates for election to the Japanese Diet were able to present their political views on television was in December 1969. NHK output in program categories is summarized in the Table.

NHK Program Categories—Percentages of Total Output
(April 1971)

	general television (GTV)	educational television (ETV)	First Radio	Second Radio	FM radio
Education	9.2	80.4	14.0	80.0	9.5
News	32.5	1.7	42.1	6.5	11.5
Culture	36.1	17.9	30.6	12.7	50.3
Entertainment	22.2	—	25.9	0.8	28.7
Total hours of daily output	18	18	19	18.5	18

Japanese program scheduling

NHK has installed a system of computerized automation for its scheduling, resource allocation, and transmitting operations, probably the most advanced in the world, with a view to giving its production staff a maximum freedom for creative work. The organization has been experimenting with the 12,000,000,000-hertz (2.5-centimetre) wave for possible metropolitan area broadcasting and with broadcasting two television sound outputs simultaneously so that a single television image could be received with sound in either of two languages. NHK has 170 medium-wave transmitters for the First Radio network, 141 for the Second, and 249 for the FM network. General and educational television use about 1,000 transmitters each, most of which are rebroadcasting or relay stations. The so-called regional broadcasting is not so much regional as local and concerned mainly with news and practical information. Local television output averages one and a half hours and local radio three hours 40 minutes daily. In addition to NHK there are 83 broadcasting organizations, members of the National Association of Commercial Broadcasters in Japan. They make use of 443 VHF-TV transmitters, 446 UHF-TV, 153 AM radio, and four FM transmitters. There are about 23,000,000 television receivers in Japan.

NHK is responsible also for Japan's external services, which are divided into a general service—*i.e.*, a worldwide service in English and Japanese broadcasting a total of 13½ hours daily—and a regional service for the Americas, Europe, Asia, Africa, and Australasia, in 23 languages.

Mexico. Altogether there are some 520 AM and 57 FM radio stations in Mexico, though many are low-powered and principally rebroadcast or relay stations. Most are commercial, and about 70 are grouped into three nationwide networks. There is a smaller number of television stations, constantly growing, many of which are grouped in networks of varying size, of which the largest and only nationwide network is Telesistema, based in the capital; another sizable network is Telecadena, based in Monterrey. Television, too, is nearly all commercial, though there are some university stations, of which the best known is Radio Universidad, run by the Universidad Nacional Autónoma de México in Mexico City; there is also the Instituto Politécnico Nacional, which operates a cultural station in the capital. In theory there is no government control over broadcasting, but in practice there is no political broadcasting critical of the government or of the leading political party. Radio stations all have to carry the Hora Nacional, an hour-long officially produced program, every Sunday evening. The government has the right to use 12.5% of the total transmitting time of all radio and television stations. This right has so far been exercised only up to less than 2% of time on the air, though the announced intention is that the Comisión de Radiodifusión should acquire the resources to make full use of the time. Except for the few noncommercial stations, the majority of radio stations do little more than broadcast recorded popular music, news, and spot advertisements.

Television, with few exceptions, is substantially devoted to entertainment; a good proportion of material originates in the United States and is dubbed in Spanish, and a little comes from the United Kingdom. Exchange of programs with other Spanish-speaking countries is on a small scale and confined to popular-appeal serials. The government has plans for a network of officially operated small stations to provide cultural and educational programs. There are estimated to be about 5,000,000 radio and 2,250,000 television receiving sets in the country.

The Netherlands. In all democratic countries governments have found it difficult to reflect minority views in broadcasting. By 1970 only in The Netherlands had a determined attempt been made to deal with this problem. Basically the Dutch system consists of one national organization, the Nederlandse Omroep Stichting (The Netherlands Broadcasting Foundation), which is responsible for the transmission of all programs, and a number of broadcasting societies (or organizations), which, through the size of their membership, have earned the right to produce a proportion of the foundation's output. The Netherlands Broadcasting Foundation also has responsibility for the production of the so-called joint programs, which account for 20% of the radio and 40% of the television transmissions. The Broadcasting Act of 1966 calls upon the responsible minister to allocate time on the air, both in radio and television, to bodies that fulfill certain conditions, in particular a sufficient membership, and that, in October 1971, included: broadcasting societies or organizations, groups aspiring to recognition as broadcasting societies, the churches, associations of a nature comparable to churches, political parties, other reputable associations of approved purpose, an advertising foundation, and educational bodies. As far as the full-fledged societies are concerned, the amount of time they have on the air is determined by their category, in turn dependent upon the number of subscribers, whose subscriptions pay for a weekly program bulletin. Some of the other bodies with time on the air may prepare their own programs or have them produced by groups with more experience. In the early 1970s there were six established broadcasting societies and one aspirant, each broadcasting from one hour per week to seven hours 45 minutes. The financing of broadcasting, when production time is allocated among so many, presents a complex problem of accountancy. The revenue comes from the sale of receiving-set licenses and from advertising profits.

Dutch broadcasting societies

The Netherlands has three radio services and two television services. There is no regional television, but two regional radio organizations exist. The main categories of overall radio output are 25 percent news, public affairs, and information; 22 percent classical music; 14 percent light music; and 28 percent entertainment and other light programs. Television output is more diversified with 32.3 percent entertainment (of which more than half is of foreign origin); 2.9 percent Dutch-produced drama; 5 percent films, mostly foreign; and 31.2 percent news, public affairs, and information. There are over 3,000,000 television receivers.

The Dutch external services beam some 340 weekly hours of shortwave transmissions to most areas of the world in Dutch and six other languages (Afrikaans, Arabic, English, Spanish, French, and Indonesian).

New Zealand. In New Zealand the relatively small population (less than 3,000,000) means that broadcasting personnel are closely in touch with their audience, whose demand for a high-standard broadcasting service presents financial problems. The National Broadcasting Service, a government department set up in 1936, was faced by the competition of the National Commercial Broadcasting Service a year later. The two were amalgamated and reorganized as a government department, the New Zealand Broadcasting Service, in 1946. The service enjoyed some degree of independence from the start, and the inauguration of a television service in June 1960 provided the opportunity for the Broadcasting Act of 1961, by which was created the New Zealand Broadcasting Corporation with a far greater constitutional autonomy. It is financed by license fees and advertising revenue. In 1968 a new three-man body, the New Zealand Broadcasting Authority, was created by act of Parliament with broad powers but primarily to adjudicate applications to set up new privately owned stations. Four such commercial stations have since been authorized, and in late 1970 there were hearings about a second television channel and the introduction of colour, both of which the New Zealand Broadcasting Corporation claims it should handle. In 1971 New Zealand had two radio medium-wave networks and one television with a mixed output, mainly in English, though radio includes some output in Maori. The corporation has nearly 50 radio stations in 30 different cities and towns and four principal television stations with over 30 relay stations, mainly low powered. The corporation is also responsible for the Foreign Service (Radio New Zealand), which broadcasts to Australia, the Pacific Islands, and the Ross Dependency in the Antarctic in English, twice a week to Samoa in Samoan, and once a fortnight to the Cook Islands, in Rarotongan, and to Niue Island, in Niuean.

New Zealand's external services

Soviet Union. The State Committee for Television and Radio Broadcasting operates a substantial undertaking under the Soviet Union's Council of Ministers. The chairman of the committee has four deputies, respectively for television, external services, domestic radio, and for administration and finance, and there is an editorial board of 13 members. The committee controls output and is responsible for the equipment of television centres and for all personnel; but all lines, radio stations, and studios are under the control of the Ministry of Communications. Under the committee, domestic radio is run by seven Chief Editorial boards: program planning and presentation; propaganda; information (news); children; youth; literature and drama; and music, comedy, and satire. There is a joint radio and television department for sport. No program may go on the air without the approval of the editor in chief (or his deputy) of the appropriate editorial board. Though regional stations are said to enjoy a measure of autonomy, the committee controls the work of the regional committees handling radio in the various republics, regions, and districts. Radio in the Soviet Union requires between 300 and 400 transmitters for its networks and regional broadcasts. To achieve maximum coverage, it makes use of long waves, medium waves, and shortwaves, as well as FM. Moscow is responsible for five outputs as follows:

Program I is a mixed program covering the entire union; Program II is a 24-hour service with news and commentaries every half-hour, covering about 70 percent of the population; Program III is for the central parts of the Russian Soviet Federated Socialist Republic; Program IV is on FM, and there is besides a local output of some three half-hours a day for the Moscow area only on some of the channels used for Program III. The regional effort is impressive, with broadcasts in 70 languages in use within the territory of the Soviet Union. There are 23 principal regional stations. With so diverse an output there is no means of making a meaningful percentage breakdown of program categories, but Russian radio on the whole devotes more time to information, educational, and cultural programs and less to entertainment than other countries.

The Moscow television station began broadcasting in 1939 and claims to have been the first European television station to renew operation after the World War II interruption. Colour was introduced in 1967. About 70 percent of the population are within reach of a television signal, for which there are 280 main and about 1,000 relay transmitters. In 30 of the principal cities, there are two or three outputs to choose from. The satellite Molniya I, combined with 36 Orbita ground and relay stations, has greatly increased the size of the potential audience. At the Moscow television centre, Ostankino, is a 1,760-foot-high (537-metre-high) tower used for television and other communications. The services broadcast cannot be easily analyzed, and it is claimed that from Moscow six can be broadcast simultaneously. Of the three main channels, one is for the Moscow area only, a second is sent to most of the other republics of the union, and a third is educational at primary, secondary, and university levels. There is also a substantial output originated in the regional centres. There were estimated to be, in January 1972, some 40,000,000 television receivers in the Soviet Union.

The external services described above are probably the largest of any country. The output can be divided into six types: (1) for foreign countries from Moscow; (2) for foreign countries from regional stations; (3) relays of domestic services for listeners abroad; (4) broadcasts for Russians abroad, under the aegis of the Committee for Cultural Relations; (5) a service for the Merchant Marine and for fishermen; and (6) the "Peace and Progress" station. It is the Moscow output, supplemented by the foreign services from the regional stations, that has the widest coverage and makes use of nearly 70 languages, including more for Africa and Asia than any other country and including even, for example, Quechua (for Peru). The "Peace and Progress" output is in German only for Europe; in various Chinese languages, Mongolian, English, and French for Asia; in Yiddish and Hebrew for the Near East; and in Spanish, Portuguese, Creole (for Haiti), and Guarani (for Paraguay) for Latin America.

Soviet foreign-language transmissions

Sweden. The historical background of Sveriges Radio, the Swedish broadcasting monopoly, is described above; two important developments took place in 1967, embodied in the Broadcasting Law, effective from July 1 of that year. Public authorities and agencies were specifically forbidden to examine programs in advance or to attempt to prevent them from being broadcast; this meant that the government had not even the power of veto. The legal responsibility for any program rests not on the organization, its board of directors, or even the director general but on the program supervisor, and no program may be broadcast against his will. The financing is entirely from licenses for receiving sets, but the proceeds are allocated by Parliament to Sveriges Radio, which produces programs, the Swedish Telecommunications Administration, which transmits them, and the Swedish General Services Administration, responsible for the construction of broadcasting facilities.

Sweden has three radio and two television networks. A substantial number of stations and transmitters on long waves, medium waves, and shortwaves ensures national coverage of the three radio services, as well as allowing for regional broadcasting. Ten regional stations enjoy a substantial autonomy and have their own budgets, but they must negotiate with the heads of the national networks to opt out with their own regional programs up to an optimum total of 25% of the national networks. There are plans for converting six of these regional outposts into television-production centres and for breaking up regional radio production work into smaller areas than at present. In radio, one network broadcasts spoken-word programs almost exclusively with some serious music during the day; the second consists of education and serious music in the evening, and the third, a 24-hour operation, is predominantly light popular music. In television the first network, inaugurated in 1957, carries 20%

Sweden's television networks

entertainment and 9% drama and film, whereas the second network, inaugurated in 1969, carries 12½% entertainment and 21% drama and film. Colour television was inaugurated in April 1970. There are estimated to be some 2,500,000 television receivers.

Sveriges Radio is also responsible for Sweden's external services, the cost of which (as also the cost of educational broadcasts) is separately budgeted and paid for from government funds. The broadcasts are in Swedish and six foreign languages: English, French, German, Spanish, Portuguese, and Russian. They are beamed as appropriate to all parts of the world.

United Kingdom. *British Broadcasting Corporation.* A monopoly until 1954, the BBC has four radio networks: Radio 1, broadcasting mostly popular music, mainly during the day; Radio 2, primarily transmitting light music and entertainment; Radio 3, broadcasting mainly serious music during the day, educational programs in the early evening, and cultural programs in the late evening; and Radio 4, scheduling spoken word primarily, school programs in the midmorning and early afternoon, and a mixed program in the evenings. The main ingredients of overall output are: 40.7% entertainment music; 21.2% serious music; 16.7% news, current affairs, and information; 4.8% drama; 3.6% education; and 2.2% outside broadcasts, mostly sport. The BBC has two television services, the first of which transmits 12 hours a day and the second six; both have mixed programs that are coordinated to avoid conflicts. The main ingredients are news, current affairs, and information (22.9%); British and foreign films and series (15.5%); outside broadcasts, substantially sports, and sports news (15.6%); drama (8%); light entertainment (6.9%); "family" programs (6.6%); education (11.1%); and religion (2.2%).

There is substantial regional activity in both media. Of the six regions in the kingdom that formerly operated with a fair degree of autonomy, only the "national" regions remain for Scotland, Wales, and Northern Ireland. In place of the other three regions, North, Midland, and West and South, there are now eight production centres for both radio and television. Regions broadcast their own programs by opting out of Radio 4 or BBC 1 and using their own section of the corresponding network. There are special broadcasts in the Welsh language for Wales. During the last few years the BBC has inaugurated 20 local FM (VHF) stations as authorized by the government: these are mostly placed to cover the larger city areas. Competitive commercial local stations are likely to be set up in the near future under supervision of the Independent Broadcasting Authority (see below).

The BBC is also responsible for the United Kingdom's external services, which are paid for by annual grants-in-aid from the treasury. Though no longer among the leaders in quantity of output, it almost certainly remains among them in terms of penetration. Seventy transmitters, of which 26 are overseas relay stations, provide a shortwave worldwide service and a medium-wave service in many areas, including Europe (from Berlin), western Asia, and the eastern Mediterranean. Of the weekly output of about 720 hours, some 210 are in the World Service in English, and the remainder are in nearly 40 foreign languages, of which the main ones are Arabic (70 hours), French for Europe and Africa (over 40), German and Russian (over 30 each), Spanish for Spanish-speaking America (28), Polish and Czech (22 each), Hungarian (19), and Portuguese for Brazil (16).

Independent Broadcasting Authority. The Independent Broadcasting Authority (originally called Independent Television Authority) was established by act of Parliament in 1954; broadcasting began under its control a year later. Though the authority enjoys substantial independence, it does not itself produce any programs or any of the advertising; these tasks are performed by commercial program companies. These latter, organized on a regional basis, supply all the material broadcast except for news, for which a separate group, Independent Television News, was created, jointly owned and financed by the program companies.

Control of the British program companies

The program companies are under a substantial measure of control from the Independent Broadcasting Authority, which is responsible for the appointment of program companies, control of program and advertising output, and its transmission. The authority enforces codes with respect to advertising and violence on the screen. The 15 program companies broadcast throughout the week within their respective areas, except for two that share the London area. The program companies are entirely financed by spot advertising (sponsored programs are forbidden by law) in "natural breaks" in and between programs; they pay a rental to the authority to cover the latter's transmitting and administrative costs and a fiscal levy to the exchequer. The program companies cooperate in a network committee, and a substantial number of the principal programs are broadcast by all companies. The contribution to the network made by each company varies in accordance with its size and resources. The revenue of each company is substantially dependent upon the number of homes with television receivers able to receive the Independent Broadcasting Authority signal in the area it covers, which varies from 32,000 in the Channel Islands to 2,630,000 in the Midlands and 4,300,000 in the London area. So diversified an output makes valueless any percentage analysis of program categories; but the principal types of output, in order of size, are as follows: drama, including telefilm series; news, news magazines, features, and documentaries; sport; entertainment; feature films (British and foreign); education; children's programs; and religion. The Television Act of 1964 established the present Authority situation for 12 years, though it has since been given the task of supervising local commercial radio (hence its change of name); in 1976 both the BBC's charter and license and the act under which the Authority operates come up for renewal or alteration or both.

United States. So great is the broadcasting operation in the United States, so many are the stations, both radio and television, and so extensive the ramifications and links with other industries, that it is not possible to produce a summary on the lines of those for countries where broadcasting has been more tightly organized. Some idea of the magnitude of the broadcasting scene is provided by the number of broadcasting stations in operation in August 1970 as authorized by the Federal Communications Commission: radio AM, 4,911; radio FM, 2,134; educational radio FM, 420; commercial television UHF, 181; commercial television VHF, 510; educational television UHF, 108; educational television VHF, 83; television relay stations UHF, 781; television relay stations VHF, 1,691—a total of some 10,000 stations. In every category more stations had been authorized than were operating, and more have been authorized since, the largest proportional increase being in television UHF. Commercial broadcasting on television, as on radio in the past, is dominated by the three great national networks: the American Broadcasting Company, Columbia Broadcasting System, and the National Broadcasting Company. In radio, where the networks are no longer dominant, there is also the Mutual Broadcasting System; the majority of radio stations are as independent of the large networks as of the government, and many of the commercial stations specialize in a single type of output, which may be one or other of various kinds of popular entertainment music, classical music, news, or even traffic information. A few are owned by or affiliated to the national networks or to smaller local networks; some even are small local stations offering a basic fare of neighbourhood gossip interspersed with recorded music and spot advertising. After a slump following the major onset of television, radio, even network radio, has again become profitable. In television the three big networks own and operate their own stations in some of the larger cities and substantially control a majority of affiliates.

Noncommercial broadcasting is growing in the United States. The National Association of Educational Broadcasters serves educational stations with transcriptions produced by its members and by other domestic as well

as foreign broadcasters. The North American Broadcasting Corporation is also largely educational, supported by donations from foundations and other sources. There are radio stations supported by donations and subscriptions from listeners, in particular the Pacifica group. The Public Broadcasting Service has a loose organization. Its production facilities are not jointly organized and it makes use of existing noncommercial stations for its network. Its revenue is uncertain; $30,000,000 a year from a congressional appropriation, which must be renewed annually, and the rest from foundations, public generosity, and individual stations.

Another new system is community antenna television (CATV), now increasingly known as cablevision, or cable TV, originally set up in areas of poor reception or where the choice of receivable television services was poor and cablevision could offer additional choices from elsewhere. By 1964, 1,000 such systems were in operation. At the time, no one thought of "cablecasting"—*i.e.*, that the cablevision companies should originate their own programs—but in many areas cablecasting has proved a great success. Even a relatively small enterprise such as the Twin County Trans Video, of Allentown, Pennsylvania, has more than doubled its subscribers in little more than a year since it began originating its own local program. Cablevision, transmitted via direct cables connected to each television set, can offer viewers a much larger choice of programs, as well as excellent reception. There are estimated to be some 85,000,000 television receivers in the U.S.

Official external services are operated by the Broadcasting Service of the United States Information Agency, known as the Voice of America. They are broadcast to all parts of the world and have a number of relay stations overseas. Apart from English, 32 languages are used. There are also two foreign-based organizations, Radio Free Europe and Radio Liberty. In addition there is the International Broadcast Station, offering a shortwave service to Latin America in English, Spanish, Portuguese, German, and Russian; Radio New York World Wide, with a commercial service to Europe and Africa in English and to the Caribbean in English and Spanish; and World International Broadcasters, whose shortwave commercial service with a religious background is broadcast in English to Europe, the Near East, and North Africa. The American Forces Radio and Television Service has a network of shortwave stations broadcasting a worldwide service and stations in Alaska, Canada, Europe, North Africa, Ethiopia, the Caribbean, the Far and Near East, Antarctica, the North Atlantic, and the Pacific.

West Germany. Though Germany was one of the first countries to begin radio transmissions (October 1923), the present organization owes nothing to earlier development. It was the occupying powers at the end of World War II that established the present system based on nine provincial (*Länder*) organizations. All provincial organizations have a First Radio service on medium wave, supported by FM. All have a Second and Third Radio service on FM, and the Cologne group has a Fourth. Berlin has an AM channel, as well as FM for each of its three radio services. In many cases, two or more *Länder* organizations cooperate and broadcast simultaneously a single output on one of their FM services. The latter in most cases is broadcast for only three to four hours daily (the weekly output varies between 21 and 63 hours weekly), substantially and sometimes entirely devoted to foreign languages for foreign workers in West Germany. The output of the First and Second Radio services is to some extent mixed, but there is a tendency for the more serious output, especially good music, to be found on the Second rather than the First. The Saar's First service, for example, is entirely popular light music and hourly news bulletins, and the Second is cultural.

Germany's provincial organizations

The First German Television service is nationally coordinated with contributions from each *Land* organization. Each organization broadcasts between nine and 11½ hours weekly of regional material for its own audience. The Second Television service is centrally planned and produced, with headquarters in Mainz; schedules are coordinated to give the viewer a maximum choice. Each organization has also a Third Television service for only a few hours a day, often of an educational nature; this service, like the radio Third service, is sometimes produced and simultaneously broadcast by groups of two or three *Länder* organizations. The Federal government has no authority for the control of broadcasting within the Federal German territory, and legislative and administrative competence for broadcasting rests with the *Länder*. But even the *Land* governments and parliaments are legally barred from intervening beyond a statutory supervision that may not interfere with the basic independence of the broadcasting organizations. There are estimated to be some 20,000,000 radio receivers and about 17,000,000 television receivers in the Federal territory.

There are two external service organizations. Deutschlandfunk has a First Program in German on medium wave and long wave and a Second on medium wave only, broadcasting 33½ hours weekly for France, the United Kingdom, The Netherlands, northern and eastern Europe. Deutsche Welle broadcasts in 30 foreign languages to most areas of the world for a total of nearly 700 hours weekly.

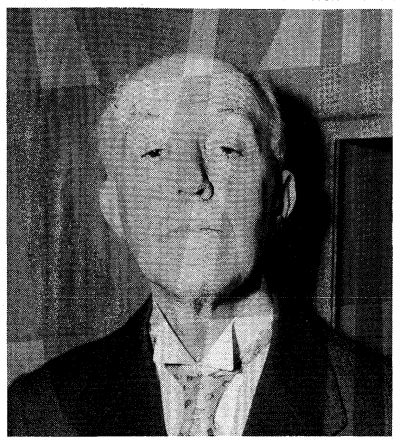
Broglie, Louis-Victor, duc de

A French theoretical physicist, Louis de Broglie was responsible for the then far-reaching idea that the electron and other material constitutents of the atom possess wavelike properties. In 1923, when Broglie put forward this idea, there was no experimental evidence whatsoever that the electron, the corpuscular properties of which were well established by experiment, might under some conditions behave as if it were radiant energy. Broglie's suggestion, his one major contribution to physics, thus constituted a triumph of intuition.

Wide World Photos



Broglie, 1958.

Early life

Born in Dieppe, France, on August 15, 1892, Broglie was the second son of a member of the French nobility. From the Broglie family, whose name is taken from a small town in Normandy, have come high-ranking soldiers, politicians, and diplomats since the 17th century. In choosing science as a profession, Louis de Broglie broke with family tradition, as had his brother Maurice (from whom, after his death, Louis inherited the title of duc). Maurice, who was also a physicist and made notable contributions to the experimental study of the atomic nucleus, kept a well-equipped laboratory in the family mansion in Paris. Louis occasionally joined his brother in his work, but it was the purely conceptual side of physics that attracted him. He described himself as "having much more the state of mind of a pure theoretician than that of an experimenter or engineer, loving especially the general and philosophical view. . . ." He was brought into one of his few contacts with the technical aspects of physics during World War I, when he saw army service in a radio station in the Eiffel Tower.

Broglie's interest in what he called the "mysteries" of atomic physics—namely, unsolved conceptual problems of the science—was aroused when he learned from his brother about the work of the German physicists Max Planck and Albert Einstein, but the decision to take up the profession of physicist was long in coming. He began at 18 to study theoretical physics at the Sorbonne, but he was also earning his degree in history (1909), thus moving along the family path toward a career in the diplomatic service. After a period of severe conflict, he declined the research project in French history that he had been assigned and chose for his doctoral thesis a subject in physics.

Theory of electron waves

In this thesis (1924) Broglie developed his revolutionary theory of electron waves, which he had published earlier in scientific journals. The notion that matter on the atomic scale might have the properties of a wave was rooted in a proposal Albert Einstein had made 20 years before. Einstein had suggested that light of short wavelengths might under some conditions be observed to behave as if it were composed of particles, an idea that was confirmed in 1923. The dual nature of light, however, was just beginning to gain scientific acceptance when Broglie extended the idea of such a duality to matter.

Broglie's proposal answered a question that had been raised by calculations of the motion of electrons within the atom. Experiments had indicated that the electron must move around a nucleus and that, for reasons then obscure, there are restrictions on its motion. Broglie's idea of an electron with the properties of a wave offered an explanation of the restricted motion. A wave confined within boundaries imposed by the nuclear charge would be restricted in shape and, thus, in motion, for any wave shape that did not fit within the atomic boundaries would interfere with itself and be cancelled out.

The first publications of Broglie's idea of "matter waves" had drawn little attention from other physicists, but a copy of his doctoral thesis chanced to reach Albert Einstein, whose response was enthusiastic. Einstein stressed the importance of Broglie's work both explicitly and by building further on it. In this way the Austrian physicist Erwin Schrödinger learned of the hypothetical waves, and on the basis of the idea, he constructed a mathematical system, wave mechanics, that has become an essential tool of physics. Not until 1927, however, did Clinton Davisson and Lester Germer in the United States and George Thomson in Scotland find the first experimental evidence of the electron's wave nature.

Later career and writings

After receiving his doctorate, Broglie remained at the Sorbonne, becoming in 1928 professor of theoretical physics at the newly founded Henri Poincaré Institute, where he taught until his retirement in 1962. He also acted, after 1945, as an adviser to the French Atomic Energy Commissariat.

For his discovery of the wave nature of the electron, Broglie was awarded the 1929 Nobel Prize for Physics. He also received, in 1952, the Kalinga Prize, awarded by the United Nations Economic and Social Council, in recognition of his writings on science for the general public. He was a foreign member of the British Royal Society, a member of the French Academy of Sciences, and, like several of his forebears, of the Académie Française.

Broglie's keen interest in the philosophical implications of modern physics found expression in addresses, articles, and books. The central question for him was whether the statistical considerations that are fundamental to atomic physics reflect an ignorance of underlying causes or whether they express all that there is to be known; the latter would be the case if, as some believe, the act of measuring affects, and is inseparable from, what is measured. For about three decades after his work of 1923, Broglie held the view that underlying causes could not be delineated in a final sense, but, with the passing of time, he returned to his earlier belief that the statistical theories hide "a completely determined and ascertainable reality behind variables which elude our experimental techniques."

BIBLIOGRAPHY. Some of the popular writings of Broglie have been translated into English: *Matter and Light: The New Physics* (1939); *The Revolution in Physics* (1953); *Physics and Microphysics* (1960); and *New Perspectives in Physics* (1962). An account of his work may be found in BARBARA LOVETT CLINE, *The Questioners: Physicists and the Quantum Theory* (1965).

(B.L.C.)

Bromeliales

The characters that separate the order Bromeliales, with its single family (Bromeliaceae), from other orders of monocotyledons (one of the two large classes of flowering plants) are the regular three-parted flowers of its members and the mealy endosperm (starchy nutrient tissue) of their seeds. The presence of water-absorbing scales on their leaves is an even more distinctive character and the one most generally used for quick identification of the group.

Within the above limits, the family (and therefore the order, since there is only the one family) has tremendous variation, as is shown by the contrast of its two best known members, the pineapple (*Ananas comosus*) and the Spanish moss (*Tillandsia usneoides*). The great majority of species are like those popular in cultivation, with a rosette of leaves that usually holds water and an inflorescence (flower cluster) that owes its colour and

beauty more to its bracts (usually leaflike appendages associated with flowers) than to its flowers.

There are well over 2,000 known species in the family Bromeliaceae, and all but one are confined to the New World. Their habitat ranges from the wettest of rain forests to the driest of deserts and from just above tidemark to treeless mountain tops.

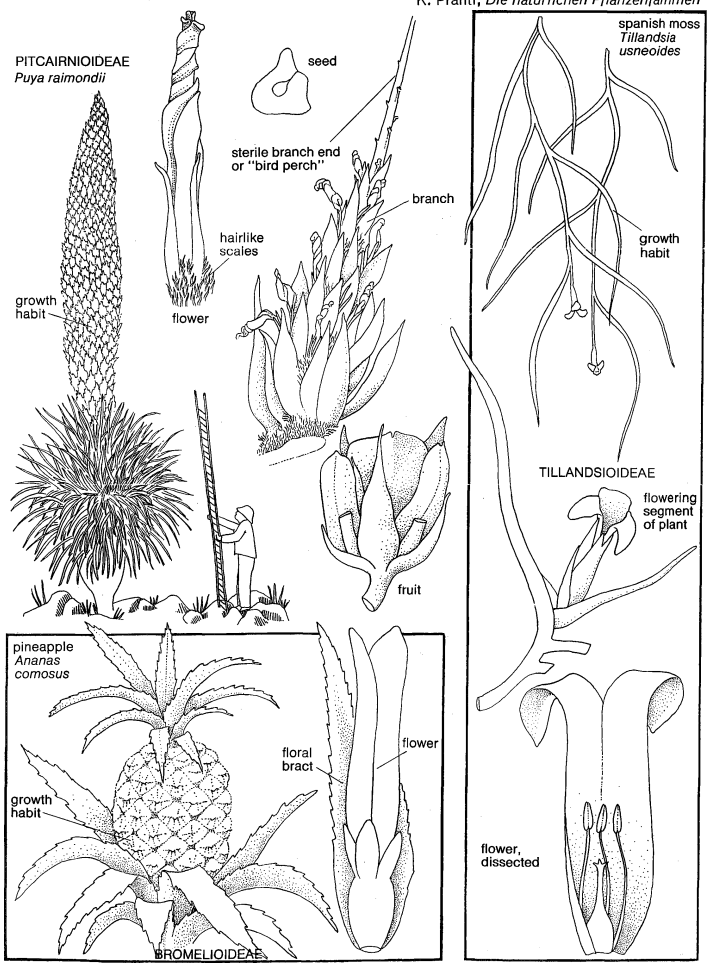
GENERAL FEATURES

Size range and diversity of structure. In size, bromeliads (*i.e.*, members of the family Bromeliaceae) range from the 30-foot (9-metre) *Puya raimondii* to the one- to two-inch high *Tillandsia bryoides* that is found roosting on it. The great majority of species, however, have flowering shoots between one and five feet high.

Although most bromeliads are "stemless" rosette plants, a good number have stems much longer than their leaves, and these stems vary from the massive pillars of *Puya raimondii* to the fine hanging threads of Spanish moss.

Most bromeliad leaves are spiny throughout or completely unarmed. The unarmed leaves are generally of two types, narrowly triangular with a dense coat of gray scales or strap-shaped with inconspicuous scales. The first type stores water in its tissues and is adapted to arid conditions. The leaves of the second form a watertight tank and adapt the plants bearing them to life in the rain forest.

Drawing by M. Moran based on A. Engle and K. Prantl, *Die naturlichen Pflanzenfamilien*



Plants and plant parts showing characteristics of the three subfamilies in the order Bromeliales.

Distribution and abundance. The range of the whole family very nearly coincides with that of Spanish moss, extending from coastal Virginia through southeastern United States, Mexico, and the West Indies to central Argentina and Chile. Spanish moss is a prominent part of the vegetation in the southeastern United States. Species of *Tillandsia* form great masses in the coastal desert of Peru, and *Deuterocohnia* covers large areas of the arid Andes of northwestern Argentina. Elsewhere, bromeliads tend to be relatively inconspicuous to a man on foot, though the story is much different when the rain forest is viewed from a helicopter or becomes dwarfed. In the rain forest, bromeliads present the greatest bulk of epiphytic vegetation, although orchids are much richer in number of species. (Epiphytes are plants that grow upon tree branches or on other aerial supports; they are not rooted in soil.)

Economic, medical, and other importance. The pineapple is by far the most important crop plant in the family Bromeliaceae and the only one that is regularly cultivated. As in the case of most other crop plants, the pineapple has thrived best far from its home, probably because it has escaped its natural enemies in this way. As far as can be determined, it evolved in the interior of South America but is best cultivated in Hawaii. At the time Columbus landed, the pineapple had already been spread by the Indians, but for use as a fibre, not as a fruit. In arid northeastern Brazil, the caroa (*Neoglaziovia*) is cropped regularly from wild growth and used as fibre in coarse bagging. Pineapple cultivation

Spanish moss has a small but constant cropping for use as cushion filling, and the Indians have used species of *Bromelia* and *Aechmea* for fibre and the leaf-spines of *Puya* for fish hooks.

Medicinally, the bromeliads have some slight drug values, but they also harbour malaria carriers in their water-tight rosettes.

NATURAL HISTORY

Life cycle. Nearly all types of pollen dispersal are represented in the family Bromeliaceae. The majority of species are insect pollinated, but there is a large amount of pollination by hummingbirds, particularly of the red-flowered species. Probably unique are the sterile branch-ends of the *Puya raimondii* group that enable pollination by perching birds. As might be suspected, some bad-smelling night-blooming species prove to be bat-pollinated. Finally, *Fosterella* is thought to be wind-pollinated, judging by the yellow cloud of pollen the flowers emit when jarred.

There are no elaborate mechanisms effecting cross-pollination, such as are found in the orchids, but there is self-sterility, differential maturity of stamens and pistil (male and female reproductive structures), and the isolation of the sexes of functionally unisexual flowers on separate plants, as in *Hechtia*. On the other hand, the flowers of some species of *Guzmania* do not open and are doubtless cleistogamous (*i.e.*, they are self-fertile and set seed without the necessity of opening to permit cross-fertilization).

Seed dispersal is by wind in the case of species with winged or plumose seeds, although some of the river-bank and deep rain forest species are thought to be waterborne. *Navia*, with no seed appendages and an unappetizing dry capsular fruit, is also thought to depend on water. Its highly localized species would indicate that its means of dispersal is extremely poor. Species with unappendaged seeds but edible baccate (berry-like, pulpy throughout) fruits depend chiefly on birds for distribution, but some dispersal by bats is also indicated. Seed dispersal

Vegetative reproduction is tremendously important in bromeliads, many species increasing mostly by this method and many more making a balanced combination of vegetative and sexual means. The rosette-forming species send out basal offsets, often in regular patterns, such as those that zig-zag up tree trunks with a rosette at every angle. The long-stemmed species elongate, branch, and break apart, with the air-borne Spanish moss the extreme example. There are a number of species, including *Tillandsia latifolia* of the Peruvian coastal desert, that are viviparous, producing small plants in place of flowers.

Establishment usually is most critical in the early seedling stage. Once past this, the chances of survival are better, although growth may be very slow. Viviparous

plants bypass this stage, but thereby miss the benefits of cross-pollination.

Ecology. Bromeliads have an external ecology like all other plants, but, in addition, the tank-forming species have an almost unique internal ecology as well. In their external relation to the environment, they show a greater range of adaptation than most flowering plants. Even the most primitive genera show a great range of adaptation. *Fosterella* is a forest type with small requirements of light, but large requirements of water and temperature. *Puya*, growing on bare Andean mountain summits, receives a maximum of light, but endures a summer-to-winter extreme in temperature cycle every twenty-four hours. Many species of *Puya* have adapted by covering their flowers with large bracts and a dense mat of wool formed by finely divided scales. *Encholirium* and *Dyckia* in Brazil and *Deuterocohnia* and *Abromeitiella* in Argentina usually grow on bare rock in the full sun. They have adapted by developing thick tough leaves with well-protected stomata (microscopic openings in leaf surfaces) that ensure a minimum moisture loss. In its different species, the genus *Pitcairnia* runs the full range of habitats from rain forest to extreme aridity, which latter environment has given rise, in a number of cases, to species with deciduous leaves. *Pitcairnia* and *Brocchinia* show the beginnings of adaptation to epiphytism. It is only a slight beginning, however, because, in their very wet rain forest, there is not such a great difference between living conditions on the ground and in the crotch of a tree trunk.

Adaptations to the environment

The subfamily Tillandsioideae shows the greatest diversity of all in adaptation to different environments. A large part of the genus *Tillandsia* has adapted to extreme aridity by the development of highly efficient leaf scales that absorb water and transmit it to the interior of the leaf blade. This characteristic is usually correlated with a long stem, as in Spanish moss. The remainder of the genus *Tillandsia* and practically all species of the other genera of Tillandsioideae have adapted in the opposite direction, with the development of tank rosettes and scales that are concentrated more on the leaf sheaths. A few species of *Tillandsia* have combined the arid type of leaf scale with a bulbous rosette.

The subfamily Bromelioideae has also adapted in both directions, but not so extremely toward aridity. There, as in the genus *Bromelia*, the development has been to a heavy thickened leaf like that of the primitive members of the subfamily Pitcairnioideae. The majority of genera have adapted to humidity by producing a tank that varies from a broad basin to a narrow tube.

With the development of the tank rosette, bromeliads have attained a second ecological relationship practically unknown in other plants. As epiphytes, they supplement their scanty food supply from the excreta and remains of a host of small plants and animals, many of which live or breed only in bromeliad tanks. Thus, they have coevolved with their aquatic guests to a very close ecological relationship.

The plant colonies in bromeliad tanks range all the way from unicellular algae to the insectivorous bladderworts (*Utricularia*), which are among the most highly developed of flowering plants. With the exception of certain mosses, no plant species are known to be limited to the tank habitat.

The species of animals in bromeliad tanks are much more numerous than those of plants and form a much more important relationship with the bromeliads. These animals range from unicellular protozoa to vertebrates, and their relationship goes from complete life history to breeding to occasional seeking of shelter. The spread of totally tank-adapted species from one bromeliad to another is not always easy to explain. Protozoa are easily spread by wind and rain, especially in the encysted state, but the dispersal of the ostracod crustacean, *Elpidium*, is more difficult to account for. This tiny animal, which measures about a tenth of an inch long and looks like a shrimp enclosed in a clam shell, has no means of locomotion out of water, yet manages to inhabit the great majority of tanks in southern Brazil. Crabs, such as *Sesarma miersii*, which are found in salt to brackish water from the West Indies to Uruguay, not unsurprisingly, turn up in bromeliads growing a few feet above high tide mark. *Metopaulias depressus*, a crab species of Jamaica, however, is found in bromeliads above the 2,500-foot (800-metre) elevation.

As elsewhere, insects outnumber all other classes of animals in the tanks in number of species and individuals. Best represented is the order Diptera (flies), especially mosquitoes, but a good number of other insect orders are commonly found. Several species of Odonata (dragonflies and damselflies) breed there, with their larvae preying on the mosquito larvae. All the strictly aquatic larvae are adapted to living in water that is more than half mud, but the mosquito larvae of bromeliads, unlike their terrestrial relatives, do not have to surface for air. They simply pick up oxygen given off by the leaf sheaths. The order Hymenoptera (bees, wasps, and ants) is represented chiefly by ants, but only after the tank, or at least its outer leaves, is drained. Whether the ants contribute to the bromeliad's growth is being investigated, but it does not appear to be as advantageous to the plant as the presence of aquatic species. The ants also appear to prevent occupation of the rosettes by mosquitoes.

Frogs and salamanders are the only vertebrates using the tank itself, although snakes are sometimes found sheltering in the rosettes. The amphibians not only breed there, but the mostly nocturnal adults shelter there during the daylight hours. Probably the greatest adaptation is reached by a frog in semi-arid northeastern Brazil that inhabits the long tubes of certain species of *Billbergia*. It not only holes up there during the day but very effectively plugs the hole with its hard-topped head, thereby keeping the tube more humid, to its own advantage and to that of the plant.

Snakes in rosettes

FORM AND FUNCTION

Vegetative characteristics. Roots are normal in form and function in the primitive subfamily Pitcairnioideae; that is, they absorb food and moisture through the root hairs and pass it up through the larger roots to the rest of the plant. In the species that grow on rock, however, the larger roots take on the function of adhesion. The roots are basal in most Pitcairnioideae, but in species of *Puya* with prostrate stems they may sprout anywhere, each piercing several leaf sheaths before reaching the ground. In several species of *Navia*, the roots emerge all along the erect stem, but turn down and stay within the cortex (outer plant sheath) until reaching the ground.

In the subfamilies Tillandsioideae and Bromelioideae, the roots have lost most of their absorptive function and become mere holdfasts, the leaves taking over as absorbing organs. Finally, in several species of *Tillandsia*, such as the Spanish moss, the roots have lost even the function of adhesion and have disappeared. In some species of *Bromelia*, the roots have no contact with the ground, but end in the leaf-axils (upper angles between leaf and stem), where a mat of coarse scales gives them considerable moisture.

Stems of bromeliads are solid and have scattered vascular bundles as in a corn stalk. In long-stem types as diverse as the pineapple and the Spanish moss, the stem can be fragmented, each part capable of living and forming a new plant. The "stemless," or rosette, types have a very short, broadly conical stem that usually gives rise to offshoots ranging from short ascending shoots to long, slender, and scaly rhizomes (horizontal, creeping stems, rootlike in appearance).

Leaves of bromeliads are spirally arranged and usually occur in many ranks, but in a number of tillandsias (genus *Tillandsia*) and a few species of the subfamily Bromelioideae they are two-ranked. Nearly always the sheath and leaf blade are distinct. In the primitive subfamily Pitcairnioideae and in the long-stemmed species of *Tillandsia* the sheaths are tightly overlapping and lack scales on the covered parts. The tank types have sheaths that make watertight contact along their edges, but they have considerable open space elsewhere, and they have

Leaf arrangement and structure

a greater concentration of scales than do the blades. The leaf blades also vary in shape and function. The greatest variation in form occurs in the genus *Pitcairnia*, with every gradation from the broad petiolate (stalked) blades of species in the deep jungle to the grasslike deciduous ones on sun-drenched rocks. Their function, however, is relatively simple, the position and number of stomata being adjusted to the best use of sunlight and moisture. In the genus *Tillandsia* there is much less variation in form, but more in function, through the development of scales that imbibe salts as well as water, and thus take over the functions of roots.

Flower and fruit characteristics. The scape, or stalk, of the inflorescence is usually well-developed and is located at the terminal end of the stem. Functionally, it is a specialized stem that feeds the inflorescence. Like the stem, it contains no living cells at maturity except in the genus *Deuterocohnia*. In that group, just below the cortex, there is a sheath of live tissue, like the cambium (a zone of cell division contributing to growth in stem thickness) of dicotyledons, but which has no ability to form rings of wood and bark. Instead, it keeps the axis of the inflorescence active and enables it to put forth new branches year after year as old ones wither and fall. In most cases the scape is covered with brightly coloured bracts that quickly distinguish it from the stem, and, in many species of the subfamily Bromelioideae, these provide the most beautiful part of the plant.

The inflorescence varies in form from a much branched cluster to a single flower. Nearly always the bracts are more showy than the flowers. The flowers consist of three sepals, three petals, six stamens in two series, and a pistil of three carpels (segments of the female reproductive unit). The ovary runs all the way from wholly superior (*i.e.*, the sepals, petals, and stamens attach at the base of the ovary) to wholly inferior (*i.e.*, the other flower parts appear to attach at the upper end of the ovary their fused basal parts enclosing it) in the genus *Pitcairnia* alone, but its position usually is significant in determining the limits of the genera. The ovules are appendaged in most cases, but in all members of the subfamily Bromelioideae the appendage is lost in the mature seed, and in the subfamily Pitcairnioideae it develops into a wing or tail, and in the subfamily Tillandsioideae into a plume. The fruit can be a regularly opening capsule or a berry, or have an intermediate form that is dry like a capsule and has winged seeds but only ruptures irregularly with age.

EVOLUTION

Fossil record. Six species of fossil plants have been ascribed to the family Bromeliaceae. The only one from the New World is almost certainly a cycad. The remaining five are all European and thus are not very likely to be bromeliads, as judged on a geographical basis, and they show no really distinctive bromeliad character in any case. Thus fossil evidence is no help in determining the evolution of the group.

Phylogeny. Without the support of any good fossil evidence, the phylogeny (evolutionary history) of the family Bromeliaceae must be inferred from morphology (form and structure) with some help from geographical distribution. It is generally agreed that primitive flowers have numerous simple free parts spirally arranged and that evolution has taken place by the reduction, specialization, and merging of these parts and their change to a whorled or opposite position of like parts. On such a basis, bromeliads, with whorled reduced flower parts, are not primitive, but neither are they very far advanced. Whether their farinose (mealy) endosperm places them above or below the family Liliaceae is purely speculation, but the separation must have been far back in the evolution of the monocotyledons.

Criteria used to determine evolutionary status in flowers

Geographical evidence is confusing when applied to the evolution of the whole family, but is clearer when correlated with its internal development. If the Bromeliaceae family is as primitive as its floral morphology would indicate, why has it not spread further in the Old World, like some of its more specialized associates, such as the families Xyridaceae (order Commelinales), Eriocaulaceae (Eriocaulales), and Commelinaceae (Commelinales)? Like the families Rapateaceae and Mayacaceae (both in the order Commelinales), it has a single species native to Africa. This spanning of the South Atlantic may be viewed as fortification of the hypothesis of continental drift, but it is doubtful if the families are old enough to have been present when the continents were supposedly joined.

It is generally agreed that within the family Bromeliaceae, evolution has developed three well-marked subfamilies, with the Pitcairnioideae the most primitive, and the Tillandsioideae and Bromelioideae derived separately from their ancestral stock, which is thought to have been not greatly different from the living genera *Fosterella*, *Puya*, and *Pitcairnia*. In *Brocchinia paniculata* the solid seed wing of the Pitcairnioideae shows a tendency to split, like the plumose seed of the Tillandsioideae; but the advanced characteristics of *Brocchinia* indicate that this must be a case of parallel evolution and not of direct descent.

Pitcairnia shows a development in the direction of the Bromelioideae, with some Amazonian species having nearly or quite inferior ovaries. They retain their appendage, however, when the ovule matures into a seed.

Arguments as to which of the two advanced subfamilies is closest to the Pitcairnioideae depend upon which characteristics are emphasized. Primitive species of *Tillandsia* have superior ovaries, appendaged seeds, and dehiscent (splitting open along definite lines) fruits, like primitive species of Pitcairnioideae. On the other hand, the subfamily Bromelioideae has spiny leaves and the same type of epidermal (surface) scales as the subfamily Pitcairnioideae.

Centres of distribution

Geographic evidence shows a centring of the primitive genera of the Pitcairnioideae and Tillandsioideae subfamilies in the northern Andes. It is almost impossible to say just which genera of the Bromelioideae are primitive, but the subfamily as a whole centres on eastern Brazil. Within genera, expansion patterns are so clear that evolution must have been very recent or is still rapidly continuing, as in *Dyckia*, in which species are very fluid and difficult to define.

CLASSIFICATION

Distinguishing taxonomic features. In the order of their importance, the distinguishing characteristics of the family Bromeliaceae are the definite number of flower parts, the form of the flower parts, the farinose character of the endosperm, and the highly evolved epidermal scales. The exact number of flower parts distinguishes them from the primitive monocotyledons. The uniformity of these parts and their lack of specialization separate them from both the higher monocots such as the orchids and from most of their immediate relatives as well. Their farinose endosperm separates them from the family Liliaceae (lilies) and related families, and finally their absorptive leaf scales are practically unique.

Annotated classification. The Bromeliaceae were very early recognized as a distinct family, and recent studies have only led to their further isolation, going from the order Farinosae in earlier classification systems to an order of their own in modern arrangements. The division into three subfamilies has been almost unanimously accepted since its first appearance in a monograph in 1896. In 1929 one authority proposed *Navia* as a fourth and most primitive group because of its lack of a seed appendage, but later studies have shown that the seed appendage is actually present in early stages and is later lost; thus, the genus is now considered to be advanced rather than primitive.

ORDER BROMELIALES

Largely herbaceous perennials, rarely shrubby, the more advanced floral types largely epiphytic. Roots usually present, but their absorptive function often taken over by the leaves. Leaves spirally arranged, usually rosulate, and with distinct sheaths and blades, bearing peltate (shieldlike) scales that serve to absorb and transmit moisture. Inflorescence simple or compound, usually bearing brightly coloured conspicuous bracts. Flowers perfect (both sexes present) or sometimes

functionally unisexual and dimorphic (male and female flowers exhibit different forms), radially symmetric or nearly so. Perianth (sepals and petals) of 2 unlike series, the sepals and petals free or connate (fused). Stamens 6 in 2 series; filaments free or variously joined. Ovary superior to inferior, 3-celled; placentae axile (ovule attachment to a central stalk in ovary). Fruit capsular or baccate. Seeds winged, plumose, or naked. Embryo small, located at the base of the copious, mealy endosperm. About 2,000 species, all but 1 confined to the New World.

Family Bromeliaceae

The only family in the order, it has the characters of the order.

Subfamily Pitcairnioideae (including Navioideae)

Usually terrestrial, herbaceous or shrubby. Leaves mostly spinose-serrate (*i.e.*, the serrations or marginal teeth end in spines). Ovary superior to (rarely) inferior. Fruit usually capsular. Seeds with entire appendages (lost in *Navia*).

Subfamily Tillandsioideae

Usually epiphytic, herbaceous. Leaves always unarmed; cells of the leaf scales symmetrical, arranged in groups of 4. Ovary usually superior. Fruit capsular. Seeds with plumose appendages.

Subfamily Bromelioideae

Largely epiphytic herbs. Leaves usually spinose-serrate. Ovary inferior. Fruit baccate. Seeds unappendaged.

Critical appraisal. It is doubtful if further research will do more than solidify subfamily lines, but there are large opportunities to clarify generic and subgeneric relationships. Studies of pollen in the subfamily Bromelioideae, for example, although necessarily limited to broad sampling, have already disclosed both correlations and contradictions. Complete studies of the substomal openings (the tissue structure in the region of the stomata, tiny openings in the leaves) in certain genera show uniformity in some and variation along species limits in others.

Brontë Family

The Brontë sisters survive as living figures in the popular imagination because their lonely and tragic lives were imbued with the same emotional intensity as the heroes and heroines of their novels. Charlotte Brontë, whose *Jane Eyre* and other novels achieved the most immediate influence, presented with frankness and ardour women in conflict with their natural desires and their social condition. Emily Brontë, the best poet of the three, wrote the fierce and tragic *Wuthering Heights*, eventually acclaimed both as the first social revolutionary novel and the predecessor of the novel of flux and sensation. And Anne Brontë, with none of her sisters' fire, has found champions to defend the quiet strength and the integrity and realism of *Agnes Grey*.

LIVES

Their father was Patrick Brontë, an Irishman from County Down, who was able to attend Cambridge despite his humble birth through his own savings and help of the Wesleyan Methodists. Allusions to Methodism are infrequent but significant in the sisters' writings, and their passion has been interpreted as a Methodist passion transferred to secular objects. Patrick Brontë took his degree in 1806. While a curate at Hartshead, Yorkshire, he met and married Maria Branwell in 1812, and there his elder daughters Maria (1813–25) and Elizabeth (1814–25) were born. He then served at Thornton, Yorkshire, where Charlotte was born on April 21, 1816; Patrick Branwell on June 26, 1817; Emily Jane on July 30, 1818; and Anne on January 17, 1820. Three months after

The Brontë sisters (left to right) Anne, Emily, and Charlotte, oil painting by P.B. Brontë (their brother) *c.* 1835. In the National Portrait Gallery, London.

Anne's birth, the father became rector of Haworth, near Bradford, Yorkshire, where he remained for the rest of his life. There Mrs. Brontë died of cancer on September 15, 1821.

Early childhoods

After Mrs. Brontë's death, her sister Elizabeth Branwell joined the household at Haworth. Branwell was her favourite, but she instructed the girls, especially in needlework, and did her duty by them. She never became close to them, however, and her austere Methodism oppressed them, especially Anne. Branwell was educated by his father, a man of marked intelligence (he published some books of poetry and miscellaneous prose and stimulated his children's intellectual interests), fond of his family but eccentric and unsocial in his habits, though a conscientious parson. Thus the children were left very much to themselves. They read whatever they could lay their hands on, including newspapers, and rambled on the moors. They were happy and very precocious, but this sequestered upbringing left the girls with a crippling shyness and deprived Branwell of the companionship of his peers, which might have proved steadying.

In 1824 the father sent Maria and Elizabeth to school at Wakefield but soon transferred them to the recently opened Clergy Daughters' School at Cowan Bridge, near Kirkby Lonsdale, Lancashire, where Charlotte and then Emily joined them. The fees were low, the food unattractive, and the discipline harsh. When Charlotte recorded her memories of this school in the Lowood of *Jane Eyre*, she was unaware of exaggerating. Her description was challenged, however, and the subject has been much debated. It is agreed that, during the months the Brontë sisters were there, the school was badly run and the girls sickly. What exaggeration existed was derived from the keen sensibilities of a highly intelligent and passionate child, who had seen her two elder sisters sicken and taken home to die, an experience that left deep traces on both Charlotte and Branwell.

Creation of fantasies

Charlotte and Emily returned home in June 1825, and for over five years the children learned and played there. There they began those sustained imaginative games that led to an enormous output of midget books written in minute script, which have attracted much attention. The four children created the imaginary Kingdom of Angria and jointly elaborated its wars, its politics, and its aristocracy and their feuds and loves. At some time, probably in 1831 when Charlotte was sent to Miss Wooler's school at Roe Head, near Huddersfield, Emily and Anne seceded and founded their own Kingdom of Gondal, leaving Charlotte and Branwell to conduct the affairs of Angria. These complex romantic sagas were kept going by the sisters well into their 20s. Negligible as literature, they

were the training ground of the Brontë genius. Themes and situations in their published works were first adumbrated there and worked on at all stages from adolescence to maturity. Many Angrian chronicles are extant, but all the Gondal prose has been destroyed. It is plain, however, from the manuscripts that many of Emily's poems are dramatic utterances of Gondal characters, and from them it has proved possible to draw a dubious outline of the lost corpus. The Angrian and Gondal daydreams have a deep psychological interest. Charlotte early recognized the compensatory nature of her dream and was troubled by guilt at the discrepancy between it and the sober, restricted life before her. There is no sign that Emily felt this division. She filled Gondal with the growing weight of her own thoughts and emotions until the fantastic husk fell off and Gondal was revealed as Yorkshire. Anne wrote Gondal verse and prose, but her novels are strictly and responsibly realistic, bearing no trace of the dream, which may have become, for her, chiefly a medium of communication with Emily. Branwell's tragedy seems to have been that he ceased to be able to distinguish between obsessive daydream and reality.

At Roe Head, where she stayed a year, Charlotte made some lasting friendships; her correspondence with one of her friends, Ellen Nussey, which continued till her death, has provided much of our knowledge of her. In 1832 she came home to teach her sisters, and for three years they lived, studied, and wrote together at Haworth. The whole family delighted in drawing, and all except Charlotte were musical. The moors, with their changes of weather and season, were their exhilarating playground. In all their books the Brontës show themselves to be country women. In 1835 Charlotte returned to Roe Head as a teacher. She wished to improve her family's position, and this was the only outlet that was offered to her unsatisfied energies. Branwell, moreover, was to start on his career as an artist, and it became necessary to supplement the family resources. Emily accompanied Charlotte as a pupil but was too homesick to remain, and her place was taken by Anne. The work, with its inevitable restrictions, was uncongenial to Charlotte. She fell into ill health and melancholia and took fright at the state of health of the always delicate Anne, who left at the end of 1837. In the summer of 1838 Charlotte terminated her engagement. Emily, who had spent six exhausting months as teacher in Miss Patchett's school at Law Hill near Halifax, had also resigned her post, and the sisters were at home again.

In 1839 Charlotte declined a proposal from the Rev. Henry Nussey, her friend's brother, and some months later one from another young clergyman. She and Anne also made brief and unsuccessful experiments as governesses in 1839. The hardships and anomalies of the position are reflected in their novels and impressed public opinion, but it is doubtful if Charlotte, touchy and inhibited by her duties from imaginative creation, could ever have been contented in such a post. Anne endured better and presently established herself with the Robinsons at Thorpe Green, near Boroughbridge, Yorkshire, where she stayed for four years (1841–45). At the same time Charlotte's ambition to make the practical best of her talents and the need to pay Branwell's debts urged her to spend some months as governess with the Whites at Upperwood House, Rawdon. Branwell's talents for writing and painting, his good classical scholarship, and his social charm had engendered high hopes for him. He had sent specimens of his writing to Wordsworth but had received no encouragement; Charlotte, at about the same time (January 1837), had had a similar experience with Robert Southey. At the end of 1837 Branwell had set up as a portrait painter in Bradford and had worked steadily for a year; but he was fundamentally unstable, weak willed, and intemperate, and the venture collapsed. After six months as a tutor in Broughton-in-Furness, he was working as clerk in charge at Sowerby Bridge on the Leeds and Manchester Railway (September 1840) and from there was transferred to Luddenden Foot but was dismissed in January 1842 for culpable negligence.

Meanwhile his sisters had planned to open a school together, which their aunt had agreed to finance, and in February 1842 Charlotte and Emily went to Brussels as pupils to improve their qualifications in French and acquire some German. Emily also studied and later taught the piano. The talent displayed by both brought them to the notice of Constantin Héger, a fine teacher and a man of unusual perception. Charlotte was on the whole happy, though as a staunch Protestant she despised her Catholic surroundings. Emily, while working with stubborn resolution, pined for the liberty of home. The death of Miss Branwell in October summoned them to Haworth. She had bequeathed each of her nieces a sum that may have amounted to £300 (specification is lacking), but they put their money aside for a greater need. Emily remained at Haworth to keep house while Branwell joined Anne as tutor at Thorpe Green and Charlotte returned to Brussels as pupil-teacher. She stayed there during 1843 but was lonely and depressed. Her friends had left Brussels, and Madame Héger appears to have become jealous of her. The nature of Charlotte's attachment to Héger and the degree to which she understood herself have been much discussed. His was the most interesting mind she had yet met, and he had perceived and evoked her latent talents. His strong and eccentric personality appealed both to her sense of humour and to her affections. She offered him an innocent but ardent devotion, but he tried to repress her emotions. The letters she wrote to him after her return may well be called love letters. When, however, he suggested that they were open to misapprehension, she stopped writing and applied herself, in silence, to disciplining her feelings. Shirley's indignation at Moore's assumption that she loves him (in Charlotte's novel *Shirley*) may well reflect part of the author's reaction. However they are interpreted, her experiences at Brussels were crucial for her development. She received a strict literary training, became aware of the resources of her own nature, and gathered material that served her, in various shapes, for all her novels.

Education in Brussels

In 1844 Charlotte attempted to start a school she had long envisaged in the parsonage itself, as her father's failing sight precluded his being left alone. Prospectuses were issued, but no pupils were attracted to distant Haworth. In 1845 Anne left the Robinsons, and soon afterward Branwell was dismissed, charged with making love to his employer's wife. The sisters believed the fault lay with Mrs. Robinson. Charlotte transmitted this view to Elizabeth Gaskell, the novelist, who embodied it in the first edition of her *Life of Charlotte Brontë* (1857) but was forced by Mrs. Robinson's representatives to withdraw and apologize for the passages in question. Whatever happened, it finished Branwell. He spent the last three years of his life at Haworth, incurring debts, drinking, taking opium, alternately blaspheming and repenting until he died of his excesses—a profound grief to his father and sisters, an obstacle to his sisters' hopes, and a great and tragic stimulus to their genius.

In the autumn of 1845 Charlotte came across some poems by Emily, and this led to the publication in 1846 of a joint volume of *Poems by Currer, Ellis and Acton Bell;* the pseudonyms were assumed to preserve secrecy and avoid the special treatment they believed reviewers accorded to women. The book was issued at their own expense. It received few reviews and only two copies were sold. Nevertheless, a way had opened to them, and they were already trying to place the three novels they had written. By midsummer of 1847 Emily's *Wuthering Heights* and Anne's *Agnes Grey* had been accepted for publication by T.C. Newby, but Charlotte had failed to place *The Professor.* She had, however, nearly finished *Jane Eyre,* begun in August 1846 in Manchester where she was staying with her father, who had gone there for an eye operation. When Smith, Elder and Company, declining *The Professor,* declared themselves willing to consider a three-volume novel with more action and excitement in it, she completed and submitted it at once. It was accepted, published less than eight weeks later (on Oct. 16, 1847), and had an immediate success. In December Newby brought out *Wuthering Heights* and *Agnes Grey,*

First publications

and in June 1848 Anne's *Tenant of Wildfell Hall*, which sold well. Reviewers had already suggested that *Wuthering Heights* was an earlier work by Currer Bell, Charlotte's pseudonym. Now Newby offered the American rights of *The Tenant* as by the author of the successful *Jane Eyre*, and in July Charlotte and Anne were forced to go to London to acknowledge their identities to their publisher.

The year that followed was a tragic one. On September 24 Branwell died. Emily caught cold at his funeral, came down with acute tuberculosis, refused all medical help, and died on December 19. Immediately afterward Anne, Emily's closest friend, sickened of the same disease; Charlotte put aside *Shirley*, on which she was working, to nurse her. Anne submitted dutifully to treatment but died on May 28, 1849, at Scarborough. Charlotte completed *Shirley* in the empty parsonage, and it appeared in October. In 1850 Smith, Elder and Company republished *Wuthering Heights* and *Agnes Grey* with Charlotte's "Biographical Notice" of her sisters. In the following years Charlotte went three times to London as the guest of her publisher, George Smith, and his mother, met Thackeray and other literary men and women, and sat for her portrait by George Richmond. She went twice to the Lake Country, where she stayed in 1851 with Harriet Martineau, the writer, went to Scotland, and visited Mrs. Gaskell in Manchester and entertained her at Haworth. *Villette* came out in January 1853. Meanwhile, in 1851, she had declined a third offer of marriage, this time from James Taylor, a member of Smith, Elder and Company. Her father's curate, Arthur Bell Nicholls (1817–1906), an Irishman, was her fourth suitor. It took some months to win her father's consent, but they were married on June 29, 1854, in Haworth church. They spent their honeymoon in Ireland and then returned to Haworth, where her husband had pledged himself to continue as curate to her father. He did not share his wife's intellectual life, but she was happy to be loved for herself and to take up her duties as his wife. She began another book, *Emma*, of which some pages remain. Her pregnancy, however, was accompanied by exhausting sickness, and she died on March 31, 1855. Nicholls stayed in Haworth until Patrick Brontë's death in 1861, when he went back to Ireland.

ASSESSMENT

The absorbing personal history of the Brontë family has stimulated many writers. Haworth is a place of pilgrimage and Haworth parsonage a Brontë museum. Plays and novels have been written about them. Each of the family has had partisans and, in the attempt to define their distinct natures, the close bonds of temperament, conviction, imagination, and pooled experience have sometimes been undervalued. Emily, the least known and praised in her lifetime, has proved the most interesting for modern biographers and critics. There has been a corresponding tendency to withhold justice from Charlotte as a writer and a woman. Yet without Charlotte's ambition we should not have had Emily's writings. Her editing of them, now under censure, was aimed at removing obstacles between the contemporary reading public and work that she deeply admired. In what she wrote of her sisters, she had it in mind to defend their "dear names" against the charges of coarseness and brutality that had been launched at their novels.

Emily's poems, often unfinished and very unequal, show the influence of Scott and the Border ballads but at their rare best transmit the flavour of a unique and powerful personality. She had a strong lyrical note, a beautifully spontaneous and flexible metre, and, at her best, a powerful and precise—though limited—diction. Her work on *Wuthering Heights* cannot be dated, and she may well have spent a long time on this intense, solidly imagined novel. It is distinguished from other novels of the period by its dramatic and poetic presentation, its abstention from all comment by the author, and its unusual structure. It recounts in the retrospective narrative of an onlooker, which in turn includes shorter narratives, the impact of the waif Heathcliff on the two families of Earnshaw and Linton in a remote Yorkshire district at the end of the 18th century. Embittered by abuse and by the marriage of Cathy Earnshaw—who shares his stormy nature and whom he loves—to the gentle and prosperous Edgar Linton, Heathcliff plans a revenge on both families, extending into the second generation. Cathy's death in childbirth fails to set him free from his love–hate relationship with her, and the obsessive haunting persists until his death; the marriage of the surviving heirs of Earnshaw and Linton restores peace.

Wuthering Heights

The way the tale begins at the 11th hour may derive from French classical tragedies that Emily read in Brussels. The method of direct narrative, heard in oral storytellers, is used with deliberate effect to recount an action that culminates through two generations, for which the model may have been Shakespeare's later romantic plays. There is no confusion, though some awkwardness. Everything is thoroughly worked out. Sharing her sisters' dry humour and Charlotte's violent imagination, she diverges from them in making no use of the events of her own life and showing no preoccupation with a spinster's state or a governess's position. Working, like them, within a confined scene and with a small group of characters, she constructs an action, based on profound and primitive energies of love and hate, which proceeds logically and economically, making no use of such coincidences as Charlotte relies on, requiring no rich romantic similes or rhetorical patterns, and confining the superb dialogue to what is immediately relevant to the subject. The sombre power of the book and the elements of brutality in the characters affronted some 19th-century opinion. Its supposed masculine quality was adduced to support the claim, based on the memories of Branwell's friends long after his death, that he was author or part author of it. While it is not possible to clear up all the minor puzzles, neither the external nor the internal evidence offered is substantial enough to weigh against Charlotte's plain statement that Emily was the author or a reference to Branwell's extant writings. Modern interest in myth and symbol has stimulated fresh approaches. Lord David Cecil (*Early Victorian Novelists*, chapter 5, 1934) regards Emily's characters as types of the cosmic forces of storm and calm, which replace the principles of good and evil; both are good in their proper relations, but tragedy results from their mismating. A widely different approach has been made by David Wilson ("Emily Brontë: First of the Moderns," *Modern Quarterly Miscellany*, number 1, 1947), who interprets the story of Heathcliff and Catherine Earnshaw as a metaphor of the social struggle going on in the turbulent Pennine district under Emily's eyes—a struggle in which she saw evil and degradation on both sides. This illuminating suggestion has been carried further by other writers who insist on Emily's conscious social passion. These studies give a new dimension to the book but should not obscure the depth of her imaginative response to the wild and remote nor the fact that what matters most to her is the freedom and energy, in love and hate, of the individual human spirit. *Wuthering Heights* masters the reader by its passion and fullness of meaning; its rapid, concrete presentation; its resonant, concise dialogue; and the courage, unparalleled in the contemporary novel, with which it accepts the tragic logic of its assumptions. It is not a flawless masterpiece, but it is unexhausted.

Critical interpretations

Anne is commonly described as gentle and pious. In chaste and shapely verse she examines her thoughts and feelings in the light of moral and religious truth. Her novel *Agnes Grey*, probably begun at Thorpe Green, records with limpidity and some humour the life of a governess. George Moore called it "simple and beautiful as a muslin dress." *The Tenant of Wildfell Hall* presents an unsoftened picture of a young man's debauchery and degradation and sets against it her Arminian belief, opposed to Calvinist predestination, that no soul shall be ultimately lost. Her outspokenness raised some scandal, and Charlotte deplored the subject as morbid and out of keeping with her sister's nature, but the vigorous writing indi-

cates that Anne found in it not only a moral obligation but also an opportunity of artistic development.

Charlotte's first novel, *The Professor* (published posthumously, 1857), shows her extreme reaction from the Angrian indulgences of her girlhood. Sober in colouring and discreet in action, it is nevertheless satirically lively and, like all her fiction, prickles with personality. Told in the first person by an English tutor in Brussels, it is based on Charlotte's experiences there, with a reversal of sexes and roles. The necessity of her genius, reinforced by reading her sister's *Wuthering Heights*, modified this restrictive self-discipline; and, though there is plenty of satire and dry, direct phrasing in *Jane Eyre*, what carried it to success was the fiery conviction with which it presented a thinking, feeling woman, craving for love but able to renounce it at the call of impassioned self-respect and moral conviction. Jane Eyre, an orphan and governess to the ward of Mr. Rochester, falls in love with her Byronic and enigmatic employer. Her love is reciprocated, but on the wedding morning it comes out that Rochester is a married man and keeps a mad and depraved wife in the attics of his mansion. Jane leaves him, suffers hardship, and finds work as a village schoolmistress. When Jane learns, however, that Rochester has been maimed and blinded, trying vainly to rescue his wife from the burning house she set afire, Jane seeks him out and marries him. There are melodramatic naïvetés in the story, and Charlotte's elevated rhetorical passages—though genuine and powerful in their kind—do not much appeal to modern taste, but she maintains her hold on the reader. The novel is subtitled *An Autobiography*, and Charlotte follows Anne in putting her tale in the mouth of a governess, but, except in Jane's impressions of Lowood, the autobiography is not Charlotte's. Personal experience is fused with suggestions from widely different sources and the Cinderella theme may well come from Samuel Richardson's *Pamela*. The action is carefully motivated, and apparently episodic sections, like the return to Gateshead Hall, are seen to be necessary to the full expression of Jane's character and the working out of the threefold moral theme of love, independence, and forgiveness. The landscape background, geared closely to the phases of the action, carries into the novel a lyricism only partially anticipated by Ann Radcliffe and Sir Walter Scott.

Charlotte intended *Shirley* to be "real, cool and solid," avoided melodrama and coincidences, and widened her scope. Setting aside Maria Edgworth and Scott as national novelists, *Shirley* is the first regional novel in English, full of shrewdly depicted local material—Yorkshire characters, church and chapel, the cloth workers and machine breakers of her father's early manhood, and a sturdy but rather embittered feminism. It is not, however, easy to elicit a dominant theme. Of her two heroines, Shirley, on Mrs. Gaskell's authority, was a "representation" of Emily in ampler circumstances, and Caroline, at least in some parts, approximates Anne. While Charlotte was writing, both sisters died, and it is arguable that the course of the novel was diverted. Caroline, who in the earlier chapters seems marked for the spinsterhood that was so much in Charlotte's and Anne's minds, is dismissed to married happiness, while Louis Moore, abruptly introduced in the last third of the book, carries out with Shirley the master–pupil love relationship that occurs in all Charlotte's novels.

Villette In *Villette* she recurs to the Brussels setting and the first-person narrative, disused in *Shirley;* the characters and incidents are largely variants of the people and life at the Pension Héger. Against this background she sets the ardent heart, deprived of its object, contrasted with the woman happily fulfilled in love. The action is seen through the personality of the sober-seeming governess Lucy Snowe, whose struggle for detachment stimulates the reader to attain it. Charlotte said her heroine was morbid and unamiable and refused to divert tragedy from her but allowed her to achieve a useful and honourable independence.

The influence of Charlotte's novels was much more immediate than that of *Wuthering Heights*, which was described for many years as without posterity. Charlotte's combination of romance and satiric realism had been the mode of nearly all the women novelists for a century. Her fruitful innovations were the presentation of a tale through the sensibility of a child or young woman—in which Dickens followed her; her lyricism—in which the genius of romantic poetry entered the novel; and the picture of love from a woman's standpoint—with which she unwittingly startled a section of Victorian opinion. The two sides of her nature were never fully harmonized and this results in what Virginia Woolf called the "jerking of the planes." Her special mastery lies in her intense participation in her story and its transmission to readers.

MAJOR WORKS

POETRY: *Poems by Currer, Ellis and Acton Bell* (1846). Separate editions of the *Complete Poems* of Charlotte and Anne Brontë were published in 1923 and of Emily Brontë in 1924.

NOVELS: CHARLOTTE BRONTE (pseudonym Currer Bell): *Jane Eyre: An Autobiography*, ed. by Currer Bell, 3 vol. (1847); *Shirley: A Tale*, 3 vol. (1849); *Villette*, 3 vol. (1853); *The Professor: A Tale* (1857); *Emma* (1860), a fragment, published in *The Cornhill Magazine.*

EMILY BRONTE (pseudonym Ellis Bell): *Wuthering Heights*, 2 vol. (1847).

ANNE BRONTE (pseudonym Acton Bell): *Agnes Grey* (1847); *The Tenant of Wildfell Hall*, 3 vol. (1848).

BIBLIOGRAPHY. LIONEL STEVENSON, "The Brontës," in the *New Cambridge Bibliography of English Literature*, vol. 3, pp. 864–873 (1969), lists bibliographies, collections and composite works, editions, and critical and biographical books and articles from 1846 to 1966.

Manuscripts: Letters and literary manuscripts of the Brontës are preserved in the following centres in England: Brontë Parsonage Museum, Haworth; British Museum; the libraries of Manchester and Leeds universities; Fitzwilliam Museum Library, Cambridge; and in the United States: the Berg Collection, New York Public Library; Harry Elkins Widener Memorial Library, Harvard University; Wren Library, Texas University; Henry F. Huntingdon Library and Art Gallery, San Marino, California; J. Pierpont Morgan Library, New York City; and the Bonnell Collection, Philadelphia.

Editions: The best working edition is *The Shakespeare Head Brontë*, 19 vol. (1932–38).

Biography and criticism: E.C. GASKELL, *The Life of Charlotte Brontë*, 2 vol. (1857, many later editions), raised controversy and was modified in the third edition. It is indispensable. See MARGARET LANE, *The Brontë Story: A Reconsideration of Mrs. Gaskell's Life of Charlotte Brontë* (1953, reprinted 1971). The Haworth edition, *The Life and Works of Charlotte Brontë and Her Sisters*, 7 vol. (1899–1900), was edited by C.K. SHORTER and H. WARD, who had access to material in the hands of Mr. Nicholls and published all of Charlotte's available letters in C.K. SHORTER, *The Brontës: Life and Letters*, 2 vol. (1908). The first supplement, however, was provided by T. WEMYSS REID in *Charlotte Brontë: A Monograph* (1877). During the 20th century a formidable body of biographical and critical investigation and assessment appeared. The publication *in extenso* of the early writings began with *Legends of Angria*, ed. by FANNIE E. RATCHFORD and W. CLYDE DE VANE (1933), and Miss Ratchford has studied them in *The Brontës' Web of Childhood* (1941) and *Gondal's Queen* (1955). The Brontë manuscripts have yielded fresh verse by Emily and Anne, and their complete poems have been published. The first biography of Emily by A.M.F. ROBINSON, *Emily Brontë* (1883), to which Ellen Nussey contributed information but did not approve the conclusions, was followed by ROMER WILSON, *All Alone: The Life and Private History of Emily Jane Brontë* (1928); MURIEL SPARK and DEREK STANFORD, *Emily Brontë: Her Life and Work* (1953); JACQUES BLONDEL, *Emily Brontë* (1955); and JOHN HEWISH, *Emily Brontë* (1969). Other studies include: ADA HARRISON and DEREK STANFORD, *Anne Brontë: Her Life and Work* (1959); and WINIFRED GERIN, *Anne Brontë* (1959), *Branwell Brontë* (1961), *Charlotte Brontë* (1967), and *Emily Brontë* (1971). *The Clue to the Brontës* by G. ELIZABETH HARRISON (1948), follows up the Brontës' Methodist connections. The Brontë Society publications (1895–) include biographical, topographical, and critical contributions. The following studies are important: MAY SINCLAIR, *The Three Brontës* (1912); E. DIMNET, *Les Soeurs Brontë* (1910; Eng. trans., *The Brontë Sisters*, 1927); IRENE COOPER WILLIS, *The Authorship of Wuthering Heights* (1936); LAURA L. HINKLEY,

The Brontës, Charlotte and Emily (1945); PHYLLIS E. BENTLEY, *The Brontës* (1947) and *The Brontë Sisters* (1950); LAURENCE and E.M. HANSON, *The Four Brontës* (1949); INGA STINA EWBANK, *Their Proper Sphere: A Study of the Brontë Sisters As Early-Victorian Female Novelists* (1966); and W.A. CRAIK, *The Brontë Novels* (1968).

(J.M.S.T.)

Brown, Robert

Robert Brown is best known for establishing the concept of the continuous motion of minute particles suspended in a fluid, the Brownian movement, as a property of both organic and inorganic matter. In addition, he recognized the fundamental distinction between the conifers and their allies (gymnosperms) and the flowering plants (angiosperms), recognized and named the nucleus as a constant constituent of living cells in most plants, and improved the natural classification of plants by establishing and defining new families and genera. He contributed substantially to knowledge of plant morphology, embryology, and geography, in particular by his original work on the flora of Australia.

Brown, drawing by W. Brockedon, 1849. In the National Portrait Gallery, London.

Brown was born on December 21, 1773, at Montrose, Scotland, the son of a Scottish Episcopalian clergyman. He studied medicine at the universities of Aberdeen and Edinburgh and, at the age of 21, joined the British Army as an ensign and assistant surgeon. During the five years his regiment spent in Ireland, he divided his time between his official medical duties and self-education.

A visit to London in 1798 brought Brown to the notice of Sir Joseph Banks, president of the Royal Society, whose herbarium at Soho Square contained many Australian plants that, together with his rich botanical library, were readily accessible to visiting scientists. Banks had travelled with Capt. James Cook on the 1768–71 voyage of the "Endeavour" and had thereby acquired a lasting interest in New Holland, as Australia was then called. By December 1800, the Admiralty had prepared plans for a surveying voyage along the northern and southern coasts of Australia under the command of Matthew Flinders. Impressed by Brown's enthusiasm and abilities, Banks recommended him for the post of naturalist aboard Flinders' ship, "Investigator."

Expedition to Australia

Brown promptly accepted and sailed with the expedition on July 18, 1801. A duplicate set of herbarium specimens of Australian plants given him by Banks enabled him to obtain an intimate knowledge of many plants of Australia before his arrival there. The "Investigator" reached King George's Sound, Western Australia, an area of great floristic diversity, on December 8, 1801. Until June 8, 1803, and while the ship circumnavigated Australia, Brown made extensive plant collections, which were portrayed by the great botanical artist Ferdinand Bauer.

Returning to England on October 13, 1805, Brown devoted his time to classifying the approximately 3,900 species he had gathered. The results of his Australian trip were partially published in 1810 as his *Prodromus Florae Novae Hollandiae . . .*, a classic of systematic botany and his major work, which contains much information relevant to plant taxonomy as a whole. Disappointed by its small sale, however, he published only one volume. Brown's close observation of minute but significant details was also shown in his publication on *Proteaceae*, in which he demonstrated how pollen-grain characters could assist the definition of genera. In 1810 Banks appointed Brown as his librarian and in 1820 bequeathed him a life interest in his collections. Brown transferred them to the British Museum in 1827, when he became keeper of its newly formed botanical department.

In 1828 he published a pamphlet, *A Brief Account of Microscopical Observations . . .*, in which he recorded that, after having noticed moving particles within living pollen grains of *Clarkia pulchella*, he examined both living and dead pollen grains of many other plants and found similar particles. Experiments with organic and inorganic substances, reduced to powder and suspended in water, then revealed such motion to be a general property of matter in that state. This phenomenon has long been known as Brownian movement (*q.v.*). In 1831, while dealing with the fertilization of *Orchidaceae* and *Asclepiadaceae*, he noted the existence of a structure within cells that he termed the nucleus of the cell. These observations testify to the range and depth of his pioneering microscopical work and his ability to draw far-reaching conclusions from isolated data or selected structures.

Brownian movement and the cell nucleus

Brown died in London on June 10, 1858.

BIBLIOGRAPHY. There is no definitive biography but J.B. FARMER, "Robert Brown, 1773–1858," in F.W. OLIVER (ed.), *Makers of British Botany*, pp. 108–125 (1912); and W.T. STEARN, "Brown, Robert," in the *Dictionary of Scientific Biography*, vol. 2, pp. 516–522 (1970), provide concise outlines of his career and major scientific achievements.

(W.T.S.)

Brownian Movement

Brownian movement is a term used to describe many physical phenomena in which some quantity is constantly undergoing small, random fluctuations. The oldest example, described by the discoverer, Scottish botanist Robert Brown, in 1827, is the motion of microscopic particles suspended in a liquid or gas. In 1900 L. Bachelier published his "Théorie de la Speculation," in which the variation of prices on the Paris Bourse was analyzed in terms of random fluctuations. Bachelier's work anticipated many results obtained decades later by physicists and mathematicians.

Examples of Brownian movement. A homely example of Brownian movement is the relative position of one individual within a stream of pedestrians moving along a sidewalk. His position will undergo random fluctuations; over a period of time, he may gradually drift toward the front or the back or the centre of the stream. In biology the size of a large population of any living organism undergoes constant fluctuations as individuals are born and die, and, therefore, a gradual increase or decrease may be studied as an example of Brownian motion. Any electrical instrument is subject to random fluctuations in input, for example, because of unpredictable variations in the electrical current. These variations can result in an oscillation or Brownian motion of the output, or dial reading, of the instrument, so that the theory of Brownian motion is not only important in electrical engineering but also imposes limitations on the attainable accuracy of scientific measurements.

Basic process

If a number of particles subject to Brownian movements are present in a medium and there is no preferred direction for the random oscillations, then over a period of time the particles will tend to be spread evenly throughout the medium. Thus, if A and B are two adjacent regions and, at time t, A contains twice as many particles as B, at that instant the probability of a particle

leaving A to enter B is twice as great as the probability that a particle will leave B to enter A. A physical process in which a substance tends to spread steadily from regions of high concentration to regions of lower concentration is called diffusion. Thus, diffusion is a macroscopic manifestation of Brownian motion on the microscopic level. As a consequence, it is possible to study diffusion by simulating the motion of a Brownian particle and computing its average behaviour; this example illustrates the Monte Carlo method that has been made possible by high-speed computing machines. A few examples of the countless diffusion processes that are studied in terms of Brownian motion include the diffusion of pollutants through the atmosphere, the diffusion of "holes" (minute regions in which the electrical charge potential is positive) through a semiconductor, and the diffusion of calcium through bone tissue in living organisms.

History of explanations. By "classical Brownian motion" is meant the random movement of microscopic particles suspended in a liquid or gas. Brown was investigating the fertilization process in *Clarkia pulchella*, a newly discovered species of flower, when he noticed a "rapid oscillatory motion" of the pollen grains suspended in water under the microscope. Others had noticed this phenomenon (Georges de Buffon [1707–88] and Lazzaro Spallanzani [1729–99] appear to have been aware of it), but Brown was the first to study it. Initially, he believed that such activity was peculiar to the male sexual cells of plants, but then he was startled to observe that pollen of plants dead for over a century showed the same movement, and he called this a "very unexpected fact of seeming vitality being retained by these 'molecules' so long after the death of the plant." Further study revealed that the same motion could be observed not only with particles of other organic substances but even with chips of glass or granite or particles of smoke.

Early explanations attributed the motion to thermal convection currents in the fluid. When observation showed that nearby particles exhibited totally uncorrelated activity, however, this simple explanation was abandoned. By the 1860s theoretical physicists had become interested in Brownian movement and were searching for a consistent explanation of its various characteristics: a given particle appeared equally likely to move in any direction, further motion seemed totally unrelated to past motion, and the motion never stopped. An experiment (1865) in which a suspension was sealed in glass for a year, showed that the Brownian motion remained unchanged. More systematic investigation in 1889 determined that small particle size and low viscosity of the surrounding fluid resulted in faster motion.

Since higher temperature (Figure 1) also led to more rapid Brownian motion, in 1877 it was suggested that its cause lay in the "thermal molecular motion in the liquid environment." The idea that molecules of a liquid or gas are constantly in motion, colliding with each other and bouncing back and forth, is a prominent part of the kinetic theory of matter developed in the third quarter of the 19th century by the physicists J.C. Maxwell, L. Boltzmann, and R.J.E. Clausius in explanation of heat phenomena.

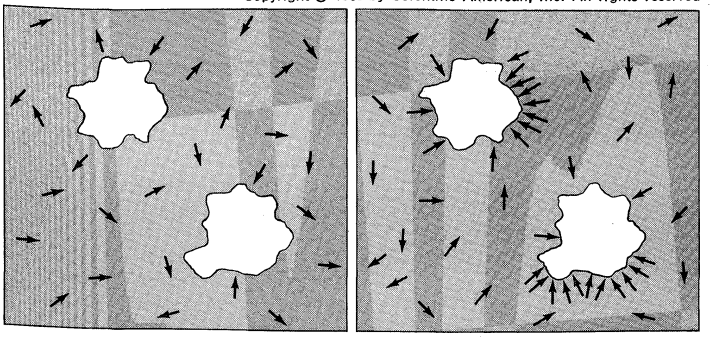

Figure 1: (Left) Random motion of a Brownian particle. (Right) Random discrepancy between the molecular pressures on different surfaces of the particle that cause motion.

According to the theory, the temperature of a substance is proportional to the average kinetic energy with which the molecules of the substance are moving or vibrating (any body in motion has kinetic energy). It was natural to guess that somehow this motion might be imparted to larger particles that could be observed under the microscope; if true, this would be the first directly observable effect that would corroborate the kinetic theory. This line of reasoning led Albert Einstein in 1905 to produce his quantitative theory of Brownian motion. Similar studies were carried out on Brownian movement, independently and almost at the same time, by M. Smoluchowski, who used methods somewhat different from Einstein's, and the contributions of both have been fundamentally important in subsequent developments.

Einstein's calculations

Calculations. Einstein wrote later that his major aim was to find facts that would guarantee as much as possible the existence of atoms of definite finite size. In the midst of this work, he discovered that, according to atomistic theory, there would have to be an observable movement of suspended microscopic particles. Einstein did not realize that observations concerning the Brownian motion were already long familiar.

Reasoning on the basis of statistical mechanics, Einstein showed that for such a microscopic particle the random difference between the pressure of molecular bombardment on two opposite sides would cause it constantly to wobble back and forth. A smaller particle, a less viscous fluid, and a higher temperature each would increase the amount of motion one could expect to observe. Over a period of time, the particle would tend to drift from its starting point, and on the basis of kinetic theory it is possible to compute the probability (P) of a particle moving a certain distance (x) in any given direction (the total distance it moves will be greater than x) during a certain time interval (t) in a medium whose coefficient of diffusion (D) is known, D being equal to one-half the average of the square of the displacement in the x-direction. This formula for probability "density" allows P to be plotted against x. The graph is the familiar bell-shaped Gaussian "normal" curve (Figure 2), which typically arises when

From R. Hersh and R. Griego, "Brownian Motion and Potential Theory."

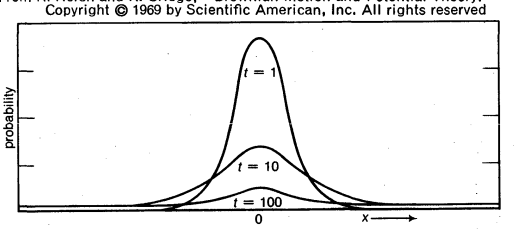

Figure 2: Bell-shaped curves showing probable position of a Brownian particle. The horizontal axis of the graph denotes the distance travelled in a given direction, assuming that at a time $t = 0$ the particle is at point $x = 0$. The vertical axis measures the probability that the particle will be at any given point (x) at time $t = 1$, 10, and 100 seconds, respectively, for the three curves.

the random variable is the sum of many independent, statistically identical random variables, in this case, the many little pushes that add up to the total motion. The equation for this relationship is

$$P = \frac{e^{-x^2/4Dt}}{2\sqrt{\pi Dt}}.$$

Each value of t gives us a different graph for P and x. For increasing values of t, the graphs become flatter and more spread out because the longer the elapsed time the greater the likelihood that the particle will travel far from its starting point. On the other hand, for any t, the point $x = 0$ always has the greatest probability density, since the particle is likelier to be near its starting point than near any other particular point. One formula obtained by Einstein shows that the diffusion of a particle is speeded by a rise in temperature and by a reduction in the size of the particle and in the viscosity of the liquid. The com-

plete equation for the coefficient of diffusion, D, is

$$D = \frac{RT}{6\pi N_A \eta r},$$

in which R is the universal gas constant, T is absolute temperature, η is the viscosity of the liquid, r is the radius of the particle (assumed to be a sphere), and N_A is Avogadro's number (the number of molecules in a gram-molecular weight of gas). Einstein invited the experimentalists to subject his calculations to the test.

Perrin's experiments

The introduction of the ultramicroscope in 1903 aided quantitative studies by making visible small colloidal particles whose greater activity could be measured more easily. R. Zsigmondy (1905) and T. Svedberg (1911) made important measurements of this kind. J. Perrin was successful in verifying Einstein's analysis, and for this work he was awarded the Nobel Prize for Physics in 1926. Perrin's most famous accomplishment was the application of Einstein's formula to compute Avogadro's number, N_A. In order to do this, it was necessary to know D and r as accurately as possible; the other quantities in the formula are easily measurable or are well-known universal constants. To determine D, Perrin used an automatic camera to record the positions of a particle at 30-second intervals. Squaring the successive displacements along each axis, averaging, and dividing by two, one obtains an experimental value for D. To control r, he used a technique of fractional centrifuging to obtain highly uniform particles. Their size could be determined by coagulating them into chains whose length could be accurately measured and whose links could be counted. A second determination of Avogadro's constant was made by studying rotational Brownian movement—that is, the random change in spatial orientation, that is, rotation, of a particle because of molecular bombardment. Einstein derived a formula that determines the average of the square of the rotation per unit time ($RT/4\pi N_A \eta r^3$). To check this formula, it was necessary to use particles so large that they could be observed under an ordinary microscope, for the ultramicroscope shows each suspended particle only as a speck of light, not as a solid object. Perrin used particles of mastic, a natural gum, about $\frac{1}{2,000}$ inch in diameter, with occlusions of foreign matter below their surfaces as index marks. Thus he was able to observe the rotational motion of the particles, finding an average rotation of 14.5° per minute, as compared with a theoretical value of 14°. Perrin obtained no less than four independent measurements of Avogadro's number. His work established the physical theory of Brownian motion and ended the skepticism about the existence of atoms and molecules as actual physical entities.

Wiener's theory

Although Perrin's experiments confirmed the physical theory of Brownian motion, from a mathematical viewpoint there were still grave difficulties to be faced. While the expected displacement of a Brownian particle could be explained by the Einstein–Smoluchowski theory, this was far from true with respect to the random motion of an individual particle. Such a motion was in some sense chosen at random from a certain set of possible motions. To explain precisely what was meant by choosing at random from the uncountably infinite set of possible motions was a mathematical challenge of major proportions. The U.S. mathematician Norbert Wiener in 1918 and following years gave the first rigorous meaning to the notion of a random motion or a random curve. An idea of what is involved can be obtained by supposing that only finitely many speeds are permitted, and changes in speed are permitted only at multiples of a fixed time interval. Then only finitely many polygonal paths would be possible, and evidently one could in some appropriate way assign a probability to each path, with a total probability of one. If a small enough time interval is chosen and a large enough collection of possible speeds, then any continuous motion can be approximated by one of the finitely many polygonal motions. But to use this idea to assign probabilities to the set of all continuous paths is far from easy. Wiener set up a mathematical model satisfying the following laws:

(1) For each time t greater than 0, there is given a random variable $X(t)$, which is "normally distributed" (*i.e.*, the probability that $X(t)$ is between any two numbers a and b equals the area bounded by a bell-shaped curve, the lines $x = a$, $x = b$, and the X-axis).

(2) At time $t = 0$ the value of X is 0.

(3) At all future times t, the expected (mean) value of the random variable X is 0.

(4) If (t_1,t_2) and (t_3,t_4) are any two nonoverlapping time intervals, then the increment $x(t_2) - x(t_1)$ is independent of the increment $x(t_4) - x(t_3)$.

It should be clear that such a stochastic (random) process is a mathematical idealization of physical Brownian motion. The first and greatest difficulty that had to be overcome in Wiener's theory was to establish that such a family $x(t)$ actually exists—that is, to establish that the assumptions (1) to (4) are not contradictory. Wiener's original proof has subsequently been simplified and modernized by several authors. From assumptions (1) to (4) it can be shown that a single parameter, σ^2, suffices to determine completely the properties of a Wiener process. In the interpretation of the Wiener process as physical Brownian motion, σ^2 is the mean square displacement of the particle per unit time and equals twice the diffusivity of the medium. For some applications the assumption (3) has to be modified. If, for example, it be supposed that a Brownian particle, in addition to its random oscillation, undergoes a steady drift due to some constant force such as gravity, then, if the X-axis is vertical, the expected position at time t will be μt, where the constant μ is the distance the particle is pulled in unit time by the force field.

One of Wiener's most striking results was his theorem that the random path $X(t)$ is almost certain to be continuous but nowhere smooth. That is, its graph has a sharp corner at every time t. This mathematical result had been foreshadowed by Perrin's comment that the erratic paths of the particles he watched reminded him of the weird, continuous, but nowhere differentiable curves of the pure mathematicians.

Other properties of the paths in Wiener's process are less appealing to the intuition. It turns out that, with probability one, the particle traverses an infinite distance in every finite time interval, however short. This is nothing more than an inevitable consequence of the hypothesis; the trouble is that, on a very small time scale, the hypothesis of independent increments is physically unrealistic. (The next push occurs before viscosity has quite had time to damp out the last push.) The physicists L. Ornstein and G. Uhlenbeck in 1930 developed a more refined model for Brownian motion, in which velocities remain finite, although accelerations are still infinite.

The mathematics of Brownian motion has had a great influence in quantum mechanics. The path integral method of R. Feynman uses a formalism closely analogous to the computation of the probability of sets of continuous curves in Wiener's theory.

In pure mathematics the study of stochastic processes is now a major subject. The Wiener process continues to occupy a central role in this study, and mathematicians have contributed to the subject, which has established profound connections between probability, differential equations, and functional analysis.

Browning, Robert

Although his popularity has fluctuated, Robert Browning remains one of the great poets of the Victorian Age. His

poetic genius is most evident in his mastery of the dramatic monologue as a technique for powerful poetic narrative and rich psychological portraiture.

Robert Browning, photograph by Julia Margaret Cameron.

Life. Browning was born on May 7, 1812, at Camberwell in southeast London. His father, a clerk in the Bank of England, could afford to indulge his artistic and literary tastes and had a large and varied collection of books, which he encouraged his son to explore. Thus, in his youth Browning's reading was unsystematic but exceptionally wide, especially in the drama and in works of history and scholarship. It was in his father's library that he acquired the extraordinary range of interests that was to distinguish his writing; an even more powerful immediate effect was exerted by a volume of Shelley's lyrics that he read in 1826. Following Shelley's example Browning temporarily declared himself a vegetarian and an atheist, but the book had a more profound literary influence, for it introduced Browning to Keats and the other Romantic poets and thus determined the course of his life. Browning recognized that poetry was his profession. It was his fortune that he was able to devote his life to his chosen career without depending for his livelihood on the money he made by writing.

Browning's formal education was slight, although his father gave him a grounding in Greek and Latin. His mother, Sarah Anna Wiedemann, who was born in Scotland of German parentage, was an earnest Congregationalist and ensured that her son's religious education was not neglected, but his nonconformity barred him from the older English universities. In 1828 he attended classes at the University of London but left after half a session. Apart from a journey to St. Petersburg in 1834 with George de Benkhausen, the Russian consul general, and two short visits to Italy in 1838 and 1844, he lived with his parents in London until 1846, first at Camberwell and after 1840 at Hatcham. During this period (1832–46) he wrote his early long poems and most of his plays.

Browning's first published work, *Pauline: A Fragment of a Confession* (1833, anonymous), although formally a dramatic monologue, embodied many of his own adolescent passions and anxieties. A well-known Radical editor, W.J. Fox, who had already seen an earlier volume of Browning's work *Incondita* (1824, privately circulated), reviewed *Pauline* enthusiastically. Browning, however, was far more deeply affected by the unpublished criticisms of John Stuart Mill, who condemned the poet's exposure and exploitation of his own emotions and his "intense and morbid self-consciousness." It was perhaps Mill's critique that determined Browning never to confess his own emotions again in his poetry but to write objectively. Certainly in his later work he used the impersonality afforded by the dramatic form to safeguard himself against any revelation of his intimate affairs. Similarly, he objected to attempts to treat his poetry as autobiography, insisting that his poems though often lyric in expression were always "dramatic in principle, and so many utterances of so many imaginary persons, not mine."

Paracelsus, Sordello, and the plays

In 1835 he published *Paracelsus* and in 1840 *Sordello*, both poems dealing with men of great ability striving to reconcile the demands of their own personalities with those of the world. *Paracelsus* was well received, but *Sordello*, which made exacting demands on its reader's knowledge, was almost universally declared incomprehensible. Nevertheless, Browning's powers were recognized by several of the leading poets of the day, and he moved on friendly and equal terms among many young writers and artists.

Encouraged by the actor Charles Macready, Browning devoted his main energies for some years to verse drama, a form that he had already adopted for *Strafford* (1837). Between 1841 and 1846, in a series of pamphlets under the general title of *Bells and Pomegranates*, he published seven more plays in verse, including *Pippa Passes* (1841), *A Blot in the 'Scutcheon* (produced in 1843), and *Luria* (1846). These, and all his earlier works except *Strafford*, were printed at his family's expense. Although Browning enjoyed writing for the stage because of its objectivity and the close contact with his audience, he was not successful in the theatre, since his strength lay in depicting, as he had himself observed of *Strafford*, "Action in Character, rather than Character in Action." The third and seventh pamphlets in the series (1842 and 1845) were devoted to short poems, including "My Last Duchess," "Waring," "The Pied Piper of Hamelin," "Home Thoughts, from Abroad," and many others that prefigure the work of his maturity.

Elizabeth Barrett

By 1845 the first phase of Browning's life was near its end. In that year he met Elizabeth Barrett. In her *Poems* (1844) Miss Barrett had included lines praising Browning, who wrote to thank her (January 1845). In May they met and soon discovered their love for each other. Miss Barrett had, however, been for many years an invalid, confined to her room and thought incurable. Her father, moreover, was a dominant and selfish man, jealously fond of his daughter, who in turn had come to depend on his love. When her doctors ordered her to Italy for her health and her father refused to allow her to go, the lovers, who had been corresponding and meeting regularly, were forced to act. They were married secretly in September 1846; a week later they left for Pisa.

Throughout their married life, although they spent holidays in France and England, their home was in Italy, mainly at Florence, where they had a flat in Casa Guidi. Their income was small, although after the birth of their son, Robert, in 1849 Mrs. Browning's cousin John Kenyon made them an allowance of £100 a year, and on his death in 1856 he left them £11,000. Thereafter they were never harassed by lack of money, and their life was full but tranquil. Browning was not as passionately devoted as his wife to the cause of a united Italy, but he loved his adopted country and wrote many of his finest poems on Italian subjects.

On the whole, however, Browning produced comparatively little poetry during his married life. Apart from a collected edition in 1849 he published only *Christmas-Eve and Easter-Day* (1850), an examination of different attitudes toward Christianity, perhaps having its immediate origin in the death of his mother in 1849; an introductory essay (1852) to some spurious letters of Shelley, Browning's only considerable work in prose and his only piece of critical writing; and *Men and Women* (1855). This was a collection of 51 poems—dramatic lyrics such as "Memorabilia," "Love Among the Ruins," and "A Toccata of Galuppi's"; the great monologues such as "Fra Lippo Lippi," "How It Strikes a Contemporary," and "Bishop Blougram's Apology"; and a very few poems

in which implicitly ("By the Fireside") or explicitly ("One Word More") he breaks his rule and speaks of himself and of his love for his wife. Before the book appeared he wrote, "I am writing—a first step towards popularity for me—lyrics with more music and painting than before, so as to get people to hear and see." *Men and Women*, however, had no great sale, and many of the reviews were unfavourable and unhelpful. Disappointed for the first time by the reception of his work, Browning wrote to Ruskin, "A poet's affair is with God, to whom he is accountable, and of whom is his reward." In the following years he wrote little, sketching and modelling in clay by day and enjoying the society of his friends at night. At last Mrs. Browning's health, which had been remarkably restored by her life in Italy, began to fail. On June 29, 1861, she died in her husband's arms. He at once decided to "go away, break up everything, go to England, and live and work and write." In the autumn he returned slowly to London with his young son.

His first task on his return was to prepare his wife's *Last Poems* for the press. At first he avoided company, but gradually he accepted invitations more freely and began to move in society. Another collected edition of his poems was called for in 1863, but *Pauline* was not included. When his next book of poems, *Dramatis Personae* (1864)—including "Abt Vogler," "Rabbi Ben Ezra," "Caliban Upon Setebos," and "Mr. Sludge, 'The Medium' "—reached two editions, it was clear that Browning had at last won a measure of popular recognition. After the death in 1866 of his father, who had lived in Paris since 1852, the poet shared his house in Warwick Crescent with his sister Sarianna.

The Ring and the Book and later poems

In 1868–69 he published his greatest work, *The Ring and the Book*, based on the proceedings in a trial for murder in Rome in 1698. Grand alike in plan and execution, it was at once received with enthusiasm, and Browning was established as one of the most important literary figures of the day. For the rest of his life he was much in demand in society, dining out so frequently that many observers remarked on the difficulty of reconciling his intensely imaginative poetic life with his life as a high-spirited man of the London world, who appeared to have no serious occupation except planning his son's education and later advancing him in his career as an artist. He spent his summers with friends in France, Scotland, or Switzerland or, after 1878, in Italy. While he was in Scotland in 1869 he stayed with the rich and attractive Lady Ashburton and proposed to her, explaining candidly that their marriage would be of advantage to his son. When Lady Ashburton refused him Browning was distressed less by his rejection than by the subsequent gossip and recriminations.

The most important works of his last years, when he wrote with great fluency, were the long narrative or dramatic poems, often dealing with contemporary themes, such as *Prince Hohenstiel-Schwangau* (1871), *Fifine at the Fair* (1872), *Red Cotton Night-Cap Country* (1873), *The Inn Album* (1875), and the two series of *Dramatic Idyls* (1879 and 1880). He wrote a number of poems on classical subjects, including *Balaustion's Adventure* (1871) and *Aristophanes' Apology* (1875), and made a translation of the *Agamemnon* of Aeschylus (1877), which, it was said, could be understood quite easily with the help of the Greek. In addition to many collections of shorter poems—*Pacchiarotto and How He Worked in Distemper* (1876), *Jocoseria* (1883), *Ferishtah's Fancies* (1884), and *Asolando: Fancies and Facts* (1889)—Browning published toward the end of his life two books of unusually personal origin—*La Saisiaz* (1878), at once an elegy for his friend Anne Egerton-Smith and a meditation on mortality, and *Parleyings with Certain People of Importance in Their Day* (1887), in which he discussed books and ideas that had influenced him since his youth.

While staying in Venice in 1889, Browning caught cold and became seriously ill; he had time to learn of the favourable reception of *Asolando* before he died on December 12. Public recognition of his eminence, which had been successively shown by honorary degrees from the University of Oxford, an honorary fellowship of Balliol College, and presentation to the Queen, was fittingly completed by his burial in Westminster Abbey.

Characteristics of Browning's poetry. Few poets have suffered more than Browning from hostile incomprehension or misplaced admiration, both arising very often from a failure to recognize the predominantly dramatic nature of his work. The bulk of his writing before 1846 was for the theatre; thereafter his major poems showed his increasing mastery of the dramatic monologue. This consists essentially of a narrative spoken by a single character and amplified by his comments on his story and the circumstances in which he is speaking. From his own knowledge of the events described (as in "An Epistle of Karshish" and "Cleon") or by inference from the poem itself (as in "Andrea del Sarto"), the reader provides a quasi-dramatic context for the poem and is eventually enabled to assess the intelligence and honesty of the narrator and the value of the views he expresses. Thus the dramatic monologue, since it depends on the unconscious provision by the speaker of the evidence by which the reader is to judge him, is eminently suitable for the ironist. Equally, it offered the technical impersonality of the dramatist to a poet who, like Browning, distrusted the romantic exploitation of the writer's own personality. Browning's fondness for the form has, however, encouraged the two most common misconceptions of the nature of his poetry—that it is deliberately obscure and that its basic "message" is a facile optimism. Neither of these criticisms is groundless; both are incomplete.

Use of the dramatic monologue

Browning is not always difficult. In many poems, especially short lyrics, he achieves effects of obvious felicity, while even in his thorniest poems there are many passages that give an immediate poetic pleasure and many in which the force of his imagination is perfectly conveyed by the rough vigour of his language. Nevertheless, his superficial difficulties, which prevent an easy understanding of the sense of a passage, are evident enough: his attempts to convey the broken and irregular rhythms of speech, running the sense on from line to line, yet often stressing an unusual or arresting rhyme, so that it is almost impossible to read the verse quickly; his elliptical syntax, which disconcerts and sometimes confuses the reader but which can be mastered with little effort; the demands he makes on his readers' knowledge, as in *Sordello* or "Old Pictures in Florence," poems that require for full appreciation a considerable acquaintance with their subjects; and his fondness for putting his monologues into the mouths of charlatans and sophists, such as Mr. Sludge or Napoleon III, thus obliging the reader to follow a chain of subtle or paradoxical arguments—all these stand in the way of easy reading. Further, Browning frequently indulges his taste for the grotesque and yields to the temptation to display his prodigality of technical invention. Yet while there is admittedly much hasty and slipshod writing, much overcleverness, and much distortion of language into conformity with an arbitrary rhyme scheme, the surface difficulties of Browning are no greater than those of most of his successors.

But even when individual problems of style and technique have been resolved, the poem's interest is seldom exhausted. First, Browning often chooses an unexpected point of view, especially in his monologues, thus forcing the reader to accept an unfamiliar perspective. Secondly, he is capable of startling changes of focus within a poem. For example, he chooses subjects in themselves insignificant, as in "Fra Lippo Lippi" and "Master Hugues of Saxe-Gotha," and treats through them the eternal themes of poetry. This transition from particular observation to transcendental truth presents much the same challenge to the reader as do the metaphysical poets of the 17th century and much the same excitement. Thirdly, as Browning seldom presents a speaker without irony, there is a constant demand on the reader to appreciate exactly the direction of satiric force in the poem. Even in a melodious poem such as "A Toccata of Galuppi's," the valid position must be distinguished from the false at every turn of the argument, while in the major casuistic

monologues, such as "Bishop Blougram's Apology," the shifts of sympathy are subtler still.

Browning's poetry, then, is seldom simple, but its complexity is a legitimate source of poetic pleasure since it springs not from a desire to mystify and impress but from the seriousness of Browning's attitude toward his art. He wrote in 1868, "I can have little doubt that my writing has been, in the main, too hard for many I should have been pleased to communicate with; but . . . I never pretended to offer such literature as should be a substitute for a cigar, or a game at dominoes, to an idle man."

It has also been objected that Browning uses his poetry as a vehicle for his philosophy, which is not of itself profound or interesting, being limited to an easy optimism. Against this it may be argued, in the first place, that since Browning seeks to win imaginative rather than speculative conviction it is inadmissible to judge his poetry simply as versified metaphysics. Secondly, Browning's dramatic monologues must, as he himself insisted, be recognized as the utterances of fictitious persons drawing their strength from their appropriateness in characterizing the speaker, and not as expressions of Browning's own sentiments. Thus his great gallery of imagined characters is to be regarded as an exhaustive catalog of human motives, not as a series of self-portraits. Nevertheless, certain fundamental assumptions are made so regularly that they may be taken to represent Browning's personal beliefs.

Religious values

Browning normally considers the existence of a God and of a life after death as certain beyond the need of proof and often, especially in his early years, accepts the central beliefs of the Christian faith. Readers who cannot follow him in this complain that this leads him to view the human situation with an equanimity not far removed from complacency. Yet in many poems he allows his speakers to debate at length the problem of reconciling the unhappiness of mankind with the providence of a benevolent God. The solutions that he accepts in "Abt Vogler" or "Rabbi Ben Ezra," for example, may often seem too easy, but it is significant that he at least starts from a recognition that misery and evil are at large in the world; in his best work, notably *The Ring and the Book* and *La Saisiaz*, he makes such answers as a poet may to the manifold perplexities that beset men of faith.

In matters of human conduct his sympathies are with those who show loving hearts, honest natures, and warmth of feeling; certainly these qualities are never satirized. He is in general on the side of those who commit themselves wholeheartedly to an ideal, even if they fail. By itself this might suggest rather a naïve system of values, yet he also, sometimes even in the same poem, shows his understanding of those who have been forced to lower their standards and accept a compromise. Thus, although Browning is far from taking a cynical or pessimistic view of man's nature or destiny, his hopes for the world are not simple and unreasoning but qualified and considered.

Browning did not share the prevailing Romantic interest in nature, declaring that men and women interested him far more. Consequently the diversity and external picturesqueness of the settings of his poems are unimportant compared with his abiding interest in the springs of human conduct. Thus he was able to find subjects fit for poetry in the life of his own times as well as in the events of the past. In the long poems of his prime, from 1855 to 1880, he demonstrated that sustained narrative in verse was still possible in an age that furnished the poet with none of the materials of the conventional heroic poem. In these works he wrote, as none of the other great poets of the 19th century chose to write, about contemporary life, and, as nearly as he could, he used the language of his time. If this makes his poetry unmistakably Victorian, its Victorianism is its strength rather than its weakness. Even *The Ring and the Book* was felt by its first readers to be a modern poem, since it recognized that to urban readers in industrial civilizations the truly heroic action was not that which showed most strength and courage but that which showed the greatest moral resolution and intellectual power. In this poem Browning displays all his distinctive qualities. He allows a dramatic monologue to each character he portrays—to the man on trial for murder, to his young wife, whom he has mortally wounded, to her protector, to various Roman citizens, to the opposing lawyers, and to the pope, who ultimately decides the accused's fate. Each deals with substantially the same occurrences, but each, of course, describes and interprets them differently. By permitting the true facts to emerge gradually by inference from these conflicting accounts, Browning reveals with increasing subtlety the true natures of his characters. As each great monologue illuminates the moral being of the speaker, the meanness and triviality of the subject are seen to be irrelevant, for it becomes clear that nothing less than the whole ethical basis of human actions is in question. For over 20,000 lines Browning explores his theme, employing an unfaltering blank verse, rising often to passages of moving poetry, realizing in extraordinary detail the life of 17th-century Rome, and creating a series of characters as diverse and fully realized as those in any novel. Indeed, Browning's achievement in this and in his other long poems, which show his genius to the full, is most fittingly compared with that of the great 19th-century novelists, particularly Balzac.

Reputation and influence

During his lifetime his reputation was slow to recover from the general rejection of *Sordello;* even his plays were financially unsuccessful. After 1864 critical recognition came rapidly; and, while his books never sold as well as his wife's or Tennyson's, he had a considerable and enthusiastic public for the rest of his life and, what he valued more, a large circle of friends and distinguished admirers, including Carlyle, Rossetti, Benjamin Jowett, and a French critic, Joseph Milsand. In the 20th century, his reputation, along with those of the other great Victorians, has declined and his work has not enjoyed a wide reading public, perhaps in part because of increasing skepticism of the values implied in his poetry. He has, however, influenced many modern poets, such as Robert Frost and Ezra Pound, partly through his development of the dramatic monologue, with its emphasis on the psychology of the individual and his stream of consciousness, but even more through his success in writing about the variety of modern life in language that owed nothing to convention.

Critical assessments of Browning have varied widely, but as long as technical accomplishment, richness of texture, sustained imaginative power, and a warm interest in humanity are counted virtues, he will be numbered among the great English poets.

MAJOR WORKS

POETRY AND VERSE DRAMA: *Pauline: A Fragment of a Confession* (1833); *Paracelsus* (1835); *Strafford* (1837), historical tragedy; *Sordello* (1840); *Bells and Pomegranates* (eight numbers): no. 1, *Pippa Passes* (1841), a drama; no. 2, *King Victor and King Charles* (1842), a tragedy; no. 3, *Dramatic Lyrics* (1842), including "Waring," "My Last Duchess," and "The Pied Piper of Hamelin"; no. 4, *The Return of the Druses* (1843), a tragedy; no. 5, *A Blot in the 'Scutcheon* (1843), a tragedy; no. 6, *Colombe's Birthday* (1844), a play; no. 7, *Dramatic Romances and Lyrics* (1845), including "Home Thoughts, from Abroad"; and no. 8, *Luria* and *A Soul's Tragedy* (1846); *Christmas-Eve and Easter-Day* (1850); *Men and Women*, 2 vol. (1855), including "Two in the Campagna," "Bishop Blougram's Apology," "Fra Lippo Lippi," and "Love Among the Ruins"; *Dramatis Personae* (1864), including "Abt Vogler," "Rabbi Ben Ezra," "Caliban upon Setebos," and "Mr. Sludge, 'The Medium' "; *The Ring and the Book*, 4 vol. (1868–69); *Balaustion's Adventure* (1871); *Prince Hohenstiel-Schwangau, Saviour of Society* (1871); *Fifine at the Fair* (1872); *Red Cotton Night-Cap Country; or Turf and Towers* (1873); *Aristophanes' Apology* (1875), including a *Transcript from Euripides: Being the Last Adventure of Balaustion; The Inn Album* (1875); *Pacchiarotto and How He Worked in Distemper* (1876), with other poems; *The Agamemnon of Aeschylus* (1877), a translation; *La Saisiaz: The Two Poets of Croisic*, 1 vol. (1878); *Dramatic Idyls* (1879, first series; 1880, second series); *Jocoseria* (1883); *Ferishtah's Fancies* (1884); *Parleyings with Certain People of Importance in Their Day* (1887); *Asolando: Fancies and Facts* (1889).

BIBLIOGRAPHY. L.N. BROUGHTON, C.S. NORTHUP, and R. PEARSALL (comps.), *Robert Browning: A Bibliography, 1830–1950* (1953) is the standard work. PARK HONAN gives a full descriptive account of Browning studies up to 1966 in chapter 3 of F.E. FAVERTY (ed.), *The Victorian Poets: A Guide to Research*, 2nd ed. (1968). The manuscripts of *Paracelsus* and *Christmas-Eve and Easter-Day* are in the Victoria and Albert Museum; that of *The Ring and the Book* in the British Museum; and that of *Dramatis Personae* in the Pierpont Morgan Library, New York, which also holds the manuscript of *Asolando*. With this exception the manuscripts of all Browning's works published after 1870 are held by Balliol College, Oxford. The Armstrong Browning Library, Baylor University, Waco, Texas, has important Browning collections and publishes *The Browning Newsletter*.

Editions: Of the many editions of Browning's works, the most complete is that of AUGUSTINE BIRRELL (1915). A variorum edition edited by R.A. KING *et al.* is in progress.

Letters: T.L. HOOD (ed.), *Letters of Robert Browning* (1933); R. CURLE (ed.), *Robert Browning and Julia Wedgwood* (1937); W.C. DEVANE and K.L. KNICKERBOCKER (eds.), *New Letters of Robert Browning* (1950); E.C. MCALEER (ed.), *Dearest Isa: Robert Browning's Letters to Isabella Blagden* (1951); *Learned Lady: Letters from Robert Browning to Mrs. Thomas FitzGerald, 1876–1889* (1966); P. LANDIS and R.E. FREEMAN (eds.), *Letters of the Brownings to George Barrett* (1958); G.R. HUDSON (ed.), *Browning to His American Friends* (1965); E. KINTNER (ed.), *The Letters of Robert Browning and Elizabeth Barrett Browning, 1845–1846*, 2 vol. (1969).

Biography: W.H. GRIFFIN (completed by H.C. MINCHIN), *The Life of Robert Browning*, 3rd ed. rev. (1938, reprinted 1966), is the standard biography, now rather dated. M. WARD, *Robert Browning and His World*, 2 vol. (1967–69), is the best modern life. Two lively accounts of Browning that make no attempt at impartiality are G.K. CHESTERTON'S sympathetic *Robert Browning* (1903) and B. MILLER'S hostile *Robert Browning: A Portrait* (1952). HENRY JAMES, *William Wetmore Story and His Friends*, 2 vol. (1903), gives the most vivid picture of Browning as he appeared to those who knew him.

Criticism: W.C. DEVANE, *A Browning Handbook*, 2nd ed. (1955), is an indispensable commentary on every aspect of the poems. R.W. LANGBAUM, *The Poetry of Experience* (1957), relates Browning's handling of the dramatic monologue to modern literary ideas. R.D. ALTICK and J.F. LOUCKS, *Browning's Roman Murder Story* (1968), is a detailed study of *The Ring and the Book*. More general accounts of Browning's poetry may be found in R.A. KING, *The Focusing Artifice* (1969); W.D. SHAW, *The Dialectical Temper* (1968); and P. DREW, *The Poetry of Browning: A Critical Introduction* (1970). B. LITZINGER and D. SMALLEY (eds.), *Robert Browning: The Critical Heritage* (1970), presents in chronological order the most important reviews and studies of Browning by his contemporaries. A selection of more recent critical work may be found in B. LITZINGER and K.L. KNICKERBOCKER (eds.), *The Browning Critics* (1965); and P. DREW (ed.), *Robert Browning: A Collection of Critical Essays* (1966).

(Ph.D.)

Bruckner, Anton

A composer of strikingly original symphonic works, Anton Bruckner is less well known for his sacred music, in which the great tradition of Austrian church music, in the view of many music historians, reached its final and most perfect consummation. To Bruckner, composition had the significance of a liturgical art, and he brought to it the same zeal that a God-fearing priest might bring to the enactment of the sacred rites. It is precisely this spiritual content that has caused his music to remain a closed book to many people, even when the passage of time has swept away many of the misconceptions about the composer. Bruckner's intense devoutness was an essential component of his personality, for he appears to have felt most acutely that he was an instrument of God. A measure of his greatness lies in the purely altruistic nature of his life and work, undefiled by materialistic values.

Creative influences. (Josef) Anton Bruckner was born in Ansfelden, a small village near Linz in Upper Austria, on September 4, 1824. His musical talent was soon recognized, and in the spring of 1835 he was sent to Hörsching to learn the organ from his godfather. His father's illness brought this interlude to a sudden end, and Bruckner returned to Ansfelden to assist his father in his duties as village schoolmaster and organist. After his father's death in June 1837, Bruckner was accepted as a choirboy by the prior of Sankt Florian Abbey near Linz. Here he spent the next three years, receiving a broad general education, with particular emphasis on musical instruction. Following in his father's footsteps, he undertook a teachers' training course in 1840–41, after which he received appointments as an assistant teacher in Windhaag, 1841–43, Kronstorf, 1843–45, and, finally, once again at Sankt Florian.

Bruckner's second stay at Sankt Florian, from 1845 to 1855, was a critical period in his artistic life. The turning point in the gradual transition from the life of a teacher to that of a musician and composer was probably his appointment—provisionally in 1848, officially in 1851—as organist of Sankt Florian Abbey. Nevertheless, during the early 1850s, Bruckner attended a teachers' training course at Linz and went a stage further in 1855 by successfully completing the necessary examination for a high school teacher's certificate. The advice and encouragement of several people, however, convinced Bruckner that his future lay in music. Finally, in 1856, he secured the position of cathedral organist in Linz.

A few months earlier, Bruckner had been accepted as a pupil by Simon Sechter, a musician known for his contrapuntal works, and with him, between 1855 and 1861, he pursued an intensive course of counterpoint, undertaken partly by correspondence and partly during his visits to Vienna during holidays. The course culminated in a final examination, the main part of which was a practical examination. An initially skeptical panel of judges, consisting of some of Vienna's most prominent musicians, was left with no doubts of Bruckner's capabilities as both a performer and an improviser.

Bruckner's 12 years in Linz were years of both happiness and disappointment. His happiness lay in his numerous friendships and in his association with the Frohsinn choir, which he conducted in 1860–61 and 1868. He was aware also of an increasing facility in composition, particularly after 1861, when as part of a course in musical form and orchestration he undertook a thorough study of Richard Wagner's opera *Tannhäuser*. This was Bruckner's first acquaintance with the music of the composer before whom in later years he would stand in awe. The Wagnerian example provided a perfect foil to Sechter's contrapuntal training and led to the composition of his first major works—the three great masses, the *Overture in G Minor*, *Symphony No. 0 in D Minor*, and *Symphony No. 1 in C Minor*. Bruckner's disappointments in the Linz years stemmed largely from his failure to find a

Influence of Wagner

suitable marriage partner. His many proposals of marriage were rejected without exception, and his strong religious convictions made it impossible for him to enter into any physical relation outside of marriage.

Opposition and final recognition. In 1867 Sechter died and Bruckner, having recovered from a nervous breakdown, applied for the vacant position of organist at the *Hofkapelle* in Vienna. His application was rejected, but he was offered a professorship of harmony and counterpoint at the Vienna Conservatory and an unpaid provisional appointment as court organist. Ten more years were to elapse before Bruckner was made a full member of the *Hofkapelle*, and his attempts to secure a lectureship at the University of Vienna were to be unsuccessful until 1875. The latter delay was caused largely by the hostility of the powerful Viennese critic and dean of the University's music faculty, Eduard Hanslick, who was a champion of the German composer Johannes Brahms and antipathetic toward Wagner. For years, Bruckner was quite erroneously branded as a disciple of the latter.

The last 28 years of Bruckner's life were spent in Vienna, devoted to the composition of symphonies 2 to 9, the last of which remained unfinished, the *String Quintet in F Major*, the *Te Deum*, *Psalm CL*, *Helgoland*, and several smaller sacred and secular choral works. He rarely moved far from the capital, except for visits to France in 1869 and to England in 1871 to represent Austria as an organ virtuoso. In the 1880s and early 1890s he travelled to various German towns to hear performances of his symphonies and major sacred works. During these years he had to battle against the apathy of the public and the hostility of many critics besides Hanslick. His pupils and others sympathetic to his cause stood by him, however, and he gradually gained recognition. In 1891 the University of Vienna put the official seal on this recognition by conferring on him the honorary degree of doctor of philosophy. He died in Vienna on October 11, 1896.

MAJOR WORKS

Orchestral works

SYMPHONIES: *No. 0 in D Minor* (1864, rev. 1869); *No. 1 in C Minor* (first or "Linz" version, 1865–66; second or "Vienna" version, 1890–91); *No. 2 in C Minor* (1871–72, rev. 1875–76, and later); *No. 3 in D Minor* (*Wagner Symphony*), five versions (1873–90); *No. 4 in E flat Major* (*Romantic*), four versions (1874, 1877–78, 1878–80, 1887–88); *No. 5 in B flat Major* (1875–76, rev. 1876–78, and later); *No. 6 in A Major* (1879–81); *No. 7 in E Major* (1881–83, rev. 1885); *No. 8 in C Minor*, three versions (1884–85, 1886–87, 1888–90); *No. 9 in D Minor* (finale in sketch only; first three movements, 1887–94; finale 1894–96).

Chamber music

String Quintet in F Major (1878–79), rev. 1883–84, and later.

Vocal music

LARGE-SCALE SACRED WORKS: *Short Chorale Mass in C Major*, for contralto, two horns, and organ (*c.* 1842); *Chorale Mass in F Major*, for Maundy Thursday, for unaccompanied four-part chorus (1844); *Requiem in D Minor*, for chorus, orchestra, and organ (1848–49, rev. 1894); *Psalm CXIV*, for five-part chorus and three trombones (1852); *Missa Solemnis in B flat Minor*, for solo voices, chorus, and orchestra (1854); *Mass No. 1 in D Minor*, for soprano, chorus, and orchestra (1864, rev. 1876 and later); *Mass No. 2 in E Minor*, for eight-part chorus and wind instruments (1866, rev. 1876 and later); *Mass No. 3 in F Minor* (*Grosse Messe*), for solo voices, chorus, orchestra, and organ (1867–68, rev. 1876–90); *Te Deum*, for soprano solo, chorus, orchestra and organ (1881, rev. 1883–84); *Psalm CL*, for soprano solo, chorus, orchestra, and organ (1892).

SMALLER SACRED WORKS: *Pange Lingua in C Major*, for four-part chorus (1835, rev. 1891); *Ave Maria*, for four-part chorus and organ (1856); offertory, *Afferentur*, for four-part chorus and trombones (1861); *Pange Lingua*, for chorus in the Phrygian mode (1868); antiphon, *Tota pulchra es*, for tenor, chorus, and organ (1878); *Ecce Sacerdos*, for chorus, three trombones, and organ (1885).

CANTATAS: Festive cantata, *Preiset den Herrn*, for solo voices, male chorus, brass and woodwind instruments, and timpani (1862); *Germanenzug* (1863), *Das deutsche Lied* (1892), and *Helgoland* (1893), all three for male-voice choir, with brass instruments.

BIBLIOGRAPHY. The main repository of Bruckner's autograph scores, personal papers, and memorabilia is the Music Section of the Austrian National Library in Vienna. Bruckner's letters have been published in two collections, *Gesammelte Briefe*, ed. by M. AUER and ed. by F. GRAFLINGER (both works 1924). The standard biography is A. GOLLERICH and M. AUER, *Anton Bruckner: Ein Lebens-und Schaffensbild*, 4 vol. (1922–37). Other important biographies include those by M. AUER, 6th ed. (1966); F. BLUME in *Die Musik in Geschichte und Gegenwart*, vol. 2 (1952); R. HAAS (1934); E. KURTH, 2 vol. (1925); L. NOWAK (1947, 1964); A. OREL (1925); H.F. REDLICH, 2nd ed. (1963); and H.H. SCHONZELER (1970). Critical evaluations of Bruckner's symphonies have been made by W. ABENDROTH, *Die Symphonien Anton Bruckners* (1940); A. HALM (1914); and R.W.L. SIMPSON, *The Essence of Bruckner* (1967); of his sacred works by M. AUER (1927); further critical studies may be found in *Bruckner-Studien*, ed. by FRANZ GRASBERGER (1964).

(A.C.H.)

Bruegel, Pieter, the Elder

Generally accepted as having been the greatest Flemish painter of the 16th century, Pieter Bruegel has, from his own day to the present, been one of the most popular painters of any period or country. With a seemingly inexhaustible power of narrative inventiveness, his canvases wittily expose human shortcomings and folly, often in bold images of peasant life. Bruegel often, but not exclusively, depicted erring mankind under the images of peasants, which not only earned him the nickname "Peasant Bruegel" but also led to the belief that he was a peasant himself. The discovery of his close personal association with such leading humanists of his time as the Antwerp geographer Abraham Ortelius has put an end to this legend and focussed attention on aspects of his work that reveal him as a man well-versed in the humanities. Recent studies of the religious and philosophical implications of his imagery have aligned him in spirit to the Dutch humanist–writer Desiderius Erasmus, to the great French writer François Rabelais, and to such Dutch religious reformers as the philosopher, politician, and engraver Dirck Coornhert (1522–90). In addition, Bruegel has come now to be seen not as the last of the Flemish primitive painters but as the greatest artist of northern Europe within a wider so-called Mannerist tendency that dominated much of the art of the later 16th century throughout most of Europe. If occasionally he used the fantastic subject matter, the demons and the monsters, and even the manner of depiction, of a Dutch painter of allegory, Hieronymus Bosch, it is now clear that this was simply a matter of his own deliberate choice. Deliberate, too, was the apparently primitive form of his human figures, reductions to basic, cubic shapes more characteristic of 20th-century art, and certainly very different from those of his Flemish contemporaries.

Relation to the humanistic tradition

"Hunters in the Snow," oil on panel by Pieter Bruegel, the Elder, 1565. In the Kunsthistorisches Museum, Vienna.

Studies of nature in the Impressionistic painting of the late 19th century have led to a renewed appreciation of the freshness and beauty of Bruegel's landscape paintings. Despite his own pessimistic view of mankind, he saw nature as a great positive and eternal force untouched in its purity by the doings of man. Throughout his life, landscape played a large part in his work; and in all the history of landscape painting, he is counted among the great creators of new types. He was not content merely to continue the Flemish tradition of the vast panoramic view, though his keen observation endowed it with greater credibility and reality of detail. He discovered and portrayed in his paintings and drawings a great variety of landscape forms, from magnificent alpine scenery to the lowlands and the stormy seas on which, to a considerable extent, Dutch landscape art of the 17th century was based. The Flemish painter Peter Paul Rubens, who owned 12 paintings by Bruegel, also came under his spell both in landscape and in some figural compositions. It is a measure of Bruegel's historical importance that he exerted a strong influence on the painting of the Low Countries for a long time and that his landscapes and other works of varied subject matter were endlessly imitated.

Early influences. Though there is sufficient evidence for the high esteem Bruegel enjoyed among his contemporaries and in the following generation, there is but little information about his life. Only the main outlines can be drawn, from a few surviving documents and the biography contained in Karel van Mander's *Het Schildèr-boeck* (*Book of Painters*) published in Amsterdam in 1604, 35 years after Bruegel's death. Neither the place nor the date of Bruegel's birth has been established with certainty. Rather than trusting van Mander's somewhat confused reference to a village called Breughel, of which there are several in the Low Countries, many scholars are now inclined to accept the city of Breda, now in The Netherlands, as his birthplace. A contemporary and, on the whole, well-informed source, Lodovico Guicciardini's *Descrittione di tutti i Paesi Bassi* (1567; "Description of All the Low Countries"), refers to the artist as Pietro Brueghel di Breda. Bruegel was received as a master into the Antwerp painters' guild in 1551. Assuming that he had undergone the usual period of apprenticeship of the time, he was probably born around 1525, possibly as late as 1530.

According to van Mander, Bruegel was apprenticed to Pieter Coecke van Aelst, a leading Antwerp artist who had located in Brussels a few years before his death in December 1550. The head of a large workshop, Coecke was a sculptor, architect, and designer of tapestry and stained glass. He had travelled in Italy and in Turkey and was a person with wide, mainly humanistic, interests. By translating and publishing architectural books of the contemporary Italian architect Sebastiano Serlio and of the ancient Roman Vitruvius, he contributed greatly to the spread of the ideas of the Italian Renaissance in the Low Countries. Although Bruegel's earliest surviving works show no stylistic dependence on Coecke's Italianate art, connections with Coecke's compositions can be detected in later years, particularly after 1563, when Bruegel married Coecke's daughter Mayken. In any case, the apprenticeship with Coecke represented an early contact with a humanistic milieu. Through Coecke Bruegel became linked indirectly to another tradition as well. Coecke's wife, Maria Verhulst Bessemers, was a painter known for her work in watercolour or tempera, a suspension of pigments in egg yolk or a glutinous substance, on linen. The technique was widely practiced in her hometown of Mechelen (Malines) and was later employed by Bruegel. It is also in the works of Mechelen's artists that allegorical and peasant thematic material first appear. These subjects, unusual in Antwerp, were later treated by Bruegel. His work in 1551 on the wings of an altarpiece (now lost) for the chapel of the glovemaker's guild in the Church of St. Rombaut at Mechelen undoubtedly gave him the opportunity to enhance his knowledge of the art of this city. At this time Bruegel was an assistant to the Antwerp master Pieter Baltens, who, though an older artist, later came himself under the influence of Bruegel.

The influence of the artistic traditions of Mechelen

Italian pilgrimage. In 1551 or 1552, Bruegel set off on the customary northern artist's journey to Italy, probably by way of France. From several extant paintings, drawings, and etchings, it can be deduced that he travelled beyond Naples to Sicily, possibly as far as Palermo, and that in 1553 he lived in Rome for some time where he worked with a celebrated miniaturist, Giulio Clovio, an artist greatly influenced by Michelangelo and later a patron of the young El Greco. The inventory of Clovio's estate shows that he owned a number of paintings and drawings by Bruegel as well as a miniature done by the two artists in collaboration. A seascape with many ships and a burning town, inserted in the decorative framework of a major miniature by Clovio (Towneley Lectionary, New York Public Library), has recently been attributed to Bruegel. It was also in Rome, in 1553, that Bruegel produced his earliest signed and dated painting, a "Landscape with Christ and the Apostles at the Sea of Tiberias." The holy figures in this painting were probably done by Maarten de Vos, a painter from Antwerp then working in Italy.

Thus the earliest surviving works, including two drawings with Italian scenery that were sketched on the southward journey and dated 1552, are landscapes. A number of drawings of Alpine regions, produced between 1553 and 1556, indicate the great impact of the mountain experience on this man from the Low Countries. With the possible exception of a drawing of a mountain valley by Leonardo da Vinci (Royal Library, Windsor Castle, England), the landscapes produced as a result of this journey are almost without parallel in European art for their rendering of the overpowering grandeur of the high mountains. Very few of the drawings were done on the spot, and several were done after Bruegel's return, at an unknown date, to Antwerp. The vast majority are free compositions, combinations of motifs sketched on the journey through the Alps. Some were intended as designs for engravings commissioned by Hieronymus Cock, an engraver who was Antwerp's foremost publisher of prints.

Impact of the mountains on his work

From imitation to independence. Bruegel was to work for Cock until his last years, but, from 1556 on, he concentrated, surprisingly enough, on satirical, didactic, and moralizing subjects, often in the fantastic or grotesque manner of Bosch, imitations of whose works were very popular at the time. Other artists were content with a more or less close imitation of Bosch, but Bruegel's inventiveness lifted his designs above mere imitation and he soon found ways to express his ideas in a much different manner. His early fame rested on prints published by Cock after such designs. But the new subject matter and the interest in the human figure did not lead to the abandonment of landscape. Bruegel, in fact, extended his explorations in this field. Side by side with his mountain compositions, he began to draw the woods of the countryside, turned then to Flemish villages, and, in 1562, to townscapes with the towers and gates of Amsterdam (drawings in Musée des Beaux-Arts, Besançon and Museum of Fine Arts, Boston).

The double interest in landscape and in subjects requiring the representation of human figures also informed, often jointly, the paintings Bruegel produced in increasing number after his return from Italy. All of his paintings, even those in which the landscape appears as the dominant feature, have some narrative content. Conversely, in those that are primarily narrative, the landscape setting often carries part of the meaning. Dated paintings have survived from each year of the period except for 1558 and 1561. Within this decade falls Bruegel's marriage to Mayken Coecke in the Church of Notre-Dame de la Chapelle in Brussels in 1563 and his move to that city in which Mayken and her mother were living. His residence recently was restored and turned into a Bruegel museum. There is, however, some doubt as to the correctness of the identification.

In Brussels, Bruegel produced his greatest paintings, but only few designs for engravings, for the connection with Hieronymus Cock may have become less close after Bruegel left Antwerp. Another reason for the concentra-

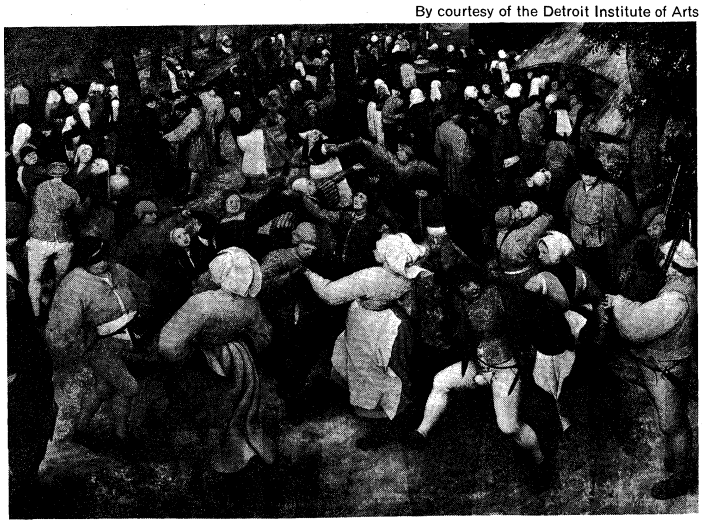
tion on painting may have been his growing success in this field. Among his patrons was Cardinal Antione Perrenot de Granvelle, president of the council of state in the Netherlands, in whose palace in Brussels the sculptor Jacques Jonghelinck had a studio. He and Bruegel had travelled in Italy at the same time, and his brother, a rich Antwerp collector, Niclaes, was Bruegel's greatest patron, having by 1566 acquired 16 of his paintings. Another patron was Abraham Ortelius, who in a memorable obituary called Bruegel the most perfect artist of the century. Most of his paintings were done for collectors, and although these included works of a religious character, no commissions for churches are known after the Mechelen altarpiece. Bruegel received what would have been his most honourable commission and an act of public recognition from the Brussels city council, a series of works commemorating the digging of the Brussels–Antwerp Canal. According to van Mander, death interfered with the project. No painting forming part of the series is known, nor is there information on whether he completed any part of the commission.

Bruegel died on September 5/9, 1569, and was buried in Notre-Dame de la Chapelle in Brussels. He was survived by his wife and two sons, Pieter (1564–1638) and Jan (1568–1625). Both of them became painters, Pieter known as "Hell Brueghel," Jan, as "Velvet Brueghel." Through them their father, known to history as Pieter Bruegel the Elder, became the ancestor of a dynasty of painters that survived into the 18th century. Jan honoured his parents' memory by erecting over their tomb an epitaph, which he had adorned by Rubens with a painting of "Christ Giving the Keys to St. Peter."

The dynasty of Bruegels

Artistic evolution and affinities. In addition to a great many drawings and engravings by Bruegel, 45 authenticated paintings from a much larger output now lost have been preserved. Of this number, about a third is concentrated in the Vienna Kunsthistorisches Museum, reflecting the keen interest of the Habsburg princes in the 16th and 17th centuries in Bruegel's art. Since Bruegel signed and dated many of his works, it is not difficult to trace his artistic evolution. In his earliest surviving works he appears as essentially a landscape artist, indebted to, but transcending, the Flemish 16th-century landscape tradition as well as to Titian and to other Venetian landscape painters. After his return from Italy, he turned to multifigure compositions, representations of crowds of people loosely disposed throughout the picture and usually seen from above. Here, too, antecedents can be found in the art of Hieronymus Bosch and of other painters closer in time to Bruegel.

By courtesy of the Detroit Institute of Arts



"The Wedding Dance in the Open Air," oil on panel by Pieter Bruegel, the Elder, 1566. In the Detroit Institute of Arts.

In 1564 and 1565, under the spell of Italian art and especially of Raphael, he reduced the number of figures drastically, the few being larger and placed closely together in a very narrow space. In 1565, however, he turned again to landscape with the celebrated series known as "Labours of the Months." In the five of these that have survived, he subordinated the figures to the great lines of the landscape. Later on crowds appear again, disposed in densely concentrated groups.

Bruegel's last works often show a striking affinity with Italian art. The diagonal spatial arrangement of the figures in "Peasant Wedding" recalls Venetian compositions. Though transformed into peasants, the figures in such works as "Peasant and Bird Nester" (1568; Kuntshistorisches Museum, Vienna) have something of the grandeur of Michelangelo. In the very last works, two trends appear; on the one hand, a combined monumentalization and extreme simplification of figures and, on the other hand, an exploration of the expressive quality of the various moods conveyed by landscape. The former trend is evident in his "Hunters in the Snow" (1565; Kunthistorisches Museum, Vienna), one of his winter paintings. The latter is seen in the radiant, sunny atmosphere of "The Magpie on the Gallows" and in the threatening and sombre character of "The Storm at Sea," an unfinished work, probably Bruegel's last painting.

The influence of other artists on Bruegel's work, rather than detracting from its greatness, showed his wide familiarity with contemporary art and his ability to adapt it for his own purposes. In fact, his work reflects his constant observation, exploration, and experimentation. He studied the changes in nature's moods brought about by the seasons in the series of "The Months," his feeling for nature transforming and enlivening a traditional subject. Particularly attracted by winter, he captured its various aspects in at least four paintings besides the famous "Hunters in the Snow" in the series "The Months."

Works of nature and of man

Range of vision and interest. He was no less interested in observing the works of man. Noting every detail with almost scientific exactness, he rendered ships with great accuracy in several paintings and in a series of engravings. A most faithful picture of contemporary building operations is shown in the two paintings of "The Tower of Babel" (one, 1563, Kunsthistorisches Museum, Vienna; the other, not dated, Museum Boymans-van Beuningen, Rotterdam). The Rotterdam "Tower of Babel" illustrates yet another characteristic of Bruegel's art, an obsessive interest in rendering movement. It was a problem with which he constantly experimented. In the Rotterdam painting, movement is imparted to an inanimate object, the tower seeming to be shown in rotation. Even more strikingly, in "The Magpie on the Gallows," the gallows apparently take part in the peasants' dance shown next to them. The several paintings of peasant dances are obvious examples, and others, less obvious, are the processional representations in "The Way to Calvary" and in "The Conversion of St. Paul." The latter work also conveys the sensation of the movement of figures through the constantly changing terrain of mountainous regions. This sensation had appeared first in the early mountain drawings and, later, in different form, in "The Flight into Egypt" (1563; Count Seilern Collection, London). Toward the end of his life, Bruegel seems to have become fascinated by the problem of the falling figure. His studies reached their apogee in a rendering of successive stages of falling in "The Parable of the Blind." The perfect unity of form, content, and expression marks this painting as a high point in European art.

The subject matter of Bruegel's compositions covers an impressively wide range. In addition to the landscapes, his repertoire consists of conventional biblical scenes and parables of Christ, mythological subjects as in "Landscape with the Fall of Icarus" (two versions, Musées Royaux des Beaux-Arts and D.M. van Buuren Collection, Brussels), the illustrations of proverbial sayings in "The Netherlandish Proverbs" and several other paintings. His allegorical compositions are often of a religious character, as the two engraved series of "The Vices" (1556–57) and "The Virtues" (1559–60), but they included profane social satires as well. The scenes from peasant life are well known, but a number of subjects that are not easy to classify include "The Fight between Carnival and

Lent" and "Children's Games" (1559 and 1560, both Kunsthistorisches Museum, Vienna) and "Dulle Griet" also known as "Mad Meg" (1562; Musée Mayer van den Bergh, Antwerp).

Although the surface meaning of Bruegel's works generally is obvious, modern research has called attention to some deeper significance that is not always easily elucidated. There seems to be much justification in the words in Ortelius's obituary of Bruegel, "In all his works more is implied than is depicted." Moreover, van Mander speaks of drawings that Bruegel asked that his wife burn when he was on his deathbed, either from remorse or for fear that she might get into trouble. These destroyed drawings might have been political, directed against the Spanish oppression of the Low Countries, or religious, against the Roman Catholic Church. Considering the biographer's remarks in the light of the extant works and their general character, there seems to be no possibility for believing these works to have contained political implications. The one painting that has been assumed to refer to the Spanish Duke of Alba's reign of terror, "The Massacre of the Innocents" (two versions, Hampton Court, England, and Kunsthistorisches Museum, Vienna) was probably painted shortly before Alba's arrival in the Low Countries in 1567.

Religious views

As for religious unorthodoxy, which Bruegel expressed in a veiled way, it has been suggested that the painter may have been associated with the "Familia Caritatis" or "Family of Love," a contemporary heretical movement indulging in mysticism. If Bruegel's religious convictions were in fact unorthodox, it is more likely that he shared the views of Dirck Coornhert, a friend of Ortelius and one of the engravers working for Cock. It has recently been shown how closely many of Bruegel's works mirror the moral and religious ideas of Coornhert, whose writings on ethics show a rationalistic, commonsense approach. He advocated a Christianity free from the outward ceremonies of the various denominations, Roman Catholic, Calvinist, and Lutheran, which he rejected as irrelevant. In an age of bitter conflicts arising out of religious intolerance, Coornhert pleaded for toleration. Bruegel, of course, castigated human weakness in a more general way, with avarice and greed as the main targets of his criticism that was ingeniously expressed in the engraving "The Battle Between the Money Bags and Strong Boxes." This would have been in keeping with Coornhert's views as well, which permitted taking part outwardly in the old forms of worship and accepting the patronage of Cardinal Granvelle.

MAJOR WORKS

"The Adoration of the Kings" (*c.* 1556; Musées Royaux des Beaux-Arts, Brussels); "The Fight Between Carnival and Lent" (1559; Kunsthistorisches Museum, Vienna); "The Netherlandish Proverbs" (1559; Staatliche Museen Preussischer Kulturbesitz, Berlin); "The Triumph of Death" (*c.* 1562; Prado, Madrid); "The Suicide of Saul" (1562; Kunsthistorisches Museum, Vienna); "View of Naples" (*c.* 1562–63; Galleria Doria-Pamphili, Rome); "The Tower of Babel" (1563; Kunsthistorisches Museum, Vienna); "The Way to Calvary" (1564; Kunsthistorisches Museum, Vienna); "The Adoration of the Kings" (1564; National Gallery, London); "Labours of the Months" (1565; three in Vienna, one in Prague, and one in New York); "The Massacre of the Innocents (*c.* 1565–67; Hampton Court, Middlesex, England); "The Wedding Dance" (1566; Detroit Institute of Arts); "The Sermon of St. John the Baptist" (1566; Budapest Museum of Fine Arts); "The Conversion of St. Paul" (1567; Kunsthistorisches Museum, Vienna); "The Cripples" (1568; Louvre, Paris); "Peasant Wedding" (*c.* 1567; Kunsthistorisches Museum, Vienna); "The Parable of the Blind" (1568; Museo e Gallerie Nazionali di Capodimonte, Naples); "The Magpie on the Gallows" (1568; Hessiches Landesmuseum, Darmstadt); "The Storm at Sea" (Kunsthistorisches Museum, Vienna).

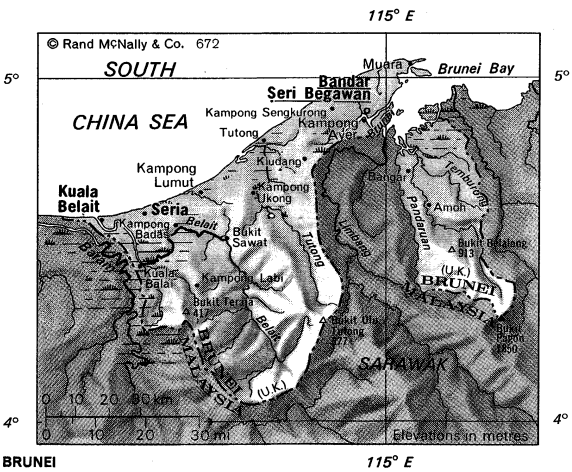
Brunei

Brunei is a small, British-protected Islāmic sultanate situated on the north coast of Borneo. It has an area of only 2,226 square miles (5,765 square kilometres) and a population of about 136,000. It is bounded to the north by the South China Sea and on all other sides by the Malaysian state of Sarawak, which also divides the state into two separate and unequal enclaves; the western enclave is the larger. The capital is Bandar Seri Begawan (formerly the city of Brunei).



Brunei is one of the largest oil producers in the British Commonwealth and enjoys one of the highest standards of living in Southeast Asia. It is one of the few remaining countries in the world without personal income tax.

Relief, drainage, and soils. Except for the narrow coastal plain, the country is rugged and hilly, with maximum altitudes of a little more than 3,000 feet in the southeast. The country is drained by the Belait, Tutong, Brunei, and Temburong rivers, all of which flow generally northward to the sea. The Belait is the largest river in the country. In the hilly region soils are mainly infertile laterites (red soils with a high content of iron oxides and aluminum hydroxide), but a narrow coastal stretch has alluvial and peat soils deposited by the rivers.

The rivers

Climate. The climate is governed by the equatorial monsoons (rain-bearing winds). The average range of temperatures is between 76° and 86° F (24° and 30° C). The annual rainfall varies from 100 inches in the coastal areas to more than 200 inches in parts of the interior. Most of the rainfall is brought by the northeast monsoon in November and March. From June to August the southwest monsoon season is relatively dry.

Vegetation and animal life. About 75% of the country is covered with tropical rain forest, characterized by a

large variety of hardwood species; large stretches of forest are inaccessible. Along the coast, hardwood casuarinas (often planted as shade trees) grow in the sandy soils, while peat and mangrove swamps occur along the poorly drained upper Belait and Tutong rivers and around Muara, a town in the extreme northeast portion of western Brunei. In 20 percent of the area, primary forest has been cleared for temporary cultivation, after which a secondary forest growth has occurred. The forests are inhabited by lions, tigers, and monkeys as well as by a variety of birds, insects, lizards, and snakes.

The landscape under human settlement. The interior is sparsely populated by indigenous peoples who clear areas of the forest for temporary cultivation. Permanent settlers and cultivators—Malays, Ibans, Kadazans (or Dusuns), and a few Chinese—occupy the river valleys and coastal areas. They live in thatched-roofed wooden or bamboo houses raised on stilts and cultivate rice, pepper, or sago on small farms. Coconut palms and a few fruit trees are planted around their houses, and, occasionally, rubber is grown on small holdings. In coastal areas fishing supplements agriculture. Farmers are poor, for agricultural productivity is low.

Urban settlement

Most of the population lives near the oil fields at Seria and Kuala Belait. The largest concentration of urban population is at Bandar Seri Begawan, the capital, which is situated nine miles up the Brunei River. Whereas wooden houses are found in the rural areas, the city has apartment buildings, hotels, a shopping centre, a commercial centre, and port facilities. Alongside the modern section of the city is the older section known as Kampong Ayer, where 10,000 Brunei Malays live in small houses on stilts along the inlets of a broad, winding river. These houses are interconnected by footbridges, and communication with land is via small boats.

People and population. Brunei, with a total population of 177,000 in the late 1970s, is a mixture of different Southeast Asian ethnic groups. About 66 percent of the population is Malay, 23 percent Chinese, 6 percent other indigenous peoples, and 5 percent Indian or other. Almost two-thirds of the people are Muslims, although in the remote interior there are still a few adherents to spirit worship. A small proportion of the indigenous population is Christian, and the Chinese are usually Buddhist, Taoist, or Confucianist.

Brunei, Area and Population

	area		population	
	sq mi	sq km	1971 census	1975 estimate
Districts				
Belait	1,052	2,725	42,400	51,300
Brunei and Muara	220	570	72,800	87,200
Temburong	450	1,166	5,200	6,100
Tutong	503	1,303	15,900	17,700
Total Brunei	2,226*	5,765*	136,300	162,400*

*Details do not add to total given because of rounding.
Source: Official government figures.

During the 1960–71 intercensal period, the annual rate of population increase was 4.5 percent; more than a quarter of the total increase (52,000 persons), however, was attributable to immigration. The natural growth of the population was thus estimated to be a rather high 3.3 percent per annum. The high rates of natural increase and immigration continued into the late 1970s but were easily outpaced by the increase in oil revenues, allowing the standard of living to rise rapidly.

The national economy. Petroleum, discovered in 1929, now forms the backbone of Brunei's economy, accounting for 99 percent or more of its export earnings and giving its inhabitants the highest per capita income in East Asia, exceeding even that of the Japanese. Brunei draws crude oil from the original onshore well at Seria and from offshore wells that stretch for 700 miles between Bandar Seri Begawan and Seria and ships it by pipeline to the Lutong refinery in Sarawak. Production is increasing, and total reserves are estimated at 1,900,000,000 barrels. New fields continue to be found offshore, and prospecting continues on land. The main sources of revenue are taxes on and royalties from oil and investments abroad.

Oil production

Agricultural and forestry products—rubber, pepper, wood, and cork—account for less than 1 percent of the export earnings. Rubber is mainly a smallholder crop, and only small amounts are produced on estates; productivity is generally low. Pepper is cultivated at Labi in Belait district. Other agricultural crops—rice, sago, and local fruits—are grown on a small scale. Production does not meet local demand; hardly more than a quarter of the rice requirement is produced locally. Sago—grown in the remote areas for food, sago flour, and thatching materials—is cultivated in peaty swamps and takes from eight to 10 years to mature.

Accessible forest regions supply an expanding timber industry, which exports sawn timber.

Transport. Road transport is poorly developed. A main trunk road links the capital to the oil towns of Seria and Kuala Belait, while another road links the coast to the pepper-growing district at Labi. Elsewhere in the interior, rivers are the main means of communication.

Brunei is served by two river ports—at Bandar Seri Begawan and at Kuala Belait—and both have wharves. A deepwater port at Muara was completed in 1973. Passenger ferry services are in operation between Bandar Seri Begawan and Labuan, in Malaysia, and between Bandar Seri Begawan and Bangar. At Bandar Seri Begawan there are an airport and several landing strips for helicopters. Royal Brunei Airlines and other airlines operate passenger service to and from Brunei, and domestic services are provided by the defense forces.

Administration and social conditions. In accordance with Brunei's first written constitution (1959), as amended in 1965, there are a Privy Council (which advises the sultan), a Council of Ministers, and an elected Legislative Council of 20 members and a speaker appointed by the sultan. Executive authority belongs to the *mentri besar* (chief minister), who is an ex-officio member of the Legislative Council and the Council of Ministers. The sultan presides over the Council of Ministers, on which also sits the high commissioner, representing the United Kingdom. Elections are officially held every five years, but the last were held in 1965 and further elections were postponed indefinitely.

Internal security is maintained by the Royal Brunei Malay Regiment, equipped with armoured vehicles, helicopters, air-cushion vehicles, and coastal and riverine patrol boats. The 6th Gurkha Battalion is stationed there.

Social welfare

Brunei is a welfare state, and social facilities are well developed. Medical services for rural areas include a "flying doctor" service to the villages, outdoor clinics, and travelling dispensaries. Education at the primary and secondary levels is available in English, Malay, and Chinese. Primary education is universal, and tuition is free. Free hostel accommodation and free transport are provided for pupils in remote areas. There is a pension scheme for the aged, disabled, and sick.

Future prospects. Brunei is making rapid progress with the aid of its income from petroleum. Lack of trained labour, however, constitutes a drawback.

BIBLIOGRAPHY. The Economist Intelligence Unit's *Quarterly Economic Review, Malaysia, Singapore, and Brunei* (no. 33), quarterly with an annual suppl., is a source of information on Brunei's economy, including data on its sources of revenue, trading partners, and petroleum industry. The first biennial *Brunei Statistical Yearbook,* published by the STATE SECRETARIAT, ECONOMIC PLANNING UNIT, STATISTICS DIVISION, covered the period 1973/74–1974/75 and provided official data on all aspects of the country's economic and social life. STATE SECRETARY, *State of Brunei Annual Report* (1946–), offers a basis for evaluating the success of the development plan (although published several years after the title year recorded in it); it also gives a concise account of social, economic, political, and cultural aspects of Brunei's national life. For financial analysis, STATE SECRETARY, *Estimates of Revenue and Expenditure* (annual, 1955–), provides insight into domestic and international factors that influence Brunei's economy.

(Ha.Se./Ed.)

Brunelleschi, Filippo

Although the renown of the architect Filippo Brunelleschi springs from his achievement in constructing the celebrated dome of Florence Cathedral (Duomo) and from his designs for the other buildings that were the prelude to Renaissance architecture in Italy, he began his career as a goldsmith and sculptor, went on to invent ingenious machines and mechanical devices, and founded the systematic application of the rules of scientific perspective. Brunelleschi also concerned himself with problems of time and motion (he reportedly made clocks), statics, hydraulics, and mathematics. Although some documents relating to Brunelleschi's professional activities have survived from the 15th century, they provide little information of a personal nature about the man who is regarded as one of the pioneers of Italian Renaissance art. Most of what is known about Brunelleschi's life and career is based on a biography written in the 1480s by an admiring younger contemporary identified as Antonio di Tuccio Manetti. Despite its inaccuracies and the fact that it was written four decades after Brunelleschi's death in 1446, Manetti's *Vita di Filippo Brunelleschi* remains the richest source of information about the great Renaissance master.

Alinari

Interior of S. Spirito, Florence, designed by Filippo Brunelleschi, begun 1436.

Early years. Filippo Brunelleschi was born in 1377 in Florence, the second of three sons of Ser Brunellesco di Lippo Lapi, a notary of some distinction, and Giuliana Spini. After training as a goldsmith and sculptor, he applied for registration in the Arte della Seta and in 1401 was designated a master. Although no documented works remain from Brunelleschi's earliest creative period, some of the small figures representing prophets and Church Fathers that adorn a silver alter in the Cathedral of Pistoia have convincingly been attributed to the young artist and dated *c.* 1399. Brunelleschi competed with Lorenzo Ghiberti and five other sculptors in 1401 to obtain the commission to make the bronze reliefs for the door of the Baptistery of Florence. Brunelleschi's trial panel depicting "The Sacrifice of Isaac" (Bargello, Florence) is the high point of his career as a sculptor. His ability to arrest narrative action at the moment of its greatest dramatic impact and the vigorous gestures and animated expressions of the figures account for the merit of his panel. It was Ghiberti, however, who was declared the winner, although the facts surrounding the jury's decision cannot be interpreted clearly. Brunelleschi's extreme disappointment at losing the commission probably accounted for his decision to concentrate his talents on architecture instead of sculpture. It also resulted in a lifelong hostility toward Ghiberti, although this resentment did not prevent them from collaborating on other projects when it was expedient. Brunelleschi did not, however, abandon his skill as a sculptor. No documented works after the competition panel remain, but the following are attributed to him: from the period 1410–15 a wood crucifix (Gondi Chapel, Sta. Maria Novella, Florence), a polychrome wood statue of Mary Magdalene (lost in a fire in 1471), and a small gilded metal figure produced jointly with Donatello in 1415 (lost); from the 1440s are the polychrome terra-cotta reliefs of the four Evangelists (beneath the dome of the Pazzi Chapel, Sta. Croce, Florence). The style of Brunelleschi's sculpture in the four decades between the Pistoia altar figures and the reliefs of the Pazzi Chapel underwent little change. He expressed himself primarily in the style of late Gothic art, creating attenuated figures wrapped in liquid draperies and placed in shallow layers of space. His most direct models have been traced to the late medieval workshops of French 14th-century goldsmiths.

Competition with Ghiberti

While still in the early phase of his architectural career (probably *c.* 1410–15) Brunelleschi rediscovered the principles of linear perspective construction known to the Greeks and Romans but buried along with many other aspects of ancient civilization during the Middle Ages. Brunelleschi demonstrated his findings with two painted panels, now lost, depicting Florentine streets and buildings. From Manetti's descriptions it is clear that Brunelleschi had understood the concept of a single vanishing point, toward which all parallel lines drawn on the same plane appear to converge, and the principle of the relationship between distance and the diminution of objects as they appear to recede in space. By using the optical and geometric principles upon which Brunelleschi's perspective devices were based, the artists of his generation were able to produce works of astonishing realism. On two-dimensional surfaces they were able to create extraordinary illusions of three-dimensional space and tangible objects, so that the work of art appeared to be either an extension of the real world or a mirror of nature. Although the laws governing perspective construction were brought to light by Brunelleschi, they were codified for the first time by the Humanist architect Leon Battista Alberti. In 1435 Alberti set them down in *Della pittura*, his famous treatise on painting, which included a warm dedication to Brunelleschi—undoubtedly an expression of Alberti's debt to his friend's revolutionary discovery.

Rediscovery of linear perspective

Solving complex problems of engineering and statics was another facet of Brunelleschi's wide-ranging abilities. His renowned mechanical inventions were immortalized in the Latin epitaph inscribed on his tomb in Florence Cathedral:

> How valiant Filippo the Architect was in the Daedalian art both the wonderful vault of this celebrated temple and the many machines invented by his divine genius document.

While most of his technical inventions related to the construction of the dome of Florence Cathedral, some of them reached as far afield as theatre production. One of Brunelleschi's most famous machines, probably invented around 1435–40, provided the setting for a liturgical drama celebrating the mystery of the Annunciation in the church of S. Felice in Florence. Suspended from the rafters of the church, the apparatus represented the dome of heaven. It contained complex movable sections and was operated by a hidden windlass.

Architectural career. The machines that Brunelleschi invented for the construction of the soaring dome of the Florence Cathedral and its lantern (a structure set on top of the dome to help illuminate the interior) and his scheme for the construction itself, represent his greatest feats of technological ingenuity. The cathedral was begun in 1296; during the 14th century the nave was completed and work commenced on the complex octagon of the east end. By 1418 construction reached the stage at

which the technical problems of constructing a vault above the enormous dimensions of the octagon had to be solved. These problems had involved previous generations of cathedral architects in bitter disputes. It was Brunelleschi who worked out a successful method to vault the dome, invented the machinery necessary to carry it out, and designed the structure's crowning lantern and its lateral tribunes (semicircular structures). He was named chief architect (*capomaestro*) of the dome project in 1420 and remained in that office until his death in 1446.

Florence Cathedral commission

In 1418 the cathedral officials announced a prize for models presenting technical devices for the construction of the dome, designed in the late Gothic period as an eight-sided vault of pointed curvature without exterior buttresses (structures built for additional support). Brunelleschi, along with many others (including his arch rival Ghiberti) submitted a model. In 1420 a decision was reached in favour of Brunelleschi's model, which demonstrated that the dome could be constructed without the traditional armature, or skeletal framework, by placing the brickwork in herringbone patterns between a framework of stone beams. This construction technique had been evolved by the ancient Romans and had possibly been first observed by Brunelleschi on his supposed trip to Rome (*c.* 1401) with his friend the sculptor Donatello, when both of these giants of early-Renaissance art are believed to have studied classical sculpture and architecture. In 1420 Brunelleschi's dome was begun; in 1436 the completed structure was consecrated, and in the same year his design for its lantern was approved. (The lantern, however, was not completed until after his death.) The imagination and the engineering calculations that led to the successful erection of the dome established Brunelleschi's fame.

Mid-20th-century criticism has modified the earlier approach to Brunelleschi's buildings as the foundations of Renaissance architecture. They are now understood in the context of two worlds—that of the waning Gothic period and also of the incipient Renaissance. Brunelleschi, therefore, is seen as an artist still profoundly dependent on Gothic forms of architecture and construction but with a vision of art and science that was based on the Humanistic concept of the ideal. This is borne out by his first major architectural commission, the Ospedale degli Innocenti (Hospital of the Innocents, or Foundling Hospital), where it is not clear whether his contribution was restricted to the arcaded portico that forms the building's facade or extended to the design of the rear portions of the building. Although Brunelleschi's name first appears in the hospital's construction records in 1421, he was probably at work on the building as early as 1419–20. His last documented association with the project was in 1426. After he left the project it was completed with deviations from his original plan, but his portico was generally regarded as the first example of the Renaissance style in architecture. This judgment must now be qualified to accommodate changing perspectives of the Renaissance. Although the portico is composed of many novel features, morphologically it still is related to traditions of Italian Romanesque and late Gothic architecture. The truly revolutionary aspects of the building emanated from Brunelleschi's intuitive sense of the formal principles of the classical art of antiquity. The Innocenti facade offered a new look in Florentine architecture and a marked contrast to the medieval buildings that preceded it. Its lingering late-medieval echoes were subordinated to the new style that provided the facade with its antique air: a wall delicately articulated with classical detail (such as Corinthian capitals, pilasters, tondi, and friezes), modular construction, geometrical proportions, and symmetrical planning.

Association with the Medici

By the early 1420s Brunelleschi was the most prominent architect in Florence. At this time the powerful and influential Medici family commissioned him to design the sacristy of S. Lorenzo (known as the Old Sacristy to distinguish it from Michelangelo's "new" 16th-century sacristy in the same church) and the basilica of S. Lorenzo itself. Work was begun in 1421. The sacristy was completed (without its decoration) by 1428. Construction on the basilica was halted at that time but began again in 1441 and lasted into the 1460s.

The S. Lorenzo structures are considered keystones of the early Renaissance architectural style. In form the church did not depart from the traditional basilican church with nave (central aisle), side aisles, and apse (a semicircular projection at the end of the nave). What Brunelleschi added to the conventional format was a new vocabulary using his own interpretation of antique designs for the capitals, friezes, pilasters (rectangular columns set into the wall), and columns. Further, his design of the church as a whole was one of unusual regularity, where the separate parts of the church rationally corresponded to each other and created a profound visual and intellectual harmony.

Brunelleschi designed the Old Sacristy (originally intended as a Medici family mausoleum) as a cube vaulted with a hemispherical dome. The structural and decorative units that delineate the architectural surface of the walls of the Old Sacristy and of the basilica proper are of particular elegance and restraint characteristic of Brunelleschi's work at this time.

Work for the Pazzi family

Around 1429 another wealthy and influential Florentine family, the Pazzi, commissioned Brunelleschi to design a chapel adjacent to the monastic church of Sta. Croce that was intended to be a chapter house (a place of assembly for monks to conduct business). Work probably did not begin before 1442; the building still was not complete in 1457. Modern archaeological investigation has revealed that the porch, famous for the beauty of its design and the elegance of its elaborate ornamentation, is not part of Brunelleschi's original project and that he intended to leave visible the outer curve of the barrel-vaulted sections of the roof, now covered by masonry. Brunelleschi used mathematical modules and geometric formulas for the plan and elevation of the Pazzi Chapel, as he had in S. Lorenzo, but he arranged the space in a more complex and sophisticated manner in the later building. A hemispherical dome covers a central square, which is extended on either side so that the square forms the centre of a rectangle. The minor spatial compartment, opening off a third side of the main square, is a corresponding square apse covered by a dome and containing the altar. The creamy wall surface of the Pazzi Chapel is marked off in geometric patterns by dark gray stone. The clarity, coolness, and elegance for which Brunelleschi's architecture is noted are seen in this small, harmoniously proportioned chapel.

Another example of Brunelleschi's experiments with central planning is one of his most enigmatic buildings, Sta. Maria degli Angeli, built for the Camaldolese monastery in Florence. It was begun in 1434 but left incomplete in 1437 (remaining in an unfinished state until the 1930s, when it was completed in a controversial manner). The building was planned as a central octagon with a 16-sided exterior. A chapel opened on each of the eight sides of the interior octagon, terminating in a deeply recessed apse at the end. Eight niches were cut into alternate facets of the exterior walls. Sta. Maria degli Angeli was Brunelleschi's most revolutionary design. It represented a perfectly centralized structure, more formally consistent than the Old Sacristy. Brunelleschi's model for this building has not been agreed upon by the critics, who have variously suggested monumental vaulted remains of ancient Roman architecture, such as the Temple of Minerva Medica in Rome or the late-medieval chapel-ringed octagon of Florence Cathedral. Instead of emphasizing the two-dimensional quality of his earlier works, Brunelleschi asserted the malleable nature of the wall mass and the plasticity of the structural and decorative architectural units. Many scholars therefore regard Sta. Maria degli Angeli as the beginning of a mature phase of Brunelleschi's architectural career, a phase dominated by solid rather than plane geometry and by sculptural space-molding elements. The late date, however, of the flat Pazzi Chapel, and the simultaneous construction of many of Brunelleschi's projects, tend to invalidate sharp distinctions between early and late styles in his career.

Brunelleschi's church of S. Spirito in Florence was designed either in 1428 or 1434, depending on the interpretation of the documents. The architect devised several unusual features for this building; one of the most interesting was a facade oriented to provide the building with a large entrance square overlooking the Arno River (this early example of Renaissance urban planning was never realized). Work on the church was begun in 1436 and proceeded through the 1480s. In 1486 the present facade with three portals was agreed upon in place of Brunelleschi's original scheme for a four-portal facade.

A basilican church with a centrally planned eastern end, S. Spirito is ringed by semicircular chapels opening off the dome-vaulted side aisles, the transept, and the apse. These chapels accounted for a unique aspect of the design, for the exterior walls of the church were meant to conform to the shape of the chapels in a sequential series of curves. After Brunelleschi died, however, the protruding round chapels were walled over with the flat conventional exterior now visible. Rather than creating its walls as flat surfaces onto which are pressed thin rectilinear members (pilasters), a style perfected in S. Lorenzo and the Pazzi Chapel, Brunelleschi designed S. Spirito with a feeling for its weight, gravity, and plasticity. The building, therefore, can be associated stylistically with Sta. Maria degli Angeli, and also with the four semicircular tribunes above the sacristies of Florence Cathedral. Brunelleschi's model for these tribunes was approved in 1439; the first one was completed in 1445, and the remaining three were finished in the 1460s. They are composed of deeply concave semicircular niches crowned with a shell device and separated by thick walls to which have been applied Corinthian half columns with projecting entablatures. In form and in mood, the tribunes were closer to monumental antique architecture than anything constructed in Florence up to that time, and they foreshadowed the strong profiles and massive grandeur of the buildings of Leon Battista Alberti and Donato Bramante (1444–1514).

Role as a residential and military architect

Brunelleschi's role as architect of residential buildings is difficult to assess, although Manetti relates that he was summoned from far and wide to design palaces. No documentary evidence exists for the houses and palaces with which biographers and scholars have credited him, the most significant of which (all in Florence) are the Pitti Palace, a rejected plan for the Palazzo Medici–Riccardi, and the Palazzo Bardi–Busini. Each of these palaces contains novel features that are tempting to attribute to Brunelleschi's inventiveness, but definitive proof of his influence or authorship has not been offered.

The manifold architectural abilities of Brunelleschi also are attested to by his military architecture, some of which is partially extant. He is associated with the building and rebuilding of fortifications in Pisa, Rencine, Vicopisano, Staggia, Castellina, Rimini, and Pesaro. In 1430 he was involved in a plan to convert the city of Lucca into an island by building a dam and deflecting the Arno River.

Brunelleschi was active through the early 1440s, and probably continued to be until shortly before his death. He died in Florence on April 15, 1446, and he is buried in Florence Cathedral. His burial place is marked by a wall monument composed of a marble half-length figure in relief, an idealized portrait of the architect carved by his adopted son, Andrea di Lazzaro Cavalcanti, and by the epitaph composed by the Florentine Humanist Carlo Aretino (Carlo Marsuppini).

Private life and assessment. An image of the personality of Brunelleschi can be pieced together from fragments contained in surviving source materials and documents. Although he never married, he was devoted to his adopted son and heir, Andrea di Lazzaro Cavalcanti (known as Il Buggiano), a sculptor, whose career he promoted. Many pieces of church furniture (pulpits, tabernacles, altar tables, lavabos, etc.) attributed to Brunelleschi were in fact designed by Brunelleschi but executed by Il Buggiano. Brunelleschi was an irascible and argumentative man, and he was secretive, believing it imprudent to share his inventions and ideas. These characteristics were consistent with the highly competitive atmosphere of early-15th-century Florence. He not only sustained his bitter rivalry with Ghiberti throughout his lifetime but he also had acrimonious arguments with many other artists, including his friend Donatello. Brunelleschi also wrote sonnets, which seem to have been largely inspired by anger; for his known sonnets were created as public invectives against his enemies.

Above all, Brunelleschi was a practical man. Not inclined to theorizing or codifying, he changed the course of architecture through persistent attention to problems of structure and space. Although he was respected and admired by the greatest Humanists of his generation, his approach to antiquity was not academic or doctrinaire. Using the classicizing elements of Tuscan medieval architecture as the medium through which he approached the venerated classical world, he imparted to his buildings a unique elegance and grace that were uncharacteristic of ancient Roman architecture. Convincing prototypes for his buildings can be discovered in the Byzantine-influenced structures of northeastern Italy, in Tuscan Romanesque and Italian late Gothic architecture, as well as in the ruins of ancient Rome. The most impressive symbol of the synthesis of Brunelleschi's two worlds is the harmonious juxtaposition of the "Gothic" dome of Florence Cathedral and its Renaissance tribunes, these structures being brilliantly unified by the ingenuity of "the valiant Filippo."

MAJOR WORKS

Spedale degli Innocenti (Foundling Hospital), Florence (1419–26); Barbadori Chapel, Sta. Felicita, Florence (*c.* 1420); Palazzo di Parte Guelfa, Florence (facade and grand salon, *c.* 1420); dome of Florence Cathedral (1420–36); Old Sacristy, S. Lorenzo, Florence (1421–28); basilica of S. Lorenzo, Florence (1421–29, 1441–60s); Sta. Maria degli Angeli, Florence (1434–37, unfinished); lantern of Florence Cathedral (1435 ff.); S. Spirito, Florence (1436–80s); tribunes of Florence Cathedral (1439 ff.); Pazzi Chapel, Sta. Croce, Florence (?1442–60s).

BIBLIOGRAPHY. The most important biography of Brunelleschi, informatively annotated, is ANTONIO MANETTI, *Vita di Filippo di Ser Brunellesco* (1812 and later editions; Eng. trans., *The Life of Brunelleschi*, ed. by H. SAALMAN, trans. by C. ENGGASS, 1970). Fundamental studies of Brunelleschi and his work, not translated, are CORNELIUS VON FABRICZY, *Filippo Brunelleschi: Sein Leben und seine Werke* (1892); L.H. HEYDENREICH, "Spatwerke Brunelleschis," *Jahrbuch der Preussischen Kunstsammlungen*, 52:1–28 (1931); P. SANPAOLESI, *Brunelleschi* (1962); and E. LUPORINI, *Brunelleschi, Forma e Ragione* (1964); in English are F.D. PRAGER and G. SCAGLIA, *Brunelleschi: Studies of His Technology and Inventions* (1970); C. ARGAN, "The Architecture of Brunelleschi and the Origins of Perspective Theory," *Journal of the Warburg and Courtauld Institute*, 9:96–121 (1946); P. SANPAOLESI, biography of Brunelleschi in the *Encyclopedia of World Art*, vol. 2 (1960), with bibliography; and P.J. MURRAY, *Architecture of the Italian Renaissance* (1963).

(I.Hy.)

Bruno, Giordano

Giordano Bruno, a 16th-century philosopher, astronomer, and mathematician, is significant for his theories of the infinite universe and the multiplicity of worlds, in which he rejected the traditional geocentric (or Earth-centred) astronomy and intuitively went beyond the Copernican heliocentric (Sun-centred) theory, which still maintained a finite universe with a sphere of fixed stars. Bruno is, perhaps, chiefly remembered for the tragic death he suffered at the stake because of the tenacity with which he maintained his unorthodox ideas at a time when both the Roman Catholic and the Reformed churches were reaffirming rigid Aristotelian and Scholastic principles in their struggle for the evangelization of Europe.

Unorthodox ideas

Early career in Italy and Geneva. Bruno was born in 1548 at Nola, Italy, near Naples, the son of a professional soldier. He was named Filippo at his baptism and was later called "il Nolano," after the place of his birth. In 1562 Bruno went to Naples to study the humanities, logic, and dialectics (argumentation). He was impressed by the lectures of G.V. de Colle, who was known for

his tendencies toward Averroism—*i.e.*, the thought of a number of Western Christian philosophers who drew their inspiration from the interpretation of Aristotle put forward by the Muslim philosopher Averroës—and by his own reading of works on memory devices and the arts of memory (mnemotechnical works). In 1565 he entered the Dominican convent of San Domenico Maggiore in Naples and assumed the name Giordano. Because of his unorthodox attitudes, he was soon suspected of heresy. Nevertheless, in 1572 he was ordained as a priest. During the same year he was sent back to the Neapolitan convent to continue his study of theology. In July 1575 Bruno completed the prescribed course, which generated in him an annoyance at theological subtleties. He had read two forbidden commentaries by Erasmus and freely discussed the Arian heresy, which denied the divinity of Christ; as a result, a trial for heresy was prepared against him by the provincial father of the Order, and he fled to Rome in February 1576. There he found himself unjustly accused of a murder. A second excommunication process was started, and in April 1576 he fled again. He abandoned the Dominican Order, and, after wandering in northern Italy, he went in 1578 to Geneva, where he earned his living by proofreading. Bruno formally embraced Calvinism; after publishing a broadsheet against a Calvinist professor, however, he discovered that the Reformed Church was no less intolerant than the Catholic. He was arrested, excommunicated, rehabilitated after retraction, and finally allowed to leave the city. He moved to France, first to Toulouse —where he unsuccessfully sought to be absolved by the Catholic Church, but was nevertheless appointed to a lectureship in philosophy—and then in 1581 to Paris.

Career in France, England, and Germany. In Paris Bruno at last found a congenial place to work and teach. Despite the strife between the Catholics and the Huguenots (French Protestants), the court of Henry III was then dominated by the tolerant faction of the Politiques (moderate Catholics, sympathizers of the Protestant king of Navarre, Henry of Bourbon, who became the heir apparent to the throne of France in 1584). Bruno's religious attitude was compatible with this group, and he received the protection of the French king, who appointed him one of his temporary *lecteurs royaux*. In 1582 Bruno published three mnemotechnical works, in which he explored new means to attain an intimate knowledge of reality. He also published a vernacular comedy, *Il Candelaio* (1582; "The Candlemaker"), which, through a vivid representation of contemporary Neapolitan society, constituted a protest against the moral and social corruption of the time.

In the spring of 1583 Bruno moved to London with an introductory letter from Henry III for his ambassador Michel de Castelnau. He was soon attracted to Oxford, where, during the summer, he started a series of lectures in which he expounded the Copernican theory maintaining the reality of the movement of the Earth. Because of the hostile reception of the Oxonians, however, he went back to London as the guest of the French ambassador. He frequented the court of Elizabeth I and became associated with such influential figures as Sir Philip Sidney and Robert Dudley, the earl of Leicester.

In February 1584 he was invited by Fulke Greville, a member of Sidney's circle, to discuss his theory of the movement of the Earth with some Oxonian doctors; but the discussion degenerated into a quarrel. A few days later he started writing his Italian dialogues, which constitute the first systematic exposition of his philosophy. There are six dialogues, three cosmological—on the theory of the universe—and three moral. In the *Cena de le Ceneri* (1584; "The Ash Wednesday Supper"), he not only reaffirmed the reality of the heliocentric theory but also suggested that the universe is infinite, constituted of innumerable worlds substantially similar to those of the solar system. In the same dialogue he anticipated his fellow Italian astronomer Galileo Galilei by maintaining that the Bible should be followed for its moral teaching but not for its astronomical implications. He also strongly criticized the manners of English society and the pedantry of the Oxonian doctors. In the *De la causa, principio e uno* (1584; Eng. trans., *Concerning the Cause, Principle, and One*, 1950) he elaborated the physical theory on which his conception of the universe was based: "form" and "matter" are intimately united and constitute the "one." Thus, the traditional dualism of the Aristotelian physics was reduced by him to a monistic conception of the world, implying the basic unity of all substances and the coincidence of opposites in the infinite unity of Being. In the *De l'infinito universo e mondi* (1584; Eng. trans. *On the Infinite Universe and Worlds*, 1950), he developed his cosmological theory by systematically criticizing Aristotelian physics; he also formulated his Averroistic view of the relation between philosophy and religion, according to which religion is considered as a means to instruct and govern ignorant people, philosophy as the discipline of the elect who are able to behave themselves and govern others. The *Spaccio de la bestia trionfante* (1584; Eng. trans., *The Expulsion of the Triumphant Beast*, 1964), the first dialogue of his moral trilogy, is a satire on contemporary superstitions and vices, embodying a strong criticism of Christian ethics—particularly the Calvinistic principle of salvation by faith alone, to which Bruno opposes an exalted view of the dignity of all human activities. The *Cabala del cavallo Pegaseo* (1585; "Cabal of the Horse Pegasus"), similar to but more pessimistic than the previous work, includes a discussion of the relationship between the human soul and the universal soul, concluding with the negation of the absolute individuality of the former. In the *De gli eroici furori* (1585; Eng. trans., *The Heroic Frenzies*, 1964), Bruno, making use of Neoplatonic imagery, treats the attainment of union with the infinite One by the human soul and exhorts man to the conquest of virtue and truth.

Polemics against mathematicians and philosophers

In October 1585 Bruno returned to Paris, where he found a changed political atmosphere. Henry III had abrogated the edict of pacification with the Protestants, and the King of Navarre had been excommunicated. Far from adopting a cautious line of behaviour, however, Bruno entered into a polemic with a protégé of the Catholic party, the mathematician Fabrizio Mordente, whom he ridiculed in four *Dialogi*, and in May 1586 he dared to attack Aristotle publicly in his *Centum et viginti articuli de natura et mundo adversus Peripateticos* ("120 Articles on Nature and the World against the Peripatetics"). The Politiques thereupon disavowed him, and Bruno left Paris.

He went to Germany, where he wandered from one university city to another, lecturing and publishing a variety of minor works, including the *Articuli centum et sexaginta* (1588; "160 Articles") against contemporary mathematicians and philosophers, in which he expounded his conception of religion—a theory of the peaceful coexistence of all religions based upon mutual understanding and the freedom of reciprocal discussion. At Helmstedt, however, in January 1589 he was excommunicated by the local Lutheran Church. He remained in Helmstedt until the spring, completing works on natural and mathematical magic (posthumously published) and working on three Latin poems—*De minimo*, *De monade*, and *De innumerabilibus sive de immenso*—which re-elaborate the theories expounded in the Italian dialogues and develop Bruno's concept of an atomic basis of matter and being. To publish these, he went in 1590 to Frankfurt am Main, where the senate rejected his application to stay. Nevertheless, he took up residence in the Carmelite convent, lecturing to Protestant doctors and acquiring a reputation of being a "universal man" who, the Prior thought, "did not possess a trace of religion" and who "was chiefly occupied in writing and in the vain and chimerical imagining of novelties."

Final years in Venice and Rome. In August 1591, at the invitation of the Venetian patrician Giovanni Mocenigo, Bruno made the fatal move of returning to Italy. At the time such a move did not seem to be too much of a risk: Venice was by far the most liberal of the Italian states; the European tension had been temporarily eased after the death of the intransigent pope Sixtus V in 1590; the Protestant Henry of Bourbon was now on

the throne of France, and a religious pacification seemed to be imminent. Furthermore, Bruno was still looking for an academic platform from which to expound his theories, and he must have known that the chair of mathematics at the University of Padua was then vacant. Indeed, he went almost immediately to Padua and, during the late summer of 1591, started a private course of lectures for German students and composed the *Praelectiones geometricae* and *Ars deformationum*. At the beginning of the winter, when it appeared that he was not going to receive the chair (it was offered to Galileo in 1592), he returned to Venice, as the guest of Mocenigo, and took part in the discussions of progressive Venetian aristocrats who, like Bruno, favoured philosophical investigation irrespective of its theological implications. Bruno's liberty came to an end when Mocenigo—disappointed by his private lessons from Bruno on the art of memory, and resentful of Bruno's intention to go back to Frankfurt to have a new work published—denounced him to the Venetion Inquisition in May 1592 for his heretical theories. Bruno was arrested and tried. He defended himself by admitting minor theological errors, emphasizing, however, the philosophical rather than the theological character of his basic tenets. The Venetian stage of the trial seemed to be proceeding in a way that was favourable to Bruno; then, however, the Roman Inquisition demanded his extradition, and on January 27, 1593, Bruno entered the jail of the Roman palace of the Sant'Uffizio (Holy Office). During the seven-year Roman period of the trial, Bruno at first developed his previous defensive line, disclaiming any particular interest in theological matters and reaffirming the philosophical character of his speculation. This distinction did not satisfy the inquisitors, who demanded an unconditional retraction of his theories. Bruno then made a desperate attempt to demonstrate that his views were not incompatible with the Christian conception of God and creation. The inquisitors rejected his arguments and pressed him for a formal retraction. Bruno finally declared that he had nothing to retract and that he did not even know what he was expected to retract. At that point, Pope Clement VIII ordered that he should be sentenced as an impenitent and pertinacious heretic. On February 8, 1600, when the death sentence was formally read to him, he addressed his judges, saying: "Perhaps your fear in passing judgment on me is greater than mine in receiving it." On February 17 he was brought to the Campo di Fiori, his tongue in a gag, and burned alive.

Denounced to the Inquisition

Influence. Bruno's theories influenced 17th-century scientific and philosophical thought, and since the 18th century, have been absorbed by many modern philosophers. As a symbol of the freedom of thought, Bruno inspired the European liberal movements of the 19th century, particularly the Italian Risorgimento (the movement for national political unity). Because of the variety of his interests, modern scholars are divided as to the chief significance of his work. Bruno's cosmological vision certainly anticipates some fundamental aspects of the modern conception of the universe; his ethical ideas, in contrast with religious ascetical ethics, appeal to modern humanistic activism; and his ideal of religious and philosophical tolerance has influenced liberal thinkers. On the other hand, his emphasis on the magical and the occult has been the source of criticism as has his impetuous personality. Bruno stands, however, as one of the important figures in the history of Western thought, a precursor of modern civilization.

BIBLIOGRAPHY

Editions: Modern editions of Bruno's works are (*Latin*): *Opera latine conscripta*, ed. by FRANCESCO FIORENTINO *et al.*, 3 vol. in 8 parts (1879–91, reprinted 1962), supplemented by *Due dialoghi sconosciuti e due dialoghi noti* (1957) and "*Praelectiones geometricae*" *e* "*Ars deformationum*" by GIOVANNI AQUILECCHIA (1964), which were unknown to the previous editors. (*Italian*): *Dialoghi Italiani*, by GIOVANNI GENTILE, 3rd ed. by GIOVANNI AQUILECCHIA (1958), is the standard edition of the six dialogues. "Concerning the Cause, Principle and One," in SIDNEY GREENBERG, *The Infinite in Giordano Bruno* (1950); *Cause, Principle and Unity*, by JACK LINDSAY (1962); "On the Infinite Universe and Worlds," in DOROTHEA WALEY SINGER, *Giordano Bruno: His Life and Thought* (1950); *The Expulsion of the Triumphant Beast*, anon. (1713) and by A.D. IMERTI (1964); *The Heroic Frenzies*, by P.E. MEMMO, JR. (1964).

Biography: VINCENZO SPAMPANATO, *Vita di Giordano Bruno* (1921), with an appendix of documents reprinted with new documents in *Documenti della vita di Giordano Bruno*, ed. by VINCENZO SPAMPANATO and GIOVANNI GENTILE (1933); *Il sommario del processo di Giordano Bruno*, ed. by ANGELO MERCATI (1942), a summary and partial transcription of the minutes of the trial; GIOVANNI AQUILECCHIA, *Giordano Bruno* (1971), a synthetic but exhaustive biography, with a bibliographical appendix that substantially brings up to date that contained in VIRGILIO SALVESTRINI, *Bibliografia de Giordano Bruno, 1582–1950*, 2nd posthumous ed. by LUIGI FIRPO (1958).

Critical studies: GIOVANNI GENTILE, *Il pensiero italiano del Rinascimento*, 4th ed. (1968), which considers Bruno as a precursor of the 19th- and 20th-century philosophical Idealism; P.H. MICHEL, *La Cosmologie de Giordano Bruno* (1962), which reacts to the metaphysical interpretation of Bruno's system; PAUL O. KRISTELLER, *Eight Philosophers of the Italian Renaissance* (1964); FRANCES A. YATES, *Giordano Bruno and the Hermetic Tradition* (1964), which reacts to the progressive interpretation of Bruno's thought by considering it as belonging to the occult tradition based on the texts of the pseudo-Hermes Trimegistus; and *The Art of Memory* (1966), which includes a study of Bruno's mnemotechnic works considered against their historical and philosophical background; and FULVIO PAPI, *Antropologia e civiltà nel pensiero di Giordano Bruno* (1968), which includes an original discussion of Bruno's views on human attitudes and civilization.

(G.A.)

Brussels

Brussels in the early 1970s consisted of an agglomeration of more than 1,000,000 inhabitants, divided into 19 administratively autonomous communes centring on Inner Brussels, the capital of the Kingdom of Belgium. Though the average visitor might remain unaware of this dispersal of local government powers, it implies many disadvantages for the inhabitants and holds the key to an understanding of much of the condition of life in the contemporary city. It has impeded the harmonious development of the spreading built-up areas that reflect the continued population influx which has occurred since 1830, and a rational solution to the traffic problem—a crucial difficulty for more than half a century—has been rendered practically impossible.

The importance of local government powers

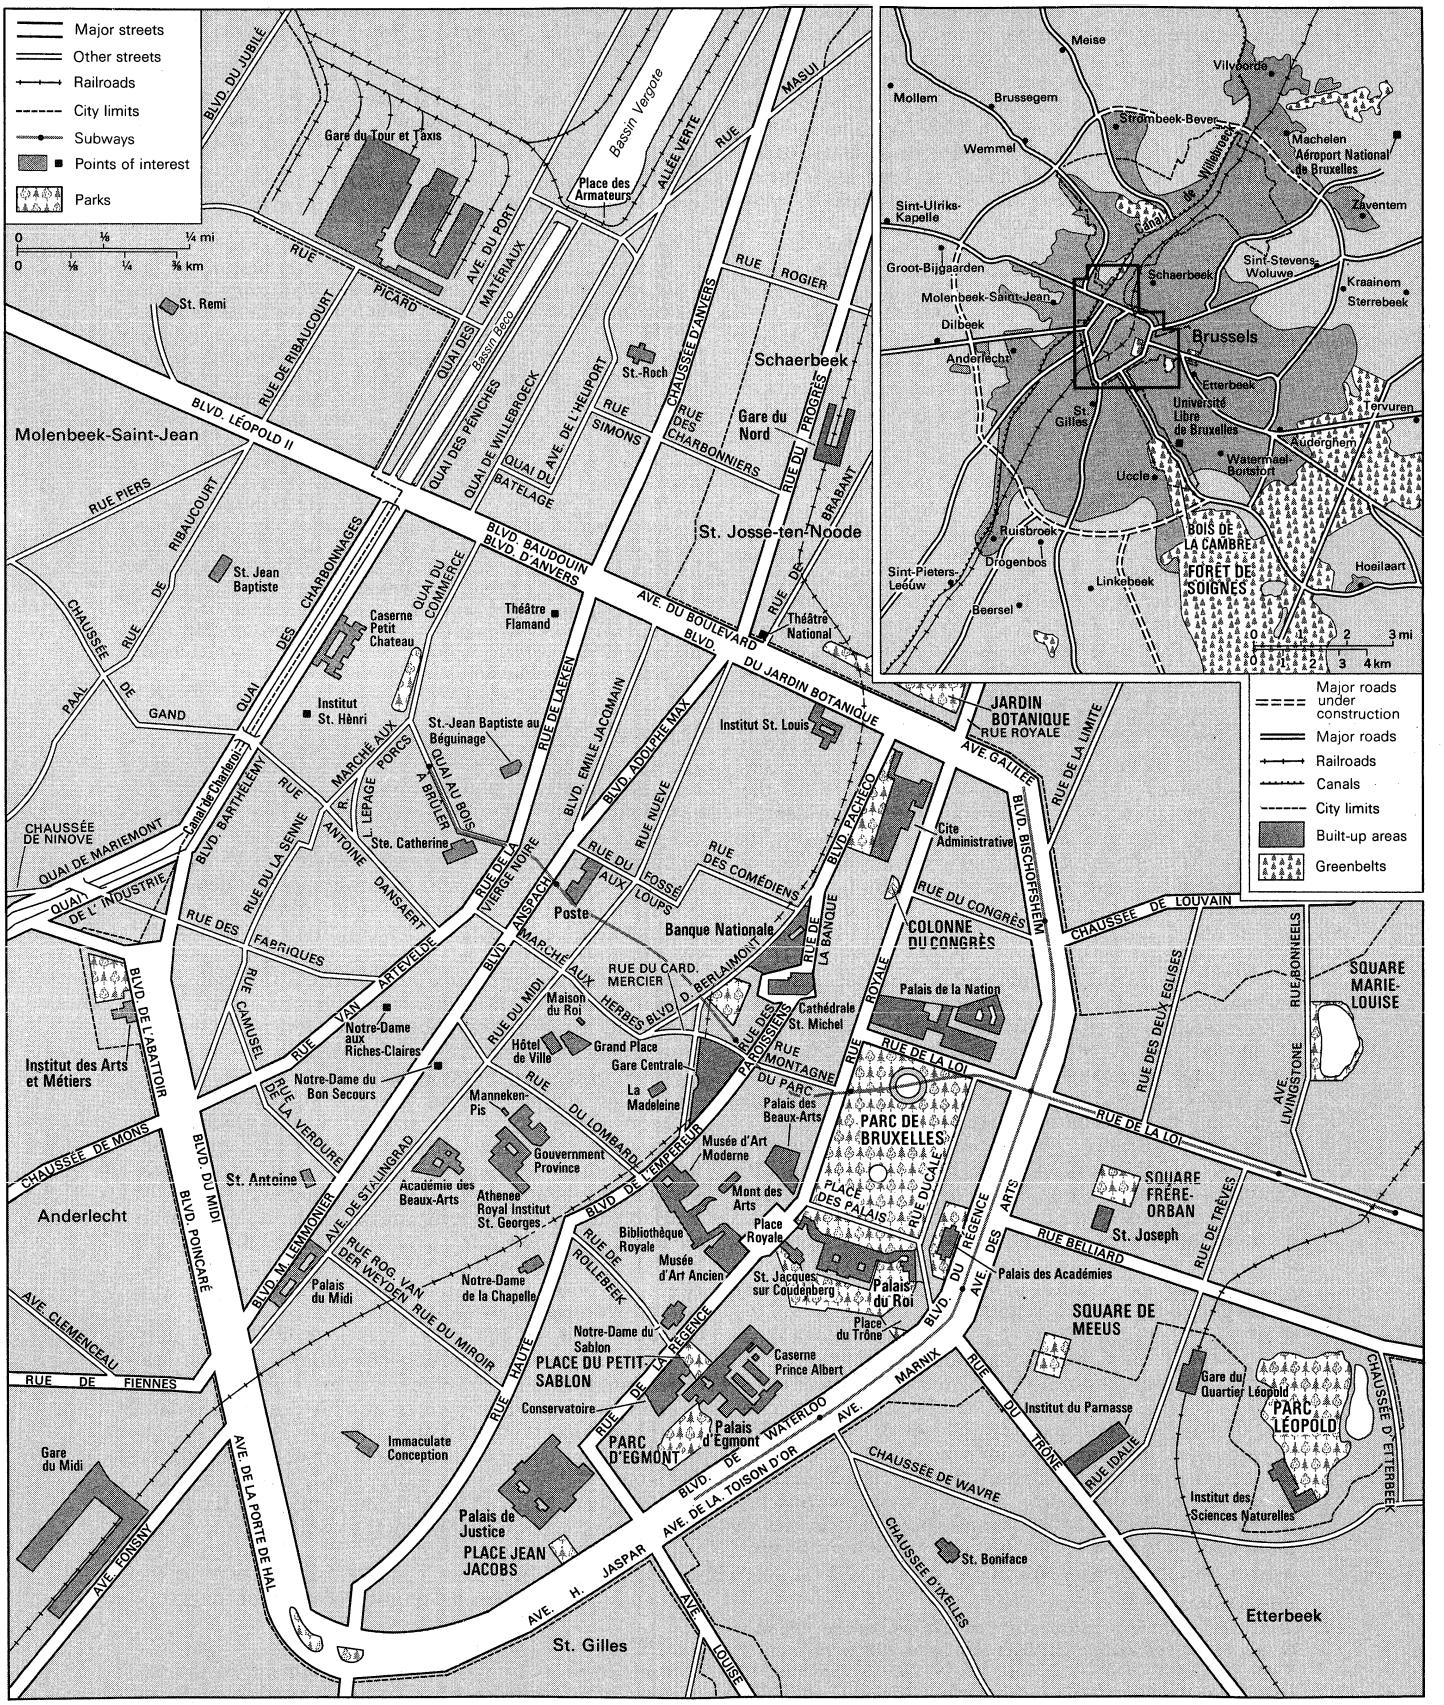
A further major problem arises from the geographic location of the city, which places it in the Flemish linguistic zone, only a few miles north of the invisible "frontier" separating the Flemish community and the French-speaking community, which between them constitute the Belgian nation. The majority of residents in the Brussels agglomeration, however, speak French, and the area has been the principal venue for often-disruptive clashes between Flemings and Walloons, which have served as a real threat to national unity.

In spite of these difficulties, the historic city, in addition to acting as a major European tourist and cultural attraction, functions simultaneously as regional metropolis, national capital, and international centre. The last-named role has flourished since the city became host to the European communities (made up of the European Economic Community, or European Common Market; the European Coal and Steel Community; and the European Atomic Energy Community) as well as to the North Atlantic Treaty Organization (NATO) headquarters. Over 80 ambassadors are now accredited to the king of the Belgians, to the European Common Market, or to NATO.

HISTORY

Brussels owes its origin to the establishment, in the 6th century, of a fortified castle on a little island in the River Senne (Flemish Zenne), a tributary of the Schelde (French Escaut) flowing from south to north, and to an east–west economic route linking the Rhenish towns with those in the county of Flanders.

A market and bartering place developed under the protection of the dukes of Brabant, at the point where road and river crossed. Craftsmen and merchants settled in



Central Brussels and (inset) its metropolitan area. For most places, French names have been used; Flemish equivalents have equal official standing.

increasing numbers in the locality, which they called Bruoc-sella (the Settlement in the Marshes). By the 11th century the little community was protected by encircling ramparts with towers and seven fortified gateways.

During the 12th, 13th, and 14th centuries the manufacture of luxury fabrics, exported to fairs in the Champagne region of France, Paris, Venice, and elsewhere, occupied thousands of workers. It also made fortunes for a few enterprising merchant families, who developed into seven dynasties that, with the help of the duke of Brabant, acquired a position of complete political mastery. In control of business and municipal affairs, they also exercised power as magistrates, giving rulings on disputes and conflicts arising among the inhabitants; the prevailing regime was, in fact, strongly plutocratic in nature.

Abuse of such powers provoked violent popular uprisings, in 1280, in 1303, in 1421. This last upheaval led to a more democratic system, with local powers divided between the patrician families, on the one hand, and the emergent guilds of craftsmen and other workers, on the other.

Events of particular significance in the 14th century were the invasion of the duchy of Brabant by the Count of Flanders' troops, their occupation of Brussels, the town's liberation, and the construction immediately afterward (1357) of huge surrounding fortified walls, which survived until 1830.

Burgundian era

In 1430 the duchy was merged in the possessions of the duke of Burgundy. The Burgundian period, which lasted until 1477, was one of political and artistic prestige. Brussels became the seat of the central administrative bodies for the ducal possessions in the Low Countries, which constituted a rich centre of art and culture. Pictures by Rogier van der Weyden, the officially appointed town painter, sculptures in wood, large tapestries with historic motifs, plate, jewelry, and other products by Brussels craftsmen came to be exported in all directions.

Brussels began to beautify itself: by the marketplace, the Hôtel de Ville (Town Hall) (1402–54) rose proudly, with its tall perforated steeple surmounted by a statue of the archangel Michael, the city's patron saint. Various Gothic churches and cathedrals—the Cathedral of St. Michel and Ste. Gudule, Notre-Dame du Sablon, Notre-Dame de la Chapelle—and the ducal Coudenberg Palace, with its extensive park, added to the architectural splendour.

Brussels retained its position as a capital during the reign of Charles V (1515–55), Holy Roman Emperor. The three government councils (the Council of State, the Privy Council, and the Finance Council) were established there permanently. The population reached nearly 50,000. In the later part of the 16th century the Canal de Willebroeck (Kanaal van Willebroek) was dug to provide a direct link with the Rupel and the Schelde rivers; in other words, with the port of Antwerp. Replacing the sandy little river, this channel was to play an important commercial role.

Baroque churches

The reign of Archduke Albert and Isabella (1598–1633) left its mark on the urban surroundings with the construction of a series of fine churches in the Italo-Flemish Baroque style: St. Jean Baptiste au Béguinage, Notre-Dame aux Riches-Claires, Notre-Dame du Bon Secours, and others, nearly all of which are still in existence. The second half of the 17th century witnessed repeated invasions by the armies of Louis XIV of France. During a bombardment by his troops in 1695, hundreds of buildings were destroyed by fire, including the various craft headquarters. Out of this catastrophe there arose the new guild houses, constituting the architectural marvels now surrounding Grand Place, the heart of the Old Town.

Three-quarters of a century later, the upper part of the town was the scene of urban planning on a large scale, which resulted in the Place Royale (Royal Square) and a park on the French model, perfectly symmetrical, surrounded by Neoclassic buildings lining rue Royale, rue Ducale, rue de la Loi, and the Place des Palais. The former Court Chapel was replaced by the church of St. Jacques sur Coudenberg. The largest building in the rue de la Loi has served as national Parliament since 1830; it houses the Chamber of Representatives and Senate.

Following the Brabant revolt against the government of Emperor Joseph II of Austria, the French republican armies made their appearance, and the Belgian principalities were annexed to France. Under the Napoleonic empire, Brussels was reduced to the rank of chief town of the French *département* of the Dyle, losing into the bargain all authority over its satellite villages.

One of the consequences of Napoleon's defeat at Waterloo was the creation of the Kingdom of The Netherlands, which lasted 15 years (1815–30). During this period Brussels shared the status of capital with The Hague. Its appearance changed appreciably, above all because of the demolition of the city walls and their replacement by treelined boulevards, as well as the digging of the Canal de Charleroi, which from 1832 onward made waterborne transport possible from as far as the province of Hainaut to the port of Antwerp via the capital.

Independence of Belgium

In 1830 came revolution; Belgium won its independence, and, in the constitution adopted by the National Congress, Brussels, which had played a major role in the fighting, was named the capital of Belgium and the seat of government.

MODERN BRUSSELS

Topography. Since Belgium became an independent kingdom in 1830, Brussels has been transformed, in the Old Town as well as in the surrounding communes. The determining factor in this metamorphosis has been incessant population pressure, which caused a building boom and the development of an ever-widening network of streets, avenues, and roads crisscrossing the countryside, urbanizing the neighbouring villages.

At first the urban tentacles only pushed forward along the seven or eight routes radiating from the city's toll gates, but subsequently they also spread out along many new roads after the toll system was abolished, in 1860.

The suburbs expanded rapidly beyond the town gates, so that by the end of the 19th century the territory of several of the first ring communes was completely or almost completely covered by residential building. The expansion, moreover, continued vigorously in the following century, in spite of enemy occupation during World Wars I and II. All four points of the compass were involved: north and south along the valley of the Senne, east and west on the undulating plateaus separated by the tributaries of the Senne (Maalbeek, Woluwe, and others).

As a result, the landscape was entirely changed. With rare exceptions, the ponds and pools of earlier days were filled in, most of the hollows were banked up, the clear streams covered over and converted into sewers, the small woods cut down, fields, pastures, and orchards parcelled out for development, and footpaths eliminated. The River Senne became a main sewer running under the wide, straight boulevards of Inner Brussels, linking the North (1841) and the South (1869) railway stations.

Greater Brussels is not entirely built over, mainly because, with the increasingly common use of rapid means of transport, urban development has been by means of leapfrogging to satellite communities rather than by continuous, uninterrupted expansion. If the Middle Ages had endowed Inner Brussels with a geometric pentagonal configuration, modern times gave the sprawling metropolis the appearance of an amoeba. Its boundaries are continually changing, though legislation in the latter third of the 20th century on the linguistic problem may cause the outlines to be fixed rigidly (the laws being popularly known as the *carcan*, or "straitjacket").

Inner Brussels is divided between the commercial quarter and the upper town, where the principal governmental buildings are situated. The commercial quarter extends from the western outer boulevards to a little east of the central boulevards and includes the Grand Place. This square is occupied on its south side by the town hall and on its north by the ornate Maison du Roi (almost entirely rebuilt during 1873–95), which contains the historical museum. One of the curiosities of this quarter is the Manneken-Pis Fountain (1619), noted for a bronze statue of a boy urinating and known to the people of Brussels as their oldest "citizen."

The upper town is the remaining eastern area of the city proper. It is crossed from southwest to northeast by a thoroughfare formed by the rue de la Régence, which, at the Place Royale, becomes the rue Royale. On this street are the Palais du Roi and the Palais de la Nation. The latter was erected (1779–83) by the Austrian governors and after independence became the home of the Senate and the Chamber of Representatives. It stands at the intersection of the rue Royale and the rue de la Loi, an area that has become a symbol for the national government. Between the Palais de la Nation and the Palais du Roi is a large public park, extending along the rue Royale, and nearby are the Bibliothèque Royale (Royal Library), the Musée d'Art Moderne (Museum of Modern Art), and the Musée d'Art Ancien (Museum of Ancient Art).

The people. In the Old Town (the Pentagon), population continued to grow until 1890, reaching 159,374 from 99,552 inhabitants in 1831. The numbers then decreased successively from 141,558 in 1900 to 104,718 in 1930, 66,570 in 1961, and 60,000 in 1966.

A period of expanding population was thus followed by a very marked decline in density. Inner Brussels was partially emptied of inhabitants. By annexing some adjacent areas (in 1853, 1864, and again in 1921), the losses were nevertheless counterbalanced, and the total reached 200,433 in 1930. A decline set in thereafter, and in 1970 the figure had gone down to just over 160,000.

The same phenomenon of rising density followed by a fall occurred in the inner ring of abutting communes, the turning point occurring in 1910. These seven communes, which among them had only 21,338 inhabitants in 1831, contained a population of more than 500,000 in 1961. In the second ring of communes, during the period 1831 to 1961 the population rose from 16,283 to 350,309.

20th-century immigration

The immigrants came from all over: at first from the villages of Brabant, then from farther afield—whether from the Walloon provinces or the Flemish provinces—and from beyond the national frontiers, from European countries and overseas. In 1961 the number of inhabitants of foreign nationality amounted to 31,000 (French, Italian, Dutch, German, British, Spanish, American).

The influx of foreigners has proceeded apace since then. It has been calculated that between 1962 and 1966, for example, the number of people arriving from abroad to settle in one of the 19 communes of Brussels just exceeded 100,000. In this four-year period the largest contingents of newcomers originated from Spain, North Africa (Algerians, Moroccans, Tunisians), France, and Italy. In some of the decaying areas of Brussels a solid group of foreigners replaced the original residents. In the St. Gilles area, for example, the proportion of foreigners, mainly Spanish, reached one-third by the 1970s, and some primary schools had more foreign children than Belgian children. The former city-centre inhabitants moved outward toward more open areas on the outskirts. It is here that the well-to-do families, the officials of the European institutions, and the representatives of Brussels subsidiaries of important foreign firms establish themselves: the detached single-family house and the luxury villa, with its green lawns, flower beds, and trees, are multiplying, contrasting with the burgeoning inner-city skyscrapers.

The economy. In the early days of national independence, in the 1830s, food markets in the Old Town were supplied by the neighbouring villages. These have since been urbanized, and there are hardly any peasants left. Industrial, commercial, and service activities have been substituted for rural work.

On Greater Brussels' south–north axis, along the valley of the Senne, where canals and docks servicing the port of Brussels have been developed and where the railway lines run, an exclusively industrial zone has sprung up, which is being extended year by year both northward and southward. A maritime station and huge warehouses have been erected near the docks. At the same time, domestic and foreign banking institutions and insurance companies have appeared in the commercial centre in increasing numbers.

Economic and financial importance of the city

Most of the big Belgian industrial and commercial concerns have their registered offices in Brussels, so it constitutes the decision-making centre for economic and financial affairs. All the more so since, with the establishment of the European Common Market, many multinational corporations have set up their regional coordinating offices there.

United States companies with offices in Brussels numbered well over 400 by the early 1970s, and nearly a fifth of them functioned as European headquarters. An indication of Brussels' economic importance can be derived from the fact that there were well over 25,000 employers in the metropolis and nearly 500,000 manual workers, clerks, and shop assistants. There are also many independent craftsmen working in the flourishing luxury trades.

In sum, Brussels has developed into an international economic centre, with an important stock exchange and annual commercial fair.

Political and governmental institutions. A de facto capital since the 15th century, Brussels became the de jure capital of the Kingdom of Belgium in 1830. The king has his palace there, facing the Palais de la Nation, which houses the Chamber of Representatives and the Senate. For a long time the various ministries were close by, but several have migrated to the Résidence Palace and to an enormous functional administrative block.

The Belgian constitution stipulates that matters concerning individual communes only are to be settled by the local council, according to principles laid down in the constitution. In 1836 Parliament passed the "organic" communal law, which provided for the autonomy of each commune. This explains why Greater Brussels for long was governed by 19 separate authorities and not by one single authority.

Constitutional change of 1970

In December 1970 Parliament drastically amended the constitution to provide for the recognition of five large urban agglomerations (Brussels, Antwerp, Ghent, Liège, and Charleroi), as well as federations of communes. This paved the way for the administration of Greater Brussels by an "Agglomeration Council" empowered to deal with a series of technical problems involving the 19 communes as a whole. Five of the new federations of communes surround Greater Brussels. Each of the 19 communes of Brussels continued, however, to have its own council, municipal establishments, burgomaster, and alderman.

The council is a deliberative assembly whose members are elected by universal suffrage; the aldermen are chosen by the councillors from among themselves; the burgomaster is appointed by the king, being usually selected from among the councillors. Representing the head of state in the commune, it is his duty to see that general and provincial laws and regulations are carried out. He acts as local chief of police, and in emergencies he can take whatever steps are necessary to maintain or restore public order. The burgomaster of Brussels is a political figure of importance.

Local government employees in the communes are under the control of either the council and college or the registrar or the burgomaster. The most important official is the communal secretary, serving the council, the aldermen, and the burgomaster and coordinating the work of the various administrative departments.

Public services. Brussels' communal services have proliferated since 1830 under the impact of increased population and the demands of modern technological civilization. The effect of larger scale and faster speed has inevitably meant staff inflation in existing administrative departments as well as the creation of many new ones, such as the water, gas, and electricity administrations and the departments for youth and sports, for the aged, for burial services, and for education and the fine arts. Inner Brussels has played an exemplary role in setting up scholastic institutions, most notably its generous contributions to the foundation in 1834 of the Université Libre de Bruxelles (Free University of Brussels) and to its development.

Several of the communal industrial administrations have been replaced by intercommunal corporations (water, gas, electricity). The public transport services (trams and buses) have been entrusted to a corporation of this kind. The construction and maintenance of motorways, however, is the responsibility of the Belgian state; that is to say, the Ministries of Public Works and of Communications, which has developed a "semimetro" network (electric train routes running half underground) designed to cover Greater Brussels.

Responsibility for the Belgian railway system, of which Brussels is the focal point, is entirely in the hands of a national company. The electrified lines to neighbouring countries all pass through Brussels stations. A special line links the Gare Centrale (Central Station) and the Aéroport National de Bruxelles (Brussels National Airport) in less than 20 minutes.

Recreation and cultural life. Brussels is an artistic and tourist centre, with a wide variety of cultural activities.

Educational institutions

In addition to the Free University—divided into a French-speaking university and a Flemish-speaking university—the Institut Saint Louis faculties (Catholic), the royal academies of science, medicine, French language and literature, and Flemish language and literature, and various other institutes of higher learning are based there, as are the Military College, the Albert I Library, and many communal and national museums.

The Palais des Beaux-Arts provides a cultural centre for those interested in painting, sculpture, films, music, literature, and the theatre. It is the headquarters of the Philharmonic Society and the National Federation of Youth and Music. The Queen Elizabeth International Music Competition attracts connoisseurs every year. Midday poetry readings and midday concerts are held weekly. Most of the communes in the agglomération have, on the model of the Palais des Beaux-Arts, established cultural centres that organize exhibitions, various stage shows, and concerts.

Foremost among some 30 theatres is the Théâtre National (National Theatre). Théâtre Royal de la Monnaie, with a long-standing reputation, has been rejuvenated by a dynamic management. Cinemas are still plentiful, in spite of television competition.

Many secular and religious monuments of architectural interest embellish the Old Town and some of the suburbs. And not far from the urban centre are scenic walks in the magnificent beech groves of the Forêt de Soignes and its offshoot, the Bois de la Cambre.

BIBLIOGRAPHY. The standard books are: A. HENNE and A. WAUTERS, *Histoire de la ville de Bruxelles*, 3 vol. (1845, reprinted 1970), with detailed coverage of monuments; A. WAUTERS, *Histoire des environs de Bruxelles . . .*, 3 vol. (1851–57); and G. DES MAREZ, *Guide illustré de Bruxelles, monuments civils et religieux*, 4th ed. brought up to date and supplemented by A. ROUSSEAU (1958), an excellent handbook. For further reading: P. GOUROU, *L'Agglomération bruxelloise, eléments de géographie urbaine* (1958), a study by a leading French urban geographer; L. VERNIERS, *Bruxelles et son agglomération de 1830 à nos jours* (1958) and *Un Millénaire d'historie de Bruxelles, depuis les origines jusq'en 1830* (1965), a general view of urban evolution; R. MOLS, *Bruxelles et les Bruxellois* (1961); G. JACQUEMYNS, *Histoire contemporaine du Grand-Bruxelles* (1936).

Bryopsida

The mosses are comparatively small green plants, most of which are comfortably visible to the unaided eye but much better seen with a hand lens. They constitute the class Bryopsida of the division Bryophyta. Commonest in moist, shady locations, mosses are perhaps best known for those species that carpet woodland and forest floors. Mosses, which number about 600 genera and 15,000 species, have trailing or erect stemlike structures called caulids and leaflike appendages called phyllids, organs that differ in many respects from the stems and leaves of higher plants.

The name moss often has been misapplied to other plants, among them Spanish moss (a flowering plant), club mosses (fern relatives), sea mosses (marine algae or seaweeds), and reindeer moss and beard moss (lichens). A phylum of marine invertebrates consists of creatures so mosslike in appearance that they are called Bryozoa, meaning "moss-animal."

In spite of little direct economic importance, with the exception of peat mosses (*Sphagnum*) discussed later, mosses are of interest scientifically because they exhibit a conspicuous alternation of generations, provide clues to past floras, and are valuable plants for studies in plant physiology. They also play a role in the natural biotic community and even an esthetic one for man.

GENERAL FEATURES

Mosses range in size from the microscopic terrestrial forms (*Ephemerum, Nanomitrium*), difficult to see without a hand lens, to the robust, erect moss *Dawsonia* of Australia and neighbouring areas, which may be over two feet tall, with "leaves" an inch long.

Common names are infrequent for the mosses, but some kinds are named for their interesting form (Figure 1): tree moss (*Climacium*); wind-blown moss (*Dicranum*); feather moss (*Ptilium*); extinguisher moss (*Encalypta*); turkish-slipper moss (*Diphyscium*); rose moss (*Rhodobryum roseum*); bug-on-a-stick (*Buxbaumia*), which lacks an easily visible leafy stem; and elfin-gold (*Schistostega*), a stage of which contains lens-shaped cells that can reflect available light from the crevices of caves or cellars.

Geographic distribution

Mosses are found almost everywhere except in marine water or salt waters. They occur from the Antarctic to the Arctic; in the latter they are an important part of the tundra vegetation. They also are abundant in tropical and temperate rain forests, where they may hang in festoons from the trees and form deep cushions on soil, logs, and boulders. They are scarce but not absent in

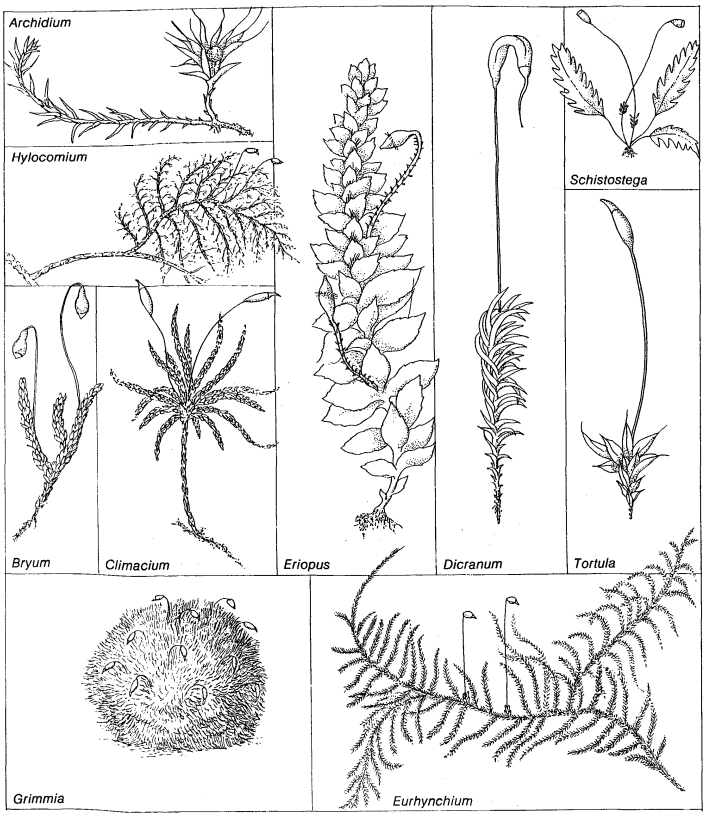

Figure 1: Diversity among bryid mosses.
Drawing by M. Pahl based on *An Evolutionary Survey of the Plant Kingdom* by R.F. Scagel, G.E. Rouse, J.R. Stein, R.J. Bandoni, W.B. Schofield, T.M.C. Taylor. © 1965 by Wadsworth Publishing Company, Belmont, California. Reprinted by permission of the publisher.

deserts, and aquatic forms are frequent in seeps, springs, brooks, and on the margins of freshwater bodies. A very few (*e.g., Grimmia maritima*) are found on rocks along the seashore, above the tideline.

Although much of the literature implies that mosses are widely dispersed over the world, most of them have distribution patterns that more or less match those of seed plants. Some, such as *Gollania turgens*, have peculiar ranges not easily explained on a basis of presently known facts; such species may be useful in testing the validity of long-range dispersal, persistence in microenvironments when other larger plants have been eliminated, and other theories in plant geography.

Useful mosses

Only the bog or peat mosses in the genus *Sphagnum* have significant direct economic value. They are the chief components of peat bogs, often covering acres and filling lakes and kettle holes left by glacial activity. Through slow decomposition these mosses change into peat as the older growth is pushed under water by new growth at the top. Under compression in nature, peat can be changed into lignite, which is used as fuel in peaty areas. Some *Sphagnum* species absorb and retain 35 times their dry weight of water and synthesize sphagnol, chemically akin to phenol and somewhat effective as an antiseptic.

Bog water used to be carried on long sea voyages because it only very slowly became stagnant. *Sphagnum* moss is still used locally by primitive people for diapers and menstrual pads and as recently as World War I was a component of many surgical dressings. Peat is useful in conditioning soils, for packing nursery stock and cut flowers, and as litter in animal quarters, where it absorbs odour as well as moisture.

Other mosses were used rather extensively in the past. Pigeon wheat, or hair-cap moss (*Polytrichum*), and carpet moss (*Hypnum*) have been used as filler in bedding. Pigeon wheat, often over a foot high, has been used in making brooms and dusters, and the stems stripped of their leaves and outer layers were plaited into baskets and other articles. Mosses have been used as ornaments, especially on women's hats, and for Christmas decorations in Latin America, where bales of mosses are gathered and shipped from the mountains each December. Some mosses retard erosion; species of *Pogonatum* forming extensive feltlike mats are particularly effective in stabilizing exposed slopes.

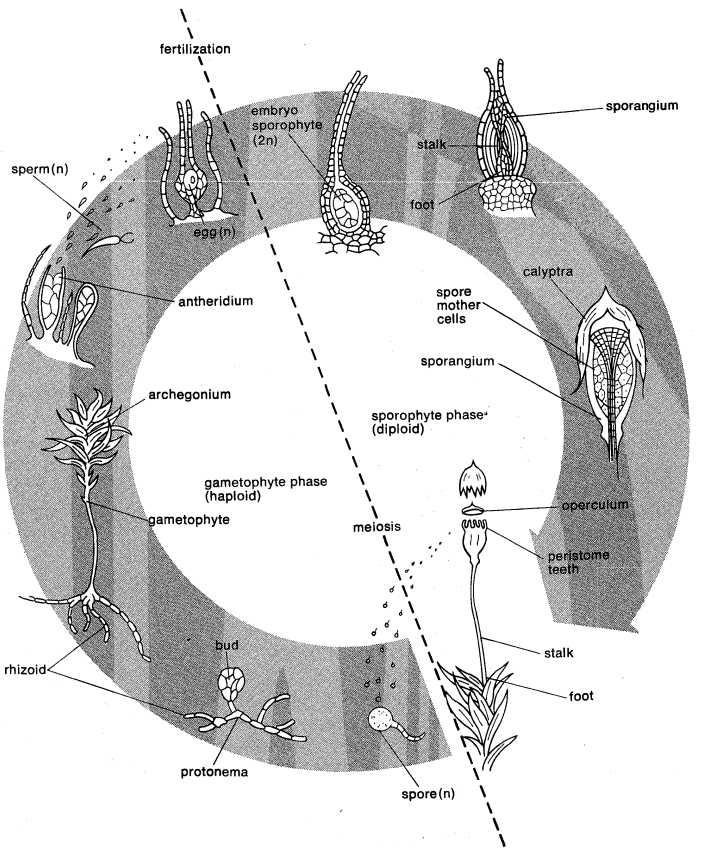
Some mosses are used in landscaping, especially in the moss gardens of Japan, notably in Kyōto. While most mosses are very sensitive to pollution, one species, *Tortula pagorum*, seems to do better in a polluted atmosphere than in clean air. Mosses have been used as indicators of forest conditions; their abundance may reveal unpolluted fog zones and layers of humid air.

NATURAL HISTORY

Life cycle. The mosses, like the liverworts, exhibit a well-defined alternation of generations between a gametophyte phase, whose cells contain a single set of chromosomes (n), and a sporophyte phase, whose cells contain a double set of chromosomes (2n). It is convenient to begin discussion of the moss life cycle with the spore (Figure 2). When a spore (n) alights in a favourable spot, it germinates into an inconspicuous threadlike network called a protonema, a juvenile gametophyte. In time, the protonemata produce buds that give rise to adult gametophytes (n).

The adult gametophyte is the conspicuous leafy green, photosynthetic plant popularly called moss. It contains, at maturity, two kinds of sex organs: the archegonia, or female organs, each of which can produce a single, large egg (n); and the antheridia, or male organs, each of which produce numerous small motile sperm (n). The zygote, or fertilized egg (2n), formed in the basal portion of the archegonium by the union of an egg and a sperm, begins the sporophyte phase.

The young sporophyte (2n), embedded in the nutritive tissue of the enlarged archeogonium (now called the calyptra), grows very rapidly. Eventually its needlelike seta ruptures the top part of the calyptra and carries it aloft like a hood, beneath which the spore capsule (sporangium) develops. At maturity, sporocytes, or spore



mother cells (2n) in the sporangium, undergo reduction division (meiosis) and produce spores (n). The spores are then shed, and the cycle repeats.

Habitat range. Mosses restricted to a particular type of rock or to the bark of a specific kind of tree cannot, of course, extend beyond the range of these substrates. Mosses such as the silvery bryum (*Bryum argenteum*), the cord moss (*Funaria hygrometrica*), and the horntooth moss (*Ceratodon purpureus*) are common and almost cosmopolitan in distribution. Some species, however, are characteristic of vegetation types; *Anomodon rugelii* seems restricted to the eastern deciduous forest of North America, and the stair-step moss (*Hylocomium splendens*) is seldom found outside the northern coniferous forest and the tundra.

Special habitat restrictions

There are many curious restrictions to habitats among the mosses. Members of the family Splachnaceae, which require much nitrogen, are usually found on dung, badly decayed carcasses, and owl pellets; the most extensive growth known occurs on the soil at Point Barrow, Alaska, where whales were once butchered by the Eskimos. Another group, of which *Merceya* is an example, is called the "copper mosses"; they are usually found on or near copper-containing soil, but it is not clear whether copper or sulfur, or a combination of the two, is a prerequisite for their growth. *Didymodon tophaceus, Fissidens grandifrons, Eucladium verticillatum,* and additional moss species seem to grow best on limestone rocks in waters heavily charged with calcium salts. In the Americas, *Pleurochaete squarrosa* is characteristic of limestone in *Juniperus* barrens.

In some forests, tree seeds seem to germinate better in a moss carpet. Mosses, along with liverworts, lichens, and often algae, are usually the first plants to colonize new or recently exposed substrates. In new mineral soils, such as volcanic sand, they build up organic material. On logs they delay water loss, facilitating the growth of decay organisms. Rocks are more rapidly fragmented by the freezing of water retained by mosses and by the actions of chemicals secreted by these plants. Mosses serve as habitats for mites, tardigrades, and insects and are used as materials for some bird nests. Mice and lemmings harvest the spore capsules of the larger mosses for food.

FORM AND FUNCTION

The gametophyte. *The protonemal phase.* Almost as remarkable as the contrast between the gametophyte and the sporophyte phase is the difference between the juvenile gametophyte, or protonema, and the adult gametophyte. The almost microscopic protonemata may be thalloid (irregularly leaflike or ribbonlike) or threadlike; they often resemble richly branching algal webs, especially in the order of Bryales. After a period of growth and the attainment of a certain size and maturity, a protonema produces buds that will develop into adult gametophytes.

The adult gametophyte. The individual moss plant that one usually observes is the green plant with narrow leaflike phyllids arranged spirally along a stemlike caulid. The gametophytes of some mosses resemble tiny trees with clusters of branches on the tip of the main shoot; others are unbranched and erect or branched at the base of the caulid, with parallel shoots; still others recline along the ground and branch irregularly. The phyllids are usually of simple outline and often resemble true leaves; they are usually one cell thick.

At certain times of the year, sex organs develop among the phyllids at the lip of a caulid: the flask-shaped female archegonium and the elongated male antheridium. In some species, called homothallic, both kinds of sex organ occur on the same individual gametophyte; other species are heterothallic, the archegonia occurring on one individual and the antheridia on another.

In the acrocarpous mosses, archegonia are borne terminally on the main stem; in the pleurocarpous forms they occur on very short lateral branches. The former are more often erect plants, the latter, prostrate.

In identifying mosses by use of the gametophyte, the phyllids are more useful than the caulids. Variations occur in the shape of the phyllids, the nature of their margins, and the presence or absence of a midrib (costa). Also of interest is the apex of the phyllid: it may be rounded, acute, or extremely slender, sometimes ending in a hair. The bases sometimes may form short wings down the caulid and at times have areas of specialized alar cells in the angles. Phyllids of *Aloina* have short, upright filaments on top, and those of the Polytrichaceae have ribbonlike plates (lamellae) of green cells longitudinally attached by one edge to the upper surface. The size and shape of cells in the phyllid, and the thickness of the cell walls, are useful characters, as is the nature of the external surface of the phyllid, which may be smooth or covered with minute or larger "pimples" (papillae). In a few species (*Thelia*) the papillae are unusually large, and with fantastic shapes.

Use of the phyllids in identification

The sporophyte. The moss sporophyte, in contrast to that of the liverwort, usually elongates gradually throughout its development. The mature sporophyte is embedded in the basal portion of the archegonium by a "foot," through which nutrients may diffuse from the gametophyte. The sporange is usually elevated on a stemlike seta (absent in a few species), which sometimes has a differentiated central strand that may serve as a conductive tissue (water, however, seems to diffuse into the plants through most surfaces).

The sporangium is often cylindrical (sometimes curved) but in some species is spherical or ovoid. Usually under the calyptra is a differentiated lid (operculum), which falls off at maturity. The operculum may be a short cone or, at the other extreme, a very slender, beaked "dunce cap." When it falls, the opening left sometimes is naked but more often is surrounded by one or two rings (peristomes) of slender, triangular teeth; the absence or presence of peristomes and, if present, whether they are composed of one or two rows of teeth are highly significant in identifying mosses. These teeth flare outward when dry, apparently enhancing wind dissemination of the spores. The shape of the peristome teeth and their markings (whether smooth, punctate, or striated) are useful, as is the presence or absence of stomates with guard cells in the basal half of the sporange.

The spore-bearing tissue is in the shape of a hollow cylinder surrounding a central column (columella) of sterile cells. The spores are unicellular and small, usually much less than 1/10 millimetre in diameter. Some germinate within the sporange and give the appearance of being multicellular. Nearly all spores have chloroplasts, which increase in number as the protonema develops. In most mosses the spores appear uniform; but in at least one species of *Macromitrium* there are two size types, which may reflect an incipient heterospory characteristic of the higher plants, the larger spore apparently giving rise to female gametophytes and the smaller to male gametophytes.

Asexual reproduction

Perhaps the most frequent type of reproduction in the mosses (and in some the only method known) is asexual. Each cell of the gametophyte and most cells of the sporophyte seem capable of developing into a new gametophyte if provided with a suitable environment. Often specialized cells or groups of cells (gemmae, propagula, or brood bodies) grow from the caulids or phyllids and when broken loose may grow into new plants. Most amazing is the growth under certain conditions of a sporophyte from some vegetative portion of the gametophyte—for instance, from the tip of a phyllid. Segments of developing sporophytes can give rise to new protonemata, which form gametophytes with twice the usual number of chromosomes per nucleus.

The chromosomes of mosses are small, and the number per nucleus is relatively low. The basic number ranges between 6 and 13 (with the exception of *Sphagnum*, which has 21) with the commonest probably being 11. One of the curiosities of mosses is the occurrence of tiny "m" chromosomes, of unknown significance.

The mosses have proved to be valuable cytological and

genetic material because it is relatively easy to double the number of chromosomes per nucleus by using segments of a young sporophyte in culture as the source of new protonemata.

Some mosses exhibit sex chromosomes, which often control size as well as sex of gametophytes. In one species of *Homaliadelphus* the male gametophytes are small enough that they can grow as epiphytes upon the phyllids of the female.

Physiological responses. Mosses respond physiologically in much the same manner as higher plants. Both gametophytes and sporophytes are provided with chloroplasts, which photosynthesize to produce carbohydrates and starch grains. Food also may be stored in spores and gemmae in the form of oil droplets.

The requirements of mosses for various minerals are not essentially different from those of vascular plants. Mosses can grow, however, in dilute cultures or even in distilled water for some time. Most of them respond to changes in light quality, intensity, and periodicity. Two of the most easily observed responses are the formation of buds on the protonema and the growth of these buds into leafy gametophytes, which are influenced by the factors mentioned above and also by growth promoting and regulating substances and other chemicals. *Funaria hygrometrica*, *Physcomitrium turbinatum*, and related species are mosses most commonly grown in culture.

Terrestrial gametophytes grown at low light intensities or high humidities or both become spindly and yellow, with elongated caulids and reduced phyllids, much as do the stems and leaves of seed plants under such conditions. This response may help explain why it is frequently difficult to identify the various forms of a single species developed in different habitats.

Resistance to fungi and insects

Mosses seem to resist infestations by most fungi and are not usually seriously damaged by insects. They do possess an antibiotic material not yet fully identified and exploited, which may account for their antifungal properties. Some fungi (*Pleurotus* and *Pestalozzia* species), however, do parasitize mosses, and others can intermingle with protonema to form lichen-like associations.

Mosses can withstand extremes of temperature and of desiccation. They have the remarkable ability to remain dormant under very warm environments or dry environments or both and quickly revive and grow again under suitable conditions. This is true in the case of the remarkable black species of *Grimmia* and other genera that grow on hot, dry, exposed rocks.

EVOLUTION AND CLASSIFICATION

Fossil distribution. Not many mosses are known from the geological record. Fossils from Permian rocks in the U.S.S.R. resemble the modern genera *Mnium*, *Bryum*, and *Sphagnum*, but no reproductive structures have been found. *Sphagnum* has been reported also from Jurassic and Cretaceous beds. The largest number of fossil mosses, and the best preserved, are found in the peats of the Pliocene and Pleistocene beds, many of which can be related to modern genera and some to species still living today.

Distinguishing taxonomic features. The characters that separate the class Bryopsida (mosses) from the rest of the Bryophyta and that distinguish the subclasses, primarily, are those found in the sporophyte, particularly the sporange. They include the presence or absence of a slowly elongating seta, or pseudopodium (a false seta formed as a specialized branch of the gametophyte), the degree of specialization in the exterior of the sporange, the amount of its internal differentiation, and the nature of the opening through which the spores are dispersed. The nature of the protonema, the first structure formed following spore germination, is also significant.

Annotated classification. The following classification is modified from a classical taxonomic scheme.

CLASS BRYOPSIDA

Protonema usually filamentous; seta or pseudopodium gradually elongating; the sporange with a tough epidermis, opening by a deciduous operculum or by 4 slits down the side (rarely without either), and with a sterile columella in the centre. Mature gametophyte never thalloid. About 600 genera and 15,000 species.

Order Sphagnales (peat or bog mosses)

Protonema thalloid, at maturity usually erect and much branched with many phyllids, very absorbent by reason of many large, empty cells with pores in the walls. Seta lacking, but sporophyte borne on a pseudopodium. Sporange spherical with operculum, but no peristome. Spore-bearing tissue thimble-shaped over a domelike columella. Usually found in bogs or on wet acid substrates. A single genus, *Sphagnum*.

Order Andreaeales (granite mosses)

Protonema thalloid; at maturity usually erect, small, dark, with many compactly arranged phyllids. Seta lacking, but sporophyte borne on a short pseudopodium. Capsule cylindrical without operculum, opening by 4 equidistant, longitudinal slits. Spore-bearing tissue shaped like an elongated thimble over a finger-shaped columella. Usually found on exposed, noncalcareous rock; occasionally on sand in bed of intermittent streams at high latitudes. Represented by the genus *Andreaea*, with about 100 species, and a problematical species or two.

Order Bryales (true mosses)

Protonema filamentous; at maturity, erect, ascending or prostrate, usually with many phyllids, variously coloured. Seta present in most species (pseudopodia always absent). Sporange cylindrical to spherical usually with a deciduous operculum beneath which is the peristome (occasionally lacking). Spore-bearing tissue shaped like a hollow cylinder around a sterile, central columella. Stomata frequently present in the basal half of the capsule. Found on various substrata in many environments. The bulk of the genera (500) and species of mosses; including *Bryum*, *Mnium*, *Eriopus*, *Hylocomium*, and *Funaria*.

Critical appraisal. An earlier, time-honoured classification still enjoying currency places the mosses in the class Musci of the division Bryophyta. Some systems have restricted the division Bryophyta to include only the mosses (the liverworts then becoming the Hepatophyta). The mosses have enough characters in common with the liverworts to indicate that they are rather closely related, however, and should be placed together in the division Bryophyta. The classification used in this article is one of several that may find wider acceptance as more information accumulates.

The order Bryales, in contrast to the other two orders, is much more variable in all respects and may be subdivided into families in several ways. It has been suggested that some families (*e.g.*, Polytrichaceae) be given the rank of an order. When the great diversity within the Bryales is considered, it seems more manageable to retain these divergent forms within this order. Some botanists would raise the orders Sphagnales, Andreaeales, and Bryales to subclass or class rank. Until more is known about their origin and more data is available about extant species, no taxonomic arrangement can be made with security; perhaps it may never be done.

Bryozoa

The bryozoans, also called polyzoans or ectoprocts, comprise the phylum Bryozoa of which there are about 4,000 extant species. The bryozoans are a widely distributed, aquatic, invertebrate group, members of which form colonies composed of numerous units called zooids. Until the mid-18th century, bryozoans, like corals, were re-

garded as plants; hence their name, which means "moss animals." Seventy-five years later, the bryozoans (then called Polyzoa) were distinguished from the coelenterates, and the characteristic structure of the zooid was first described.

Bryozoans may be separated into three classes: Phylactolaemata (freshwater dwelling); Stenolaemata (marine); and Gymnolaemata (mostly marine). The order Cheilostomata (class Gymnolaemata), containing 600 genera, is the most successful bryozoan group.

GENERAL FEATURES

Bryozoan colonies are found in both fresh and salt waters, almost invariably as growths or crusts on other objects. Freshwater bryozoans, which are frequently inconspicuous, are found among vegetation in clear, quiet, or slowly flowing water. Marine species range from the shore down to the ocean depths but are most plentiful in the shallow waters of the continental shelf. They cover seaweeds, form crusts on stones and shells, hang from boulders, or rise from the seabed. Bryozoans readily colonize submerged surfaces, including ship hulls and the insides of water pipes.

The zooid walls, which constitute the matrix (or substance in which living cells are embedded) of the colony, generally are calcareous (*i.e.*, impregnated with calcium carbonate) and bryozoans, therefore, have left a fossil record. The phylum has a long geological history, and many earth strata, from the Ordovician onward (*i.e.*, from about 500,000,000 years ago), are characterized by bryozoan fossils.

Size range. Bryozoan colonies vary in size. The very small genus *Monobryozoon*, which lives between marine sand particles, consists of little more than a single zooid less than one millimetre in height. The coralline genus of European seas *Pentapora*, however, is found in clumps that occasionally are one metre or more in circumference; and a warm-water genus, *Zoobotryon*, hangs from harbour pilings in chains or clumps that may be one half metre in length. Colonies that form crusts generally cover only a few square centimetres; erect colonies may rise only two to five centimetres.

Appearance. The texture of the colonies is variable. Some colonies, especially those in fresh water and on sea shores, are gelatinous or membranous; others are tufted, with flat fronds (leaflike structures) or whorls of slender branches, whose horny texture results from light deposits of lime in zooid walls. Still other colonies are hard and have calcified skeletons. Such colonies may form rough-surfaced, reddish patches or may rise in slender branching twigs (such as those that form a network in the beautiful lace corals *Retepora* or *Sertella*).

Colonies

The colonies, diverse and complex in structure, are composed of individual zooids or compartments; and each zooid is a complete and well-organized animal. A bryozoan colony usually has many zooids, which may be of one type or of types that differ both functionally and structurally. Neighbouring zooids are united and may communicate by tiny pores present in the zooids' walls. Many zooids have slender tentacles at one end on which are found cilia (hairlike projections) that propel tiny particles of food toward the zooid mouth. The mouth opens into a digestive tract that is divided into several regions and terminates at an anus, which is outside (but near) the tentacles. If zooids are disturbed, they withdraw their tentacles inside the body cavity. Only if the zooids have transparent walls, such as in the *Bowerbankia* and the *Membranipora*, is the digestive tract visible. The tentacles and digestive tract together are called the polypide of the zooid.

NATURAL HISTORY

Primary zooid

Life cycle. *Budding.* A colony is formed by asexual budding, from initially either a primary zooid (or ancestrula) or a resting bud. The ancestrula originates from a sexually produced larva. New zooids then are budded to produce colonies of definite shape and growth habit. In the freshwater class Phylactolaemata, the primitive zooids are cylindrical in form, and the budding pattern results in a branched colony. In more highly evolved phylactolaemates, colonies are compact, and discrete zooids can be recognized only with difficulty. New polypides (*i.e.*, tentacles plus digestive tract), which originate by ingrowth of a cell layer called the epithelium, remain suspended within a common colonial coelom, or body cavity.

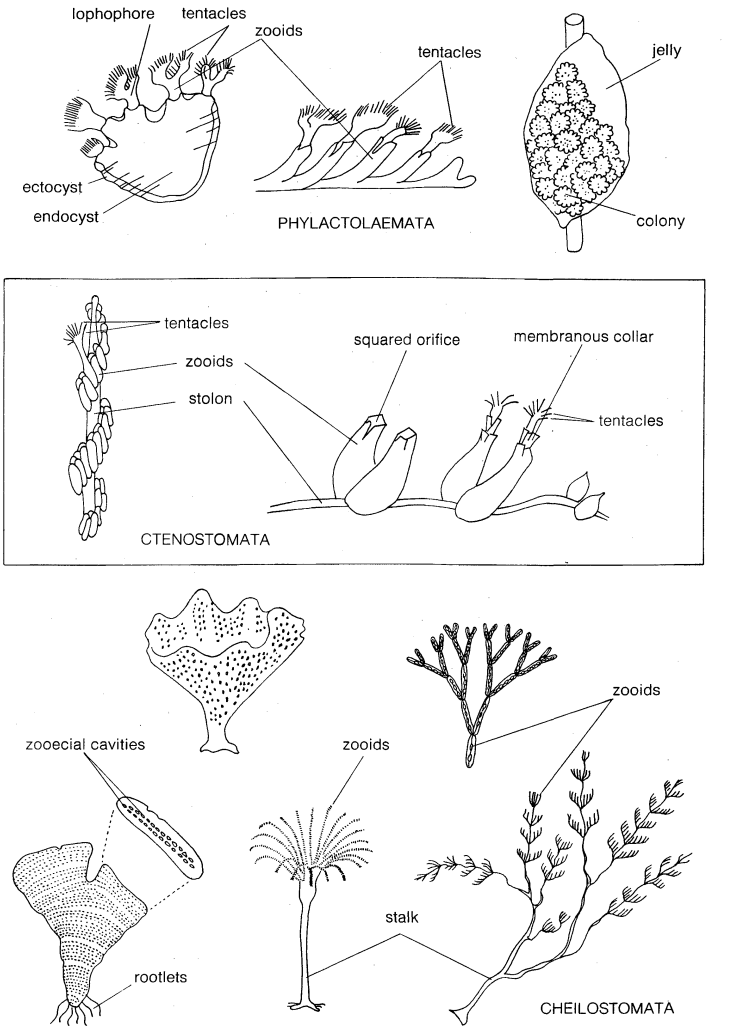

Figure 1: Growth forms of bryozoan colonies.

Among living members of the primitive (and mainly fossil) marine class Stenolaemata, the long and slender zooids have calcified tubular skeletons. A larva metamorphoses into a hemispherical primary disk (or proancestrula). A cylindrical extension grows from the proancestrula, and the matrix of the colony then is built up by repeated divisions of the zooidal walls. Internal walls of the colony are termed septa. The growth and budding zones of the colony are found at its outer edges. Cells from the surface epithelium push inward to produce the polypide, and the septa create a chamber around the polypide. The walled portion of a zooid is termed the cystid.

In the class Gymnolaemata, in which the zooids frequently are flattened, budding occurs as transverse septa form and cut off parts of the primary zooid (or other parent zooid); each part is called a daughter cystid. As each cystid enlarges to become a zooid, a polypide forms inside. In the important order Cheilostomata, budding usually produces rows of identical zooids that radiate from the primary zooid and adhere to each other. Although the rows divide periodically to keep pace with the increasing circumference of the colony, they maintain their adherence to each other. Successive zooids in a row are separated by transverse septa, but adjoining rows are sep-

arated by double walls. Simple or complex interzooidal pores are present, nevertheless, in the walls and in the septa.

Reproduction. Mature zooids in the classes Gymnolaemata and Phylactolaemata are generally hermaphroditic (*i.e.*, both male and female reproductive organs in one animal); small gonads are attached in clusters to the membrane that lines the body wall or the polypide. Among living stenolaemates, however, most zooids contain only testes (male gonads). The few female zooids enlarge to form spacious brood chambers that are called gonozooids. During development, a young embryo squeezes off groups of cells that form secondary embryos; these in turn may form tertiary embryos. In this way, many larvae can develop in a single brood chamber.

Among the freshwater phylactolaemates, the fertilized egg develops in an internal embryo sac; a larva, which already contains the first polypide, is formed there, then liberated. Phylactolaemates also produce special dormant asexual buds, called statoblasts; these develop on the funiculus, a tissue cord that links the stomach to the zooid wall. As it grows, each statoblast becomes surrounded by a hard protective case that may also include an air-filled float and slender, hooked spines. Statoblasts, which usually develop in late summer, are liberated as the colony disintegrates with the approach of winter. Statoblasts survive dry and freezing conditions and can initiate a new colony when favourable climatic conditions recur.

Statoblasts

In gymnolaemates one oocyte at a time usually enlarges and bursts from the ovary into the coelom (body cavity). The oocyte then is fertilized and transferred to a brood chamber. This may be an undifferentiated part of a zooid; usually among the cheilostomates, however, each reproducing zooid develops a special globular or hooded ooecium in which the embryo grows. The ciliated larvae, spherical and often about ¼ millimetre in diameter, are liberated when fully developed and may swim first toward the light and thus away from the parent colony; later, however, the larvae avoid light as they seek a place in which to settle. Metamorphosis of larvae to adults probably occurs a few hours after larvae are liberated.

In certain genera (*e.g.*, *Membranipora*) of the class Gymnolaemata, each zooid produces many tiny eggs, which are fertilized by sperm from another zooid as they are shed directly into the sea. The fertilized eggs develop into triangular, bivalved larvae, known as cyphonautes, which for several weeks live among, and feed on, plankton. Larvae from brood chambers and cyphonautes settle in a similar way; *i.e.*, both locate a suitable surface and explore it with sensory cilia. Attachment is achieved by flattening a sticky holdfast, which pulls the larva down on top of it. As metamorphosis proceeds, larval organization degenerates, and the first polypide develops inside a primary zooid.

Ecology. *Freshwater bryozoans.* Freshwater bryozoans live mainly on leaves, stems, and exposed tree roots in shallow water; before drinking water was filtered, however, freshwater bryozoans regularly polluted water supply pipes. Though not uncommon, freshwater bryozoans are inconspicuous in pools, lakes, or gently flowing rivers, especially in slightly alkaline water. The few species of the freshwater class Phylactolaemata tend to be widely distributed, presumably as a result of the ease with which statoblasts can be scattered.

Marine bryozoans. The most familiar marine bryozoans are those that inhabit shores, though they occur in greater numbers below tidemarks. Dredge hauls of stones and shells yield colonies in abundance. Colonies also occur on the ocean bed, even at great depths, but the frequently muddy bottom of the oceanic abyss is an unfavourable habitat. A few species tolerate hypersaline or brackish waters; on the other hand, the predominantly marine Gymnolaemata have a freshwater representative, *Paludicella.*

Bryozoans along shores

Shallow, sheltered channels that have currents but are protected from severe waves are typical bryozoan habitats. Open coastlines support fewer species, but noncalcareous species occur abundantly on intertidal algae in temperate waters. A familiar genus is the lacy *Membranipora* (class Gymnolaemata), found throughout the world and well adapted to living on kelp weeds at, and just below, the low-water mark. Although the zooid walls of *Membranipora* colonies are calcified, they contain flexible joints, which allow the colony to bend as the alga sways in the waves. *Membranipora*, which may cover large areas with a million or more zooids, always grows predominantly toward the youngest part of an algal frond. Overhangs, which form when soft rock erodes along a shoreline, and the shaded pilings of jetties and piers are other favoured bryozoan habitats. Since they do not require light and can grow in dark places, bryozoans can avoid competition from algae that could smother them. Sea slugs and sea spiders appear to be the principal predators of bryozoans.

FORM AND FUNCTION

Zooids. The details of zooid structure vary from class to class. Among the zooids of the freshwater class Phylactolaemata, the lophophore (*i.e.*, the ridge from which the tentacles originate) is generally horseshoe shaped, and the tentacles are more numerous than are those in the gymnolaemates (*e.g.*, *Bowerbankia*). The body wall is muscular, and there are no transverse parietal muscles. In zooids of the class Stenolaemata, the walls form a slender calcareous tube, which cannot be pulled inward to turn the tentacles outward; instead, body fluid is forced from one part of the zooid to another by internal muscles.

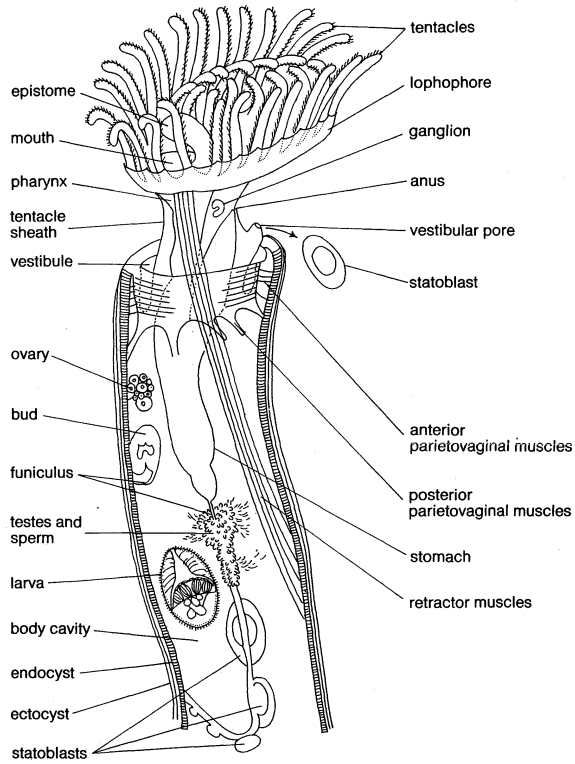

Figure 2: Mature *Plumatella* zooid (class Phylactolaemata).

Zooids rarely are longer than one millimetre. Since the most primitive type is cylindrical, the bryozoan ancestor probably was wormlike. Tentacles, spread to form a funnel at the free end of the zooid, arise from the lophophore, which surrounds the mouth. In *Bowerbankia* (class Gymnolaemata), the digestive canal forms a deep loop; the pharynx descends to the gizzard and stomach, and the rectum rises to an anus, which lies just outside the lophophore. Although the walls of the zooid are covered by a cuticle and are protective in function, they lead to the lophophore by means of a structure called a tentacle sheath (or introvert). When feeding zooids are disturbed, powerful retractor muscles withdraw the tenta-

cles, by pulling them down inside the introvert. The inrolled end of the zooid then terminates in an opening called an orifice. The tentacles leave the sheath by an indirect mechanism. Contraction of muscles called the transverse parietal muscles pulls the zooid wall inward and compresses the internal fluid, the resulting increase in pressure pushing the tentacles out again as the retractor muscle relaxes.

In shape, *Bowerbankia* is not typical of the class Gymnolaemata. During gymnolaemate evolution, a transition from tall cylindrical zooids to short flattened zooids probably occurred. During the evolution of zooids typical of certain genera of the order Ctenostomata to the rigid zooids typical of the order Cheilostomata, for example, a critical development may have been calcification of lateral walls. Primitive cheilostomes (*e.g.*, *Membranipora*) have box-shaped zooids with rigid side walls but a flexible membranous front. The mechanism for turning the tentacles outward is dependent upon this membrane. Transverse parietal muscles span the coelom from the side walls to the frontal membrane; their contraction pulls the membrane inward and creates the pressure increase necessary to push out the tentacles.

Although the anascan suborder represented by *Membranipora* is an abundant and successful group, these animals are only a starting point in the cheilostome trend toward stronger and better protected zooids. In the diversified and even more successful ascophoran suborder represented by *Schizoporella*, for example, the frontal membrane, which appears to be absent, actually has been converted into, or perhaps replaced by, a delicate membranous sac (called an ascus) that fulfills the same function; *i.e.*, it communicates with the exterior through a small opening at the orifice. The transverse parietal muscles are inserted on the ascus, and their contraction dilates it. Water from outside flows into the ascus as it expands, while the coelomic fluid is simultaneously compressed. The ascophoran frontal wall has both cellular and cuticular covering layers and is penetrated by tissue-filled structures called pseudopores. Further calcification can take place outside that already present, so that the wall grows thicker with time without affecting the inner volume of the zooid.

Zooid polymorphism in cheilostomes

Zooid polymorphism exists among the colonies of the Cheilostomata, and the operculum, a flap that functions as a pivotal lid at the orifice of most cheilostomes, seems to have been of particular significance in the evolution of the specialized zooids of this order. The avicularium type of zooid has a small body and a rudimentary polypide; the operculum, however, is proportionally larger, has strong adductor (closing) muscles and has become, in fact, a jaw. Avicularia are found among normal zooids but usually are smaller and attached to normal zooids, as in *Schizoporella*. In *Bugula* the avicularia are moveable on short stalks, and closely resemble miniature birds' heads; hence the name avicularium. Another specialized form of zooid is the vibraculum, in which the operculum has become a whiplike seta (*i.e.*, hairlike projection). The functions of avicularia and vibracula are not yet known with certainty, but both types of zooids may help to keep the colony free from particles and epizoites (*i.e.*, organisms that attach to the surface of the colony but do not parasitize it).

Physiology. Respiratory, circulatory, and excretory systems are absent in bryozoans. The capture of plankton is the major role of tentacles, which spread in a manner similar to that of a funnel, with the mouth at the vertex. Long lateral cilia (*i.e.*, hairlike projections) create a water current that flows into the top of the funnel and out between the tentacles. Shorter frontal cilia direct food particles toward the mouth; from there they are sucked into the gut by the pharynx. Diatom shells, if ingested, are pulverized in the gizzard of those species that have one; digestion and absorption occur in the stomach. Although digested products must be transmitted from one zooid to another, the mechanism by which this process occurs is not yet known with certainty.

The polypide degenerates periodically during the lifetime of a zooid, and a compact mass, called a brown body, frequently remains in its place. A new polypide soon differentiates from living cells of the cystid.

The small nervous system of bryozoans is associated largely with the tentacles. It is not yet known if any interzooidal nervous coordination occurs. There are no special sense organs.

EVOLUTION AND PALEONTOLOGY

The Bryozoa have a long history. From the Lower Ordovician (430,000,000 to 500,000,000 years ago) onward, a majority of limestone formations, especially those with shale alternations, are rich in bryozoan fossils. The skeletons of calcified bryozoans are easily preserved. Stenolaemates are found abundantly as fossils; after their appearance in the Lower Cretaceous (110,000,000 years ago), cheilostome fossils also are abundant. The soft-bodied phylactolaemates, on the other hand, have left no fossil record, and fossilized ctenostomes are rarely found.

Oldest bryozoan fossil

The most ancient stenolaemate or bryozoan of any kind is the genus *Archaeotrypa*, believed to be a ceramoporoid bryozoan from the Upper Cambrian (about 500,000,000 years ago). The ceramoporoids, a group belonging to the order Cystoporata, flourished during the Ordovician and were certainly the earliest established bryozoan group to leave a fossil record. Although they declined during the Silurian (395,000,000 to 430,000,000 years ago), the ceramoporoids evidently were the progenitors of a more advanced group, the fistuliporoids, which were successful until the end of the Permian (225,000,000 to 280,000,000 years ago).

Dominant among the early Paleozoic (225,000,000 to 570,000,000 years ago) stenolaemates, however, was the order Trepostomata, which evolved rapidly during the Ordovician and attained its peak of evolutionary development during the upper part of the same period. The long, slender zooids of trepostomes grew together to form large, solid colonies. As a zooid grew longer and longer, diaphragms (or transverse partitions) were deposited. The trepostomes declined in importance after the Ordovician, perhaps as a result of competition from the cryptostomes, and were extinct by the close of the Permian (225,000,000 years ago).

The geological history of the order Cryptostomata contrasts markedly with that of the Trepostomata. Cryptostomes evolved rapidly during the Ordovician, without matching the early success of the trepostomes; thereafter, however, the cryptostomes flourished for millions of years and were the dominant bryozoans during the Devonian (345,000,000 to 395,000,000 years ago), the Carboniferous (280,000,000 to 345,000,000 years ago), and Permian periods. Then suddenly (in geological terms), and for reasons not yet explained, the cryptostomes dwindled, and the order became extinct soon after the end of the Paleozoic Era (225,000,000 years ago).

Primitive cryptostomes were similar to the trepostomes but evolved a freely erect, more delicate kind of colony that was flat and leaflike in one group, the ptilodictyoids, with two zooid layers placed back to back; in another group, the rhabdomesoids, colonies were a branching arrangement of slender stems, in which the zooids were disposed around a central axis. Fronds formed a lacy network in a third group called the fenestelloids, originating either as a fan or funnel, in *Fenestella*, or as a spiral, in *Archimedes*.

The Cyclostomata were unimportant during the Paleozoic, although living tubuliporoid genera like *Berenicea* and *Stomatopora* first appeared during the Ordovician. Alone among the Stenolaemata, however, the cyclostomes survived into the Mesozoic Era (225,000,000 to 65,000,000 years ago), diversified, and flourished during the Jurassic (136,000,000 to 190,000,000 years ago) and Lower Cretaceous. Several new groups evolved and still survive.

Although the ctenostomes (class Gymnolaemata) have never been very numerous, they apparently gave rise (during the Early Cretaceous) to the cheilostomes, thus far the most successful group of bryozoans to have

evolved. The more primitive anascan type, with calcified side walls but a frontal membrane, was successful. An early offshoot, in which the membrane is covered by a shield of modified spines, was abundant but then declined. An ascophoran type also evolved from the anascans early in cheilostome history.

CLASSIFICATION

Distinguishing taxonomic features. Both colony type and zooid morphology are used to classify bryozoans. Zooidal characters, however, are more reliable. The cylindrical zooids are of rather uniform appearance throughout the Stenolaemata, and classification, therefore, is difficult. Wall structure and the morphology of the embryo chambers are important taxonomic characters. In cheilostomes the skeletal features of the zooids, particularly the presence, extent, and structure of the frontal wall—together with shape of the orifice, type of ooecia, and zooid polymorphism—provide the most important distinguishing taxonomic criteria. Among ctenostomes and phylactolaemates, whose zooids lack skeletal features, colony form is more important. Statoblasts are of taxonomic value. Internal characters have been used less, but the presence or absence of a gizzard, number of tentacles, and colour of developing embryos are considered to be of taxonomic significance.

Annotated classification.

PHYLUM BRYOZOA

Sedentary, aquatic invertebrates; form colonies of zooids by budding; each zooid with circular or crescentic lophophore surrounding a mouth from which slender, ciliated tentacles arise; anterior part of body forms an introvert within which the lophophore can be withdrawn; alimentary canal deeply looped; anus opens near mouth but outside lophophore; excretory organs and a blood vascular system absent; each zooid secretes a rigid or gelatinous wall to support colony; about 4,000 extant species.

Class Phylactolaemata

Zooids basically cylindrical, with a crescentic lophophore and an epistome (hollow flap overhanging mouth); body wall non-calcareous, muscular, used for everting the lophophore; coelom continuous between zooids; new zooids arise by replication of polypides; special dormant buds (statoblasts) are produced; zooids monomorphic; exclusively freshwater; cosmopolitan; apparently primitive, but with no certain fossil record; about 12 genera.

Class Stenolaemata

Fossil except for some Cyclostomata; zooids cylindrical; body wall calcified, without muscle fibres; not used for everting the lophophore; zooids separated by septa; new zooids produced by division of septa; limited polymorphism; marine; Ordovician to present; about 550 genera.

Order Cyclostomata

Orifice of zooid circular; lophophore circular; no epistome; zooids interconnected by open pores; sexual reproduction involves polyembryony, usually in special reproductive zooids; Ordovician to present; all seas; about 250 genera.

Order Cystoporata

Zooid skeletons long and tubular, interconnected by pores and containing diaphragms (transverse partitions); cystopores (not pores but supporting structures between the zooid skeletons) present; Ordovician (?Cambrian) to Permian; about 50 genera.

Order Trepostomata

Colonies generally massive, composed of long tubular zooid skeletons with lamellate calcification; without interzooidal pores; orifices polygonal; sometimes with numerous diaphragms, zooid walls thin proximally, thicker distally; Ordovician to Permian; about 100 genera.

Order Cryptostomata

Colonies mostly with foliaceous or reticulate fronds or with branching stems; zooid skeletons tubular, shorter than in trepostomes; without pores; with diaphragms; proximal portions thin walled, distal portions funnel-like and separated by extensive calcification; Ordovician to Triassic; about 130 genera.

Class Gymnolaemata

Zooids cylindrical or squat, with a circular lophophore; no epistome; body wall sometimes calcified; nonmuscular; eversion of lophophore dependent on deformation of body wall by extrinsic muscles; zooids separated by septa or duplex walls; pores in walls plugged with tissue; new zooids produced behind growing points by formation of transverse septa; zooids polymorphic; mainly marine; all seas; Ordovician to present; about 650 genera.

Order Ctenostomata

Zooids cylindrical to flat; walls not calcified; orifice terminal or nearly so, often closed by a pleated collar; no ooecia or avicularia; Ordovician to present; about 40 genera.

Order Cheilostomata

Zooids generally shaped like a flat box, walls calcified; orifice frontal, closed by a hinged operculum; specialized zooids, such as avicularia, commonly present; embryos often developing in ooecia (brood chambers). Cretaceous to present; about 600 genera.

Critical appraisal. Classification of bryozoans began in 1837 when the freshwater and marine Bryozoa were separated as Lophopoda and Stelmatopoda, respectively. These names were replaced by Phylactolaemata and Gymnolaemata in 1856. Although division into two classes became generally accepted and is retained by some zoologists, studies on cyclostomes led to the naming of the third class, the Stenolaemata, formerly part of the Gymnolaemata. The cyclostomes and the fossil trepostomes were placed in the new class, which was acceptable to many paleontologists. In recent years, the work of geologists has settled the position of the cryptostomes (in the Stenolaemata). The most satisfactory system, therefore, separates the bryozoans into three classes, distinct since the beginning of the fossil record.

Most of the bryozoan orders were named many years ago: Cheilostomata, Ctenostomata, and Cyclostomata in 1852; Trepostomata in 1882; and Cryptostomata in 1883. In 1964, a Russian bryozoologist introduced a new order, Cystoporata, to include the Paleozoic ceramoporoids and fistuliporoids. The limits of the Cystoporata have not yet been satisfactorily defined. One modification may occur in the future; that is the segregation of the fenestelloid and non-fenestelloid cryptostomes into separate orders.

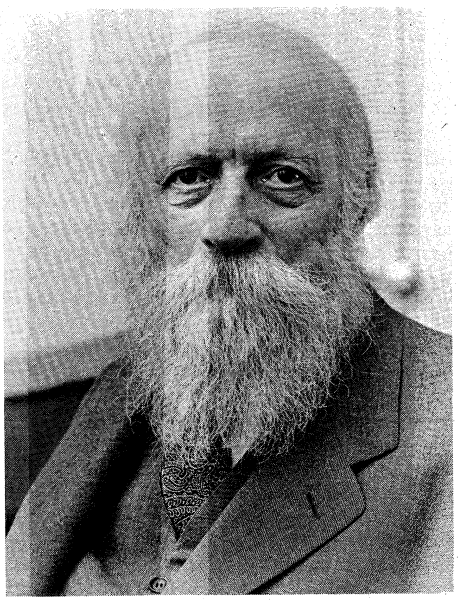
BIBLIOGRAPHY. E. ANNOSCIA, *Briozoi* (1968), an introduction to the study of Bryozoa (in Italian), but including an extensive and valuable glossary of special terms with their equivalents in English, French, German, Russian, and Spanish; R.S. BASSLER, "Bryozoa," in R.C. MOORE (ed.), *Treatise on Invertebrate Paleontology*, pt. G (1953), a useful book with definitions of all known bryozoan genera, although in need of revision; P. BRIEN, "Bryozoaires," in P.P. GRASSÉ (ed.), *Traité de zoologie*, 5:1054–1335 (1960), an advanced zoological treatise in French, with an especially good account of the Phylactolaemata; L.H. HYMAN, *The Invertebrates*, vol. 5, *Smaller Coelomate Groups*, pp. 275–515 (1959), an advanced zoological treatise; J.S. RYLAND, *Bryozoans* (1970), a general survey of the phylum for the nonspecialist, including both fossil and living bryozoans, and *Phylum Bryozoa* in T.J. PARKER and W.A. HASWELL, *Text-Book of Zoology*, 7th ed., vol. 1 (1971), an up-to-date textbook.

There is no comprehensive account of the geological history and stratigraphic distribution of Bryozoa, although there are some fine monographs on the bryozoan fauna of particular formations. These can be traced from the bibliographies of the works listed here, or from sect. 8 of the *Zoological Record*, published annually.

(J.S.R.)

Buber, Martin

Martin Buber, the German-Jewish and Israeli religious philosopher, biblical translator and interpreter, and master of German prose style, was one of the most influential figures in 20th-century spiritual and intellectual life. As one of the last great figures of German Jewry, he is comparable with the first one, the 18th-century philosopher Moses Mendelssohn. Each of them not only benefitted from German culture but also enriched it by his lifeworks, including a translation of the Hebrew Bible into German. But whereas Mendelssohn's translation of the Pentateuch (the first five books of the Bible) was partly intended to teach Jewish youth pure German, Buber's translation of the whole Bible (begun in collaboration with Franz Rosenzweig) preserved a Hebrew flavour to lead the reader to the original word and to the life and spirit that it expressed.



Buber.
By courtesy of Israel Information Services

From Vienna to Jerusalem. Buber was born February 8, 1878, in Vienna, Austria, to Carl Buber, an agronomist, and his wife—both assimilated Jews. When Martin was three his mother left his father, and the boy was brought up by his grandparents in Lemberg (now Lvov, Ukrainian S.S.R.). The search after the lost mother became a strong motive for his dialogical thinking—his I–Thou philosophy (see below).

Galician boyhood and university days

Solomon Buber (1827–1906), the Lemberg grandfather, a wealthy philanthropist, dedicated his life to the critical edition of Midrashim, a part of the nonlegal rabbinic lore. His works show him as a Hebrew gentleman-scholar who was also interested in Greek linguistic parallels. His wife, Adele, was even more a product of the 19th-century Enlightenment movement among east European Jewry that sought to modernize Jewish culture. Though influenced by both, and taught Hebrew by Solomon, young Martin was drawn more to Schiller's poems than to the Talmud. His inclination toward general culture was strengthened by his grammar school education, which provided him with an excellent grounding in the classics. During his adolescence his active participation in Jewish religious observances ceased altogether.

In his university days—he attended the universities of Vienna, Berlin, Leipzig, and Zürich—Buber studied philosophy and art. His doctoral dissertation (Vienna, 1904) dealt with the theories of individuation in the thought of two great mystics, Nicholas of Cusa and Jakob Böhme, but it was Friedrich Nietzsche's proclamation of heroic nihilism and his criticism of modern culture that exerted the greatest influence on Buber at that time. The Nietzschean influence was reflected in Buber's turn to Zionism and its call for a return to roots and a more wholesome culture. On the invitation of the Zionist leader Theodor Herzl, in 1901 he became editor of the Zionist weekly *Die Welt* ("The World"). But soon a significant difference of opinion developed between the two men. Buber favoured an overall spiritual renewal and, at its core, immediate agricultural settlements in Palestine, as against Herzl's emphasis on diplomacy to bring about the establishment of a Jewish homeland secured by public law.

Consequently, Buber resigned his post the same year he assumed it; he remained a Zionist but generally stood in opposition to official party policies and later to official state policies of Israel. He was among the early protagonists of a Hebrew university in Jerusalem.

In 1916 Buber founded the influential monthly *Der Jude* ("The Jew"), which he edited until 1924 and which became the central forum for practically all German-reading Jewish intellectuals. In its pages he advocated the unpopular cause of Jewish-Arab cooperation toward a binational state in Palestine.

After his marriage (1901) to a non-Jewish, pro-Zionist author, Paula Winckler, who converted to Judaism, Buber took up the study of Ḥasidism. His *Chassidischen Bücher* (1927) made the legacy of this popular 18th-century east European Jewish pietistic movement a part of Western literature. In Ḥasidism Buber saw a healing power for the malaise of Judaism and mankind in an age of alienation that has shaken three vital human relationships: those between man and God, man and man, and man and nature. They can be restored, he asserted, only by man's again meeting the other person or being who stands over against him, on all three levels—the divine, human, and natural. Buber maintained that early Ḥasidism accomplished this encounter and that Zionism should follow its example.

Study of Ḥasidism

In *Paths in Utopia* (English translation of the original Hebrew; 1949) he referred to the Israeli kibbutz—a cooperative agricultural community the members of which work in a natural environment and live together in a voluntary communion—as a "bold Jewish undertaking" that proved to be "an exemplary non-failure," one example of a "utopian" socialism that works. Yet he did not ascribe ultimate success to it. His reservation stemmed from the fact that, generally, members of the kibbutz disregarded the relation between man and God, denying or doubting the existence or presence of a divine counterpart. In the interpersonal area they fulfilled God's commandment to build a just community while yet denying the divine origin of the implicit imperative. Buber as an educator tried to refute these ideological "prejudices of youth," who, he asserted, rightly criticize outworn images of God but wrongly identify them with the imageless living God himself.

Buber's pedagogical work reached a climax under the new conditions created by the Nazi assumption of power. In November 1933 he became head of the newly reopened Freies Jüdisches Lehrhaus for Jewish adult education in Frankfurt am Main. In 1934 he became director of the whole organization of Jewish adult education and retraining of Jewish teachers in Nazi Germany, where Jewish teachers and students were being progressively excluded from the educational system. He was a courageous spokesman of spiritual resistance. As against the Nazi nationalism of "blood and soil," he stressed that, while the Jew must maintain his authentic Jewish existence, the educational aim could not be racist (*Völkisch*). His old slogan "to be human in a Jewish way" was now completed by the demand to be Jewish in a humane way.

After the Nazi secret police forbade his public lectures and then all of his teaching activities, he immigrated as a man of 60 to Palestine. He activated his Hebrew and soon took part in the social and intellectual life of the Palestinian Jewish community. He was appointed to a professorship in social philosophy at Hebrew University in Jerusalem, a post he held until 1951. He was the first president of the Israeli Academy of Sciences and Arts. After the establishment of the State of Israel and with the beginning of mass immigration from the Islāmic countries, Buber initiated the founding of the Teachers Training College for Adult Education in Jerusalem and became its head (1949). This college trained what were probably the best educators for the immigrants from the Middle East and North Africa, many of them having been chosen from among the immigrants.

Years in the Holy Land

As a teacher of adults, Buber enjoyed the cooperation of his political adversaries and sometimes also of his religious adversaries. Though he denied the obligatory character of Jewish religious Law and emphasized a nonlegalistic prophetic type of religion, some of the Orthodox also worked with him. Buber's endeavours in adult education were based on his insight that adults again become educable when crisis threatens their spurious security.

From mysticism to dialogue. Buber's manifold activities were inspired by his philosophy of encounter—of man's meeting with other beings. An early mystical period culminated in *Daniel* (1913), five dialogues on "ori-

entation" and "realization," man's two basic stances toward the world. Orientation takes the world as a static state of affairs governed by comprehensible laws. It is a receptive, analytical, or systematizing attitude. Realization, on the other hand, is a creative, participative attitude that realizes the possibilities in things, experiencing through one's own full reality the full reality of the world. It operates within an open horizon of possibilities.

The *Reden über das Judentum* (1923; "Talks on Judaism") mark another step in his development. The early "Talks" were delivered in 1909–11 before large Zionist student audiences in Prague; each of the speeches tries to answer its opening question: "Jews, why do we call ourselves Jews?" To half-assimilated Zionists in search of a rationale for their Jewish existence, Buber offered his theories regarding the essence of Judaism, basing his quest for it on his listeners' assumed identity as "Jews." In some of the "Talks," as well as in *Daniel,* the mystic element still prevails, but Buber later abandoned the notion of a mystical union between man and God and embraced instead the notion of their encounter, which presupposes and preserves their separate existence.

This basic view underlies Buber's mature thinking; it was expressed with great philosophic and poetic power in his famous work *Ich und Du* (1923; *I and Thou*). According to this view, God, the great Thou, enables human I–Thou relations between man and other beings. Their measure of mutuality is related to the levels of being: it is almost nil on the inorganic and botanic levels, rare on the animal level, but always possible and sometimes actual between human beings. A true relationship with God, as experienced from the human side, must be an I–Thou relationship, in which God is truly met and addressed, not merely thought of and expressed.

Ich und Du

Between man and man, the I–Thou relationship into which both parties enter in the fullness of their being—as in a great love at its highest moment or in an ideal friendship—is an exception. Generally, we enter into relationships not with the fullness of our being but only with some fraction of it. This is the I–It relationship, as in scholarly pursuits in which other beings are reduced to mere objects of thought or in social relations (*e.g.,* boss and worker) wherein persons are treated largely as tools or conveniences. This form of relationship enables the creation of pure and applied science as well as the manipulation of man by man. Buber's ethical concept of the "demarcation line"—to be drawn anew every day between the maximum of good that can be done in a concrete situation and the minimum of evil that must be done in it—calls for an I–Thou relation whenever possible and settles for an I–It relation whenever necessary —*e.g.,* for the purpose of human survival and security.

Toward God, any type of I–It relationship should be avoided, be it theoretical by making him an object of dogmas, juridical by turning him into a legislator of fixed rules or prayers, or organizational by confining him to churches, mosques, or synagogues. Buber's so-called religious anarchism—his rejection of any fixed rules of behaviour in the relation between man and God—opened to him new insights in his works on the Bible but also served as a block to an objective evaluation of biblical, let alone Talmudic, Law. He saw the Bible as originating in the ever-renewed encounter between God and his people, followed by a tradition that authentically reflected this experience and another that distorted it to serve later ideological aims. He ascribed most of the legal prescriptions of the Talmud to the "spurious" tradition removed from the Thou relation with God. This interpretation has been criticized as one-sided and subjective; Buber mitigated it somewhat in his later years.

Buber's "religious anarchism"

After the religious philosopher Franz Rosenzweig, Buber's friend and fellow translator of the Bible, read *Ich und Du,* he remarked: "Buber gives more recognition to the 'Thou' than anybody before him, but he wrongs the 'It'." To this Buber replied, many years later, that had he lived in a time when the Thou was flowering, he would have "sounded the praises of the It," but that in his time, when the Thou was withering, he had to do the reverse. This argument between Buber and his closest and greatest friend indicates his attitude toward normative Judaism. While Rosenzweig tried to live it as much as possible and became more and more a practicing Jew, Buber stood his ground as one who embodied his Judaism in no prescribed, special manner. This, in addition to his political views (*i.e.,* his opposition to Zionist policy toward the Arabs), set him apart from his own people. It made him, however, their main spokesman in the Jewish–Christian dialogue. In his *Zwei Glaubensweisen* (1950) he construed two religious types according to their approach to God: one called by the Hebrew term for trust, *emuna,* spelling mutual confidence between God and man (I and Thou), and the other called by the Greek term for faith, *pistis,* spelling the belief in the factuality of crucial events in salvation history—*e.g.,* Paul's statements about Jesus' life, death, and Resurrection. Judaism for Buber was the classical example of *emuna* and Christianity of *pistis,* although there was a good deal of *pistis* in historical Judaism and a good deal of *emuna* in historical Christianity. His Christian opponents on this and other matters still found a common ground with Buber, because he agreed to a dialogically open, if not dogmatically defined, universe of discourse in which they could talk fruitfully with one another.

Dialogue with Christians

The final years. In his last years a group of kibbutz members turned to him with their personal and communal problems. *Sihot lohamin* (1967; Eng. trans., *The Seventh Day,* 1970), published by them shortly after the Six-Day War, testifies to Buber's living spirit by its self-searching attitude on ethical questions of war and peace and on Arab–Jewish relations.

Buber died June 13, 1965. An unprecedented event occurred at his funeral in Jerusalem, a high state function: a delegation of the Arab Students' Organization placed a wreath on the grave of one who strove mightily for peace between Israel's and Palestine's two peoples.

MAJOR WORKS

Some of Buber's works were written in Hebrew and later translated into German or English or both. Other works, particularly collections of essays, were published originally in German and later translated into English. Those of his writings that appeared only in Hebrew are not listed here.

PHILOSOPHICAL WORKS: *Ich und Du* (1923; *I and Thou,* 1937 and 1970); *Rede über das Erzieherische* (1926); *Bildung und Weltanschauung* (1935); *Die Frage an den Einzelnen* (1936); *Netivot be-utopya* (1947; *Paths in Utopia,* 1949; *Pfade in Utopia,* 1950); *Das Problem des Menschen* (1948; published in *Dialogisches Leben,* 1947; "What Is Man?" in *Between Man and Man,* 1947); *Zwei Glaubensweisen* (1950; *Two Types of Faith,* 1951); *Zwischen Gesellschaft und Staat* (1952); *Bilder von Gut und Böse* (1952; *Images of Good and Evil,* 1952; *Good and Evil, Two Interpretations,* 1953); *Eclipse of God* (1952; *Gottesfinsternis,* 1953).

BIBLICAL AND RELIGIOUS WORKS: *Daniel: Gespräche von der Verwirklichung* (1913; rev. ed. 1919); *Die Schrift,* 15 vol. (1926?–?37; rev. ed., 1954–62), a translation of the Hebrew Bible into German; *Königtum Gottes,* vol. 1 of *Das Kommende* (1932; Eng. trans. from the 3rd German ed. of 1956, *Kingship of God,* 1966); *Gog u-megog* (1941; *For the Sake of Heaven,* 1945; *Gog und Magog,* 1957); *Torat ha-nevi'im* (1942; *The Prophetic Faith,* 1949; *Der Glaube der Propheten,* 1950); *Moshe* (1945; *Moses,* 1946 and 1952); *Ha-tzedeq we-ha'awon* (1950; *Right and Wrong,* 1952); *Elija: ein Mysterienspiel* (1963).

HASIDISM: *Die Geschichten des Rabbi Nachman* (1906, rev. ed. 1955; *The Tales of Rabbi Nachman,* 1956); *Die Legende des Baalschem* (1908; *The Legend of the Baal-Shem,* 1955); *Die chassidischen Bücher* (1927; Eng. trans. in 2 vol., *Tales of the Hasidim,* 1947–48; later German ed. *Die Erzählungen der Chassidim,* 1949); *Der Weg des Menschen nach der Chassidischen Lehre* (1948; *The Way of Man, According to the Teachings of Hasidism,* 1950; 2 vol., *Hasidism and the Way of Man,* 1958, 1960).

OTHER WORKS: *Ben 'am le-'artzo* (1945; *Israel und Palästina,* 1950; Eng. trans. from the German, *Israel and Palestine,* 1952); *Bücher und Menschen* (1952); *An der Wende* (1952; *At the Turning,* 1952); *Der Mensch und sein Gebild* (1955).

BIBLIOGRAPHY. MOSHE CATTANE (comp.), *A Bibliography of Martin Buber's Works (1897–1957)* (1958).

Biographies: HANS KOHN, *Martin Buber: Sein Werk und seine Zeit* (1930; new ed. with a postscript by ROBERT WELTSCH, 1963), the authoritative biography; "My Way to

Hasidism" in *Hasidism and Modern Man* (1958); "Autobiographical Fragments: Martin Buber," in SCHILPP and FRIEDMAN, ch. 1 (cited below); AUBREY HODES, *Martin Buber: An Intimate Portrait* (1971), worthwhile reading, though not fully reliable in all factual details.

Writings on Buber: PAUL ARTHUR SCHILPP and MAURICE FRIEDMAN (eds.), *The Philosophy of Martin Buber* (1967), 30 critical essays by different authors on Buber's impact on such fields as theology, philosophy, Zionism, Hasidism, and education; SIDNEY and BEATRICE ROME (eds.), "Interrogation of Martin Buber," in *Philosophical Interrogations*, new ed. (1970), queries by various thinkers and scholars with answers by Buber; HANS URS VON BALTHASAR, *Einsame Zwiesprache: Martin Buber und das Christentum* (1958; Eng. trans., *Martin Buber and Christianity: A Dialogue Between Israel and the Church*, 1961), a Roman Catholic scholar's friendly but critical answer to *Two Types of Faith;* ARTHUR A. COHEN, *Martin Buber* (1957), a critical appreciation from a more traditional Jewish standpoint; MALCOLM L. DIAMOND, *Martin Buber: Jewish Existentialist* (1968), an empathetic analysis of one central aspect of Buber's thought; MAURICE FRIEDMAN, *Martin Buber: The Life of Dialogue* (1960), the pioneer work on Buber in English; WILL HERBERG, *The Writing of Martin Buber* (1956), an excellent introduction and a good selection of quotations from Buber's work; ROY OLIVER, *The Wanderer and the Way: The Hebrew Tradition in the Writings of Martin Buber* (1968), a personal testimony of a former follower and student of Gandhi for whom Buber's biblical work became a turning point; GRETE SCHAEDER, *Martin Buber: Hebräischer Humanismus* (1966), a standard work, partly done under Buber's personal supervision; AKIBA ERNST SIMON, "Jewish Adult Education in Nazi Germany As Spiritual Resistance," in *Yearbook I* of the Leo Baeck Institute, pp. 68–104 (1956), deals largely with Buber's initiative, educational philosophy, and practical leadership; "Martin Buber and German Jewry," in *Yearbook* III, pp. 3–39 (1958), deals *inter alia* with Buber's relation to Herzl, H. Cohen, and F. Rosenzweig.

(A.E.Si)

Bucer, Martin

Martin Bucer, an important Protestant Reformer of the 16th century, who is best known by scholars for his ceaseless attempts to make peace between conflicting reform groups, influenced not only the development of Calvinism (one of the three classical Reformation groups —the other two being Lutheranism and Anglicanism) but also the liturgical development of the Anglican Communion.

Bucer, medal by Friedrich Hagenauer, 1543. In the Archives et Bibliothèque de la Ville de Strasbourg.
By courtesy of the Archives et Bibliotheque de la Ville de Strasbourg

Born at Schlettstadt, Alsace, France, on November 11, 1491, Bucer entered the Dominican monastic order in 1506. He was sent to study at the University of Heidelberg, Germany, where he became acquainted with the works of the great Humanist scholar Erasmus and Martin Luther, the founder of the Protestant Reformation. In 1521 Bucer withdrew from the Dominicans and entered the service of the count palatine of the Rhine, one of the seven electors of the Holy Roman emperor. The following year he became pastor of Landstuhl, where he married a former nun. Excommunicated by the church in 1523, he made his way to Strassburg, where his parents' citizenship assured him of protection. His personal charm, intellectual abilities, and zeal eventually gained him a position of leadership in Strassburg and southern Germany.

Early career as a Protestant Reformer

Under the influence of Erasmus, he had accepted the ideals of Christian Humanism and the Renaissance, which called for a rebirth of what the Humanists believed was the true good, the original rightness, in man and society.

When caught up in the enthusiasm of the Reformation that was rapidly spreading in northern Europe, Bucer became a Protestant Reformer. He envisioned a renewal of man and society that was based on his earlier Humanist views, and he believed that such a renewal would result from the preaching of the true gospel and from faithful adherence to the divinely given pattern of living found in the Bible. This reform through conversion, piety, and discipline found its fullest expression in the massive program for the reformation of England that he presented to King Edward VI of England in 1551.

Bucer's adopted city, Strassburg, lay between the area influenced by the most important Swiss Reformer, Huldrych Zwingli—south Germany and Switzerland—and the area influenced by Luther—north Germany. After 1524 Luther and Zwingli clashed over the meaning of the words, "This is my body," a central phrase in the liturgy of the Lord's Supper. Summoned to Marburg by the landgrave, Philip of Hesse, in 1529, the two leading Reformers and other Reformers engaged in a colloquy to settle the dispute. Luther held to the traditional view that Christ was "really present" in the bread and wine of the sacrament of the Lord's Supper; Zwingli espoused a "spiritual" interpretation that was common among the Humanists; Bucer believed that the two opposing views could be reconciled. But when, at the end of the colloquy, Zwingli and Bucer proffered their hands in fellowship to Luther, he refused.

Bucer as mediator

Believing that the rift between the two reform movements could be bridged, Bucer participated in nearly every conference on religious questions held in Germany and Switzerland between 1524 and 1548. In the various colloquies between Protestants and Catholics or between German Lutheran and Swiss Reform churchmen, Bucer often advocated the use of obscure language and ambiguous formulas when explicit agreement between the opposing parties was impossible to attain. His justification for the use of ambiguity was that he believed that the essential goal was the reform of the people and the doctrinal issues could be worked out later. At Basel, in 1536, Bucer participated in the writing of the First Helvetic Confession, a document that was considered by many Reformed theologians to veer too much toward Luther's views, especially regarding the Lord's Supper. At Wittenberg, Germany, in the same year, Bucer took part in a conference between Lutheran and Reformed theologians, including the Lutheran Philipp Melanchthon, a Humanist theologian with whom he has often been compared. It appeared for a time as though Bucer and Melanchthon were about to achieve their goal of ending the dispute over the Lord's Supper, a dispute that had split the Reformation on the Continent into two major groups. Luther, in satisfaction over the apparent agreement that Bucer and Melanchthon had helped to bring about, declared, "We are one, and we acknowledge and receive you as our dear brethren in the Lord." Bucer is reported to have shed tears at Luther's words. Melanchthon subsequently drew up the Wittenberg Concord incorporating the agreement, but, to Bucer's and Melanchthon's disappointment, it failed to effect a lasting union. The Swiss were unhappy that Bucer had made concessions that leaned toward the doctrine of the real presence, and some thought that he should formally recant his statements as they were incorporated in the Wittenberg Concord.

Even though Bucer was criticized for his evasive approach and concealment of the issues in the controversies between the adherents of Zwingli and Luther, the civil authorities in many south German areas sought his advice and guidance in arranging compromises based on edicts by local authorities. Since Bucer regarded these compromises as tailored to local circumstances, he soon

was charged by all parties as having no conviction except that the end justifies the means. In his defense he claimed that each of these compromises was only a temporary measure, that he hoped that further changes gradually would be made. Bucer's policy of agreement by compromise was seen in a better light when it was applied to the problem of religious toleration. Under Bucer's policies there was less persecution of Anabaptists—the left wing of the early Reformers who espoused revolutionary concepts in political and social organization—and other minority groups in Strassburg than in most of Europe.

Bucer's policy of pragmatic solutions of problems proved to be especially difficult in the case of the bigamy of Philip, landgrave of Hesse. Philip, who had given much support to Luther, Bucer, and other Reformers, had serious marital problems but thought it inadvisable to divorce his wife. Bucer helped him to persuade Luther, Melanchthon, and others to sanction a second wife, on the basis of Old Testament plural marriages. In an effort to keep the scandal of Philip's bigamy secret, falsehoods were told, and the matter caused much damage to the Reformers' reputations.

Apart from promoting intra-Protestant union, Bucer had long dreamed of healing the Protestant–Catholic rift, and in this effort he engaged in secret negotiations with certain liberal, reform-minded Catholics. The emperor Charles V, for political reasons, was pursuing similar aims. Fearing a Turkish invasion of central Europe, he wanted, at almost any price, to restore unity between the princes of Germany. He accordingly called for the Colloquy of Regensburg, between Catholics and Protestants, in 1541. Charles selected three Catholic and three Protestant theologians (including Bucer) to discuss the anonymous Regensburg Book, which proposed steps toward Catholic–Protestant union. When Charles used Bucer's rather far-reaching concessions in his secret negotiations with the liberal Catholics as the basis for an official solution of the controversy over the Reformation, Bucer, taken by surprise, denied any participation in a scheme for union. Both Catholics and Protestants rejected the Regensburg Book. Charles settled the matter for a time by subduing the Protestant powers, which would not accept any religious compromise by military force, and by enforcing his own compromise scheme, the Augsburg Interim of 1548.

Although the Augsburg Interim did not concede much more to Catholicism than some of his own earlier compromise solutions had, Bucer vigorously opposed its acceptance by Strassburg. His view was that even a poor compromise was justified if it made some progress toward reform but that if Strassburg accepted the Augsburg Interim it would be a step backward. The armies of Charles, however, prevailed, and Strassburg discharged Bucer and several other Protestant ministers, all of whom were invited to England by the Archbishop of Canterbury, Thomas Cranmer. There Bucer supported the official, cautious reform program of Cranmer and Nicholas Ridley against the more radical reform of the English Church urged by the Zwinglian John Hooper and the Scottish Reformer John Knox. *The First Prayer Book of Edward VI* (1549), the liturgical book of the newly reformed English Church that contained evidence of Lutheran influence, was submitted for formal criticism to Bucer, who could not speak English. His assessment, the *Censura,* delivered to the Bishop of Ely a month before Bucer died, pointed out the vague Lutheranisms of the prayer book. *The Second Prayer Book of Edward VI* (1552), utilizing Bucer's criticism, offended the conservatives in the English Church and did not satisfy the more radical Reformers; it remained in force for about eight months. Bucer's influence as a mediator, however, continued to have its effect in subsequent attempts at compromise in the English Church in the 16th century. He died in England on February 28, 1551.

BIBLIOGRAPHY. The standard biography in English is HASTINGS EELLS, *Martin Bucer* (1931). MIRIAM U. CHRISMAN, *Strasbourg and the Reform* (1967), provides a good history of the city in Bucer's time. FRANCOIS WENDEL, *Calvin: Sources et évolution de sa pensée religieuse* (1950; Eng. trans., *Calvin: The Origins and Development of His Religious Thought,* 1963), discusses Bucer's influence upon Calvin. WILHELM PAUCK (ed.), *Melanchthon and Bucer,* pp. 155–394 (1969), gives an English translation, with an excellent introduction and commentary, of Bucer's *On the Kingdom of Christ,* presented to King Edward VI for the reform of the whole of English society. CONSTANTIN HOPF, *Martin Bucer and the English Reformation* (1946), is a scholarly study of Bucer's role in England and is supplemented on liturgical matters by G.J. VAN DE POLL, *Martin Bucer's Liturgical Ideas* (1944). Among the few monographs in English on Bucer's theology is W. PETER STEPHENS, *The Holy Spirit in the Theology of Martin Bucer* (1970). Each of the above works contains an extensive bibliography. The definitive edition of the collected works of Bucer is now in progress, the Latin works edited by FRANCOIS WENDEL *et al.* (1955–), and the German works edited by ROBERT STUPPERICH *et al.* (1960–).

(L.J.T.)

Bucharest

Bucharest (Romanian Bucureşti), capital of Romania and the most easterly of European capitals except Moscow, stands in the Romanian Plain on the Dîmboviţa River, a tributary of the Argeş (itself a tributary of the Danube), 25 miles (40 kilometres) from the southern frontier of the country. Its physical development reflects the long and eventful history of the region, which has archaeological remains dating from the earliest periods of European prehistory and architectural survivals that serve as a reminder of the long period of Ottoman domination. Following Romanian independence (1878), the city underwent an extensive, planned transformation as the political, economic, administrative, and cultural centre of Romania. With its suburban communes, the city now covers an area of 234 square miles (605 square kilometres). In 1977 its population was 1,934,025, or 9 percent of the total population of the whole country, compared with 340,000 in 1912. (For information on related topics, see BALKANS, HISTORY OF THE; OTTOMAN EMPIRE AND TURKEY, HISTORY OF THE; ROMANIA.)

The site. The winding course of the Dîmboviţa was straightened and diked in 1882 to open the way for urban development along the once marshy floodplain, lying only some 175 to 260 feet (53 to 82 metres) above sea level. The river actually runs for 15 miles (24 kilometres) through the city, dividing it into almost equal halves.

The climate is moderately continental, temperatures averaging 73° F (23° C) in summer and 27° F (−3° C) in winter. Occasionally there are particularly hot summers, usually followed by exceedingly cold winters. The well-watered nature of the region, together with favourable climate and soil conditions, has created a flourishing growth of vegetation. Bucharest is renowned for the number and extent of its green areas, and it is fringed by attractive natural landscapes with meadows and oak groves. A chain of nine landscaped lakes lying to the north, along the Colentina Valley, further enhances the area. All of these beauty spots are much used for rest and recreation.

Historical development. The physical growth of Bucharest took place in several stages, each reflecting historical conditions, in particular the long (15th to 19th century) period of direct and indirect Turkish and Greek domination.

The earliest period. Apart from fortified monasteries and churches on small "islands" in the floodplain, the first recorded urban development took place on the terraces marking the northern slopes of the Dîmboviţa Valley. But the first settlement is much older than the Middle Ages. According to one tradition, the town was founded by a shepherd named Bucur; according to another, the founder was a fisherman. Recent archaeological excavations, revealing remains of the Paleolithic, Bronze, and Iron ages as well as Roman and early medieval relics, have demonstrated that the area now covered by the city has experienced a very long period of almost continuous occupation.

Continuity of settlement

The medieval period and its legacy. The first written appearance of the name Bucureşti dates from September

20, 1459, when it was recorded in a document of Vlad Ţepeş (Vlad IV the Impaler), whose rule (1456 to 1462, and again in 1476–77) of Walachia offered the area a brief respite from the ever-present Turkish threat. The Prince appreciated the strategic situation of the ancient settlement, located as it was on a trade route between Braşov (a town to the north that commanded the far side of the Predeal Pass) and the Danube River. He built the fortress of Bucharest—the first of many fortifications—with the aim of holding back the Turks who were threatening the existence of the Walachian state and particularly its then capital, Tîrgovişte, 43 miles away to the northwest, on the exposed southern flank of the Carpathians. Further fortifications were erected during the mid-16th-century reign of Mircea Ciobanul (Mircea the Shepherd), who built what became known later as the Curtea Veche (Old Court), part of which survives as the city's oldest building. This structure was sited in the vicinity of the present-day Piaţa de Flori (Flower Square).

Under the Ottoman suzerainty that was eventually established, Bucharest developed rapidly as the main economic centre of Walachia, becoming the capital in 1659. This growth was accompanied by changes in the physical appearance of the town and also in its social structure. The town spilled over its early limits, spreading across to the right, or southern, bank of the river, although growth in this zone of low hills, rising to just over 300 feet (90 metres), was very modest until the 19th century. Within the old core, the population continued to grow, with tradesmen and craftsmen—and their new, taller buildings—becoming more and more numerous. The names of some streets—Uliţa Blănarilor (Furriers' Lane), Uliţa Şelarilor (Saddlemakers' Lane), Uliţa Şepcarilor (Capmakers' Lane)—testify to the emergence of guild organizations. Uliţa Lipscanilor was named after the annual fair held in the German city of Leipzig, where many Bucharest merchants traded their goods. As early as the reign (1688–1714) of Prince Constantin Brâncoveanu (Brîncoveanu), large, broad thoroughfares were built. These were known as *poduri* ("bridges"—*i.e.*, streets paved with logs), and they were of significance in forming the present street patterns of the city.

Development of guilds

The census of 1798 recorded that the town had more than 6,000 houses and about 50,000 inhabitants. Strong class distinctions were reflected in the living conditions. At this time government was no longer in the hands of native princes but was controlled instead by Phanariotes (*i.e.*, Greeks originating in the Phanar district of Constantinople) appointed by the authorities of the Sublime Porte.

The 19th and 20th centuries. In 1821 a popular uprising, led by the great Walachian national hero Tudor Vladimirescu, ended Phanariote rule. Bucharest, like many European cities, entered a period of effervescence; the people of Bucharest, for example, played an important role in the revolutions that shook the continent of Europe in 1848. Again, in 1859, civic unrest played a part in forcing the union of Walachia and Moldavia, followed in 1862 by the proclamation of Bucharest as the capital of the Romanian state. These events, coupled with a land reform in 1864 and the final achievement of national independence in the war of 1877–78, gave a strong impetus to the economic development of both the nation and its capital city.

Popular unrest

The increasing number of financial transactions focussed on the city resulted in the establishment of the National Bank (1880) and other banking institutions. In the last 15 years of the 19th century, important public edifices were built, many of them along the main thoroughfare known as Calea Victoriei (Victory Avenue), the name celebrating the newly won independence. The new structures included the Romanian Athenaeum (1888), the Post Office (1900), and the Savings Bank. Nearby are the National Bank and the Palace of Justice (1895; in French neo-Renaissance style). Further progress was signified by the introduction of the first electric tramway, operated along the new thoroughfare called Obor-Cotroceni.

After World War I, Bucharest strengthened its position as the most important economic, political, and cultural centre of a greatly enlarged country. The architectural legacy is very clear, with some modern villas and public buildings incorporating traditional elements as a reaction to the more anonymous "international" styles used for many of the apartment buildings.

Further growth took place after World War II, and since the nationalization of land in 1948 this has been characterized by large-scale projects and a marked architectural uniformity.

World War II and after

On the evening of March 4, 1977, Bucharest was shaken by a severe earthquake (7.2 on the modified Richter scale), which killed some 1,400 people and injured 7,600. The central part of the city was hardest hit, many apartment buildings, hospitals, and cultural institutions being destroyed or seriously damaged.

The economy. Modern industries were introduced in the late 19th century to supplement the workshops of the artisans. During the 1920s and '30s industrialization continued, largely on the basis of private enterprise. Following the nationalization of industry in 1948, many of the old enterprises were amalgamated and re-equipped. In addition, many new factories have been built. By the 1970s, the reordered urban economy concentrated on the production of engineering products, notably machine tools and agricultural machinery, as well as electrical and automotive equipment, buses, trolleybuses, and a wide variety of other goods, including consumer goods. Some 18 percent of the entire industrial production of Romania stems from Bucharest, which is also the largest commercial centre of the country, with about 5,900 state and cooperative trading units.

Educational and cultural life. By the later 1970s Bucharest had 50 faculties of higher education, serving about 71,000 students, compared with 13 faculties and 18,000 students in 1940. There were 13 specialized institutions of higher education, with curricula ranging from agronomy to fine arts. The most important centres for higher education were the "Gh. Gheorghiu-Dej" Polytechnic Institute (founded 1819) and the University of Bucharest (founded 1864). In addition, there were several important academies in both arts and sciences, as well as numerous research institutes conducting scientific work. Bucharest has three central libraries (the Library of the Academy of the Socialist Republic of Romania and the Central State Library, both with many valuable manuscripts, and a central university library) and many public library units.

There are 19 theatres, some of which—for example, the National Theatre "I.L. Caragiale" and the Theatre of Opera and Ballet of the Socialist Republic of Romania—have long traditions. Bucharest is also the seat of the state philharmonic orchestra and many other professional and amateur musical groups, many of them with a strong folk interest. Every third year, the Georges Enesco International Festival (for violin, piano, and vocal music) takes place in the city. Among the many museums are the Museum of the History of the City of Bucharest and the Art Museum of the Socialist Republic of Romania, the latter being the largest of its kind in the country, maintaining large collections of national, European, and Oriental art. Among other notable museums is a highly original ethnographic collection, the Village Museum (founded 1936), made up of peasant houses brought from various parts of the country, complete with outbuildings, furniture, and the household objects appropriate to each region.

The city has a great number of churches, usually small, in Byzantine style. Apart from the Curtea Veche (Old Court) Church, the Antim Monastery (1715) and the churches of SS. Stavropoleos (1724) and Spiridon (1747) are of considerable architectural interest. There are also a Roman Catholic cathedral, several Protestant churches, and a number of synagogues.

The city is a medical centre, providing a variety of medical services, generally free of charge. For recreational purposes, there are also numerous sports grounds, covered gymnasiums, and stadiums, the largest (the "23

August") having nearly 100,000 seats. The large expanse of parkland on the northern edge of the city, surrounding the lakes of the Colentina Valley, is also an important recreational asset.

Town planning and the contemporary topography. Major works in town planning were carried out in the late 19th century, and since the 1930s development has been coordinated by an urban plan, periodically updated. The present plan envisages a maximum urban area of some 38,400 acres (15,500 hectares), to contain the population of 2,300,000 expected by the year 2000. The main trend in recent years has been the construction of new residential districts in outlying areas, each with a planned modern aspect including a variety of services. New avenues have been opened, other streets have been rebuilt, and important new buildings have appeared on the major city thoroughfares.

Republic Square—with the new palace hall, seating 3,000 people, and other new buildings as well as the historic Creţulescu Church (1722)—has become one of the most beautiful squares of the town. It is harmoniously linked to Palace Square, which is surrounded by an imposing group of administrative, political, and cultural buildings including the headquarters of the Communist Party of Romania, the Art Museum (housed in the former Royal Palace), and the massive round building of the Romanian Athenaeum, notable for its columned facade. Nearby, in the heart of Bucharest, lies the junction of the almost straight thoroughfares that traverse the city from north to south (Nicolae Bălcescu Boulevard and 1848 Boulevard) and from east to west (Republicii Boulevard and Gh. Gheorghiu-Dej Boulevard). Here, near the university, rise the National Theatre "I.L. Caragiale" and the 25-story Intercontinental Hotel.

Large areas of old housing in the inner city, however, await redevelopment, and this must be given high priority in the immediate future, to prevent a further outward expansion of the built-up area.

Municipal services

Bucharest was among the first cities in the world to be lighted by kerosine (1856) and gas (1871), and this lighting system was maintained, in part, until after World War II. After 1950 electric lighting was extended over the whole urban area, and the number of paved streets was greatly enlarged and the water and sewerage systems were expanded.

Bucharest has become a modern city, whose complexity can be illustrated by taking the route into the city from the international airport at Otopeni. After 10 miles, the road enters the city on the main north–south thoroughfare, passing the smaller Băneasa Airport. After crossing a bridge over Lake Herăstrău, in the vicinity of the Museum of Folk Art "Dr. N. Minovici" (1905), the large Scînteia Square is reached. In the background, on the right, stands Scînteia House, with the largest printing enterprise in the country, a monument to Soviet influence by virtue of its architecture and the circumstances of its construction. Ahead lies the hall housing the national economy exhibition, and on the left is the Park of Culture and Rest, at 470 acres the largest park in the city, encompassing the Village Museum, an open-air theatre (seating 2,800 people), and a number of other facilities including a flower exhibition. From Scînteia Square the main thoroughfare passes by a triumphal arch (built in the 1930s to commemorate the achievement of Greater Romania after World War I), crosses a public garden (the Kisselef Park, modelled on the Parisian Champs-Élysées), and enters Victory Square. This square is dominated by the modern building of the Council of Ministers, near which rises a natural history museum. From Victory Square, streets lead in several directions. To the left, passing by the Dinamo Sports Park, Ilie Pintilie Boulevard leads to the Ştefan cel Mare Highway, which goes to the old Obor Market, now the site of a large market hall, and, farther, to the modern Titan district. To the right, an older avenue leads to Griviţa Road and the North Railway Station. Ahead appears, on the one hand, a series of modern boulevards: Ana Ipătescu, General Magheru, Nicolae Bălcescu, and 1848, the latter leading to Union Square, dominated by the hill on which the Palace of the Grand National Assembly stands, with Liberty Park beyond. On the other hand, by contrast, lies Victory Avenue, one of the oldest thoroughfares, originally dating from 1702.

The heart of the city

These old and new streets are crossed in the heart of the city by other avenues forming the east–west axis. To the west of the university—near which are the Museum of the History of the City of Bucharest and the oldest hospital of the town, the Coltea, founded in 1704, a visitor crosses Victory Road and reaches the attractive Cişmigiu Lake and Garden, which have dominated the city centre for more than a century. In the western part of the Gh. Gheorghiu-Dej Boulevard (formerly Vest–Est Boulevard), not far from the Romanian opera building and the building of the Faculty of Medicine (1903), rises the Pioneers' Palace, headquarters of the Communist organization for children. The same quarter—Cotroceni—is dominated by the building of the Military Academy, and behind it extends Drumul Taberei, a modern residential quarter. Farther west, the route passes the botanical garden (1884) and the largest clothing factory in the country, and then, surrounded by factories and apartment buildings, merges with the highway leading northwest to the city of Piteşti.

Eastfoto

Palace Square near the heart of Bucharest, Romania. The former Royal Palace (foreground) now houses the Art Museum of the Socialist Republic of Romania.

A further issue in planning concerns the wider city region. This includes the suburban communes, which together account for 130,000 people (compared with 1,930,000 for the whole municipality of Bucharest); much of the increase in population anticipated by 1990 may be accommodated in these peripheral districts. An important question is the extent to which agricultural land should be preserved, a consideration that is especially important on the western side of the city, where favourable conditions of soil, topography, groundwater, and microclimate are reflected in extensive irrigation works and hothouses. Planners are discussing, on the one hand, the merits of a deeper suburban belt all around the city against, on the other, the attractions of expanding the city along certain axes enjoying road and rail communications. Bucharest has enormous physical capacity for expansion, and, although the high cost of dispersal is likely to result in continued high-density development, there are many possibilities to consider in deciding the future urban form.

Budapest

Regarded as one of the most beautiful international cities of the modern period, Budapest, the capital of Hungary, has a unique reputation and character. Strategically located on the Danube River, commanding the approaches to the Great Hungarian Plain (the Great Alföld), it dominates most aspects of Hungarian national life and, with a resident population exceeding 2,000,000 in 1976, is the third largest city in the Soviet bloc, after Moscow and Leningrad. In addition to its economic importance, the contemporary status of Budapest is enhanced by a magnificent natural setting, offering fine panoramas across the city; by its historic relics, museums, and noted thermal baths; by a unique and friendly atmosphere; and by an international accessibility.

As the political, administrative, industrial, and commercial centre of the Hungarian People's Republic, Budapest has close ties with the rest of the country. These links are facilitated by its position at the focal point of the Hungarian road and rail systems. That it is the seat of the Hungarian government and Parliament reflects its national political and administrative role, while its local functions are mirrored in its being the administrative centre of Pest County (*megye*) and Buda rural district (*járás*). Budapest also acts as the host to a number of international bodies: the Danube Commission has its headquarters in the city as do the World Federation of Democratic Youth and several permanent committees of the Council for Mutual Economic Assistance (Comecon), the east European economic and trade organization.The European significance of Budapest is reflected in its international transport links; it lies on a waterway connecting eight countries, and transcontinental highways and railways converge upon it. Budapest is also the centre of an industrial agglomeration of 44 smaller settlements that are linked to the city for planning purposes.

International bodies in the city

The capital acquired the name Budapest in 1873 when the communities of Pest (on the left bank of the Danube), Buda (on the right bank), and Óbuda (Old Buda) to the north were amalgamated. During the subsequent hundred years, the functions of the former royal boroughs were integrated and most of the neighbouring settlements were also included within the city boundary. The city has, in fact, fulfilled an administrative role almost without interruption since Buda emerged as the royal residence in the aftermath of the Mongol invasion of 1241.

Six road bridges, including the Széchenyi Chain Bridge (Széchenyi Lánchíd, built by the Scottish engineer Adam Clark), two railway bridges, and a tunnel carrying the east–west underground railway link Buda with Pest. All the bridges were demolished by the retreating German forces at the end of World War II but have since been rebuilt. Elizabeth Bridge (Erzsébet-híd), reconstructed as a suspension bridge, crosses the Danube in one span.

One-fifth of the population of Hungary resides in the capital, and a further 200,000 to 300,000 commute to work in the city each day. In the mid-1970s about 512,000 were employed in the industries of the city, an 18 percent reduction from 1968, after the decentralization of plants to provincial centres began to reduce this number.

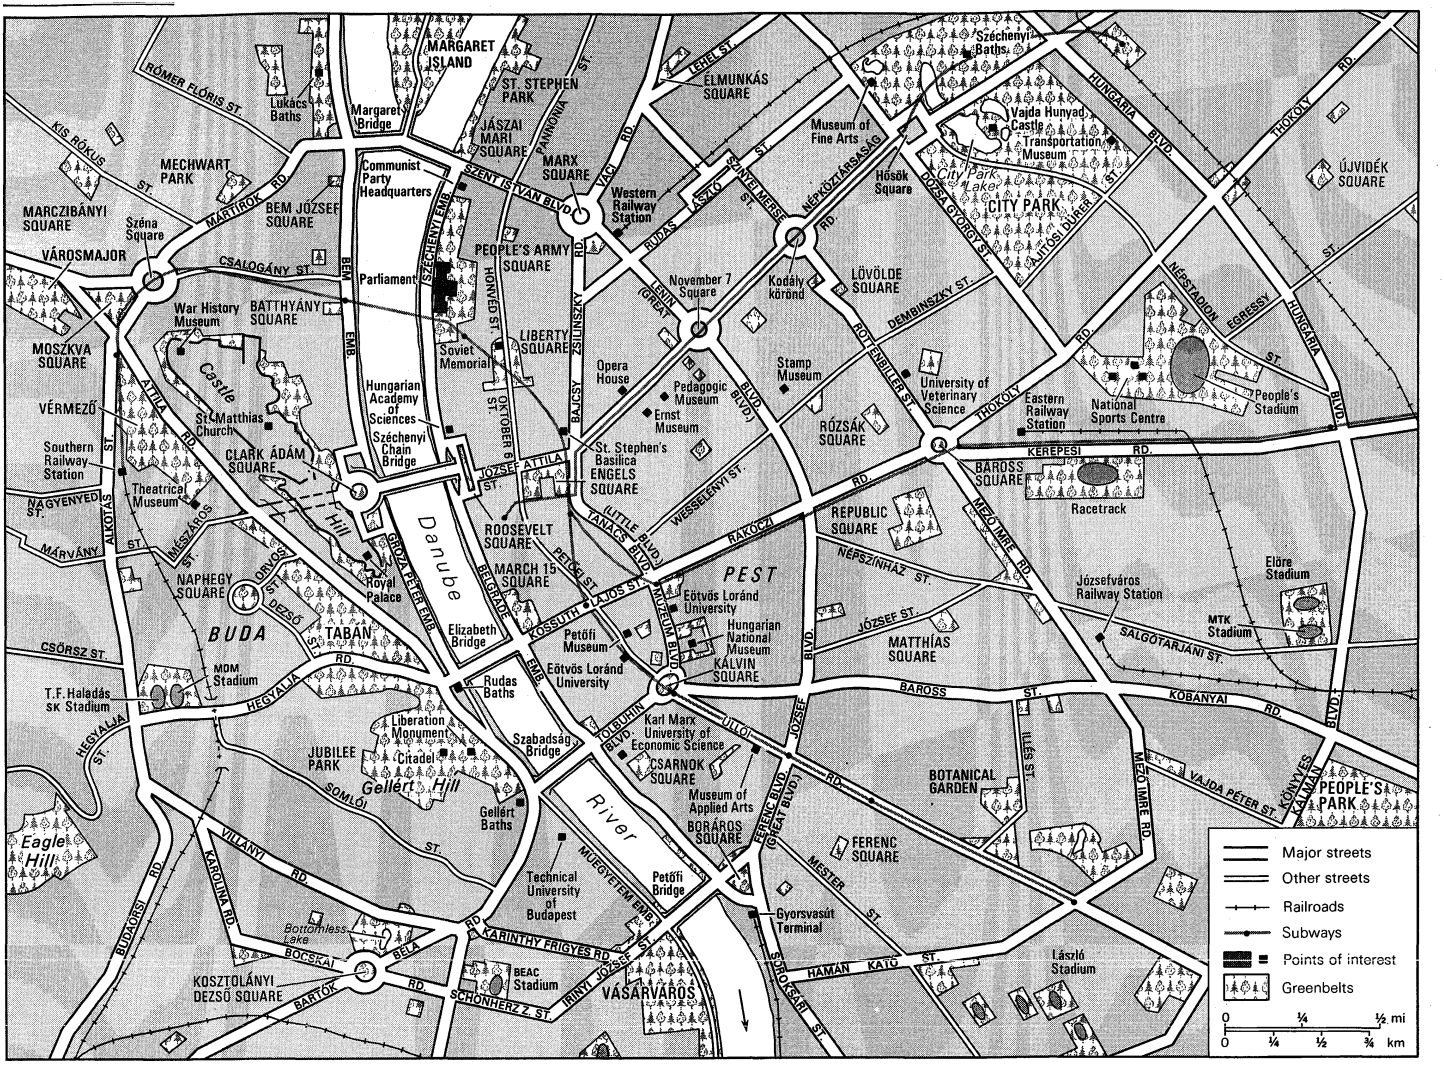
Historical development. From early times the significance of the site of Budapest has been appreciated, combining as it does a defensive with a communications function; the river was always fordable at this point. Archaeological evidence shows that the site has been continuously settled since at least the 3rd millennium BC, and Copper, Bronze, and Iron Age man lived there. The Eravisci tribes, of Celtic origin, lived at the foot of Gellért Hill, 771 feet (235 metres) above sea level, and also farther north in what was to become Óbuda. This settlement was called Ak-Ink, meaning "ample water," from which was derived Aquincum, the name given to the civilian town and military camp established by the Romans at the end of the 1st century AD. By the time the Magyar tribes entered the Pannonian Basin in the 9th century, Aquincum, over which had flowed the great Eurasian migrations that followed the fall of the Roman Empire, had ceased to exist. Although there is evidence that some of the Roman buildings were used as shelter, the focus of settlement moved south.

The Roman settlement

This shift was consolidated by the construction of a stone fortress on a rocky spur overlooking the west bank of the Danube by King Béla IV, in the years following the Mongol invasion of 1241. The fortress became known as Buda Castle and the spur as Castle Hill (Várhegy). Soon a settlement sprang up at its base and another on the riverbank opposite, which were to grow respectively into the towns of Buda and Pest. In the 15th century Buda emerged as the most important handicraft and trading centre of the country, and during the reign (1458–90) of Matthias I Corvinus it also became a seat of learning. Buda and Pest were occupied by the Turks in 1541, and during the ensuing period of Turkish domination (to 1686) both towns declined.

During the more stable years of the early 18th century, the two towns again prospered, and by the 1790s Buda had become the seat of national government. Buda, Pest, and a re-emergent Óbuda now began to follow separate paths of economic specialization. Buda and Óbuda were characterized mainly by handicrafts and agriculture; Pest, which was increasingly identified with industry and commerce, rapidly outstripped its neighbours in significance. Throughout the centuries, Buda and Pest had suffered considerably from winter and spring flooding. As a result of the great disaster of 1838, when both towns were devastated, it was decided to regulate the Danube by constructing an extensive series of embankments; these did much to mold subsequent urban layout. The introduction of steamship navigation on the Danube in 1830 and the beginnings of railway construction (the first railway line, from Pest to Vác, was opened in 1846) further assisted the industrial development of Pest. In addition to the industrial and trading companies, numerous cultural institutions also emerged during this period, including the Hungarian National Museum (Magyar Nemzeti Múzeum) and the Hungarian Academy of Sciences (Magyar Tudományos Akadémia), paving the way for the declaration of Pest as the official capital of Hungary in 1848.

Two events occurring within five years of each other provided the institutional framework for urban expansion in the second half of the 19th century. The first was the Compromise (Ausgleich) of 1867 with Austria, which formally recognized Hungarian independence within the political framework of the Dual Monarchy, Austria–Hungary; this agreement was instrumental in increasing



Central Budapest.

Amalgamation

both the administrative and financial roles of the city. The second was the formal recognition of the strong mutual ties between Buda, Pest, and Óbuda with their amalgamation into one administrative unit in 1873, since when Budapest has developed as an organic whole. Concurrently, mechanization was providing the stimulus for further industrialization. Budapest was evolving into one of the most important centres for the production of agricultural machinery in Europe, and as a consequence engineering had become a dominant component in the urban economy by the end of the 19th century. Industrial zones emerged on the northern, eastern, and southern outskirts of the city, turning the former settlements of these areas into industrial suburbs.

From a relatively small town of 54,000 in 1800, the population of Budapest expanded to 302,000 by the time of the first census in 1869, and thereafter rose at a rate of almost 4 percent per year to total 1,110,000 by 1910. It was during this phase of explosive growth that present Budapest took shape. The last four decades of the century saw the construction of the Great Boulevard (Nagykörút), the Little Boulevard (Kiskörút), and important radial arteries such as the present People's Republic (Népköztársaság) Road. The restored Royal Palace, the new Parliament building (1904), together with the Danube bridges succeeded in blending the architectural heritage of the past with the needs of an expanding modern city.

At the outbreak of World War I, Budapest fulfilled well the role of capital of a country of more than 18,000,000 people. This situation was radically changed in 1920 when, as a result of the Treaty of Trianon, which created new nation-states from the former territories of Austria–Hungary, Budapest found itself the overly large capital of a country with a population of less than 8,000,000. No other town was sufficiently large to counterbalance the magnetic pull of Budapest in all aspects of Hungarian life, a state of affairs that exists to this day. As a consequence, even though grave economic problems confronted the country during the interwar years—partly because of loss of territory and the need to adjust the economy accordingly, and later as a result of the world depression—Budapest still managed to grow in terms of population, industry, and built-up area. Four more city districts were added to the 10 that were formed at the time of the union of Buda, Pest, and Óbuda, and by 1941 the population had grown to 1,713,000.

World War II

The city suffered severe damage during World War II. Nine in 10 of the factories were partly or totally destroyed, and 85 percent of all dwellings were demolished or seriously damaged. Practically all forms of transport were destroyed, and by the end of the siege in 1945 the population had fallen by between a quarter and a third.

The first phase of the postwar era was thus one of reconstruction. In 1950 the area of the city was extended to include the outer industrial suburbs and was divided into the 22 districts that still provide the framework for local government. Services were gradually extended to the outer suburbs, which are linked to the central area by a rapid and cheap public transport system. Nevertheless there are still many peripheral parts of the city, both on the Buda side and in Pest, that lack paved streets and public utilities such as sewerage and piped water. Morphologically these areas are of rural rather than urban aspect. The industrialization of the city continued during the 1950s and early '60s; thereafter attempts were made

to decentralize industry to provincial towns, although many enterprises have expressed opposition to this policy. The pattern of industrial development is, however, changing, moving away from labour-intensive heavy industry to more modern sectors that are capital-intensive.

Urban structure plan

Since 1971 the development of the city has been guided by the principles embodied in a revised urban structure plan. The structure plan does not contain detailed planning objectives but rather defines the general zoning of land use within the city. According to its conception, new high-density residential areas will dominate the northern sector of the city, residential neighbourhoods will be separated from industrial districts, office employment will be removed from the central city to the suburbs, and industry will be distributed more evenly throughout the urban area to reduce pollution.

The setting. Budapest lies across the Danube at the centre of the Carpathian Basin on the ancient route linking the Great Hungarian Plain with northern Transdanubia. The city contains marked topographic contrasts. Pest is situated on a flat and featureless plain, the Pest Plain, on the left, or eastern, bank of the river; Buda, by contrast, is located on the higher river terraces and slopes of the Buda Hills where they sweep down to the western bank of the Danube. The summit of Gellért Hill in Buda is surmounted by the Liberation Monument and the former citadel, which now houses a tourist hotel, a restaurant, and a museum. The Castle Hill district, 554 feet (169 metres) above sea level, provides the setting for the restored Royal Palace, which is now a combined museum, library, and picture gallery. John's Hill (János hegy), 1,736 feet (529 metres) above sea level, is the highest point in the Buda Hills. Easily reached by chair lift, the lookout tower at the summit provides a panoramic view of the whole city. The Danube, in addition to its transport function, supplies some of the most appreciated recreational settings for the population. The more prosperous citizen can build his second home along the Danube Bend, some 22 miles (35 kilometres) upstream. Trade-union organizations have workers' rest homes along the Roman Shore, on the northern outskirts of the city, while Margaret (Margit) Island is a favourite place for walking and sports.

A fault running under the Danube is the source of numerous thermal springs, the waters of which range in temperature from 63° to 165° F (17° to 74° C) and contain radium. Medicinal baths—among them the Gellért, Rudas, Lukács, and Széchenyi baths—have been built where the waters (which were known and used as long ago as Roman times) reach the surface.

The climate of Budapest is transitional between the more extreme continental conditions of the Great Hungarian Plain and the climate of Transdanubia, which is more temperate and western European, with abundant precipitation. Mean annual temperature is 52° F (11° C), ranging from a July average of 72° F (22° C) to 30° F (−1° C) in January. Mean annual precipitation is 24 inches (600 millimetres).

Open lands

Budapest covers a total of 203 square miles (525 square kilometres), of which only 45 percent is the built-up area of the city; the remainder comprises agricultural land and open country, largely wooded. The network of roads and streets is 2,274 miles (3,660 kilometres) in length, and parks, of which the most important are Margaret Island, City Park (Városliget), and People's Park (Népliget), cover more than 3,000 acres (1,230 hectares).

The people. Average residential density in the city is approximately 10,100 persons per square mile (3,915 per square kilometre), ranging from 70,000 per square mile in the inner-city districts of tall apartment buildings (districts I, V, VI, VII, and VIII) to 3,500 per square mile in the outer areas (districts XVI, XVII and XXII). Although the explosive phase of population increase ended in 1910, the rate of growth remained relatively high during the interwar period and subsequently to the mid-1960s. Throughout that period the migration to the city of people from rural areas and other towns was the primary component of growth. After 1964 the influx of migrants declined significantly, a product of the combined effects of an acute housing shortage and deliberate policy; as deaths also exceeded births in a number of years, the rate of population growth slowed down markedly.

Within the city important shifts of population have been taking place as a result of inner-city redevelopment and the construction of new residential areas in the outer suburbs. The redevelopment of Óbuda as a residential quar-

Parliament Building and the town of Pest on the eastern bank of the Danube, seen from the castle of Buda.

ter of uniform multistory apartment buildings, housing many thousands of families, was virtually complete by 1976, and major slum clearance had begun in Józsefváros. The focus of new construction moved south to Pesterzsébet and Kelenföld and north to Újpalota, Káposztásmegyer, and Békásmegyer. Despite the large investment in these projects and the use of modern prefabricated techniques of construction, however, the housing shortage remains severe, and there is evidence of considerable overcrowding in the city. The net effect of these changes is a steady shift of people from the inner city, where some districts are declining in population, to the suburban periphery.

Employment

The economy. Wage earners comprise two-thirds of the population of the capital, and two-fifths of them are employed in industry. The tertiary sector, however, is undergoing the most dynamic development and by the mid-1970s employed a quarter of all workers. The growing administrative role of Budapest has also meant a commensurate rise in the number and proportion of civil servants, who by that time represented more than 11 percent of total wage earners. Industrial development has been an important stimulus to the growth of Budapest. Initially food processing, primarily milling, was predominant. By the first decade of the 20th century, heavy industry had outstripped other forms of production, and the engineering factories, which still play an important role in the city's economy, date from this time. Light industry, particularly textiles, telecommunications, and instrument manufacture, became significant branches during the interwar years, and after World War II many of the new technologically based industries, such as electronics and vacuum engineering, took their place in the expanding urban economy.

The decentralization of industry after the mid-1960s meant a steady reduction in the proportion of the nation's industrial workers employed in Budapest, from more than 50 percent of the national total in 1938 to 28 percent in 1975. Many of the capital's large plants participated in this process by setting up new branches in the provinces instead of expanding in Budapest. Although the number of industrial jobs in the capital is actually contracting, selective expansion of those sectors that cannot function efficiently elsewhere—especially the technologically advanced, the exporting, and the urban supply industries—will continue. The overall result should be a significant extension of industrial land use to enable existing industry to spread itself as new processes and improved factory amenities are introduced, to facilitate the removal of plant from the city centre, to make provision for new space-extensive processes such as the manufacture of prefabricated housing units, and to allow a reduction in the average length of journeys between residence and factory.

Concentration in the central business district

Budapest is a monocentric city in which commerce is overwhelmingly located in and around the central business district. In consequence, the suburbs generally possess a lower level of facilities per capita than many rural areas do. Another consequence is that the central business district is finding it increasingly difficult to function efficiently; competition for existing space is intense, and traffic congestion is severe. The resolution of these problems lies in the creation of a network of suburban service centres, and major centres, each serving 150,000 to 300,000 inhabitants, are planned for Óbuda, Moszkva Square, Lágymányos, Újpest, Zugló, and Kispest.

As in other metropolitan areas, agriculture is a low-grade activity in the immediate environs of Budapest, although market gardening and the cultivation of flowers and peach orchards on the southern slopes of the Buda Hills meet some of the city's requirements.

Transportation. Budapest plays a vital role in the transport and communications services of Hungary. The main highways and railways radiate from the city, and traffic on the Danube also stresses its centrality. The largest railway stations and busiest freight yards are found there, and long-distance buses provide regular services to most of the towns and cities of Hungary. Csepel Free Port handles international freight traffic on the Danube, and there vessels of the member countries of the Danube Commission can dock, negotiate cargoes, and take on supplies. All the Danubian countries maintain shipping agencies in Budapest, whose authority covers the free port. In addition to the conventional facilities of modern freight yards, cold storage, and warehouses, the free port is equipped to handle container traffic.

The Csepel Free Port

The urban transport system consists of a network of bus, tram, and trolley-bus routes, while suburban railways connect outlying districts with the city centre. Although car ownership is rising rapidly, city policy is to improve public transport still further and thus prevent the deterioration seen in so many Western cities. At the core of this policy is the construction of a rapid-transit rail system, mostly underground, and its integration with existing modes of transport. The first link was completed in 1973 when the east–west Metro from the Southern Railway Station to the Fehér Road interchange in south Zugló was opened. In the same year the Millennium Underground, completed in 1896, was extended. The second phase of the program is a north–south artery from Újpest to Kispest, expected to be finished in 1985. A south Buda section to Kelenföld and Budafok was planned to follow.

International commerce is also important. Budapest has gained a reputation for its international fairs and industrial and agricultural exhibitions. The city is also the centre of most foreign trade companies and embassies.

Cultural life, administration, and services. Budapest is a cultural, scientific, and artistic centre. Almost all the activities of the Hungarian Academy of Sciences are conducted there, and about 50,000 students, including 1,000 from abroad, study at the city's universities and colleges. The 20 theatres and three concert halls confirm a lively interest in the arts, and the museums and art galleries contain valuable and extensive collections. The city is also the centre of Hungarian sports life, and many world competitions have been held in People's Stadium (Népstadion) and at other nearby grounds and halls.

Tourism

Tourists contribute a sizable income to the city. Their needs for accommodation are catered to by 31 hotels, including the Duna Intercontinental and the Budapest, whose construction was partly financed by Western capital, by two camping sites, and by rooms in private dwellings let through the state travel agency (IBUSZ). A Hilton Hotel in the Castle District was also partly financed by Western interests.

Overall control of local government is exercised by Budapest Metropolitan Council; executive decisions affecting the whole city and the maintenance of essential services (upkeep of roads, etc.) are its responsibility. Routine administration, however, is the task of the 22 directly elected metropolitan district councils (for instance, the collection of property taxes and planning permission for new private residential development). Members of the Budapest Metropolitan Council are elected by the Metropolitan district councillors. Public utilities are generally up to European standards. Health centres, dispensaries, and hospitals, operating under the national health scheme, provide for public health.

Following the postwar reconstruction of the city and the continuing struggle to cope with the 19th-century legacy of slums and backward outer districts, the Budapest of the late 1970s has taken on a more modern appearance. Extensive housing developments have gone a long way to improve the living conditions of the city's population, although the fulfillment of the aim that every family should have its own dwelling is still some distance away. Significant improvements, mapped out in long-term city plans, will continue to be made in the decades ahead.

Buddha

The Buddha, Siddhārtha Gautama, was the founder of Buddhism, one of the great world religions and philosophical systems that, in turn, produced a great culture with its own peculiar art, architecture, sculpture, and enormous literature in Pāli, Sanskrit, Chinese, Tibetan, and many other languages.

The term buddha, literally meaning "awakened one" or "enlightened one," is not a proper name but rather a title, such as messiah (the christ). Thus, the term should be accompanied by an article, such as "the Buddha" or "a buddha" (because of a belief that there will be innumerable buddhas in the future as there have been in the past). The personal name of the Buddha known to the history of this present world is Gautama (in Sanskrit), or Gotama (in Pāli). Therefore, in using the term the Buddha, it is generally assumed that it refers to Gautama the Buddha.

The story of the Buddha's life, as recorded here, is based on the Pāli texts of the *Tipiṭaka* (the "Triple Canon," or the "Three Baskets"), which is recognized by scholars as the earliest extant record of the Buddha's discourses, and their Pāli commentaries. Thus, in this article the Pāli as well as the Sanskrit spellings will be used for most names and terms. In the ancient Pāli texts the Buddha is designated Gotama. The style and technique of these ancient texts, followed in this biography, provide a record—sometimes symbolical, sometimes legendary, and always graphic—of the life of the revered Teacher. Just as there has been a vigorous search for the "historical Jesus" by Christian and other Western-oriented scholars, so also among some Western Orientalists there has been a scholarly search for the "historical Buddha," the history of whom the Buddhists themselves never questioned and which had never interested them or posed a problem of importance for them. This article will concentrate on Gautama the Enlightened One as depicted in the Buddhist scriptures and legends that developed about the man, his teachings, and his activities.

THE BIRTH AND EARLY LIFE OF THE BUDDHA

The Buddha was born about the year 563 BC in the kingdom of the Sakyas (on the borders of present-day Nepal and India). As the son of Śuddhodana, the king, and Mahāmāyā, the queen, the Buddha thus came from a Kṣatriya family (*i.e.*, the warrior caste or ruling class).

Mother's dream of the birth of the Buddha

The story of the Buddha's life, however, begins with an account of a dream that his mother Mahāmāyā had one night before he was born: a beautiful elephant, white as silver, entered her womb through her side. Brahmins (Hindu priests) were asked to interpret the dream, and they foretold the birth of a son who would become either a universal monarch or a buddha. Ten lunar months after the conception, the Queen and her retinue left Kapilavastu, the capital of the Sakya kingdom, on a visit to her parents in Devadaha. She passed through Lumbinī, a park that was owned jointly by the people of both cities. There, she gave birth to the Buddha in a curtained enclosure in the park on the full-moon day of the month of Vesākha (May). The site of his birth, now called Rummindei, lies within the territory of Nepal. A pillar placed there in commemoration of the event by Aśoka, a 3rd-century-BC Buddhist emperor of India, still stands.

Immediately upon hearing of the birth of the Buddha, the sage Asita (also called Kāḷa Devala), who was King Śuddhodana's teacher and religious adviser, went to see the child. From the auspicious signs on the child's body, Asita recognized that this child would one day become a buddha, and he was overjoyed and smiled. Because he was very old, however, he grew sad and wept, knowing that he would not remain alive to see the child's subsequent enlightenment. Śuddhodana, because of this strange display of alternate emotions, was concerned about possible dangers to the child, but Asita explained why he had first smiled and then wept and reassured the King about the child's future. Both the sage and the King then worshipped the child.

On the fifth day after birth, for the name-giving ceremony, 108 Brahmins were invited, among whom eight were specialists in interpreting bodily marks. Of these eight specialists, seven predicted two possibilities: if the child remained at home, he would become a universal monarch; if he left home, he would become a buddha. But Koṇḍañña, the youngest of the eight, predicted that he would definitely become a buddha. Later, this same Koṇḍañña became one of the Buddha's companions and was one of his first five disciples. The child was given the name Siddhārtha (in Sanskrit), or Siddhattha (in Pāli), which means One Whose Aim Is Accomplished.

On the seventh day after his birth, his mother died, and the child was brought up by her sister Mahāprajāpatī Gautamī, Śuddhodana's second consort.

Signs of the Buddha's eventual career

A significant incident in the Buddha's boyhood is recorded in ancient Pāli commentaries. One day, the little Siddhārtha was taken to the state plowing festival, in which the King, with his ministers and the ordinary farmers, took part, according to the traditional custom of the Sakyas. The boy was left with his nurses in a tent under a *jambu* tree. The nurses, attracted by the festivities, left the Prince alone in the tent and went out to enjoy themselves. When they returned, they found the boy seated cross-legged, absorbed in a trance (Sanskrit *dhyāna;* Pāli *jhāna*). The king was immediately informed and saw his little son in the posture of a *yogin* (a practitioner of psychological, physiological meditation techniques). Upon seeing his son sitting in this fashion, he worshipped the child a second time. Many years later, the Buddha himself, in one of his discourses (the *Mahā-Saccaka-sutta*, "The Great Discourse to Saccaka," of the *Majjhima Nikāya*, or the "Collection of the Middle Length Sayings of the Buddha"), briefly mentions his attaining to the first *dhyāna* under the *jambu* tree.

The young prince was brought up in great luxury, but his father, always worried that his son might leave home to become a homeless ascetic as the Brahmins had predicted, took every care to influence him in favour of a worldly life. According to the *Aṅguttara Nikāya* ("Collection of the Gradual Sayings of the Buddha"), a canonical text, the Buddha himself is reported to have said later about his upbringing:

"*Bhikkhus* [monks], I was delicately nurtured, exceedingly delicately nurtured, delicately nurtured beyond measure. In my father's residence lotus-ponds were made: one of blue lotuses, one of red and another of white lotuses, just for my sake. . . . Of Kāsi cloth was my turban made; of Kāsi my jacket, my tunic, and my cloak . . . I had three palaces: one for winter, one for summer and one for the rainy season. *Bhikkhus*, in the rainy season palace, during the four months of the rains, entertained only by female musicians, I did not come down from the palace."

At the age of 16, Siddhārtha married his cousin, a princess named Yasodharā, also 16 years old. Although Śuddhodana tried his utmost to make Siddhārtha content by providing him with luxury and comfort, the young prince's thoughts were generally elsewhere, occupied with other concerns.

THE FOUR SIGNS OF THE GREAT RENUNCIATION

The effect of suffering on the young Siddhārtha

The Four Signs. The turning point in Gautama's life came when he was 29 years old. One day, while out driving with his charioteer, the prince Siddhārtha saw "an aged man as bent as a roof gable, decrepit, leaning on a staff, tottering as he walked, afflicted and long past his prime." The charioteer, questioned by the Prince as to what had happened to the man, explained that he was old and that all men were subject to old age if they lived long enough. The Prince, greatly perturbed by this sight, went back to the palace and became absorbed in thought. Another day, again driving with his charioteer, he saw "a sick man, suffering and very ill, fallen and weltering in his own excreta, being lifted up by some . . . ." Because Siddhārtha was perturbed, the charioteer explained, as before, that this was a sick man and that all men are subject to sickness. On a third occasion the Prince saw a dead body and again the charioteer provided the explanation. Finally, Siddhārtha saw "a shaven-headed man, a wanderer who has gone forth, wearing the yellow robe." Impressed with the man's peaceful and serene demeanour, the Prince decided to leave home and go out into the world to discover the reason for such a display of serenity in the midst of misery.

This account should probably not be taken literally. It is difficult to believe that by the age of 29 Siddhārtha had not seen an old man or a sick man, even if the sight of a corpse is excluded. A psychological factor, however, should be taken into consideration: a common phenomenon may one day, unexpectedly, produce in a man a psychological crisis because of various combining circumstances. Old age, sickness, and death, in this account, symbolically represent human suffering in general. Siddhārtha, touched by the suffering of humanity and out of compassion for the world, decided to leave home and go in search for a solution to the problem of suffering.

On his way back to the palace after seeing the yellow-robed ascetic, Siddhārtha received the news of the birth of his son, whom he named Rāhula.

The great renunciation. Upon receiving this news, the Prince decided to make what is known as the great renunciation: giving up the princely life to become a wandering ascetic. Waking up in the middle of the night, he ordered Channa, his charioteer and companion, to saddle his favourite horse, Kanthaka, and went to the bedchamber to have a last look at his sleeping wife and their son. He did not enter the chamber for fear of awakening his wife, which would be a sure obstacle to his plan. He thought he would one day come to see them again.

Beginning of the quest for the truth

That night Siddhārtha left the city of Kapilavastu, accompanied by his companion Channa. By dawn he had crossed the Anomā River. He then gave all his ornaments to Channa, assumed the guise of an ascetic, and sent Channa and Kanthaka back to his father.

As an ascetic, Gautama (henceforth, he will be called Gautama) went south, where centres of learning and spiritual discipline flourished, and arrived at Rājagaha (modern Rājgīr), the capital of the Magadha kingdom. Bimbisāra, the king of Magadha, was impressed by the handsome appearance and the serene personality of this strange ascetic and visited him when he was seated at the foot of a hill. The King, after he discovered that the ascetic was a former prince, offered him every comfort and suggested that he should stay with him to share his kingdom. Gautama, however, rejected the King's offer, saying that he had no need again of those things that he had renounced and that he was in search of truth. Bimbisāra then requested that, when Gautama obtained the Enlightenment, he return to visit Rājagaha again, to which Gautama agreed.

THE SEARCH FOR THE TRUTH AND THE GREAT ENLIGHTENMENT

The search for the truth. Leaving Rājagaha, Gautama went in search of teachers to instruct him in the way of truth. Two of them the Buddha himself mentioned by name in several discourses. He first went to Āḷāra Kālāma, a renowned sage, and expressed his wish to follow Āḷāra's system; Āḷāra gladly accepted Gautama as his pupil. Gautama studied and rapidly mastered Āḷāra's whole system and then asked his teacher how far the master himself had realized that teaching. Āḷāra told him that he had attained the "sphere of no-thing" (*ākiñcaññāyatana*). Gautama soon attained the same mystical state himself. Āḷāra admitted that that state was the highest he could teach and declared that Gautama and himself were now equals in every respect—in knowledge, practice, and attainment—and invited the Sakyan ascetic to guide, along with him, the community of his disciples. The Buddha spoke of this occasion in the *sūtra* (or *sutta*, "discourse"): "In this way, *bhikkhu*s, did Aḷāra Kālāma, my teacher, set me, his pupil, on the same level as himself and honoured me with the highest honour." Gautama, however, was not satisfied with attaining the "sphere of no-thing," though it was a very high mystical state. He was in quest of absolute truth, Nirvāṇa, and thus he left Āḷāra Kālāma.

He then went to Uddaka Rāmaputta, another great teacher, who taught him to attain the "sphere of neither-perception-nor-nonperception" (*nevasaññā-nāsaññāyatana*), a higher mystical state than the former. Gautama, however, was not satisfied with this either and searched further for the truth.

Travelling through the Magadha country, Gautama arrived at a village, called Senānigama, near Uruvelā, and, according to his own words, found "a beautiful stretch of land, a lovely woodland grove, and a clear flowing river with a pleasant ford, and a village for support close by." He was joined there by a group of five ascetics, among whom was Koṇḍañña, the Brahmin who had predicted at the name-giving ceremony that the child Siddhārtha would definitely become a buddha one day.

The Buddha's practice of asceticism

Gautama's real struggle in his search for the truth began at Uruvelā. Here, for nearly six years, he practiced various forms of severe austerities and extreme self-mortifications. These austerities were vividly described in detail by the Buddha himself in several discourses (*e.g.*, in the *Majjhima Nikāya*). What he looked like and what happened to him as a result of these austerities is depicted in the following words from the ancient text:

> Because of so little nourishment, all my limbs became like some withered creepers with knotted joints; my buttocks like a buffalo's hoof; my back-bone protruding like a string of balls; my ribs like rafters of a dilapidated shed; the pupils of my eyes appeared sunk deep in their sockets as water appears shining at the bottom of a deep well; my scalp became shrivelled and shrunk as a bitter gourd cut unripe becomes shrivelled and shrunk by sun and wind; . . . the skin of my belly came to be cleaving to my back-bone; when I wanted to obey the calls of nature, I fell down on my face then and there; when I stroked my limbs with my hand, hairs rotted at the roots fell away from my body . . . .

A Gandhāra (Greco-Buddhist) statue (of between the 2nd and 4th centuries AD) depicts the Buddha in this emaciated state.

As a consequence of all these severe bodily austerities, Gautama became so weak that he once fainted and fell down and was believed by some to be dead. By these experiences, he realized that such mortifications could not lead him to what he sought; he thus changed his way of life and again began to eat proper amounts of food.

His five companions, who had much faith and confidence in him, were disappointed at his rejection of extreme asceticism and left him in disgust. Gautama thus remained alone in Uruvelā, regained his health and strength, and then followed his own path to enlightenment.

The great Enlightenment. One morning, seated under a banyan tree, Gautama accepted an offering of a bowl of milk rice from Sujātā, the daughter of the landowner of the village Senānigama. This was his last meal before his Enlightenment. He spent the day in a grove of sal trees and in the evening went to the base of an *assattha* tree, now known as *bodhi* tree (*Ficus religiosa*), and sat cross-legged, determined not to rise without attaining enlightenment.

At that point, the greatest of Gautama's struggles began: Māra, the evil one, the tempter who is the lord of the world of passion, determined to defeat him and pre-

The struggle with Māra, the tempter

vent him from attaining enlightenment; he approached Gautama with his hideous, demonic hordes. Gautama, however, sat unmoved in meditation, supported only by the ten *pāramitās* ("great virtues") that he had perfected during innumerable past lives as a *bodhisattva* ("buddha-to-be") in order to attain enlightenment. (In order to attain buddhahood, all *bodhisattvas* ["buddhas-to-be"—*i.e.*, those who aspire to become buddhas] have to perfect, during innumerable lives, these ten *pāramitās*: charity, morality, renunciation, wisdom, effort, patience, truth, determination, universal love, and equanimity.) Māra was thus vanquished and fled headlong with his armies of evil spirits.

The battle with Māra is graphically and vividly described in the old commentaries and depicted in painting on the walls of Buddhist temples. In the *Padhānasutta* ("Discourse on the Exertion") of the *Suttanipāta*, one of the earliest canonical texts, the Buddha states that, when he was practicing austerities by the River Nerañjarā in Uruvelā, Māra approached him, speaking such words as: "You are emaciated, pale, you are near death. Live, Sir, life is better. Do meritorious deeds. What is the use of striving?" After some preliminary words, Gautama replied to Māra:

"Lust is your first army; the second is dislike for higher life; the third is hunger and thirst; the fourth is craving; the fifth is torpor and sloth; the sixth is fear (cowardice); the seventh is doubt; the eighth is hypocrisy and obduracy; the ninth is gains, praise, honour, false glory; the tenth is exalting self and despising others. Māra, these are your armies. No feeble man can conquer them, yet only by conquering them one wins bliss. I challenge you! Shame on my life if defeated! Better for me to die in battle than to live defeated . . . ." Māra, dejected and overcome with grief, then disappeared. The fight with Māra was a mythologized struggle between good and evil, an inner struggle.

Having defeated Māra, Gautama spent the rest of the night in deep meditation under the tree. In the first watch of the night (6 PM to 10 PM), he gained the knowledge of his former existences (*pubbenivāsānussati-ñāṇa*). In the middle watch (10 PM to 2 AM), he attained the "superhuman divine eye" (*dibba-cakkhu*), the power to see the passing away and rebirth of beings. In the last watch (2 AM to 6 AM), he directed his mind to the knowledge of the destruction of all cankers and defilements and realized the Four Noble Truths. In the Buddha's own recorded words: "My mind was emancipated, . . . Ignorance was dispelled, science (knowledge) arose; darkness was dispelled, light arose."

The realization of the Four Noble Truths

Thus, Gautama, at the age of 35, attained the Enlightenment, or Awakening, and became a supreme buddha during the night of the full-moon day of the month of Vesākha (May), about the year 528 BC, at a place now called Buddha Gayā, or Bodh Gayā.

Contemplation on the truth. After his Enlightenment the Buddha spent several weeks (five or seven weeks according to different accounts) in Uruvelā, meditating on the various aspects of the *dhamma* ("truth") that he had realized, particularly on the most important and difficult doctrine of causal relations, known as the dependent origination or the conditioned genesis (*paṭiccasamuppāda*). This doctrine views everything as relative and interdependent and teaches that there is no eternal, everlasting, unchanging, permanent, or absolute substance, such as the soul, the self, or the ego, within or without man.

Four weeks after his Enlightenment, again seated under a banyan tree, the Buddha is reported to have thought to himself: "I have realized this Truth which is deep, difficult to see, difficult to understand . . . comprehensible by the wise. Men who are overpowered by passion and surrounded by a mass of darkness cannot see this Truth which is against the current (*paṭisotagāmin*), which is lofty, deep, subtle and hard to comprehend."

With these thoughts in mind, the Buddha hesitated trying to explain to the world the truth that he had just realized. He then compared the world to a lotus pond: In a lotus pond there are some lotuses still under water; there are others that have risen only up to the water level; and there are still others that stand above water and are untouched by it. In a similar way, in this world there are men of different levels of development. Some of them would understand the truth; the Buddha thus decided to teach what he had comprehended in the great Enlightenment.

Decision to teach the truth

His problem, however, was concerned with whom he should first teach this *dhamma*, this truth. He first thought of his two former teachers, Āḷāra Kālāma and Uddaka Rāmaputta; but they had already died by this time. He then thought of the five companions who had left him and were now staying in Isipatana near Bārāṇasī (now Vārānasi) and decided to go there.

On meeting the five ascetics, the Buddha told them that now he was a "perfected one" (*arahant*), a "fully awakened one" (*sammāsambuddha*), that he had realized the "immortal" (*amata*), and that he wished to instruct and teach them the *dhamma*. They replied to him:

> But, Reverend Gautama, even by all that conduct, that practice, that austerity, you did not realize this supreme knowledge, this supreme state. So how can you now realize it when you live in abundance, when you have given up striving and have reverted to a life of abundance?

The Buddha denied to them that he had given up striving and that he had reverted to a life of abundance. He requested again that they listen to him. Again, however, they replied in a similar manner. A third time the Buddha repeated what he said before and asked them to listen to him, and they repeated their remark.

The Buddha then asked them a very personal question: "Do you admit, monks, that I have never spoken anything like this before?" They were struck by such straightforwardness and knew how sincere and earnest he was. Convinced that he had attained what he claimed to have attained, they no longer addressed the Buddha as "Reverend Gautama," but changed their attitude toward him and answered him: "Lord, you have not." The Buddha then delivered to them his first sermon, known as the "Dhammacakkappavattana-sutta" ("Setting in Motion the Wheel of Truth"), at Isipatana, now called Sārnāth (near Vārānasi, [Benares]), where an ancient *stūpa* (building containing a religious relic) marks the spot.

The substance of this *sūtra* is as follows: a man who has left home and gone forth (*pabbajita*) should not follow two extremes, namely self-indulgence and self-mortification. Avoiding these two extremes, the Tathāgata (He Who Has Discovered the Truth—*i.e.*, the Buddha) has discovered the "middle path" (*majjhimā paṭipadā*) leading to vision, to knowledge, to calmness, to awakening, to Nirvāṇa. This middle path is known as the Noble Eightfold Path consisting of right view, right thought, right speech, right action, right mode of living, right endeavour, right mindfulness, and right concentration. The first noble truth is that man's existence is *dukkha*, full of conflict, dissatisfaction, sorrow, and suffering. The second noble truth is that all this is caused by man's selfish desire; *i.e.*, craving or *taṇhā*, "thirst." The third noble truth is that there is emancipation, liberation, and freedom for man from all this, which is Nirvāṇa (Pāli Nibbāna). The fourth noble truth, the Noble Eightfold Path, is the way to this liberation.

The teaching of moderation and the Eightfold Path

THE FOUNDING OF THE SANGHA

At the end of the sermon, these five monks, the Buddha's first disciples, were admitted by him as *bhikkhus* and became the first members of the *sangha* ("order"). A few days later, this sermon was followed by the *Anattalakkhaṇa-sutta*, dealing with the doctrine of no-self, at the conclusion of which all five *bhikkhus* became *arahants* ("perfected ones").

The Buddha spent about three months in Vārānasi. During this period an important and influential wealthy young man named Yasa became his disciple and entered the order. His father and mother, along with his former wife, also were converted. They were the first lay disciples to take refuge in the "Triple Jewel": the Buddha, the *dhamma* (truth), and the *sangha* (the order). Later, four of Yasa's close friends followed his example and entered the order. Enthusiasm for this new movement be-

came so impelling that 50 of their friends also joined them in the *sangha*. All these became *arahants* in due course, and the Buddha soon had 60 disciples who were perfected ones.

Conversions to the Buddha's teachings

The Buddha addressed this group in the following words and sent them out into the world to spread his message of peace, compassion, and wisdom:

> Bhikkhus, I am freed from all fetters, both divine and human. You, too, are freed from all fetters, both divine and human. Wander forth, bhikkhus, for the good of the many, for the happiness of the many, out of compassion for the world. . . . Let not two of you go by one road [*i.e.*, go in different directions]. Teach the *Dhamma* which is good at the beginning, good in the middle, and good at the end. . . . There are people who will understand the *Dhamma*. I, too, bhikkus, will go to Uruvelā to teach the *Dhamma*.

The 60 disciples went in various directions to spread the teaching of the Buddha. The Buddha himself set out for Uruvelā. On the way he converted 30 young men, who then entered the order. In the region of Uruvelā he also converted three leading ascetics along with a large number of their disciples. To these ascetics, formerly known as "matted hair" (*jaṭilas*), the Buddha delivered the famous "Fire Sermon" (the "Ādittapariyāya-sutta"), which states that all man's existence is burning with the fire of lust, the fire of hate, and the fire of delusion. This *sūtra* ("discourse") is perhaps better known to the Western world as the source of Section III of the poem *The Waste Land* by the U.S.-born English poet T.S. Eliot.

From Uruvelā the Buddha went on to Rājagaha, the capital of Magadha, fulfilling his promise to visit King Bimbisāra after his Enlightenment. Large numbers of people, including the King, became his lay disciples. The King offered his park, Veḷuvana, as a monastery site to the Buddha and his order. During this visit a very important event that had far-reaching effects took place: Sāriputta and Moggallāna, two Brahminic ascetics who later became the Buddha's two chief disciples, joined the order. Sāriputta had first heard of the Buddha and his new teaching from Assaji, one of the original 60 disciples. At the express request of his father, the Buddha visited Kapilavastu with a large number of his disciples. In that city, where as prince he had once lived in great splendour and luxury, he went about begging for his food from house to house. His father, King Suddhodana, was grieved and upset by this, but, upon learning that this was the custom of all buddhas, he conducted the Blessed One and his disciples to eat a meal at the palace.

Conversion of members of the Buddha's family

All the ladies of the court went to him to offer reverence, except his former wife Yasodharā. She refused, saying that the Blessed One himself would come to her if he thought she had any virtue in her and that she would then worship him. The Buddha, with his two chief disciples and the King, went to see her in her apartment. She fell at his feet, clasped his ankles with her hands, and put her head on his feet.

The Buddha's father, his aunt Mahāpajāpatī, Yasodharā, and large numbers of Sakyans (members of the Buddha's clan) became his followers. On the following day he ordained his half-brother Nanda and a few days later his son, Rāhula. All this troubled the old King so much that he personally requested the Buddha to lay down a rule that no son should be ordained without the consent of his parents. Accordingly, the rule was formulated, and it continues to be followed up to the present by the *sangha*.

Anāthapiṇḍika, a banker of Sāvatthi, the capital of Kosala kingdom, had met the Buddha at Rājagaha and had become deeply devoted to him. He invited the Blessed One to his city, where he built for him the famous monastery at Jetavana. This monastery in Sāvatthi virtually became the headquarters of the Buddha's activities. Here, he spent most of his time and delivered most of his sermons. The Buddha and his new teaching became so popular that monasteries were built for him and his *sangha* in almost all the important cities in the valley of the Ganges, and the number of his followers among all classes of people increased rapidly.

The order of nuns, *bhikkhunī-sangha*, was instituted, after some hesitation. Ānanda, the Buddha's cousin and later his chief attendant and constant companion, pleaded with the Master on behalf of women. The Buddha's own aunt Mahāpajāpatī Gautamī and her friends were the first women to enter the order.

Members of some hostile sects, who became jealous of the Buddha's success and popularity, made several attempts to vilify him.

Attacks against the Buddha's authority

Devadatta, one of the Buddha's cousins, an ambitious man of ability and guile, was his rival from early days. He too joined the order but was never sincerely devoted to the Master. He became popular and influential with some people, however, and, about eight years before the Buddha's death, Devadatta conceived the idea of becoming the Buddha's successor and suggested to him that the leadership of the *sangha* should be handed over to him in view of the Master's approaching old age. The suggestion, however, was rejected. The Buddha stated that he would not pass on the leadership of the order to anyone, not even to Sāriputta or Moggallāna. Thus, no one was named as the future leader of the *sangha*, which was established on democratic principles, and everything was (and is) decided by majority vote. Its constitution was (and is) the *vinaya* (the "discipline," consisting of rules to guide the material and spiritual and the individual and communal life of the members of the order), which was laid down by the Master.

After this rebuttal Devadatta vowed vengeance. He made three cleverly designed attempts on the life of the Buddha, all of which failed. Devadatta next tried to bring about a schism in the *sangha*, taking with him a group of newly ordained monks to establish a separate community. All those who were misled by Devadatta, however, were later persuaded to go back to the Master by Sāriputta and Moggallāna. After this event Devadatta became very seriously ill and died after about nine months of illness.

THE DEATH OF THE BUDDHA

After the Buddha had trained learned, well-disciplined followers and his mission was fulfilled, at the age of 80, with a group of *bhikkhus*, he set out on his last journey, from Rājagaha toward the north. As usual, he passed in leisurely fashion through cities, towns, and villages, teaching the people on his way and stopping wherever he wished.

In due course he arrived at Vesālī, the capital city of the Licchavi. The Buddha spent that rainy season not in the park in Vesālī, which had just been donated to him by Ambapālī, the celebrated courtesan of that city, but in an adjoining village called Beluvagāma. There the Buddha became seriously ill, almost dying (*māraṇantika*). He thought, however, that it was not right for him to die without preparing his disciples who were near and dear to him. Thus, with courage, determination, and will, he bore all his pains, got the better of his illness, and recovered; but his health was still poor.

The Buddha's attempt to recover his health

After the Buddha's recovery, Ānanda, his most devoted attendant, went to his beloved Master and said:

> Lord, I have looked after the health of the Blessed One. I have looked after him in his illness. But at the sight of his illness, the horizon became dim to me, and my faculties were no longer clear. Yet there was one little consolation: I thought the Blessed One would not pass away until he had left instructions concerning the Order of the Sangha.

The Buddha, full of compassion and feeling, replied:

> Ānanda, what does the Order of the Sangha expect from me? I have taught the *dhamma* without making any distinction as to exoteric and esoteric. With regard to the Truth, the Tathāgata has nothing like the 'closed fist of a teacher' (*ācariya-muṭṭhi*), who keeps something back. Surely, Ānanda, if there is anyone who thinks that he will lead the *sangha* and that the *sangha* should depend on him, let him set down his instructions. But the Tathāgata has no such idea. Why should he then leave instructions concerning the *sangha?* I am old now, Ānanda . . . eighty years old. As a worn-out cart has to be kept going by repairs, so, it seems to me, the body of the Tathāgata can only be kept going by repairs. . . . Therefore, Ānanda, dwell by making yourselves your island, making yourselves, not anyone else, your refuge; making the *dhamma* your island, the *dhamma* your refuge, nothing else your refuge.

The Buddha's decision to die

Later on, the Buddha told Ānanda that he had decided to die after three months and asked him to assemble in the hall at Mahāvana all the *bhikkhus* who were at that time residing in the neighbourhood of Vesālī. At this meeting, the Buddha first advised the monks to follow what he had taught them and to spread it abroad for the good of the many, out of compassion for the world, and then announced that he had decided to die after three months.

Leaving Vesālī, the Buddha gazed at the city in which he had stayed on many occasions and said: "This will be the last time, Ānanda, that the Tathāgata will behold Vesālī. Come, Ānanda, let us proceed. . . ."

Stopping at several villages and townships, the Buddha eventually arrived at Pāvā and stayed in the park of Cunda the goldsmith, who was already one of his devoted followers. At his invitation the Buddha and the *bhikkhus* went to his house for a meal. Cunda had prepared, besides various delicacies, a dish called *sūkara-maddava*. This is interpreted in the ancient Pāli commentaries in several ways: (1) as pork (this is generally accepted), (2) as bamboo sprouts trodden by pigs, (3) as a kind of mushroom growing in a spot trodden by pigs, (4) as a rice pudding rich with the essence of milk, or (5) as a special preparation (an elixir?) intended by Cunda to prolong the Buddha's life. Whatever it might have been, the Buddha asked Cunda to serve him with *sūkara-maddava* and to serve the *bhikkhus* with other dishes. At the end of the meal, the Buddha requested Cunda to bury in a hole whatever was left of the *sūkara-maddava*, saying that no one would be able to assimilate it except a Tathāgata. This was the Buddha's last meal.

After it the Buddha became sick and suffered violent pains but bore them without complaint. He set out for Kusinārā, accompanied by Ānanda and other *bhikkhus*. Explaining that he was tired, he stopped and rested in two places. On the way, the Buddha said to Ānanda:

> Now it may happen, Ānanda, that someone should stir up remorse in Cunda by saying that the Tathāgata died after eating his meal. Any such remorse in Cunda should be dispelled. Tell him, Ānanda, that you heard directly from my mouth that there are two offerings of food which are of equal fruit, of equal profit: the offering of food before the Enlightenment and the offering of food before the *Parinibbāna* (the passing away) of a Tathāgata. Tell him that he has done a good deed. In this way Ānanda, you should dispel any possible remorse in Cunda.

The Buddha arrived at Kusinārā (the modern Kasia, also called Kuśinagara) toward evening, and, on a couch between two sal trees in the park Upavattana of the Mallas, he "laid himself down on his right side, with one leg resting on the other, mindful and self-possessed." This was the full-moon day of the month of Vesākha (May).

Final conversations with Ānanda and other monks

Ānanda inquired of the Buddha how and what they should do with his remains. He told Ānanda they should not occupy themselves with honouring the remains of the Tathāgata but rather to be zealous in their own spiritual development. The lay devotees, he said, would busy themselves with that task.

Ānanda, in remorse, left the immediate area and cried out: "My Master is about to pass away from me—he who is so kind to me." The Buddha inquired where Ānanda was and, on being told that he was weeping, called to him and said: "No, Ānanda, don't weep. Haven't I already told you that separation is inevitable from all near and dear to us? Whatever is born, produced, conditioned, contains within itself the nature of its own dissolution. It cannot be otherwise." Then, the Master spoke to the *bhikkhus* in praise of Ānanda's wonderful qualities and abilities. The Mallas, clansmen, of Kusinārā came with their families to pay homage to the Blessed One. A wandering ascetic named Subhadda asked for permission to see the Buddha, but Ānanda refused, saying that the Blessed One was tired and that he should not be troubled. The Buddha, overhearing the conversation, called Ānanda and asked him to allow Subhadda to see him. After an interview with the Buddha, Subhadda joined the order the same night, thus becoming his last direct disciple.

The Buddha then addressed Ānanda:

> It may be, Ānanda, that to some of you the thought may come: 'Here we have the Word of the Master who is gone; ' our Master we have with us no more.' But, Ānanda, it should not be considered in this light. What I have taught and laid down, Ānanda, as *Dhamma* (Truth, Doctrine) and as *Vinaya* (Discipline), this will be your Master when I am gone. . . . If the Sangha (Order) wish it, Ānanda, let them, when I am gone, abolish lesser and minor precepts (rules).

The Buddha next addressed the *bhikkhus* and requested them three times to ask him if they had any doubt or question that they wished clarified, but they all remained silent. The Buddha then addressed the *bhikkhus*: "Then, *bhikkhus*, I address you now: transient are all conditioned things. Try to accomplish your aim with diligence." These were the last words of the Tathāgata. A week later, his body was cremated by the Mallas in Kusinārā.

A dispute over the relics of the Buddha between the Mallas and the delegates of rulers of several kingdoms, such as Magadha, Vesālī, and Kapilavastu, was settled by a venerable old Brahmin named Doṇa on the basis that they should not quarrel over the relics of one who preached peace. With common consent, the relics were then divided into eight portions to the satisfaction of all. *Stūpas* were built over these relics, and feasts were held commemorating the Buddha.

ASSESSMENT OF THE PERSONALITY AND CHARACTER OF THE BUDDHA

Not much information is available about the physical appearance of the Buddha. Caṅkī, a highly respected Brahmin leader, is reported to have said that "the recluse Gotama is lovely, good to look upon, charming, possessed of the greatest beauty of complexion, of a sublime colour, a perfect stature, noble of presence."

The reputation of the Buddha in his own time

He had a unique reputation as a great teacher and a trainer of men. His conversion and taming of Aṅgulimāla, a murderer and bandit who was a terror even to the King of Kosala, is an example of his great powers and abilities. People who went to see and hear him were fascinated and so quickly converted to his new teaching that his opponents described him as having some "enticing trick" (*āvaṭṭanī-māyā*). The King of Kosala said that those who went with the idea of confounding the Buddha in debate became his disciples at the end. Full of compassion (*karuṇā*) and wisdom (*paññā*), he is recognized as knowing how and what to teach each individual for his own benefit according to the level of his capabilities. He is known to have walked long distances to help one single person.

The Buddha, affectionate and devoted to his disciples, was always inquiring after their well-being and progress. When he was staying in a monastery, he paid daily visits to the sick ward. Once, he himself attended a sick monk neglected by others and on that occasion said: "He who attends on the sick attends on me."

The Buddha as a social reformer

As a social reformer, the Buddha condemned the caste system that was a long-established and respected institution in India and recognized the equality of man. He also perceived the connection between economic welfare and moral development. Trying to suppress crime through punishment, he said, was futile. Poverty (*dāḷiddiya*), according to the Buddha, was a cause of immorality and crimes; therefore, the economic condition of people should be improved.

He appreciated both natural and physical beauty. On several occasions he was moved aesthetically, as he told Ānanda how delightful certain places were to him. At Vesālī he told the *bhikkhus* that, if they had not seen the *devas* (gods) of Tāvatiṃsa (Heaven), they should look at the handsome Licchavis, beautifully and elegantly dressed in different colours.

The Buddha was a strict "disciplinarian." King Pasenadi could not understand how the Buddha maintained such order and discipline in the community of *bhikkhus*, when he, a king, with the power to inflict punishment, could not maintain it as well in his court. The Buddha, however, kept order and discipline on the basis of a mutual love, affection, and respect that exists between teacher and pupil.

Many miraculous powers were attributed to the Buddha, but he did not consider these of any importance. Once, when one of his disciples performed a miracle in public, the Buddha reproached him and laid down a rule that his disciples should not perform miracles before the laity. In his view, the greatest miracle was to explain the truth and to make a man realize it.

Behind his philosophy and strict ethics, the Buddha had a quiet sense of humour. A conceited Brahmin, who was in the habit of discrediting others, questioned him as to the qualities of a true Brahmin. In a list of such high qualities as freedom from evil, purity of heart, the Buddha gently included "not discrediting."

The portrait of the Buddha, as can be inferred from the lines of the ancient texts, is thus one of a man of both great wisdom (*mahāpaññā*) and great compassion (*mahākaruṇā*) moved by the spectacle of human suffering and determined to free men from its fetters by a rational system of thought and a way of life.

BIBLIOGRAPHY

Canonical sources: The Collection of the Middle Length Sayings (*Majjhima-nikāya*), vol. 1, trans. by I.B. HORNER, "Pali Text Society Translation Series No. 29 (1954): "Discourse on the Ariyan Quest" (*Ariyapariyesana-sutta*, No. 26); and the "Greater Discourse to Saccaka" (*Mahāsaccaka-sutta*, No. 36), contain the story of the Buddha from the great renunciation up to the first sermon, including some aspects of the Buddha's private life; in the same volume, the "Great Discourse on the Lion's Roar" (*Mahāsīhanāda-sutta*, No. 12), contains a vivid description of the Buddha's severe austerities before the Enlightenment. *The Book of the Discipline*, vol. 4 (*Mahāvagga*), pp. 1–28, trans. by I.B. HORNER, ("Sacred Books of the Buddhists Series," vol. 14, 1962), includes an account from the Enlightenment up to the time of sending out the first 60 disciples as missionaries. "The Book of the Great Decease" (*Mahāparinibbāna-sutta*, No. 16) in the *Dialogues of the Buddha* (*Dīgha-nikāya*), vol. 2, trans. by T.W. and C.A.F. RHYS DAVIDS (1910; 3rd ed. reprinted 1966, "Sacred Books of the Buddhists Series," vol. 3), contains a fairly detailed narration of the final stage of the Buddha's life and his last journey.

Commentaries and later works: The *Buddhist Birth Stories* (*Jātaka* commentary), trans. by T.W. RHYS DAVIDS (1880; new ed. by MRS. RHYS DAVIDS, 1925), in the introductory section relates the Buddha's life with accompanying legends and miracles up to the time of his acceptance of the Jetavana monastery in Sāvatthi. See also HENRY CLARKE WARREN, *Buddhism in Translations* (1896, reprinted 1963).

Modern works: Information according to Tibetan sources may be found in W.W. ROCKHILL, *The Life of the Buddha* (1884). Information from some Sanskrit and Chinese sources is available in SAMUEL BEAL, *The Romantic Legend of Sâkya Buddha* (1875). EDWIN ARNOLD, *The Light of Asia* (1961), is a popular retelling in poetic form of the life and teaching of the Buddha. ALFRED FOUCHER, *La Vie du Bouddha d'après les textes et les monuments de l'Inde* (1949; abridged Eng. trans., *The Life of Buddha*, 1963), is a study according to both ancient texts and monuments of India. HERMANN OLDENBERG, *Buddha: His Life, His Doctrine, His Order* (1882), is a standard work, although some of its opinions and ideas expressed are now outdated. E.J. THOMAS, *The Life of Buddha As Legend and History* (1927; 3rd ed. rev., 1949, reprinted 1969), critically examines the original sources, sometimes advancing unnecessary speculations and theories, probably because of a lack of contact with the living traditions and their interpretations, and contains a useful bibliography. A modern Hindu philosopher's estimation may be found in SARVEPALLI RADHAKRISHNAN, *Gautama the Buddha*, (1945, reprinted in his translation of the *Dhammapada*, 1950).

(Wa.R.)

Buddhism

Buddhism is a pan-Asian religion and philosophy that has played a central role in the spiritual, cultural, and social life of the Eastern world. This article surveys Buddhism as a whole, in its various aspects, schools, and areas. (For a specific discussion of the philosophical aspect, see also BUDDHIST PHILOSOPHY.)

The article is divided into the following sections:

I. General observations
II. The foundations of Buddhism
  The life and teachings of the Buddha
    Life of the Buddha
    Teachings of the Buddha
  The ancient schools
    Theravāda (Sthaviravāda)
    Sarvāstivāda (P'i-t'an, Chü-she/Kusha)
    Sautrāntika
    Mahīśāsaka
    Dharmaguptaka
    Sammatīya
    Canonical texts
    Vinaya schools: Lü/Ritsu
  The transitional schools
    Mahāsaṅghika
    Lokottaravāda
    Vātsīputrīya
    Satyasiddhi
III. Mahāyāna
  Nature and characteristics
  Basic teachings
    The Buddha: divinization and mutiplicity
    The *bodhisattva* ideal
    The three Buddha bodies
    New revelations

  The prospects for the future

I. General observations

Buddhism originated in India in the 5th century BC in an area that extended roughly from Vārānasi to Gayā, Rājagṛha, Pāṭaliputra, Vaiśālī, Kuśinagara, and Pāvā (*i.e.*, in the regions of Magadha, the Malla, the Kāśī, and the Vṛjji) and in a period of great fervour in speculative, mystical, and religious life. There was an ongoing codification of sacrificial ritual (Brāhmaṇa), not without philosophical insights; a deepening of the theory of *karman* (deeds and their results in future existences); and a formulation of the initial insights of the *Upaniṣads* (ancient Hindu treatises), which declared the only reality to be an inner entity, *ātman*, which is either unique or the reflex in an individual of a single principle (*brahman*), outside of which all is only temporal—fleeting, changing, unreal. Ascetic branches were perfecting theories and

practices of great antiquity (which came together in Yoga), not only native to India but analogous to certain magical and psychotherapeutic traditions throughout most of Asia—from India to China. Other schools held that any effort intended to modify life's destiny was in vain and that all ends with death. The Jaina school, having a tradition perhaps more ancient than Buddhism's classified the number and correlations of the various *karman*.

Buddhism developed in two directions. One, usually called Theravāda by its present-day adherents, remained relatively faithful to what it considered to be the true tradition of the Buddha's teachings. The other is called Mahāyāna, "the means of salvation adapted to a larger number of people," by its followers, who call the first Hīnayāna, "the means of salvation restricted to a smaller number of people" (or simply the greater and lesser vehicles). Both paths lead to Nirvāṇa (salvation); what matters is to be inside Buddhist doctrine, not outside it.

In its spread, Buddhism influenced the currents of thought and religion in other countries. Following the diverse religious aspirations and the passage of time, the iron law of *karman* was replaced by more yielding principles or devotional ecstasies. Finally there developed in India a movement called Tantra, the aim of which was to obtain liberation more speedily and which was influenced by gnostic and magical currents pervasive at that time.

For all the discussion on the two paths of salvation—the gradual and the instant—and the various ways of interpreting the key Mahāyāna concepts of the "void" and the mind-element, the ethics remain fundamentally the same. The monastic organizations suffered the influence of diverse historical situations, yet their structure remains the same. The Buddha, the original teacher, is always the revealer of the esoteric doctrine. In the later doctrines, his preaching is not just that given to his first disciples: he multiplies himself in numberless epiphanies —all manifestations of a single immutable reality—and he emphasizes the certainty of the void and the relativity of all appearances. He reinforces the belief in the presence of the Buddha within men.

In spite of all these vicissitudes, Buddhism did not negate its basic principles. Instead they were reinterpreted, rethought, and reformulated, bringing to life an immense literature that has always been regarded by followers of the Mahāyāna and Tantra as *Buddhavacana*, the word of the Buddha. Consequently, from the first sermon of the Buddha at Sārnāth to the last recent derivations, there is an indisputable continuity—a development or metamorphosis around a central nucleus—by virtue of which Buddhism is not confused with other religions. Thus, in spite of its diffusion, the discussion of Buddhism should proceed not by countries but by branches—branches of a single trunk, as is done in the presentation below.

II. The foundations of Buddhism

THE LIFE AND TEACHINGS OF THE BUDDHA

Life of the Buddha. Little is known of the life of Gotama (Gautama) Siddhattha (Siddhārtha), the founder of Buddhism. The term Śākyamuni, by which he is often called, designates a sage of the Śākyas, a warrior clan of the southern borderland of Nepal. Born about 563 BC, Gautama soon became aware of the futility of social life and was convinced that excessive philosophical discourse keeps men from the most important thing—right living. He saw that the shadow of death rests on all living creatures and that nothing is eternal. Legend attributes his final decisive renunciation to encounters with a sick man, an old man, a dead man, and, finally, a serene mendicant ascetic. It also tells of the repeated attempts by his father to turn him from his purpose. At last, he abandoned his home, wife, and son and associated with the most famous spiritual masters of his time. He learned Yoga, a meditative discipline, which he practiced in the extreme until he realized that to be effective meditation requires a healthy body. Thus he discovered the path that leads to the correct knowledge of the nature of persons and things and of their appearance and disappearance.

Gautama's path to Enlightenment

Under the pipal tree in Gayā (subsequently called Bodh Gayā) in about 525 BC, he achieved Enlightenment (*bodhi*), and thus became a (or the) Buddha (Enlightened One). The question then arose: should he keep for himself the truth he had discovered or should he preach it to others? The Hindu gods Indra and Brahmā, according to legend, descended from their heavens and begged him to reveal his liberating doctrine to all. This he did, preaching without rest until his death in about 480 BC at Kuśinagara.

Teachings of the Buddha. The teaching attributed to the Buddha was transmitted orally by his disciples prefaced by the phrase, *evaṃ mayā śrutam* ("Thus have I heard"); therefore, it is difficult to say whether his discourses were related as they were spoken. They usually allude, however, to the place, time, and community where he preached; and there is concordance between various versions. An attempt was made by Buddhist councils in the first centuries after the Buddha's death to establish his true and original teachings (see BUDDHISM HISTORY OF, *Early Buddhist Councils*).

The basic Buddhist terms below are given in both Pāli and Sanskrit at their first appearance where they differ (*e.g.*, *anicca*, *anitya*) and thereafter in Sanskrit, which is more familiar in Western literature.

Impermanence, no-self, and misery. According to the Buddha, all is impermanent (*anicca*, *anitya*), a flowing reality, whether of external things or the psychophysical totality of human individuals; thus a succession and concatenation of microseconds called *dhamma*, *dharma* (hereafter, *dharmas*; not to be confused with *dharma*, meaning "law" or "teaching"). The Buddha departed from the main lines of traditional Indian thought in not asserting an essential or ultimate reality in things. Moreover, contrary to the theories of the *Upaniṣad*s (Hindu sacred treatises), Gautama maintained that an *ātman* ("self" or "soul") does not exist: there is nothing within us that is metaphysically real. Thus, along with impermanence, he affirms the theory of *anattā*, *anātman*, or *nairātmya*, the nonexistence of an eternal "I," or *ātman*. Yet human beings are caught in the cycle of births and deaths (*saṃsāra*) because the extinction of life—if the effect of a completed deed (*karman*) has not been stopped —does not mean the end of existence but a projection toward a new existence. He also perceived and taught that existence is subject to misery connected with the unpleasant, especially sickness and death, and separated from the pleasant.

The Four Noble Truths. Awareness of these fundamental realities led the Buddha to formulate the Four Noble Truths: the truth of misery (*dukkha*, *duḥkha*); the truth that misery originates within us from the craving for pleasure and for being or nonbeing; the truth that this craving can be eliminated; and the truth that this elimination is the result of a methodical way or path that must be followed. Thus, there must be an understanding of the mechanism by which man's psychophysical being evolves; otherwise men would remain indefinitely in *saṃsāra*, in the continual flow of transitory existence.

Misery and its cure

The law of dependent origination. Hence the Buddha formulated the law of dependent origination (*paṭiccasamuppāda*, *pratītya-samutpāda*), whereby one condition arises out of another, which in turn arises out of prior conditions. Every mode of being presupposes another immediately preceding mode from which the subsequent mode derives, in a chain or series of causes. The original condition is ignorance (*avijjā*, *avidyā*); then come the cooperating karmic agents (*saṅkhāra*, *saṃskāra*, literally "aggregates" or "compounds"; mental qualities, dispositions, and habits); then consciousness (*viññāna*, *vijñāna*); and then "name and form" (*nāma-rūpa*), the naming and materiality of things. The five sense organs and the mind (*satāyatana*, *ṣaḍāyatana*), thereupon condition contact (*phassa*, *sparśa*). Contact in turn causes the psychic, mental, or emotional response to sense objects (*vedanā*). This is the antecedent of the ensuing craving evoked by the objects (*taṇhā*, *tṛṣṇā*). From this comes the grasping for, or attachment to, those same objects (*upādāna*), an essential condition because it determines *bhava*, coming into exis-

tence, and, hence, *jāti*, "birth," with its consequent *jarā-maraṇa*, "old age" and death, and, so, misery. Thus, the misery that is bound up with all sensate existence is accounted for by a methodical chain of causation.

The *pratītya-samutpāda* is the law of interdependence or reciprocal conditioning of phenomena within the totality of physical, psychic, and psychosomatic existence. It is the subject of solitary meditation by the Buddhist aspirant. It is initiated by one's own ignorance, together with the cooperating karmic agents representing the inheritance from the past. Present life is the effect constituted by consciousness and its derivatives, the mental faculties and corporeity (*nāma* and *rūpa*), the six sensory "bases," contact or impression, and the psychic or mental response. In the present state, man accumulates a karmic charge projected into the future. This is caused by craving for enjoyment, grasping for sensuous impressions, the notion of "I" and "mine," and attachment to false theories; thus, the law of dependent origination takes men again into space and time (*bhava*), with consequential birth and death (their future). Consciousness, therefore, is the ripening (*vipāka*) of the past life. It has five different ways of apprehending: with the eye, ear, nose, tongue, and body; thus, it bears the responsibility for a new rebirth (*patisandhi-viññāna*). It also conditions *nāma-rūpa*, name and form; "name," because this presupposes an awareness of the things named (*i.e.*, mental faculties, or mind), and "form" because without bodily or material form sensate beings would not exist. Corporeity is reduced to the physical elements that exist both in external things and in the body: earth, water, fire, air, and the forces that join them—solidity, fluidity, heat, and motion—to which correspond the five sense organs and the five sense fields.

Consciousness and its consequences

The law of dependent origination of the successive states of life and understanding remains invariable and fundamental in all schools of Buddhism, although there are diverse interpretations of it.

The Eightfold Path. Given the awareness of this law, the question arises as to how one may escape the continually renewed cycle. Here ethical conduct enters in. It is not enough to know that misery pervades all existence and the way in which life evolves; there must also be a purification that leads to the overcoming of this process. Such a liberating purification is effected by following, with a sincerity reinforced by continual meditation, the noble Eightfold Path: the right mode of seeing things, right thinking, right speech, right action, right mode of living, right effort in every mode of being, right mindfulness, right meditation. The term right (true or correct) is used to distinguish sharply between the precepts of the Buddha and other teachings.

Nirvāṇa. The ultimate goal to be achieved through following the Eightfold Path is Nibbāna, Nirvāṇa; but the Buddha does not explain what it is or what it is not because it cannot be expressed in general terms and escapes all definitions. Nirvāṇa is a condition that is realized when *karman* and the consequential succession of lives and births (*saṃsāra*) have been definitely overcome. Expositions of the subtleties of the doctrine of Nirvāṇa largely deal with this process.

Saṅgha (community). The disciples gathered around the Buddha made up the *saṅgha* (community). They could possess nothing and lived on alms. The Buddha was the "Teacher" (*sattha, śāstṛ*), or, borrowing a word from the world of merchants, among whom Buddhism fared especially well, the "head caravaneer," the guide along the route that leads to salvation. The *saṅgha* was the group of properly ordained disciples. Its members comprised neophytes (*sāmaṇera, śrāmaṇera*) and fully ordained monks (*bhikkhu, bhikṣu*). The most excellent member was the *arahant, arhat* ("saint," or worthy one") who had achieved the complete detachment that leads to Nirvāṇa. The Buddha provided the example that the others could follow. The power of his attraction was in his being an Enlightened One who kindled faith (*saddhā, śraddhā*) in others.

The "Three Jewels" and the Threefold Refuge. The force of his conviction and example exalted the disciples; consequently, the three factors of adherence to the Teacher were: faith in the Buddha, in the law or doctrine taught by him (*dhamma, dharma*), and in the community (*saṅgha*), the repository of his teaching. These are the Three Jewels in which a devout layman (*upāsaka* if male, *upāsikā* if female) takes refuge (*saraṇa, śaraṇa*). "I take refuge in the Buddha, I take refuge in the law, I take refuge in the community," is the traditional Buddhist affirmation.

The traditional Buddhist affirmation

The appeal of the Buddhist teaching. According to the Buddha's teaching, the universal aim is salvation, the attainment of Nirvāṇa; this, however, requires a great span of time (the *Jātaka* stories, which tell about the previous lives of the Buddha, demonstrate this); but the important thing is that the way has been found, that "one has set out on the path." Several features favoured the rapid success of the Buddha and of his doctrine. Buddhism was open to all, regardless of caste (an important factor in Indian society), because the Buddha did not recognize any essential difference among men; the difference among them, in his view, derived solely from their diverse moral and karmic maturity.

THE ANCIENT SCHOOLS

Buddhism may be divided into three main branches: (a) the ancient schools (currently represented by Theravāda), (b) Mahāyāna, and (c) Tantrism, the esoteric branch, which, though distinctive, is inseparable from Mahāyāna. Each branch has several subgroups. According to the ancient chronicles, the Buddhist community had broken up into a number of schools, the so-called 18 schools (although there were more than 18) during its first three centuries.

The development of the most important schools of Buddhism is summarized in the chart.

The various schools or branches were not limited to a particular region. Mahāyāna and Tantrism flourished side by side with Theravāda for many centuries in Ceylon (now Sri Lanka) and Southeast Asia. In the 7th century, various sects coexisted in Central Asia, India (often in the same area), and Southeast Asia.

Theravāda (Sthaviravāda). The Theravāda (Sanskrit, Sthaviravāda) school is regarded as the transmitter of ancient Buddhism. Hence it is of fundamental importance to consider its main doctrines and practices.

Cosmology. In the Theravāda view there is a plurality of universes surrounded by water and mountain chains. Every universe has three planes: (a) the "sphere of desire" (*kāmadhātu*); (b) the sphere of material form (*rūpadhātu*) but removed from sensuous desire; and (c) the sphere of immateriality or the formless (*arūpadhātu*). On the plane of desire, creatures and their mode of being are divided into five or six species: demons; *preta*, a species of wandering, famished ghosts; animals; men; gods; and a sixth group not universally acknowledged, the *asura* (demigods). The matter of the world is made up of four elements: earth, water, fire, and air, held together in various combinations.

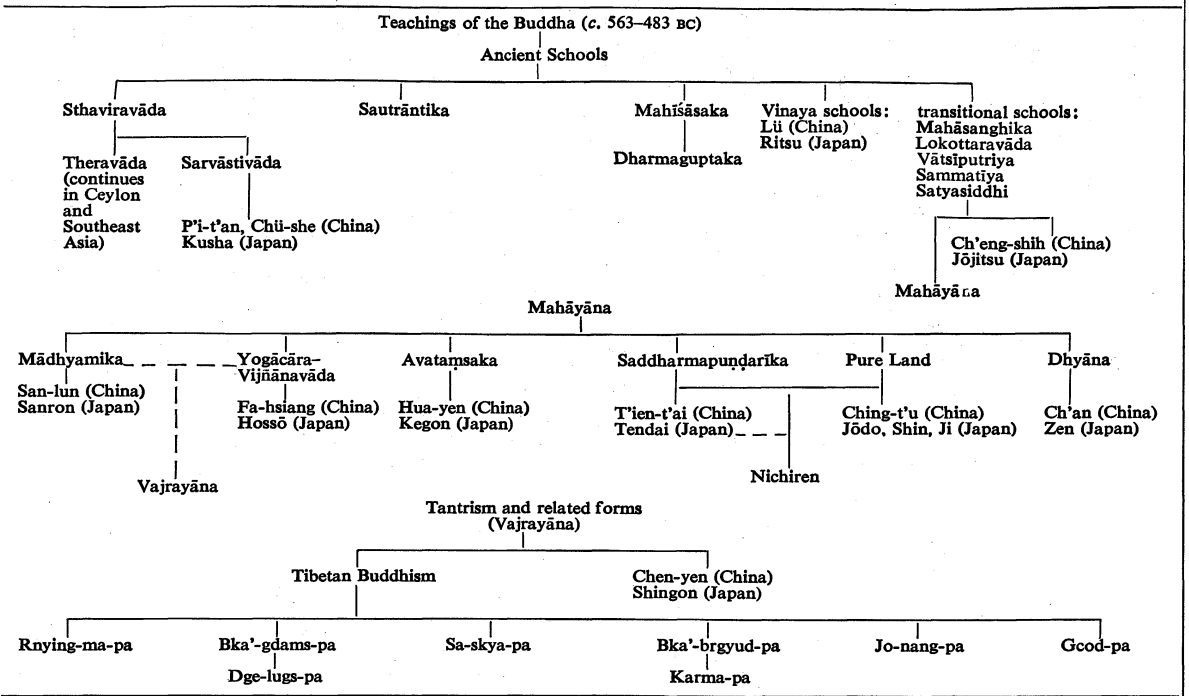
Plurality of universes, planes, and cycles

Time moves in cycles (*kalpas*), involving a period of involution (destruction by fire, water, air), of stability, of renewal, and of duration, at the end of which the cycle moves again into a period of destruction and repetition of the subsequent periods. The *kalpas* are made up of four ages (*yugas*)—Kṛta, Tretā, Dvāpara, and Kali—of progressively decreasing happiness and life-span.

Human existence is a privileged state because the Buddha is born only among men. Moreover, man has the capability of choosing that which can lead him to do good works (which will result in a good birth) or bad works (and thus a bad birth); and, above all, he has the possibility of becoming a Buddha. All of these capacities and activities are reduced to a series of *dharmas*, instant points in continual motion or changing states, subject to appearing, aging, and disappearing.

Classification of dharmas. *Dharmas* are divided and subdivided into many groups. The essential ones that concern man's psychophysical person are the five components (*khandha, skandha*), the 12 bases (*āyatana*), and the 18 sensory elements (*dhātu*). The five components, or

The Buddhist Schools*



*Solid line denotes direct derivation; broken line, indirect derivation.

skandhas, are: a) *rūpa*, materiality, or form; b) *vedanā*, feelings of pleasure or pain or the absence of either one; c) *saṃjñā*, cognitive perception; d) *saṃskāra*, the forces that cooperate to condition the psychic activity of an individual, from tactile sensations to emotions, memory, the disposition for concentration (*samādhi*), and the reasoning faculty (*paññā, prajñā*)—*i.e.*, all of the impulses and conscious factors that determine the psychic inclination and volitional tendency of thought; and e) *vijñāna*, the six modes of apprehension related to the five senses, in addition to the general mind organ (*manas*), and consciousness as such.

The 12 bases, or *āyatanas*, include the five sense organs, such as the eye; the five related sense fields, such as the visible world; and *manas*, the general mind organ, or instrument of thought, and that toward which it is turned—*i.e.*, not things as such but things as they are reflected in mental perception.

The 18 elements, or *dhātus*, comprise the five sense organs and the *mano-dhātu* (mind element), their six correlated objects, and the six consciousnesses (*vijñāna*) of the eye, ear, nose, tongue, body, and *manas*.

Thus the classification of *dharmas* is an increasing elaboration of the psychophysical components of the human person and their corresponding objects. These lists may converge, but repetitions are derived from different codifications of the original teaching. For example, also listed are the faculties (*indriyas*) through which one comes to components of major importance: the five sense organs and the mind mentioned above; vitality; the experience of passion, pain, joy, sadness, or indifference; masculine and feminine potentialities; and faith (*śraddhā*), energy, mindfulness, concentration (*samādhi*), and wisdom—the five moral or spiritual faculties. The last three are of particular importance to the Buddhist.

Clearly in this ancient (Theravāda) version, Buddhism is not concerned with metaphysical problems but with man in his psychosomatic components, because only through his awareness of their interrelation, combination, and operation, and of the way to cultivate some and to suppress others can he arrive at the state of an *arhat* ("worthy one"). Its aim is not to promulgate a metaphysics but to liberate man by employing his psychic mechanism in a way to stop his *karman*.

Through the classification of *dharmas* a person comes to be seen as an aggregate of many elements working together, ruled in his becoming by the law of *karman*, whether good or bad, and thus destined to suffer good or bad consequences. All of this rests on the presupposition that there is no metaphysical entity such as an "I" or *ātman* outside of time, but that there is a psychosomatic aggregate situated in time, the freedom of choice of which allows it to perform this or that act, which can be with or without overflows and thus capable or not capable of consequences.

Knowledge of *dharmas* a step toward liberation from rebirth

Such classifications do not have a doctrinal goal; rather, they are preparatory distinctions that guide whoever accepts the teaching of the Buddha in passing from the temporal to the atemporal plane and overcoming the cycle of rebirths. Here enter the seven factors of Enlightenment: clear memory, the exact investigation of the nature of things, energy and sympathy, tranquillity, impartiality, and a disposition for concentration. These are assisted by subsidiaries, such as love for all living creatures, compassion, delight in that which is good or well done, and, again, impartiality. The last four are known as the "incommensurables," the necessary preconditions for liberation from *karman* and *saṃsāra*.

The stages leading to arhatship. The way that leads the disciple to the stages of *arhat*ship traverses an immense number of lives, during which the aspirant gains true insight into the nature of things.

One who believes in the teachings of the Buddha and practices them passes through four stages. (1) He who has entered into the stream; *i.e.*, begun the process leading to release from rebirth, can take two paths: that of devotion and that of intellectual discipline. His chances of rebirth are reduced greatly. (2) After that comes the stage of one who returns only once. (3) The third stage is that of one who does not return again, for he has freed himself from the lower bonds (belief in a permanent self, doubt, belief in mere morality or rites, sensual passion, and malice). He can obtain liberation in the time that runs from death until rebirth in a paradise, or even while in this existence. (4) The *arhat* gains freedom from death because he has accomplished all that he proposed and had to do in order to achieve his condition. He is free from all bonds, even desire for existence in the formed or formless worlds, excitability, ambition, and ignorance.

Nirvāṇa

The Buddha. The state of the Buddha, the perfectly Enlightened One, is Nirvāṇa—a state from which one does not return. It is beyond death, not caused, not born, not produced; it is beyond all becoming and devoid of all that makes up a human person. There are two kinds of Nirvāṇa. One is achieved by the Buddha while still alive but only until the last and most tenuous remains of *karman* have been expended. When these disappear, the Buddha dies and then enters the Nirvāṇa without remains.

The Buddha has been given many other names, the most common of which are Arhat and Tathāgata (one who has reached perfection). The Theravādin scriptures, in the later stages, express a belief in previous Buddhas before Gautama (six in one list, more in others) and also in a future epochal Buddha, Metteyya (or Maitreya), who presently dwells in the Tuṣita Heaven and who will come into the world when evil increases and this age comes to an end.

Meditation. The states of *dhyāna* ("meditation" or trance), *samāpatti* (attainments), and *samādhi* (concentration) of the Yoga school of Hinduism are found in Buddhism but with a different content and practice. *Jhāna, dhyāna* here is a meditation that effects a moral and intellectual purification and is usually divided into four stages, or *dhyāna*s. In the first stage, the meditator achieves detachment from sensual desires and impure states of mind through analysis and reflection and, thereby, an emotional state of satisfaction and joy. In the second stage, intellectual activities are abated to a complete inner serenity; the mind is in a state of "one-pointedness" or concentration (*ekaggatā, ekāgratā*), joy, and pleasantness. In the third stage, every emotion, including joy, has disappeared, leaving the meditator indifferent to everything while remaining completely conscious; he is in a state of well-being. The fourth stage is the abandoning of any sense of satisfaction, pain, or serenity because any inclination to a good or bad state of mind has disappeared. The meditator thus enters a state of supreme purity, indifference to everything, and pure consciousness.

At this point the meditator begins the *samāpatti*s (or further *dhyāna*s). Beyond all perception of form, withdrawn from the influence of perception, immune to the perception of plurality, concentrating on infinite space, he reposes in the condition of spacial infinity. Going beyond this stage and concentrating on the limitlessness of consciousness, he remains in that state. Proceeding further and concentrating on the nonexistence of everything whatsoever, he remains in a state in which there is absolutely nothing. Even further on, he remains in a state in which there is neither perception nor nonperception.

Psychic emptying out and nullification

This kind of meditation is somewhat different from the mystical contemplation of other Indian schools. It comprises the quiescence of all psychic activities and the transcending of contemplation itself. A progressive nullifying of every psychic activity and emotional or mental faculty, with the attainment of each successive stage of *dhyāna* or *samāpatti*, this form of meditation does not aim at finding or realizing a presence already contained within us but at the cessation of the more subtle aspects of consciousness. Thus it is an empty solitude that gradually liberates until it equals the immovable, uncreated, and infinite vastness of space, wherein the very factors that led one there dissolve because their function has been exhausted. The goal of the states of concentration is to attain supernatural consciousness and, finally, that mental jump into what is called Nirvāṇa.

Also to be noted in this connection is the notion of the unconditioned (*asamkhata, asaṃskṛta*), a *dharma* that is produced without depending on any cause; *i.e.*, something that is not born, does not last, does not change, and does not cease to be. In Theravāda, Nirvāṇa is regarded as an *asaṃskṛta*; other schools include space (*ākāśa*), *tathatā*, the "suchness of things," and *dharmatā*, the "being of things" among *asaṃskṛta*s.

Sarvāstivāda (P'i-t'an, Chü-she/Kusha). This group detached itself from the Sthavira school, the precursor of Theravāda, around the time of Aśoka (emperor of India *c.* 273–232 BC, an illustrious Buddhist convert) and spread from Mathurā into Kashmir (northwest India). The fundamental point of its dissent was that the Sthavira school based itself mainly on the sermonic and narrative *Sutta, Sūtra* division of the Buddhist canon, whereas the Sarvāstivāda stressed the dogmatic and abstract *Abhidamma, Abhidharma* section (see below, *Canonical texts*). The name Sarvāstivāda means the doctrine that everything exists (*sarvam asti*). This school held that all things, past and future as well as present, exist, because the cognizing agent, at the moment of thinking of them, could not have contact with them if they did not exist. The same is true of *karman*. Things that bind and things that are capable of being bound exist together; however, a *puggala, pudgala*—an enduring underlying being, the composite person—does not exist. All that exists are name and matter. Matter (*rūpa*) has aspects, hence characteristics, and is therefore definable. The other components (*skandhas*), the human person and mental experiences, are substances with characteristics and hence are knowable.

A branch of this school, the Mūla-Sarvāstivāda, was widely diffused in India, Central Asia, Burma, Thailand, Cambodia, and Indonesia.

Vasubandhu's *Abhidharmakośa* (4th or 5th century), the basic text for the study of Buddhist philosophy, was based on the Sarvāstivāda *Abhidharma* but interpreted it according to its author's Sautrāntika propensities (see below *Sautrāntika*). It became the basic text for the development of Sarvāstivāda in China and Japan, which is designated by the short form of the title: Chinese Chüshe, Japanese Kusha, for *kośa* ("treasure"). Before the Chinese translations of Vasubandhu's work in the 6th and 7th centuries, Sarvāstivāda *Abhidharma* doctrine was represented in China by the P'i-t'an school, based on texts of the Gandhāra and Kashmir branch of Sarvāstivāda (P'i-t'an is the Chinese abbreviation for *Abhidharma*). Summarizing, interpreting, and confuting the theories of various masters in regard to external and psychosomatic *dharma*s, time, and categories, the *Abhidharmakośa* has always been regarded as the basis of Buddhist dogma in China, as also in Tibet.

Sautrāntika. This school is so named (*sūtra* plus *anta*, "end") because it gave pre-eminence to the *sūtra* portion of the canon. Its followers trace their school back to Ānanda, a close disciple of the Buddha. For them, the karmic factors (*saṃskāra*) are insubstantial and momentary, disappearing as soon as they have been manifested only to reappear again to give rise to a new aggregate. There is continual motion by virtue of which a person passes from one condition to another. Thus there exists not only a continuum of psychic states but also the modification of them, since each series arises at each instant distinct from any other but corresponding to the initial force of the impulse. Again, however, the individual being (*pudgala*) does not exist in an absolute sense. Nor does the past or future exist in a direct sense. Between one state and another there exists the same connection that there is between a seed and the fruit, which is manifested by means of the tree. Every thought or act is pervaded by a sort of very subtle impregnation that in turn is capable of impregnating the subconscious so as to generate new correlated psychic situations. The school is of great importance because its tenets were precursors of the Vijñānavāda (see below *Yogācāra/Vijñānavāda*).

Mahīśāsaka. The Mahīśāsaka (Pāli Mahiṃsāsaka) apparently took its name from its founder (but according to others, from the name of a place). Its origins go back to a disagreement concerning disciplinary rules that occurred at the first Council of Rājagṛha (483 BC); however, some of their theses seem to have developed later than the Sarvāstivāda. The Mahīśāsakas felt that the state of an *arhat* is irreversible, and they did not accept the existence of a transmigrating being. They were especially numerous in southern India.

Dharmaguptaka. This branch separated from the Mahīśāsaka school toward the end of the 2nd or the beginning of the 1st century BC. It recognized as its original master Maudgalyāyana, one of the first disciples of

the Buddha, although its actual founder may have been Dharmagupta (3rd century BC?). It was still to be found in scattered places in the 7th century. The Dharmaguptakas added two new "baskets," or collections (*piṭaka*), a *Bodhisattvapiṭaka* and *Dhāraṇīpiṭaka*, to the regular *Tripiṭaka* of the Buddhist canon (see below *Canonical texts*). They held that the Buddha was not part of the *saṅgha*—consequently, a gift given to him is infinitely superior to one given the *saṅgha*—and that the body of an *arhat* has no karmic outflows. They emphasized the merit that derives from the cult of the *stūpa*—a mound, often containing relics—which is a centre of devotion in lay Buddhism. The individual person (*pudgala*) is purely nominal because a person is nothing but his psychophysical components. States of contemplation and meditation of the past and future are without objects. The path of the Buddha and the *bodhisattva* is distinct from that of the *śrāvaka* (disciple). Perhaps due to its connection with the Mahāsāṅghika school (see below), its tenets contain foreshadowings of the Mahāyāna version of Buddhism.

Sammatīya. This branch, a derivation of the Vātsīputrīya school founded in the 3rd century BC, had a wide diffusion. According to the reports of Chinese Buddhist pilgrims in the 7th century, its followers were numerous along the Ganges Valley; and the school flourished in Gujarāt and in eastern India, as well as in Campā (or Champa, later Indochina); a 16th-century Tibetan account states that it still flourished during the Pāla dynasty that ruled Bengal up to the end of the 11th century. The Sammatīyas maintained that the rejection of moral infections is gradual and that there is a complete awareness. An act vanishes but it leaves a thrusting, a commitment to fructify, to have consequences. A person (*pudgala*) is an essence not wholly identical with his components. The knowable is at the same time both describable and indescribable. An *arhat* can fall from his state. The Sammatīyas have tendencies toward an ontological concept of the *pudgala*—that it is real though undefinable. They insist on the merit that stems from generosity; *i.e.*, gifts of food or things useful to everyone (for example, a hospital or a well). They posit an intermediate existence between death and rebirth.

Sammatīya doctrines

Canonical texts. The above schools possessed a canon of which only the Theravāda version is entirely extant in the original. Of the versions of other schools, such as the Mūla-Sarvāstivāda, parts of the Vinaya section and fragments of other works in Sanskrit or local dialects exist.

The canon consists of three *piṭaka*s ("baskets," or collections) hence called *Tripiṭaka* (Pāli *Tipiṭaka*): (1) *Vinaya*, a collection of disciplinary rules not always stated directly but often introduced through a story referring to the earlier lives of the Buddha to show the results of a good or bad act. (2) *Sūtra*, sermons and dicta attributed to the Buddha. (3) *Abhidharma*, the dogmatic section, abstract and impersonal in form and content.

In China the Buddhist scriptures were also collected in a *Tripiṭaka* (Chinese *Ta-ts'ang Ching*, "Great Storehouse Scripture," or *San-ts'ang*, "Three Collections"), accepted also in Korea and Japan but divided into different and more numerous sections. Because of the prevalence in it of Mahāyāna works, the Chinese *San-ts'ang* has little in common with the Pāli *Tripiṭaka* of the Theravāda. It was composed of works (many now lost) that came from India, Central Asia, or Tibet and were translated into Chinese with commentaries and critical treatises by Chinese and Korean authors.

The Tibetan canon consists not of three but of two collections, the *Bka'-'gyur*, or *Kanjur* ("Translation of the Buddha-word") and the *Bstan-'gyur*, or *Tanjur* ("Translation of Teachings"). The *Bka'-'gyur* [pronounced Kanjur] contains all that has been attributed to the revelation of the Buddha, consisting predominantly of Mahāyāna and Tantric works. The *Bstan-'gyur* [pronounced Tenjur] includes works by interpreters and commentators, with Indian treatises on non-Buddhist subjects, such as poetry, grammar, astrology, and medicine.

The Tibetan canon

The first texts of Theravāda Buddhism were introduced in Ceylon by Mahinda, Aśoka's son, and they were written in Pāli. Pāli is considered to be a form of Māgadhī, the language of the Magadha region, spoken by the Buddha himself but modified by the time of Aśoka. In any case, it was adopted as the canonical language by the Buddhists of Ceylon, Burma, Thailand, Cambodia, and Laos. The oral tradition was written down at the order of the Ceylonese king Vaṭṭagāmani in the 1st century BC and revised by Buddhaghosa, an Indian monk-scholar of the 4th–5th century AD who was the author of the *Visuddhi-magga*, ("Way to Purity"), a systematic work on the whole *Tripiṭaka*, regarded as orthodox Theravāda teaching.

Vinaya schools: Lü/Ritsu. The development of schools based on an emphasis on the *Abhidharma* and *Sūtra* "baskets" has been indicated above in the presentation of Sarvāstivāda and Sautrāntika. As for the Vinaya, however, although it constituted an integral part of the *Tripiṭaka* and regulated and consecrated the norms of monastic life, it gave rise to a school of its own only in China and Japan, apparently without any Indian precedent. The Lü-tsung (Vinaya school) originated in China in the 7th century during a period of highly intellectualist Buddhism and stressed observance of the ethical precepts and disciplinary rules. In the following century it was introduced into Japan by the famous Chinese priest Chienchen (Japanese Ganjin) at the invitation of the Japanese emperor and was known as Risshū or Ritsu (Japanese for Vinaya). The emphasis of Vinaya in Japan was on the correctness and validity of ordination (initiation) into the *saṅgha*, especially for monks and nuns; and controversy ensued between those who stressed the formal, external aspect and those who stressed the spiritual, internal aspect of vows and discipline. A reformed Ritsu school was established in the 13th century, based on a "self-vow discipline," marking a return to the validity of spontaneous vows, beyond any formalism, in accordance with Mahāyāna teachings. The Vinaya Lü-tsung, with its ethical, disciplinary emphasis, so congenial to the Chinese mind, continued to play a vital part in Chinese Buddhism down to modern times; Ritsu, whose teachings were in principle accepted by most Japanese Buddhists, still had its temples and following at mid-20th century.

THE TRANSITIONAL SCHOOLS

Mahāsaṅghika. According to traditional accounts, the Mahāsaṅghikas (Adherents of the Great Order, or Assembly) split off from other Buddhists in the 3rd century BC, in what may have been the original schism. Their emphasis was on a more open community, a less strict version of the discipline, and a metaphysical view of the Buddha, all of which were later developed by Mahāyāna (see below). They focussed not on the historical Buddha and his teachings but on the transcendent Buddha. In their view, the Buddha is *lokottara* ("transcending the world"), indestructible, completely devoid of all worldly impurities, with stainless *karman*. Pronouncing a single word the Buddha can be heard by all creatures, whose understanding of his words, however, depends on their karmic purity. His body is perfect, for the body through which he reveals himself is not his true body; it is instead an apparitional body (*nirmāṇakāya*). Being above the world, he has boundless power and life; he neither sleeps nor dreams. Even in the state of a *bodhisattva*, prior to his final birth, the Buddha entered the maternal womb completely pure. All *bodhisattva*s can remain as long as they will among the inferior creatures (beasts, demons, etc.) for the purpose of leading creatures to salvation. The knowledge of things occurs in a single instant: all is void (*śūnya*) and without self; the ultimate end of the way of seeing is an instantaneous recognition that reveals the singular and proper character of all things.

The *lokottara* ("transcendent") Buddha

The Ekavyāvahārika, a branch of Mahāsaṅghika, asserts that everything is a representation, that *saṃsāra*, Nirvāṇa, and the *dharma*s of the world in which we exist (*laukika*), as well as those that transcend the world, are nothing but mere designations.

Lokottaravāda. The only surviving part of the Mahāsaṅghika canon, the *Mahāvastu*, is derived from Lokottaravādins, who stem from the Mahāsaṅghikas. They assert that things of this world do not possess any reality

at all; on the contrary, they exist as atemporal *dharmas* beyond this world. Two principles are absolutely real, the two kinds of void (*śūnyatā*): of persons and of things. The way that leads to the overcoming of a given stage is real and its result also because it provides us with the knowledge of those two kinds of "voidness." The (or a) Buddha is completely supramundane (*lokottara,* hence the name Lokottaravāda) and his historical life and actions are mere appearance, convention, mental image. This is the docetic view of the Buddha.

Vātsīputrīya. The Vātsīputrīyas (or Pudgalavādins) split off in the first half of the 3rd century BC. They affirmed the existence of an enduring person (*pudgala*) distinct from both the conditioned (*saṃskṛta*) and the unconditioned (*asaṃskṛta*); the sole *asaṃskṛta* for them is Nirvāṇa. The *pudgala* really exists and can transmigrate from life to life, unlike all other things, none of which possess this property. The Vātsīputrīyas refer to a text in which the Buddha speaks of a "bundle," (*i.e.*, the components of a human being, the *skandhas*) and of one "who carries the bundle." If consciousness exists, there must be a subject of consciousness, the *pudgala;* it is this alone that transmigrates. The Vātsīputrīyas recognized an intermediate life between death and rebirth, and they did not exclude the possibility that a *bodhisattva* can become a Buddha in this existence.

The Sammatīya school, which also propounded these doctrines, is regarded variously as an offshoot of the Vātsīputrīya, the origin of the latter, or synonymous with them. It is sometimes regarded as one of the four main ancient schools, under which all the rest may be grouped.

Satyasiddhi. The Satyasiddhi school, probably derived from the earlier Sautrāntika school, is based on the *Satyasiddhi-śāstra,* a book attributed to Harivarman, a 3rd–4th century Indian writer, and known only in its Chinese version (4th–5th century). It gave birth to a school in China (Ch'eng-shih) and Japan (Jōjitsu) that maintained all things are merely designations devoid of reality. Men are enveloped in the illusion that either the ego (*pudgala*) or the world (*dharmas*) is real, whereas neither is. The past does not exist, the future has not yet come to be; and the present, as soon as it comes into being, disappears. Hence, the sense of continuity is illusory.

Harivarman, like the Lokottaravādins, postulates a void, both of the *dharmas* and of the ego: no *dharmas* of any sort exist, though from the point of view of relative truth *dharmas* may appear to exist. In China this doctrine was sharply attacked as destructive nihilism by the San-lun school (see below *San-lun*). It is perhaps improper to speak of Satyasiddhi as a school; it refers rather to certain centres that attached particular importance to the *Satyasiddhi-śāstra* without ignoring the rest of the Buddhist teachings. (In Japan, Jōjitsu is considered part of the Sanron school.)

III. Mahāyāna

Arising in India, the Mahāyāna version of Buddhism spread to Central Asia, China, Japan, Java, Sumatra, and even Ceylon (Abhayagiri monastery). It became the pan-Asiatic form of Buddhism and involved basic shifts in doctrine and approach for which, however, there were precedents in earlier schools. It taught that neither the self nor the *dharmas* exist. Moreover, for the elite *arahant* ideal it substituted the *bodhisattva*; *i.e.*, he who possesses the innate tendency to attain Enlightenment (*bodhi*), to become a Buddha—a disposition inherent in all men. In Mahāyāna, love for creatures is exalted to the highest; a *bodhisattva* can offer the merit he derives from good deeds for the good of others, not being concerned only with his own salvation. The mystic tension that agitated India also entered the Mahāyāna.

NATURE AND CHARACTERISTICS

Mahāyāna is not merely a metaphysics, dealing with the basic structure and principles of reality. It is rather a theoretical propaedeutic to the achievement of a desired state or condition that entered into the yogic-magical Indian tradition; hence, the coexistence of theoretical investigation and supreme experience: the former, the premise; the latter, the consequence. The convergence of meditative exercises leads to an emptying of thought to reach a point in which one proceeds from voidness to voidness and finally to the ultimate where even the most attenuated thought vanishes. Rational activity is exercised until it becomes quiescent: *prajñā* itself, the supreme wisdom, by successive emptying becomes nullified, and only in doing so does it identify with the unutterable ultimate reality; thus a state is acquired that is the summit of the meditative quest that empties itself more and more of all content, the achievement of an irreversible transcendence of the mind. It is a continuation of the rarefaction of thought that, expanding in emptiness, is nullified by an action because an "other" has entered in its place. According to the various schools, Nirvāṇa, the state of the Buddha, is also called the *dharma-kāya,* Buddhahood, the *tathatā,* the essence of the Buddha, and the absolute. It comprises an omniscience that is not knowledge in the ordinary sense but clear consciousness in which, as in a mirror, is reflected the play of appearances that do not exist. Such a state is the voidness that in Tantrism the meditator finds in his heart and, through a meditative process, brings from it the divine worlds, the infinite Buddhas, and the divinities—because that voidness is the mother of the "non-self," of what appears and what is not.

Mahāyāna as a theoretical propaedeutic to a desired state

BASIC TEACHINGS

The Buddha: divinization and multiplicity. The Buddha is viewed not merely as a human master and model, as was the historical Buddha but as a transcendent being. He multiplies himself and is reflected in a pentad of Buddhas: Vairocana, Akṣobhya, Ratnasambhava, Amitābha, Amoghasiddhi; some of these, taking the place of Śākyamuni, are revealers of doctrines and elaborate, complicated liturgies; Amitābha (or Amitāyus) is probably a fusion of ancient Indian ideas and Iranian conceptions. Dīpaṅkara, the first of the 24 Buddhas traditionally held to have preceded Gautama, is depicted with a flame rising from his shoulders, as in the religious and iconographic traditions of kingship of Iran and Central Asia. As Mahāyāna developed, a great deal of literature called *Buddhavacana* (Revelation of the Buddha)was circulated, but it had nothing to do with the ancient canons; on the contrary, it was proposed as the highest revelation, superseding prior texts. In this literature the teaching is viewed not as merely of one kind but as on various levels, each adapted to the intellectual capacity and karmic propensities of those who hear it. The Buddha is no longer the historical sage of the Śākyas but is now supramundane (*lokottara*). Even the *saṅgha* is of two types: that of this world and that beyond it.

The bodhisattva ideal. The essential premise of the *bodhisattva* ideal is to generate in one's own self the thought of Enlightenment and to fulfill the vow to become a Buddha, foregoing entrance into Nirvāṇa in order to remain in the world as long as there are creatures to be saved from suffering. With that vow the aspirant begins the career of a *bodhisattva,* which traverses 10 stages or spiritual levels (*bhūmi*) and purifies him through the practice of the 10 perfections (*pāramitā*). These levels, which become progressively higher and higher, elevate the *bodhisattva* to the condition of a Buddha. The first six levels are preliminary, representing the true practice of the six perfections (generosity, morality, patience, vigour, concentration, and wisdom), an indispensable condition because the *bodhisattva* should have complete mastery over ecstasies and the various modes of concentration through constant exercise, so that those sublimations become his own manner of being. Irreversibility occurs as soon as he reaches the 7th stage. From that moment the *bodhisattva* assumes the true Buddha nature, even though his nature is to be further purified and fortified in the stages that follow; this is the moment when, having performed his duty, he engages in activity aimed at completely fulfilling the obligations of a *bodhisattva.* The difference between this and the preceding six

The ten spiritual stages (*bhūmi*) and the ten perfections (*pāramitā*)

stages is that now his activity is explained as an innate and spontaneous impulse manifested unconstrainedly and therefore not subjected to doubts; this can happen because his behaving in such a manner is by now of his very nature. Everything for him is now uncreated, ungenerated; his body becomes identified more and more completely with the essential body (*dharma*), Buddhahood, omniscience.

The three Buddha bodies. The three bodies (*tri-kāya; i.e.*, modes of being) of the Buddha, which became a subject of major discussion in the Mahāyāna, are rooted in the Theravāda teachings: the physical body consisting of four elements, the mental body, and the body of the law. It is with the Mahāyāna, however, that the theory of the three bodies enters into the salvation process and assumes central significance in the doctrine. The phenomenal body (*nirmāṇakāya*) is a manifestation of the Buddha among creatures to teach them the path to liberation, even though for some schools it is nothing but an illusory appearance of eternal reality. The enjoyment (or bliss) body (*sambhogakāya*) is the body to which contemplation can ascend, in particular supramundane contemplative stages where that body manifests to the *bodhisattva* its splendor and reveals doctrines unintelligible to unenlightened men. The unmanifested body of the law (*dharmakāya*) already appears in the *Saddharmapuṇḍarīka*, or *Lotus Sūtra*, a transitional text that became central in many Mahāyāna devotional schools (see below *Saddharmapuṇḍarīka* and *Nichiren*); in many Mahāyāna texts Buddhas are infinite, but all partake of an identical nature—the *dharmakāya*. As anticipated in ancient schools, the Buddha is the law (*dharma*). "He who sees the law sees me; he who sees me sees the law." There is identification of the Buddha with an eternal *dharma*, with Enlightenment (*bodhi*), and hence with Nirvāṇa; later, real existence will be opposed to the mere appearance of existence, and voidness, the "thingness of things," an undefinable condition, present and immutable within the Buddhas, will be stressed. All is in the *dharmakāya;* nothing is outside of it, just as nothing is outside of space; transcendence and immanence come together. Other schools posit a presence innate within men even if it is not perceived, like a gem hidden in dross, which shines in its purity as soon as the veil of ignorance is removed: but it is differentiated into five Buddhas who constitute the elements (*skandhas*) of the person; it then is the "diamond body" since the beginning, but also the supreme beatitude that is expressed in the symbol of the union of the god and his consort. It is omnipresent. Above the multiplicity of all the Buddhas exists the Ādi-Buddha, the primeval Buddha. Various "families" of divinities are derived from the Buddhas, an expansion of the One into a multiplicity; so that, through meditation, man can reverse the way and go from multiplicity back to the One. Besides these three bodies, there is another one, the body in itself (*svābhāvikakāya*), because in the Buddhas is inherent the very nature of Buddha-being.

Buddha as *dharma*

New revelations. New revelations are made not only to men on earth but also in the heavenly paradises by Śākyamuni and other Buddhas. The teaching evolves uninterruptedly in the universe because worlds and paradises are infinite and all Buddhas are consubstantiated with the essential body. The assemblies to which they speak consist not only of *śrāvaka*s (disciples) but also of *bodhisattva*s, gods, and demons. The authors of the new doctrines were captivated by exaltations that often make their discourses logically implausible: phantasmagoria of celestial choruses, fabulous visions in which shine flashes of new speculations, and trains of thought under the influence, more or less conscious, of speculative and mystical Indian traditions. The texts, from which new trends spring, overflow with repetitions and modulate the same arguments with variations in reading; but they are considered as teachings to be propagated when the time is ripe.

The task of Mahāyāna thinkers was very difficult because it was not easy to produce a completely logical arrangement from this prolix literature. The appearance of some of these books is surrounded with legend. The *Prajñāpāramitā* and the *Avatṃsaka-sūtra*s, for instance, are said to have been concealed by the *nāga*s, demigods living at the bottom of lakes and rivers, in miraculous palaces. There are various *Prajñāpāramitā* ("Perfection of Wisdom") texts, from those having 100,000 verses to those having a single verse. The *Prajñāpāramitā-sūtra*s announce that the world as it appears to us does not exist; reality is the indefinable "thingness of things" (*tathatā, dharmaṇām dharmatā*), voidness (*śūnyatā*) is "the absolute," "that without signs or characteristics" (*animitta*). The fundamental assumption of the *Prajñāpāramitā* is expounded in a famous verse (*Vajracchedikā*): "like light, a mirage, a lamp, an illusion, a drop of water, a dream, a lightning flash; thus must all compounded things be considered." Not only is there no "self," but all things lack a real nature (*svabhāva*) of their own. There are two truths: relative truth, which "applies to things as they appear," and absolute truth, the intuition of voidness (it can be of 10, 14, 18, or 20 kinds).

The "Perfection of Wisdom" (*Prajñāpāramitā*) *sūtra*s

THE MAHAYANA SCHOOLS

Mahāyāna comprises the following main schools: the Mādhyamika, the Yogācāra or Vijñānavāda (Vijñaptamātratā), the Avataṃsaka, the school of the identity of the paths to salvation (*ekāyana*) represented by the *Saddharmapuṇḍarīka* (Lotus of the True Law), the various devotional (Pure Land) schools, and the Dhyāna school (Ch'an in China, Zen in Japan).

Mādhyamika (San-lun/Sanron). Mādhyamika or Madhyamaka (Doctrine of the Middle View) also known as Śūnyavāda (Theory of Negativity or Relativity) is an important philosophical school of Buddhism founded by the great Indian logician Nāgārjuna probably in the 2nd or 3rd century AD. His teachings and those of his close disciple Āryadeva attempt to assume a middle position between the extremes of existence and nonexistence or affirmation and negation, by revealing the contradictory nature of various philosophies and yet not assuming a dogmatic stance themselves. In the 5th century two rival Mādhyamika groups debated Nāgārjuna's intentions. One group, led by Bhāvaviveka, believed that Mādhyamika should assume a philosophical position of its own against other systems of thought. The second group, headed by Buddhapālita, preached the reduction of philosophical arguments, including one's own, to absurdity, in the hope that this process would lead to an intuitive realization of a reality beyond all ordinary and relative cognition. This latter branch of Mādhyamika was supported by the 7th-century commentator, Candrakīrti, whose works reinforced the belief that this doctrine of *reductio ad absurdum* was originally taught by Nāgārjuna.

The Mādhyamika school of thought was spread to China from India by the missionary translator of Indian-Kuchan parentage Kumārajīva, in the 5th century. Among the many texts that he translated from Sanskrit into Chinese were *Mahāprajñāpāramitā-śāstra* ("Great Perfection of Wisdom Treatise") attributed to Nāgārjuna, and his *Mādhyamika Kārikā* ("Treatise of the Middle Way"), and *Dvādaśaṃukha-* or *Dvādaśa-dvāra-śāstra* ("The Twelve Topics or Gates Treatise"), and also Āryadeva's *Śata-śāstra* ("One Hundred Verses Treatise"). The latter three works became the basic texts of the Chinese San-lun (Japanese Sanron) or Three Treatise school of Mādhyamika. For a brief period of time this school was challenged by a more positivistic form of Mādhyamika called the Ssu-lun or "Four Treatise" school, which also accepted the *Mahāprajñāpāramitā-śāstra* as a basic text. This school, however, was soon overwhelmed by San-lun as taught by Kumārajīva's disciple, Seng-chao, and later by Chi-tsang. Both of these Chinese Mādhyamika masters restated Nāgārjuna's thesis in numerous influential commentaries. A Korean disciple of Chi-tsang named Ekwan (Hui-kuan) then spread San-lun (Korean Samnŏn) to Japan in 625, thus completing the rapid spread of Mādhyamika thought from India to China and to Japan. This school, however, never gained popularity among the masses; it remained rather the basis for logical and philosophical thought among the learned few, rarely

forming a separate or independent sect. As a basic philosophical thesis of Buddhism, Mādhyamika is still intensely studied by Japanese monks.

The middle way

Nāgārjuna and his followers attempted to arrive at a middle position, devoid of name and character and beyond all thought and words, by first employing a rigorous logic to demonstrate the absurdity of various philosophical positions, including Brahmanic (early Hindu), Hīnayāna, and Mahāyāna thought. On the assumption that any contradiction is proof of error, Nāgārjuna took any point of view that would reveal the error of his opponents. Yet, he did not therefore accept the opposing point of view but only used it as a means to show the relativity of the system he was attacking. He was just as willing to refute his first position. In this way he claimed adherence to no doctrine.

With this method of reduction to absurdity or contradiction, Nāgārjuna attempted to prove that all worldly thought is empty (*śūnya*) or relative and to point to his belief that the true path is that of the middle, between, or more correctly, above extremes. This has been called the doctrine of emptiness of all things; but, as has been pointed out, this too is relative and should be seen only as a means of argumentation, later to be transcended.

Nāgārjuna revealed this middle path most clearly in his paraphrase of the Eightfold Truth of Buddhism. He stated:

> Nothing comes into being, nor does anything disappear. Nothing is eternal, nor has anything an end. Nothing is identical, nor is anything differentiated. Nothing moves here, nor does anything move there.

In presenting these pairs of opposites, Nāgārjuna taught that anything that can be conceptualized or put into words is relative. This led to the Mādhyamika identification of Nirvāṇa and *saṃsāra*. Both are empty concepts with the truth lying somewhere beyond.

After the emptiness or relativity of the world has been proved, the question arises how man is to go beyond this position. Nāgārjuna answered that men are not irreconcilably caught in this world, for this world can be used as a ladder leading to the absolute—beyond all duality. The transition that can be effected from this world to salvation has been called Nāgārjuna's doctrine of two truths.

Nāgārjuna's doctrine of two truths

The relative truth is of this existence. By the logical method all propositions can be destroyed. This leads to the realization that all is emptiness and from this to the intuition of an absolute truth beyond all conceptions. The link between these two truths—the relative and the absolute—is the Buddha. He experienced the absolute truth, which is *niṣprapañca—i.e.*, inexplicable in speech and unrealizable in ordinary thought; and yet he returned to point to this truth in the phenomenal world. By following this path, man can be saved.

Thus, Nāgārjuna taught that through the middle path of Mādhyamika, which is identified as the Buddha's true teachings, man is guided to an experience beyond affirmation and negation, being and nonbeing. Mādhyamika is a philosophy that can rightly be called a doctrine of salvation, for it claims to present man with a system that leads to rescue from his situation.

Yogācāra/Vijñānavāda (Fa-hsiang/Hossō). The Yogācāra (or Vijñānavāda) school is traditionally ascribed to the brothers Asaṅga and Vasubandhu (5th century AD), to which may be added Sthiramati (6th century). These writers were systematizers of doctrines already being taught and contained in such literature as the *Laṅkāvatāra-sūtra* and the *Mahāyāna-śraddhotpada-śāstra* (attributed to Aśvaghoṣa, but probably an apocryphal book written in Central Asia or in China). Yogācāra explored and propounded basic doctrines that were to be fundamental in the future development of Mahāyāna and that influenced the rise of Tantrism (see below).

Its central doctrine is that only consciousness (*vijñānamātra;* hence the name Vijñānavāda) is real; that thought or mind is the ultimate reality. External things do not exist; nothing exists outside the mind. The common view that external things exist is due to an error or misconception that is removable through a meditative process that brings a complete withdrawal or "revulsion" from these fictitious externals and an inner concentration and tranquillity; that is, through the practice of Yoga (hence, the alternative name Yogācāra, or Yoga practice).

Store consciousness (*ālaya-vijñāna*)

A store consciousness (*ālaya-vijñāna*) is postulated as the receptacle, or storehouse, of the imprint of thoughts and deeds, the *vāsanā* (literally, "perfuming") of various karmic seeds (*bījas*). The "seeds" develop into touch, mental activity, feeling, perception, and will, corresponding to the five *skandhas*. Then ideation (*manas*) develops, which sets off a self or mind against an outer world. Finally comes the awareness of the objects of thought via sense perceptions and ideas. The store consciousness must be purified of its subject-object duality and notions of false existence and restored to its pure state, equivalent to the absolute, "suchness," Buddhahood, the undifferentiated.

Corresponding to this process of false imagination (*vikalpa*), right knowledge, and suchness are the three modes in which things are, the *svabhāvas*: (1) the mere fictions of false imagination (*parikalpita-svabhāva*); (2) the relative existence of things, under certain conditions or aspects (*paratantra-svabhāva*); and (3) the perfect mode of being corresponding to right knowledge (*pariniṣpanna-svabhāva*). The latter state of consciousness and being is that ultimately attained by the *bodhisattva* in Buddhahood. Corresponding to this threefold version of the modes of being and awareness is the *tri-kāya* doctrine of the Buddha noted above (the apparitional, enjoyment, and *dharma* bodies), a doctrine that was put into its systematic, developed form by Yogācāra thinkers.

The special characteristics of Yogācāra are its emphasis on meditation and a broadly psychological analysis, in contrast with the other great Mahāyāna system, Mādhyamika, where the emphasis is on logical analysis and dialectic.

The ideation (or consciousness) school of thought, called Yogācāra (or Vijñānavāda) in India, was represented in China primarily by the Fa-hsiang (or Dharmalakṣaṇa) school, called Hossō in Japan. The basic teachings of Yogācāra became known in China primarily through the work of Paramārtha, a 6th-century Indian missionary-translator (he also made known the teachings of the opposite Abhidharma or Kusha realist school). His translation of the *Mahāyāna-saṃparigraha-śāstra* provided the foundation for the She-lun school, which preceded the Fa-hsiang school as the vehicle of Yogācāra thought in China. Fa-hsiang was founded by Hsüang-tsang, a 7th-century Chinese pilgrim-translator, and his main disciple, K'uei-chi. Hsüang-tsang went to India and studied the doctrines derived from Dharmapāla (died 507) and taught at the Vijñānavāda centre at Valabhī. When he returned to China he translated Dharmapāla's *Vijñapti-mātratā-siddhi* and many other works. His teachings mainly followed the line of Dharmapāla but also included the ideas of other Indian teachers (Dignāga, Sthiramati, etc.); they were expressed systematically in his works *Fa-yuan-i-lin-chang* and *Wei-shih-shu-chi*, the basic texts of the Fa-hsiang school.

Characteristic of *dharmas* (*dharmalakṣaṇa*)

Fa-hsiang is the Chinese translation of the Sanskrit *dharmalakṣaṇa* (characteristic of *dharma*), referring to the school's basic doctrine of the peculiar characteristics (*lakṣaṇa*) of the *dharmas* that make up the world that appears in human ideation, rather than to their essential nature (*svabhāva*). The connection of this so-called idealist school with the "realist" Abhidharma-Kusha school (see above *Sarvāstivāda*) is evident, though many new elements are introduced. There are five categories of *dharmas*: (1) eight mental *dharmas* (*cittadharma*), comprising the five sense consciousnesses, cognition, the cognitive faculty, and the store consciousness; (2) 51 mental functions or capacities, dispositions, and activities (*caitaśikadharma*); (3) 11 elements concerned with material forms or appearances (*rūpa-dharma*); (4) 24 things, situations, and processes not associated with the mind—*e.g.*, time, becoming (*citta-viprayuktasaṃskāra*); and (5) six noncreated or nonconditioned elements (*asaṃskṛtadharma*)—*e.g.*, space or "suchness" (*tathatā*).

Hsüang-tsang's work *Ch'eng wei-shih lun* explained how there can be a common empirical world for individuals

who construct or ideate particular objects and who possess distinct bodies and sensory systems: the universal "seeds" in the store consciousness account for the common appearance of things and particular "seeds" for the differences.

Fa-hsiang was brought to Japan on various occasions, according to the traditional accounts: first by Dōshō, a Japanese priest who visited China, studied under Hsüang-tsang, and established the teaching (now called Hossō) at Gangō-ji monastery, and then by other priests, Japanese and Korean, who studied in China under Hsüang-tsang, K'uei-chi, or their disciples. Thus, the Japanese claim to have received the Hossō teaching in a direct line from its originators, and it continues to have a living and significant role in Japanese Buddhism.

Identity of proximate and ultimate

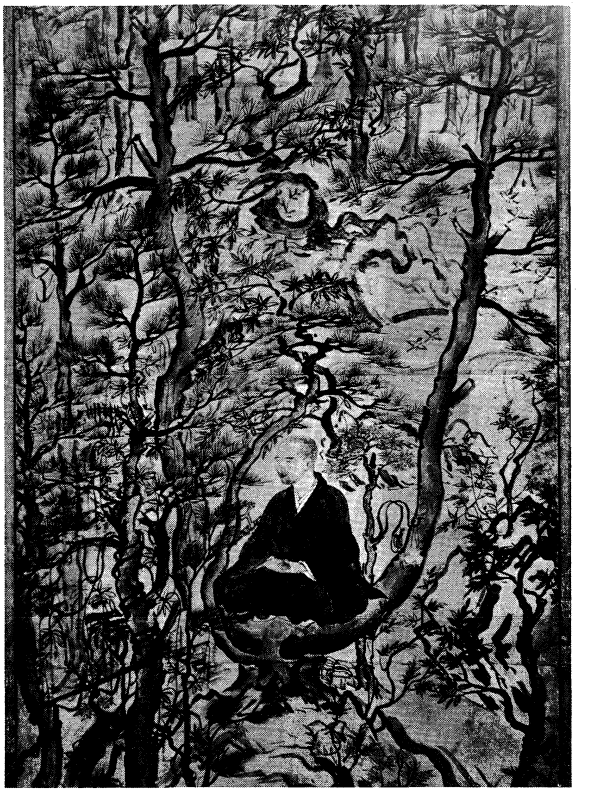
Avataṃsaka (Hua-yen/Kegon). In contrast with the Fa-hsiang (Hossō) concentration on the specific characteristics, the differentiations of things, and its separation of facts and ultimate principles, the Avataṃsaka school (called Hua-yen in China, Kegon in Japan) stressed the sameness of things, the presence of absolute reality in them, and the identity of facts and ultimate principles. It took its name from the *Avataṃsaka-sūtra* ("Wreath *sūtra*" or "Garland *sūtra*"), which, according to traditional legend, was first preached by the Buddha Vairocana expressing the perfect truth revealed in his Enlightenment but then kept secret when it proved incomprehensible to his hearers, being replaced with easier doctrines. The *sūtra* tells of the pilgrimage of a young man in a quest to realize *dharma-dhātu* ("totality" or "universal principle"). Extant are three Chinese versions and one Sanskrit original (the *Gaṇḍavyūha*) of the last section only. There is no trace of an Indian sectarian development and the school is known only in its Chinese and Japanese forms.

The school was preceded in China by the Ti-lun school, based on a translation (early 6th century) of Vasubandhu's *Daśabhūmika-sūtra*, concerning the 10 stages of a *bodhisattva* on the way to Buddhahood; since this work was related to the *Avanaṃsaka-sūtra*, the Ti-lun adherents readily joined the Hua-yen school established in the late 6th century (?) by Tu-shun (Fa-shun), the first patriarch (died 640). Fa-tsang (or Hsien-shou), the third patriarch (died 712), is considered the real founder because he systematized the teachings; hence, it is also called the Hsien-shou school. His student, Ch'eng-kuan (of Ch'ing-liang monastery; died *c.* 820 or *c.* 838), wrote famous commentaries on the *Avataṃsaka-sūtra* and defended the purity of the faith against heresy. After the death of the fifth patriarch, Tsung-mi, in 841, Hua-yen declined, during the general suppression of Buddhism that ensued in China. But it greatly influenced the development of Neo-Confucianism (a significant movement in Chinese thought beginning in the 11th century) and is regarded as the most highly developed form of Chinese Buddhist thought. It was brought into Japan by pupils of Fa-tsang and an Avataṃsaka missionary from Central India during the period *c.* 725–740, and began a vital and important development there that has continued down to the present day.

Causation by "totality" (*dharma-dhātu*)

The main doctrine of this school is the theory of causation by *dharma-dhātu; i.e.*, that all of the elements arise simultaneously, that the whole of things creates itself, further, that ultimate principles and concrete manifestations are interfused, and that the manifestations are mutually identical. Thus, in Fa-tsang's example of the golden lion in the Imperial palace, gold is the essential nature or principle (*li*) and lion is the particular manifestation or form (*shih*); moreover, as gold, each part or particle expresses the whole lion and is identical with every other part or particle. Applied to the universe, this model means that all phenomena are the expressions of absolute reality, the ultimate suchness or voidness, while still retaining their phenomenal character; each is both "all" and "one." All the constituents of the world (the *dharmas*) are interdependent, cannot exist independently; and each possesses a sixfold nature: universality, speciality, similarity, diversity, integration, differentiation.

The ideal is a harmonious totality of things encountered in the perfectly enlightened Buddha. The Buddha-nature is present potentially in all things. There are an infinite number of Buddhas and Buddha realms. There are myriads of Buddhas in every grain of sand and a Buddha realm at the tip of a hair.



The Japanese priest Myōe (1173–1232), venerated as the restorer of the Kegon sect, depicted at his daily meditation while seated in a tree near his monastery. Detail of a hanging scroll, light ink and colour on paper, 13th century. In the Kōzan-ji, Kyōto, Japan.
From Dietrich Seckel, *The Art of Buddhism* (1964); reproduced by permission of Holle Verlag

The universe is fourfold: a world of factual, practical reality; a world of principle or theory; a world of principle and facts harmonized; and a world of factual realities interwoven and mutually identified. The latter is the harmonious whole taught by Hua-yen/Kegon, while the first three are the peculiar emphasis of other schools. Hua-yen/Kegon classifies various grades or aspects of Buddhist teachings, ranging from the most elementary to the most complete—the doctrine taught by Hua-yen/Kegon and expressing the perfect knowledge attained by the Buddha Vairocana and communicated in the *Avataṃsaka-sūtra*.

Saddharmapuṇḍarīka (T'ien-t'ai/Tendai). The T'ien-t'ai/Tendai school is one of the most important developments in Chinese and Japanese Buddhism; it is significant not only for its doctrines, which in many respects are similar to Hua-yen/Kegon, but also for its practical devotional influence. Its doctrines and practices are focussed on the Indian *Saddharmapuṇḍarīka-sūtra* ("Lotus of the True Law *sūtra*") or *Lotus Sūtra*, also central in the Nichiren school (see below), and recited in Zen temples; the *sūtra* is one of the best known and most popular of Mahāyāna Buddhist texts. (The *Mahāparinirvāṇa* and *Mahāprajñāpāramitā-sūtra*s were also important in the development of T'ien-t'ai/Tendai.) The school, which apparently had no separate development as such in India, is sometimes also called Lotus (Fa-hua in Chinese; Hokke in Japanese) but is usually known as T'ien-tai in China and Tendai in Japan, after the mountain in southeast China where the basic interpretation of the *Lotus Sūtra* was first propounded in the 6th century. Prior to this, the original Sanskrit text was studied extensively in China; it was translated into Chinese early in the 5th century by Kumārajīva, and it was taught in North

China by the monks and first patriarchs, Hui-wen and Hui-ssū. The latter's student, Chih-i, who settled on Mt. T'ien-t'ai and established a famous monastery there, is regarded as the true founder of the school because he propounded the systematic and definitive interpretation of Lotus doctrines. These later became known in Japan, where Saichō (later Dengyō Daishi), a Buddhist priest who studied them first in Japan and then on Mt. T'ien-t'ai, founded a new Tendai Lotus Sect (early 9th century) and a monastery on Mt. Hiei that was to become a great centre of Buddhist learning. With Shingon (see below), with which it was closely connected, it became perhaps the most important religious and philosophical influence on the Japanese spirit. Tendai has been markedly syncretistic, striving to include various Buddhist tendencies, from Vinaya to Shingon and Zen, and also Shintō, the Japanese national cult.

The one way that includes all ways

The *Lotus Sūtra*'s main purpose is to establish the one way (or "vehicle" or "career") for attaining salvation (Buddhahood). It claims to be the definitive and complete teaching of the Buddha, here presented as a transcendent eternal being, surrounded by myriad *arhat*s, gods, *bodhisattva*s, and other figures; one who propounds the true doctrines through sermons, lectures, imaginative parables, and miracles. Religious merit is attributed to preaching, reciting, and hearing the *sūtra*, which is not merely a statement of the nature of things but a central object of devotion. The three ways of salvation preached by the Buddha are adjusted to the level and situation of the hearers and all are expressions of the one way: *śrāvakayāna*, the way of the disciples (*śrāvaka*s), aimed at being *arhat*s; *pratyekabuddhāyana*, the way of those who aim at salvation for themselves alone; and *bodhisattvayāna*, the way of those (the *bodhisattva*s) who on the point of attaining salvation give it up to work for the salvation of all other beings. All are forms of the one way, the *buddhāyana*. Being a Buddha is the one aim for all.

As systematized in the T'ien-t'ai/Tendai version of the *Lotus Sūtra*, the Buddha's teachings are divided into five periods and eight doctrines. The periods are: (1) The Avataṃsaka, or Hua-yen/Kegon, propounded vainly immediately after the Buddha's Enlightenment; (2) the *Āgama*s (scriptures), or Deer Park period, preachings to reach those of ordinary human capacities; (3) the *Vaipulya*, or Fang-teng, broad and equal, or development period, Mahāyānistic teachings intended for all men; (4) Mahāprajñāpāramitā, or Ta-pan-jo-po-lo-mi-to, preaching absolute voidness and the falsity of all distinctions; and (5) the *Saddharmapuṇḍarīka* and the *Mahāparinirvāṇa-sūtra*, or Wisdom period, teaching the identity of contrasts, unity of three "vehicles," and supreme character of the *Lotus Sūtra*. The classification of doctrines is: abrupt, gradual, secret or mystic, indeterminate, Piṭaka or Hīnayāna, common, special, and round or perfect. These characterizations of doctrines are applied to the five periods to classify more precisely the vast materials of Buddhist teaching.

The threefold truth

Central to T'ien-t'ai/Tendai doctrine is the threefold truth principle (following Nāgārjuna's [?] commentary on the *Mahāprajñāpāramitā*): (1) that all things are void, without substantial reality, (2) that all things have temporary existence, and (3) that all things are in the mean or middle state, synthesizing voidness and temporary existence, being both at once. The three truths are a harmonious unity, mutually including one another, and the mean or middle truth is equivalent to the absolute thusness. The world of temporary appearances is thus the same as absolute reality.

T'ien-t'ai/Tendai propounds an elaborate cosmology of 3,000 realms. First are the 10 basic realms, respectively, of Buddhas, *bodhisattva*s, *pratyeka-buddha*s, *śrāvaka*s, heavenly beings, fighting spirits (*asura*), men, hungry spirits or ghosts (*preta*), beasts, and depraved hellish beings. Since each includes the other nine and their characteristics, the 10 are squared to 100 realms. Each of these in turn is characterized by the 10 features of thusness manifested through phenomena: form, nature, substance, power, action, cause, condition, effect, compensation, and ultimacy; so the 100 realms are re-multiplied to 1,000. Furthermore, each of the 1,000 realms comprises three divisions; living beings, space, and the aggregates (*skandha*s); hence, the whole of things consists of 3,000 realms.

These 3,000 realms interpenetrate one another, are mutually immanent, and are immanent in one moment of thought; "one thought is the three thousand worlds." The universe is not produced by thought or consciousness but is manifest in it, and thereby also the absolute Thusness: hence, the central importance on concentration (*chih*) and insight (*kuan*) in T'ien-t'ai, to realize the unity of things and their manifestation of the ultimate.

Pure Land (Sukhāvatī/Ching-t'u/Jōdo, Shin, and Ji). The main text of the Pure Land schools is the *Sukhāvatīvyūha* (*Pure Land Sūtra*) written in northern India probably before the beginning of the 2nd century AD. (There are two original versions of the *Sukhāvatīvyūha*. The longer one includes an emphasis on good works; the shorter version emphasizes faith and devotion alone.) This *sūtra* tells of a monk, Dharmākara, who heard the preaching of Lokeśvararāja Buddha many aeons ago and asked to become a Buddha. After millions of years of study, Dharmākara promised to fulfill a number of vows if he finally attained Buddhahood. He vowed to establish a Pure or Happy Land (Sanskrit Sukhāvāti; Chinese Ching-t'u; Japanese Jōdo), also known as the Western Paradise, where no evil would exist, the people would be long-lived, and would receive whatever they desired, and from where they might attain Nirvāṇa. Dharmākara then revealed in a number of vows the means by which this Pure Land can be reached. Several of these vows emphasize meditation and good works on earth as a prerequisite, but the 18th one (a famous vow in the later development of the Pure Land school) states that one may merely call the name of the Buddha at death to be reborn in the Pure Land. Many years after these vows, Dharmākara attained Buddahood and now sits in his Pure Land fulfilling his promises of helping men achieve salvation. Here he is known as the Buddha of Unlimited Light (Sanskrit Amitābha; Chinese O-mi-t'o-fo; Japanese Amida) or the Buddha of Unlimited Lifespan (Amitāyus). He is flanked by Avalokiteśvara (Chinese Kuan-yin; Japanese Kannon) on his left and Mahāsthāmaprāpta on his right, who assist Amitābha in bringing the faithful to his Pure Land.

The Buddha of Unlimited Light

The Amitābhist doctrine spread from India to China by the 3rd century AD, where, through the work of five patriarchs, a sect based on it gradually became the most popular form of Buddhism. The sect was then transferred to Japan by the followers of the Tendai school, who attempted to weld the many sects of Buddhism into one system. By the 13th century AD, the Pure Land sect had separated from the Tendai school and spread among the common people of Japan through the work of two outstanding figures, Hōnen and Shinran.

The basic doctrines of the Pure Land sect differ widely from the doctrines of the early Buddhists. The Pure Land's leaders have generally taught that a man reaches salvation from this Earth not by individual effort or the accumulation of merits but through faith in the grace of the Buddha Amitābha. The main practice of those who follow the Pure Land teachings is not the learning of the texts, nor meditation on the Buddha but rather the constant invocation of the name Amitābha. This practice, based on the 18th vow of Amitābha, is called *nien-fo* in Chinese and *nembutsu* in Japanese (see also below *Nichiren*). Furthermore, in Pure Land Buddhism, the attainment of Nirvāṇa is not the goal; it is rather to become reborn in the Pure Land of Amitābha.

Invocation of the name (*nembutsu*)

These doctrines and the practice of invoking the name Amitābha gained great popularity in China and Japan, where it was believed that the world had reached a degenerate period, in which the Buddhist doctrines were no longer clear and men no longer possessed the purity of heart or determination to attain salvation by self-endeavour. Therefore, all men of every section of society could only hope to be saved by the grace of Amitābha. As the Pure Land sect spread from India to China and

then to Japan, this doctrine of grace became more and more radical until individual actions were said to play no part in the attainment of salvation.

There is little available data on the practices of the Amitābhist believers in India, but scholars hold that while *nembutsu* was used, the main emphasis was upon meditation and worship of the Buddha. In China this stress on meditation and rites weakened, as indicated in the teachings of the three most important Pure Land patriarchs, T'an-luan, Tao-ch'o, and Shan-tao, during the 6th–7th centuries. T'an-luan was originally a follower of Taoism, who, while searching for the elixir of immortality, was converted to the Pure Land doctrine by an Indian monk. Dedicating his life to the spread of this doctrine, T'an-luan preached the invocation of the name Amitābha and declared that even evil men were eligible for the Pure Land if they sincerely uttered the *nembutsu*. He warned, however, that the lowest hell awaited those who reviled the Buddhist *dharma*.

T'an-luan was followed by Tao-ch'o, who argued that in this degenerate age men must take the "easy path" to salvation of complete trust in Amitābha, for men no longer possessed the capacity to follow the more difficult path of the saints. His disciple, Shan-tao, believed by the Japanese Pure Land sect to be the incarnation of Amitābha, was primarily responsible for shaping the doctrines of Pure Land Buddhism. This evangelist distributed many copies of the *Pure Land Sūtra* and wrote a famous commentary in which he taught that rebirth in the Western Paradise is effected primarily by *nembutsu*. This must be supplemented, however, by the chanting of *sūtra*s, meditation on the Buddha, worshipping of Buddha images, and singing his praises.

Salvation by Amitābha's grace: Hōnen and Shinran

The work of Shan-tao inspired Hōnen, the founder of the Pure Land sect (Jōdo-shū) in Japan, to declare that in this evil period man must put complete faith in the saving grace of Amitābha Buddha and constantly invoke his name. Hōnen, who was a very learned scholar and well-versed in Buddhist knowledge, wrote a treatise (*Senchaku hongan nembutsu-shū*) expressing his beliefs. While this treatise proved popular among the common people, as were his teachings generally, it was burned by the monks of Mt. Hiei and his teachings were vigorously opposed by the established Buddhist priesthood. One of his disciples, Shinran, who was exiled at the same time, was the founder of a more radical sect named the True Pure Land sect (Jōdo Shinshū, or Shin). Shinran married, with Hōnen's consent, proving that one need not be a monk to attain the Pure Land; and he popularized his doctrines by preaching in Japanese villages. In his teachings he rejected all *sūtra*s except the *Pure Land Sūtra* and rejected the vows of Amitābha in this *sūtra*, that stress individual merit. Basing his doctrines on the 18th vow, Shinran discouraged any attempt to accumulate merits, for he felt that this stood in the way of absolute faith and dependence on Amitābha. Furthermore, he rejected Hōnen's practice of continual invocation of Amitābha, believing that the faithful need only say the *nembutsu* once in order to attain salvation. Any repetition after this *nembutsu* must be seen as praise of Amitābha and not as bringing merit or affecting one's salvation. Thus it can be seen that with Shinran the doctrine of grace, which had little meaning in early Indian Buddhism, gained total ascendancy. A third Pure Land sect grew up around the itinerant teacher, Ippen. He travelled throughout Japan, advocating the chanting of Amida's name at set intervals throughout the day, hence his school was called the Ji ("Times") sect, or Ji-shū.

Music, dance, drama (Nō plays), and the tea ceremony have been important forms of expression of Shin. Since the late 19th century it has engaged in extensive educational and social welfare programs and played a significant role in Japanese life. It is the largest single Buddhist sect in Japan.

Nichiren. The indigenous Japanese Nichiren school is related both to the *Lotus Sūtra* and Pure Land schools, for it, too, is centred on the "Lotus of the True Law" and also emphasizes fervent faith and the repetition of a key phrase. Hence it has been aptly called "Lotus-pietism" by a famous scholar in Japanese Buddhism. Its distinctiveness is rooted in the extraordinary personality and character of its founder; significantly, it is named after a man, a historical person, not after a book or a doctrine.

Nichiren's life and teachings

Nichiren (1222–82), the son of a poor fisherman, became a monk at an early age and studied at Mt. Hiei, the centre of the Tendai school. Nichiren was frustrated, however, by the many paths of Buddhism promising salvation and left Mt. Hiei for 10 years to search for the true path. When he emerged from his independent studies he taught that the *Lotus Sūtra* (*Saddharmapuṇḍarīka-sūtra*) contains the final and supreme teaching of the Buddha Śākyamuni (Gautama) and offers the only true way to salvation. According to Nichiren's interpretation of this *sūtra*, the three forms of the Buddha—the universal or law body (*dharmakāya*), the enjoyment body (*sambhoga-kāya*), and the phenomenal body (*nirmāṇakāya*)—should be granted equal respect, as they are important aspects of the Buddha Śākyamuni. Also, following the teachings of Chih'i, the Chinese founder of T'ien-t'ai/Tendai, that the *Lotus Sūtra* is the essence of Buddhism, Nichiren held that this same Buddha-nature was possessed by all men and could be realized only by proper worship of the *Lotus Sūtra*. Furthermore, Nichiren felt that his time, which was marked by political upheaval and unrest, was the period of degeneration known in the *Lotus Sūtra* as the time of the latter-day *dharma* (*Mappō*). During this time the purity of the Buddhist doctrines could be kept only by the *bodhisattva*s. Nichiren identified himself as an incarnation of several of these *bodhisattva*s, especially the *bodhisattva* of supreme conduct (Viśiṣṭacāritra; Japanese Jōgyōbosatsu) and believed that his mission was to propagate the true teachings of the *Lotus Sūtra* in Japan, which he felt would become the new repository of the Buddhist *dharma*.

In attempting to guide Japan to the Buddhist *dharma* as he interpreted it, Nichiren drew great criticism for his strong-willed and uncompromising attitude. In one treatise Nichiren wrote that the unrest in Japan was caused by the chaotic state of religious beliefs, a condition that could be corrected only by adopting the teachings of the *Lotus Sūtra*. He taught that if men turned to this *sūtra*, they would realize their true Buddha-nature, perceive that suffering is illusion, and see that this world is a paradise. If men—*i.e.*, the Japanese—did not follow the teachings of the *Lotus Sūtra*, however, natural disasters and invasions would result. With firm confidence in the righteousness of his cause, Nichiren attacked the Shingon and Amida sects of Buddhism for neglecting the true Buddha of the *Lotus Sūtra*, Śākyamuni, and attacked Zen for placing stress only upon Śākyamuni's historical form. These sharp criticisms led Nichiren to be exiled twice and almost brought his execution, from which he was saved in a miraculous fashion, according to his account and the belief of his adherents.

The two main religious practices advocated by Nichiren

Nichiren advocated two main religious practices based on his interpretation of the *Lotus Sūtra*. The first is the worship of the *honzon* (or *gohonzon*), a *maṇḍala* (symbolic diagram) designed by Nichiren, representing the Buddha-nature that is in all men as well as the three forms of the Buddha Śākyamuni. The second is the repetition of the phrase *namu Myōhōrenge-kyō* (salutation to the *Lotus Sūtra*), a practice called *daimoku* ("title"), as the affirmation of the devotee's belief in the teaching and efficacy of the *Lotus Sūtra*. This repetition was not only to be done orally but in every action of the true believer. Nichiren also taught that there should be a sacred place of ordination (*kaidan*) where the believer could receive training in the doctrines of the *Lotus Sūtra* in order that he might keep the true spirit of this document. This sacred place might be seen as wherever the believer in the *Lotus Sūtra* lives, for there is the Buddhist truth. The *honzon*, *daimoku*, and *kaidan* comprise "the three great secret laws" (or "mysteries") that are regarded as the essential teaching of Nichiren—the *sandai-hihō*.

Nichiren's fervent faith brought him wide fame and many devotees, and at his death he chose six disciples to continue his work. This sect was simply known as Nichi-

ren-shū (Sect of Nichiren). It still controls the main temple founded by Nichiren at Mt. Minobu. One of his disciples, Nikkō, however, soon began another sect known as the Nichiren-shō-shū (True Sect of Nichiren), which taught that Nichiren, not Śākyamuni, was the saviour and that the *maṇḍala* painted by Nichiren was alone efficacious in saving mankind. In the 20th century these sects have gained many devotees. Within the Nichiren-shū the Reiyū-kai (Association of the Friend of the Spirit) arose in 1925. This sect, which preaches a combination of ancestor cult and the doctrines of Nichiren, places faith not in the Buddha or *bodhisattvas* but in the *maṇḍala*, in which all saving power is concentrated. The Risshō-Kosei-Kai (Society for Establishing Righteousness and Friendly Relations) split from Reiyū-kai in 1938. This sect teaches the recitation of the *daimoku* as an affirmation of faith in the teaching of the *Lotus Sūtra*, and the worship of the Buddha Śākyamuni. Like Reiyū-kai, it also allows the veneration of ancestral spirits. Risshō-Kosei-Kai gained many converts after World War II, but its success was soon eclipsed by Sōka-gakkai, the lay movement of Nichiren-shō-shū. Sōka-gakkai (Value Creation Society) was founded by Makiguchi Tsunesaburo in 1930, dedicated to educational research and the extension of Nichiren-shō-shū. Its founder insisted on the practical values of worldly gain and satisfaction as well as the attainment of goodness and beauty and taught that Nichiren was to be worshipped as the True Buddha predicted in the *Lotus Sūtra*. The members also fervently practice *daimoku* and worship the *honzon* as the repository of magical power. After World War II, Sōka-gakkai, under the leadership of Toda Jōsei, grew rapidly through a technique of evangelism called *shakubuku* ("break and subdue") in which the resistance of the other person is destroyed by forceful argument. A zealous missionary movement, it has spread to many foreign countries, including the United States. Thus, Nichiren's teaching and personality are still strong influences today.

Sōka-gakkai

Dhyāna (Ch'an/Zen). The Dhyāna (Chinese, Ch'an; Japanese, Zen) school of Buddhism emphasizes meditation as the way to immediate awareness of ultimate reality, an important practice of Buddhism from its origin in India, and derives its name from the Sanskrit term for meditation, *dhyāna*. The meditative emphasis in other schools of Indian origin, such as Yogācāra, has been noted above. Ch'an, with its special training techniques and doctrines and its Taoist influence, however, is generally considered a specifically Chinese product.

While scholars point out that 4th–5th-century Chinese Buddhist monks, such as Hui-yüan and Seng-chao, were teaching doctrines and practices similar to those of the Ch'an school before the traditional date of its arrival in China, standard Chinese texts name a South Indian monk, Bodhidharma, who came to China about AD 520, as its founder. Bodhidharma is held by Ch'an devotees to be the 28th patriarch of the Indian meditational school, which began with the monk Kāśyapa, to whom the Buddha Śākyamuni revealed his supreme teaching. This teaching is found in the *Laṅkāvatāra-sūtra*, an important text for the early Ch'an school, which relates that all beings possess a Buddha-nature, often equated with *śūnya* (the void) in Ch'an, and that realization of this fact is Enlightenment (Chinese Wu; Japanese Satori). The truly enlightened one cannot explain this ultimate truth or reality, for it is beyond the ordinary duality of subject and object. Books, words, concepts, and teachers cannot convey it. It must be realized in direct personal experience.

The Enlightenment experience: Satori

Bodhidharma, who came to be known as the first patriarch of Ch'an in China, passed his mantle to Hui-k'o; and this line of transmission continued to the fifth patriarch, Heng-jen. After his death a schism occurred between the adherents of the Northern school founded by Shen-hsui, which held that Enlightenment must be attained gradually, and the Southern school of Hui-neng, which taught that true wisdom, as undifferentiated, must be attained suddenly and spontaneously. Furthermore, the Southern school tended to neglect rituals and literature and rely on teaching passed from master to pupil, adopting as well an iconoclastic attitude toward the Buddha. It was reasoned that if all things contain the Buddha-nature, then the Buddha could rightfully be equated with a dung heap. The two schools had fundamentally differing views of the Buddha-mind or Buddha-nature. Eventually the Southern school won out, and its victory is attested in the standard Chinese Ch'an texts, which name Hui-neng as the true and only sixth patriarch, as opposed to the counterclaim of Shen-hsui and the Northern school. Hui-neng's *Platform Scripture* (Chinese: *T'an Ching*) became a key text of the Ch'an school.

Two branches of Ch'an Buddhism developed from the Southern school in the 9th century: Lin-chi (Japanese Rinzai) and Ts'ao-t'ung (Japanese Sōtō). The former relied heavily on the *kung-an* (Japanese *koan*), a paradoxical question or answer that aimed at inducing the student to realize that all conceptualization is wrong and led him suddenly beyond this to Enlightenment. The *kung-an* were often accompanied by shouts and slaps from the master to provoke anxiety and, from this, an instant realization of the truth. This consisted of sitting in meditation under the direction of a master and allowing the mind to be free of all notions. Both schools followed the doctrine of Hua-hai, who taught that a monk who did not work would not eat. This practice not only made the Ch'an schools self-sufficient, helping to save them from the purge of parasitic Buddhist monks by the government in 845, it expressed the Ch'an stress on acting naturally and spontaneously in whatever task one is performing. This emphasis on spontaneity and naturalness greatly influenced Chinese painters and writers, who devoted long hours to the practice of technique so that they might act spontaneously when an inspiration arose.

The *kung-an* or *koan*

Most scholars believe that Ch'an Buddhism was influenced by Taoism. Like the Buddha-nature, the Tao (Way) was thought by the Taoists to reside in all beings. Moreover, its realization could not be taught, as it was above all duality and conceptualization. This doctrine, like that of the Ch'an school, led the Taoists to the use of paradoxes in an endeavour to point to the truth. Furthermore, the Taoists' emphasis on the natural life might have influenced the Ch'an practices. But Ch'an, independently of Taoist influence, developed many ideas already present in Indian Buddhism, such as meditation and the Buddha-nature, to fit the Chinese mentality.

Ch'an (Zen) Buddhism was introduced into Japan as early as the 7th century, but it did not flower until the 12th century, in the work of two monks, Eisai and Dōgen. Eisai, founder of the Rinzai school in the 12th century, was a Tendai monk who wished to restore pure Buddhism to Japan and with that aim visited China. When he returned, he taught a strict meditational system based on the use of the *koan* phrases; however, this was taught as only one element in the Tendai system. Unlike the Ch'an schools, Eisai also taught that Zen should defend the state and could observe ceremonial rules and offer prayers and incantations. These teachings influenced the warrior class and led to a Zen influence over the martial arts of archery and swordsmanship. Zen influence can also be seen in the Nō play, in poetry, flower arrangement, and the tea ceremony, all of which stress grace and spontaneity.

Dōgen, who established the Sōtō school in Japan in the 13th century, joined the Tendai monastery of Mt. Hiei at an early age, after the death of his mother and father had dramatically taught him the transitoriness of life. Searching for the true path of Buddhism, he, like Eisai, journeyed to China, where he fell under the influence of a Chinese Ch'an master. Upon his return to Japan he taught a discipline of "sitting straight" (*zazen*) without any effort being directed toward achieving of Enlightenment. Unlike his Chinese counterparts, however, Dōgen studied scriptures and criticized those who did not. These Zen sects still exist in Japan and deeply influence its culture. By mid-20th century Zen had become perhaps the best known of the Buddhist schools in the Western world.

Zazen

IV. Tantrism and related forms

TANTRISM (VAJRAYANA, MANTRAYANA)

Tantrism, also known as Vajrayāna (the Diamond Vehicle) or Mantrayāna (the Path of the Sacred Formulas),

is a school of Buddhism that gained prominence in various parts of India and Ceylon. Scholars infer that, because of the esoteric nature of Tantric practice and doctrine, this school might have been developing quietly from the 2nd or 4th centuries AD, when Buddhist tradition associates Nāgārjuna or Asaṅga with its origins. Although a modified version of Tantrism, apparently without sexo-yogic practices, spread to China and then to Japan where it became known as Shingon (see below *Shingon*), most scholars associate the Tantric tradition with Tibet (see below *Tibetan Buddhism*).

Identity and unity of opposites

Although Tantrism is essentially nonspeculative, describing numerous yogic or contemplative stages that an aspirant must experience before achieving Enlightenment, rather than elaborating doctrines, it holds the Mahāyāna identification of Nirvāṇa and *saṃsāra* as a basic truth. Tantrism carries this identification of the world of misery and the state of Enlightenment further by teaching that Nirvāṇa as *śūnyatā* (voidness) is one side of a polarity that must be resolved with *karuṇā* (compassion of the *bodhisattva*). *Karuṇā* is the means (*upāya*) or dynamic aspect of this world, whereas *śūnyatā* is seen as passive wisdom (*prajñā*) that possesses an absolutely indestructible or diamond-like (*vajra*) nature beyond all duality. Enlightenment arises when these seeming opposites are realized to be in truth one. This realization, which is known experientially and not through a purely cognitive process, is portrayed in Tantric imagery and practice as the union (*maithuna*) of the passive female deity (*yum*), which signifies wisdom or voidness, with the dynamic male (*yab*), signifying compassion without attachment. Such a union, called *yab-yum* (father-mother) in Tibetan, is not a satisfaction of physical impulses but a symbol of the unity of opposites that brings eternal bliss (*mahāsukha*) or Enlightenment.

Tantrists believe that as all things are in truth of one nature—the void—the physical-mental processes can be used as a vehicle for Enlightenment. In the *Kālacakra Tantra* it is written that the Buddha taught that in this age of degeneration (*Kali yuga*) one must achieve Enlightenment through one's own body, which contains the whole cosmos. This doctrine is taught in all the Tantras. Tantric specialists warn, however, that in order to use correctly the body's processes to achieve an identification of the void with compassion, the aspirant must follow absolutely the instructions of a master or teacher who has been initiated into the mysteries of Tantrism. Such a master alone can direct the pupil's every step so that he learns to control his mental and physical processes instead of being dominated by them. Therefore, the first step toward Enlightenment in Tantric practice is the undergoing of initiation (*abhiṣekha*) by an initiated master.

The path to initiation

The master first endeavours to direct the student to compassion through meditation on the transitoriness of life, the relation of cause and effect of one's actions, and the general suffering of mankind. After this sympathy for the suffering of mankind is aroused, the master guides his pupil in yogic, or contemplative, exercises that help to produce inner experiences that correspond to the various stages of spiritual growth. This process of advancement toward Enlightenment involves the identification of the initiate with gods or goddesses that represent various cosmic forces. These gods are first visualized with the help of *mudrās* (meditative gestures and postures), *mantras* (sacred syllables and phrases), and icons, all of which are believed to possess the essence of the divinities to be invoked. The icons are portrayed in a *maṇḍala*, a sacred design that represents the universe as an aid to meditation. After this visualization, the initiate identifies with the divinities and finds that each in turn is *śūnyatā*, or voidness.

The culmination of this process, called *vajrasattva yoga*, gives the initiate a diamond-like body beyond all duality. Four stages in the process are described in four different groups of *tantras*, the *Kriyātantra*, *Caryātantra*, *Yogatantra*, and *Anuttarayogatantra*. These four stages are likened to the fourfold phases of courtship: the exchange of glances, a pleasing or encouraging smile, the holding of hands, and consummation in the sexual act. The first stage involves external ritual acts, whereas the second combines these outward acts with contemplation. The third stage involves only contemplation and the fourth is the unification of all dualities in the sexual act. This last stage, however, is divided into two phases. The first involves the use by the initiate of his controlled imagination, which allows him to experience the union on an ideational level. The second phase is the *maithuna*, or sexual coupling. This act, however, cannot be construed as an ordinary physical mating, because the initiate has already realized the voidness of all things, allowing him to act with perfect control over his emotions and without attachment. Whereas the ordinary sexual act gives rise to only momentary pleasure, this *maithuna* is the symbol for the attainment of Enlightenment and eternal bliss.

Tantric Buddhist priest performing a ritual, holding a hand-drum and a bell.
William MacQuitty, London

These Tantric practices have been unjustly condemned as a degeneration of Buddhism by those who do not look beyond the surface to the depth of Tantric doctrines. It is quite easy to misinterpret the *Guhyasamāja Tantra* when it states that adultery and eating of human flesh are actions of the *bodhisattva* (*bodhisattvacaryā*) if one does not realize that this imagery points to the belief that voidness alone exists, beyond good or evil, or that the initiate must act only with compassion for the benefit of the salvation of the world. Once the true depths of Tantric doctrines and practices are perceived, this school can be designated as a development of Buddhist thought that emphasizes the attainment of Enlightenment through a graduated process of meditation under the direction of an initiated teacher.

TIBETAN BUDDHISM

The distinctive form of Buddhism that developed in Tibet is a synthesis of Mahāyāna and Vajrayāna thought, both of which were current in north India during the main period of transmission to Tibet (7th to 11th century). The two traditions complemented and interacted with one another, the first stressing the gradual understanding of an established body of doctrine and the other the use of mystical means to achieve a more sudden transformation. Tibetan Buddhism has adopted also in modified form many practices from the pre-existing Bon cult,

such as oracular priests, some local divinities, and a notion of divine kingship (see also below *Buddhism and other Asian religions: Buddhism and Tibetan religion*).

History. Buddhism, according to the Tibetan tradition, was first given recognition in Tibet during the reign (620?–649) of Srong-brtsan-sgam-po, two of whose wives were early patrons of the religion and later regarded in popular tradition as incarnations of the Buddhist saviouress, Tārā. The religion received active encouragement from Khri-srong-lde-btsan during whose reign (775–797) the first monastery was built at Samye, the first seven monks were ordained, and the celebrated Tantric master Padmasambhava was invited from India. A great deal of legend surrounds Padmasambhava, who was a *mahāsiddha* ("master of miraculous powers"); he is credited with subduing the Bon spirits and demons and subjugating them to the service of Buddhism. Contemporaneous with Padmasambhava was another Indian monk, Śāntirakṣita, whose disciple, Kamalaśīla, represented the Indian point of view in the debate at the Council of Samye (792–94) as to whether the Indian or Chinese (Ch'an) forms of Buddhism should be followed in Tibet; the Indian side (according to the orthodox view) was proclaimed the winner. Buddhism also received encouragement from Ral-pa-can (reigned 815–838), the third of the "religious" (*i.e.*, Buddhist) kings; but after his assassination in 838 it suffered a period of suppression.

The 10th to 11th century revival in Tibet

Buddhism was again revived in the 10th to the 11th century by the ruling noblemen in western Tibet, who encouraged the travel by Tibetans to India in quest of books and masters and the translation of sacred texts. Foremost among the great translators was Rin-chen bzang-po. With the arrival in 1042 of the renowned Indian master Atīśa, Buddhism became firmly established as the dominant religion of Tibet. Atīśa, like other Mahāyāna masters, emphasized the importance of monastic discipline and direct transmission of doctrine from master to disciple.

By the 14th century the Tibetans had translated all of the Buddhist literature they could obtain and had produced their own canon, the *Bka'-'gyur* (*Kanjur* or *Kagyur;* "Translation of the Buddha-word") and the *Bstan-'gyur* (*Tenjur* or *Tangyur;* "Translation of Teachings"). Separate orders of monks began to develop around particular masters and, as the growing monastic establishments acquired temporal power, intense rivalries arose. In the struggles—more often motivated by a contest for political power than by religious differences—rival monasteries allied themselves with one or another powerful clan. In the 17th century the head of the Dge-lugs-pa order—who belonged to the series of those believed to be reincarnated abbots, known by the honorific title of Dalai Lama—appealed to the Mongol chieftain Güühri Khan for help in the struggle against the rival Karma-pa sect, whose patrons were the rulers of Gtsang. After Güühri Khan's defeat of the Gtsang forces, he awarded the country of Tibet to the Dalai Lama as a religious gift. From 1642 until Chinese Communist occupation of the country in the 1950s, the Dge-lugs-pa has been the dominant sect in Tibet and the Dalai Lama the effective ruler.

Sects. *Bka'-gdams-pa.* The Bka'-gdams-pa (Kadampa, Those Bound By Precept) was a sect based on the teachings of Atīśa and founded by his chief disciple, 'Brom-ston, who emphasized austere discipline. The central practice of the sect was the purification of the mind, which required the elimination of intellectual and moral blemishes in order for a clear vision of the "emptiness" (*śūnyatā*) to be obtained. The sect relied on the *Prajñāpāramitā* and related texts and also made use of *mantras*. The Bka'-gdams-pa order was absorbed in the 15th century by the Dge-lugs-pa sect, described below.

Sa-skya-pa. The Sa-skya-pa order derives its name from the Sa-skya monastery founded in 1073 by 'Khon Dkon-mchog rgyal-po. The first five Sa-skya-pa masters promoted a great translating activity from Sanskrit and prepared the ground for Bu-ston, a 13th- to 14th-century scholar who revised the translated texts in order to ascertain their authenticity and to eliminate the dubious versions. Under the abbot 'Phags-pa, in the 13th century, the Sa-skya-pa enjoyed considerable political power. 'Phags-pa conferred initiation according to the *Hevajra Tantra* on Kublai Khan (founder of the Mongol dynasty in China) and in turn was appointed *ti-shih* (Chinese: Imperial preceptor) and invested with the authority to govern Tibet, though under the control of the Mongol court.

The Sa-skya-pa system

The Sa-skya-pa system is also called the "path and its fruit" (*lam-'bras*). The Buddhist path as presented here evolves in three stages: (1) the actual moment, the particular existence in which the seeker finds himself; (2) the road to be followed, during which he learns what is to be accepted or rejected and the mystical experiences that are realizable with the help of various forms of meditation and Yoga; and (3) the result, the attainment of Buddhahood. This experience can be attained through meditation while travelling on the path or during the intermediate stage between death and a new life.

In Tibetan Buddhism, everything is centred on the *sems* (Sanskrit *citta*), the mind element, which is exalted in a "body of sublime knowledge" and thus, through successive moments, can be transformed into the diamond body; *i.e.*, Buddhahood. This *sems* is not only a mind element; it is also light, and it is precisely on the question of the relationship between the two—the mind element and the light—that notable differences between the various Tibetan schools become apparent. Whereas the Sa-skya-pa consider light as a specific characteristic of the mind element, the Dge-lugs-pa, for example, assert that light is its very nature.

There was no aspect of Buddhist thought with which the Sa-skya-pa did not occupy themselves. They attempted a classification of the Tantras (the Tantric scriptures) even before that made by Mkhas-grub-rje in the 14th and 15th centuries. The Sa-skya-pa established branches in many parts of Tibet and gave rise to a subsect, the Ngor-pa, founded by Kun-dga' bzang-po in 1429.

Bka'-brgyud-pa. The Bka'-brgyud-pa (Transmitted Command) stresses the direct transmission of esoteric teaching from master to pupil, without which the teaching would be lost. The order traces its spiritual lineage from the Indian master Tilopa, who transmitted the teachings to the Indian yogi Nāropa, who in turn was the master of Marpa, the 11th-century householder-teacher who in turn was the master of Mi-la ras-pa, the most renowned poet of Tibet and a great ascetic. The latter's songs are the profound expression of his inner spiritual experiences and are often difficult to understand. Mi-la ras-pa's follower, Sgam-po-pa, had several disciples who established separate subschools based on his teaching, one of which was the influential Karma-pa.

The Bka'-brgyud-pa stressed, among other techniques, the exercises of Haṭha Yoga (a Yoga emphasizing breathing and special postures) and posited as the supreme goal the *mahāmudrā* (the "Great Seal") or the overcoming of dichotomous thought in the very being of Buddhahood. Frequent reference is made by the Bka'-brgyud-pa to the "Six Teachings of Nāropa." These techniques for attaining Enlightenment, either in this life or at the moment of death, deal with (1) self-produced heat; (2) the illusory body; (3) dreams; (4) the experience of the light—*i.e.*, the mind; (5) the state of existence intermediate between death and rebirth (Bardo); and (6) the passing over from one existence into another.

Nāropa's "Six Teachings"

Rnying-ma-pa. The Rnying-ma-pa (Nyingmapa; the Old Order) claim to most purely preserve the spirit of the teachings of the 8th-century miracle worker Padmasambhava. It makes fuller use than the other schools of a group of "rediscovered" texts said to have been hidden since the period of Buddhist persecution following the assassination of Ral-pa-can, the third religious king, in the 9th century; the texts began to reappear in the 14th century.

The school divides revelation into nine progressively superior groups and also subdivides the Tantras in a somewhat different manner from the traditional classification. Six groups are enumerated: (1) *kriyā*, or ritual; (2) *upayoga*, convergence of the two truths and meditation on the pentad of Buddhas; (3) *yoga*, the evocation of the god and identification of the self with the god; meditation on the *maṇḍala* (ritual drawing); (4) *mahāyoga*, med-

itation on the factors of human consciousness (*skandhas*) as divine forms; (5) *anuyoga*, secret initiation into the presence of the god and his consort; meditation on the "voidness" in order to destroy the illusoriness of things; (6) *atiyoga*, meditation on the union of the god and his consort, leading to the experience of bliss. Those initiated into the *kriyātantra* can attain Buddhahood after seven lives; the *upayoga*, five lives; the *yoga*, three lives; the *mahāyoga* in the next existence; the *anuyoga* at death; and the *atiyoga* in the present existence.

Jo-nang-pa. The Jo-nang-pa takes its name from the Jo-nang monastery founded by Shes-rab rgyal-mtshan (1292–1361), whose master had been a disciple of Candranātha, a Kashmiri. The school reflects the direction taken by Indian Buddhism during its last centuries; and in the formulation of its doctrine of emptiness suggests possible parallels, however indirect, with the Hindu schools of Śaivism and Vedāntic philosophy. As a consequence, it was considered heterodox by the other schools, and its monasteries were forced to close. The Jo-nang-pa assert that the only reality is the *tathāgata-garbha* (the Matrix of the Buddhas) present in each person. Things are empty: he who meditates and that on which he meditates are but the luminous mind element, essentiality itself. To talk of the fruit of meditation is only a way of speaking, for the effect is already inherent in the cause. Blemishes are illusory appearances. Liberation is not a new situation but rather the liberation of essentiality from such blemishes. The *tathāgata-garbha* is emptiness itself; in other words, it is devoid of all that is other than itself. In fact, if the blemishes were inherent in the mind element, they could not be cancelled, for the mind element would disappear with the cancellation of the blemishes.

The *tathāgata-garbha*

Gcod-pa. The Gcod ("cut off") rite and school developed out of Zhi-byed-pa, brought to Tibet from India in the 11th century by Pha-dam-pa Sangs-rgyas. It assumes that the dichotomous process by which thoughts flow keeps man away from awareness of "voidness." All opposites, good and evil, life and death, must therefore be cancelled through the symbolic sacrifice of the body. This is accomplished by meditations performed at night in cemeteries or in places where corpses are exposed. The practitioners of Gcod conjure up imagined demons until they are able to bring before themselves the terrible-appearing forms of Tibetan iconography. Then the practitioners eliminate the demons by reabsorbing them in the heart, thus demonstrating their nonexistence.

Dge-lugs-pa. The Dge-lugs-pa (Gelugpa, the Virtuous) constitute the reformed sect in Tibet; its members are commonly known as Yellow Hats from the colour of their head cover. Their founder, Tsong-kha-pa, attended the most important schools in 14th-century Tibet, the Sa-skya-pa, Bka'-brgyud-pa, and Bka'-gdams-pa. His own school is considered the continuation of the Bka'-gdams-pa. Tsong-kha-pa was prompted to initiate the reform of monastic discipline by what he considered to be a general laxity of morals, an increasingly less rigorous observance of monastic rules, and the prevalence of deviations in the interpretation of the Tantras. He imposed respect for the traditional rules of the Vinaya and placed renewed emphasis on dogmatics and on logic as aids to salvation. His treatise, the *Lam-rim chen-mo* ("The Great Gradual Path"), is based on the *Bodhipathapradīpa* by Atīśa. In it Tsong-kha-pa presents the process of mental purification leading to victory, ascending through the 10 spiritual levels (*bhūmi*) to Buddhahood. The essential points of such a process are the state of quiescence and the state of enhanced vision. Tsong-kha-pa attributed great importance to the study of logic and instituted the regular holdings of debates at monasteries. Competing monks sought to reach, by means of formal logic and in the presence of an abbot of great learning, an unassailable conclusion on a chosen topic. Various ranks of monks were established on the basis of examinations, the highest being that of *dge-bshes* (the philosophers).

Tsong-kha-pa's account of the stages of the path

This insistence on doctrinal and logical problems did not exclude interest in the Tantras, and Tsong-kha-pa's *Sngags-rim chen-mo* ("The Great Gradual Tantric Path") deals with Tantric ritual. The Tantric schools, however, were open only to those students who had previously mastered theoretical learning. The literature of the Dge-lugs-pa is enormous, including also the gigantic collections of the Dalai and Panchen Lamas, both of whom are members of this school.

The Dge-lugs-pa assert that the nature of the mind element (*sems*) is light, which constitutes the cognitive capacity. The continuum of each person, therefore, is a thinking and luminous energy, which is in either a coarse or subtle state, the latter state achieved only after purification through meditation and contemplation.

SHINGON

Shingon (Chinese Chen-yen) or True Word Buddhism is an esoteric Sino-Japanese school that derives its name from the Japanese term for *mantra* (Sanskrit; a mystical doctrine or formula; hence, Mantrayāna). This school, which flourished most prominently in Japan from the 9th century, when it was introduced by the monk Kūkai, appears to be closely associated with the late (Tantric) form of Mahāyāna Buddhism called Mantrayāna that was transported from India to China in the 7th and 8th centuries notably by three Buddhist monks: Śubhakarasiṃha, Vajrabodhi, and Amoghavajra. Śubhakarasiṃha brought Mantrayāna to China from the famous Indian centre of Buddhist learning at Nālandā and was instrumental in translating into Chinese the *Mahāvairocanasūtra* the most important text of Shingon Buddhism. Soon after Śubhakarasiṃha, a second monk, Vajrabodhi, arrived from Nālandā and translated another important Shingon text, the *Vajraśekhara-sūtra* ("Diamond Peak *sūtra*"). His pupil, Amoghavajra, taught the Chinese monk Hui-kuo, who in turn passed his learning on to Kūkai, the founder of Shingon in Japan.

Kūkai, better known by his posthumous name Kōbō Daishi (Great Master Who Propagated the *Dharma*), was an exceptional scholar, poet, painter, and calligrapher who early in life wrote a treatise comparing Confucian, Taoist, and Buddhist thought, naming the latter as superior. Although he had trained for government service, he experienced a change of heart and became a Buddhist monk. In pursuit of the pure Buddhist doctrine, he, like many great monks of his time, journeyed to China, where he met the Chen-yen master Hui-kuo, who recognized Kūkai's potentiality and bestowed upon him the esoteric teachings of his school. After the death of Hui-kuo, Kūkai returned to Japan to receive many governmental honours and to establish a monastery on Mt. Kōya as the centre of Shingon Buddhism.

In propagating the teachings of his sect, Kūkai wrote many important texts, including the *Jūjū shinron* ("The Ten Stages of Consciousness") and the *Sokushin-jōbutsugi* ("The Doctrine of Becoming a Buddha with One's Body During One's Earthly Existence"). In the first of these documents, Kūkai presented a theory of the development of the spiritual life of human beings by placing the teachings of Buddhist schools and several other religions into a hierarchical system. Kūkai taught that the first stage of human spiritual development was one in which man is completely controlled by his instincts. In the second stage, which Kūkai identifies with Confucian teachings, man attempts to live a proper moral existence. The third stage is that of Brahmanism and Taoism, where the individual strives for supernatural powers and heavenly rewards. The fourth and fifth stages of spiritual development are taught by the Hīnayāna schools and are characterized by man's striving for self-enlightenment. The next stages, from six to nine, are Mahāyānist paths identified with the teachings of Hossō, Sanron, Tendai, and Kegon, which lead the individual to compassion for others. The zenith of spiritual development is identified by Kūkai with the esoteric teachings of Shingon.

The hierarchy of religions

The Shingon school preached that it possessed the highest and purest doctrine, for its beliefs were not based on the teachings of the historical Buddha Śākyamuni, who expounded the doctrine with limitations of his audience in mind, but on the timeless and immutable teachings of the Buddha in his *dharmakāya*, or cosmic body. This

Buddha, named Mahā-Vairocana, was felt to be beyond all earthly dualism and impurity but at the same instant to be within all things as their Buddha-nature.

In Shingon the realization that one's own Buddha-nature is identical with Mahā-Vairocana is Enlightenment. This Enlightenment, as depicted in the title of Kūkai's treatise mentioned above, can be achieved in this world while possessing a human body. In order to achieve this enlightened state, however, one must be given the secret doctrine of Shingon. The gift of this doctrine is handed down to the aspirant only orally by the Shingon master.

The three ritual mysteries of Shingon

The truth that the master reveals is founded on the three ritual mysteries of the body, speech, and mind. These mysteries invoke the cosmic forces embodied in the form of Buddhas and *bodhisattva*s with which the aspirant identifies until he can become one with Mahā-Vairocana. The mystery of the body involves *mudrā*s: various devotional gestures of the hands and fingers in accordance with the Buddha to be invoked, postures of meditation, and the handling of such sacred instruments as the *vajra* (diamond) and the lotus. The mystery of speech involves the recitation of *dhāraṇi*s or *mantra*s, which are mystical verses and sounds believed to be the essence of the cosmic forces with which one wishes to commune. The mystery of the mind involves yogic contemplation of and absorption in the Buddha Mahā-Vairocana and his attendants.

The aspirant was further helped in his quest to identify his Buddha-nature with the cosmic Buddha by means of two sacred drawings, or *maṇḍala*s, often placed on the Shingon altar. These *maṇḍala*s, believed to contain all the power of the cosmos, were drawn in accordance with the teaching of Hui-kuo that the doctrines of the Buddha Mahā-Vairocana were so deep and abstruse that their meanings could be conveyed only in art. One *maṇḍala*, known as the *vajra-dhātu* (Japanese *kongō-kai*), portrayed the Buddha Mahā-Vairocana sitting upon a white lotus in deep contemplation, surrounded by the Buddhas of the four regions. This symbolized Mahā-Vairocana's indestructible, immutable, or potential aspect. The second *maṇḍala*, the *garbha-dhātu* (Japanese *taizō-kai*) or womb-world, revealed Mahā-Vairocana sitting on a red lotus surrounded by innumerable Buddhas, *bodhisattva*s, and Hindu gods, with consorts. This represents the cosmic Buddha's dynamic manifestation in which he is immanent in everything. Through the correct meditation on these two *maṇḍala*s it was believed that the aspirant would realize the unity beyond the diversity of the world.

The emphasis of Shingon upon ritual, symbolism, and iconography, coupled with the government's praise of Kūkai and the bestowal upon him of the shrine for the protection of the country, led to a great popularity of Shingon among the Japanese. Many people came to use Shingon rites, believed to control the forces of the cosmos, to ward off evil and bring supernatural help in everyday life. The popularity of Shingon was one of the causes for the growth of Ryōbu Shintō (Two Aspects Shintō), which identified Shintō gods with *bodhisattvas*. While this combination of more this-worldly concerns with esoteric Buddhism led to some schisms in Shingon, it has continued in the 20th century as one of Japan's strongest Buddhist sects.

V. Practices and institutions

ETHICS

Buddhist ethics from the beginning have been committed to the middle way between asceticism and hedonism that was announced in the noble Eightfold Path. In affirming the Threefold Refuge in the Buddha, *dharma*, and *saṅgha*, the Buddhist adherent commits himself to achieving a certain way of life, to which the Buddha pointed the way.

The ten precepts

Although Buddhism on the whole eschews mandatory dogmas and specific injunctions to which the adherent must conform, there are traditional precepts that list the obligations or moralities (*śīla*s) to be observed. The five precepts (*pañca-śīla*) for the layman prohibit killing, stealing, engaging in sexual misconduct, lying, and drinking intoxicating liquor. There are five additional precepts for monastic novices and laity committed to this stricter regime: not to eat during prohibited hours; not to take part in festivals and amusements; not to use garlands, perfumes, or ointments; not to use a bed (or chair) that is too large or luxurious; not to accept money (for oneself). Taken together, these comprise the ten precepts (*dasa-śīla*). In many, but not all, traditions, the injunction against sexual misconduct has been interpreted as enjoining celibacy for monks and nuns. Although Buddhism distinguishes between non-Buddhists, members of the *saṅgha*, and lay devotees, there is no distinction of caste, social class, or ethnic origin.

By emphasizing the obligatory nature of charity, hospitality, and love for every living being, Buddhism revalues ethics as the foundation of society. The *Dhammapada*, a popular ethical text, states, "Abstention from sin, doing good works, and purifying one's mind, this is the teaching of Buddhism," and, furthermore: "One does not repay evil with evil, but one repays evil with good." The fact that no distinction is made among men except on spiritual grounds and that, among the essential virtues, one finds love, compassion, joy, and equanimity for all that which is good—all this makes for deep human warmth. Buddhism is characterized by an acute psychological sense, which acknowledges that men are not all capable of understanding the law in the same manner, hence the necessity for the masters or the preachers (*dharma-bhāṇaka*) to adapt themselves to the moral and intellectual preparation or capacity of the person to whom they are speaking. Education cannot be a single and generic teaching but rather a gradual, individual process. Perfection is attained not through an instant flash but through continuous exercise and example; hence the necessity for spending time with helpful persons who can cooperate toward the aspirant's internal purification. Obstinate attachment to a single point of view, whether good or bad, is to be avoided. Conformism of any kind is an obstacle to serenity of spirit.

Triumph of the ethical over the metaphysical emphasis

India has often been suffocated by the metaphysics that sees everything as illusion; for in illusion one runs the risk of no longer caring either for good or for evil. Some might say that this danger also threatened Mahāyāna when it asserted that everything is "voidness," that there is neither good nor bad. Mahāyāna, however, even in its metaphysical flights, did not fall short of the ethical values of ancient Buddhism. On the contrary, it enlarged the horizons of Buddhism by stressing the importance of the *bodhisattva* state as the ultimate ideal for men in this life, foregoing Buddhahood for the time being. This implied the renunciation of extinction in the Nirvāṇa in order to stay in life for the purpose of serving as an example to others, to spread the word of the Buddha, to sacrifice oneself for the triumph of the law, that is, for the happiness of everyone. Thus, there is emphasis on the value of sympathy (*maitrī*), of compassion (*karūṇa*), and of joyful participation (*muditā*) in the good performed by others, an ideal of love and fellowship toward every living being, to which the past lives of the Buddha (as told in the *Jātaka* tales) serve as an incentive. Admittedly, the exaltation of the acts of heroism and charity of the *bodhisattva*s ran the risk of provoking a momentary ardour without its thereby being translated into continuous everyday practice. Nevertheless, the ideal capacity of transferring the merit of one's own actions for the benefit of others is a brake to egoism, especially self-serving spiritual egoism, and stimulates fellow feeling.

Social ethics and good works

The gift and the sacrifice remain always at the top of the ten "perfections." A gift does not only mean charity; it is primarily the gift of the law, that is, the teaching of the law for everyone's benefit. From the time of Aśoka, Buddhists have been promoters of works destined to the common good: construction of wells, irrigation projects, bridges, hospitals, shelters for both men and animals. In fact, Buddhism extends its solidarity also to wild animals, since they also participate in the nature of the Buddha. This was not a new principle in India, where the injunction against harming any form of life (*ahiṃsā*) is an ancient norm; but Buddhism conferred upon it a greater extension. Also pre-eminent is another "perfection," the moral energy (*vīrya*), the unshakable tenacity, the active

responsibility, the courage of one's own ideas, and the perseverance to struggle for the common good.

All of this tends to develop in the faithful a spirit of social cooperation and active participation in society, fostered by the *saṅgha*, which radiates upon all people the benefit of its prayers. The monasteries traditionally have been centres of education and medical service for laymen. The teaching inculcates the fear of the consequences of sin and stimulates the imitation of ideals of humaneness or of compassion. The Buddhist is required to be always alert and aware of what he does, thinks, and says because sin is threefold: physical, mental, and verbal. Although he is solicitous of his own salvation, he cannot isolate himself from the infinite crowd of converts and those who can be converted. Thus, the sense of human solidarity is strengthened. Both men and women participate in the Buddhist society.

A certain laxity did not fail to manifest itself when the certainty of the maturation of *karman* became weak in people's minds. Among the devotional and Tantric schools the confidence that with prayers, hymns, and liturgies man could purify himself from the evil he committed stifled the old moral rigour. The devotee dreamed of redemptions instead of the strict and implacable law of *karman* and was also able to abdicate the responsibilities with which it had been invested by the Buddha.

Relaxations of the "moralities"

In this new dispensation, the use of meat and alcoholic beverages (in former times strictly forbidden) was tolerated. It was normal for some Tantric monks to cohabitate with women who were not their wives, but this can not be considered a relaxation of moral standards; the Tantric adept was no longer bound by common morality, and in any case the sexual act was undergone as a ritual act with symbolic meaning, not for the pleasures of the senses. According to the new rules one might even kill when it became necessary, not for personal advantage, but to prevent a sinner from committing other crimes and thus render his own *karman* heavier. This authorized Buddhists to resort to weapons when the community was threatened. The monasteries themselves became great economic and political powers and waged war against one another (in Tibet and Japan). The assertion of one's own individuality inspires the anticonformism of Ch'an (Zen), which is supreme freedom. Without the authority of a god to command man to be good, and without even the future lure of reward after death (the *bodhisattva* renounces immediate participation in Nirvāṇa in order to bring salvation to others), Buddhism places an autonomous value on one's actions. The good is good for its own sake. Above all, the ever-present thought of death, the certainty of the common misery, and the awareness that everything will unfailingly pass away have induced in the hearts of Buddhists a serenity of spirit (see also BUDDHIST PHILOSOPHY: *Buddhist Ethics*).

MONASTIC INSTITUTIONS

Traditionally, Buddhists have expressed their faith by taking refuge in the Buddha, in his teachings (*dharma*), and in the *saṅgha*. The *saṅgha* is the assembly of Buddhist monks that has, from the origins of Buddhism, authoritatively studied, taught, and preserved the teachings of the Buddha. In their communities monks have served the laity through example and, as directed by the Buddha, through the teachings of morality (*śīla*). In exchange for their service the monks have received support from the laity, who thereby earn merit. Besides serving as the centre of Buddhist propaganda and learning, the monastery offers the monk an opportunity to live apart from worldly concerns, a situation that has usually been believed necessary or at least advisable in order to follow strictly the path of the Buddha to release.

The origin and development of the saṅgha. According to scholars of early Buddhism, at the time of the Buddha in northeastern India there existed numerous religous mendicants or almsmen who wandered and begged individually or in groups. These men had forsaken the life of a houseowner and the attachment with worldly affairs that this involves in order to seek a doctrine that would meaningfully explain life and offer salvation. When such a seeker met someone who seemed to offer such a salvatory message, he would accept him as a teacher (guru) and wander with him. The situation of these mendicants is summed up in the greeting with which they met other religious wanderers. This greeting asked, "Under whose guidance have you accepted religious mendicancy? Who is your master (*sattha*)? Whose *dharma* is agreeable to you?"

The yearly rain retreat

These groups of mendicants that formed around one teacher broke their wanderings during the rainy season (*vassa*) from July through August. At this time they gathered at various rain retreats (*vassavāsa*), usually situated near villages. Here they would beg daily for their few needs and continue their spiritual quest. The Buddha and his followers appear to have been one of the many groups that founded such a yearly rain retreat. After the Buddha's death, however, his followers did not separate but continued to wander and enjoy the rain retreat together. In their retreats the followers of the Buddha's doctrines probably built their own huts and lived separately, but their sense of community with other Buddhists led them to gather fortnightly at the time of the full and new moons to recite the *Pātimokkha* or assertion of their faith in the Buddha's *dharma*. This ceremony, in which the laity also participated, was called the *uposatha*.

Within the first several centuries of the Buddha's death, the rain retreats were forsaken for permanent monastic settlements (*vihāras*). There appear to be two major reasons for this change in the mode of living. First, the followers of the Buddha were able, through their confession of a common faith, to build up a certain coherent organization. Secondly, the laity gave meritorious gifts of land and raised buildings in which the followers of the Buddha might live permanently, assured of a supply of the staples of life and also fulfilling the Buddha's directive to minister to the laity. In this manner small *vihāras* were raised in northeastern India, where Buddhism remained a rather parochial sect of monks and laymen until the rise of the Mauryan empire and the reign of King Aśoka around 250 BC. This king, who controlled or was honoured in much of India, was a follower of the Buddha's doctrine, and Aśoka's active help and prestige gave Buddhism a more universal perspective.

From the practice of a few monks living together, sometimes in hillside caves, there developed in about the 5th century AD *mahāvihāras*, or great monasteries, serving as universities, such as Nālandā. These universities served as centres of Buddhist learning and propaganda, drawing monks from China and Tibet and sending forth missionaries to these lands. These institutions were open to the outside influence of a resurgent Hinduism, however, which is one of the factors that weakened Buddhism and led to its disappearance from India in the 13th century.

The monks that such *mahāvihāras* attracted and sent out spread Buddhist monasticism to Southeast Asia, Tibet, China, and Japan. While the new environments led to architectural changes, including such minor ones as the introduction of new guardian deities derived from the indigenous folklore, and major changes such as the meditational hall or the hall for the recitation of the name of Amida serving Ch'an (Zen) and Pure Land monks, respectively, the monasteries continued to serve as (1) centres of missions and learning and (2) as retreats. These are the two important functions of monasteries throughout the Buddhist world. It should be noted, however, that in China there are two distinct types of monasteries: the large public monasteries and the small hereditary institutions. The former, populated by only 5 percent of the monks in China, are orthodox institutions following rules that are essentially the same as Buddhist monasteries in other lands. The hereditary monasteries serve the rural area and on the average are manned by only five monks. They are hereditary institutions in the sense that the abbot of the small monastery adopts a monk who inherits the endowment and responsibilities of the monastery.

Continuing functions of the monasteries

Internal organization of the saṅgha. The development of the *saṅgha* from a group of wandering mendicants

loosely bound together by their faith in the Buddha and his teachings, to monks living closely together in a permanent monastery necessitated the development of rules and a degree of hierarchical organization. It appears that the earliest organization within Indian monasteries was democratic in nature. This democratic nature arose from two important historical factors. First, the Buddha did not, as was the custom among the teachers of his time, designate a human successor. Instead, the Buddha taught that each monk should strive to follow the path that he had preached. This decision of the Buddha placed every monk on the same footing. There could be no absolute authority vested in one person, for the authority was the *dharma* of the Buddha. Secondly, the region in which Buddhism arose was noted for a system of tribal democracy, or republicanism. When a serious question demanded attention in the region, the male inhabitants would meet to decide upon a course of action, often electing a temporary ruler. This republican tradition, which supported the anti-authoritarian nature of the Buddha's teaching, was adopted by the early *saṅgha*.

Democracy and hierarchy in the *saṅgha*

When an issue arose, all the monks of the monastery assembled. The issue was put before the body of monks and discussed. If any solution was forthcoming, it had to be read three times, with silence signifying acceptance. If there was debate, a vote might be taken or the issue referred to committee or the arbitration of the elders of a neighboring monastery. As the *saṅgha* developed, a certain division of labour and hierarchical administration was adopted. The abbot became the head of this administrative hierarchy and was vested with almost unlimited powers over monastic affairs. The anti-authoritarian character of Buddhism, however, continued to assert itself. In China, for instance, the abbot continued to refer all important questions to the assembled monks, who have elected him as their leader. Similarly, in Southeast Asian countries Buddhism shows a great dislike for hierarchy, making rules difficult to enforce in the numerous almost independent monastic units.

As the Buddhist *saṅgha* developed, specific rules and rites were enacted that differ very little in all Buddhist monasteries even today. The rules by which the monks are judged and the punishments that should be assessed are found in the Vinaya texts (Vinaya literally means "That Which Leads"). The *Vinaya Piṭaka* of the Theravāda canon, which is the most complete of the various Buddhist schools, contains precepts that were supposedly given by the Buddha as he judged a particular situation. While in the majority of cases the Buddha's authorship can be doubted, the attempt is made to refer all authority to the Buddha and not to one of his disciples. The heart of the Vinaya texts is the *Pātimokkha*, originally a statement of faith, which, in the course of the *saṅgha*'s development, became a list of monastic rules. The rules are recited by the assembled monks every fortnight, with a pause after each one, so that any monk who has transgressed this rule may confess and receive his punishment. While the number of rules in the *Pātimokkha* differs in the various schools, with 227, 250, and 253, respectively in the Pāli, Chinese, and Tibetan canons, the rules are essentially the same. The first part of the *Pātimokkha* deals with the four gravest sins, which necessarily lead to expulsion from the monastery. They are sexual intercourse, theft, murder, and exaggeration of one's miraculous powers. The other rules, in seven sections, deal with transgressions of a lesser nature, such as drinking or lying.

The novice's way

In the Theravāda countries—Ceylon (modern Sri Lanka), Burma, Thailand, and Cambodia—the Buddhist community is composed of monks (*bhikṣus*) and nuns (*bhikṣuṇī*s), male and female novices (*śrāmaṇera*s and *śrāṃanerī*s), and laymen and laywomen (for ceremonies of initiation or ordination, see below *Ceremonies and festivals*). In some Theravādin countries, notably Burma and Thailand, almost every layman must join the monastery for a period of instruction and meditation. Thus, all men in these countries can to a certain extent be considered monks. This increases lay participation in monastic affairs. In the Mahāyānist countries of Tibet and China there is a stage of one year before the aspirant can become a novice. This is a year of probation when the aspirant does not receive tonsure and remains subject to governmental taxation and service, while receiving instructions and performing menial tasks within the monastery. At the end of this one-year probationary period, the aspirant must pass a test, including the recitation of part of a well-known *sūtra*—the length depending upon whether the applicant is male or female—and a discussion on various doctrinal questions. In China, one usually does not progress beyond the novice stage unless he or she is of exceptional character or is affiliated with the government.

According to Vinaya rules, entry into the *saṅgha* is an individual affair, dependent upon the wishes of the individual or his family. In China, however, ordination has often been under the control of the state. During some dynasties, the state conducted the examinations held to determine entry or advancement in the *saṅgha*. Ordination could be obtained not only through such examinations but also by the favour of the emperor or through the purchase of an ordination certificate from the government. This selling of ordination certificates was at times abused by the government in order to fill its treasury.

The life of a Buddhist monk was originally one of wandering, poverty, begging, and strict sexual abstinence. The monks were supposed to live only on alms, to wear clothes made from cloth taken from rubbish heaps, and to possess only three robes, one girdle, an alms bowl, a razor, a needle, and a water strainer used to filter insects from the drinking water (so as not to kill or imbibe them). Most Buddhist schools still stress celibacy, although the Shin sect of Japan has encouraged abolition of the monastic discipline and some Tantric schools have allowed sexual intercourse as symbolic of the attainment of release. Begging, however, has tended in all schools to become merely a symbolic gesture used to teach humility or compassion or to raise funds for special purposes. Also, the growth of large monasteries has often led to compromises on the rule of poverty. While the monk might technically give up his property before entering the monastery—although even this rule is sometimes relaxed—the community of monks might inherit wealth and receive lavish gifts of land. This acquisition of wealth has led at times not only to a certain neglect of the Buddhist monastic ideal but to the attainment of temporal power. This factor, added to the self-governing nature of Buddhist monasteries and the early Buddhist connection with Indian kingship, has encouraged the interaction of the *saṅgha* and the state.

Relaxation of poverty rule

Fujihira—Monkmeyer

Burmese Buddhist monks receiving rice from a laywoman, while making their daily rounds of alms.

The saṅgha and the state. The early Buddhist *saṅgha* in India appears to have been treated by Indian rulers as

a self-governing unit not subject to their power unless it proved subversive or was threatened by internal or external disruption. Aśoka, the Buddhist king whose personal faith and prestige helped Buddhism grow from a regional to a universal religion, appears to have been applying this policy of protection from disruption when he intervened in Buddhist monastic affairs to expel schismatics. He came to be remembered, however, as the Dharmarāja, the great king who protected and propagated the teachings of the Buddha. His was looked upon as a golden age, and in Theravāda countries Aśoka's image as a supporter and sponsor of the faith is used to judge political authority. In general, Buddhism in Theravāda countries is either heavily favoured or officially recognized by the government, so that the golden age of interaction of the government and monks can be viewed as an obtainable goal. The *saṅgha*'s role in this interaction is to preserve the *dharma* and to act as the spiritual guide and model, revealing to the secular power the need for furthering the welfare of the people. While the *saṅgha* and the government appear as two separate structures, there is some intertwining, for monks (often of royal heritage) act as temporal advisers; and the king, as all laymen—at least in Thailand—spends some time in the monastery. It should also be pointed out that Buddhist monastic institutions serve as a link between the rural peoples and the urban elites, helping to unify the various Theravāda countries.

In China, the relationship between the *saṅgha* and the state has fluctuated. At times Buddhism has been seen as a foreign religion, a state within a state or a drain on national resources of men and wealth. This attitude has led to sharp purges of Buddhism and to rules to curb its influence. Some of the rules attempted to limit the number of monks and to guarantee governmental influence in ordination through state examinations and the granting of ordination certificates. Buddhism, however, especially that of the Ch'an school, which taught that a monk must work daily or not eat, survived these rules and purges. At other times, such as during the T'ang dynasty (7th to 10th century AD), Buddhism was considered almost the state religion. The government created a commissioner of religion to earn merits for the state by erecting temples, monasteries, and images in honour of the Buddha.

In Japan from the 10th to the 13th century, monasteries gained great landed wealth and temporal power. They formed large armies of mercenaries and monks that took part in wars with rival religious groups as well as in temporal struggles. In Japan such monastic power waned in the 14th century; but in Tibet, the Dge-lugs-pa order was able to gain such power—mainly through negotiating with the invading Mongols—that its leader, known as the Dalai Lama, became the centre for both religious and secular power. This power lasted from the 17th century until the flight of the Dalai Lama from the Chinese occupation forces in 1959.

CEREMONIES AND FESTIVALS

The religious year. *Uposatha.* The four monthly holy days of ancient Buddhism continue to be observed in the Theravāda countries of Southeast Asia. The *uposatha* days—the new moon and full moon days of each lunar month and the eighth day following the new and full moons—have their origin, according to some scholars, in the fast days that preceded the Vedic-*soma* sacrifices. Laymen and monk alike pay strict attention to the observance of religious laws during the *uposatha* days. Laymen may choose to visit a monastery and to give alms to the monks. The *uposatha* service typically includes the repetition of the precepts, offering of flowers to the Buddha image, the recitation of Pāli *sutta*s, and a sermon by one of the monks for the benefit of the visitors. The more pious laymen may vow to observe the eight precepts for the duration of the *uposatha*. These are the five precepts normally observed by all Buddhists—not to kill, steal, lie, take intoxicants, or commit sexual offenses—upgraded to include complete sexual continence, plus injunctions against eating food after noon, attending entertainments or wearing bodily adornments, and sleeping on a luxurious bed. The monks observe the *uposatha* days by assembling in pairs for mutual confession of sins and by listening to the recitation by one of their members of the *Pātimokkha*, or rules of conduct, contained in the *Vinaya Piṭaka*.

Anniversaries. The three major events of the Buddha's life—his birth, Enlightenment, and entrance into final Nirvāṇa (*i.e.*, death)—are invariably commemorated in all Buddhist countries but not everywhere on the same day. In the Theravāda countries the three events are all observed together on Vesak, the full moon day of the sixth lunar month (Vaiśākha), which usually occurs in April. (The Māgha Pūjā takes place three months earlier—on the full moon of February—and celebrates the Buddha's first exposition of the *Pātimokkha*.)

Commemorations of Buddha's birth, Enlightenment, and final Nirvāṇa

In Japan and other Mahāyāna countries, the three anniversaries of the Buddha are observed on separate days (the birth April 8, the Enlightenment December 8, and the death February 15). Festival days honouring other Buddhas and *bodhisattva*s of the Mahāyāna tradition are also observed, and considerable emphasis is placed on anniversaries connected with the patriarchs of each sect. Padmasambhava's anniversary, for example, is especially observed by the Rnying-ma-pa sect in Tibet; and the birthday of Nichiren is celebrated by his followers in Japan.

Vassa. The beginning of *vassa*, the three-month, rainy-season retreat from July to October, and its conclusion are two of the major festivals of the year among Theravāda Buddhists, particularly in Burma, Cambodia, Thailand, and Laos. The retreat has largely been given up by Mahāyāna Buddhists. It is an accepted practice in countries such as Thailand for a layman to take monastic vows for the *vassa* period and then to return to his lay life. Commonly, the number of years a monk has spent in monastic life is expressed by counting up the number of *vassa*s he has observed.

The end of *vassa* is marked by joyous celebration. The month following is a major occasion for presenting gifts to monks and acquiring the consequent merit. The *kaṭhina*, or robe-offering ceremony, is a public event during this period and usually involves a collective effort by a village or group of villages to bestow gifts on an entire monastery. A public feast and display of the robes and other presents on a "wishing-tree" are the usual components of the ceremony. The *kaṭhina* season is climaxed by the making and presentation of the *mahākaṭhina* ("great robe"), a particularly meritorious gift that requires the cooperation of a number of people, for the entire operation of producing the robe—from symbolically spinning the thread to stitching the cloth—is supposed to be completed in a single day and night. The robe commemorates the act of the Buddha's mother, who on hearing that he was about to renounce worldly life, wove his first mendicant robes in one night.

All Souls festival. The importance of the virtues of filial piety and the reverence of ancestors in China and Japan has established Ullambana, or All Souls Day, as one of the major Buddhist festivals in those countries. In China, worshippers in Buddhist temples make "boats of the law" (*fa-ch'uan*) out of paper, some very large, which are then burned in the evening. The purpose of the celebration is twofold: to remember the dead and to free and let ascend to heaven the *preta*. The *preta* are the spirits of those who died as a result of an accident or a drowning and as a consequence were never buried; their presence among men is thought to be dangerous. Under the guidance of Buddhist temples, societies (*hui*, *Yu-lan-hui*) are formed to carry out ceremonies for the *preta*—lanterns are lit, monks are invited to recite sacred verses, and offerings of fruit are presented. An 8th-century Indian monk, Amoghavajra, is said to have introduced the ceremony into China, from where it was transmitted to Japan. During the Japanese festival of Bon, two altars are constructed, one to make offerings to the spirits of dead ancestors and the other to the souls of those dead who have no peace. Invocations to Amida and Odori-nembutsu (the chanting of invocations accompanied by dancing and singing) are features of the Bon celebrations.

Remembrance of the dead and liberation of the unquiet spirits

Popular traditions. *New Year's and harvest festivals.* The New Year's festival—like the harvest festival, funeral rites, and exorcistic ceremonies—is an example of Buddhism's involvement in pre-existing local traditions. On the occasion of the New Year, images of the Buddha are in some countries taken in procession through the streets. Worshippers visit Buddhist sanctuaries and circumambulate the *stūpa*, or sacred image, and monks are fed and presented gifts. One of the most remarkable examples of the absorption of local custom was the Smonlam festival in Tibet, celebrated on a large scale in Lhasa until the beginning of Chinese Communist rule in the 1950s. The festival was instituted in 1408 by Tsong-kha-pa, the founder of the predominant Dge-lugs-pa sect, who transformed an old custom into a Buddhist festivity. Smonlam took place at the beginning of the winter thaw, when caravans began to set out once again and the hunting season was resumed. The observances included exorcistic ceremonies, performed privately within each family to remove evil forces lying in wait for individuals as well as for the community as a whole, and propitiatory rites, performed to ward off evil such as droughts, epidemics, or hail, during the coming year. During the more public propitiatory rites, the *saṅgha* cooperated with the laity by invoking the merciful forces that watch over good order; and processions, fireworks, and various amusements created an atmosphere of hopefulness. Through the collaboration of the monastic community and the laymen, a general reserve of good *karman* was accumulated to see everyone through the dangerous moment of passage from the old year to the new.

The harvest festival celebrated in the Tibetan villages during the eighth lunar month was quite different in nature from the New Year ceremonies. Most commonly, offerings of thanks were made to local deities in rites that were only externally Buddhist. The same interplay between Buddhism and folk tradition is observable elsewhere. In Sri Lanka at harvest time, for example, there is a "first fruits" ceremony that entails offering the Buddha a large bowl of milk and rice.

An integral part of the harvest celebrations in many Buddhist countries is the sacred performance of an episode in the life of a Buddha or a *bodhisattva*. In Tibet, troupes of actors specialize in performances of Buddhist legends. In Thailand, the recitation of the story of Phra Wes (Sanskrit Viśvāntara) constitutes one of the most important festival events of the agricultural calendar.

Pilgrimages. Many local temples have their own festivals, associated with a relic enshrined there or an event in the life of a sacred figure. Some of these, such as the display of the tooth relic at Kandy, Sri Lanka, are occasions for great celebrations, attracting many pilgrims. Other favourite pilgrimage sites are the Buddha's birthplace at Lumbinī in Nepal; the spot where he achieved Enlightenment, at Bodh Gayā, Bihār state; where he preached his first sermon "setting in motion the wheels of the law" at Sārnāth, near Vārānasi; and the site of his death, at Kuśinagara, near Gorakhpur, Uttar Pradesh. In China, each of the four sacred mountains—O-mei, Wu-t'ai, P'u-t'o, and Chiu-hua—is dedicated to a different *bodhisattva*, whose temples and monasteries are located on the mountainside. Pilgrimages to distant shrines are often undertaken in fulfillment of a vow, as for example after recovery from an illness.

Passage rites. *Ordination.* Admission to the *saṅgha* involves two distinct acts, *pabbajjā*, *pravrajyā*, which consists of renunciation of secular life and acceptance of monasticism as a novice (*sāmaṇera*, *śrāmaṇera*) and *upasaṃpadā*, the official consecration as a monk (*bhikkhu*, *bhikṣu*). The evolution of the procedure is not entirely clear; in early times, the two acts probably occurred at the same time. Subsequently, the Vinaya established that *upasaṃpadā*, or full acceptance into the monastic community, should not occur before the age of 20, which, if the *pravrajyā*, ceremony took place as early as the age of 8, would mean after 12 years of training. Ordination could not occur without the permission of the aspirant's parents. The initial Pāli formula was *ehi bhikkhu*, "Come, O monk!"

The rite established in ancient Buddhism remains essentially the same in the Theravāda tradition. To be accepted, the postulant shaves his hair and beard and dons the yellow robes of the monk, leaving his right shoulder uncovered. He bows to the abbot or senior monk, to whom he makes his petition for admittance, and then seats himself with legs crossed and hands folded, pronouncing three times the formula of the Triple Refuge ("I take refuge in the Buddha, I take refuge in the *dharma*, I take refuge in the *saṅgha*.") He repeats after the officiating monk the Ten Precepts, and vows to observe them. Thereafter, in the presence of at least 10 monks (fewer in some cases) the postulant is questioned in detail by the abbot—as to the name of the master under whom he studied, whether he is free of faults and defects that would prevent his admission, has committed any infamous sins, is diseased, mutilated, or in debt. The abbot, when satisfied, thrice proposes acceptance of the petition; the chapter's silence signifies consent. The ceremony is basically the same for ordination as a nun.

The *Upasaṃpadā* rite

Bodhisattva vows. In Mahāyāna Buddhism, new rituals were added onto the ceremony of ordination prescribed by the Pāli Vinaya. The declaration of the Triple Refuge is as central an assertion as ever, but special emphasis is placed on the candidate's intention to achieve Enlightenment and his undertaking of the vow (*praṇidhāna*) to become a *bodhisattva*. Five monks are required for the ordination: the head monk, one who guards the ceremony (*karmācārya*), a master of secrets (the esoteric teachings, such as *mantra*s), and two assisting officiants.

Abhiṣeka. The esoteric content of Vajrayāna tradition requires a more complex ceremony of consecration. In addition to the other ordination rites, preparatory study, and training in Yoga, the Tantric neophyte receive *abhiṣeka* (literally, "sprinkling," of water). This initiation takes several forms, each of which has its own corresponding "wisdom" (*vidyā*), rituals, esoteric formulas, and one of the five Buddhas of the supreme pentad. The initiate meditates on the *vajra* ("thunderbolt") as a symbol of Vajrasattva Buddha (the Admantine Being), on the bell as a symbol of the void, and on the *mudrā* (ritual gesture) as "seal." The intent of the initiation ceremony is to produce an experience that anticipates the moment of death. The candidate emerges reborn as a new being, a state marked by his receipt of a new name.

Tonsure ceremony. In some Theravāda countries, such as Burma and Thailand, the first part of the ordination into the monastic community, the *pabbajjā*, is an experience normally undergone by every male child and constitutes, in effect, the principal rite of passage into adulthood. The ceremony generally takes place at puberty, from about the age of eight onward. In commemoration of Śākyamuni's renunciation of his princely heritage, the child is first dressed in rich garments. Then, after a ritual bath, he puts on monastic garb and his head is shaved. After the ceremony he spends some time in a monastery receiving religious instruction and leading the life of a novice; then he returns to his parents' home and his regular education.

Funeral rites. The origin of the Buddhist funeral observances can be traced back to Indian customs. The cremation of the body of the Buddha and the subsequent distribution of his ashes are told in the *Mahāparinibbāna Sutta* ("Sūtra on the Great Final Deliverance"). The early Chinese travellers, such as Fa-hsien, described cremations of venerable monks. After cremation, the ashes and bones of the monk were collected and a *stūpa* built over them. That this custom was widely observed is evident from the large number of *stūpa*s found near monasteries.

With less pomp, cremation is also used for ordinary monks and laymen, though not universally. In Sri Lanka, for example, burial is the more usual method. In Tibet also, because of the scarcity of wood, cremation is rare. The bodies of great lamas, such as the Dalai and Panchen Lamas, are placed in rich *stūpa*s in attitudes of meditation, while lay corpses are exposed in remote places to be devoured by vultures and wild animals.

Buddhists generally agree that the thoughts held by a person at the moment of death are of essential signifi-

Beliefs about the state and journey of the dead

cance. For this reason, sacred texts are read to the dying man to prepare his mind for the moment of death or to the newly dead, since the conscious principle is thought to remain in the body for about three days following death. In Tibetan, Mongolian, and Chinese lamaseries, a lama recites the famous *Bardo Thödrol* (commonly referred to in English as *The Tibetan Book of the Dead*).

The dead are believed to experience the supreme void as pure, colourless light. If the dead cannot retain that realization and thus secure release from rebirth, the second most desirable state is rebirth in the paradise of Amitābha. Accordingly, officiating monks invoke the mercy of Amitābha Buddha and of his assistant, the compassionate *bodhisattva*, Avalokiteśvara. Another book frequently read during funeral ceremonies is the *Bhaiṣajya-guru-vaiḍūrya-prabhāsa*, which expounds the 12 vows made by the Buddha in his previous lives to come to the aid of suffering creatures. Those who honour the vows for a year and three months and follow the precepts of the book are thought to be reborn in the paradise of Amitābha. At the moment of death eight *bodhisattva*s will come to show the dead the way, or Amitābha himself may descend from his Pure Land and come to meet the dead who have invoked him sincerely. The event is frequently depicted in Chinese, Japanese, and Tibetan iconography.

Protective rites. Buddhism does not exclude, even in the Theravāda, exorcistic and magical rites. In South Asian countries, notably Sri Lanka, a monk is frequently called in during crises such as a serious illness or death to recite the *Parittas*. These consist of various verses, any one of which is considered to be efficacious in providing protection against a variety of dangers, by instilling in the minds of the listeners a suitably calm state. At least one of the spells is alleged to have been given by the Buddha himself—the *Khanda Paritta*, providing protection against snakebite.

SYMBOLISM AND ICONOGRAPHY

The Buddha image. *Aniconic symbols.* In early Buddhist art (prior to the 1st century AD), the Buddha was never represented in human form. On the relief sculptures decorating *stūpa* railings and gateways at Bhārhut and Sāñchī (2nd–1st century BC) his presence was indicated by aniconic (imageless) symbols such as footprints, a throne, the Bo tree under which he achieved Enlightenment, and the *stūpa*, which symbolized his final deliverance, or death. Some symbols, first used to represent the Buddha in a particular event, later continued to symbolize an aspect of his doctrine, *e.g.*, the *dharma-cakra* ("wheel of law"), used to indicate the Buddha's presence in early reliefs depicting his first sermon at Sārnāth (Uttar Pradesh; near Vārānasi), is also used to symbolize his law. Numerous literary references and representations in art attest to the worship of these symbols: the *stūpa-pūjā* was essentially worship (*pūjā*) of the Buddha, inasmuch as the *stūpa* represented the Buddha.

Origin of the human image. The growing popular expressions of devotionalism, encouraged by the *bhakti* (devotional) movements current within Hinduism in the centuries immediately preceding the beginning of the Christian Era, presumably led to a demand for more approachable representations of the Buddha. The earliest images of the Buddha in human form date from the 1st century AD and come from the Gandhāra region (broadly speaking, northwest Pakistan and eastern Afghanistan) and Mathurā (in present-day Uttar Pradesh, India), both areas then under the rule of the Kuṣāṇas, an Indo-Scythian dynasty. Though the question of the origin of the Buddha image has aroused considerable controversy in the past, the evidence now available suggests independent development in the two regions. The Gandhāran sculptors drew upon Greco-Roman models and portrayed the Buddha with a youthful Apollo-like face, sometimes dressed in robes similar to the Roman toga, whereas the Mathurā images were based on prototypes of Indian *yakṣa* (nature deity) images and exhibited a similar sense of inner power, with wide shoulders and legs firmly planted.

The Gandhāra (Greco-Roman) and Mathurā (Indian *yakṣa*) components

The first artists were guided also by the Indian conception of the *mahāpuruṣa*, or "great soul" (one destined to become either a universal teacher or—as in the case of the Buddha—a spiritual teacher). The *lakṣaṇa*s, or "signs" that a *mahāpuruṣa* bore on his body, were enumerated in Indian texts and included features that were adapted by the developing Buddhist iconography. Among these, the *uṣṇīṣa* (protuberance on the top of the cranium), the *ūrṇā* (mole in the middle of the forehead), and symbolic signs on the hands and the feet are the most distinctive.

The Buddha images that came into being at Gandhāra and Mathurā influenced each other, and there gradually developed in the Gupta period (4th–7th century AD) workshop of Mathurā and Sārnāth the classic representation of the Buddha that was to spread throughout the Buddhist world. This shows the Buddha with a serene, inward-looking expression, slightly smiling lips, hair arranged in a series of spiral curls, dressed in a monastic robe most often covering both shoulders, backed by a nimbus and, if seated, generally in a cross-legged posture and on a lotus throne.

Standard forms. The Buddha is depicted standing, sitting, or, less commonly, stretched out on his right side in the position of *parinirvāṇa* (final deliverance; *i.e.*, death). His distinctive hand positions (*mudrā*s) serve to call to mind particular episodes in the life of the Buddha or attitudes expressed by him, the most popular being the preaching of the law (*dharmacakra-mudrā*), the calling of the Earth to witness (*bhūmisparśa-mudrā*), reassurance (*abhaya-mudrā*), meditating (*dhyāna-mudrā*), and gift bestowing (*varada-mudrā*).

In addition to this stylized iconographic image, the Buddha is also represented in narrative scenes. Of these, the events associated with his conception and birth, his Enlightenment, his preaching, and his death are particularly popular. The reliefs of the Gandhāra school drew in great detail upon the Buddha life and legend, as did the reliefs of Amarāvati in southeast India.

Mahāyāna and Vajrayāna elaboration. The various Buddhas of the past were represented in early Indian art by means of their aniconic symbols, particularly the trees associated with each of them. When the figural representation of Śākyamuni Buddha came into being, these other Buddhas also began to be represented. At first there was little to distinguish the image of one Buddha from that of another, but in the course of time each came to be known by specific sets of gestures and symbols. Very similar was the development of the various *bodhisattva* images. The compassionate Avalokiteśvara and the *bodhisattva* of wisdom, Mañjuśrī, were particularly popular; and to them were added a whole pantheon, each distinguished by his own specific attributes, just as Mañjuśrī, who in one of his forms is provided with a book, a sword, and a lion mount.

Bodhisattva images

The movement toward a progressively complex and conventional iconography culminated in medieval Indian art and in the arts of Tibet and Nepal. A fivefold ordering of celestial, or self-born, Buddhas was established and linked to other sets of five. When each of the celestial Buddhas is associated with two *bodhisattva*s, a triad is formed (*e.g.*, the Buddha Amitābha, often shown in the company of the *bodhisattva*s Avalokiteśvara and Mahāsthāmaprāpta). Vajrayāna Buddhism further elaborated upon the idea of associated "families" of Buddhas by including a feminine consort and a pacific and horrific aspect of the various Buddhist divinities.

What appears at first glance to be the product of a feverish and bizarre imagination may be understood rather as symbolic representation of doctrine. An image such as the fierce Vajrabhairava, the terrifying aspect of the *bodhisattva* Mañjuśrī—nine-headed, heavily armed, locked in sexual embrace with his consort while trampling on various creatures underfoot—was not generally intended for the view of the uninitiated. Written commentaries relate its nine faces to nine parts of the scripture, its 34 arms to multiple facets of Enlightenment, its sexual embrace to the union of *upāya* (means), symbolized as male, with *prajñā* (wisdom), symbolized as female. It is an esoteric vocabulary given visual expression.

Architectural forms. Buddhism has three main types of architectural buildings and monuments: the *stūpa*, basically a commemorative relic mound; the *caitya*, a temple enshrining a *stūpa* or an image of the Buddha; and the *vihāra*, or monastery, a residence for monks and, strictly speaking, a secular building. Often, however, *stūpa*s or images are incorporated in the monastery or the monastery complex, thus giving it a sacred character. In Buddhism, large monastic establishments have developed that possess *stūpa*s, *caitya*s, a number of monastic residences, and a variety of other buildings to cater to the needs of a particular monastic community. Sometimes, as at Nālandā (near modern Patna, Bihār state, India), they became great centres of learning.

The stūpa. The *stūpa* is the single most important monument in Buddhism, built to house relics of the Buddha or of his disciples, or to commemorate an event or place in Buddhist legend or history. Sometimes, as at Gilgit (in Jammu) and in Tibet, texts were enshrined in *stūpa*s, so that two "bodies" come together: the *stūpa* as the symbol of the spiritual body of the Buddha and the books as his verbal body.

Structure of the *stūpa*

The *stūpa* consists of a hemispheric cupola resting on a base, encircled by a balustrade that may be intersected by four gateways (*toraṇa*s). On the cupola rests a square railing or boxlike structure (*harmikā*) from which rises a shaft of metal or wood, supporting umbrellas. It may be seen in its most characteristic form at Sānchī, Madhya Pradesh, India (1st century BC–3rd century AD); and with variations is found throughout the Buddhist world.

In Sri Lanka, where it is referred to as *dāgaba* (heart of *garbha* [womb]), the form closely follows the early Indian model. In Burma, the cupola, usually gilded, rests on a steep, high base mounted by stairs. In Thailand, the cupola is often bell-shaped. In Tibet, an important type is the *stūpa* of "many doors" (*sgo-mang*), so called because it has many chapels with frescoes depicting the deities of the various Tantric cycles. The pagodas of China and Japan—derived in part from the storied watch tower and polygonal buildings already known in China and also possibly inspired by Kaniṣka's tall *stūpa* at Peshāwar, with its wooden scaffolding—are essentially turreted *stūpa*s.

The most magnificent example of a later *stūpa* is the monument (*c.* 800 AD) at Borobuḍur, in central Java; the walls of the galleries built for circumambulation are covered with stately bas-reliefs illustrating events from Buddhist scriptures. The structure is a monumental *stūpa* and a huge architectural *maṇḍala* (ritual diagram), containing meditating images of the five celestial Buddhas.

The caitya. A *caitya* originally meant "that worth being looked at"; *i.e.*, "worshipful," and referred to sacred objects such as the Bo tree as well as to *stūpa*s. In time the word came to be applied to sacred buildings or temples generally consisting of a hall containing a sacred object to be worshipped, such as a small *stūpa* or a Buddha image. Sometimes the *caitya* was carved into a cave, as at Ajantā in western India, which has ensured its preservation and has provided a clear idea of the ancient forms.

The vihāra. A monastery (*vihāra, ārāma*) was at first characteristically rectangular or square in plan, with the cells arranged around a large central courtyard. Chapels for images were also provided, and a *stūpa* sometimes placed in the centre of the court, which also served as a place for instruction. In some cases, special units called *dhamma-maṇḍapa* or *dhamma-sālā* ("*dharma*-porch") were built for assemblies prescribed by the disciplinary rules. The basic scheme, which is described in Pāli sources and confirmed by archaeological and documentary findings, was increasingly elaborated and underwent considerable variation in accordance with special needs such as climate or local architectural tradition. Some monasteries were excavated in rock, as at Ajantā and at Tun-huang, in northwestern China. In Tibet, the earliest religious buildings consisted of a rectangular hall, with the statue of the divinity placed at one end on a high pedestal and a *pradakṣiṇā* (circumambulatory) path around it.

As the communities grew to as many as 6,000–7,000 monks, veritable monastic cities developed, with assembly halls, offices for monastery functionaries, and temples, each with its own "secret" chapel for its fierce tutelary deities (*mgon khang*). In China, the monastic compound was walled and oriented to the south, with a great gateway covered by one or more roofs. This gave access to a courtyard in which stood a pagoda (comparable in function to the Indian *stūpa*) with several roofs, tapering to a pinnacle at the top. Beyond was the hall for worship and, further on, outside the "sacred area," the refectory and dormitory. This same architectural style was introduced to Korea and to Japan; the 7th-century Hōryū-ji near Nara in Japan gives a clear idea not only of the Japanese style but also of Chinese architectural models no longer standing.

The Chinese monastic compound

Ritual use of images and other supports of worship. *Image worship.* The Theravāda Pāli canon enjoins three objects of reverence for the Buddhist: relics of the Buddha's person, generally enshrined in the *stūpa;* relics of belongings, such as his alms bowl; and images of his likeness. Worship (*pūjā*) consists of presenting offerings of flowers, incense and light, of bowing down, and (in the case of *stūpa*s) of circumambulation. Worship does not necessarily imply deification of the Buddha but reverence for his teachings and for his example.

In Mahāyāna and Vajrayāna Buddhism, images, enshrined in household altars as well as in temples and monasteries, increased in importance. In the meditational schools concentration on an image of a Buddha or of a *bodhisattva* became a way of realizing spiritual truths, practiced in combination with other meditational supports, such as the *dhāraṇī, mantra, mudrā, sādhana, dhyāna,* and *maṇḍala.*

Dhāraṇī and mantra. A *dhāraṇī* is a short statement of a doctrine that sums up the essential significance of the longer text and serves as an aid to its retention. By means of a *dhāraṇī* an adept symbolically evokes the truth of a revealed text without reciting the whole of it. Though the *dhāraṇī* is, for those capable of spiritual disciplines, primarily an aid to meditation, the *dhāraṇī* serves the common man much as a magical formula, to be worn in a locket as a talisman or inserted in a sacred image to "confer life on it" (in the ceremony of consecration known as *prāṇapratiṣṭhā*). The *dhāraṇī* may sound to the uninitiated like a series of largely unintelligible words—its esoteric meaning is often transmitted directly by a teacher to his pupil.

Aids to meditation and magical formulas or sounds

The *mantra* is an even further reduction of the *dhāraṇī*, sometimes to a single syllable, the *bīja-* ("seed-") *mantra*, which is the representation in sound, just as the image is the visual representation, of the deity invoked. For example, the whole of the *Prajñāpāramitā* literature is ultimately concentrated in the *bīja-mantra* consisting of one syllable, *pram.* Repetition of this syllable, when uttered with the right insight, ritual, and concentration, is considered equivalent to recitation of an entire 8,000-stanza text.

The recitation of *mantra*s plays an important part in the devotional worship of the Pure Land and Nichiren Buddhist sects. In esoteric Buddhism (Tantra and related forms) the *mantra* also implies belief in the mystical efficacy of sound. If pronounced incorrectly or inattentively, the divinity may not be invoked, may not appear before the worshipper, or may even do him harm.

Mudrā. In Vajrayāna Buddhism, the liturgical act, to be efficacious, must include the *mantra,* properly intoned according to the respiratory methods of Yoga, accompanied by the proper symbolic ritual gesture, or *mudrā.* The various meanings of the word *mudrā* include the sense of a "sign" or "seal." The principal *mudrā*s are related to the gestures and attitudes expressed by the Buddhas in the iconographic tradition but have multiplied along with the growth of the Mahāyāna pantheon. Each divinity is invoked by a particular *mudrā* associated with that divinity.

Sādhana. A *sādhana* is a spiritual exercise, a means of attaining an inner mystical state by first evoking a divinity, then realizing an identity with the divinity, thus

Realization of divinity

experiencing the meditator's own divine nature. The *sādhana* texts give specific instructions on how to visualize a particular divinity, such as its colour, pose, ornaments, attributes, and attendants and thus also serve as manuals on iconography for the makers of images. The meditator, after undergoing preparatory rites of purification, commences concentrating until he has an inner vision of the divinity invoked, either in his own heart (the "heart" is a synonym of the void) or appearing before him, according to the specific technique employed. The *sādhanas* are methods of self-suggestion by means of which the meditator—corresponding to the void—emanates from himself the divinities and then reabsorbs them, thus achieving the awareness that all is void. The *sādhanas* differ from the *dhyānas* of meditation, which require the progressive discontinuance of thought and emotion.

Maṇḍala. A *maṇḍala* is a psychocosmogram in which the essence of a Tantric text is represented by syllables or visual symbols. Understanding of a *maṇḍala* requires both initiation and long periods of contemplation, but the spiritually adept gain from the diagram the same significance as from the sacred text. The various types of *maṇḍalas* are all basically ways of representing the projection of the one into the many (the *garbhadhātu*, or "womb-world" *maṇḍala*) or conversely, the many into the one (the *vajradhātu*, or "diamond-world" *maṇḍala*), the two characteristic forms of *maṇḍalas* used in the Shingon sect of Japan. In Tibetan initiation ceremonies *maṇḍalas* are drawn on the floor of the consecration hall with the aid of cords that have been dipped in coloured powders. *Maṇḍalas* are also painted on cloth in Nepal, Tibet, and in Japan as aids of contemplation. In certain instances the body itself may be conceived as a *maṇḍala*, with the heart as its centre, man (the microcosm) thus symbolically identified with the universe (the macrocosm).

Regional variations. As Buddhism spread—in the south by sea to Sri Lanka, Indonesia, and Indochina and in the north by the various land trade routes to Central Asia, Tibet, China, Korea, and Japan—the image of the Buddha and the iconography of other sacred figures remained substantially the same, though the artistic traditions of each country and age produced some modifications, as did the growth of new cults.

Tibet. Many specifically Tibetan aspects of Buddhist symbolism have already been noted. Also of interest is the manner in which local gods and goddesses have been assimilated to Buddhism, for nowhere is this more apparent than in Tibet. There deities of pre-Buddhist (Bon) and of Indian origin were "conquered" by Buddhist priests and pressed into service as "guardians of the doctrine" (*dharmapāla*). They are represented in art as ferocious in appearance, brandishing weapons in multiple hands and dressed in ornaments of skulls and bones taken from vanquished enemies, in keeping with their role as protectors of the faith.

Assimilation of non-Buddhist images

Central Asia. Through Central Asia passed the great caravan routes connecting India with China and western Asia, frequented by merchants and by Buddhist pilgrims, particularly in the period 400 to 700 AD. During the early centuries of the Christian Era, Central Asia was a meeting ground of many diverse religious movements, including Manichaeism and Nestorian Christianity with its Iranian substratum. The Tantric forms of Buddhism never took hold there as they did in Nepal and Tibet, and Central Asian art is generally more serene than the art of those two regions. Along the trade route into China many impressive Buddhist monuments were built, as for example at Bāmiyān (near modern Kābul), where in the 4th–5th century colossal statues of the Buddha were carved out of the rocky cliff. Khotan (a stronghold of Mahāyāna Buddhism) on the southern route, Kucha (the main centre of Hīnayāna) and Turfan on the northern, and Tunhuang, in northwest China at the eastern terminus of both routes, are sites of important monasteries, containing rock-cut sanctuaries embellished with wall painting and sculpture.

East Asia. In China, popular devotion to the Buddha Amitābha (Chinese O-mi-t'o; Japanese Amida) and the hope of rebirth after death in his Sukhāvatī (the Happy Land) gave occasion to many representations of the Buddha and of his Pure Land. The depictions of Amitābha's Pure Land, in wall paintings and in scrolls, are based on passages in the *Sukhāvatīvyūha-sūtra* and *Amitāyurdhyāna-sūtra* that describe the Buddha in the midst of celestial splendour, sitting on a lotus throne, flanked by the *bodhisattvas* who assist him, and surrounded by images of other Buddhas and *bodhisattvas*, palaces, lotus ponds, jewelled trees, and flowers. The Chinese representations of Sukhāvatī exhibit a typically Chinese sense of hierarchy and ordered arrangement. The Tun-huang caves are rich in paintings on this theme, which was popular in Japan also, a notable example being the frescoes in the Hōryū-ji near Nara (unfortunately destroyed by fire in 1949). In Japan, the vision of Amitābha descending from his paradise accompanied by his *bodhisattvas* Avalokiteśvara and Mahāsthāmaprāpta to welcome the newly dead to Sukhāvatī is expressed in a type of painting known as Amida *raigō* ("Amida coming to welcome").

The figure of Kuan-yin in Sino-Japanese art

Amitābha's companion, the *bodhisattva* Avalokiteśvara, became immensely popular in China and Japan as an independent saviour figure. In a process that is not clearly understood by scholars, Kuan-yin, as the *bodhisattva* is known in China (Kannon in Japan), apparently merged with local myths of goddesses and, in the popular mind at least, from about the 11th or 12th century was increasingly conceived as a female figure. A certain ambiguity regarding the sexual representation of the *bodhisattva* is in keeping with the view that a *bodhisattva* has reached a state of perfection that has transcended sexual differentiation, along with all other oppositions of the phenomenal world. Another explanation given in Buddhist scriptures is that the *bodhisattva* has the power to assume whatever identity—male, female or animal—is necessary to relieve suffering.

The Ch'an (Japanese Zen) sect, with its emphasis on direct, intuitive experience, brought a radically different approach to the representation of the Buddha and other sacred figures. A favourite theme was that of Śākyamuni returning from solitude after having given up the ascetic life as a means of achieving Enlightenment. Śākyamuni is shown in a realistic pose far removed from the immobile, inward-looking, meditating icons. In China in the mid-Sung period, Ch'an art developed into the "untrammeled" school of painting, the final result being a free, spontaneous style with which Ch'an found much affinity. The emphasis in Ch'an Buddhism on the direct transmission from master to pupil led to a demand for realistic portraits of the teachers, which were presented to the pupils at the end of their instruction. Such paintings were carried back from China by Japanese monks; and the style was continued in Japan, with the paintings of the patriarchs honoured in the Zen monasteries. This interest in the expression of inner spirituality through an individualized human person is magnificently realized in the carved portrait of Asaṅga (Japanese Mujaku) by the sculptor Unkei in Kōfuku-ji, in Nara.

VI. Buddhism and other Asian religions

BUDDHISM, HINDUISM, AND JAINISM

Buddhism is one branch of the multitudinous variety of Indian religion and speculation. It began in the spiritual excitement (at the time of the Buddha) in a region agitated with religious and speculative ardour and ended by dissolving into Hinduism. The growth of Buddhism was pervaded by a social and human sensibility less developed in other Indian religious and philosophical systems. Its missionary tendencies and direct communication with the people broke the bonds of Brahmanic orthodoxy. It did not sanction caste privileges or social monopolies, and it passed beyond the borders of India. Just as it accepted with unusual tolerance the religious, cultural, and magical traditions of many countries as it spread, it was unable to avoid compromise in India with local cults or to remain apart from the evolution of Indian speculation. There were exchanges of thought between Buddhist and Hindu schools. The Mādhyamika and Yogācāra schools

had a significant influence on Hindu thought. Little by little, however, Buddhism succumbed because it ended up saying the same things as Śivaism and Vedānta, albeit in different terms. It was difficult for many to see how the void was anything but a somewhat different version of the *Paramaśiva*, an undefinable reality that transcended all in its absolute indescribable essence.

The Hinduization of Buddhism

Buddha, from a human teacher, became a supramundane being and multiplied himself in infinite refractions, bringing a symbiosis in both inconographic representation and in the details of symbolism between Śiva and Avalokiteśvara. Tantrism, in both its Hindu and Buddhist forms, shelters the most primitive and ancient gods of Indian religious experience. Mystical experiences, meditational procedures, a common heritage of chants, Yoga (which in the course of time assumed the complex forms of Haṭha Yoga)—these are the basics of various methods of mental purification and exaltation that arouse the secret possibilities latent within. They transmute the indissoluble unity of the psychophysical complex into a new mode of being, so that the body, once considered by mystics of the Hīnayāna and Mahāyāna schools in their meditation on a cadaver to be an impure thing or a burden and obstacle, became in Śaivist and Buddhist schools the means of salvation.

Many of the 84 *siddhas*, "those who have reached what they desired, those who have become perfect," in Tibetan lists also appear in Hindu lists among the greatest masters of esoterism. Like the branches of the Bo tree (*aśvattha*), Buddhism returned to its roots. The masses sought an easier, quicker way to salvation, less speculative and more devotional or magical. Instead of solitary men like the *arahant* or the *bodhisattva*, who required incalculable stretches of time to reach Nirvāṇa, they preferred the immediate, solacing presence of a being, adored and invoked, who would lighten the heavy burden of *karman*—Amitābha, Lokanātha, Avalokiteśvara, Tārā. Man no longer relied on his own powers; there were gods who, if propitiated, would save him.

Mahāyāna separated into a cold dialectic or into devotional or esoteric schools that expressed the same aspirations as those of Hinduism. It took refuge in Nepal and Indonesia and mingled with Tantric cults in which *Śakti* had a notable part, as in the Sahajiyā or among the followers of *Dharma-maṅgal* in Bengal, still found today. When Islām conquered India, Buddhism withdrew into itself and became even more influenced by the current speculative, magical, and Tantric aspirations. Since the liberation of the India-Pakistan subcontinent, many "untouchables" have renounced the old religion that excluded them from civil society and have favoured Theravāda Buddhism because it emphasizes the ethical values that have overcome obsolete cults in post-Gandhian India.

Jainism kept a greater distance from Buddhism, despite its very ancient speculative heritage and common "heretical" past. More archaic, it lacked the mystical anxiety of Mahāyāna Buddhism. According to the Jainas *karman* is a ponderable and measurable element. There is for them no distinction between voluntary and involuntary sin, and above all they believe in the presence in matter of a soul (*jīva*).

BUDDHISM AND ISLAM

Islām pushed aside both Hinduism and Buddhism because they lacked a revealed book. While resisting in Zābulistān the first Arab conquest of Afghanistan, in one of the later Tantras, the *Kālacakra* (Wheel of Time), Buddhism advanced, as an attempt at monotheism, the doctrine of Ādi-Buddha, the Buddha who is above all else. The *Kālacakra* speaks of Mecca and introduces Islāmic formulas into *mantras*. After India was conquered by the Muslims, who extended themselves as far as Bengal, one of the oldest Bengali books, the *Gorakhavijaya*, which deals with the intricacies of Yoga and narrates the life of a celebrated *siddha*, Gorakṣa, was written by ʿAbd-ul-Karīm, a Muslim. Muslims were the authors of many *padyāvalīs*, poems singing the love of Kṛṣṇa and Rādhā. Through the villages there circulated anonymous and apocryphal Tantras, some even attributed to Nāgārjuna, and among the *mantras* and incantations are found Islāmic formulas. Thus for a long time the two religions coexisted in some parts of India. All the same, Buddhism suffered destructions caused by Islām, which knew only the Mahāyāna school with its manifold gods and complicated rituals—things all remote from the Islāmic concept of God. Yet there are instances of encounters between Buddhist soteriology and Islām; *e.g.*, in certain Ismāʿīlī texts such as the *Umm al-kitāb*. In Sri Lanka, Theravāda Buddhism, Islām, Hinduism, and Christianity coexist. This is due in part to the innate tolerance of a Buddhism that sees Buddha, Allah, and Jesus as different manifestations of the same entity.

BUDDHISM AND CHINESE RELIGION

Obstructions to the spread of Buddhism in China

Buddhist proselytism in China was not easy. It met with a millenary culture, a tradition of rationalism, as in Confucianism, a solid social structure, the cult of the family and, at the summit, the authority of the state. And there was Taoism, in its literary and speculative form reserved for the few and in its magical form for the many. Thus, the introduction of Buddhism came about slowly. It was often obstructed by a distinctly different mode of posing thought and expression. At first there were ambiguities and misunderstandings. Taoist and Confucian words were used that had nothing to do with the Buddhist concepts they were to express. Moreover, monastic organization represented a dangerous innovation that withdrew men from the service of the state and had a negative effect on the national wealth. Hesitancy was also caused by the fact that the new religion was foreign, the religion of "barbarians," even though in some circles Lao-tzu and the Buddha were considered identical. The doctrine of *karman* was not comprehensible because the Chinese maintained that after a certain time the soul died. On the other hand, the aspiration toward serenity and peace and the rejection of violence were easily understood by the Taoist masters. The populace, moreover, gave in to the attraction of a gospel that opened new hopes to all in the *bodhisattva* ideal and a way to an easy salvation, as promulgated by the devotional schools. Buddhism gained strength during the 2nd century AD crisis in Confucianism. Buddhism at first remained on the outside, isolated in small communities; but by the 4th century it had brought about a new ferment of ideas in China.

Interplay between Buddhism and Taoism

Translations of Mahāyāna works in the 2nd century had used Taoist expressions for key Buddhist terms, and certain Buddhist schools were formed whose discussions must be understood on the basis of the Taoist lexicon, which carried into the Buddhist camp the problem of the relation between "being" (*yu*) and "nonbeing" (*wu*). Seng-chao (AD 384–414) wrote the *Book of Chao*, an attempt to conciliate between Buddhism and Neo-Taoism. Until the T'ang dynasty, with its greatest flowering of Buddhism in China, Neo-Taoism had remained the basis of speculation; and many masters who converted to Buddhism did not forget the teachings of the Taoist sage Chuang-tzu.

Lu Ch'eng (AD 425–494) showed clearly the fundamental difference between the Indian mentality, inclined toward gradual Enlightenment, and the Chinese disposition to know the truth by intuition, without the meditation of a progressive psychic catharsis. This explains why certain texts celebrated in India and Tibet, such as those on logic, had little diffusion in China. Peculiar Indian philosophic trends were elaborated in China by Paramārtha and of Hsüang-tsang, mainly concerning the *Vijñapti-mātratā-siddhi* of Vasubandhu, which Hsüang-tsang had translated and glossed. During the period in which Buddhism was flourishing, before the great setback of the persecution of 845, there was a fruitful dialogue between Buddhist and traditional Chinese thought, as evident in the Neo-Confucianism of Chu Hsi (1130–1200). At the same time, there were original Chinese contributions to Buddhism, as, for example, in the schools of Ch'an and Hua-yen.

During the Yüan dynasty, 'Phags-pa, the lama of the Sa-skya monastery, introduced the Tibetan form of Buddhism; but seeing that Tantric literature (*i.e.*, the *Hevaj-*

ra) was unsuited to Chinese propensities, he limited himself to sending the Mongol princes short epistles, succinct summaries of the essential Buddhist dogmas.

BUDDHISM AND TIBETAN RELIGION

The native Tibetan religion: Bon

Things were quite different in Tibet. When Buddhism arrived, it did not find a culture deserving of that name. Tibet's conquest of Central Asia and its contact with India, China, and Nepal, however, plus the influx of Buddhist missionaries, created an intellectual fervour that sprouted out of a cultural vacuum. Bon, the native religion of Tibet, was largely magical, a defense against invisible powers present everywhere and harmful if not placated. Every place, every mountain pass was presided over by a spirit: the *klu*, whose abode was water and springs; the *sa-bdag*, ("soil masters"), who abide in the ground; the *btsan*, without fixed abode; or the *lha*, which was usually a sacred mountain from which the ancestral god of the family that dominated the territory had descended to earth or fallen from heaven.

The innate tendency toward magic, of which Bon was the oldest expression; rites that did not exclude the sacrifice of animals and even humans in ancient times; black magic to cause hail to fall on an enemy's field or bring about his death; and the rites of redemption from demonic forces—all these favoured the spread of Tantric texts, especially those in which magic predominated. And yet, the Tibetans, without a cultural heritage, slaves of century-old superstition, suddenly awoke and also translated, comprehended, and explicated the most difficult works of Mahāyāna speculation, carrying on the tradition of the most famous monasteries of India. Tibet represents a genuine case of cultural transplantation that presupposes an uncommon gift for dialectic and speculation, yet the Tibetans added nothing to what they were taught. They were interpreters, explainers, and lucid commentators; but except for the monks, who wrote enormous works, the masses, protected by the sacredness of the *saṅgha*, still lived under the fruitful shadow of local deities that must be propitiated and of evil forces waiting always and everywhere in ambush. Thus converged abstract speculation, formal logic, abstruse dogmatics, magic, and the ineradicable remains of an ancient religion varying from place to place, though always with strong similarities.

BUDDHISM AND JAPANESE RELIGION

The indigenous Japanese religion: Shintō

Japan also did not have any genuine speculation when Buddhism arrived. Shintō was dominant, with its complicated cosmology and theogony, in which the god Izanagi and the goddess Izanami were paramount. They created the island in the ocean, descended to it, married, and produced Amaterasu-Ō-mikami, the great goddess of the radiant sky and the sun. Each thing or being invested with some sacredness was called a *kami*, descending in a scale from Amaterasu to a stone or a worm. The *kami* were generally not represented by icons, only casually by symbols. Instead of a priestly class there were guilds of the "pure" that maintained contact with sacred objects. Others could communicate with the gods and would deliver their oracles to the chieftains.

When Buddhism entered Japan it had to define its relationship to the indigenous religion. The common feature was the magical character that Buddhism attributed to its rites and the reading of sacred texts. Buddhism arrived sporadically in the 4th century through Korean refugees and craftsmen. When the ruler of the Korean kingdom of Paekche sent an image of the Buddha and Buddhist books and monks, along with Confucian texts, in the 6th century, this aroused the opposition of certain powerful families. One ancient family (Soga), however, favoured the new religion.

Its entry became definite in the conversion of Prince Shōtoku Taishi (573–621), who became its chief spokesman and propagator. Three different elements met: the native religion of Shintō, Confucianism, and a Buddhism at first just vaguely comprehended. In the beginning Buddhism was expounded to protect the state and the emperor against calamities and diseases. In the course of time funeral customs changed, the law of *karman* and the possibility of rebirth came to be accepted, the philosophical schools were introduced, and so Buddhism gradually became the principle component of Japanese thought, inspiring art and shaping the spirit, as in Tibet.

Very technical schools such as the Hossō and the Sanron trained the Japanese mind in the subtleties of Mahāyāna literature. At the same time, Shintō found analogues with its magical use of the reading of sacred texts. The aim of protecting persons and things tended to be the same, and thus compromises came about that led to a symbiosis between Shintō and Buddhism.

The *kami* as protectors of the law and manifestations of Buddhas and *bodhisattvas*

To encourage its own acceptance, Buddhism accepted local divinities and made them objects of worship as incarnations of the Buddha or of *bodhisattvas*, Shintō chapels were often found in Buddhist temples; and many *kami* were adopted as protectors of the law. The emperor Shōmu (reigned 724–748) dreamed that the goddess Amaterasu appeared to him and declared that Japan was the land of the gods and all should be venerated, since their nature was the same as Vairocana Buddha's. The *kami* were nothing but the temporal manifestations of the Buddha and the *bodhisattvas*. In 767 an imperial decree proclaimed that the *kami* were guarding the Law of the Buddha, and Buddhist monks were authorized to officiate in Shintō temples along with Shintō priests. This was the beginning of Ryōbu Shintō ("Two Aspects Shintō"). All this led to a closer tie between the state and the various Buddhist sects, which later was broken because of the great power acquired by the monasteries.

The work of assimilation was advanced by Dengyō Daishi, founder of Japanese Tendai, and Kōbō Daishi, the Shingon founder. Before Dengyō founded the Tendai monastery on Mt. Hiei he recognized the Shintō gods as protectors of the temple. Kōbō Daishi strengthened the alliance of the two religions through the esoteric aspect of his school. Basing itself on the twofold division of being and appearance, Shingon advanced a classification of things in two groups, finally arriving at the identification of Amaterasu with Mahā-Vairocana, the cosmic Buddha, which was accepted among the adherents of Shintō.

Along with Confucianism, which was diffused more widely in later periods, Buddhism is obviously one of the leading elements of Japanese thought, so much so that Japan may consider it as its spiritual patrimony.

VII. Buddhism in contemporary Asia

BUDDHISM AND NATIONALIST MOVEMENTS

Buddhism viewed as an egalitarian, democratic, and Socialist force

Buddhism as a political force. Buddhism assumed a significant role in the movements to establish or reassert national independence in modern Asia. In these movements, Buddhism represented the basis of the national culture, notwithstanding the coexistence of certain minority sects, In Burma, where the king had been the protector of the Buddhist *saṅgha*, Buddhism took an active political role in forging the new nationalism, justifying its presence by the claim that it was the custodian of the spiritual and cultural values of the people. For decades it had proclaimed itself as being egalitarian and democratic. In 1913 Anāgārika Dharmapāla, a Buddhist leader from Ceylon (now Sri Lanka), declared that the teaching of the Buddha is primarily social and liberates man from materialistic instincts. Laksmi Narasu, an Indian Buddhist leader, maintained that the Buddha was anti-capitalist. U Nu, an eminent Burmese Buddhist statesman, said that Socialism is a corollary of the social and ethical principles of the Buddha and approved the law nationalizing landholdings. While others were of the opinion that Karl Marx had been influenced by the Buddha, U Ba Swe, another Burmese Buddhist leader, held that Marxism was the relative truth and Buddhism the absolute truth. If capitalism exists it is because man has forgotten the teachings of the Buddha.

Similarly, in Ceylon, the Mahāsaṅghasabhā movement, aiming at a united front of orthodox Buddhists, was a reaction to Western interests and the ruling class, for the most part Catholics or Protestants. Buddhism underwent Socialist and also Marxist influences, and it was even said that Marxism is a page extracted from the book of Buddhism but misinterpreted.

In such (largely Theravāda) places it is argued that Buddhism is a practice and an ethical philosophy more than a religion because it does not worship a god. Śākyamuni is a teacher, even if the masses lacking comprehension honour him as a god. Buddhism regards all men as equal because they are all subject to the same destiny of misery. It seeks to explain what causes misery and the means of liberation from it. In placing among the "Perfections" gifts, charity, and compassion, to be understood as active abnegation and a sense of sympathy for creatures, the Buddha promoted a solidarity that renders one happy by the happiness of others. Thus he had anticipated the modern methods of assistance, aid, and the elimination of social and economic inequalities in a world based on economic relations. Buddhism is not, therefore, a religion derived from a feudal culture (as some Chinese Communist writers have asserted on certain occasions) but stems from the people and works for the people. Arguments such as these, put forth most often in Burma and Ceylon, led Buddhist statesmen such as U Nu and S.W.R.D. Bandaranaike (see below *Ceylon*) to seek accords between Buddhism and Marxism, proclaiming Buddhism as the inalienable spiritual heritage of the country.

Burma. The great diffusion of Theravāda in Burma began at the time of Anawrahta (reigned 1044–1077); it enjoyed the protection of successive kings and its fortunes increased when Burma obtained its independence in 1948. Under Prime Minister U Nu the *saṅgha* was extremely powerful and Buddhism became the state religion (1961). In the following year, when General Ne Win took over the supreme control of the state, Buddhism lost much of its political influence. Ne Win followed a program of moderate socialism aimed at modernizing the country as much as possible. The Buddhists have adapted themselves to the new situation and proclaim the necessity of acting and working for social welfare, not merely in a Burmese or Buddhist society, but for mankind as a whole.

Conflict between state and *saṅgha* in Ceylon

Ceylon. In Ceylon (after 1972, Sri Lanka) the People's United Front, which was supported by those who had received European educations or were non-Buddhists for the most part, was accused of not having taken proper account of Buddhism, a historical reality. When Bandaranaike became prime minister, he included the extreme left party of Gunawardena in the government. He proclaimed Buddhism to be the religion of Ceylon, set up universities on European models, established a ministry for cultural affairs, and proposed the nationalization of schools, hoping to harmonize the needs of modern and traditional instruction. Yet the *saṅgha* perceived in these measures a menace to its power; and groups linked both to financial and monastic interests formed a conspiracy that entrusted a monk with the job of assassinating Bandaranaike, who earlier had actually been considered a *bodhisattva*. He was succeeded by his widow, Sirimavo Bandaranaike, the nationalization of schools was accomplished, and a law was proposed whereby monasteries would not be exempt from taxation, while monks were advised not to participate in political life. Mme Bandaranaike's government fell; but after an interregnum of the United National Party, she was re-elected with a leftist program in 1970. A commission was set up to draft a new constitution and proclaim Ceylon an independent republic; and relations were established with China, North Vietnam, and North Korea.

Thailand. Theravāda Buddhism is the state religion of Thailand. Since the reign of King Chulalongkorn (1873–1910) it has been considered a peaceful means for bringing unity to the country, though in the north tribal groups (Karen, Meo, Lua, Yao, and others) have remained faithful to their ancestral beliefs. The centralized church directs and coordinates the activity of missionaries whose task is to travel about during the dry season, not only to preach the law but also to cooperate in the development of the country and to teach in village schools. The work of the Thammacarik, or Dhammacarika ("pilgrims of the *dhamma*"), is to spread Buddhism among the tribal groups; but they seem to have had little success because of the independent spirit of those tribes.

Interior of the Temple of the Dawn, Thon Buri, Thailand, during Wesak, the festival commemorating the birth, enlightenment, and death of the Buddha.
Ewing Galloway

Presently two sects are found in Thailand: Mahānikāya ("the larger sect") and Dhammayuttika-Nikāya ("sect of the followers of the *dhamma*"). A patriarch is selected by the heads of the two sects; but he is officially named by the king, on the advice of the minister for religious affairs. He is assisted by a cabinet of 10 persons responsible for four bureaus, for the administration of religious property, education, propaganda, and public works, respectively. Thus, the *saṅgha* is state-directed and carries out a social function.

Vietnam, Cambodia, and Laos. Both Mahāyāna and Theravāda are to be found in Vietnam; Mahāyāna is represented by the Thien (Chinese Ch'an) and by the Tin-do sects (followers of Amitābha). While the division between the two sects was formerly strict, in recent years the two have tended to converge under the impact of lay movements that have promoted a kind of Buddhist modernism. This movement started with the Association for the Study of Buddhism founded in 1932 in Saigon and in 1934 in Hue and Hanoi. The new generation was encouraged to take up social work and ultimately to intervene in politics, under the inspiration of the General Buddhist Association for Vietnam, which was established to unite all the various Buddhist associations of Vietnam. After the political division of the country in 1954 there was a split in the Association also; the General Association of Buddhists of Vietnam remained in Saigon while the United Association of Buddhists became its counterpart in Hanoi. These associations also were joined after the death of Ngo Dinh Diem (1963), by the Theravādins (most numerous among the Khmer population). This was the beginning of the United Buddhist Congregation of Vietnam, which had

above it a High Spiritual Institute of Vietnam (Vien Tang Thong) that was responsible for the behaviour of the monks and an Institute for the Expansion of Buddhism (Vien Hao Dao). All of these groups were linked with provincial or local organizations; the two highest monks were alternatively a Mahāyānist and a Theravādin, but this situation came to an end in 1966. Meanwhile, the younger generation, both laymen and monks, had become increasingly involved in politics; they had tried to enlarge the mutual understanding among the sects and to involve Buddhists in social welfare activities. It was at this time, inspired by a Chinese tradition (chiefly connected with the *Saddharmapuṇḍarīka*), that monks began to commit suicide by burning themselves to death. As regards the situation of Buddhism in Hanoi, there is little certain information.

Monastic compounds in Cambodia

In Cambodia, where Theravāda was introduced in ancient times, and which maintained frequent contacts with Ceylon, there are Theravāda centres with monasteries in which Pāli is taught. There are common hermitages for men and women who live in separate cells for periods of variable length, but residence is obligatorily in the rainy season. It is not necessary for all the inhabitants of the monastic compounds to be monks or nuns; many of them are lay persons and practice meditation in a rather elementary way. In 1955 Prince Norodom Sihanouk established the Sang Kum Restr Niyum (or Sangkum; People's Socialist Community), which aimed to restore in a new form the ancient Trinity of nation, religion, and king. The Sangkum considered Buddhism to be a Socialist religion, an unremitting struggle against evil, and hence an essential element in the formation of a Socialist party. In both Cambodia and Laos, Buddhism and, therefore, the monks have played a significant role, with a tendency toward the left politically. The destructive conflict in Vietnam and adjacent areas in the 1960s and 1970s has made monastic life difficult. Buddhists, whether clerics or laity, were obliged to participate actively in national affairs, involving themselves in the various political currents, with a tendency toward pacifistic and pro-Communist alignments. The frequent suicides by immolation in South Vietnam were a protest against the war by monks dedicated to the Buddha's ideal of peace; they sacrificed themselves thus to exemplify and stimulate a stronger resistance against the war.

Tibet. Kuomintang China, under Chiang Kai-shek, which had never renounced its sovereignty over Tibet, even though Tibet had declared its independence in 1913 under the 13th Dalai Lama, sought to maintain good relations with it. The Nationalists had a permanent mission (not an embassy) at Lhasa, the Tibetan capital. On the occasions of annual festivals, they would distribute considerable sums of money to the most important monasteries.

Relations between Communist China and Tibetan Buddhism

As for the People's Republic of China, its constitution assured its citizens of freedom of religion. It was announced that the functions of the Dalai Lama would continue in Tibet, and the customs of the peoples and the temples would be respected. China could not forget that a great part of Asia was Buddhist and that any anti-Buddhist measures would create an unfavourable impression. In 1952 some Buddhists were invited to take part in a Peace Conference of the Asian Peoples, and in 1953 a Buddhist association was set up under the presidency of Shes-rab rgya-mtsho [pronounced Sherapgyatso], who affirmed that Buddhism was a doctrine of revolutionary character and hence not opposed to the new democracy. Thus monks were directed to participate in reforms, combat reactionaries and imperialists, and to adapt their religion to the new social situation.

Buddhist monks were permitted to receive a delegation from Laos in 1956; some temples were restored and a Buddhist academy was founded. But in 1959 the Chinese authorities proclaimed that the religion had to be gradually weakened and ultimately suppressed. In that year the Dalai Lama fled Tibet. During the disorders caused by that event, many temples were destroyed.

Chinese policy toward Tibet changed from one of toleration to one of re-education. Monks were forced to teach and to work side by side with secular persons. The new social and economic structure, the required attendance at Chinese schools, and the presence in Tibet of many Chinese (not just military) are intended to modify, if not eliminate, a tradition of centuries. In China itself, many monasteries have been closed or adapted for other uses, whereas those of historical and artistic interest have been restored at state expense as national monuments.

Before the Cultural Revolution that began in 1966, work was begun on an inventory of Chinese objects of artistic value conserved in the monasteries; excavations were begun and two archaeological journals of considerable interest were published. Large volumes were also dedicated to Tun-huang and its caves. These activities were suspended during the Cultural Revolution, but have since been resumed.

Sōka-gakkai

Japan. In Japan, new schools with political tendencies have grown out of the better known ones. Such is the Sōka-gakkai, the lay association of the Nichiren-shō-shū sect, which has its principal centre at Taiseki-ji on the lower slope of Mt. Fuji. The Sōka-gakkai was founded by Makiguchi Tsunesaburō in 1930, and through the efforts of Toda Jōsei and Daisaku Ikoda it has won over 10,000,000 adherents and has representatives in the Diet. Its three principal elements of worship are: (1) the *gohonzon*, a *maṇḍala* before which one recites; (2) the *daimoku*, or salutation to the *Lotus Sūtra*; and (3) the *kaidan*, or platform, from which one receives the teaching during assemblies at Taiseki-ji for recitation of the *daimoku* and some chapters of the Hokke-kyō (*Lotus Sūtra*).

This is the religious basis of the political activity that began in a victorious confrontation with the mine owners of Hokkaido, where the Sōka-gakkai movement had infiltrated among the workers. Its political ideas are those of Nichiren: harmony between religion and the interests of national life, with a militant, well-organized type of nationalism and a vigorous conversion technique (*shakubuku*, "break and subdue"). Its political arm is the Kōmeitō (Clean Government Party), which has adopted the principle of *Buppō minshū-shugi* (Buddhist Democracy) and opposed rearmament in defense of the "peace constitution."

THE PROSPECTS FOR THE FUTURE

Buddhism in Asia finds itself in a state of contentious contradiction, except in Burma. In countries in which it is the traditional religion it supports nationalist movements and opposes colonialism in all its forms, past and present. Though retaining tolerance, it is inclined to a certain distrust of other religions, especially of Christianity, which it sees as a rival, a reaction to the historical effects of its alliance with colonialism. Nevertheless, Buddhism is imitating Christianity's methods; *e.g.*, by organizing its own missionaries in Ceylon and Thailand. Since the last decades of the 19th century it has modified its structures to encourage associations under various titles, both local and international in scope, with the aim of disseminating the teachings of the Teacher throughout the world. Many Buddhists and sympathizers with Buddhism in the West have encouraged and spurred on the messianic spirit that gives this movement life. Opposed to this activist position is a conservative attitude that seems to arise from the *saṅgha*'s fear that Buddhism will lose its prestige. Caught between the old and the new, Buddhism finds itself in an ambiguous situation. In Ceylon there was opposition to nationalization of the schools and establishment of a university on the European model, open to both monks and laymen. The dispute was resolved by the establishment of the University of Anuradhapura solely for monks. Although the liberal wing maintains that there is nothing in Buddhism that is contrary to science, when a renowned archaeologist of Ceylon, S. Paranavitana, declared that the traditional account of the Buddha's visit there was pure legend, the monks were scandalized. In countries such as Laos and Cambodia the custom continued of regarding the king as chief patron of the law and the *saṅgha* (comparable to the *Dharmarāja* in India and the *cos-rgyal* in Tibet). In

The *saṅgha*'s opposition to modernity

Vietnam, the conflict there has been a great blow to Buddhism. The choice is inevitable: whether to be for or against the reforms required by the new social order, even at the risk of harm to Buddhism itself.

The hesitancy of the *saṅgha* and its division into contending groups have made the younger generations skeptical, doubtful, or fanatical. Buddhism anticipated certain modern ideas: the negation of God and the soul is a basic concept in the Theravāda school. Buddhism has always lived under the protective shadow of the state; or it has been sufficiently powerful to govern on its own, as in Tibet. When protection was lacking during changes of dynasties, the *saṅgha* withdrew into itself, attempting, if the new conditions permitted, to live off its own properties or charity in exchange for spiritual protection, prayers, exorcisms, and education provided by temple schools. After the persecution of 845 in China, Buddhism recovered; but it never again achieved the splendour it had in Wei and T'ang times (6th–10th centuries). It survived and there were still important thinkers and very notable mystics, but on the whole the *saṅgha* declined.

In various ways the same thing was happening in the 1970s to both Mahāyāna and Theravāda. The Mahāyāna offered less possibility of resistance because of its apparent polytheism (few understand the symbolic meaning of the images found in the temples). In Japan its prospects were better. There is a multiplicity of sects there, many of which are identified with national aspirations or have even sparked them, and the devotional schools inspire faith and comfort; Zen and the followers of Nichiren encourage self-control and freedom of action. The chances of a resurgence of Theravāda in the contemporary world are better, however, because of its innate rationalism, its ethical foundations, and its lack of myths and symbols. Yet the *saṅgha* in Theravāda countries also is being abandoned or is losing its power of attraction. If it is not able to compete with the state in education, in social service, and in genuine contributions to the economic improvement of the masses, the number of monks will continue to decline.

University students, caught up in the agony of Southeast Asia, are looking for more rewarding occupations and are not attracted by the monastic life. Yet it should not be said that Buddhism is destined to lose ground. As a mode of spiritual behaviour it still has great vitality outside the *saṅgha* itself. This can increase if Buddhism returns to its origins, to the original teaching of the Buddha, freed of the monastic structure and of the dogmatic and theological complexities that have encrusted it in the course of time. One cannot even exclude the possibility that it may carry its basic ethical message to a West uncertain and full of doubt in the face of the collapse of seemingly irrefutable values. This would seem to be indicated by the constantly increasing interest aroused by Buddhism in the West, not simply as an object of scholarly research but as the inspiration for an acceptance, not bound by worn-out or moribund traditions, of the teaching contained in the word of the Teacher—capable of renewed spiritual energy—like a sermon the Buddha continually repeats for anyone who understands it and applies it to life.

BIBLIOGRAPHY. The bibliography on Buddhism is vast; see the *Bibliographie Bouddhique* (annual since 1928). Encyclopaedias on this subject are primarily in Japanese: *Bukkyô Dai-jiten*, ed. by TOKUNO ODA (1917); *Bukkyô Dai-jiten* 5 vol., (1932–36), well indexed; and *Mikkyō Dai-jiten* (1931–33; French trans., *Hôbôgirin: Dictionnaire encyclopédique du Bouddhisme* . . ., 4 vol. to date, 1937–67). The government of Ceylon (now Sri Lanka) has undertaken the *Encyclopaedia of Buddhism*, ed. by GEORGE P. MALALASEKERA, 3 vol. to date (1961–). Since Buddhism has been diffused over a large part of Asia, scholarly works on it are generally limited to an individual country or to the areas in which the authors are specialized. A good book for the nonspecialist is CHARLES ELIOT, *Hinduism and Buddhism: An Historical Sketch*, 3 vol. (1921, reprinted 1962). The best summary of Indian Buddhism is ETIENNE LAMOTTE, *Histoire du bouddhisme indien, des origines à l'ère Śaka* (1958); see also EDWARD J. THOMAS, *The History of Buddhist Thought*, 2nd ed. (1951); and on the sects, ANDRE BAREAU, *Les Sectes bouddhiques du petit véhicule* (1955), and *La Vie et l'organisation des communautés bouddhiques modernes de Ceylon* (1957).

For an understanding of Indian Buddhism, the following accounts of the Chinese pilgrims should be consulted: HERBERT A. GILES, *The Travels of Fa-hsien* (1886, reprinted 1923); THOMAS WATTERS, *On Yuan Chwang's Travels in India, 629–645 A.D.*, 2 vol. (1904–05, reprinted 1971); and I TSING, *A Record of the Buddhist Religion As Practised in India and the Malay Archipelago (A.D. 671–695)*, trans. by JUNJIRO TAKAKUSU (1896).

A good book on the life of the Buddha is HERMANN OLDENBERG, *Buddha: His Life, His Doctrine, His Order* (1882); also EDWARD J. THOMAS, *The Life of Buddha As Legend and History*, 3rd ed. rev. (1949, reprinted 1969), An easy-to-read survey of Buddhist thought is HELMUTH VON GLASENAPP, *Der Buddhismus: Eine atheistische Religion* (1966; Eng. trans., *Buddhism: A Non-Theistic Religion*, 1970); ANDRE BAREAU, *Recherches sur la biographie du Buddha dans les Sūtrapitaka et les Vinayapiṭaka anciens* (1963), is a more technical study. For the oldest and most strictly dogmatic form of Buddhism, see NYANTILOKA MAHATHERA, *Guide Through the Abhidamma-Pitaka, Being a Synopsis of the Philosophical Collection Belonging to the Buddhist Pali Canon, Followed by an Essay on the Paticca-Samppāda*, 2nd ed. rev. by NYANAPONIKA THERA (1957); and for the history and the ritual, WALPOLA RAHULA, *History of Buddhism in Ceylon* (1956).

For Buddhism with respect to China, the work of FUNG YU-LAN, *A History of Chinese Philosophy*, 2nd ed. 2 vol. (Eng. trans. 1952–53), is valuable although only some aspects of Chinese Buddhism are considered. For the encounter between Taoist and Buddhist thought, see WALTER LIEBENTHAL, *The Book of Chao: A Translation from the Original Chinese, with Introduction, Notes and Appendices* (1948); ERIK ZURCHER, *The Buddhist Conquest of China*, 2 vol. (1959); and ARTHUR F. WRIGHT, *Buddhism in Chinese History* (1959); for a general survey, KENNETH K.S. CH'EN, *Buddhism in China* (1964). The recent history of Buddhism in China is discussed by WING-TSIT CHAN in *Religious Trends in Modern China* (1953).

For Korea and Japan, in addition to the book by Eliot that has already been cited, see his *Japanese Buddhism* (1935, reprinted 1959); AUGUST K. REISCHAUER, *Studies in Japanese Buddhism* (1917, reprinted 1970); GEORGE B. SANSOM, *Japan: A Short Cultural History*, rev. ed. (1946); EDWIN O. REISCHAUER, *Ennin's Travels in T'ang China* (1955), and (trans.), *Ennin's Diary: The Record of a Pilgrimage to China in Search of the Law* (1955); and JUNJIRO TAKAKUSU, *The Essentials of Buddhist Philosophy*, 3rd ed. (1956). On Zen the following studies are recommended: D.T. SUZUKI, *Essays in Zen Buddhism*, new ed., 3 series (1927–61); *The Training of the Zen Buddhist Monk* (1934); and the studies by HEINRICH DUMOULIN: *Zen: Geschichte und Gestalt* (1959; Eng. trans., *A History of Zen Buddhism*, 1963); *Wu mên-kuan: Der Pass ohne Tor* (1953); *Die Entwicklung des chinesischen Ch'an nach Huinêng in Lichte des Wu-mên-Kuan* (1953; Eng. trans., *The Development of Chinese Zen After the Sixth Patriarch in the Light of Mumonkan*, 1953); and *The Sutra of Wei Lang or Hui Nêng*, new ed. (1947).

For the influence of Buddhism on the economic life of China, see JACQUES GERNET, *Les Aspects économiques du Bouddhisme dans la société chinoise du V^e^ au X^e^ siècle* (1956).

A study relevant to Tibet and Mongolia that demonstrates the synthesis of Tibetan culture and its religious tradition is ROLF A. STEIN, *La Civilisation tibétaine* (1962; Eng. trans., *Tibetan Civilization*, 1972); on the schools of religion, see HELMUT HOFFMANN, *Die Religionen Tibets* (1956; Eng. trans., *The Religions of Tibet*, 1961); GIUSEPPE TUCCI and WALTHER HEISSIG, *Die Religionen Tibets und der Mongolei* (1970); and ROBERT J. MILLER, *Monasteries and Culture Change in Inner Mongolia* (1959); on the Tibetan tradition, HERBERT V. GUENTHER, *Tibetan Buddhism Without Mystification* (1966); and A. BHARATI, *The Tantric Tradition* (1965).

Works on Buddhist iconography include B.T. BHATTACHARYYA, *The Indian Buddhist Iconography*, 2nd ed. (1958); A.K. COOMARASWAMY, *Elements of Buddhist Iconography* (1935); GIUSEPPE TUCCI, *Tibetan Painted Scrolls*, 3 vol. (1949) and *Teoria e pratica del mandala* (1949; Eng. trans., *The Theory and Practice of the Maṇḍala*, 2nd ed., 1969); and FERDINAND LESSING, *Yung-Ho-Kung: An Iconography of the Lamaist Cathedral in Peking* (1942). On Buddhism and art, see ALFRED C. FOUCHER, *La Vie du Bouddha d'après les textes et les monuments de l'Inde* (1949; abridged Eng. trans., *The Life of Buddha*, 1963); HAROLD INGHOLT and ISLAY LYONS, *Gandhāran Art in Pakistan* (1957); JOHN M. ROSENFIELD, *The Dynastic Arts of the Kushans* (1967); J. LEROY DAVIDSON, *The Lotus Sūtra in Chinese Art* (1955); ALEXANDER SOPER and LAURENCE SICKMAN, *The Art and Architecture of China* (1956); and TOSHIO NAGAHIRO, *Yün-kang, the Buddhist Cave-Temples of the Fifth Century in North China* (1951–56).

For Southeast Asia, GEORGE COEDES, *Les États hindouisés d'Indochine et Indonésie*, rev. ed. (1964; Eng. trans., *The Indianized States of Southeast Asia*, 1968); S.J. TAMBIAH, *Buddhism and the Spirit Cults in North-East Thailand* (1970); and KENNETH W. MORGAN (ed.), *The Path of the Buddha* (1956).

The relationship between western thought and Buddhism and the actual position of Buddhism in East Asia is discussed in HENRI DE LUBAC, *La Rencontre du Bouddhisme et de l'Occident* (1952); GEORG SIEGMUND, *Buddhismus und Christentum* (1968); KOSHO YAMAMOTO, *Buddhism in Europe* (1967); GUY R. WELBON, *The Buddhist Nirvāna and Its Western Interpreters* (1968); HARRY THOMSEN, *The New Religions of Japan* (1963); DONALD E. SMITH (ed.), *South Asian Politics and Religion* (1969); CLARK B. OFFNER and HENRY VAN STRAELEN, *Modern Japanese Religions* (1963); and RICHARD LOWENTHAL (ed.), *Issues in the Future of Asia* (1969).

(Gi.T.)

Buddhism, History of

Originating in northern India in the 6th century BC under the leadership of Siddhārtha Gautama, the Buddha, Buddhism arose as a reaction to certain aspects of Hinduism. Spreading over much of India, and then suffering there a decline, Buddhism expanded over much of Central and Southeast Asia, China, Korea, and Japan, influencing the social, cultural, economic, and political life of the lands in which it gained prominence.

This article is divided into the following sections:

Basic characteristics and problems in the study of the history of Buddhism

Buddhism in the late 19th and 20th centuries

BASIC CHARACTERISTICS AND PROBLEMS IN THE STUDY OF THE HISTORY OF BUDDHISM

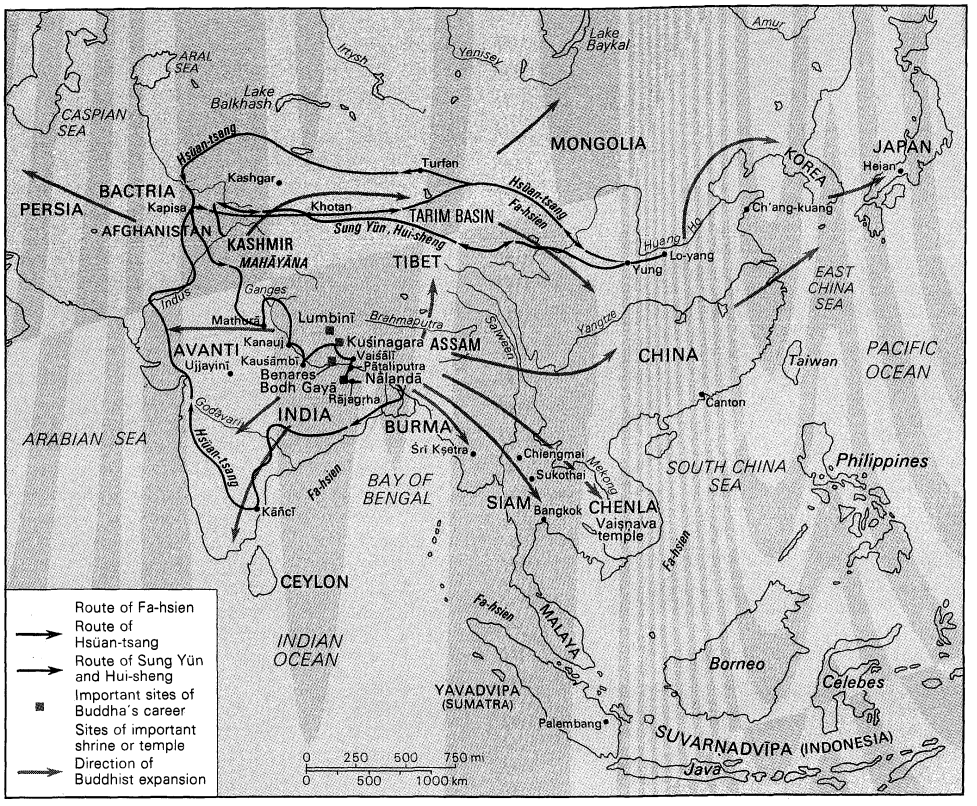
After centuries of fanciful speculation, European scholars in the 19th century began to display a disciplined curiosity about the history of the Buddhist religion. As a result of this disciplined approach, rather than mere whimsical theorizing, the foundations for the modern scientific study of Buddhism were laid. Throughout the 19th century there was a great variety of opinion regarding the nature of Buddhism and the original message of its founder, Siddhārtha Gautama, the Buddha. The analysis of even so fundamental a Buddhist concept as Nirvāṇa (annihilation, bliss, rectitude, or the release from individuality) deeply divided scholarly opinion and significantly influenced the subsequent reconstruction of Buddhist thought and piety. Some scholars, such as Jules Barthélemy-Saint-Hilaire, a French philosopher and statesman, and F. Max Müller, an Anglo-German comparative philologist, were puzzled by a religion that seemed to be both nihilistic and atheistic. Others, such as Albrecht Weber, a German Orientalist, proclaimed its founder to be a simple moralist and social reformer. The quest for the historical Buddha—in method and intent similar to the quest for the historical Jesus in Christianity—played a crucial role in all Buddhological studies because of the tendency among scholars to judge the later developments in Buddhism in terms of its "earliest gospel." (Unfortunately, many scholars have tended to identify what they regarded as the earliest scriptural traditions with the actual words of the Buddha.)

Western schools of interpretation

Modern studies of Buddhism in the West, according to Edward Conze, a German-British Buddhologist, can be divided into three schools of interpretation: the Anglo-German school; the Leningrad school; and the Franco-Belgian school. The Anglo-German school, headed by T.W. Rhys Davids, an eminent English Buddhologist, and Hermann Oldenberg, a German scholar, concentrated on the Pāli canon, the Buddhist scriptures written in an ancient Indian language, of Theravāda (Way of the Elders) Buddhism and emphasized the moral, less mystical, and practical aspects of the religion and its founder. The Leningrad school, led by Fyodor Shcherbatskoy, a Russian scholar, took its clue from Bu-ston, a historian of Tibetan Buddhism, and divided the history of Buddhism into three consecutive periods: pluralism, monism, and idealism. Relying upon the later commentatorial literature, especially the *Abhidharmakośa* ("Treasury of Higher Law") written in the 4th century AD by Vasubandhu, a founder of the Yogācāra (Idealist) school of Mahāyāna (Greater Vehicle) Buddhism, Shcherbatskoy concentrated on how the concepts of *dharma* (norm, law) and the *dharma*-elements unfolded in Buddhist thought. The result was a brilliant overemphasis on the metaphysical aspects of Buddhism. The Franco-Belgian school, to which are associated many scholars in the 20th century, was initiated by such scholars as Louis de la Vallée-Poussin, a French Buddhologist who regarded Buddhism not as a system of ideas based on the *Upaniṣads*, Hindu philosophical books (often pre-Buddhist), but as an ascetic, religious, and Indian institution based on *yoga*, a physical–psychological meditation discipline. Aware that Theravāda Buddhism was only one of about 18 early Buddhist sects, each having its own scriptural traditions, Franco-Belgian Buddhologists like Jean Przyluski, Sylvain Lévi, Paul Demiéville, and Étienne Lamotte no longer rely solely on the Pāli scriptures of the Theravādins for their reconstruction of early Buddhism. Though it may be impossible to discover the actual words of the Buddha, these scholars believe the earliest traditions of the Buddhist community can be uncovered by a careful comparative study of the existing literature of all the known early sects. When accounts in the Pāli canon and the extant Sanskrit accounts of the Sarvāstivādins (members of a sect who believe everything is real) agree, for example, a conclusion may be reached that these accounts contain a tradition antedating the split within the orthodox monastic order, the Sthāviras (from Sanskrit: the "elders"), into the Theravādins (Pāli *thera*, "elders") and Sarvāstivādins (*c.* 250 BC). Likewise, when these accounts agree with those recorded in the literature of the more liberal Mahāsaṅghikas (members of the Great Saṅgha, or Community), the conclusion may be made that scholars now have a record of what was generally accepted by nearly all early Buddhists about 140 years after the Buddha's death when the schism between the Mahāsaṅghikas and the Sthāviras took place (*c.* 340 BC).

Non-textual sources

In addition to this variety of textual resources, Buddhologists (in the latter part of the 20th century) rely more heavily upon archaeological, iconographic, and sociological fieldwork than previously was the case. This plurality of approaches, introduced by the Franco-Belgian Buddhologists, has had a constructive effect on all aspects of Buddhist studies. The scriptural tradition is now recognized as only one aspect of a much larger religiocultural complex. No longer can the doctrines and values of a monastic elite, who produced the scriptures, be equated with Buddhism per se. Nor is it any longer possible to regard the several historical forms of Buddhism that emerged across Asia, from India to Japan, as "deviations" from some pristine form of the faith. Everywhere, Buddhism has grown into symbiotic relationships with the religion of the folk (*e.g.*, apotropaic magic; and rituals of fertility, family, and healing) and the nation (*e.g.*, sacred kingship). The fact is that scholars simply do not know whether Buddhism was originally a popular cult or the spiritual philosophy of a religious virtuoso that only later became the religion of the common man.



Important sites and routes of expansion of early Buddhism.

ORIGINS AND EARLY DEVELOPMENTS

Religious movements flourishing in the 6th century BC

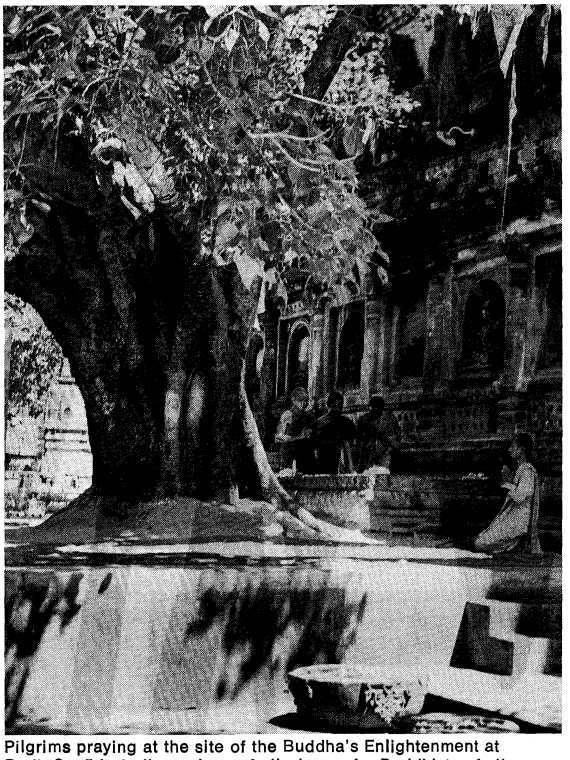
The cultural context. The northeastern region of India, during the period of the Buddha (*c.* 560–*c.* 480 BC), was virtually alive with small religious movements composed of charismatic yogic leaders who influenced people by the force of their spiritual qualities, a community rule or laws, and members of the community; *i.e.*, followers of a particular teacher and his rule. This pattern later was taken over by the Buddhists as the *tri-ratna* ("Three jewels"): (1) the Buddha, (2) the *dharma* ("rule"), and (3) the *saṅgha* ("community"). At this time in India, many were no longer content with the external formalities of Brahmanic (Hindu high caste) sacrifice and ritual. Giving up their place in society, their sacred threads (*upavīta*), and the sacred tuft of hair (*śikhā*), many of the discontented adopted the life of wandering almsmen. In northwest India, such itinerant ascetics tried to go beyond the Vedas (Hindu sacred scriptures). In the literature that grew out of this movement, the *Upaniṣads*, a new emphasis on renunciation and transcendental knowledge can be found. But northeast India, which was little influenced by the Aryans who had developed the main tenets and practices of the Hindu faith, became the breeding ground of most heterodox sects. Society in this area was troubled by the breakdown of tribal unity and the expansion of several petty kingdoms. Religiously, this was a time of doubt, turmoil, and experimentation. New sects abounded, including various kinds of skeptics (*e.g.*, Sañjaya Belaṭṭhiputta), atomists (*e.g.*, Pakudha Kātyāyana), materialists (*e.g.*, Ajita Keśakambalin), and antinomians; *i.e.*, those against rules or laws (*e.g.*, Pūraṇa Kāśapa). Among the most important sects to arise at the time of the Buddha were the Ājīvikas, who emphasized the rule of fate (*niyati*), and the Jainas, an ascetic movement stressing the need to free the soul from matter. Though the Jainas, like the Buddhists, have often been regarded as atheists, their beliefs are actually more complicated. Unlike early Buddhists, both the Ājīvikas and Jainas believed in the permanence of the elements that constitute the universe, as well as the existence of the soul.

A proto-Sāṃkhya sect (a Hindu school of thought founded by Kapila) teaching the dualism of spirit (*puruṣa*) and matter (*prakrti*) was dominant where Buddhism later arose and probably had some impact on early Buddhist thought. Despite the bewildering variety of religious communities, many shared the same vocabulary—Nirvāṇa, *yoga*, *karma* (causality), *tathāgata* ("thus-gone," or "he who has thus attained"), *buddha* (enlightened), *saṃsāra* (eternal recurrence, becoming), and *dharma*—and most were based on the practice of *yoga*.

The founding of Buddhism. According to tradition, the Buddha himself was a *yogin; i.e.*, a miracle-working ascetic. After leaving home (Kapilavastu, in northern India, present Nepal), the young Siddhārtha went to Rājagṛha, the capital of Magadha (an ancient kingdom in northeast India), and studied under two *yogins*, Ālāra Kālāma and Uddaka Rāmaputta. Because he found that their teaching did not satisfy his spiritual needs, he moved to a grove near Uruvelā, not far from Bodh Gayā. There Siddhārtha spent nearly seven years practicing yogic austerities. Finally realizing that he had been overemphasizing these practices, he adopted a milder course, called the Middle Way or Path (Mādhyamika). One night, he entered into a yogic trance, during which he first recollected his own previous existences. During the second watch of the night, he entered into a second trance, in which he acquired the "divine eye," enabling him to envisage the death and rebirth of all creatures. During the third watch, he entered an even higher state of trance, during which the "outflows" of his life—his ignorance and desires—were finally quelled. He then grasped what were called the Four Noble Truths and the principle of dependent origination. The crux of Siddhārtha's discovery was that suffering and death can be overcome only when ignorance and craving have been put aside. After his Enlightenment, the Buddha (Enlightened One) could have remained a "silent one" in a permanent state of bliss. Instead, he chose to return and work for the salvation of others. During the remaining years of his life, he devoted himself to establishing a community based on selfless, compassionate "right action." After spending about 43 years in preaching, begging, and labouring within this community, the Buddha became ill with dysentery and passed into a final state of Nirvāṇa near Kuśinagara (in northeast India).

The Enlightenment of Siddhārtha Gautama, the Buddha

From this sketch of the Buddha's life, it is apparent



Pilgrims praying at the site of the Buddha's Enlightenment at Bodh Gayā in India, a place of pilgrimage for Buddhists of all sects. The Bo tree at left is believed to be a descendant of the one under which the Buddha sat during the night before his Enlightenment.
Foto Features

that Buddhist Enlightenment is deeply rooted in the practice of *yoga*. *Yoga*, a complex of ecstatic spiritual techniques going back to the earliest period of Indian civilization, was preserved in India's hinterlands, such as the Nepalese–Indian frontier where the Buddha was born. Together with other indigenous elements in the country's religious history (*e.g.*, *pūjā*, offerings to gods, and *bhakti*, or devotionalism), *yoga* was a concrete and experimental form of religious experience. Many shamanistic elements (*i.e.*, healing practices and psychic transformations) seem to be reflected in its practice, as well as in the myths and legends that grew up around the person of the *yogin*. Among these are initiatory ordeals, celestial flights, descent into the underworld, and other magicoreligious feats. In the Buddha's legendary biography are found numerous yogic–shamanistic elements. According to some stories, he was able to fly through the air. He also is reported to have dismembered his body, letting his limbs fall to the ground, and then magically reassembled them. In a previous life, he is said to have given his body to feed starving animals and demons. Texts describe him as "burning," a term reflecting the heat-fire symbolism common to both the Vedic and yogic–shamanistic traditions. Early Buddhist thought likewise exhibits aspects of the pre-Aryan inheritance; for example, the five classes of "superknowledge" (*abhijñā*) that included: (1) miraculous or magical powers, (2) the "divine eye," (3) "divine hearing," (4) knowledge of another's thoughts, and (5) recollection of one's previous existences. As noted above, the Buddha himself, on the night of his Enlightenment, was able to recollect all of his previous existences, and later in the night he acquired the "divine eye" enabling him to see the death and rebirth of all creatures.

Early developments of Buddhism in India. Perhaps as a response to the crisis in the traditional ethos of Indian culture in northeastern India, Buddhism creatively revalorized tribal and folk traditions. In the *Mahāparinibbāna Sutta* (a Buddhist text in sermonic or dialogue form), the Vajjian tribal confederacy is made the model for the Buddhist community. The practical aspects of the new Buddhist *dharma* were soon appropriated by the emerging trading class, largely of the Vaiśya (Hindu merchant) caste. The layman was an integral part of the early Buddhist community, not only because he supported the monastics but because he himself could become a "streamwinner" destined only for happy rebirths in heaven (*sagga*) and, finally, Enlightenment. The early Buddhist community (*saṅgha*) included monks, nuns, laymen, and laywomen alike. The layman's ethic, though not identical with that of the monks, was nevertheless "Buddhist." Even the scriptures gave him practical advice, such as how to avoid clever people who want only to deceive and cheat him. Greediness was believed to stem from laziness, and not from ambition. The ideal of the Buddhist merchant was, therefore, not simply to avoid wasting money, but to make it. Still, the layman was not as concerned about Nirvāṇa as he was about winning a better rebirth. For him, the Buddha as saviour and lord (Bhagavat) was more important than the *dharma*. From the piety of the lay Buddhist arose such well-established Buddhist practices as *Buddha-pūjā* (worship), the veneration of relics, and the building of *stūpa*s (reliquaries).

Influence of the *bhakti* movement

A crucial influence on early Buddhism was the *bhakti* movement, a pietistical development in Indian religious life going back to the time of Śākyamuni (Sage of the Śākyas, Gautama Buddha). *Bhakti* stressed the need for faith in and devotion to a saviour-diety, who, in turn, provided the faithful with the means of salvation. This was a radically different outlook from that of the Buddha, who insisted that, after his decease, his disciples should follow only the *dharma*. *Bhakti*'s emphasis on faith is seen even in the "Three Refuges" common to all branches of Buddhism; *i.e.*, the vow to take refuge in Buddha, *dharma*, and *saṅgha*. The Buddha now becomes the Lord (Bhagavat) who actively sets about saving the faithful. This led to the actual worship of the Buddha (*Buddha-pūjā*). In this worship, the *stūpa* became of prime importance. Pilgrims, coming from great distances, circumambulated the *stūpa* (originally, a reliquary mound), bearing flowers and incense to be offered as gifts to the Lord.

BUDDHISM IN INDIA

From the beginning, there was a close relationship between monks and laymen. The early Buddhist monastic community was not regarded as something set apart from the world but, rather, as the means for promoting the "welfare and happiness of the many." Originally, the wandering ascetics moved about constantly, settling down only during the monsoon season. Only in the Buddhist community did it become the rule (probably by the 4th century BC) to live together during the three months of inclement weather. From this experience was born the ritual affirmation of the community rule (Pātimokkha). Gradually, these rain retreats (*vassāvāsas*) gave way to permanent monastic settlements. Only when the differences between monk and layman were later emphasized did there arise the notion of an exchange of layman's support for monk's merit. By the time of the Muslim invasion of India (10th century AD), laymen had little interest in the restoration of Buddhism. Jainism, on the other hand, continued to maintain close relations between monk and layman and perpetuated its traditional discipline even among the uncloistered. This was one reason why Jainism survived the Muslim invasions of India, and Buddhism did not.

Early Buddhist councils. The early Buddhist councils (*sangītis*, or "recitals") were largely concerned with the purity of the faith and practice of the monastic community. Unfortunately, the councils pose an enormous problem to the historian because each major sect has its own account and opinion of them. Legend and even myth have so coloured these accounts that scholars cannot be sure when and where they took place or even who took part in them. Though many scholars deny its very existence all Buddhist traditions maintain that a council was called at Rājagṛha immediately after the Buddha's death. According to legend, this council (comprising 500 *arhat*s, or monks) was responsible for the composition of the *vinaya* (monastic discipline), under the monk

Upāli, and the *dhamma* (*i.e.*, the *sūtras*), under the monk Ānanda, even though the latter was supposedly brought to trial at the same council. Though there were memorizers of *sūtras* (*sūtra-dhara*) and the *vinaya* (*vinaya-dhara*), as well as authorized commentators (*mātṛkā-dhara*) at work in the community during the period of the first three Buddhist councils, the scriptures as such existed only in an inchoate oral (yet normative) form. More scholars are prone to accept the historicity of the second council that was held at Vaiśālī when a controversy broke out between a certain Yasa and the monks of Vajji. The ten points of discipline observed by the Vajjian monks, and opposed by Yasa, permitted storing salt in a horn, eating in the afternoon, and drinking buttermilk after meals. These and other lax rules were condemned by the council.

The work of the third council

According to tradition, a third council was called by King Aśoka at Pāṭaliputra (Patna) about 250 BC. According to some accounts, the *Tripiṭaka* (Buddhist canon) was completed by this council and missionaries were sent out to various countries. Moggaliputta Tissa, president of the council, supposedly completed his *Abhidhamma* (Higher Dharma) treatise, the *Kathāvatthu* ("Points of Controversy"), during this council. More significant was the controversy that arose between the Sarvāstivādins and the Vibhajyavādins (usually identified with the early Theravādins) over the reality of past and future states of consciousness (*cittas*). After the Sarvāstivādin view that such states actually exist was condemned, the sect withdrew from the lower Ganges Valley to Madhurā in the northwest. There it appears to have continued to develop as a transitional school between the older, more conservative schools and the nascent Mahāyāna (Greater Vehicle) movement. A fourth council was believed to have been held under King Kaniṣka, probably in the 1st century AD, at Jalandhar or in Kashmir. This council seems to have been limited to the composition of commentaries. Because there is no evidence of Mahāyāna at this council, and because only Sarvāstivādin and Sthaviravādin viewpoints seem to have been represented, scholars generally conclude that this was actually a sectarian synod rather than an actual ecumenical Buddhist council. At any rate, the fourth council, whose work was recorded in Sanskrit, has never been recognized by southern Buddhists.

Early sectarian schisms. About 140 years after the Buddha's death, the Buddhist community, which had long been divided into many informal factions, became openly divided between two sects, the Mahāsaṅghika (Great Council) and the Sthāviras (those who stood for the tradition of the elders at the council of Pāṭaliputra).

Origins of Mahāyāna and Hīnayāna (Theravāda) Buddhism

These were the forerunners of the great split of Buddhism into Mahāyāna (Greater Vehicle) and Theravāda, or Hīnayāna (Lesser Vehicle), respectively—southern Buddhists prefer Theravāda, rather than the designation Hīnayāna, which, they believe carries with it a negative connotation. The Sthāviras, in turn, later gave rise to the Sarvāstivādins (those who teach that "everything" exists; *i.e.*, space, past, present, future, and Nirvāṇa) and the Sautrāntikas (who rejected the *Abhidharma* in favour of the *sūtras*). Another line of descent led from the Sthāviras to the Theravādins of Ceylon and Southeast Asia.

Theravādins. The Theravādins (Way of Elders) maintained that the ideal Buddhist is the *arhat*, the accomplished ascetic who wins Nirvāṇa through his own efforts. Actually, he is a monk within the monastic *saṅgha*. Though the Theravādin *arhat* naturally "took refuge in the Buddha," his emphasis was not on the grace of the Saviour, but on his *dharma*. In its "theology," Theravāda tended to make distinctions. It insisted that Nirvāṇa was beyond the realm of empirical reality and that the Buddha (Gautama or Śākyamuni Buddha, who attained final Nirvāṇa in the 5th century BC) was separable from the *dharma* that he taught. It maintained that the *arhat* and layman have different roles to play both in society and in religion.

Mahāyānists. These distinctions were broken down by Mahāyāna. Arising in areas where Buddhists no longer could control the state, Mahāyānists focussed their attention on celestial Buddhas, Buddhafields, and *bodhisattvas* (Buddhas-to-be). In fact, the *bodhisattva* now became the ideal Buddhist. He was a man—monk or layman—who postponed his own enjoyment of Nirvāṇa in order to win salvation for all sentient creatures. To this end, he took vows in the presence of a Buddha that, having crossed the stream of suffering, he would ferry others across. His aim is not merely to attain the "wisdom" of the Theravādin *arhat* but rather to practice compassion and selflessness. He was said to fulfil six perfections: charity, morality, forbearance, striving, meditation, and wisdom. Though the *bodhisattva* ideal was not new with Mahāyāna, it did receive a new emphasis and a new ontological (theory of Being) foundation in this school. The compassion of the *bodhisattva* breaks down the distinctions that Theravāda insists upon. Finding the elitist split between *arhat* and layman intolerable, Mahāyānists teach that, as long as the "accomplished one" is distinguished from others, he is still susceptible to the pride that breeds illusion and suffering. Mahāyāna finds the solution to this problem in the identity of the phenomenal world (*saṃsāra*) and Nirvāṇa, both growing out of the Void (*śūnyatā*). In the Void all discriminations, all theories, all contradictory projects, and ideas have their ground. All dualisms are abolished. Subject does not differ from object, yes from no, saint from sinner. Thus, the *bodhisattva*, in his compassion, breaks down all distinctions and pride, dissolving them in emptiness.

One extremely complicated school of Mahāyāna Buddhism was known as Yogācāra (*yoga* practice) or Vijñānavāda (consciousnessism, or mind-only). According to the teachings of this school, subjects and objects do not exist. Only mind exists. The regularity of sense impressions men have of the world is because of a perceptual "storehouse" (*ālaya-vijñāna*) that has been inherited from all previous impressions. Salvation consists in reducing this "storehouse" to absolute reality, or suchness. Two brothers, Asaṅga and Vasubandhu, who lived in the 4th century AD, were the founders of Vijñānavāda. The younger, Vasubandhu, wrote the well-known Hīnayāna work, the *Abhidharmakośa* ("Treasury of the Higher Law"), before being converted to the mind-only position by his brother.

Another school of great historical importance was the Mādhyamika, or school of the Middle Path or Way, founded by Nāgārjuna in the 2nd century AD. By using very subtle, if not devious, logic, Nāgārjuna sought to reduce all other doctrines and theories to self-contradictions. At the same time, he refused to offer alternatives to the positions taken up by opponents. His aim was, by confounding all doctrines, to point to the essential emptiness (*śūnyatā*) of all things. Stated negatively, his position was that nothing comes into being, nor does anything disappear. Nothing is infinite or finite. Nothing is identical or different; nothing moves hither, nothing moves thither. By means of such negative feats of logic, Nāgārjuna tried to free men from all contradictory entanglements. Salvation, not a more refined philosophy, was his ultimate goal.

Expansion of Buddhism. *Buddhism under the Maurya-an dynasty.* To the rulers of the kingdoms and republics arising in northeast India, the patronage of heteroprax (differing practices) sects was one way of avoiding the meddling of Brahmins (high-caste Hindus) in the affairs of state. The first Mauryan emperor, Candragupta (*c.* 321–*c.* 297 BC), patronized Jainism and finally became a Jain monk. His grandson, Aśoka, who ruled over the greater part of the subcontinent from 269–238 BC, became the archetypal Buddhist king. Aśoka attempted to establish a "true *dharma*" in his realm based on the virtues of self-control, impartiality, cheerfulness, truthfulness, and goodness. Though he did not found a state church, he did attempt to make for the state a church that would include Hindu, Jaina, Ājīvika, and Buddhist alike. His aim was to create a religious and social milieu that would enable all "children of the King" to live happily and attain heaven in the next life. Thus, he created a "welfare state" by setting up medical assistance for men

The goals of Aśoka

and beasts, maintaining reservoirs and canals, and promoting trade. A system of *dharma* officers (*dhammamahāmattas*) was set up to provide for the empire magistrates, district attorneys, preachers, bureaucrats, social workers, and spies. The lay ethic preached by the King of the *dharma* (*dhamma-rāja*) and his officers was focussed on the layman's obligations in this world. Though Aśoka created a new ideal of kingship that would have powerful repercussions in Ceylon and Southeast Asia, the various problems posed by a state of such vast dimensions in India proved greater than could be solved by even such an inspired ideology. Soon after Aśoka's death, the Mauryan Empire began to crumble.

Developments under the Gupta dynasty. Though Buddhism was spreading through Central Asia, Ceylon, and China, in India there was a concurrent revival of Brahmanism and a steady growth of *bhakti*. Gradually, Buddhism absorbed various elements from these Indian traditions so that, by the time of the Gupta period (*c.* AD 300–*c.* 600), some Hindus were practicing *Buddha-pūjā*, regarding the Buddha as an *avatar* (incarnation) of the important Hindu deity Viṣṇu (Vishnu). Under the Guptas, some monasteries lost the spirit of the cloister and merged with other like-minded centres to form monastic clusters (*mahāvihāras*), functioning as liberal-arts institutions. The most famous of these was built at Nālandā, where the curriculum went far beyond canonical Buddhism. Nālandā soon became the leading centre for the study of Mahāyāna, which was fast becoming the dominant sect in India.

Visits of Chinese pilgrims. Though Buddhist institutions seemed to be faring well under the Guptas, various Chinese pilgrims, visiting India between AD 400 and 700, could discern an internal decline in the Buddhist community and the beginning of the reabsorption of Indian Buddhism by Hinduism. Among these pilgrims were Fa-hsien, Sung Yün, Hui-sheng, Hsüan-tsang, and I-ching.

The travelogues of these Chinese travellers provide the historian with invaluable information about Asian cultures from the Sāsānian (Persian) Empire in the west to Sumatra and Java in the east, and from Turfan in Central Asia to Kāñcī in the south of India. In 399 Fa-hsien left China, crossed the Gobi Desert, and visited various holy places in India. He then returned to China via Ceylon and Java, taking with him numerous Buddhist scriptures and statues. The most famous of the T'ang (a Chinese dynasty that ruled from AD 618–907) travellers was the monk Hsüan-tsang, who left China in 628 without imperial permission. Like Fa-hsien, he found both Hīnayānists and Mahāyānists in Central Asia. In 630 he attended an assembly of various Buddhist sects at Kapisa. When he arrived in northwest India, he found "millions of monasteries" reduced to ruins by the Huns, a Central Asian nomadic people who had even reached the gates of Rome in the 5th century. Many of the remaining Buddhists were turning to Tantrism, an esoteric psychic–physical system of belief and practice. In the northeast, he visited various holy places and studied Yogācāra, a Mahāyāna system, and Indian philosophy at Nālandā. After visiting Assam and southern India—intending to study Hīnayāna in Ceylon but being prevented from doing so by civil wars in that country—he returned to China with about 600 *sūtras*. After being received by the Chinese emperor T'ai-tsung in 645, he spent the rest of his life translating and studying the scriptures he had brought back. Another Chinese traveller, I-ching, went to Sumatra, Śrivijaya, and Malaya. In India, he visited Bodh Gayā and other Buddhist sites and, like Ḥsüan-tsang, studied at Nālandā. In 695, after an absence of 24 years, he returned to China.

The journeys of Hsüan-tsang

The decline of Buddhism in India. After the destruction of numerous Buddhist monasteries in the 6th century AD by the Hūṇa (Hun) king Mihirakula, Buddhism revived but moved east, where it flourished for a time under the Buddhist Pāla kings (8th–12th centuries AD). These kings continued to protect the monastic centres (*mahāvihāras*), building such new centres as Odantapurī, near Nālandā, and establishing a system of supervision for all such institutions. Under the Pālas, Tantrism (*i.e.*, Vajrayāna) became the dominant sect. Adepts of this sect, called *siddhas*, identified Nirvāṇa with the passions, maintaining that one could "touch the deathless element with his body." Though some of its practices seemed excessive, scholars of this school sought to revalorize some of the most archaic elements in Indian religion, by means of the techniques of Yogācāra and the philosophy of the Mādhyamika school. During this period, the university of Nālandā became a centre for the study of Tantra and the practice of Tantric magic and rituals. Under the Pāla kings, contacts with China decreased as Indians began to turn their attention to Tibet and Southeast Asia.

Causes for the decline

Scholars do not know all of the factors that contributed to the disappearance of Buddhism from India. Some have maintained that Buddhism was so tolerant of other faiths that it was simply reabsorbed by the dominant Hindu tradition. This did occur, although Indian Mahāyānists occasionally displayed a hostile attitude toward *bhakti* and Hinduism in general. Buddhism in India, having become mainly a monastic movement, probably paid little heed to the laity. Some monasteries became wealthy enough to have slaves and hired labourers to care for the monks and tend the lands they owned. Thus, after the Muslim invaders sacked the Indian monasteries in the 12th century AD, Buddhism became a minority in India. After the destruction of the monasteries, the Buddhist laity showed little interest in restoring the "Way."

In India, Buddhism began to spread under the Maurya dynasty from its place of origin in Magadha and Kośala. The next major Buddhist centres to arise were probably Mathurā and Ujjayinī to the west. About 100 years after the demise of the Buddha, invitations were supposedly sent out for the Council at Vaiśālī to such far-off places as Patheya, Avanti, Kauśāmbī, Kanauj, and Saṅkasya. Buddhism lost its royal patronage with the rise of the Śuṅgas, but by this time the religion had won a popular footing, as is witnessed by the Kārlī caves and the Sāñchī and Bharhūt *stūpas*, all built during the Śuṅga-Kāṇva period (185–28 BC). It was also at this time that King Menander and many Yavanas (Greeks) living in northwest India are said to have been converted. By the 1st century AD, Buddhism flourished under King Kaniṣka in Afghanistan, Bactria, Kashgar, Yarkand, Khotan, and Kashmir. At this time, the religion was spreading throughout Central Asia. During the first Christian centuries the Chinese became acquainted with the "Way" of the Buddha.

Missionaries had been sent out under King Aśoka in the 3rd century BC to Ceylon and Southeast Asia. In the latter area, the Mon peoples were among the first to adopt Buddhism, later transmitting the faith to their conquerors, the Burmese, Khmer, and Thai. Buddhism probably passed from India to Southeast Asia both by land, through Assam, and by sea. Another line of penetration, more difficult to reconstruct, ran from Central Asia through southern China down into Southeast Asia. Such peoples as the Thai were already familiar with Buddhism by the time they arrived in the peninsula in the 9th century AD. Mahāyāna was introduced in the southern part of the peninsula, in the kingdom of Funan in the 5th century AD, and passed to the Khmer by the 6th century. Before the 5th century, Buddhism had penetrated as far as Java and Sumatra.

In the north, Mahāyāna spread from China to Korea by the 4th century AD. From Korea it was introduced in Japan by the 6th century AD, and, by the 7th century, it had been introduced in Tibet.

BUDDHISM IN CENTRAL ASIA AND CHINA

Developments in Central Asian kingdoms. The spread of Buddhism from India to China through Central Asia is still not completely understood by historians. In the Tarim Basin in Central Asia, there was a confusing welter of languages, religions, and cultures, and, as the new religion passed through this area, it took on a new look. Some Mahāyānist *sūtras* were probably written or edited here. Shamanism, Zoroastrianism (an Iranian religion founded by Zoroaster, a *c.*-7th–6th-century-BC prophet), Nestorian Christianity (an Eastern heretical church that

Syncretistic developments

did not accept the orthodox decrees of the Council of Chalcedon, 451), and, later, Islām all penetrated these lands. There is evidence of some degree of syncretism between Buddhism and Manichaeism, an Iranian dualistic religion that was founded in the 3rd century AD. Some of the Mahāyāna *bodhisattva*s, such as Amitābha, Avalokiteśvara, Mañjuśrī, and Kṣitigarbha, may have been inspired, in part, by Zoroastrian influence. The missionary expansion of northern Indian schools into Central Asia was greatly aided by the support given by the Indo-Scythian King Kaniṣka (?78–103 AD) of the Kuṣāṇa (Kushan) dynasty. In addition to purportedly calling together a Buddhist council, he also patronized the art of Gandhāra, an Indian kingdom now in Pakistan, which had introduced Persian and Greek elements into Buddhist iconography. By the 1st century BC, Buddhism had probably been introduced in Eastern Turkistan, where there were numerous Indian colonies. According to tradition, a son of Aśoka founded the kingdom of Khotan around 240 BC. The grandson of this king supposedly introduced Buddhism in Khotan, where it became the state religion. In the northern part of Chinese Turkistan, Buddhism spread from Kucha to the kingdoms of Agnideśa (Karashahr), Kao-ch'ang (Turfan), and Bharuka (Aksu). Even after the decline of these states, Buddhism continued to flourish under the patronage of the Uighur Turks until the 11th century. Chinese travellers noted that Hīnayānists were strongest in Turfan, Shanshan, Kashgar, and Kucha, and Mahāyāna was found in Yarkand and Khotan. In some places both were to be found. After the rise of Islām (7th century AD) and the decline of the T'ang dynasty (618–907) in China, Central Asia ceased to be the important crossroads of Indian and Chinese culture it once had been.

Developments in China. Though there are reports of Buddhists in China as early as the 3rd century BC, Buddhism was not actively propagated in that country until the early centuries of the Christian Era. Tradition has it that Buddhism was introduced after the Han emperor Ming (AD 58–76) had a dream of a flying golden deity that was interpreted as a vision of the Buddha. Accordingly, the Emperor dispatched emissaries to India who subsequently returned to China with the *Sūtra in Forty-two Sections*, which was deposited in a temple outside the capital of Lo-yang. In actuality, Buddhism entered China gradually, first through Central Asia and, later, by way of the Malay Archipelago (around the 6th–7th centuries AD).

Buddhism during the Han dynasty (206 BC–AD 220). The Buddhism that first became popular in China during the Han dynasty was deeply coloured with magical practices, making it congruent with popular Chinese Taoism (a combination of folk beliefs and practices and philosophy). Instead of the doctrine of no-soul, early Chinese Buddhists taught the indestructability of the soul. Nirvāṇa became a kind of immortality. They also taught the theory of *karma*, the values of charity and compassion, and the need to suppress the passions. Until the end of the Han dynasty, there was a virtual symbiosis between Taoism and Buddhism and a common propagation of the means for attaining immortality through various ascetic practices. It was widely believed that Lao-tzu, the founder of Taoism, had been reborn in India as the Buddha. Many Chinese emperors worshipped both Lao-tzu and the Buddha on the same altar. The Buddhist *sūtra*s that were translated first into Chinese—namely those dealing with such topics as breath control and mystical concentration—utilized a Taoist vocabulary to make the Buddhist faith intelligible to the Chinese. After the Han period, in the north of China, Buddhist monks were often used by non-Chinese emperors for their political–military counsel as well as for their skill in magic. At the same time, in the south, Buddhism began to penetrate the philosophical and literary circles of the gentry. One of the most important contributions to the growth of Buddhism in China during this period was the work of translation. The most important of the early translators was the learned monk Kumārajīva, who, before he was brought from Tibet in AD 401, had studied the Hindu Vedas, the occult sciences, and astronomy, not to mention both the Hīnayāna and Mahāyāna *sūtra*s. His translations paved the way for the rise of the Chinese school of Mādhyamika (San-lun, or the Three Treatises, school).

Developments during the 6th century. In the 6th century, an important school arose in China that sought to integrate the various schools and *sūtra*s of Buddhism. The T'ien-t'ai sect (a rationalist school of thought), under the leadership of Chih-i, sought to arrange the bewildering plethora of *sūtra*s according to "five periods and eight teachings" of the Buddha. The effect of this was to demonstrate that these teachings had evolved from the "simple" truths of Hīnayāna to the more "advanced" insights of Mahāyāna. The highest wisdom was the recognition that in every particle of dust, in every moment of thought, the whole universe is contained.

Origins of T'ien-t'ai and Pure Land Buddhism

At about the same time, the school of Amitābha pietism, known as Pure Land Buddhism, was also making progress in China. In India, believers in the devotional cult that emphasized the worship of Amitābha (Chinese O-mi-t'o) Buddha taught that one can win rebirth in the Pure, or Happy, Land after death by various methods, such as (1) hearing the name of Amitābha, (2) by arousing the thought of Enlightenment and meditating as few as ten times on Amitābha, or (3) by showing a simple desire to be born in the Western Paradise (Sukhāvatī, or "Happy Land"). Thus, one had to cooperate with the "other-power" of Amitābha—it was not simply a matter of "salvation by faith alone." In China, the Pure Land school emphasized what it called the "easy path," one that was appropriate for what it regarded as the "latter days" of the *dharma*, which, it was widely believed, began around AD 550. Coming after the age of the "True Dharma" and that of the "Counterfeit Dharma," this final age was regarded as a period of decadence during which the earlier "path of the saints" had become too difficult for men to follow. According to one of the leaders of the Pure Land school, Shan-tao (7th century), the "primary act" that would lead to rebirth in the western paradise was the recitation of the name of O-mi-t'o. Nevertheless, "secondary acts," such as meditation, *sūtra* chanting, and singing, should also be practiced. Primitive Buddhism had generally emphasized "self-power," as can be seen in such important sayings of the Buddha as, "Be ye lamps *unto yourselves*, be ye a refuge *unto yourselves*." The "other-power" of O-mi-t'o taught by Pure Land Buddhism was based on the doctrine of *pariṇāmanā*, or the transfer of merits from a Buddha or *bodhisattva* to a sentient being. This kind of "pietism" was deeply influenced by the folk tradition. Under the influence of Tantra, Pure Land's principal *bodhisattva*, Avalokiteśvara, was transformed into a feminine deity and was homologized with the Tibetan mother-goddess, White Tara. This *bodhisattva* was known as Kuan-yin in China and as Kannon in Japan.

Developments during the T'ang dynasty (618–907). The golden age of Buddhism in China occurred during the T'ang dynasty. Though the T'ang emperors were usually Taoists themselves, they tended to favour Buddhism, which had become extremely popular. Under the T'ang, the government extended its control over the monasteries and the ordination and legal status of monks. From this time forward, the Chinese monk styled himself simply *ch'en*, or "a subject." This new age saw the rise of several new Buddhist schools in China—San-lun (Three Treatises school), Fa-hsiang (Dharma-characteristic), Hua-yen (Flowery Splendour), and Pure Land under Shan-tao. There was a great expansion in the number of Buddhist monasteries and temple lands. This was also the age of many pilgrimages to India, heroic journeys that greatly enriched Buddhism in China both by the *sūtra*s and the spiritual and intellectual inspiration brought back from "the Country of the Elephant."

The Ch'an sect—better known in the West by its Japanese name, Zen—traces its history back to Bodhidharma, who came from India to Canton in 470 and then went to North China in 520. It is said that he was able to meditate so deeply that once, while facing a wall in medita-

Origins and teachings of Ch'an, or Zen, Buddhism

tion for nine years, his legs fell off, and that he once cut off his eyelids to prevent them from disturbing his meditation. Ch'an, or Zen, combines the metaphysics of Śūnyavāda and Vajrayāna (especially their emphasis on the Void and the identity of *saṃsāra* and Nirvāṇa) with the doctrine of sudden Enlightenment taught by the Chinese monk Tao-sheng in the 5th century. Ch'an was violently antitraditional, insisting that awakening (*wu;* Japanese *satori*) had nothing to do with reciting scriptures. The Ch'an master I hsüan told his disciples,

> kill everything that stands in your way. If you should meet the Buddha, kill the Buddha. If you should meet the Patriarchs [of Ch'an], kill the Patriarchs. If you should meet the *arhat*s on your way, kill them too.

In the Lin-chi branch of Ch'an, the disciple was subjected to beatings and verbal paradoxes called *kung-an* (*kōan* in Japanese). The Ts'ao-tung branch, however, emphasized "sitting in meditation." Though early Ch'an seems to have admitted there could be stages of Enlightenment, the school gradually began to emphasize a sudden awakening. In contrast to other Buddhist monks, Ch'an monks engaged in physical labour. They had the rule: "one day no work, one day no food." This had the fortunate result of making them less dependent on the rulers and laity of China and may be the reason why they were the only sect to survive the persecution of Buddhism in 845 in fairly good stead, when 4,600 Buddhist temples, 40,000 shrines, and 260,500 monks and nuns succumbed to a governmental proscription.

Developments during the Sung dynasty (960–1279). During the Sung dynasty, Ch'an had a decisive impact on landscape painting. Artists used flowers, rivers, and trees, executed with sudden deft strokes, as symbols of the flux and emptiness at the bottom of all things. The bamboo was a typical symbol of this sort, its straight, hard wood representing rectitude, its hollow centre, the Void.

As Buddhism spread through China, it naturally absorbed the spirit of the people. Its genius, compared with that of Indian Buddhism, was pragmatic and this-worldly. Monasteries operated oil presses and general stores, maintained roads, planted trees, and indulged in commerce and moneylending. In the face of the opposition it met from the Chinese family system, Buddhists could spread the ideal of celibacy only by emphasizing the merit that a monk brought to his whole family. In China, the comparatively democratic, or anarchic, Indian *saṅgha* was gradually transformed into a monastic system rigidly controlled by the state. Monks were granted their ordination certificates in government offices staffed by Confucian bureaucrats. More important, however, were the changes made in the basic symbols and ideas of the religion: the affirmation of the soul, belief in countless Buddha-worlds and Buddhas, the harmonization of the various sects (in T'ien-t'ai), and the emphasis on an easy or sudden Enlightenment (Pure Land and Ch'an). These tendencies seem to reflect the general tendency of the Chinese to concretize the abstract and harmonize the contradictory.

BUDDHISM IN KOREA AND JAPAN

Developments in Korea. Buddhism was first introduced into Korea when that peninsula was still divided into the three kingdoms of Paekche, Koguryŏ, and Silla. After Buddhism was brought to the northern kingdom of Koguryŏ from China in the 4th century, it gradually spread throughout the other Korean kingdoms. As often happened, the new faith was first accepted by the court and then extended to the people. After the unification of the country by the kingdom of Silla in the 660s, Buddhism began to flourish throughout Korea. The monk Wonhyo (flourished 7th century) was one of the most impressive scholars and reformers of his day. He was married and taught a kind of "ecumenical" version of Buddhism that included all branches and sects. He tried to use music, literature, and dance to express the meaning of Buddhism. Another scholar of the Silla era was Uisang, who went to China and returned to spread the Hwaom sect in Korea. The Chinese Ch'an sect (Zen) was introduced in the 8th century and, by absorbing the Korean versions of Huayen, T'ien-t'ai, and Pure Land, gradually became the dominant school of Buddhism in Korea, as it did in Vietnam.

Characteristics of early Korean Buddhism

Early Korean Buddhism was characterized by a this-worldly attitude. It emphasized the pragmatic, nationalistic, and aristocratic aspects of the faith. Still, an indigenous tradition of shamanism influenced the development of popular Buddhism throughout the centuries. Buddhist monks danced, sang, and performed the rituals of shamans. During the Koryŏ (Koryŭ) period that followed (935–1392), Korean Buddhism reached its zenith, but then began to decline. During the first part of this period, the Korean Buddhist community was active in the publication of the famous *Tripitaka Koreana,* one of the most inclusive editions of the Buddhist *sūtra*s up to that time. After 25 years in research, a monk by the name of Uich'on published an outstanding three-volume bibliography of Buddhist literature. Uich'on also sponsored the growth of the T'ien-t'ai sect in Korea. He emphasized the need for cooperation between Ch'an and the other "Teaching" schools of Korean Buddhism. Toward the end of this period, Buddhism began to suffer from internal corruption and external persecution, especially that promoted by the Neo-Confucianists. The government now began to put limits on the privileges of the monks, and Confucianism replaced Buddhism as the religion of the state. Though the Yi dynasty (1392–1910) continued these restrictions, Buddhist monks and laymen fought bravely against the invasion of the Japanese armies under Toyotomi Hideyoshi (1537–98) in 1592 and 1596. In the decade before the annexation of Korea by Japan (1910), some effort was made to unify Korean Buddhism. These efforts, as well as the subsequent efforts of Buddhist "missionaries" from Japan, were largely in vain.

Developments in Japan. *Introduction of Buddhism to Japan.* Though Buddhism in China sent its roots down into the subsoil of the family system, in Japan it found anchorage in the nation itself. The Buddhism that was initially introduced into Japan in the 6th century from Korea was regarded as a talisman (charm) for the protection of the country. The new religion was accepted by the powerful Soga clan but was rejected by others, thus causing controversies that resembled the divisions caused by the introduction of Buddhism in Tibet. In both countries, some believed that the introduction of Buddhist statues had been an insult to the native deities, resulting in plagues and natural disasters. Only gradually were such feelings overcome. Though the Buddhism of the Soga clan was largely magical, under the influence of Prince Shōtoku, who became regent of the nation in 593, Buddhism recovered part of the religious depths that it had lost in its initial transmission to Japan. Shōtoku lectured on various scriptures that emphasized the ideals of the layman and monarch, and he composed a "Seventeen Article Constitution" in which Buddhism was adroitly mixed with Confucianism as the spiritual foundation of the state. In later times, he was widely regarded as the incarnation of the *bodhisattva* Avalokiteśvara.

Early sectarian developments. During the Nara period (710–784), Buddhism actually became the religion of the state. Emperor Shōmu actively propagated the faith, making Nara—with its "Great Buddha" statue (Daibutsu)—the national cult centre. Provincial temples (*kokubunji*) made the system effective at the local level. The Kegon sect (the Japanese version of the Chinese Hua-yen)—a sect that emphasized the doctrine of the interpenetration of all things—provided the ideology for the new Buddhist state. During the Nara period there were six different sects that were active. Two of these schools were of Hīnayāna extraction: Kusha, a Sarvāstivādin sect based on Vasubandhu's *Abhidharmakośa* ("Treasury of Higher Law"), and Jōjitsu, a Sautrāntika school, which made use of Harivarman's *Satyasiddhi* ("Completion of Truth"). Sanron was the Japanese version of the Chinese Three Treatises school (San-lun) that was based, as the name implies, on three fundamental texts: the *Mādhyamika-śāstra* ("Treatise on the Middle Way"), the *Śata-śāstra* ("One-hundred Verses Treatise"), and the *Dvādaśa-dvāra*

Sects active during the Nara period

("Twelve Gates"). The numerous texts of the Hossō sect were summarized in the *Vijñaptimātratāsiddhi* ("Completion of Mere Ideation") by Dharmapala. Kegon (similar to the Hwaom sect in Korea) was a cosmotheistic sect, emphasizing that every existence in the universe can commune with the cosmic soul embodied in the Buddha's person, which concentrated on the *Avataṃsakasūtra* ("Wreath Scripture"). The Ritsu school was mostly concerned with maintaining the *vinaya* discipline. Except for Kegon and Hossō, these schools were merely academic alternatives. At this time, the ideal of universal salvation, taught by the *Lotus Sūtra*, and emphasis on the role of the layman, as taught in the *Vimalakīrtisūtra*, were officially propagated. It soon became obvious to the throne that ecclesiastics were becoming too active in politics. During the reign of Shōmu's daughter, the monk Dōkyō, who was acting as her regent (or "king of the *dharma*"), tried to become emperor. Only the resistance of the aristocracy saved Japan from becoming a Buddhist theocracy on the order of Tibet. Partly because of this pressure from the monastic community, the court decided to move to Heian-kyō (Kyōto) in 794.

In 804 the monk Saichō was sent to China and returned to Japan later to preach the doctrines of T'ien-t'ai (Japanese Tendai). Though the Hossō sect had taught that there were some who could not be saved, Tendai stressed a gospel of universal salvation. The nationalistic overtones of Japanese Buddhism continued to be heard in the new schools of the Heian period. Tendai's monastic complex on Mt. Hiei was known as the "Chief Seat of the Buddhist Religion for Ensuring the Security of the Country." Shingon Buddhism was a form of Tantrism that was introduced into Japan by the monk Kūkai in the early 9th century. Shingon (True Word) Buddhism emphasizes the unity of the believer with the Buddha as he performs various esoteric rites. The two *maṇḍala*s (picture-charts, or cosmoplans) called the "thunder-bolt-element-circle" and the "womb-element-circle" are of primary importance in Shingon Buddhism. With Tendai and Shingon, Dual Shintō, the joint worship of the Shintō gods (*kami*) and Buddhist deities and Buddhas, began.

Shingon Buddhism

Development of Japanese Pure Land sects. Though Japanese Amida (Sanskrit Amitābha) pietism can be traced back to Hui-yüan (333–416) in China, it was Ennin (794–864) who first brought the practice of *nembutsu* (recitation of Amida's name) to Japan. The Tendai sect nourished the new piety and the Tendai monk Kūya (903–972) taught a communal recitation of Amida's name. His movement was later restored by another shamanistic Amidist, Ippen (1239–89). This resulted in the formation of the Ji (Times) sect, so called because it stressed the recitation of the hymn of Shan-tao six times every day. Another Amidist leader was Ryōnin (1072–1132), who founded the Yūzū Nembutsu (All-Permeating Amida Buddha) sect, in which the teachings of the *Lotus Sūtra* were blended with Amida piety. The popular Shugen-dō (mountain religion) became deeply impregnated with the practice of *nembutsu*, which was regarded as a prophylactic against evil spirits (*goryō*). Thus, long before the Kamakura period (1192–1333), when it became truly popular, the cult of Amida had taken root in the religious subsoil of Japanese folk piety. The Pure Land school (Jōdo-shū) was systematized in Japan by Hōnen (1133–1212), and his follower, Shinran (1173–1262), gave a new and radical emphasis to the teachings of the sect. Shinran, who married and lived "neither as a monk nor layman," began a movement that has been compared to the Lutheran Reformation in Christianity. Rejecting the entire merit-*karma* way of thinking, Shinran taught that men could be saved even by a single invocation of Amida. But even then, he maintained, it was Amida who inspired the invocation. This marked what could be called the high point of *tariki* (salvation by faith in other powers) in the history of Buddhism. In the 15th century. Rennyo shaped Shinran's teachings and followers into a sect that came to be called True Pure Land (Jōdo-Shinshū). This sect had its own armies and extensive temple lands. In the 20th century the Pure Land sects have more adherents than any other Buddhist group in Japan.

Development of Nichiren and Zen Buddhism. In the 13th century, Japanese Buddhism produced its one "prophet," the monk Nichiren (1222–82). This charismatic and abrasive leader taught that salvation could be won by reciting the words *namu Myōhōrengekyō* ("salutation to the *Lotus Sūtra*") and did not hesitate to attack other, contradictory doctrines. the fulfillment of his prediction of the Mongol attacks on Japan brought him fame throughout the country. Much of his nationalistic spirit lives on today in the followers of Sōka-gakkai (Value Creation Society).

During the Kamakura period Zen (Chinese Ch'an) began to be popular in Japan. The Lin-chi (Japanese Rinzai) school was introduced by the monk Eisai (1141–1215), who also wrote a tract called "Propagate Zen, Protect the Country." In the 13th century, Dōgen (1200–53) introduced the Ts'ao-tung school of Zen (Sōtō, in Japanese) with its emphasis on "sitting in meditation" (za-zen). The Fuke sect, a community of wandering monks, was founded by Kakushin in 1255. Zen soon became associated with the most important facets of medieval Japanese art and culture, infusing them with its own unique spirit. Because it taught its followers a direct and unhesitating style of life, Zen became popular with Japan's military class. Later, in 1654, the Ōbaku school of Zen was established by the Chinese priest Yin-yüan Lung-ch'i (Japanese Ingen Ryūki). This school showed similarities to Rinzai, but also made use of Amidist practices.

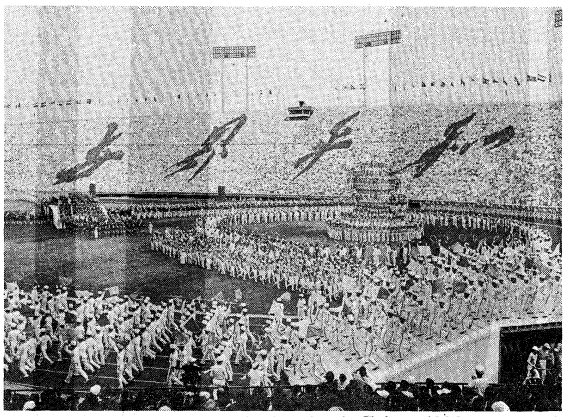
During the chaos of the Ashikaga period (1338–1573), many Buddhist monasteries took up arms to protect themselves and to extend their holdings. An exception to this was the Zen sects that were active even during this period, developing and refining Japanese culture and aesthetics and introducing Neo-Confucianism to Japan—a doctrine that would later turn upon Buddhist patrons with a vengeance. Christianity, another rival of Japanese Buddhism, was introduced in 1549 by Francis Xavier.

Developments during the Tokugawa period (1603–1867). Under the Tokugawa shogunate (a feudal system), Buddhism became an arm of the government. Temples were used for registering the populace—one way of preventing the spread of Christianity that the feudal government regarded as a political menace. This association with the Tokugawa regime made Buddhism quite unpopular at the beginning of the Meiji period (1868–1912), at least among the elite. At that time, in order to set up Shintō as the new state religion, it was necessary for Japan's new ruling oligarchy to separate Shintō from Buddhism. This led to the confiscation of temple lands and the unfrocking of many Buddhist priests. During the period of ultranationalism (*c.* 1930–45), Buddhist thinkers called for uniting the East in one great "Buddhaland" under the tutelage of Japan. After the war, however, Buddhist groups, new and old alike, began to emphasize Buddhism as a religion of peace and brotherhood. During the postwar period, the greatest visible activity among Buddhists has been among the "New Religions" such as Sōka-gakkai and Risshō-Kōsei-kai (Society for Establishing Righteousness and Friendly Relations). During this period, Sōka-gakkai entered politics with the same vigour it had traditionally shown in the conversion of individuals. Because of its highly ambiguous but conservative ideology, the Sōka-gakkai-based political party (the Kōmei-tō) is regarded with both suspicion and fear by many Japanese. In spite of a certain measure of ecumenical cooperation between some of the "New Religions," Japan today abounds with a plurality of Buddhist sects as does no other Buddhist country in the world.

Buddhism as a state religion

BUDDHISM IN TIBET AND THE HIMALAYAN KINGDOMS

Developments in Tibet. Tantra was not very important in China or Japan, though it did exist in these countries. In Tibet, however, it played a more important role. Buddhism was introduced in Tibet by the 7th century, but, only by the middle of the following century, with the arrival of Padmasambhava, a Tantric master from India, did the religion begin to dominate the indigenous shamanistic practices called Bon. It was at this time that the Tibetans decided to follow Indian rather than Chi-



Grand finale to a Sōka-gakkai gathering in Tokyo, 1967. Great numbers of followers make formations on the field, while others in the stands hold placards spelling out "world peace."

nese Buddhism. A curious mixture of shamanism, Tantrism, and Indian Mādhyamika gradually became the core of what came to be known erroneously as Lamaism, the religion of the "superior ones." A persecution of Buddhism under King Glang-dar-ma in the 9th century was a great setback for Tibetan Buddhism, and it was not until the 11th century, with the arrival of the Indian monk Atīśa, that the religion began to prosper once again. During the 11th century the famous Sa-skya monastery of the "Yellow Hats" sect rose to prominence.

The role of the Lamas

Under the Mongols, the abbots of this monastery became the theocratic rulers of Tibet. Known as Dalai Lamas (Great Ocean Lamas), these rulers were regarded as incarnations of Avalokiteśvara. The head of the Tashilhunpo monastery, west of Lhasa, was known as the Paṇchen Lama (Wise and Great Lama) and was thought to be the incarnation of Amitābha. Unlike the Dalai Lama, the Paṇchen Lama was thought to be merely a spiritual ruler. Tibetan monasteries were controlled by aristocratic abbots who were free to marry and pass along their monastic possessions to their sons. Monks often played the role of warriors and the monasteries themselves became armed fortresses. The history of Tibetan Buddhism is filled with intrigue and the lust for power. The Manchus in the 18th century and, after them, the Nationalist Chinese, the Chinese Communists, and the British have all tried to exploit the division of power between the Paṇchen and Dalai Lamas for their own ends. In 1959, after the Dalai Lama fled to India, the Chinese Communists took over his temporal powers.

Developments in the Himalayan kingdoms. *Nepal.* Buddhism in Nepal has been influenced both by India and Tibet. Though the Buddha was born in the southern part of the country at Lumbinī, about 15 miles (24 kilometres) from Kapilavastu, the Buddhist religion seems to have been actively propagated only later, probably under Aśoka. By the 8th century AD, Nepal had fallen into the cultural orbit of Tibet. A few centuries later, as a result of the Muslim invasions of India, both Hindus (such as the Brahmanic Gurkha aristocracy) and Buddhists took refuge in the country. In modern times, Buddhist prayer wheels and flags are reminders of the direct influence of Tibetan Buddhism. The Indian heritage is especially evident in the caste system that embraces Buddhists and non-Buddhists alike The Śiva *liṅga* (phallic symbol), so popular in Nepalese Hinduism, is regarded by Buddhists as the lotus in which Ādi-Buddha was revealed to Mañjuśrī and the early Buddhas.

Bhutan. In Bhutan, a Tibetan Lama introduced Buddhism and a Tibetan style of hierarchical theocracy in the 17th century AD. The Duk-pa ('Brug-pa) sect of Buddhism that arose in Bhutan was a kind of "unreformed" Lamaism. The Tibetan Bka'-brgyud-pa sect, which stressed the magical benefits of living in caves, had a direct influence on Bhutanese Buddhists. Few monks in this country are celibate.

Sikkim. In Sikkim, most of the population originally came from Nepal and preserved their ancient Nepalese castes (or tribal identity). Tibetan and Bhutanese tribes are also present, having brought with them their native religious traditions. In the 17th century AD, Tibetans usurped the government, with the result that even the aboriginal Lepchās were influenced by Tibetan Buddhism.

BUDDHISM IN CEYLON AND SOUTHEAST ASIA

Developments in Ceylon. In Ceylon, Theravāda Buddhism took shape as a complete religiosocial system, and from Ceylon, beginning in the 11th century, a reformed Theravāda Buddhism spread to Southeast Asia. In spite of its reputation for staunch orthodoxy, the history of Theravāda in Ceylon was one of constant struggle against Hinduism, Tantrism, and various types of Mahāyāna. Though the Mahāyānist influence was strongest in the 4th century, by the 8th century esoteric Buddhism had become powerful enough on the island to have some impact on the development of Mantrayāna in both India and China. Under Tamil kings from South India, Sinhalese Buddhism was threatened with reabsorption by both Hinduism and Mantrayāna from the 9th through the 11th centuries. Three times in the history of the island the valid Theravāda ordination lineage had to be renewed by foreign ecclesiastics (in the 11th and 15th centuries, when monks were brought to Ceylon from Burma, and again in the 18th century, when Thai monks from Ayutthaya restored the succession).

Transmission of Buddhism by Mauryan missionaries

Buddhism took root in Ceylon with the arrival of Aśoka's son Mahinda and his six companions. Sent as missionaries by the Mauryan emperor, these travellers converted King Devānampiya Tissa and many of the nobility. Under King Tissa, the Mahāvihāra monastery was built, an institution that was to become the centre of Sinhalese orthodoxy. After Tissa's death (*c.* 207 BC) Ceylon fell into the hands of the Tamils until the time of Duṭṭhagāmaṇī (101–77 BC), a descendant of Tissa, who overthrew the Tamil king Eḷāra. During this time, as a reaction to the threat posed by the Tamils, Buddhism and Sinhalese nationalism became closely intertwined. Again, it was probably because of this danger that the Pāli canon was first written down under King Vaṭṭagāmaṇī Abhaya in the 1st century BC. This king also built the Abhayagiri monastery, the main centre of the various Mahāyāna movements in Ceylon. These heterodox tendencies, which provoked a popular rebellion, were openly supported by King Mahāsena (AD 276–303). Under Mahāsena's son, Śrī Meghavarṇa, the "Tooth of the Buddha" was brought to Abhayagiri and made the national palladium. Next to the Pāli canon itself, the Theravāda faith was probably most clearly spelled out by the scholar Buddhaghosa in the 5th century AD. Studying a Mahāvihāra, Buddhaghosa translated Sinhalese works into Pāli and wrote exegetical works of his own. In the 11th century, King Vijayabāhu sought to reform the *saṅgha* by appointing a *saṅgharāja* (ruler of the order) to rule over all monastics on the island and by reestablishing the valid line of ordination.

In modern times, Ceylon fell prey to the Western colonial powers (to the Portuguese in 1505–1658, the Dutch in 1602–1796, and finally the British in 1796–1947). Under King Kittisiri Rājasiha (1747–81) the ordination lineage was once again renewed by monks dispatched from Thailand. The monastic community in Ceylon (now Sri Lanka) is divided into three major bodies: (1) the Siam Nikaya, founded in the 18th century, a conservative and wealthy sect that admits only members of the Goyigama, the highest Sinhalese caste; (2) the Amarapura sect, founded in the 19th century, which has opened its ranks to members of lower castes; and (3) the reformed splinter group from the Siam Nikaya called the Ramanya sect. Only the Amarapura and Ramanya sects have been active in politics, the Siam sect becoming involved only when its own interests have been threatened.

Characteristics of Ceylonese Buddhism

As conservative as it may be, the Theravāda tradition of Ceylon cannot be regarded as "pure" Buddhism. It includes the worship of Hindu gods as well as local

spirits. The main-line tradition that emerged on the island was characterized by an emphasis on the historical person of the founder (and not on his transcendent or cosmological nature). As for religious practice, the *bodhisattva* ideal never seemed to detract from the emphasis laid upon being a disciple (*śrāvaka*) of the Buddha. By regarding them as a means of recalling the life of the founder, images and relics were made "theologically" acceptable. The *dharma* became equated with the new Pāli canon. Because of the *dharma*-power they contained, the scriptures were often chanted as spells to ward off evil. One of the most outstanding features of Sinhalese Buddhism has been its nationalistic spirit. The Sinhalese Buddhist kings perpetuated the ideals of Aśokan kingship. They also enlarged this ideology by promoting the popular homologization of the figure of the Buddhist king with the Buddha and *bodhisattva*. In particular, it was Maitreya (the only *bodhisattva* generally recognized by Theravādins) who was most frequently associated with the king.

Developments in Southeast Asia. The peoples of Southeast Asia have not been mere satellites of the more powerful Indian and Chinese civilizations. On the contrary, the cultures that arose in these three vast areas might better be thought of as developments within a greater Austroasiatic civilization, sometimes referred to as "Asia of the monsoons." For this reason, the transmission of Buddhism and Hinduism to Southeast Asia can be regarded as the spread of the religious symbols of the more "advanced" elements within this Austroasiatic cluster to peoples sharing some of the basic religious presuppositions and traditions.

Chinese influence in the area was more or less limited to what is now North Vietnam (ancient Annam). In contrast to the Chinese penetration of the area, the Indian influence was spread peacefully, by merchants and missionaries. In the 2nd century BC India's trade routes in Central Asia had been cut off by the Romans, who, at the same time, showed an interest in purchasing spices, gold, and fine wood from Indian merchants. These merchants turned to Southeast Asia for these products. From that time until the beginning of the 14th century, there were close relations between India, Ceylon, and the Indianized states of Southeast Asia in both trade and culture.

Conversion of Burmese and Khmer peoples to Theravāda

Burma. In the region that is now central Thailand and southern Burma, the Mons were among the first to be influenced by Indian culture and Buddhism. They subsequently played an important role in the conversion of the Burmese and Khmer peoples to Theravāda. By the 3rd century AD, the Pyu, a Tibeto-Burmese tribe, had established themselves in Lower Burma and had made their capital, Śrī Kṣetra, a centre of Theravāda learning. In spite of inroads made by Mūla (fundamental)-Sarvāstivādin and Mahāyāna ideas, the Pyu kingdom remained a stronghold of Theravāda until its fall in the 9th century. In Upper Burma at this time, the Aris, a Tantric sect, flourished. The Mahāyāna *bodhisattva*s Avalokiteśvara, Maitreya, and Mañjuśrī were also known in this area. Under King Anawrahta (1044–77) Upper and Lower Burma were united in a new Theravāda state. Burmese Buddhism was soon troubled by a controversy over ordination that lasted for 300 years. One school held that its ordination pedigree, going back to missionaries sent out by Aśoka, was valid. Another insisted that only ordinations in the line of succession established by the Sinhalese monastery of Mahāvihāra should be recognized. King Dhammazedi (reigned 1472–92) settled the controversy in favour of the Sinhalese faction. This crucial decision contributed to the development of the conservative orthodoxy of Burmese Buddhism.

Thailand. The Thai, who had begun to move into Southeast Asia by the 9th century AD, originated in China, where they came into contact with Mahāyāna Buddhism. By the 12th and 13th centuries, they had come under the spell of the reformed Sinhalese form of Theravāda that was then sweeping through Southeast Asia. In the 13th century, Thai kingdoms were set up at Sukothai and Chiengmai, the capital of the Lan Na Thai kingdom. By the 14th century the Pāli tradition had been taken over from Sukothai, and, by the 16th century, Chiengmai had become a leading centre of the Theravāda. Under King Tiloka (reigned 1442–87), the "Emerald Buddha" was adopted as the national palladium (*cf.* the "Tooth of the Buddha" in Ceylon). In 1350 a powerful Thai kingdom arose at Ayutthaya. This kingdom conquered Angkor, the Khmer capital, in 1431, and from the conquered Khmer people the Thais of Ayutthaya absorbed elements from the Brahmanic tradition that continued to be an asset to Thai statecraft even in the kingdom of Bangkok established by King Rama I (reigned 1782–1809). The kingdom of Bangkok became the dominant Thai state after the fall of Ayutthaya to the Burmese in 1769.

Indochina. In Laos, Buddhist statues of Mahāyāna inspiration have been discovered dating from the 11th and 12th centuries AD. Initially, Laotian Buddhism came under the influence of the Khmers, and both Mahāyāna and Theravāda traditions were recognized. Later, in the 14th century, Theravāda became the dominant faith. In 1356, King Fa Ngum, at the prompting of his wife, invited a Theravāda mission from Cambodia to visit Laos.

At the southern extremity of the Indochinese Peninsula, one of the earliest known states was Funan. A Sanskrit variety of Hīnayāna was first introduced here. Later, under King Kaundinya Jayavarman in the 5th century, Hinduism and Mahāyāna were introduced. The Khmer kingdoms at Chenla (6th century) and at Angkor (9th century) inherited many items from the culture of Funan. At these two capitals Śaivism (worship of the Hindu god Śiva) was the basis of the state cult, though Vaiṣṇavism (worship of the Hindu god Viṣṇu) and Mahāyāna Buddhism were also to be found. In the 11th and 12th centuries Śaivism declined, and Vaiṣṇavism and Mahāyāna seemed to increase in strength (witness the Vaiṣṇava temple at Angkor Wat in Cambodia). Under Jayavarman VII (reign dates 1181–*c.* 1215, possibly as late as 1219) the power of the Khmer Empire reached its apex. A Brahmanic–Mahāyāna Buddhism became the foundation of the state. A radical change soon took place when the conquered Mons began to spread Theravāda (*c.* 1200–1350) among the Khmers. By the time of the capture of Angkor in 1431, the conversion of the Khmers to Theravāda seems to have been complete.

Vietnamese Buddhism

Vietnam is the only country in Southeast Asia where both Theravāda and Mahāyāna continue to exist side by side. Theravāda seems to have been introduced by the Khmer minority in the country and is still found mainly on the Cambodian border. The Mahāyāna sects were limited, for the most part, to varieties of Zen and Pure Land. The first *dhyāna*, or "meditation," school was introduced by Vinitaruci, an Indian monk who had come to Vietnam from China in the 6th century. In the 9th century a school of "wall meditation" was introduced by the Chinese monk Vo Ngon Thong. A third major Zen school was established in the 11th century by the Chinese monk Thao Durong. From 1414 to 1428, Buddhism in Vietnam was persecuted by the Chinese, who had again conquered the country. Tantrism, Taoism, and Confucianism were also filtering into Vietnam at this time. Even after the Chinese had been driven back, a Chinese-like bureaucracy closely supervised the Vietnamese monasteries. The clergy was divided between the highborn and Sinicized (Chinese-influenced), on the one hand, and those in the lower ranks who often were active in peasant uprisings.

Indonesia. With the help of Indian missionaries, such as the monk Guṇavarman, Buddhism had gained a foothold on Java well before the 5th century AD. The religion was also introduced at about this time in Sumatra, and, by the 7th century, the King of Śrīvijaya on the island was a Buddhist. When the Chinese traveller I-ching visited this kingdom in the 7th century, he noted that Hīnayāna was dominant in the area but that there were also a few Mahāyānists. It was also in the 7th century that the great scholar Dharmapala of Nālandā university visited Indonesia, or Suvarṇadvīpa as it was called. The Śailendra dynasty, which ruled over the Malay Peninsula and a large section of Indonesia from

the 7th to the 9th century, promoted Mahāyāna and erected Buddhist monuments at Mendut, Kalasan, and Borobuḍur in Java. From the 7th century onward, Tantrism spread throughout Java and Sumatra, coming originally from Bengal. King Kertanagara of Java (reigned 1254–92) was especially devoted to Tantrism. Buddhism was also introduced in Bali and Borneo, but local variations of Hinduism ultimately dominated the religious life of these islands.

BUDDHISM IN THE LATE 19TH AND 20TH CENTURIES

Both the character of the various national and religious traditions and the kind of encounter experienced with Western colonial powers conditioned the response of Buddhism to the challenges of the modern age. The adequacy of this response and the strength of Buddhism in the various Asian cultures are difficult to measure, because the vitality of a religion cannot be measured in terms of its institutions alone and also because no accurate index of secularization is available. In some areas, such as in China, the historian is hindered by a simple lack of information, but he does know, however, that the Buddhist community suffered considerable damage during the rampages of the Red Guard (1966–69) especially in Tibet.

Influence of Western colonialism

Of the Buddhist nations, only Thailand and Japan escaped colonization by Western powers. Thus, Buddhism could not help becoming involved in the struggle against colonialism and the creation of new polities all over Asia. In Ceylon there were only five ordained monks left after the expulsion of the Portuguese. Under the less fanatical Dutch and British, the Sinhalese began to convert to Christianity, often for pragmatic reasons. In the second half of the 19th century, Buddhism produced a counteroffensive movement led by Mohottivatte Gunananda, who studied the Christian Scriptures and the Western critics of Christianity and then challenged the Christian missionaries to debates. The Buddhist Theosophical Society, founded by Col. Henry S. Olcott, an American, in 1880, and the Maha Bodhi Society, founded in 1891 by the monk Dharmapala (David Hewavitarane), made significant contributions to the revival of Buddhism in Ceylon. Once again the Buddhist nationalism of the medieval kings became the inspiration of Sinhalese politics. After the British withdrawal from the island (1947), S.W.R.D. Bandaranaike, leader of the Sri Lanka Freedom Party, became prime minister in 1956 with the help of Buddhist nationalists. Unable to control the excessive demands of extremists, violence erupted between Buddhists and the Tamil minority (1958–59). Though monks campaigned for him during this election, disenchanted monks were also responsible for his assassination in 1959. He was succeeded by his wife, during whose regime (1960–65 and 1970–) Ceylon moved far to the left politically.

Cambodia's prince Norodom Sihanouk and Burma's former prime minister U Nu have also been outstanding, if ultimately unsuccessful, Buddhist nationalists. In Ceylon and Southeast Asia, Buddhist politicians have leaned toward neutralism and have professed a religious commitment to peaceful coexistence. The Aśokan welfare state has been the model for Buddhist Socialism. In Japan, however, the Kōmei-tō, the political wing of Sōka-gakkai, has made accommodations with capitalism and an extreme form of nationalism.

In India, Buddhist politics is virtually synonymous with the name Bhimrao Ramji Ambedkar, leader of the untouchable, or scheduled, caste of Mahārāshtra. As early as 1935, Ambedkar had decided that he could never find justice for his people within Hinduism. Still, it was only in 1956, two months before his death, that Ambedkar, together with as many as 600,000 followers, converted to Buddhism at a mass conversion ceremony held at Nagpur. Since 1930, Ambedkar had regarded Gandhi as an enemy of the scheduled caste (Gandhi believed that India could not survive without a reformed "four caste" system, minus untouchables). Today, Ambedkar's Buddhism is often regarded as the external religious rhetorical form of his Republican Party.

Buddhists often have been forced into the political arena. In Vietnam, the Buddhist community was not politically activated until it was mistreated by the excessively partisan Roman Catholic and anti-Buddhist Ngo Dinh family. In 1963, the government forbade the flying of the Buddhist flag during the May 8 celebration of Buddha's birthday, though Roman Catholics were allowed to fly their flag. The riot that erupted because of this order was put down by well-armed government troops. Understandably, the coup against the Diem regime on November 1, 1963, was actively supported by militant Buddhists. Buddhists in this country have been divided between a moderate group led by Thich Tam Chau and a more militant wing led by Thich Tri Quang. Usually claiming to be politically neutral, the Buddhist call for peace has often been treated by the Saigon government as weakness in the face of Communism. Since 1963 there have been over 30 self-immolations of monks in South Vietnam protesting the ruin of their country.

In spite of its alleged otherworldiness, Buddhism, under certain circumstances, has contributed to the modernization of Asian cultures. In Thailand, Buddhist kings of the Chakri dynasty, together with a reform movement within the monastic community (the Thammayutika Nikaya), contributed strongly to the modernization of the country. Members of the Thammayutika sect have been able to control half of the key positions in the *saṅgha*, though they make up less than 5 percent of the total membership. In Ceylon and Southeast Asia, great efforts have been made to improve the content and relevance of monastic education.

Role of the laity in modern Buddhism

Though poorly educated monks have lost respect among the Western-educated Buddhist elite, new movements have arisen that give the layman a greater religious role. Laymen's meditation groups have been formed, and in Japan powerful new sects, such as Sōka-gakkai and Risshō-Kōsei-kai, have developed as lay movements. The religious education of the layman has lately received more attention, as in the founding of the Buddhist Sunday School Movement in Thailand in 1958. The traditional virtues of the layman, such as compassion (*karuṇā*) and love (*mettā*), have been deemed to be more relevant in the modern world than virtues practiced in the cloister. Above all, the *bodhisattva* ideal has played a dominant role in Buddhist social thought.

One of the great benefits of the World Fellowship of Buddhists, founded in 1950 by G.P. Malalasekera, has been the role it opened up to laymen. Under the auspices of this ecumenical movement, layman and monk, Mahāyānist and Theravādin, have enjoyed an unprecedented encounter. Parallel to the Buddhist ecumenical movement has been the consolidation of national Buddhist communities. Several Buddhist nations, especially Ceylon, Thailand, and Japan, have shown a new interest in Buddhist missions abroad. Probably the most ambitious undertaking of contemporary Buddhism was the sixth great Buddhist Council held in Rangoon, Burma, 1954–56, which, among other accomplishments, re-edited the sacred scriptures of Buddhism.

Some Buddhist writers have gone to great lengths to promote Buddhism as a rational, scientific alternative to the antinomies exposed in Western thought by the battles between Christian dogma and science. They have been quick to point out the Buddha's "empirical" attitudes, the Buddhist concepts of cause and effect, and the flux of elements in Buddhist metaphysics as anticipations of modern scientific views. Still, it cannot be said that Buddhism has generally come to grips with the intellectual problems posed by modern philosophy and science. There are exceptions to this, of course, such as the Zen philosophies of the late Nishida Kitarō (1870–1945) and Nishitani Keiji.

BIBLIOGRAPHY

Buddhism in general: Comparatively recent, concise but scholarly, are the following treatments of Buddhism in general: E. CONZE, *Buddhism: Its Essence and Development* (1951 and 1959); R.H. ROBINSON, *The Buddhist Religion: A Historical Introduction* (1970); and KENNETH K.S. CH'EN, *Buddhism: The Light of Asia* (1968). A helpful aid is E.

ZURCHER, *Buddhism: Its Origin and Spread in Words, Maps and Pictures* (1962). Older studies are H. OLDENBERG, *Buddha: Sein Leben, sein Lehre, sein Gemeinde* (1890; Eng. trans., *Buddha: His Life, His Doctrine, His Order*, 1882); and C.A.F. RHYS DAVIDS, *Buddhism: A Study of the Buddhist Norm* (1912). CHARLES ELIOT, *Hinduism and Buddhism: An Historical Sketch*, 3 vol. (1921, reprinted 1962), especially when considered together with his *Japanese Buddhism* (1935, reprinted 1959), comprises a major historical account of the whole of Buddhism in English. An important and scholarly study of the earlier development of doctrine is E.J. THOMAS, *The History of Buddhist Thought*, 2nd ed. (1951). GUY WELBON, *The Buddhist Nirvāna and Its Western Interpreters* (1968), traces and interprets the history of the West's attention to and study of Buddhism.

Buddhism in India: Among the various works on the life of the Buddha are E.J. THOMAS, *The Life of the Buddha in Legend and History*, 3rd rev. ed. (1949, reprinted 1969); and ALFRED FOUCHER, *La Vie de Bouddha*, (1949; abridged Eng. trans., *The Life of Buddha*, 1963). A.K. COOMARÀSWAMY wrote of this and other topics in Buddhism from a Hindu perspective in *Buddha and the Gospel of Buddhism* (1916, reprinted 1964). For a very good study of Buddha's life and the subsequent history, see SUKUMAR DUTT, *The Buddha and Five After-Centuries* (1957). Dutt's *Buddhist Monks and Monasteries of India* (1962), traces the early history of the *sangha*, especially on the basis of archaeological remains in India. For a study of yoga techniques in Buddhism, see the chapter by that title in MIRCEA ELIADE, *Le Yoga: immortalité et liberté* (1954; Eng. trans., *Yoga: Immortality and Freedom*, 1958). For materials and discussion of the early Buddhist councils and their effect upon the development of the various Buddhist schools, see ANDRE BAREAU, *Les Premiers conciles bouddhiques* (1955); E.J. THOMAS, *The History of Buddhist Thought* (1933); and LOUIS DE LA VALLEE POUSSIN, "Councils (Buddhist)," in vol. 4 of the *Encyclopaedia of Religion and Ethics*, ed. by JAMES HASTINGS. Indispensible for the development of doctrine is E. CONZE, *Buddhist Thought in India* (1962).

Theravāda Buddhism: For Buddhism in Ceylon, see WALPOLA RAHULA, *History of Buddhism in Ceylon: The Anuradhapura Period, 3rd century B.C.–10th Century A.C.* (1956). An important recent study of religion and society in Ceylon is H. BECHERT, *Buddhismus, Staat und Gesellschaft in den Ländern des Theravāda Buddhismus*, vol. 1, *Gerundlagen, Ceylon* (1966). For recent developments in Ceylon, see "Religious Revival and Cultural Nationalism," in W.H. WRIGGINS, *Ceylon: Dilemmas of a New Nation* (1960). For Southeast Asia, see GEORGE COEDES, *Les États hindouisés d'Indochine et d'Indonésie*, 3rd ed. (1964; Eng. trans., *The Indianized States of Southeast Asia*, 1968), and *Les Peuples de la Peninsule Indochinoise* (1966; Eng. trans., *The Making of Southeast Asia*, 1967), which discuss the impact both of Indian civilization and of Buddhism on this area of Asia. Many important studies of the relationship between Buddhism and society in particular Southeast Asian nations have recently appeared. For Burma, see especially E. SARKISYANZ, *Buddhist Backgrounds of the Burmese Revolution* (1965); DONALD E. SMITH, *Religion and Politics in Burma* (1965); and MELFORD E. SPIRO, *Buddhism and Society: A Great Tradition and Its Burmese Vicissitudes* (1970). Other valuable studies of Burmese Buddhism are NIHAR RAJAN-RAY, *An Introduction to the Study of Theravāda Buddhism in Burma* (1946); and KENNETH E. WELLS, *Thai Buddhism: Its Rites and Activities*, rev. ed. (1960). The best studies of Buddhism in Vietnam are in French; see especially essays by DURAND and MAI-THO-TRUYEN in *Présence du Bouddhisme*, ed. by R. DE BERVAL (1959). For a discussion of some contemporary problems of Asian Buddhism in general and Theravāda in particular, see ERNST BENZ, *Buddhas Wiederkehr und zie Zukunft Asiens* (1963; Eng. trans., *Buddhism or Communism: Which Holds the Future of Asia?*, 1965).

Mahāyāna Buddhism: For Mahāyāna Buddhism in China and its development from its earliest days to modern times, see KENNETH K.S. CH'EN, *Buddhism in China: A Historical Survey* (1964), which includes an extensive bibliography. For a thorough presentation of doctrinal development, see E. ZURCHER, *The Buddhist Conquest of China*, 2 vol. (1959), a superb study of the history of Chinese Buddhism until 400 AD. See also ARTHUR F. WRIGHT, *Buddhism in Chinese History* (1959), a lucidly written scholarly account. The philosophical ideas of Mahāyāna as these developed in the various sects of China and Japan are presented in JUNJIRO TAKAKUSU, *The Essentials of Buddhist Philosophy*, 3rd ed. (1956). For a presentation of a Japanese monk's acute observations of Buddhism in China in the 9th century, see E.O. REISCHAUER, *Ennin's Travels in T'ang China* (1955). HOLMES WELCH, *The Practice of Chinese Buddhism, 1900–1950* (1967), is an important study of contemporary Buddhist monasticism in China. ALICE GETTY'S illustrated *The Gods of Northern Buddhism*, 2nd ed. (1928, reprinted 1962), is one of the best presentations of the history of the Buddhist icon in China, Tibet, Korea, and Japan. HEINRICH DUMOULIN, *Zen: Geschichte und Gestalt* (1959; Eng. trans., *A History of Zen Buddhism*, 1963), is an account of the history of the Zen school in both China and Japan. Of the many writings on Zen by D.T. SUZUKI, see especially his *Essays in Zen Buddhism*, 3 series (1927–61), and his *Zen and Japanese Culture* (1959). Two standard works include Buddhism in the course of a presentation of the range of religious history in Japan; they are M. ANESAKI, *History of Japanese Religion* (1930, reprinted 1963); and the more recent *Religion in Japanese History* by J.M. KITAGAWA (1966), which includes a bibliography of works in Japanese and Western languages.

Tibetan Buddhism: HELMUT HOFFMANN, *Die Religionen Tibets* (1956; Eng. trans., *The Religions of Tibet*, 1961), a scholarly and standard work, also treats the relationship between Buddhism and the older Bon religion of Tibet. W.Y. EVANS-WENTZ, a theosophist who lived and studied for years in Tibet, introduced some important and interesting Tibetan works to the West; see his *Tibetan Book of the Great Liberation* (1954) and *Tibetan Book of the Dead*, 3rd ed. (1960). See also DAVID L. SNELLGROVE, *Buddhist Himalaya: Travels and Studies in Quest of the Origins and Nature of Tibetan Religion* (1957) and *Himalayan Pilgrimage: A Study of Tibetan Religion by a Traveller Through Western Nepal* (1961); and GIUSEPPE TUCCI, *Tibetan Painted Scrolls*, 3 vol. (1949).

Translated sources: A translation from the Pāli texts is HENRY CLARKE WARREN, *Buddhism in Translations* (1896, reprinted 1963), old but still very useful. Another good source is *Buddhist Texts Through the Ages*, ed. by E. CONZE (1954). The *Edicts of Asoka*, have been translated by N.A. NIKAM and RICHARD MCKEON (1958). Many important Buddhist texts may be found in translation in the "Sacred Books of the East." In this series the *Sutta Nipata* is in vol. 10; the *Vinaya Texts* in vol. 13, 17, and 20; the *Saddharma Pundarika* or *The Lotus of the True Law* in vol. 21; and *Mahāyāna Texts* in vol. 49. An important Ch'an (Zen) text of China is *The Platform Sutra of the Sixth Patriarch*, newly translated with a valuable introduction by PHILIP B. YAMPOLSKY (1967). An important Japanese Zen text is one by DOGEN, recently translated and made available as *A Primer of Sōtō Zen* by R. MASUNAGA (1971). GARMA C.C. CHANG'S translation, *The Hundred Thousand Songs of Milarepa* (abridged edition 1962), is a lucid representation of the poetry and prose of a classic of Tibetan Buddhism.

(J.M.K.)

Buddhist Mysticism

Mysticism in Buddhism is a definite, recognizable form of experience and type of awareness that may be approached and interpreted in various ways. Mysticism is found in all forms of Buddhism—in Theravāda ("Way of the Elders," also known as Hīnayāna, or "Lesser Vehicle"), the predominant form in present-day Southeast Asia and Ceylon; in Mahāyāna (or "Greater Vehicle"), the predominant form in east Asia; and in Tantric (magical) and Tibetan Buddhism, prevailing at present in the Himalayan regions. In the course of history the mystical element in Buddhist thought became ever more clearly emphasized. The climax was reached when, about the 1st century AD, the transition from early Buddhism into Mahāyāna had been effected. Early Buddhism was codified selectively in the Theravāda canon and remained static; the latter proliferated into distinct lines of thought. Buddhist mysticism will be dealt with here in terms of its distinctive nature, its regional interpretations, and its techniques of realization.

NATURE AND GOALS

Universal mystical aspects. Buddhist mysticism, like other forms of mysticism, insists on the ineffability of the mystical experience, because it defies expression in terms that are intelligible to anyone who has not had analogous experience. The knowledge involved is never merely intellectual but is a kind of felt knowledge in which things are seen in a different perspective and take on a new significance. Related to its ineffability is the timeless quality of this experience, which means that the mystic seems to be outside of time and space, oblivious to his surroundings and the passage of time.

Ineffability and timelessness

The earliest Buddhist mysticism was concerned with the

emptying of subjective Being, considered to be the greatest obstacle to the individual's spiritual growth. This passing into a new dimension of Being was described in terms of a flame going out: it was merely extinguished; it could not be said that it had gone somewhere. In this emptying process the limits that constitute the individual's being, as defined by an analysis of both physical and mental components, were transcended, although all these components were said to be retained. The experience of this new dimension of being was a vision in marked contrast to normal perception—"beyond the reach of mere logic."

The timelessness of the mystical experience underlines the verifiable fact that those experiences that are felt to be most profound and significant cannot be adequately described in terms of past, present, and future or of "earlier than" and "later than." All that the texts say is that there exists a sense of something "unborn, not become, not made, uncompounded" and that the feeling of being born and transitory serves to re-emphasize the timeless and ineffable reality.

Most characteristic, even of the earliest form of Buddhism as codified in the Tipiṭaka, the Theravāda canon, is the emphasis on the path that man must traverse in order to attain his goal. The path is not so much an inert link between two points, such as *saṃsāra* (the bondage to the circumstances of existence) and Nirvāṇa (enlightenment or escape from *saṃsāra*), as the individual's effort to free his being from alien constraints and to break through into a new and more rewarding dimension of Being. This effort presupposes the ability to use and even to know the different modes of Being. Knowledge of Being, not absorption of the self into divine or cosmic Being, is therefore the keynote of Buddhist mysticism. In order to know who the mystic is, one must know what he represents; in order to know what he represents, one must know what it means for man to be; and in order to know what it means for man to be, one must know the difference modes of Being, since they are all that there is or can be. This noetic or cognitive quality of the mystic experience in Buddhism, referred to by the term "eye of knowledge" (*jñānacakṣur*), contains within it moments or facets of appreciation and evaluation. In this immediate apprehension of Being there is no sense of union with the divine, conceived in terms of personality or superpersonality (as in the Hindu *Ātman-Brahman* concept, which posits the identity of the self and the cosmos).

While early Buddhism was analytical in its attempt to free Being from the imposition of subjectivity, Mahāyāna continued the analytical process by extending it to objective Being. In its rejection of subjectivism and objectivism, it emphasized the nature of Being-as-such, which was experienced in enlightenment (*bodhi*). While the various philosophical trends associated with the emergence and development of Mahāyāna dealt with the intellectual problem of being, shorn of all its positive and negative qualifications, the *Tantras* (forming the literature of Mantrayāna—"vehicle of magical spells"—or Vajrayāna —"vehicle of the thunderbolt of awareness"—commonly referred to as Tantric Buddhism) dealt with the existential problem of how it is or feels to be. The Mahāyāna may be said to look at Being, Tantric Buddhism to act through Being.

Peculiarly Buddhist character. Inasmuch as Buddhist mysticism is a mysticism concerned with the analysis of existence, the effort to free Being from alien constraints centres on the separating of some portions of existence and then placing them in relevant relation to one another inside Being. This is done, for example, by contemplative concentration (*dhyāna*) on a particular item (a coloured patch, for example), which then is seen as a unique instance. Such concentration is closely related to aesthetic or intrinsic perception. In contemplative concentration, the practitioner does not see something different, but he sees differently the same thing that others see. This implies the ability to perceive the ineffable, that which cannot be put into words. Trying to force it into words changes it and makes it something other than it is, something that may be like it yet is different from it. The critique of the earlier forms of comtemplative concentration by the later Buddhists, particularly by those belonging to Japanese Zen or the schools close to Zen, with their emphasis on enlightenment (Satori) itself, merely reaffirms the ineffability of the mystic experience. While the earlier forms of Buddhism fixed their gaze on particular phenomena, the later ones took the whole of the psychic energy or mind as the meditative object. Concentration—that is, becoming grounded in the real and not running after the ephemeral—is itself asceticism in the original meaning of practice, not in the subsidiary meaning of mortification of the flesh. As a rule, the Buddhists rejected mortification, although such instances also occurred and may have been due to imitation of essentially non-Buddhist practices.

Contemplative concentration

Goals of Buddhist mysticism and meditation. All meditational techniques aim at enabling the practitioner to come closer to his being, which, in its fulfillment, is felt as an enrichment of the personality with corresponding loss of fear (*abhaya*, "fearlessness") and anxiety, generally referred to as "liberation" (*mokṣa*, *vimokṣa*, *mukti*). It is a kind of self-actualization in the sense that the practitioner becomes more integrated and less split, more independent of his lower needs, less ego centred as a thing of the world. The self-actualization culminates in "integration" (*samādhi*), which does not imply a molding or shaping according to some preconceived postulates. In order to actualize his own potentialities, the practitioner has to traverse the path discriminately. What the final actualization is said to be depends on the particular goal that a man sets himself. Here the different attitudes of earlier and later Buddhism are of decisive importance. The former is self-contained, the latter all-encompassing in orientation.

Means of achieving the goals. The most common means is referred to by the Indian term *yoga* (physical and mental discipline), which in Buddhist mysticism has the specific connotation of harnessing all that is in man to a certain goal and never implies a union with a postulated absolute. Breathing techniques (*prāṇāyāma*) and recitations of *mantras* (magical spells) form an important part, inasmuch as they help to "protect mind from going astray into its own fictions." Similarly, evocative formulas (*dhāraṇi*) are used in the empathetic visualization (*sādhanā*) of the psychic powers appearing in the polarities of male and female. Inasmuch as the aspirant tries to pattern his life after the envisaged content of enlightenment, he adopts certain postures (*mudrās*) that outwardly seem to be gestures and attitudes but, seen from within, are said to be the "imprints" of Being on the aspirant's individual being.

REGIONAL HISTORY

In India and Southeast Asia. The growth of Buddhist mysticism in India coincides with the development of the various Buddhist philosophical schools, particularly with the Yogācāra—which held that only consciousness itself is real—and Mādhyamika—which held both subject and object to be unreal and whose central doctrine is *śūnyatā* ("emptiness")—systems and their interactions (see also BUDDHIST PHILOSOPHY). These disciplines formed the intellectual framework of Tantric Buddhism, the climax of Buddhist mysticism, which spread from Kashmir and Bengal throughout Asia. Applied mysticism, as distinguished from philosophical mysticism, is represented by the "great accomplished ones" (*mahāsiddas*) in India. Tradition counts 84 *mahāsiddhas*. Very little is known about their lives and times, except that they ranged over the whole period of Mahāyāna in India and that they came from different walks of life. Among the *mahāsiddhas* notable for the spread of mysticism are the Brahmin Saraha; the hunter Śabarī; the prince Nāropa and his teacher, the oil-maker Tilopa; and King Indrabhūti and his sister Princess Lakṣmīṃkarā. All of them expressed their experiences in songs, many of them recorded in the Indian vernacular languages. Only fragments have been preserved in the original; for the rest the Tibetan translations are invaluable. It is evident that such songs, or lyric poems—vague in doctrinal content but rich in suggestive imagery—can be used by any group for its spe-

Mahāsiddhas

cific exegesis. In this way Buddhist mysticism exerted a lasting influence on Hinduism and in India was finally absorbed by it. Thus Matsyendranātha, the semimythical founder of the Nātha Yogis—a group of wandering Hindu ascetics still found in present-day India—is claimed by both Buddhists and Hindus as their follower.

While in India the mystic element remained linked to the renunciative trend (even though its symbol language had erotic overtones, which by analogy pointed to the ecstatic feeling tone of the mystical experience), in Southeast Asia Buddhist mysticism blended with political ideas. Hīnayāna Buddhism had come to Southeast Asia in the 4th century, and by the 7th century, Sumatra was an important Buddhist centre. In 717 Vajrabodhi introduced Tantric forms of worship. The mystic genius of the Śailendra period (*c.* 752–832) in Java found its expression in the famous Borobuḍur monument depicting simultaneously the cosmos and the personality. Southeast Asian mysticism is furthermore marked historically by the syncretism of Hinduism—as embodied in both Vaiṣṇavism (worship of the Hindu god Viṣṇu [Vishnu]) and Śaivism (worship of the Hindu god Śiva [Shiva])—and Tantric Buddhism.

In Cambodia, the syncretism of Vaiṣṇavism and Śaivism under Suryavarman II (1113–50) was further advanced by a blending with Mahāyāna Buddhism, which ultimately gave rise to a mystical cult of Śiva-Buddha. Today, however, Theravāda Buddhism dominates Southeast Asia.

In Central Asia and Tibet. It is now a well-established fact that Buddhism had reached Central Asia by the 2nd century AD, but a clear picture of its tenets in the Central Asian oasis states is provided only by sources dating from the 4th century. One of the most important centres was Kucha (China), where Hīnayāna and Mahāyāna existed side by side, with each trend alternately dominating the scene between the 4th and 7th centuries. Afterward it remained predominantly committed to Hīnayāna Buddhism. The existence of mystical Buddhism by the 4th century is well attested. The monk Fo T'u-ch'eng, reaching northern China in 310, was famous for his magic formulas. Between 402 and 412 Kumārajīva translated *dhāraṇī* texts (evocative formulas), and the Indian monk Dharmakṣema is said to have taught sexual practices, which are believed by certain people to constitute or lead to mystical experiences, among the northern Liang. In view of the fact that Kumārajīva translated Hīnayāna, Mahāyāna, *dhāraṇi*, and *dhyāna* (meditation) texts, great tolerance seems to have prevailed, and the mystically minded person could choose any suitable formulation for expressing his experience.

Buddhism was present in Tibet during the reign of Srong-brtsan-sgam-po (died 650), whose Chinese and Nepalese wives were devout Buddhists. At first Buddhism was restricted to the court, and the priests were Indian and Chinese. In the 8th century the two trends of Buddhism—the one conventionally academic and monastic, represented by Śāntirakṣita and Kamalaśīla, two Indian scholars active in Tibet; the other unconventional, mystical, and ritualistic, initiated by the Indian missionary Padmasambhava—were well established. The 11th and 12th centuries were singularly important for the development of mysticism. Foremost is the Bka'-brgyud-pa school, spiritual head of which was Mar-pa (1012–96), disciple of the Indian Nāropa. He was succeeded by Mila Ras-pa, a strict ascetic whose teaching was transmitted by Sgam-po-pa (1079–1153). The latter's disciples subsequently established no less than six famous schools. During the second half of the 11th century, Dam-pa Sangs-rgyas, a Brahmin from South India, visited Tibet; but, although he wrote nothing, he bestowed Tantric initiations upon suitable persons. One of his followers was Lab-kyi sgron-ma, who lived sometimes as a nun and sometimes as a married woman. Her teaching, the *gcod-yul*, is still practiced today. This teaching aims at curbing the emotions by practicing compassion and cultivating discrimination between the real and the illusory. While there are no essential differences in doctrine between the various orders, the techniques of realization and the attachment to particular tutelary deities are the distinguishing features.

Tibetan Bka'-brgyud-pa school

In China, Japan, and Korea. Buddhist mysticism was brought to China by monks from Central Asia as early as the 3rd century, when Chu Lü-yen translated some *dhāraṇīs* (AD 260). Mysticism spread during the 4th and 5th centuries, when Fo T'u-ch'eng and Dharmarakṣa translated many Indian texts. It flourished during the T'ang period (618–907) and disappeared with the general decline of Buddhism due to its persecution in 845.

Philosophical mysticism was represented by the Ch'an meditative school (Japanese Zen), whose origin is mythical. Other schools in which the mystical element is very strong are the T'ien-t'ai (Japanese Tendai), founded by Hui-wen (550–577), and the Hua-yen (Japanese Kegon, Sanskrit Avatamsaka), initiated by Tu-shun (also known as Fa-shun; 557–640), systematized by Fa-tsang (640–712), and restored to its original purity by Ch'eng-kuan (*c.* 760–820/838). Although deriving their impetus from Indian sources, all these schools are purely Chinese developments. Applied mysticism, the "True Word" (Chinese Chen-yen, Japanese Shingon) school, also known as "Secret Doctrine," though of importance in Japan, was never a school in itself in China. Its origin goes back to the monk Śrīmitra (between 335 and 342), who translated into Chinese several texts containing *dhāraṇīs*.

Indian mystics in China

The real mystical movement began with three able Indian teachers: Śubhakarasiṃha (637–735); Vajrabodhi (633–733), and his disciple Amoghavajra (705–774), who became the instructor of three successive Chinese emperors.

I-hsiang (625–702) from Silla, a state of Korea, founded the first Hua-yen school in Korea, where Buddhism had already arrived in 372. The totalistic principle by which the emperor Shōmu (reigned 724–748) intended to govern Japan was that of this school, which had been brought to Japan in 730 by Fa-tsang's disciple Tao-hsüan. This principle implies that in the same way as the various Buddhas are representations and manifestations of the Buddha Mahāvairocana, so the government organization is the representation of the Emperor. Today the Tōdai-ji temple at Nara, still the largest wooden structure in the world, is the only prominent monastery belonging to this school. The Tendai (Chinese, T'ien-t'ai) school in Japan was founded by Dengyō Daishi, disciple of the school's sixth patriarch, Chan-jan (712–782). At present there are three branches, Sammon, Jimon, and Shinsei. The founder of the "True Word" school in Japan was Kōbō Daishi (Kūkai; 774–835). His is the mystical doctrine called Tōmitsu, as distinguished from Taimitsu, handed down by Jikaku Daishi (784–864) of the Tendai school. Both schools are alike in emphasizing the possibility of becoming a Buddha in this life, in considering the phenomenal world as the self-representation of the absolute, and in upholding the idea that the absolute, its manifest as well as its functional aspects are mutually interpenetrating, but they differ in their teaching of these tenets. The Tōmitsu makes use of two *maṇḍala*s (ritual meditation diagrams), the *vajradhatu-maṇḍala* and the *mahākaruṇagarbha-maṇḍala*, while the Taimitsu recognizes a third, the *susiddhi-maṇḍala* which in the Tōmitsu forms part of the *Mahākaruṇagarbha-maṇḍala*. Or, the Taimitsu may employ the *mahākaruṇagarbha-maṇḍala* and the *susiddhi-maṇḍala* at the exclusion of the *vajradhātu-maṇḍala*. Zen was introduced to Japan several times. While all these schools are still flourishing in Japan, in Korea, Zen achieved the dominant role. The Hua-yen school also flourished for some time in the Korean kingdom of Silla, but the Tantric form does not seem to have been widespread.

TECHNIQUES OF REALIZATION

The relationship between man and reality. Since throughout its history Buddhism in its mystical aspect represents an existence-mysticism with a strong poetic quality, the problem of what man is going to be has loomed large and has been the guiding principle of the Buddhist path. Early Buddhism conceived of its goal in terms of the *arhat*—"he who has overcome the enemy."

the enemy being the triad of passion, hatred, and ignorance and the fetters that they have created in man. In his approach to this goal the aspirant frees himself successively from ten fetters. He does so by pursuing four stages and enjoying the fruition of each. By "entering the stream" (that will carry the aspirant to his goal) and then having become a "person in the stream," he rids himself of three fetters, namely, the view that his physical existence is the whole truth, skepticism or doubting, and the belief that rites and observances have any effect. In becoming a "once-returner," he rids himself of two other fetters, sensuality and the desire for sensuous and sensual relations, which tie him down to this world, and ill will, which grudges others what they have. As a "non-returner" he frees himself from any attachment to the world of sensuous forms and also from the desire for formlessness. An *arhat* becomes free from conceit, self-righteousness, and ignorance (the inability to understand reality, not the failure to know something). According to the intensity of this experience, nine varieties of mystic accomplishment are distinguished, while from the noetic point of view six types are recognized. The first five are prompted by faith rather than by intellectual acumen and therefore are unable to maintain this experience; hence the aspirant lapses from his exalted state. Only those who, by their superior intellectual acumen, are able to continue in this mystical state are never relapsing and "unperturbable" (*akopya*).

Concepts of Buddhahood

With the emergence of the Mahāyāna school the interiorization of the problem of what man is going to be resulted in the ideal of Buddhahood. For Mahāyāna the central question was what was the experience that has made the historical Buddha worthy of the name "The Enlightened One"? It was this Buddhahood experience that he wanted his disciples to gain for themselves through his teaching and that by implication was attainable by everyone. The term buddha, a participle of the Sanskrit verbal root *budh*, "to awake," has been interpreted in different ways, most commonly as "awareness" and "awakening" (*bodhi*), the characteristics of an "Enlightened One (Buddha). The awareness is all-encompassing, while the awakening comprises self-awakening, as from deep sleep; the rousing of others from the sleep of ignorance; and the unity of the awakening process with ultimate reality or Being-as-such. In this sense, the attainment of Buddhahood is a self-validating moment that carries its own intrinsic value. Negatively, it is an escape from the fog caused by conflicting emotions and primitive beliefs about reality; positively, it is an awareness that sees reality as it becomes manifest in a system of concepts or words or relations without getting lost in it. There are thus two kinds of awareness: one seeing reality in its intrinsic uniqueness, the other remaining aware of the danger of losing the possibility of seeing reality with complete freshness when—as happens ordinarily—things are seen by classifying, comparing, evaluating, and using them.

This existential experience is known on the basis of the above two approaches as *vimuktikāya* (existence in freedom) and *dharmakāya* (existence in infinite richness). The doctrine of the Buddha's *kāya*s (literally "bodies"), realms or forms of existence, which range in number from three to ten, is one of the most complicated problems of Buddhist studies and is still largely unsolved. The

Tri-kāya

triad (*tri-kāya*) of *dharmakāya* ("existence body"), *sambhogakāya* ("enjoyment body"), and *nirmāṇakāya* ("transformation body") figures most commonly in the description of Buddhahood as an existential experience. The *dharmakāya* is an end experience, while the other two *kāya*s are means-experiences. The *dharmakāya*, referring to the mystic experience of wholeness, is a name for an absolute value-fact. In its realization, reality is felt to be absolutely positive, good, and valuable, and this value-sense communicates itself through the means-experiences of *sambhogakāya* and *nirmāṇakāya*. The *sambhogakāya* is twofold: referential (*parasambhogakāya*) and nonreferential (*svasambhogakāya*). In its latter aspect, it is self-sufficient and not in need of anything, a continuous delight as may be felt in the perception of an aesthetic object; in the former, this delight communicates with other experiences. *Nirmāṇakāya* is a term for genuine existence that itself becomes a stimulus for others to find their own true being. It therefore may manifest itself in any guise. All three *kāya*s (none of which is literally a "body" in any real sense of the word) represent existential patterns or functions. They are not separate entities but fuse with each other and form a unity that in philosophical terms is called *svābhāvikakāya* (the state of Being itself). Even here the experience of absoluteness has been instrumental in coining this term, as it indicates the autonomy, self-sufficiency, and self-containedness of the experience of Being. Ultimately, therefore, the *kāya*s are facets of Being rather than parts of it.

The mystic experience not only makes perception richer and permits the person to see all the intrinsic qualities of the object simultaneously and to see also that they are necessary to each other, but the experience also is emotionally more satisfying, because it has gone beyond any ordinary needs and drives. This aspect was termed *mahāsukhakāya* ("existence in absolute bliss") and was developed within Tantric Buddhism. It is not an innovation or additional form of existence. Already in the Pāli canon, *Nirvāṇa* had been described as bliss, quite distinct from any other ordinary feeling of happiness.

Special characteristics of Tantric mysticism

Peculiar to Tantric Buddhism is the idea that Buddhahood can be realized during a person's lifetime by various practices and that Buddhahood is not merely the realization of a wider vision but also a physical phenomenon; body and mind, in Tantric Buddhism, are abstractions from a uniquely vivid reality, not different and differently evaluated entities. This idea constitutes an unconditional acceptance of Being. Each individual represents and constitutes reality. Consequently, what in other Buddhist disciplines were considered as obstacles and had to be suppressed are here utilized for the realization of Buddhahood.

An important concept used in Tantric and non-Tantric contexts is *mahāmudrā* (the "Great Seal"). It is the leitmotiv of the Tibetan Bka'-brgyud-pa school, which was organized by sGam-po-pa, the famous disciple of Mi-la Ras-pa, disciple of Mar-pa who studied under the Indian Nāropa, and has theoretical and practical content. Theoretically, as the "Great Seal," it is a term for the absolute unity of reality, for "seal" denotes a pattern that serves as an integrating focus for a wide range of specific activities; and it also indicates that there is no going beyond reality. Practically, it teaches the way to secure an inner immunity that cannot be assailed by hopes and fears. In the process of "sealing" reality the experiential character is evident. Reality, which comprises man and the world not as correspondences but as a unity, is "bliss" (*sukha*) and also an "utter openness" (*śūnya*). In this unity Buddhist mysticism combines its philosophical conclusion that there can be no ontology (theory about the nature of being), in the traditional Western way, with its experiential quality of absolute positiveness.

Means and modes of the relationship. *Concepts of action.* The means of attaining the goal have been laid down in the various canonical texts, the large *Mahāyāna-śūtra*s (texts), and, above all, in the literature of the *Tantra*s (the texts of Tantric Buddhism), which uses a highly technical and symbolic language that has remained a stumbling block to understanding for noninitiates. Inasmuch as the mystic sees the world in a different light and therefore also draws different conclusions in the sphere of conduct, his actions in the world will necessarily be influenced accordingly and will constitute a way of life not always sanctioned by society. The mystic's conduct (*caryā*) involves both intelligence (*prajñā*) and a moral framework (*upāya*). Intelligence is a discriminative and appreciative function of the mind, which sees men and things as transitory and hence unsuited to serve as a reliable basis for an adequate way of life and which pays attention to the open dimension (*śūnyatā*) out of which the transitory things emerge and in which they participate. The moral framework is the application to goal achievement of this insight. In order to be able to perceive and attend to the open dimension, it is necessary

that the noetic function is itself as nothing or utterly open (*śūnya*); and since in the mystic experience at its peak the only possible emotions are kindliness (*maitrī*) and compassion (*karuṇā*), the mystic's reaction to the world is compassion in an absolute sense (*mahākaruṇā*). Foreshadowed in early Buddhist literature, this idea was elaborated in Mahāyāna and Tantric texts: "Enlightenment is the indivisibility of (cognitive) openness and (active) compassion."

Multiple approaches. The classification of the essentially mystical works, the *Tantras*, is mainly based on the different approaches to goal realization, which is nothing less than Buddhahood. Traditionally four kinds of *Tantras* have been distinguished: *Kriyātantra*, *Caryātantra*, *Yogatantra*, and *Anuttarayogatantra*. *Kriyātantra* is basically ritualistic and devotional in character and is counted the lowest because of the emphasis Buddhist mysticism places on the intellectual acumen (*prajñā*) of the aspirant; in this case, faith (*śraddhā*) predominates over intelligence, and the relation of the aspirant toward the powers that motivate him and appear to him in the guise of gods and goddesses is that of servant to master. In the second kind of *Tantra—Caryātantra*—faith and intelligence are evenly distributed. Intelligence as the discriminative function moves to its apex in the last two kinds of *Tantras*. In the *Caryātantra*, the dependence relation of master and servant has given way to a feeling of friendship in which each partner is equally respected. In the *Yogatantra*, the contemplative and discriminative processes are even more developed, and this produces a greater intimacy between friends, approximating to a feeling of identity.

The four kinds of *Tantras*

The *Anuttarayogatantra* is divided into the so-called *Father Tantra*, *Mother Tantra*, and *Nondual Tantra*. In all of them the symbolic approach to the realization of the goal is the outstanding characteristic. The *Father Tantra* emphasizes the developing stage (*utpannakrama*), which is a vision of the world and those that live in it in a transfigured way. The so-called physical world is said to be a heavenly mansion, and those that live in it are gods and goddesses. The technique of producing the developing stage corresponds to the active part (*upāya*) of the imaginative process. In the *Mother Tantra* the fulfillment stage (*sampannakrama*) is the main topic. It is the appreciation of the vision in all its beauty and splendour, and this corresponds to the appreciative part (*prajñā*) of the same imaginative process that operates in the developing stage. In the *Nondual Tantra* both stages are experienced as a unity. Here the mystic experience culminates in a feeling of absolute identity. Paradoxically, the highest attainment of identity or selfhood is simultaneously a transcending of itself, a going beyond selfhood.

The symbolic approach to Buddhahood, which characterizes Buddhist mysticism, is described in a code language that can be interpreted by the aspirant either literally or metaphorically, according to his own intellectual level of understanding. It is important to know that this code language—precisely because it is a code language—does not refer to any objective existence of what is pointed to. The physical and symbolical codes belong to two different logical levels. This applies in particular to the various *yoga* techniques, where the *yogic* body is conceived of as a structural pyramid or cone in which the central part of an imaginary chart consists of focal points of experience (*cakra*), innervated by the awakening of sensations moving along certain bodily channels (*nāḍi*, *lalanā*, *rasanā*, and *avadhūti*).

An important role is played by the *maṇḍala* ("circle"), which is a blueprint of orientation in the development of the mystical vision. On the one hand, it is a projection of the mystic's vision of his universe in terms of a divine mansion and its gods and goddesses; on the other, it is an evocative means to assist in the creation of the vision. According to the Hua-yen school and the Tantric forms of Buddhist mysticism, a *maṇḍala* is an ornament of the Buddha-mind.

There are many different approaches, depending on the aspirant's temperament and abilities, and much misunderstanding has been due to the interpretation of the code language in a one-sided manner. This happened in the case of the use of *mudrās* (gestures and positions). Apart from gestures, this term can also be interpreted both as "woman" and "imprint." Failing to realize the ambiguous character of the code language, Easterners and Westerners alike have interpreted the code terms of Buddhist mysticism in a literal sense and have created the idea of an "eroticized" Buddhism that actually existed only in their own minds. Even the male–female icons (*yab-yum*) of Tibet and Nepal do not evoke erotic feelings in practitioners of Buddhist mysticism but are always understood as polarity symbols, illustrating the intimate relationship between appreciation (*prajñā*) and action (*upāya*).

The states of achievement. Although the ultimate achievement was Buddhahood, throughout its development, Buddhist mysticism recognized various states. Such were, in the early phase, the *arhat* and the Pratyeka-buddha—a person who had realized Buddhahood but did not communicate his realization to others. When the ideal shifted from self-centredness to altruistic participation, the *bodhisattva* (Buddha-to-be) concept was elaborated and ten stages were codified. The first stage of joyfulness initiates the path of seeing, on which the nonontological character of self and nonself is realized, is related to liberality (*dāna*), and thereby opens the way to further progress. The subsequent stages are related to the other perfections (*pāramitā*) such as discipline (*śīla*), patience with and acceptance of things as they are (*ksānti*), endeavour and perseverance (*vīrya*), concentration (*dhyāna*), and insight (*prajñā*). These are followed by the higher stages of morally significant action (*upāya*), of commitment to gain enlightenment (*praṇidhāna*) by not being taken in by conventional characteristics, of the ten powers of Buddhahood (*bala*), and of being able to communicate the highest realization to all the world equally (*jñāna*).

The ten stages of Buddhahood

The last stage is, for all practical purposes, already the attainment of Buddhahood. Since Buddhist mysticism eschewed a static conception of its goal, additional stages were named. This was essentially a device to prevent the aspirant from becoming complacent, and it also presented a vast picture of the world in which everyone could feel at home. Ultimately, the various stages and the achievements of each of them indicate the manner in which reality manifests itself in and before the human mind, just as the moon takes various shapes in the waves of the ocean.

BIBLIOGRAPHY. S. SPENCER, *Mysticism in World Religion* (1963); and F.C. HAPPOLD, *Mysticism* (1964), contain valuable samplings of Buddhist mysticism in relation to other forms of mysticism. A. BHARATI, *The Tantric Tradition* (1965), deals with Hindu and Buddhist mysticism with a valuable bibliography. Historical rather than doctrinal works include: K.K.S. CH'EN, *Buddhism in China* (1964); D.L. SNELLGROVE and H.E. RICHARDSON, *A Cultural History of Tibet* (1968); and CHARLES ELIOT, *Japanese Buddhism* (1935, reprinted 1959). Though obsolete, this work is not yet superseded. D.T. SUZUKI, *Essays in Zen Buddhism*, 3 series (1927–61), is devoted exclusively to Zen. H.V. GUENTHER, *The Life and Teaching of Nāropa* (1963), *Tibetan Buddhism without Mystification* (1966), and *The Royal Song of Saraha* (1969), include standard translations with important analyses of mystical techniques. J. TAKAKUSU, *The Essentials of Buddhist Philosophy*, 3rd ed. (1956), emphasizes the philosophical aspects.

(H.G.)

Buddhist Mythology

Buddhist mythology consists of the numerous legends, myths, and tales of Buddhism throughout Asia. The mythology may be divided into two basic types: (1) myths concerning the historical Buddha, Gautama (late 6th–early 5th century BC) called here by his clan name Śākyamuni ("Sage of the Śākya dynasty") and (2) myths concerning celestial Buddhas and *bodhisattvas* ("Buddhas to be"). Fundamental to Buddhist mythology is the simple story of Śākyamuni's attainment of enlightenment or Nirvāṇa—the release or escape from the endless cycle of rebirths inherent in ordinary human destiny—despite a variety of temptations brought forth by an evil tempter

named Māra. All of the major sectarian forms of Buddhism, such as Theravāda ("Way of the Elders," also called Hīnayāna, or "Lesser Vehicle," the predominant school in Southeast Asia), Mahāyāna ("Greater Vehicle," the predominant school in East Asia), Tantric (magical), and Tibetan Buddhism, have such mythological dimensions. Sources for mythology are found in literature, in art, and in archaeology.

ROLES AND FUNCTIONS OF MYTH

Myth has played an essential and all-pervading role in the history of Buddhism. Its analysis was already a delicate task in the early historical period (*c.* 500–100 BC). Myth became far more complex in the classical Mahāyāna period (*c.* 100 BC–AD 800) and evaded altogether precise presentation, as Buddhism, already a complex cultural growth, coalesced in its varying stages of development with local indigenous beliefs throughout the whole of Asia (*c.* AD 100 onward). Since the 19th century it has begun to coalesce with Western rationalizing and liberal thought, resulting in a new demythologized version of the historical Buddha Śākyamuni's teachings.

Myths in Buddhism

In Buddhism three different kinds of myth are found: (1) fundamental cosmological myth—*e.g.*, the "dogma" of continual rebirth together with the whole imagined structure of phenomenal existence (see *Cosmological myths* below); (2) fundamental religious myth, or myth employed as symbolic expression of a radical religious insight—*e.g.*, the myth of the Buddha, the perfected or "divinized" man, or again of Māra, the devil, who represents the force of spiritual evil; and lastly (3) myth as a deliberate fabrication from legends and fragmentary myths, put together in order to justify or to explain certain traditionally accepted beliefs, an example of this being the early traditional account of the first Buddhist council at Rājagṛha, which was invented very early in order to prove that the sacred scriptures in the forms that the different sects preserved them were actually the recited word of Śākyamuni himself. Except for the third kind, myth is not fictitious and may often be true in its intended symbolic sense. Thus by treating Buddhism as a mythology, one detracts in no way from its positive value as one of the great religions of the world.

TYPES AND SOURCES OF MYTH

Śākyamuni Buddha in traditional literary accounts. The traditional biographies of Śākyamuni, in whatever language they are written, all derive ultimately from early Indian extracanonical rearrangements of the still earlier, scattered canonical accounts of his great acts, which were supposedly recited at Rājagṛha together with the rest of the canon within a year of his decease. The best known of the Indian "biographies" are the Sanskrit works, the *Mahāvastu* and the *Lalitavistara;* the Chinese *Abhiniṣkramaṇa-sūtra,* translated from an Indian original; and the Pāli *Nidānakathā,* as well as the commentary on the *Buddhavaṃsa.* These early works themselves are the result of a continual traditional growth, and to ascertain the dates of their final versions helps in no way to estimate the actual age or reliability of much of the material they contain. All that can be said is that this material agrees substantially with the earliest known fragmentary canonical accounts on the one hand, while on the other, once presented in coherent biographical form, it shows little or no change in the later "national" versions of the story. The later Singhalese, Thai, Burmese, and Cambodian stories are all firmly based on the earlier Pāli versions. The Koreans and Japanese have derived their accounts direct from the Chinese, which in turn are derived, via Central Asia, from Indian sources. The Tibetans, who represent the extreme limits of Indian Buddhist developments, draw their versions from the same earlier Indian versions. The biography of Śākyamuni included by the Tibetan historian Bu-ston (1290–1364) in his *History of Buddhism* differs from other traditional accounts only by its listing of the later Mahāyāna doctrines as part of Śākyamuni's teaching program on earth. All in all, the unity of the mythological and quasi-historical interpretations of the life and death of the "historical" Buddha, in whatever Buddhist country they have been retold, remains very impressive.

Myths and biographies of the Buddha

The claim of the Theravādin Buddhists of Ceylon, Burma, and Thailand to represent unadulterated "original Buddhism" is really based not on their possession of early traditions lost to the Mahāyāna countries but rather on their having remained faithful to the early enthusiastic acclamation of Śākyamuni as the one and only Buddha of the present world age. It certainly cannot be based on the often wrongly supposed, greater historical plausibility of their canonical literature, as preserved in Pāli since the 1st century BC. The only other early canonical literature surviving in an Indian language in any great substance is the *Vinaya* (the rules of monks) of a northwest Indian sect, the Mūla-Sarvāstivādins; and internal textual evidence suggests that in some places this has priority over the Pāli version. The comparative lateness of the appearance of such texts as these does not mean that they do not contain some of the very earliest traditional material.

All of the early canonical accounts agree in describing Śākyamuni's experience of enlightenment as a definitive victory over Māra, the Evil One, and as resulting in a threefold knowledge, that of his own previous births, that of the births and deaths of all other sentient beings, combined with the saving knowledge of his final release from the whole unhappy process. However symbolically one may treat the descriptions of the various possible spheres of rebirth among gods, men, animals, ghosts (*preta*), and the denizens of hell, belief in the cosmological myth of continual rebirth is fundamental to Buddhism. Śākyamuni was acclaimed "Great Sage" (Mahāmuni) and Lord (Bhagavat) not because he achieved a state of spiritual equilibrium in the present life but because he attained the supramundane state of Nirvāṇa. There are no textual indications that he was ever regarded by his followers as a kind of Socratic sage but rather as a typical perfected *yogin* (ascetic with magical powers) of his day, possessed as was then expected of miraculous powers and divine insight, combined with an altogether extraordinary concern for the spiritual advancement of others. Thus from the first his state of enlightenment or Buddhahood was recognized as "transcendent" (*lokottara*), and as the living transient embodiment of such supramundane knowledge. Śākyamuni was identified with the pre-Buddhist Indian myth of the "Great Man" (*mahāpuruṣa*), now conceived of as the predestined religious genius who appears on earth whenever the circumstances are ripe. He was thus accepted as the seventh in an imagined series of previous Buddhas. Why the seventh is not known, unless the number was derived from astronomical association, and the question may be pointless from the mythical viewpoint. His contemporary, Mahāvīra, leader of the Jains, was linked to a similar series of 24. The essential mythical idea consists not in the numbers but in the notion of predestination and fulfillment. The title Tathāgata, meaning probably "the one who has reached such (perfection)," is regularly used by Śākyamuni of himself, and it would seem likely (whatever 19th-century demythologizing scholars might say to the contrary) that he did indeed use this title. Apart from such utter confidence in his achievement, his religious movement would doubtless have died with him.

The appearances of Buddhas

Not only do Buddhas appear at predestined times but the final appearance of any Buddha is the culmination of a whole series of previous lives, during which he gradually advances towards enlightenment. Such a belief accords with the whole world view in which Buddhism had its origin, and it may be supposed fairly that Śākyamuni believed this of himself. In any case the earliest known Buddhist tradition most certainly presented him as so believing, and it is scarcely disputable that Śākyamuni inspired the belief. The essential Buddha myth thus belongs to the very origins of the religion, and the cult of the living master is logically followed by the cult of the deceased master who has passed into the transcendent state of Buddhahood. Popular mythology soon set to work to give some tangible substance to the fundamental myth, and no scholar would doubt that the stories of

Śākyamuni's previous lives (*Jātaka*), included in such profusion in the early canonical texts, are later accretions, culled haphazardly from Indian folk literature in order to fill the gaps in general knowledge concerning "dogma" that was fundamental to faith in the Buddha.

Another example of fundamental myth that is subsequently decked out in the trappings of popular mythology is Māra, the Evil One, who represented the force of spiritual evil that Śākyamuni was conscious of having confronted and overcome. Māra is explicitly identified as Concupiscence and as Death, the twin foes of all those who strive toward the tranquil and immortal state of Nirvāṇa. At the same time he is identified popularly with all of the demons and evil spirits of popular belief, and the texts usually describe him in these terms. The close relationship of fundamental myth as based on a radical religious insight and of popular mythological expression has been well illustrated by the eminent British student of Buddhism, Trevor O. Ling (see *Bibliography*). One notes that the definitive victory over Māra, on whatever spiritual or popular level this may be understood, remains an inalienable element of the myth and is just as important as the belief, universally attested in the earliest traditions of all Buddhists, in the omniscience and the miraculous powers of Śākyamuni.

Since Śākyamuni's followers were interested in him as a marvellous being and a transcendent Buddha, such historical reminiscences as may have been preserved in the story are incidental to the recounting of such things as the great acts of his previous lives, his miraculous birth in his last life, the drama of his final enlightenment while sitting under the pipal (Bo) tree, his stupendous decision to convert and save others (as symbolized by his first sermon in the Deer Park near Banaras), and his final decease at Kuśinagara. The historical sites of these four main events appear to have been clearly remembered. Śākyamuni may well have been born of noble (Kṣatriya) lineage, but the whole story of Śākyamuni's early life is a concoction of legends. The 45 years that he seems to have spent as head of his religious order can be reconstructed only in the most general terms, lacking all chronology. The description of his last journey and death appears to have a recognizable historical basis. Whether the human figure of a gentle religious sage created by means of careful, rational selection from all of the available material has any historical value at all is, however, seriously open to doubt (see also BUDDHA).

Śākyamuni Buddha in Asian art and archaeology. The primary Buddhist monument, both in time and in Buddhist usage to this day, is the *stūpa*, originally a reliquary mound or tumulus. The cult of the *stūpa* may be attested archaeologically from the 3rd century BC onward, but the canonical literary tradition of all Buddhist lands links this all-important cult to the great events associated with Śākyamuni's decease. Mythologically it becomes the supreme symbol of the Buddha in his transcendent state of immortality. Carved stonework preserved from the 2nd century BC onward, especially from the ancient *stūpas* of Sāñchī and Bhārhut in India, reveal the total identity of the great Buddha myth, as revealed in the texts and the monuments. The scenes portrayed are those not only of the great events of Śākyamuni's last life but also the great events of his previous births (*Jātaka*). It is noteworthy that in the earliest period (viz., the centuries BC) the transcendent lord is represented by symbols, a tree indicating his enlightenment, a wheel his first preaching, and a miniature *stūpa* his final Nirvāṇa. Such was felt to be the sanctity of his being, that even as *bodhisattva* of the *Jātaka* stories and of the last life up to the great enlightenment, he was at first not physically portrayed. The tree cult was itself an ancient pre-Buddhist mythology which coalesced with the act of the enlightenment as performed beneath the Bo tree (pipal or *ficus religiosa*). The wheel was both the symbol of the universal monarch (*cakravartin*) and of the Buddha as universal guide and teacher. The *stūpa* cult, with its extraordinary preoccupation with human relics, may have been a special Buddhist development, related to the clearly expressed faith in Nirvāṇa as a transcendent immortal state. It is in marked contrast with the usual Hindu (Brahmanic) horror of mortal remains as unclean. Śākyamuni began to be figured in sculpture in northwest India from about the 1st century BC onward, and stereotyped presentations of him soon became the model for future use throughout Asia. Common types of Buddha image are that of his calling the earth to witness against Māra by touching it with the finger tips of the right hand, the meditating Buddha protected by a cobra's hood, or Buddha lying on his right side as he enters final Nirvāṇa. The Buddha protected by a cobra's hood represents a coalescing of the Buddha myth with the pre-Buddhist cult of snakes as protecting divinities (the *nāga* cult), but it was justified canonically by a special early legend. This particular image and the "earth witness" one have been very popular in Southeast Asian lands. Iconographically, the Buddha image was adapted to all of the main scenes of Śākyamuni's life, and while the later *stūpas* in India and Southeast Asia achieve ever greater artistic splendour, they remain fundamentally the symbols of Śākyamuni's transcendence, and they continue to be decorated by scenes from his previous lives as well as from his last life. Famous examples are Amarāvatī in South India, *c.* 3rd century AD (some of its stone carvings are preserved in the British Museum), and Borobuḍur in Java, 9th century AD. Borobuḍur is "Mahayānist" in that it is also the symbol of the Five Celestial Buddhas (of which more below), but it reveals the close association between later developments and the great Buddha myth of Śākyamuni.

Devotees worshipping at a *stūpa*, the monument that symbolizes the Buddha's *parinirvāṇa*, or final transcendence. Detail of a Bhārhut *stūpa* railing, mid-2nd century BC. In the Indian Museum, Calcutta.

Depiction of the Buddha through symbols

Temples and indeed whole monasteries hewn out of the rock were used by Buddhists at least from the 2nd century BC until the 8th century AD and probably later. Early ones, famous for their temples with internal *stūpas* set in a kind of sanctuary, are Bhājā, Bhedsa, and Kārlī, all within reach of Bombay; others famous for the development of the iconography of the Buddha figure are Kanheri (near Bombay), Nāsik, Ellora, and, especially, Ajantā. At Ajantā are also preserved fine murals dating from the 1st century BC to the 9th century AD. These mainly represent Śākyamuni in his last and in his previous lives as a compassionate *bodhisattva*.

The traditions of imagery relating to Śākyamuni thrive to this day chiefly in Ceylon and the other Buddhist lands of Southeast Asia where Theravādin Buddhism prevails, but even in the Mahāyāna countries of Nepal, Tibet, China, Japan, Mongolia, and Korea the same iconographic traditions are preserved whenever an image or painting of Śākyamuni is required. Nowhere, thus, are they really lost so long as Buddhism remains.

Celestial Buddhas and bodhisattvas in literary sources. The starting point of all of the later developed Buddhology was the great Buddha myth under one aspect or another. The early idea of a series of Buddhas in time, first seven and later 24, allowed very soon for the idea of a future Buddha, the *bodhisattva* Maitreya. Next was mooted the possibility of other Buddhas in other Buddha lands elsewhere through endless space. Vague popular knowledge in northwest India of the great Iranian divinity Ahura Mazdā seems to have led to the general belief in a Great Buddha of the West, known as "Boundless Light" (Amitābha) or "Boundless Life" (Amitāyus). From its beginnings in northwest India this particular cult spread across Central Asia to China, Korea, and Japan, where it has had an enormous influence to this day. In Indian beliefs this Western Buddha was balanced with the Buddha of the East, the "Imperturbable" (Akṣobhya), who iconographically is identical with Śākyamuni in the "earth-witness" posture. The cult of the "Imperturbable" Buddha probably derives from the actual Buddha cult at Bodh Gayā, the historical place of enlightenment. In addition to Amitābha of the West and Akṣobhya of the East, there are three others—Vairocana, Ratnasambhava, and Amoghasiddhi—that comprise the Five Celestial Buddhas (for the centre of the universe and the four compass points). Vairocana, the "Resplendent" (centre), is the universal sage or *cakravartin* Buddha, indicated by his gesture of preaching and by the symbol of the wheel. Ratnasambhava, the "Jewel Born" (South), represents the Buddha's selfless giving and is indicated by the gesture of giving gifts—right hand open, pointing outward and downward. Amoghasiddhi, "Infallible Success" (North), represents his miraculous power to save and is indicated by the hand gesture of giving protection—right hand raised, palm outward and pointing upward. The Five Celestial Buddhas, also sometimes called Dhyāni Buddhas, seem to be hypostases (concrete manifestations) of Śākyamuni.

Five Celestial Buddhas

From Ryujun Tajima, "Les Deux Grands Mandalas et la Doctrine de l'Esoterisme Shingon," *Bulletin de la Maison Franco-japonaise* (Nouvelle serie, VI); published by Presses Universitaires de France, Paris, 1959

The five celestial Buddhas, shown in the centre and at the four points of the compass, with *bodhisattvas* (Buddhas-to-be) seated on the petals in between. Central section of a *garbha-dhātu maṇḍala* (Japanese *taizō-kai*), a ritual drawing used in worship of the Japanese Shingon sect.

The cult of Śākyamuni in his previous lives as future Buddha (*bodhisattva*) likewise develops manifold forms. Maitreya, the Buddha yet to come, is already known in the earlier period, but from the 1st century onward there is a great cult of celestial *bodhisattvas*, who respond to the same human needs of Buddhists as do the great gods of the developing Hindu pantheon for other Indian devotees. Especially popular are Mañjughoṣa ("Gentle Voice") or Mañjuśrī ("Glorious Gentle One"), the representative of divine wisdom; Avalokiteśvara, the "Lord of Compassion"; and Vajrapāṇi, "the one who wields the ritual thunderbolt (*vajra*)" and as lord of *yakṣas*, a class of local Indian divinities, enters the pantheon as a great protector. In accord with later developments, these three *bodhisattvas* are associated with the three primary Buddhas, Śākyamuni Vairocana, Amitābha, and Akṣobhya. With the development of the set of Five Buddhas, attendent *bodhisattvas* are allocated symmetrically to each. Such a balanced systematization was, however, a gradual process and can be traced in the main Mahāyāna *sūtras* (texts).

"The Lotus of the Good Law" (*Saddharmapuṇḍarīka*), a text existing before the 2nd century AD, reveals a great theophany (divine manifestation) of Śākyamuni as glorified lord of the universe. The text of the *Sukhāvatī-vyūha* recounts the wonders of Amitābha's Western "Land of Bliss" (Sukhāvatī). The *Karunāpuṇḍarīka* ("The White Lotus of Compassion") is a text concerned with a Buddha Padmottara of the southeast direction but treats also of other Buddhas, especially Amitābha and Śākyamuni, as well as of their previous manifestations as *bodhisattvas*. An important distinction is made between Pure Buddha Lands, like that of Amitābha, and Impure Buddha Lands, such as the present world in which Śākyamuni appeared. Śākyamuni is praised as the more noble because out of his great compassion he chose an Impure Land. A whole new mythology, of great importance in Far Eastern Buddhism, developed in association with the Pure Buddha Lands. In popular aspiration these replaced for Buddhists the paradises of the ordinary Indian gods, which already formed part of the fivefold or sixfold "wheel of life"—a metaphor for and diagrammatic schematization of the cycle of rebirths. But in the case of the Pure Buddha Lands there was the great added advantage of never falling back into unhappy states of existence. Faith alone suffices to ensure one's rebirth in Amitābha's Western paradise. This particular Buddhist devotion may have begun in northwest India whence it certainly reached China via Central Asia. It had some following in India and Nepal, whence it passed to Tibet, but Amitābha usually remains in later Indian tradition as merely one important member of the Five Buddha group. The "Five Buddha" complex finds its primary expression in a text known as the "Symposium of Truth of All the Buddhas" (*Sarvātathāgatattvasaṃgraha*), in which Śākyamuni, as Vairocana, appears as the central Buddha. Another related text is the *Mahāvairocana-sūtra*, important for Japanese Tantric Buddhism (Shingon). The set of Five Buddhas represents the limits of Mahāyāna Buddhological developments, preparing the way for the psychophysical theories of the *Tantras*. The set of five was correlated not only with the centre and four compass points, viz, the macrocosm, conceived as a unity of the Five Great Elements but also with the microcosm of the human personality with the Five Components (*skandhas*) —*rūpa* (material qualities) *vedanā* (feeling or sensation), *saṃjñā* (perception), *saṃskāra* (components of consciousness), and *vijñāna* (consciousness)—and with the Five Great Evils (Ignorance, Wrath, Desire, Malignity, and Envy), typifying normal phenomenal existence. At this stage mythology is developed as a psychological symbolism. These developments had a great vogue in India from the 8th century onward, thus overlapping with Mahāyāna proper. They spread to Southeast Asia, especially Java and Sumatra, to Nepal, and to Tibet. Tantric Buddhism reached China also in the 8th century, and, before dying out, it passed on to Japan, where as Shingon it still exists. Ceylon, Burma, Siam, and Cambodia were less affected, even by the Mahāyāna forms, because of the extraordinary combative strength of Theravādin Buddhism.

With the *Tantras*, Buddhist mythology begins at last to part company with the original Buddha myth and clearly

links up with the Hindu mythology in a scarcely disguised form. Akṣobhya, thus, has as his fierce Tantric form what is in effect the fierce form of the Hindu god Śiva (Shiva), given, however, his fierce names special to Buddhist Tantric tradition. Known as Heruka, Hevajra, or Saṃvara, he is all one and the same. He is known in Japan in this fierce form as Fudō ("Imperturbable"). The Indian god Bhairava, a fierce bull-headed divinity, adopted by Tantric Buddhists as Vajrabhairava, also known as Yamāntaka "Slayer of Death," and identified as the fierce form of the gentle Mañjuśrī, was accorded quasi-Buddha rank.

Objects of special devotion

Some *bodhisattvas* have become the object of very special devotion. Chief of these is Avalokiteśvara, the Lord of Compassion, who as patron saint of Tibet is believed to reincarnate in the Dalai Lamas. As Kuan-yin in China, Kwannon in Japan, and Kwandyeieum in Korea, this *bodhisattva* is confused with his feminine counterpart Tārā (of whom more below) and becomes a kindly madonna. The *bodhisattva* Kṣitigarbha ("womb of the earth"), who was of no great significance in India and hence of none in Nepal and Tibet, seems to have attracted a cult of himself as lord of the underworld in Central Asia, whence it spread to China and the Far East generally. Known as Ti-ts'ang in Chinese and Jizō in Japanese, he is Lord of hell and so the centre of afterdeath liturgies. Popular cross identifications occur everywhere in Buddhism in the case of minor divinities but seldom with those of quasi-Buddha rank.

Celestial Buddhas and bodhisattvas in art and archaeology. It is mainly from archaeological and artistic remains that scholars are able to trace the remarkable spread of Mahāyāna Buddhist mythology throughout the whole of Asia from the 1st century AD onward. The main points of departure were northwest India for Central Asia and the Far East, and the Bay of Bengal, especially the port of Tāmraliptī. Early Mahāyāna developments also affected South India, and thence Ceylon, Burma, and Siam, and rediscovered images of Avalokiteśvara indicate the earlier popularity of this *bodhisattva* in what are now Theravādin lands. But Bihar and Bengal remained Buddhist, largely late Mahāyāna and Tantric until the 13th century, and there is ample evidence in Java and Sumatra from iconographic remains of the popularity of the Buddhas, *bodhisattvas*, and fierce quasi-Buddha figures mentioned above. There are even traces at Pagan (Burma) in the form of images and paintings of late Mahāyāna and Tantric divinities. Alone in Southeast Asia, the island of Bali still retains a living but mixed Hindu–Tantric Buddhist culture.

Paintings and figures unearthed during the 20th century in Central Asia (Chinese Turkistan) have revealed the manner in which Buddhist architecture, iconography, and painting passed from northwest India to China and the Far East. Especially important are the paintings of Buddhas and *bodhisattvas* in the caves of Tun-huang (4th to 10th century AD). Especially popular in China, and hence in Japan and Korea, are Amitābha–Amitāyus, Vairocana, Maitreya, Mañjuśrī, Kṣitigarbha, and Avalokiteśvara (as the goddess Kuan-yin). Most of these figures were also frequently portrayed in both painting and sculpture in western Tibet, especially during the 10th to 12th centuries AD, and were made known only in the 1930s as a result of the expeditions of the eminent Italian scholar Giuseppi Tucci. In all of these cases the source of the tradition was northwest India.

The main repository of Mahāyāna and Tantric iconographic traditions is Tibet, where Buddhism travelled direct from India, mainly via Nepal, from the 8th to the 13th centuries. Until the Communist take-over of 1959 the Tibetans preserved Indian (Pala) styles of iconography, ancient techniques and styles of Indian Buddhist painting, modified and enriched in some schools by very much later Chinese influence, and the vast range of the late Mahāyāna and Tantric pantheon of deities.

RECURRENT MYTHIC THEMES

Cosmological myths. Śākyamuni is represented according to early tradition as denying all importance to the enquiry whether the universe is infinite or not, eternal or not. It was enough to realize that normal existence consisted of a wretched process of continual death and rebirth, from which, by following his teachings, one might procure one's release. Such an ordinance did not prevent his followers from accepting the general cosmological beliefs of their time, modified by conclusions drawn from his specific moral and religious teachings.

It was thus believed that the present world system, like all others throughout space, goes through the inevitable process of creation, duration, and destruction. Thus nothing of the "realm of desire" (*kāmadhātu*), in which the gods, humans, and lower creatures live, has any permanence, not even the "creator god" Brahmā, who is merely the first being to appear and the last to disappear with every recurrent cycle. Brahmā's life, of course, covers a vast period of time by human reckoning. The present world system consists of various stages, becoming, as one descends, more impure and more unhappy. First come six graded heavens, occupied by corresponding orders of gods. Next comes the world of human beings. This consists of four "continents" (*dvīpa*) that surround the central mountain (Meru), on which the gods dwell. The southern "continent," named Jambudvīpa, vaguely represents India and surrounding lands. The other living creatures, such as animals, birds, fishes, and insects, which share the world of men, are thought of as leading even more miserable lives than men do. Still more unhappy are the tormented spirits (*preta*) who help to make life still more troublesome for mankind. Below the world of men are the terrible hells in which the most excruciating torments await evildoers.

Five conditions of rebirth

Depending upon their actions men are reborn in any of these five conditions: as gods, men, animals, tormented spirits, or in the hells. Later, a sixth condition, that of Titans, was added. These five or six states represent the ever-revolving wheel of life. When the world system comes to an end, the combined potency of previous actions (*karman*) restarts the whole process, just as present individual actions (which become *karman* in the future) result in a continuous series (*santāna*) of apparently personal existences. Thus, for practical purposes, the process of existence appears as infinite, and only the practice of Buddhist teachings can bring it to an absolute end, which is the deathless state of enlightenment.

It must be stressed that Buddhists are never agnostic in any Western sense. They are justified in believing in gods, troublesome spirits, and the hells, at least to the extent that they believe in the everyday life of the ordinary world. Ultimately everything is impermanent, but at least the gods have a much longer spell of life than men do and so need to be taken into account, as do troublesome spirits, in everyday affairs. Only the contemplative sage can afford to regard them as unreal, just as he regards the world of men as a mere empty flux. Thus the pursuit of the myth of the origin and destruction of the cosmos, of the time process (*saṃsāra*), and of release from it (Nirvāṇa) is a privilege of a special elite; and Buddhist layfolk and indeed the majority of ordinary monks usually have been content to accept on faith the various findings of their philosophers, realizing meanwhile that they have to come to terms first of all with the transient phenomenal world, with its gods and its spirits, and with the prospect, not of final release but of a new life in what may be worse circumstances than the present.

With the change in philosophy from the phenomenalism of the early schools to the monistic idealism of the Mahāyāna, the process of origin and destruction was diagnosed by the elite as an illusive mental construct deriving from the apparent operation of *karman*. Thus in theory the whole time process (*saṃsāra*) is pure imagination in essence, although as a means toward release one may have to act as though taking it seriously. So long as one is still on the path toward enlightenment the perception of the higher knowledge of an absolute kind has to be tempered by actions, words, and thoughts, relative to the empirical needs of oneself and of others.

Myths of Buddhas and bodhisattvas. The Buddhas, celestial *bodhisattvas*, and the fierce quasi-Buddha mani-

festations recognized by the followers of the *Tantras* all transcend phenomenal existence in their absolute state while readily involving themselves in it for the sake of suffering living creatures. Although this idea was only fully developed by the Mahāyāna, it has already been noted that the same fundamental conception of a Buddha as transcendent in essence, but at the same time operative as world saviour in an imminent sense, belongs to the great Buddha myth constructed around Śākyamuni by the first Buddhist believers. Thus, while a small contemplative elite may always regard any Buddha as the impersonal symbol of the ineffable state of enlightenment, most of the faithful have been equally justified in approaching him as a divine saviour. Buddhism has always been a religion of faith, whether of faith in the realizability of final enlightenment or of faith in the Buddhas and *bodhisattvas* as helpers along the way. The Mahāyāna and certainly the Tantric schools vastly increased the available means of progress to suit all local tastes and propensities, but the fundamental psychology of an accepted dual approach remains scarcely changed. The mystical-philosophic approach aims at comparatively rapid results and risks wholesale denials, both bodily and mental. The slow approach, through devotion to Buddhas and *bodhisattvas* as divine beings and through the practice of morality in the everyday world, posits religious realities that the spiritual elite in theory deny but in practice readily accept, for they know their very denial is as relative to the desired end as the actual acceptance (see also *Celestial Buddhas and bodhisattvas in literary sources* above).

Local gods and demons. While the contemplative elite may deny the real existence of gods and demons together with all the rest of phenomenal existence, the majority of Buddhists from the earliest times in India, and in whatever country north to south where Buddhism has spread, have never neglected indigenous religious beliefs. It has already been noted how Māra, the manifestation of spiritual evil, is presented in the earliest literature in the terms of local demonological beliefs. It is also to be noted that the early *stūpas* and entrances to cave temples were decorated with local male and female divinities (usually referred to as *yakṣa* and *yakṣinī*) who were presumably already conceived as converted defenders of the new faith. This proved the easier way of justifying the continuance of the cult of local divinities, and it has been employed in varying degrees in every Buddhist land. There thus began to develop a pantheon of minor divinities, which from a common original stock has continued to take in new members wherever Buddhism has become an established religion. The Mahāyāna has given them a more ready official welcome, even admitting their cult as a subsidiary part of liturgies in honour of Buddhas and *bodhisattvas*. Such favoured ones are Mahākāla, the great black divinity; the mother goddess Hārītī; Kuvera, the god of wealth; and especially Hayagrīva, a fierce horse-faced god, who, now converted to the Buddhist doctrine, is very powerful in driving off unconverted demonic forces. A favourite myth, originating probably in northwest India or even in Central Asia and well established in Tibet and Mongolia, China, Korea and, Japan, was that of the Great Kings (Sanskrit: *mahārāja;* Tibetan: *rgyal-chen*) of the four quarters, who defend the frontiers of Buddhist religion. They are regularly depicted on the walls of the entrance halls of temples. Their Sanskrit names are Kuvera (north), Dhṛtaraṣṭra (east), Virūḍhaka (south), and Virūpākṣa (west).

Buddhism as a religion of faith

It is commonly believed by Tibetans related in their history books that Buddhism began to become established in their land in the 8th century only as a result of a wholesale subjugation of opposing local divinities. Some have continued to be hostile throughout the centuries and must be placated by offerings or quelled by suitable fierce rites. The indigenous priests, known as *bon*, increasingly replaced by Buddhist Tantric sorcerers, are thought to have the best control over these troublesome intruders. The same situation has existed in China, where a vast variety of local divinities has been kept in check, where possible, by Taoist priests, assisted sometimes by Buddhists, and likewise in Japan, where the local Shintō gods have never lost their power.

Quite as much in Theravādin as in Mahāyāna countries, Buddhism has everywhere had to come to terms with local beliefs, and in their everyday lives Buddhists have continued to be more preoccupied with placating local divinities or avoiding their ill effects than with worshipping the Buddha in his temple. After all, the Buddha is known to be benign. Much has been written of the power of the *nat* in Burma, the *phi* of Siam, and the various local spirits of Cambodia and Laos. Nor is Buddhism any more pure in this respect in Ceylon, where small shrines of converted Hindu and local Ceylonese divinities may be placed in the vicinity of a Buddhist temple. In all of the lands within easy reach of India—namely Ceylon, Burma, Siam to the south, and Nepal to the north—Indian (Hindu) divinities have been accepted without any sense of contradiction on the part of those who call themselves Buddhists.

Local spirits in Buddhist countries

Feminine divinities. The presence of minor feminine divinities of the kind described above, allowed to exist as "protectors" on the fringe of the religion, presents no special problem. But the elevation of feminine figures to Buddha rank requires special comment. The appearance of a universal mother goddess in Indian Buddhism is not surprising and was easily rendered "theologically" acceptable. She appears in Mahāyāna Buddhism under two aspects, as the personification of Supreme Wisdom and as the Mother of all Buddhas, as manifest especially in Mahāmāyā, the virgin mother of Śākyamuni. As universal mother, she is known as Tārā the Saviouress, may be identified with Supreme Wisdom (*Prajñāpāramitā*), and thus far is pure and chaste. In all this there is nothing that contravenes the notions of celibacy, which have in fact remained typical of Buddhist monasticism everywhere, despite occasional aberrations. The majority of Mahāyānists have never gone beyond this point, and the devotion to Kuan-yin in China, Japan, and Korea as a great mother goddess belongs to the generally acceptable Indian Mahāyāna tradition.

From the 7th century, however, a whole riot of feminine divinities began to find their way into certain circles of Buddhist *yogins*, where they were actually represented by women partners in a special kind of sexual *yoga* (physical and mental discipline). The whole process, both the actual rites as well as the actual feminine divinities, was gradually interpreted as an internal form of celibate *yoga*, for in accordance with Mahāyāna theory, enlightenment was achieved by the union of Wisdom and Method, now conceived of symbolically as female and male. Thus it became possible to present supreme Buddhahood, as represented pre-eminently by the Five Supreme Buddhas, as a union of pairs. So it came about that every celestial Buddha or quasi-Buddha might be represented as a male and female pair (Tibetan *yab-yum*). The actual sexual ritual was certainly performed at one time in India and Nepal, seemingly to a very limited extent in Tibet, and perhaps not at all in China and Japan, although the symbolism became known there and the Japanese Shingon sect has adopted it. This whole Tantric iconography very soon came to represent an esoteric and often quite grotesque symbolism, which Mahāyāna Buddhists have simply taken for granted as part of their received tradition. This particular "myth" has achieved its fullest iconographic and artistic expression in Tibet, where it has been left to Westerners and more recently to Communist Chinese to marvel at so extraordinary a development.

Kings and yogins. The great Buddha myth is a combination of the ideals of universal kingship and universal religious pre-eminence. This is clearly expressed in the myth of the prophetic utterance of future greatness by the sage Asita—an astrologer who examined auspicious signs on the infant Śākyamuni—over the child *bodhisattva*. Also in his previous life as Viśvantara, Śākyamuni had already realized the perfection of the extraordinary combination of kingship and all-abandoning asceticism. As crown prince, Viśvantara is famed for his vast generosity, and, becoming the despair of his more practical-

minded father, he accepts banishment to the forest, where he attains the ultimate of self-abnegation in giving away his children and his wife and in some accounts even his own eyes. These and all else are restored to him miraculously, and responding to the demands of his countrymen he returns home to become the best of kings. Similarly, the last life of Śākyamuni, up to the time of his great renunciation, is told entirely as a royal story.

Although the practice of Buddhist religion strictly required withdrawal from the world, or at least renunciation of its pleasures, Buddhist monks were, understandably enough, anxious to win royal support. They always needed benefactors, and what better benefactor than a king. Any suggestion of royal benefaction thus resulted in the revival of the "myth" of the vastly generous monarch. Whenever Mahāyāna tendencies were at work, also in the notion of his sanctity, he represented, in one important aspect, that of generous giving, the ideal of the *bodhisattva*. The most famous example is the Indian emperor Aśoka (3rd century BC), who certainly facilitated the spread of Buddhism and concerning whom vast legends have grown up. Among other things he is credited with having built 84,000 *stūpa*s. Surrounding countries all claim to have received Buddhism through his mediacy. On a smaller scale legends embellish the life of King Tissa of Ceylon (same period), who presided over the arrival of Buddhism. In the same context one may mention Prince Shōtoku Taishi of Japan (died AD 621) and Srong-brtsan-sgam-po of Tibet (died AD 650), noting, however, that the enthusiasm of the first for Buddhism is genuinely historical. This is also true of Tibet's two other great "kings of religion." Khrisong Detsan (second half of 8th century) and Ral-pa-chem, assassinated by enemies of the faith in AD 836.

The role of emperor Aśoka

The great *stūpa* of Borobuḍur, already mentioned, deliberately represents the self-identification of the ruling monarch of Java with the aspiration toward Buddhahood. The king presents himself as the *bodhisattva* par excellence. At the other side of the Buddhist world, the Tibetans developed the same idea when they identified their reincarnating Dalai Lama as a manifestation of their patron "saint," the *bodhisattva* Avalokiteśvara. Seen in its total Buddhist context, this idea is not as strange as Europeans appear to find it. Also by polite mythical fiction the Manchu emperors of China were regarded as manifestations of the *bodhisattva* Mañjuśrī; so too (with far more justice) was the great Tibetan religious reformer Tsong-kha-pa (1357–1419). As a result of the more limited nature of their doctrines, Theravādin countries lag far behind in these interesting developments. There such kings as Dammazed of Pegu (died 1491) or Mindon of Burma (died 1878), and even great religious ascetics, remain transient mortal beings of flesh and blood.

Under the aspect of the pre-Buddhist Indian myth of the ideal perfected *yogin*, possessed of miraculous powers, however, the greatness of the Buddhist ascetic is a theme well suited to Buddhism everywhere. The early disciples of Śākyamuni, known as *arhat*s when they achieved perfection, were conceived of as miracle-working *yogin*s, and the early canonical literature presents them in this way. This same ideal was acknowledged in Theravādin Ceylon, and the Ceylonese claim their share of *arhat*s. But it is in Tibet, which drew on the more developed Indian myth of the "great yogin" (*mahāsiddha*) of the Tantric period (8th to 12th centuries AD) that this theme shows its most luxurious development. Especially famous are Padmasambhava (also called Guru Rimpoche), an 8th-century Indian *yogin* credited with having quelled the evil spirits of Tibet, and again the strange figure of Dam-pa Sangs-rygas, a Brahmin of South India who became a Buddhist and visited Tibet and possibly China in the 11th century. Doubtless historical, Dam-pa Sangs-rygas passes right out of history into myth with his fantastic powers and equally fantastic longevity. Better known in Europe is the story of the Tibetan *yogin* Mi-la Ras-pa also 11th century. During its earlier period in China, Buddhism was more of a gentlemanly cultural pursuit than an enthusiastic religious movement, but the same mythical tendencies were soon at work. Bodhidharma (6th century), founder of Ch'an (Zen) Buddhism, is also an Indian *yogin*, appearing in quasi-historical, quasi-mythical guise. Subsequently the ideal of the Buddhist sage, as typified by the *arhat*s, is confused in Chinese thought with the Taoist immortals; and here, as in so much else, Far Eastern Buddhism developed new forms of the religion as it coalesced increasingly with the great non-Buddhist mythologies of China and Japan.

*Arhat*s and *mahāsiddha*s

SIGNIFICANCE

Myth in Buddhism is used at various intellectual levels in order to give symbolic and sometimes quasi-historical expression to apprehended or presumed religious truths. Accepted on its own terms, Buddhism is a supernatural religion in the sense that without a Buddha to reveal them, the truths remain unknown. Only after a man has received the Buddha revelation can he proceed apparently by his own efforts. This teaching was explicit in the early schools, in which the revelation was still thought of as historically related to Śākyamuni's mission in the world. Gradually the idea formed in some schools of the Buddha's continuous revelation and gracious assistance, deriving from his glorified state of time-transcending enlightenment. Thus the comparatively simple mythology of the great Buddha myth developed into the far more elaborate mythology of the Mahāyāna. The acceptance of the mythology, whether early or fully developed, depends upon faith. Without faith the whole religion crumbles to nothing, and nothing is left but a demythologized supposedly historical figure who has no special revelation to give. He becomes a wandering ascetic of 6th–5th century India BC, like the many others known to scholars, and his religion has no explanation. One must, thus, emphasize that it was the extraordinary combination of the historical Śākyamuni and the relevant myth that he was seen to fulfill that set the whole great religious tradition known as Buddhism on its varied historical course. It has been observed also how myth is continually used at second or even third remove to bolster the primary myth and to give it a more convincing expression, at least for those who do not have the means of checking the validity of the traditional materials employed. This subsidiary form of myth—*e.g.*, the stories about the recitation of the Buddhist canon soon after Śākyamuni's decease, the details of his previous lives, the stereotyped descriptions of the six spheres of rebirth—can be shown up as an artificial, imagined construction. Mahāyāna Buddhist philosophy performed precisely this task, although with arguments very different from those of modern scholarship. Yet knowledge of the relative and artificial nature of this subsidiary mythology does not necessarily destroy the fundamental myth, which is the story of salvation achieved by means that rest on premises that are always provisional but, insofar as they serve the gaining of the chief objective, never really false. Thus the state of the intelligent Buddhist believer must always be ambivalent.

BIBLIOGRAPHY. Two major general works are *Mythologie asiatique illustrée*, introduced by P.L. COUCHOUD (1928), covering the whole subject except for Ceylon and the Theravādin countries of Southeast Asia, with good illustrations; and *New Larousse Encyclopaedia of Mythology*, introduced by ROBERT GRAVES (1959), containing relevant articles on Indian, Chinese, and Japanese mythology.

Other important works include: BU-STON, *History of Buddhism*, trans. by E.E. OBERMILLER, 2 vol. (1931–32), an important short history of Indian Buddhism as seen from the traditional Mahāyāna viewpoint; PERCY BROWN, *Indian Architecture*, vol. 1, *Buddhist and Hindu Periods*, 3rd rev. ed. (1965), a standard work for tracing the development of Buddhist mythology in art and architecture; R.S. COPLESTON, *Buddhism: Primitive and Present in Magadha and Ceylon* (1908), a readable, informative account quoting traditional Buddhist sources, still very useful; CHARLES ELIOT, *Japanese Buddhism* (1935, reprinted 1959), a classical work and a useful survey; ALFRED FOUCHER, *La vie du Bouddha d'après les textes et les monuments de l'Inde* (1949; abridged Eng. trans., *The Life of Buddha*, 1963), a unique study of the legends surrounding Śākyamuni, *Les vies antérieures du Bouddha* (1955), a readable survey of Buddha's previous lives; ALICE GETTY, *The Gods of Northern Buddhism*, 2nd rev. ed. (1928), a useful

description of Buddhism's chief divinities; H. KERN, *The Lotus of the True Law* (Eng. trans. 1963), a discussion of the type of Mahāyāna *sūtra* which expressed the developing Buddhological myth; ETIENNE LAMOTTE, "La Légende du Bouddha," in *Revue de l'histoire des religions*, 134:37–71 (1947–48), an important article, arguing the futility of trying to discover an historical figure acceptable to modern expectations; T.O. LING, *Buddhism and the Mythology of Evil: A Study of Theravada Buddhism* (1962), a short and brilliant study of one particular aspect of Buddhist mythology; PAUL MUS, *Borobudur* (1935), a lengthy detailed work, covering the whole complex mythology of later Buddhism; WALPOLA RAHULA, *History of Buddhism in Ceylon* (1956), a useful survey of the period 3rd century BC to 10th AD; K.J. SAUNDERS, *Buddhism and Buddhists in Southern Asia* (1923), a brief readable account of the more external features of Buddhism in Ceylon, Burma, and Siam; D.L. SNELLGROVE, *Buddhist Himalaya* (1957), a survey of Buddhism as a living mythology as it passed from India via Nepal to Tibet, and (ed. and trans.), *Four Lamas of Dolpo* (1967), a study of the daily lives of four Tibetan lamas; F. STARR, *Korean Buddhism* (1918), three essays on the history of Buddhism in Korea, its actual condition, and on Buddhist art (a slight work, but useful where so little information is available); E.J. THOMAS, *The Life of Buddha as Legend and History*, 3rd ed. rev. (1949, reprinted 1969), an important standard work; GIUSEPPE TUCCI, *Indo-Tibetica*, 4 vol. (1932–41), an essential, well-illustrated work for any serious student of late Indian Mahāyāna and Tantric art, *Tibetan Painted Scrolls*, 2 vol. (Eng. trans. 1949), an essential work, including much historical material; L. DE LA VALLEE POUSSIN, *Le dogme et la philosophie du Bouddhisme* (1930), a very important short work, drawing the necessary distinction between Buddhist philosophy, and mythology as expressed in dogma, and showing how in practice one does not contradict the other; and ISSHI YAMADA, *Karunāpundarīka*, 2 vol. (1968), an important discussion of the development of Mahāyāna beliefs concerning celestial Buddhas and their paradises.

(D.L.S.)

Buddhist Philosophy

Buddhist philosophy is both a system of thought and a set of ethical norms offering practical guidance in everyday social affairs. This article deals with the Buddhist views regarding metaphysics and epistemology, the problems of human existence, eschatology and soteriology, ethics, psychology, and logic.

Buddhist metaphysics and epistemology. *The fundamental attitude.* Buddhism sought reform by rejecting the authority of established religions and teaching an independent ethical morality.

Buddhists are enjoined to follow the path prescribed by the Buddha. Faith is indispensable, but it is only a preliminary requirement for practicing the way. Faith, for the Buddhist, should not be in contradiction to reason. Faith unexamined by reason becomes superstition. Buddhists have accepted two standards for the truth (veracity) of a statement: it must be in accordance with the Buddhist canonical scriptures, and it must be proved true by reasoning. No Buddhist is expected to believe anything that does not meet these two tests.

The *dharmas*

Buddhism presupposes universal laws called *dharmas*, which govern human existence and may be known by reason. Personal relations should be brought into harmony with the universal norms, which apply to all existence, regardless of time and space. Metaphysical speculation concerning problems not related to human activities and the attainment of Enlightenment, such as whether the world is infinite or finite and whether the soul and the body are identical or different from each other, is discouraged.

Throughout the Buddhist world, the community has never been organized around a central authority that could decree doctrines or practices that must be observed by all followers. Buddhists of all types have been comparatively individualistic and unwilling to submit to a rigid outer authority. Agreement as to the doctrines to be held and the practices to be followed has been reached by discussion within the community, guided by the scriptures accepted as a basis for their faith. Only in Japan are there marked sectarian differences, but the authorities of the extant sects are not coercive.

All metaphysical views are only partial apprehensions of the whole truth, which lies beyond rational analysis. Only a buddha can apprehend the whole truth. Rational analysis is useful in making clear the limitations of rationality, but it is by detaching oneself from philosophical oppositions that one is able to grasp the truth. Thus, the doctrine of the Buddha is not a system of philosophy in the Western sense but is rather a path. A buddha is simply one who has walked this path and can report to others on what he has found.

The Buddha's doctrine is called a vehicle in the sense that it is like a ferryboat. One enters the Buddhist vehicle to cross the river of life from the shore of worldly experience, spiritual ignorance, desire, and suffering to the other shore of transcendental wisdom, which is liberation from bondage and suffering. If a man builds a raft and by this means succeeds in attaining the other shore, then he should abandon the raft. In the same way the vehicle of the doctrine is to be cast away and forsaken, once the other shore of Enlightenment has been attained. Just as the difference in shape, weight, and material among rafts does not matter, difference in teachings does not matter. This point of view is set forth both in Theravāda and in Mahāyāna, the major divisions of Buddhism, the former being the earlier form, prevalent in South Asia, and the latter the more liberal, prevalent in China and Japan.

The ways of faith and insight

Faith is an introductory means to the attainment of truth, not an acceptance of definite dogmas. When one takes refuge in the Three Jewels (Buddha, the teaching, and the order), it is a partial turning away from the visible to the invisible. Faith does not necessarily mean the realization of truth itself; it is important only insofar as it opens the door of the ideal state. Throughout Buddhist history there have been two currents, the devotional approach and the approach through inner knowledge, insight. The approach through the inner vision has always been regarded as the truer one, while the devotional approach has been more or less regarded as a means for the common people. The only outstanding exceptions to this have been Pure Land Buddhism (a Chinese and Japanese sect stressing worship of Amitābha Buddha—the Buddha of infinite life and splendour) and the Nichiren sect (followers of the 13th-century nationalist saint Nichiren). For them, faith is made supreme and is essential to deliverance.

The universe. Buddhism declares that everything has been brought about by causes, that there is no permanent substratum of existence. There is general agreement that the only true method of explaining any existing thing is to trace one cause back to the next, without the desire or need to explain the ultimate cause of all things. For Buddhism there is no divine creator. It asserts that the universe is uncreated, without beginning or end, and that origination, duration, destruction, and annihilation succeed one another in recurrent cyclic change.

According to Buddhist dogmatics there are three spheres, or planes, where living beings stay: (1) the immaterial plane (sphere) of existence (*arūpadhātu*), where pure spirits without material body live; (2) the material plane of existence (*rūpadhātu*), where ethereal living beings live; (3) the plane of desire (*kāmadhātu*), where living beings of gross material live and which, roughly speaking, corresponds to the natural world. The world in which human beings live, the plane of desire, is made up of four elements: earth, water, heat, and wind (later theories add space and intelligence).

Buddhist beliefs concerning the nature of the universe were shaped by belief in *karman* and rebirth. In accordance with the admittance of the doctrines of transmigration and *karman*, the Buddhists had to assume good and bad places—heavens and hells—in which people could be born according to their deeds. The Buddha did not deny the existence of divine beings and their realm. Common people preferred to look for a better world beyond, which ritualism would ensure to them. Though the traditional Buddhist cosmology is held only nominally by present-day Buddhists who have training in modern sciences, the underlying premise remains the same. The structure of the natural world is not essential in Buddhism: the Buddha's essential concern was human conduct.

The categories of living beings

Living beings. Living beings in the plane of desire are divided into five categories, two good and three bad, called "kinds of existence" (*gati*). They are (1) heavenly beings (gods), (2) men, (3) departed spirits (*preta*), (4) animals (beasts), and (5) the hellish creatures (depraved men) who live in numerous hells. Sometimes another category of existence, that of the *asura* (a demon, warlike, fighting spirit), also is predicated between gods and men. These beings, including the gods, belong to the sphere of transmigration. One result of this theory of the world has been that the Buddhist attitude toward animals has been one of kindness to fellow beings. In some countries, people visiting temples make a practice of releasing birds or fish that have been captured. There have always been many Buddhists who were vegetarians.

Birth as a human being is essential for the appreciation of the *dharma* for Enlightenment. Gods are too happy to feel a dislike for conditioned things and live too long to have any appreciation for the doctrine of impermanence. Animals, departed spirits, demons, and the damned lack sufficient clarity of mind to enable them to overcome their ignorance; therefore, the human state is in general more favourable than any other for the attainment of Enlightenment. Man is distinguished from other beings by his aptitude for goodness, a love for the *dharma*, and, consequently, by love or compassion (*mettā*) for other beings.

Problems of human existence. Always and everywhere through its long history, Buddhism has stressed the fact of human suffering. Existence is painful. The conditions that make an individual are precisely those that also give rise to suffering. Individuality involves limitation; limitation ends in suffering.

Existence as suffering

Desire causes suffering, since what is desired is transitory, changing, and perishing. It is the impermanence of the object of our craving that causes disappointment and sorrow. These desires are caused by ignorance, from which men can be freed by following the "path" taught by the Buddha. The Buddha's doctrine was not one of despair. Living amid the impermanence of everything and being himself impermanent, man searches for the way of deliverance, for that which shines beyond the transitoriness of human existence—in short, for Enlightenment. The only significant variation from the teaching that man must work out his own salvation has been the dependence of the Pure Land sect of China and Japan upon the help of the external power.

The theory of nonself. The teaching of *anātman* (Pāli *anatta*, "nonego" or "nonself") has been regarded as characteristic of Buddhist thought. The Sanskrit *ātman* is translated as "ego" or "soul," though its more literal meaning is "self," for even in early Buddhism a distinction was frequently made between the ego and the true self. The Buddha did not want to assume that there is any metaphysical substance. Life is a stream of becoming, a series of manifestations and extinctions. The concept of the individual ego is a popular delusion; the objects with which man identifies himself—fortune, social position, family, body, and even mind—are not his true self. There is nothing permanent, and, if only the permanent deserved to be called the self, or *ātman*, then nothing on Earth is self. There can be no individuality without a putting together of components. This is becoming different, and there can be no way of becoming different without a dissolution, a passing away.

The constituents of human existence

To make clear the teaching of nonego, Buddhists set forth the theory of the five aggregates or constituents (*skandhas*) of human existence: (1) corporeality or physical forms (*rūpa*), (2) feelings or sensations (*vendanā*), (3) ideations (Sanskrit *saṃjñā*; Pāli *saññā*), (4) mental formations or dispositions (Sanskrit *saṃskāra;* Pāli *sankhara*), (5) consciousness (Sanskrit *vijñāna;* Pāli *viññāna*). Human existence is only a composite of the five aggregates (*skandhas*), none of which is the self or soul. A person is in a process of continuous change, with no fixed underlying entity. In this way Buddhism swept away the traditional conception of a substance called soul, or ego, which had theretofore dominated the minds of the superstitious and the intellectuals alike.

In daily life the assumption is made that something is "mine," that "I" am something, or that something is "myself." According to Buddhism, this is erroneous. Properly applied, the method of reflection on the *skandhas* has a tremendous power to disintegrate unwholesome experience and can contribute much to a person's mental development by helping him set up the habit of viewing all things impersonally.

Denial of the ego

In early Buddhism those who got rid of the notion of ego were highly praised. Such a denial, however, does not connote nihilism or materialism. The Buddha clearly expressed what the self is not, but he did not give any clear account of what it is. The Buddha did not want to assume the existence of souls as metaphysical substances, but he admitted the existence of the self as the subject of action in a practical and moral sense. The Buddha neither affirms nor denies the existence of *ātman*. As "body" (corporeality) is a name for a system of some functions, even so "soul" is a name for the sum of the states that constitute a person's mental existence. Without functions there can be admitted no soul.

The true self. In early Buddhism "one who knows the self" was highly esteemed. The virtue of relying upon oneself also was highly stressed. The Buddha taught his disciples, "Be a refuge to yourself." On another occasion he asked a group of young men who were searching for a missing woman: "Which is better, for you to go seeking the woman, or to go seeking the Self?" It is to be noted that he did not say "your selves"; he did not think that each individual had its own self as an entity. There are two selves: the empirical self in daily life that is to be subdued and the religious self. The realization of Nirvāna can be explained as taking refuge in one's own true self. On this point the Buddha's assertion suggests a comparison with Hindu Vedānta philosophy. But the self (*ātman*) of the Vedāntists was rather metaphysical, while the Buddha's self was genuinely practical.

Mahāyāna Buddhism developed the idea of a "Buddha-nature" latent in everyone's existence. This concept of the Great Self was especially emphasized in the Mahāyāna text, the *Mahāparinirvāṇa-sūtra* (an account of the Buddha's last days, of which only the Chinese versions are extant), and was generally admitted in Vajrayāna (*i.e.*, Tantric Buddhist) texts. The idea is commonly held by Chinese, Korean, and Japanese Buddhists but not by Theravāda Buddhists, who criticize the concept for its similarity to Vedāntic philosophy.

Inquiry into the cause of suffering. The Buddha inquired into the cause of worldly suffering on the practical, psychological level and found out that the real cause of human suffering is ignorant craving (*tṛṣṇā*). Just as a physician must study a disease in order to determine a cure, so also the Buddha studied the range of suffering, its origin, its cessation, and the way that leads to its cessation.

The Four Noble Truths

His conclusions were expressed in the doctrine of the Four Noble Truths: (1) the noble truth of suffering: birth, decay, disease, death, union with the unpleasant, separation from the pleasant, and not obtaining what one wishes—all are suffering; in brief, the five aggregates that spring from clinging (that is, the conditions of individuality) are suffering. (2) The noble truth of the origin of suffering: it is the craving thirst that causes rebirth, accompanied by sensual delights; this thirst seeks satisfaction (now here, now there) as a craving for lust, for existence, or for nonexistence. (3) The noble truth of the cessation of suffering: suffering ceases with the complete cessation of that craving—the giving up, the getting rid of, the release from, and the detachment from this craving thirst. (4) The noble truth of the way that leads to the cessation of suffering: the noble Eightfold Path consists of right views, right intention, right speech, right conduct, right livelihood, right effort, right mindfulness, and right concentration. The path pointed out by Gautama is called the noble Eightfold Path; the truths enumerated are called the Four Noble Truths. All the items of the Four Noble Truths were commented upon in full detail by later dogmaticians.

The sufferings and afflictions of man originate spon-

taneously from the impetus of his innermost condition of nonknowing. The distress of craving is based upon this nonknowing or fallacious understanding, on thinking that there is something real in satisfying these desires in the mundane world. It is this mistake about the true essence of reality that is the cause of all the sufferings that affect man's life. Ignorance and false desires are the theoretical and the practical sides of one fact; in actual life the two are one. When ultimate Enlightenment dispels ignorance, the successive constituents of the individual cease to operate, and suffering as well as transmigration ends.

The formula of "dependent origination"

It was by the attainment of this supreme Enlightenment, or wisdom, that Gautama became a buddha. In its simplest form it can be expressed thus: because of ignorance (lack of knowledge), man suffers. Because of knowledge (*i.e.*, disappearance of ignorance), man does not suffer. Between the two extremes of ignorance and suffering, Buddhist thinkers have found and formulated several intermediate conditions, expressed finally in the following formula: (1) the condition of ignorance leads to (2) will-to-action (*saṃskāra*), which in turn leads to (3) consciousness, which leads to (4) psycho-physical existence, which leads to (5) the six organs of sense (eye, ear, nose, tongue, body or sense of touch, and mind), which leads to (6) contact, which leads to (7) sensation (or feeling), which leads to (8) craving, which leads to (9) attachment (or grasping), which leads to (10) becoming (or worldly existence), which leads to (11) birth, which leads to (12) decay, death, grief, lamentation, physical suffering, dejection, and despair.

This formula, called origination through dependence or "dependent origination" (Sanskrit *pratītyasamutpāda;* Pāli *paṭiccasamuppāda*), is repeated in many scriptural passages, together with elaborate explanations of each.

It is noteworthy that the law of dependent origination was taught without regard to the authority of buddhas. As expressing a universal truth, it was considered as valid externally and from eternity, independently of the advent of buddhas or action by a deity.

The term dependent origination became very popular in later Buddhism. All schools of Buddhism accepted the importance of the chain of causation, but not all interpreted dependent origination in the same way. One definition of the term widely accepted in the ancient schools, especially in the Sarvāstivāda (All Exists school), is the interconnection according to causal laws of all the elements cooperating in the formation of life through continuing cycles of progress from birth to death and from death to rebirth in successive lives. In Mahāyāna, especially in the Mādhyamika (Middle View) school, dependent origination meant the interrelational existence of all things or the relationality of things and ideas. The Vijñānavāda (Consciousness Only) school occasionally took it to mean the process of manifestation of all phenomena out of the fundamental consciousness (*ālaya-vijñāna*). The Hua-yen (Kegon) school in China and Japan interpreted the term as the interpenetration of all things in the universe throughout the past, the present, and the future, asserting that nothing can exist separately from other things and that all things are interrelated.

Voidness (*śūnyatā*). The concept of voidness (*śūnyatā*) appeared already in the ancient schools of Buddhism, but it was not elaborately theorized. Mahāyāna Buddhism found in dependent origination the basis for voidness. There is no real existence; all things are but appearances and are in truth empty. Voidness or emptiness is neither nothingness nor annihilation but is that which stands right in the middle between affirmation and negation, existence and nonexistence, eternity and annihilation. The void is all-inclusive; having no opposite, there is nothing that it excludes or opposes. It is living void because all forms come out of it, and whoever realizes the void is filled with life and power and the Bodhisattva's compassion of all beings. Voidness, which is nothing but ultimate reality, is called by other terms, such as suchness (*tathatā*) or the basis of reality (*bhūtakoṭi*).

The belief in rebirth

Karman (*freedom and determination*). The belief in rebirth—of an endless series of worldly existences repeated by every being—was in pre-Buddhist India already associated with the doctrine of *karman* and was generally accepted by both the Theravāda and the Mahāyāna traditions. According to the doctrine of *karman* (literally meaning "act" or "deed"), good conduct brings a pleasant and happy result and creates a tendency toward similar good acts, while bad conduct brings an evil result and creates a tendency toward repeated evil actions. This furnishes the basic condition for moral improvement of the individual.

Some *karman*s bear fruit in the same life in which they are committed, others in the immediately succeeding one, and others in future lives more remote. The individual is the result of a multitude of causes carried over from his past existence and intimately related to all other causes in the world. The interconnection between one individual and the whole universe is stressed in the Buddhist doctrine of *karman*.

Most Buddhists have attached much importance to the way of dying, in the belief that the nature of the rebirth corresponds to the nature of a person's thoughts in the moments preceding death. The Shin sect of Japan differs from this general view by asserting that the destiny of each person after death is fixed by his faith during his lifetime.

The acceptance by Buddhists of the belief in *karman* and rebirth while holding to the doctrine of nonself gave rise to a difficult problem: how can rebirth take place without a permanent subject to be reborn? Indian non-Buddhist philosophers attacked this vulnerable point in Buddhist thought, and many modern scholars have also considered it to be an insoluble question. The relation between existences in rebirth has been explained by the analogy of fire, which maintains itself unchanged in appearance and yet is different in every moment—what may be called the continuity of an ever changing identity. In order to meet this vulnerable point, some Buddhists later assumed a sort of soul, though calling it by different names. This assumption finally gave rise to the conception of the fundamental consciousness (*ālaya-vijñāna*) of the Yogācāra (Practice of Yoga, also called Vijñānavāda, or Doctrine of Consciousness Only) school in Mahāyāna.

Buddhist eschatology and soteriology. *The ideal state* (*Nirvāṇa*). The aim of religious practice is to be rid of the delusion of ego, thus freeing oneself from the fetters of this mundane world. He who is successful in doing so is said to have overcome the round of rebirths and to have achieved Enlightenment. This is the final goal—not a paradise or a heavenly world.

The living process is likened to a fire burning. Its remedy is the extinction of the fire of illusion, passions, and cravings. The buddha, the enlightened one, is one who is no longer kindled or enflamed. Many poetic terms are used to describe the state of the enlightened man—the harbour of refuge, the cool cave, the place of bliss, the further shore. The term that has become famous in the West is Nirvāṇa, translated as Dying Out; that is, the dying out in the heart of the fierce fire of the three cardinal sins —sensuality, ill will, and infatuation. But Nirvāṇa is not extinction, and indeed the craving for annihilation or nonexistence (*vibhave-taṇhā*) was expressly repudiated by the Buddha. Buddhists search not for mere cessation but for the eternal, the immortal. Though Nirvāṇa is often presented negatively as "release from suffering," it is to be considered in a more positive fashion: as an ideal state, as happiness, as bliss.

Extinction of illusion

The Buddha left indeterminate questions regarding the destiny of the man who has attained this ideal state or the existence of the purified saint after death, for such judgments are inapplicable to this present existence.

Though it is true that the Buddha avoided discussion of the ultimate reality that lay beyond the categories of the phenomenal world, he did not seem to have had any doubts about the absolute. He said, "There is an unborn, an unoriginated, an unmade, an uncompounded; were there not, there would be no escape from the world of the born, the originated, the made and the compounded." The Buddha believed in something that endures beneath the shifting appearances of the visible world. The posi-

tive character of Nirvāṇa is inexpressible in any terms of finite experience of human beings, for its reality transcends the realm of birth and death.

In deliverance there is no discrimination. The Buddha declared: "Just as the great ocean has one taste only, the taste of salt, just so have this doctrine and discipline but one flavour only, the flavour of emancipation." Those monks who exert themselves in the religion can be saved; they will never be reborn into suffering. But the attainment of the ideal state should be realized not only after death but also now, in this life—the "Nirvāṇa here and now."

The goal of the Buddhist

The Mahāyānistic, especially Zen, understanding of the ideal state is not as something concrete, or seizable, but as the proceeding onward toward an always elevated goal. The man who has attained deliverance should continue his actions in this world, working for the welfare of others.

In Theravāda Buddhism the goal of a monk is to attain the *arahant* state (roughly, "sainthood"); he cannot hope to become a buddha. Laymen are not expected to attain that state but may be reborn in one of the heavens. Mahāyāna Buddhism, on the other hand, professes that anyone is entitled to become a buddha, although he might have to pass through many births. According to the Pure Land school, even a layman can become a buddha by virtue of the grace of Amitābha Buddha. There is no concept of the eternally damned; both Theravādins and Mahāyānists believe that even a most vicious person can ultimately attain Enlightenment.

The buddha. The person who has attained wisdom or who has realized the universal norm (the *Dharma*, not to be confused with *dharmas*) is called the enlightened one or the awakened one (buddha). At the beginning of Buddhism, the Buddha was merely a man and nothing more, but with the lapse of time he came to be extolled more and more highly. Many miraculous powers, such as supernatural memory and levitation, were ascribed to the Buddha. From the point of view of doctrine, the magical powers were of no great importance, but they played an important role with the common people. Even the relics of the Buddha came to be esteemed for their magical potency.

Buddhism admits the existence not only of one Lord Buddha but also of other buddhas. References are made in the Pāli scriptures to seven or to 24 buddhas, though the most popular is Śākyamuni (Gautama), the founder of Buddhism. In Theravāda Buddhism devotion is paid almost exclusively to Gautama Buddha. Mahāyānists, although they remember the historic Gautama Buddha also, regard him as one of many buddhas—all of whom are manifestations of one eternal and primordial Buddha—who teach variously according to the needs of living beings in their different realms. Maitreya Buddha, the buddha of the future, was highly revered in the past throughout all the Buddhist world, though not so much in modern times. Pure Land Buddhism prefers Amitābha Buddha to Śākyamuni, though it pays homage to the latter, while Vairocana Buddha, the primordial Buddha, has been the object of much devotion in esoteric Buddhism.

Mahāyāna substitutes the eternal Buddha for the historical Buddha. According to Mahāyāna doctrine, his existence in the earthly form is not his true and proper mode of being; his historical existence seems to be quite temporary.

Threefold body of the Buddha

Mahāyāna Buddhism developed the idea of the threefold body (*tri-kāya*) of the Buddha: (1) the body of the law (*dharma kāya*)—voidness, the formless reality beyond words and thoughts, the cosmic body; (2) the body of enjoyment (*sambhogakāya*)—the void, absolute reality, enjoyed as a result of merits earned by working for the salvation of others, the perfected body; (3) the body of transformations (*nirmāṇakāya*)—the corporeal, preaching buddha, such as Śākyamuni, revealed in the empirical world, the saviour body.

Mahāyāna admits the existence of innumerable buddhas engaged in the work of saving as many suffering creatures as they can. While the concept of a saviour is not allowed in Theravāda Buddhism, it is accepted in Mahāyāna. The saviour does not bring beings directly to Nirvāṇa but makes the path easier and brings the disciple to a heaven where he may hear the preaching of the doctrine that leads the way to Enlightenment. The only exception to this concept in Mahāyāna is Pure Land Buddhism in China and Japan, which says that to be born into the Pure Land is the same as attaining Nirvāṇa.

The arhat. In Theravāda, *arhat*s (Pāli *arhant*s)—monks who have attained Nirvāṇa—have always been highly revered, and the *arhat* state is regarded as the ultimate goal of the monk. The *arhat* seeks to show that it is humanly possible to reach Nirvāṇa by his own personal efforts and to encourage others to tread the path. On the other hand, Mahāyāna Buddhists have often charged that it is selfish to seek the state of *arhat*, to seek Enlightenment for oneself rather than to work for the salvation of others.

The bodhisattva. A *bodhisattva* is a "being destined for Enlightenment," often translated "buddha-to-be." A *bodhisattva* was originally in ancient Buddhism one who was on the way to the attainment of perfect knowledge, a candidate for Enlightenment. This concept of a *bodhisattva* has been retained in Theravāda Buddhism. In Mahāyāna the altruistic inclinations and activities of the *bodhisattva* have been emphasized. The *bodhisattva* is one who has taken a vow to delay his own buddhahood in order to work for the good of others. From the outset, he identifies his ego absolutely and entirely with that of his neighbours. A *bodhisattva* renders help to others through perfecting himself in the six virtues (*pāramitās*) of generosity, morality, patience, vigour, concentration (in meditation), and wisdom.

The concept of the *bodhisattva* affected the doctrine of *karman*. Whereas some ancient schools (the Theravāda and its offshoots) held that the state of a *bodhisattva* is a result of the merits accumulated in his past lives, the Mahāsaṅghika (Great Assembly) school and the Mahāyāna schools held that a *bodhisattva* is born in this life freely and by his own intention—out of compassion for living beings, not as a result of past *karmans*.

Stages of the path. Several stages on the path to Enlightenment have generally been recognized. Theravāda Buddhism has clearly defined the four stages of spiritual attainment that must be passed through before a man can become an *arhat*: (1) entering into the stream of sanctification; (2) not being reborn on Earth (the realm of desires) more than once; (3) not returning to Earth; and (4) being in the state of *arhat*.

Mahāyāna Buddhism also assumed the existence of many steps for getting to buddhahood, the number of stages varying with different *sūtra*s and sects. Some Mahāyānists, however, asserted that the intermediate steps could be skipped and man could attain to buddhahood directly. Zen, for instance, teaches that Enlightenment comes about by means of the direct intuition of one's own nature. Japanese Tendai and Shingon sects expressed similar ideas, while Pure Land Buddhists profess that it comes by means of the grace of Amitābha Buddha.

Buddhist ethics. *The middle path.* The ethics of Buddhism have stressed the universal norms that are constant, apply to everyone, and do not conflict with human nature. The way of Gautama Buddha is called the middle path because it avoids both the extremes of the outright pursuit of worldly desires and the practice of severe disciplines of self-mortification followed by ascetics. The universal norms of human life are constant, although in each case they must be adjusted to the infinitely varying circumstances of actual life. Otherwise, there would be a danger that detailed and petty regulations might encroach unduly on the moral autonomy of the individual. This same fundamental approach to ethical problems has been preserved up to modern times throughout the Buddhist world, although its application has differed in various historical periods and areas.

Norms of human conduct

Evil actions are to be avoided by following the middle path, or the right way of ethical practice. Only Pure Land Buddhism, with its belief that all living beings are sinful

and are saved by the compassionate grace of Amitābha Buddha, departs from this view.

Compassion. The fundamental principle of Buddhist ethics is that all men should develop an attitude of compassion—a very highly esteemed virtue in Buddhism. True wisdom consists not in metaphysical sophistication but in practical knowledge expressed in compassion as the fundamental principle in social life. Compassion or love in Sanskrit is *maitrī* (Pāli *mettā*), derived from *mitra* ("friend"). Thus, the term embodies the meaning "true friendliness." If one allows the virtue of compassion or love to grow in him, it will not occur to him to harm anyone else any more than he would willingly harm himself. By widening the boundaries of what one regards as his own, he breaks down the barriers that separate him from others.

This altruistic attitude is attained by meditation on one's *dharmas* (the elements that constitute one's self). Such meditation dissolves the existence of one's self into a conglomeration of impersonal and instantaneous elements. By dissolving human existence into component parts, one is rid of the notion of self and, through that meditation, led to a limitless expansion of the self in a practical sense, because one identifies oneself with more and more living beings. The whole world and all individuals are intimately and indissolubly linked.

The practice of compassion

Love is accompanied by other mental attitudes, often described as the sublime conditions (*brahma-vihāra*). The four are love, sorrow at the sorrows of others, joy in the joys of others, and equanimity as regards one's own joys and sorrows. Each of these feelings should be deliberately practiced, beginning with a single object and gradually increasing until the whole world is suffused with such kinds of feeling.

The problem of evil. Men are always afflicted by their own evils. The most dangerous obstacles to the good life have customarily been listed in Theravāda Buddhism as the 10 bonds: (1) delusions about the existence of the ego, (2) doubt, (3) reliance upon works (ascetic discipline), (4) sensuality, (5) ill will, (6) desire for rebirth on Earth, (7) desire for rebirth in heaven, (8) pride, (9) self-righteousness, and (10) ignorance.

These evil dispositions should be conquered. The overcoming of ignorance, the last of the bonds and the fundamental principle motivating man's mundane existence, finally leads to release. The disciples of the Buddha, both clergy and laity, must gradually rid themselves of these evils through their own efforts. Having attained the final "assurance," there can then be no permanent relapse; the view of Theravāda Buddhists is that sooner or later, in this or another birth, final salvation is assured.

The five most heinous crimes are: (1) matricide, (2) patricide, (3) the murder of an *arhat*, (4) the wounding of a buddha, and (5) the creation of a schism in the order (*saṅgha*). The 10 immoral actions are: (1) killing, (2) stealing, (3) unchastity, (4) lying, (5) slandering, (6) harsh language, (7) frivolous talk, (8) covetousness, (9) ill will, and (10) false views. This definition of the moral problem has been generally accepted throughout all Buddhism.

These evil actions are to be avoided by following the right path. To the Buddha, evil is something to be conquered; inhibition should be observed assiduously. Viewed from the religious standpoint, good action as such is never a means to the final end. Yet devout Buddhists practice good actions spontaneously, without considering the results of actions concerned. In the Buddhist faith there is no conception of original sin. Eternal damnation is inconceivable for the Buddhists; even such hideous crimes as patricide are forgiven by deep repentance. The path of religion leads through morality, but, when one approaches the goal, one enters into an entirely different realm; the saint who has attained the calm of Nirvāṇa is said to be "beyond good and evil." What is called good in daily life is very often defiled with worldly desire. The ideal situation should be perfectly pure, so it is said to transcend secular good and evil (this idea was especially emphasized in Mahāyāna).

Ethical disciplines. The disciplines that create a spirit of compassion have always been stressed in Buddhism. The evil passions must be calmed, the senses must be restrained, and constant awareness of one's feelings and desires must be developed. Meditation, which is the discipline for the path to Enlightenment, was also adopted as a discipline for the ethical life, as the means for developing the awareness that checks attachment to the senses.

Secular versus monastic life

Early Buddhism stressed the necessity for monastic life to enable one to follow the disciplines necessary for attainment of the ethical ideal and for attaining Enlightenment. The rules for the layman were far less stringent than for the monk; withdrawal from the life of the householder was considered a necessity if one wished to devote himself to following the path. If the monasteries' monks would devote all their time to meditation and study, attachment to food and clothes could be curbed, sexual attachments could be eliminated, and all actions could be guarded. This otherworldly ideal has been preserved in Theravāda Buddhism to this day in the Saṅgha (the monastic order), which is still central in Buddhist life. In Tibet, too, the monastery remained the most important aspect of Buddhist community life and the centre for Buddhist disciplines—at least until Chinese rule.

On the other hand, some Mahāyāna scholars have argued that the moral disciplines could be followed and that the absolute could be comprehended in secular life. It was this type of Buddhism that was selected by the Japanese and the Nepalese and, to a large extent, by the Chinese. Even when other doctrines were accepted, the Japanese managed to impress upon them the stamp of this-worldliness. Although resignation and nonattachment may have characterized Buddhist life in Asia in general, they were often specifically repudiated by the Japanese not only in modern times but also in the remote past.

The Japanese have put heavy emphasis upon activity in human relationships. This attitude accounts for the absence of the all-inclusive monastic order in Japan, the disapproval of begging as a discipline, marriage of the priests, and similar practices that distinguish some of the features of Japanese and Nepalese Buddhism from those of the Theravāda countries.

Service. Another distinction between the ethical practices of Buddhism in the southern countries and in the northern Mahāyāna countries lies in the field of service. The this-worldly character of Japanese and Nepalese Buddhism brought the priests into close contact with the common people and their needs. In South Asian countries, where climate, rainfall, and natural fertility combine to bring harvests without great human labour, the ethics of distribution rather than of production have been emphasized. That is why, for example, almsgiving was considered so important in southern Buddhism. But in countries such as Japan, where production is of vital importance, stress has been placed on the ethics of hard work to produce the necessary food. Even monks and priests have engaged in productive labour as an expression of their Buddhist ethical principles.

One result of this attitude has been that the responsibility for service in Theravāda Buddhism has been placed largely on the individual monk as a personal matter, with comparatively less of the emphasis on social institutions that has been characteristic of Mahāyāna Buddhism. Individual householders feel free to come to the monastery for help in time of need in Theravāda countries, and many acts of mercy are performed by the monks. But in China and Japan there have been many institutions such as hospitals, orphanages, and schools that have been motivated by the Buddhist spirit.

Ethics for laymen. In both Theravāda and Mahāyāna countries the monks and priests are responsible for the spiritual guidance of the laymen, and the laymen are responsible for the support of the religious institutions. The basic ethics taught to laymen are the same in all Buddhist countries. The laymen should obey the five precepts that admonish him (1) not to kill, (2) not to take what is not given, (3) to refrain from unlawful sexual intercourse, (4) not to tell lies, and (5) not to drink intoxicating liquors. (In Tibet, Nepal, and Japan the fifth precept is often minimized.) The duties that are stressed are those between parents and children, pupils and teachers, husband and

The five precepts and virtues

wife, friend and friend, master and servants, and laymen and monks.

The virtues stressed are (1) generosity, (2) benevolence, (3) cooperation, and (4) service; these four are regarded as the fundamental ones for social life. Courtesy, sympathy, honesty, and other virtues are also encouraged.

Economic ethics. At the council of Vaiśālī, held about 100 years after the death of the Buddha, one of the issues was whether monks could accept money as a gift by laymen. The Sthaviravāda, or Theravāda (school of the Elders; precursors of the modern Buddhism of South Asia), did not permit such gifts, but monks of the Mahāsaṅghika (Great Assembly) and, later, of the Mahāyānas did.

Theravāda Buddhist monks were not permitted to engage in economic activities, to cultivate land, or to be involved in making profit. They lived only on alms. This attitude has been preserved in most Asian countries with the exception of China and Japan. In China Ch'an (known in Japan as Zen) monks began to engage in manual labour. As early as the 8th century AD, they began to cultivate fields attached to their own temples in order to secure foods. "If one did not work on a day, one should not eat on that day" became one of their favorite mottos. In China some monks engaged in philanthropic activities; they formed groups of Buddhists to lend money to people in need. The spirit of labour and service was encouraged.

This way of life was introduced into Japan. In Japan monks of many sects engaged even in such kinds of philanthropic activity as constructing roads, resthouses, hospitals, ponds, and harbours. In Japan today, priests are not prohibited from engaging in economic activities.

Meditation. In order to acquire the calmness of mind necessary for travelling the path to Enlightenment, Buddhism has always recommended meditative practices derived from ancient *yoga*, stripped of its ascetic character. Meditation practices that were originally influenced by Indian *yoga* have been followed in Theravāda Buddhism by laymen as well as by monks in Tibet, China, and Japan —nowadays chiefly through the influence of Zen.

Removal of caste barriers

Equality of men. From the time of the Buddha, Buddhism has stressed the equality of man. Buddhism removed all restrictions of caste and placed upon all members the same requirements. There was no discrimination among the monks in the early Buddhist order. This sense of equality has been theoretically preserved throughout most Buddhist orders, although it has often been impaired because of political reasons.

Tolerance. Tolerance has been an outstanding characteristic of Buddhism from earliest times. Buddhism has attempted to arrive at the truth not by excluding its opposites as falsehood but by including them as another form of the same truth. Although Buddhism was predominant in many Asian countries, there is no record of any persecution by Buddhists of the followers of any other faith. They waged no religious war. It is very difficult to have a firm conviction and at the same time to be tolerant, but the Buddha himself and many of his followers have achieved such tolerance.

Buddhists are generally noted for their liberal attitude toward other religions, whether polytheistic, monotheistic, or non-theistic. This feature is found in all Buddhist countries. Buddhists admit the truth of any moral and philosophical system, whether primitive or developed, provided only that it is capable of leading men at least part way toward their final goal.

Buddhist psychology. The psychological analysis of one's own existence was not yet systematized in early scriptures. It was due to the efforts by Abhidharma (scholastic) teachers that various aspects of human existence were elaborately analyzed and schematized.

In the Sarvāstivāda school, especially, a complex system of psychology was developed, according to which all constituent elements of human existence were classified as 75 in number. These 75 were divided into two major groups: (1) cooperating, impermanent elements (*saṃskṛta*) and (2) non-cooperating, immutable elements (*asaṃskṛta*). The former is divided into four major groups: (1) matter, (2) mind, or pure consciousness without content, (3) the 46 mental elements or faculties intimately connected with the element of consciousness, and (4) the forces that can be included neither among material nor among spiritual elements. Matter is further subdivided into the organs of sight, sound, smell, taste and touch and their sense data, and the unmanifested matter that is the vehicle of moral qualities. The 46 mental elements are divided into six groups: (1) 10 general mental faculties present in every moment of consciousness, namely, feeling (pleasant, unpleasant, and indifferent), conceptualization, will or conscious effort, sensation (caused by "contact" between object, sense organ, and consciousness), desire, intelligence, memory, attention, ascertainment, and concentration; (2) 10 universally "good" moral forces present in every favourable moment of consciousness, namely, the faculties of belief, courage in good actions, equanimity or indifference, modesty (being ashamed with reference to oneself), feeling disgust with reference to other peoples' objectionable actions, absence of greed, absence of hatred, causing no injury, mental dexterity, and endeavouring to acquire good qualities; (3) six universally "obscured" elements present in every unfavourable moment of consciousness (these are not always absolutely bad; they sometimes may be indifferent for the spiritual progress, but they are nevertheless always "obscured" in a selfish tendency), namely, the faculties of infatuation or ignorance, laziness, mental heaviness, non-believing, sloth or indolent or inactive temperament, and being addicted to pleasure; (4) two universally "bad" elements present in every unfavourable moment of consciousness, namely, the faculties of irreverance or want of humility and of not feeling indignant at offenses done by others; (5) 10 vicious elements of limited occurrence, namely, the faculties of anger, hypocrisy, envy, jealousy, approving objectionable things, causing harm, breaking friendly feeling, deceit, trickery, and complacency; and (6) eight elements not having any definite place in the above system but capable of entering into various combinations, namely, the faculties of repenting, absentmindedness, a searching state of mind, an ascertaining state of mind, attachment by mind, hatred, pride, and doubting.

The fourth group of impermanent elements, those that are neither material nor spiritual, are further subdivided into forces that effect the acquisition of the elements in an individual existence, occasionally keep some elements in abeyance in an individual existence, produce generality or homogeneity of existences, transfer an individual into the realms of conscious trance, and stop consciousness, producing either an unconscious trance or the highest trance; in addition, there are the forces of life duration, origination, subsistence, decay, and extinction, as well as the forces imparting significance to words, to sentences, and to articulate sounds. The immutable elements consist of (1) space for all *dharma*s, (2) the suppression of the manifestations of elements through the action of intelligence, and (3) the same cessation produced not through the action of intelligence. This scheme of 75 elements was developed and enlarged to that of 100 elements by the Yogācāra idealists.

The scheme of elements

One item that is noteworthy from the psychological viewpoint is that the Yogācāra advocated the theory of the eightfold consciousness: the visual consciousness, auditory consciousness, odour consciousness, taste consciousness, touch consciousness, the conscious mind, the subsconscious mind (the substrate of self-conscioueness), and the "store-consciousness," which is the fundamental consciousness.

According to the orthodox thought of the 6th-century Indian monk Dharmapāla, conveyed by the 7th-century Chinese pilgrim Hsüan-tsang to China and Japan, where it became known as the Fa-hsiang (Japanese Hossō) school, these are separate consciousnesses, existing as different entities, and the first seven of these consciousnesses are collectively termed the transformed consciousnesses. The She-lun school of China (now merged with Fa-hsiang) regarded the store-consciousness that has become pure and taintless as thusness (*tathatā*) and gave it

a special name, "taintless consciousness," designated as the ninth consciousness. Generally speaking, Buddhist psychology is highly tinged with ethical and soteriological evaluations.

Buddhist logic. Buddhist logic in its incipient stage can be noticed in 4th-century texts such as Maitreya's *Yogācārabhūmi-śāstra* ("The Science of the Stages of Yoga Practice") and Asaṅga's *Abhidharma-samuccaya* (a summary of *abhidharma*, or scholastic, doctrine), Vasubandhu's *Vādavidhi* ("Method of Dispute"), and *Vādavidhāna* ("Rule of Dispute").

The founder of the Buddhist new logic, as against the old logic set forth in the Nyāya school, was Dignāga (*c.* 400–485). He established the three-proposition syllogism, replacing the five-proposition syllogism prevalent before his time. The older, five-proposition formula consists of: (1) proposition (*pratijñā*)—*e.g.*, sound is impermanent; (2) reason (*hetu*)—because it is produced by causes; (3) example (*dṛṣṭānta*)—it is like pots; (4) application (*upanaya*)—pots are produced by causes and are impermanent in the same way as sound is also; and (5) conclusion (*nigamana*)—therefore, sound is impermanent.

In the threefold formula by Dignāga, propositions (4) and (5) are omitted. The whole scheme of syllogism is deductive, but in (3) the inductive method also is implied. The theory of the nine reasons or types of argument was also set forth by Dignāga. *Nyāyapraveśa*, by the South Indian Śaṅkarasvāmin, is a brief introduction to Dignāga's logic. In China and Japan this work was regarded as almost the only authority and was studied in great detail by traditional scholars of Buddhist logic.

The logic of Dignāga and Dharmakīrti

The logic and epistemology (really fused together) of Dignāga was elaborated upon in the 7th century by the Indian Buddhist logician Dharmakīrti. Among Indian and Tibetan thinkers he was regarded as the representative Buddhist philosopher. He admitted only two kinds of valid knowledge; *i.e.*, direct perception and inference. He asserted that in the function of mind, cognition and the cognized belong to different moments.

Dharmakīrti denied the authority of scriptures but in another way admitted Buddha as the source of all knowledge. According to him, every being is transitory, and each person assumes the continuous existence of an individual, who is nothing but a continuation of moments and who is constructed by imaginative and discriminative thinking. Objects of inference are universals, whereas objects of perception are particulars, which are nothing but moments. He distinguished between analytic inference and synthetic inference. Nonperception was limited to purely epistemological significance; relation between subject and object in cognition was a secondary one.

In Japan the traditional scholarship of Buddhist logic as conveyed by the Buddhist pilgrim Hsüan-tsang to China in the 7th century has been preserved, especially in the old capital of Nara. Zen took exactly the opposite standpoint to the formal logic of Buddhist logicians. In the Rinzai school of Zen, meditation on paradoxes (*koan*) is used to awaken intuitive insight into what transcends logical distinctions. In popular Japanese speech, Zen dialogue, or *mondo*, is equivalent to what is not understandable or what is illogical.

Buddhist Sacred Literature

Buddhist sacred literature is the name given to a vast number of works ranging from what are supposed to have been the original discourses of the Buddha—a prince who gained enlightenment in the 6th century BC—to the exegetical works that were inspired by the Buddha's teachings and to the religious and philosophic thought that, in turn, contributed to the growth of a variety of philosophical and religious works. Buddhist sacred literature consists of the religious texts of all major forms of Buddhism, including Theravāda (Way of the Elders, also known as Hīnayāna, or "Lesser Vehicle"), the predominant form in present-day Southeast Asia and Ceylon; Mahāyāna (Greater Vehicle), the predominant form in East Asia; and Tantric (magical) and Tibetan Buddhism, prevailing at present in the Himalayan regions. Included in this literature are works dealing with the regulations for the monastic life and manuals about the techniques of meditation. The following sur-

vey will describe the beginnings and the development of this literature in India as well as its diffusion through the rest of Asia by means of translations into the major Asian languages. In addition, it will touch upon the indigenous contributions of the Tibetans, Chinese, Mongolians, and Japanese. Since Buddhist literature not only significantly molded the ways of thinking and the life of the peoples of Asia but also influenced the fine arts, which, in turn, gave new impetus to thought, this interrelationship between literature and the fine arts is also examined briefly. Obviously only works that had an enduring influence can be mentioned. This article will deal with the general aspects of Buddhist sacred literature, its major texts, its significance in the life of the peoples of Asia, and its relation to the fine arts. The article is divided into the following sections:

I. Types and forms of texts
II. Major Buddhist texts
  The Pāli canon and its Asian translations: *Tipiṭaka* (*Tripiṭaka*)
    Vinaya Piṭaka
    Sutta Piṭaka
    Abhidhamma Piṭaka
  Important noncanonical texts in Pāli
    Milinda-pañha
    Writings of Buddhaghosa
    Writings of Buddhadatta
    Writings of Dhammapāla
    Ceylonese chronicles
  Mahāyāna texts
    Prajñāpāramitā literature
    Mādhyamika texts
    Avataṃsaka-sūtra
    Saddharmapuṇḍarīka-sūtra
    Sukhāvati-vyūha-sūtra
    Other Mahāyāna texts
  Tantric and Tibetan texts
    *Tantra*s
    Tibetan literature
    Mongolian texts
  Chinese and Japanese texts
  Other important texts
III. Ritual use and influence of Buddhist texts

I. Types and forms of texts

Buddhist literature originated within the community of monks and served its members as an aid to a goal realization. By striving for a goal the character of which changed in the course of time—the early ideal of becoming an *arhat* (saint) changing to that of realizing Buddhahood (the state of enlightenment as a Buddha)—the aspirant was setting an example that could be emulated, first by other monks (and nuns), and then also by the laity. This striving found its expression in what was to become the acknowledged sacred literature of the Buddhists, which, therefore, comprises both Hīnayāna and Mahāyāna works, the former concerned with the ideal of sainthood, the latter with Buddhahood through the intermediate stage of *bodhisattva*hood (the state of being a Buddha-to-be). Although it is customary to refer to Buddhist sacred literature either by the term Pāli canon or *Tripiṭaka* (Pāli *Tipiṭaka*, Chinese *san-ts'ang*, "The Three Collections"), these terms can strictly be applied only to works representing the texts that have been recognized by the *thera* ("elders") or Vibhajyavādins (Theravādins) of Ceylon. The Mahāyānists do not repudiate the *Tripiṭaka*, but for them it is but the revered foundation on which they built. The Mahāyāna works attempt to elucidate the meaning of the early texts and this elucidation has two aspects, the one theoretical and doctrinal (*i.e.*, how do human beings perceive and what is meant by this or that term) and the other reflected in the *Tantra*s (see below). When emphasis is laid on what is supposed to have been said and done by the Buddha, as is the practice of the Theravādins, a text is a "canon" or part of a set of sacred scriptures; but when emphasis is laid on interpretation and meaning, it is a religious and philosophical text, but not a canon.

Although tradition claims that a fivefold division into *nikāya*s ("collections") was worked out with the assistance of Ānanda, cousin and favourite disciple of the Buddha, at the first council (said to have been held in 483 BC), this account, apart from its legendary character, is contradicted by the opening words "Thus I have heard," which indicate that there was a long oral tradition before the discourses were put down in writing. Since, moreover, everyone was allowed to study the Buddha-word in his own dialect, there is no one version but a continuous replacement of one vernacular version by other local ones, and intermediate ones of a mixture of vernaculars and Sanskrit that finally replaced every kind of vernacular writing. It is impossible to say exactly when the oral tradition was written down.

Classification of Buddhist texts

A major problem that faced the collectors of the Buddhist texts was the classification of this extremely diverse material. The most obvious solution was the classification into "The Three Collections," reflecting the general nature of the contents. Another division into nine *aṅgā*s ("parts") is related to the literary form and specific contents. It is found in both Pāli and early Sanskrit works, although differences are noticeable. The Pāli denominations of these *aṅgā*s (with their Sanskrit equivalents in parenthesis, where applicable) are (1) *sutta* (*sūtra*), a connected narrative or collection of verses on one subject; (2) *geyya* (*geya*), a composition of mixed prose and verse; (3) *veyyākaraṇa* (*vyākaraṇa*), an "exposition" containing the whole *Abhidharma* (scholasticism or "higher subtleties of the religion"), the *sūtra*s that have no verse, and the words of the Buddha not included in the other eight *aṅgā*s; (4) *gāthā*, unmixed verses; (5) *udāna*, ecstatic utterances; (6) *itivuttaka* (*ityukta*, wrongly *itivṛttaka*), a collection of *sūtra*s beginning with the words "Thus the Buddha spoke"; (7) *Jātaka*, stories of the Buddha's previous births; (8) *abbhutadhamma* (*adbhutadharma*), discourses relating wonderful (*adbhuta*) conditions and events such as accompanying the birth of a Buddha; and (9) *vedalla* (*vaipulya*), questions posed after feeling a pleasant emotion. In Sanskrit texts, three more varieties are added: *nidāna*, a group of works that were written in response to a re-

quest or a certain event; *avadāna*, stories; and *upadeśa*, instruction. The former two are well represented in the Pāli canon but not counted as separate *aṅgā*s; the *upadeśa*s deal with esoteric doctrines and the instruction of promising disciples and indicate that esotericism was present in Buddhism at a very early stage. As to the *vaipulya*, these works have nothing but the name in common with the Pāli *vedalla*. Dealing with the acquisition of goods in this world (*artha*) and of the world to come (*dharma*), the *Vaipulya-sūtra*s are distinguished from the older *sūtra*s by a different approach and by the change of idiom. They comprise a prose version, followed by one in verse, the latter being more or less a repetition of the former or the source of the prose narrative. The Tibetans classified the whole material into "Translation of the Buddha Word" and "Translation of Treatises" and in this great division were free to arrange the material according to content.

From the 2nd century AD onward, Mahāyāna authors wrote "treatises" (*śāstra*s) in their own names. They quoted the *sūtra*s in support of their interpretations of Buddhist ideas and in so doing stimulated the composition of new *sūtra*s. Another form presented the didactic material in "memorial verses" (*kārikā*s) that sometimes had an explanation (*vṛtti*) by the author himself, on which others wrote commentaries and subcommentaries (*vyākhyā, bhāṣya*) or word by word explanations (*ṭīkā*). Mahāyāna authors excelled in devotional and edifying literature in both prose and verse form. The poetical compositions in praise of the Buddha or the ideas of Buddhism are known as *stotra* (hymns).

II. Major Buddhist texts

THE PALI CANON AND ITS ASIAN TRANSLATIONS: TIPITAKA (TRIPITAKA)

The earliest systematic and most complete collection of early Buddhist sacred literature is the Pāli *Tipiṭaka* ("The Three Collections"). Its arrangement reflects the importance that the early followers attached to the regulations of the monastic life (*Vinaya*), to the discourses of the Buddha (*Sutta*), and subsequently to the interest in scholasticism (*Abhidhamma*).

There is no complete canon of Buddhist books preserved in Sanskrit. It seems that the Sarvāstivāda school —an early sect that believed not only present mental elements or states of mind to be real but also past and future ones as well—did have the *āgama*s corresponding to the Pāli *nikāya*s and also a set of *Abhidharma* (Sanskrit form of *Abhidhamma*) texts, corresponding only in number to the Pāli set. The Mūla-Sarvāstivādins—who upheld the doctrine that "all exists really" whether transitorily or eternally, and who were closely related to the Sarvāstivādins, sharing the same ideas—possessed a *Vinaya Piṭaka* ("Basket of Discipline"), large sections of which are preserved in manuscripts found in Gilgit (Pakistani-occupied Jammu and Kashmir). Different schools of Buddhism esteemed different texts. Thus the noncanonical *Mahāvastu* ("Great Subjects") is claimed to be a book on *Vinaya* belonging to the Lokottaravādins (who held that the Buddhas are "exalted above the world" and only seem to participate in this world), but its subject matter is extremely varied and in it are found *sūtra*s corresponding to those in other kinds of texts. These divergences in tradition show that over the centuries Buddhism lost its early sectarian character and became an all-embracing spiritual movement.

The three "baskets" into which the 32 texts of the Pāli canon are divided are *Vinaya Piṭaka* ("Basket of Discipline"), *Sutta Piṭaka* ("Basket of Discourse"), and *Abhidhamma Piṭaka* ("Basket of Scholasticism").

Vinaya Piṭaka. The Pāli *Vinaya Piṭaka*, which is still in theory the rule in Theravāda monasteries, although large sections have fallen into disuse, is divided into five major parts grouped into three divisions—*Sutta-vibhaṅga* ("Division of Rules"), *Khandhaka*s ("Sections"), and *Parivāra* ("Accessory").

Sutta-vibhaṅga. *Sutta-vibhaṅga* is a commentary on the *Pātimokkha-sutta* ("Obligatory Rules"), which forms the nucleus of the *Vinaya Piṭaka*. It is the oldest part of the Pāli canon in an archaic language. It consists of two parts, the *Bhikkhu-pātimokkha* ("Rules for Monks") and the *Bhikkhunī-pātimokkha* ("Rules for Nuns"). The offenses a monk or nun is likely to commit are listed according to their gravity, as, for instance, those warranting permanent expulsion from the order (*pārājika*), those entailing temporary suspension, and those (*pācittiya*) of which a guilty person can be absolved by a formal confession before the monastic order. The commentary on the *Pātimokkha* is divided into the *Mahā-vibhaṅga* ("Great Division"; 227 rules for monks) and *Bhikkhunī-vibhaṅga* ("Division Concerning Nuns"). The latter lists additional specific rules and regulations.

Rules for monks and nuns

Khandhaka. *Khandhaka* consists of two parts, the *Mahāvagga* ("Great Grouping") and the *Cullavagga* ("Small Grouping"). The topics dealt with in these two sections have not always been clearly distinguished and also lack logical sequence. They contain rules for ordination; "observance" days, when all monks resident within the district were required to assemble for recitation of the *Pātimokkha*; descriptions of rainy-season retreats, clothing, food, and medicines; judicial rules; miscellaneous rules; instruction of nuns; and so forth. While the *Mahāvagga* can be regarded as the history of the developing Buddhist community, the *Cullavagga* supplements the details of the former to make an authoritative compilation of the Buddha's sayings, compiled in order to suppress a relaxation of disciplinary rules. This, however, led to a schism, the majority rejecting the suppressive rulings.

Parivāra. *Parivāra* contains summaries and classifications of the disciplinary rules. It is a later supplement intended not only to help monks or nuns to remember the rules but also to make them aware of the circumstances that would bring them within the orbit of these rules.

Sutta Piṭaka. By far the largest "basket" is the *Sutta Piṭaka* ("Basket of Discourse"), which consists of five collections (*nikāya*s) containing the discourses of the Buddha. Although, from a literary viewpoint, many of the discourses seem to be drawn out and repetitive, they nevertheless make rewarding reading because of the sublimity of thought and the richness and beauty of the illustrative similes that they contain. The discourses, reported by the Buddha's disciples, begin with the affirmative statement "Thus I have heard" and then relate the place and occasion of the discourse. At the end, the listener acknowledges the validity of the Buddha's exposition and asks to be counted henceforth among his followers. It is obvious that these discourses do not represent the exact words of the Buddha, although some phrases may have been his words. Still, they reveal the personality, the didactic technique, and the spirit of Buddhism. The discourses are chiefly in prose, except for stanzas illustrating or summing up a particular point. The grouping of the discourses into *nikāya*s ("collections") does not rest on a rational basis. Apparently there existed two groups of teachers (*bhāṇaka*s), who memorized certain *sūtra*s and handed them down to their disciples orally. Reciters of lengthy verses were called Dīghabhāṇakas, and reciters of medium length verses, Majjhimabhāṇakas. The other two *nikāya*s (*Saṃyutta* and *Aṅguttara*) seem to reflect a later development, their aim being to rearrange the topics dealt with in the *Dīgha* and *Majjhima Nikāya*s.

Discourses of the Buddha

Dīgha Nikāya. The *Dīgha Nikāya* ("Collection of Long Discourses") contains 34 *sutta*s, some of considerable length, presenting a vivid picture of the different aspects of life and thought at the Buddha's time. Divided into three books, it contrasts superstitious beliefs, various doctrinal and philosophical speculations, and ascetic practices with Buddhist ethical ideas, which are elucidated with the help of similes and examples taken from the everyday life of the people. By far the best *suttanta* ("discourse") is the *Mahāparinibbāna Sutta*, which gives an account of the last days of the Buddha and stresses the importance of striving for emancipation.

Majjhima Nikāya. *Majjhima Nikāya* ("Collection of Medium-Length Discourses") contains 152 *sutta*s in its

present version, while the Chinese one, preserving the lost Sarvāstivāda collection, has 222, some of which are also found in other *nikāya*s of the Pāli canon, and some of which cannot be traced. On the whole, there is not much difference in content between the two versions. Like the *Dīgha*, the *sutta*s in the *Majjhima* present Buddhist ideas and ideals, illustrating them by similes of great literary beauty.

Saṃyutta Nikāya. *Saṃyutta Nikāya* ("Collection of Kindred Discourses") has altogether 2,941 *sutta*s, classed in 59 divisions (called *saṃyutta*) grouped in five parts (*vagga*). The first *vagga* has *sutta*s that contain stanzas. The *sutta*s begin with a description of the particular occasion when the stanzas were spoken; the stanzas themselves represent a kind of questioning and answering. The second *vagga* deals with the important principle of dependent origination—the chain of cause and effect affecting all things. The third *vagga* presents the *anātman* (no-self) doctrine, which is the rejection of an abiding principle that could be termed a self or a pure ego. The fourth *vagga* is very similar to the previous one, but here it is not the philosophical principle underlying the analysis that is stressed but the transitoriness of the elements constituting reality. The fifth *vagga* is devoted to a discussion of the basic principles of Buddhist philosophy, religion, and culture.

Aṅguttara Nikāya. *Aṅguttara Nikāya* ("Collection of Item-More Discourses") contains as many as 2,308 small *sutta*s arranged according to the number of topics discussed, ranging from one to eleven. One *sutta* relates that loving kindness practiced for a fraction of a second only will yield great merit. Other *sutta*s state that there are three areas in which training is needed—in conduct, concentration, and insight—and that there are eight worldly concerns—gain, loss, fame, blame, rebuke, praise, pleasure, and pain. Here, too, similes enliven an otherwise dry presentation.

Khuddaka Nikāya. *Khuddaka Nikāya* ("Collection of Small Texts") comprises 15 separate titles:

The 15 "small texts"

1. *Khuddaka-pāṭha* ("Small Reading"), the smallest book in the entire *Tipiṭaka*. Compiled for use by primary trainees, its contents are used on various occasions. Two *sutta*s have been borrowed from the *Suttanipāta* (see below), and their recitation is regarded as very auspicious.

2. *Dhammapada* ("Verses on the *Dharma*"—the law). This work contains 423 verses in 26 chapters. Presenting the maxims of Buddhist ethics, it not only occupies an eminent place in the religious life of the peoples in Buddhist countries but is also of universal appeal, as it recommends a life of peace and nonviolence and declares that enmity can never be overcome by enmity, only by kindness.

3. *Udāna* ("Utterances"). This contains 80 utterances attributed to the Buddha or his chief disciples, when they had achieved the bliss of their emancipation or spoke in appreciation of a sublime state.

4. *Itivuttaka* ("Thus Said"). This contains 112 short pieces dealing with ethical principles, such as generosity, good and evil, greed, passion, and malice, that are considered to be the actual words of the Buddha.

5. *Suttanipāta* ("Collection of *Sutta*s"). This is one of the most important books in the *Khuddaka Nikāya*. It is partly in verses, partly in a mixed style of prose and verses. The verse part is of high poetic quality.

6. *Vimānavatthu* ("Tales of Heavenly Mansions"). This book describes the different abodes of deities, male and female, who are born in the heavens as a result of their former meritorious deeds.

7. *Petavatthu* ("Tales of Ghosts"). This work gives an account of the various purgatories and the woes of the beings reborn there as a result of their wicked deeds.

8. *Theragāthā* ("Hymns of the Elders"). This collection contains songs attributed to 264 personal disciples of the Buddha. The songs are said to have been composed when their authors experienced the bliss of emancipation. The verses stress the abstract teachings of Buddhism.

9. *Therīgāthā* ("Hymns of the Senior Nuns"). These are the songs attributed to about 100 female disciples of the Buddha. They provide rich material for the study of the position of women at the time of the Buddha. Their merit consists in their revealing the deep impression the Buddha's teaching made upon their life. A personal tone is unmistakable.

10. *Jātaka* ("Lives [of the Buddha]"). Only the verses are considered to be canonical, while the 547 tales of the Buddha's previous lives are considered a later addition. The prose stories contain legends, fables, humorous anecdotes, and short sayings, as well as lengthy romances.

11. *Niddesa* ("Exposition"). This work, consisting of two parts, *Mahāniddesa* and *Cullaniddesa*, actually belongs to the group of commentaries. The last two chapters comment on the *Suttanipāta*.

12. *Paṭisambhidā-magga* ("The Way of Analysis"). This is a kind of encyclopaedia of the philosophical ideas in the *Sutta Piṭaka*. It is primarily meant for reference and intensive study.

13. *Apadāna* ("Stories"). This is a collection of stories of the previous lives of the Buddha, the Pratyeka-buddhas (who attain enlightenment by themselves and are unconcerned about the enlightenment of others), the chief disciples, and other important figures. The concluding sentence of the collection is intended to show that even the smallest meritorious act has the potentiality of giving vast positive results even after a long time. All the stories are in verses put into the mouths of saints (both male and female).

14. *Buddhavaṃsa* ("Lineage of the Buddha"). This work relates the lives of 24 previous Buddhas, of Śākyamuni (the historical Buddha), and of Maitreya (the future Buddha), presented as being told by the Buddha himself.

15. *Cariyā Piṭaka* ("Basket of Conduct"). This collection retells several *Jātaka*s (stories of Buddha's previous lives) in verse form, illustrating the *bodhisattva*'s (Buddha-to-be's) practice of the ten perfections (*pāramitā*s) necessary for the attainment of Buddhahood.

Abhidhamma Piṭaka. The *Abhidhamma Piṭaka* ("Basket of Scholasticism") comprises seven works that, although based on the contents of the Buddha's discourses, deal with selected and specific topics that form the basis for the later philosophical interpretations.

The Pāli Abhidhamma Piṭaka. The Pāli version is a strictly Theravāda collection and has little in common with the *Abhidharma* works recognized by other schools of Buddhism. Since the Theravādins were concerned with preserving what they believed to have been the Buddha's words and not with developing Buddhist ideas, the Pāli *Abhidhamma* has had little influence outside the Theravāda tradition. It consists of seven works: (1) *Dhammasaṅgaṇi* ("Summary of *Dharma*"), an enumeration of the entities constituting reality; (2) *Vibhaṅga* ("Division"), a definition of these entities from various points of view; (3) *Dhātukathā* ("Discussion of Elements"), a classification of the elements of reality according to various levels of organization; (4) *Puggalapaññatti* ("Designation of Person"), an interesting psychological typology in which people are classified according to their intellectual acumen and spiritual attainments; (5) *Kathāvatthu* ("Points of Controversy"), a later work discussing the controversial doctrinal points among the various Hīnayāna schools, mentioning the general doctrines of the Mahāsaṅghikas—"those belonging to the great order of monks"—an early Buddhist sect from which Mahāyāna Buddhism later developed; (6) *Yamaka* ("Pairs"), dealing with basic sets of categories arranged in pairs of questions; and (7) *Paṭṭhāna* ("Activations"), a voluminous work discussing 24 kinds of causal relations.

The Sanskrit texts. While the Pāli *Abhidhamma* is significant only for the Theravādins, the Sanskrit *Abhidharma*, considered to be canonical by the Sarvāstivādins, is of much greater importance for the development of Buddhist philosophy. The Sanskrit *Abhidharma* also has seven works that are attributed to distinct authors, some of them living several centuries after the Buddha. This authorship, however, is not uniform in the Tibetan

and Chinese traditions. The seven works recognized are (1) *Jñāna-prasthāna* ("Method of Knowledge"), by Kātyāyanīputra, not well organized, but interesting for the history of ideas. (2) *Prakaraṇa* ("Treatise"), by Vasumitra, an important work that is often quoted in the *Abhidharmakośa* ("Treasure of the *Abhidharma*"), by Vasubandhu, a monumental work on Buddhist philosophy or metaphysics. (3) *Vijñāna-kāya* ("Synopsis of Consciousness"), by Devaśarman, dealing with the controversial topic of the idea of an individual (*pudgala*). (4) *Dharmaskandha* ("Collection on the law"), by Buddha's disciple Śāriputra (by Maudgalyāyana—another of Buddha's disciples—according to the Chinese tradition), a collection of *sūtra*s the Buddha delivered in the Jetavana, a park in Sāvatthi (Śrāvasti). (5) *Prajñapti-śāstra* ("Treatise on Communication"), by Maudgalyāyana, in three parts, dealing with cosmology and causality. (6) *Dhātu-kāya* ("Synopsis of Elements"), by Pūrṇa (by Vasumitra, according to the Chinese tradition), listing the *dharma*s (mental elements) of the Sarvāstivādins; the classification was accepted by all other schools, although they differed in their interpretations of the logical status of these *dharma*s. (7) *Saṇgītiparyāya* ("Discourse and Rehearsal of Sacred Tenets"), by Mahākauṣṭhila (by Śāriputra, according to the Chinese tradition), a version of the *Saṅgīti Suttanta* in the *Dīgha Nikāya*.

IMPORTANT NONCANONICAL TEXTS IN PALI

The noncanonical literature of Hīnayāna Buddhism consists, to a large extent, of commentaries on the *Tripiṭaka* texts but also includes independent works that are invaluable for the understanding of ancient Indian history and thought. Among the Pāli writers and exponents of Hīnayāna Buddhism who attempted to harmonize the apparently conflicting teachings and to grasp the inner meaning of the doctrine, four names stand out—Nāgasena, Buddhadatta, Buddhaghosa, and Dhammapāla. Nothing is known of Nāgasena except that he was the learned debater with the Greco-Bactrian ruler Menander related in the famous literary work *Milinda-pañha*. Buddhadatta and Buddhaghosa were 5th-century contemporaries, deeply versed in the Pāli tradition, while Dhammapāla was slightly later but followed the same tradition.

Writings of Nāgasena

Milinda-pañha. Nāgasena is supposed to have compiled the *Milinda-pañha* ("Questions of King Menander"). It is generally assumed that this work was written either at the time of Menander (150 BC) or shortly afterward but certainly before the time of Buddhaghosa (AD 400), who very often quotes this work as an authority. As the work stands today, it contains seven chapters. Of these the first is largely personal and historical, the others doctrinal. Since its different chapters are written in more than one style, it seems probable that some are later additions. The Chinese translation, made between AD 317 and 420 and known as the *Nāgasena-sūtra*, contains only the first three chapters of the Pāli version. Furthermore, at the end of the third chapter it is stated that the questions of King Menander have come to an end. It is, of course, likely that different versions of the text were available and that a later redactor welded them together into a single work.

The *Milinda-pañha* is undoubtedly a great literary achievement in the field of Indian prose writing. The author begins his work with an account of the past lives of himself and King Menander, which is the reason that the two are to meet again in this life. Menander, a well-informed scholar and keen debater, was disheartened when he could find no one to solve his metaphysical problems. But one day he saw Nāgasena going on his begging round. The monk's serenity made a deep impression on the King, and the latter visited him in his monastery. They had a conversation that was later resumed at the palace and which forms the subject matter of the *Milinda-pañha*. The *Milinda-pañha* presents a profound and comprehensive exposition of Buddhist metaphysics, ethics, and psychology. It is in this work that is found the famous statement that just as the parts of a chariot put together in a specific way constitute the chariot, and that there is no chariot as such over and above its parts, similarly the different components of an individual make up the individual and there is no other additional entity to hold the components together.

Writings of Buddhaghosa. Buddhaghosa is undoubtedly the most prolific and important writer in the Pāli language. There are different views about his birthplace. Certainly, he stayed at Buddh Gaya, in eastern India, for a long time, and this brought him into contact with the Ceylonese monks, because the *vihāra* (monastery) there had been built with the permission of Emperor Samudra Gupta (*c.* AD 330–380) for Ceylonese pilgrims. These monks retained Pāli as their sacred language, while India had already switched over to Sanskrit, with the Theravāda doctrine and the Pāli language dwindling into insignificance. Buddhaghosa started for Ceylon and stayed at the Mahāvihāra ("great monastery"), with its rich commentary literature, probably in Old Sinhalese. The first work he wrote was his famous *Visuddhi-magga* ("Way to Purity"), a compendium of the whole of the *Tripiṭaka*. No chronological order can be established for his other works. Using the *Mahā-aṭṭakathā* ("Great Commentary"), he wrote commentaries on the *Vinaya*, the four principal *nikāya*s, and on the seven books of the *Abhidhamma Piṭaka*. He is also credited with having written commentaries on the *Dhammapada*, *Khuddaka-pāṭha*, *Suttanipāta*, and *Jātaka*. It is now generally assumed, however, that the commentaries on the *Suttanipāta* and *Khuddaka-pāṭha* are not his work. There are also doubts —on stylistic grounds—concerning his authorship of the commentary on the *Dhammapada*. The *Jātakaṭṭhakathā* ("Commentary on the *Jātaka*") is an extensive work. The introduction to the work, the *Nidānakathā* ("Narrative of the Beginnings"), is the only biography of the Buddha in Pāli. It states that the period of the *bodhisattva*'s existence from the time of the mythical Buddha Dīpaṅkara up to his birth as a Tuṣita (a class of celestial beings) god is the "distant epoch," his descent from the Tuṣita Heaven to his enlightenment is the "intermediate epoch," and the early teaching career up to his meeting with his patrons Anāthapiṇḍika and Viśākhā is the "proximate epoch." The reference to Viśākhā's former existence sets the scene for the 547 *Jātaka* tales, which are a mine of information about the cultural life at the time of the author. The pattern of these stories is quite stereotyped. For example, an incident during the Buddha's life is explained by an episode in one of his previous lives. In all cases the *bodhisattva* (Buddha-to-be) has the leading role. The stories range from short narratives to full-fledged romances. Their themes have exerted a tremendous influence on the fine arts and subsequent narrative literature. In a large number of these stories, the *bodhisattva* is an animal caring for his fellow animals. The general tone is one of charity and self-sacrifice, which finds its climax in the *Vessantara-jātaka* ("Birth as Vessantara"), where the *bodhisattva* parts not only with his material possessions but also with his wife and children, with whom he is, of course, reunited in reward for his self-denial.

Stories of the Buddha's previous lives

Writings of Buddhadatta. Buddhadatta, a contemporary of Buddhagosa, was a native of Uragapura, the present Uraipur, South India. He had gone to Ceylon to study at the Mahāvihāra (great monastery) in Anuradhapura. On his return he wrote his works in a monastery on the banks of the Kaveri River. His *Abhidhammāvatāra* ("The Coming of the *Abhidhamma*"), although a summary of Buddhaghosa's commentaries on the *Abhidhamma Piṭaka*, stands supreme. In no way did he follow Buddhaghosa blindly. He reduced Buddhaghosa's five metaphysical ultimates—*i.e.*, form, feeling, sensations, motivations, and perception—to four, namely, mind, mental events, forms, and Nirvāṇa (enlightenment or emancipation). This creative classification, similar to that of the Sarvāstivādins, makes him a philosopher in his own right rather than a commentator who merely restates things in new terms.

Writings of Dhammapāla. Dhammapāla, probably a South Indian, is credited with having written commentraries on all the works left untreated by Buddhaghosa, whom he mentions in his work, the *Paramattha dīpanī*

("Elucidation of the True Meaning"). In the *Paramattha Mañjūsā* ("Jewel Box of the True Meaning"), his commentary on Buddhaghosa's *Visuddhi-magga* ("Way to Purity"), he quotes a verse from the Hindu scripture *Bhagavadgītā* and frequently mentions the views of other schools and teachers. This work provides valuable information about intellectual activity in Hīnayāna circles.

Ceylonese chronicles. At the close of the 4th century AD there existed in Ceylon an older work, a kind of chronicle, of the history of the island from its legendary beginning onward. It probably formed part of the *Mahāaṭṭhakathā*, the commentary literature of the canonical writings that formed the basis of the works by Buddhaghosa and others. The historical information therein is reflected in the *Dīpavaṃsa* ("History of the Island"), which appears to be a poor redaction in Pāli of an older Old Sinhalese version. The *Mahāvaṃsa* ("Great Chronicle") by Mahānāma, continued in the *Cūlavaṃsa* ("Little Chronicle"), shows much greater skill in the use of the Pāli language and makes liberal use of other material. It is an artistic composition containing rich historical material.

MAHAYANA TEXTS

Only a small part of the vast Mahāyāna literature in Sanskrit has been preserved in its original version; for the most part translations into various Central Asian languages as well as into Chinese and Tibetan are the only sources. This literature can be divided into a philosophical one, stimulating the development of different schools of thought, and an edificatory literature that greatly appealed to the masses.

Prajñāpāramitā literature. The *Prajñāpāramitā* ("Perfection of Wisdom") literature is not an innovation but an exposition of the profounder meaning of the Buddha's teachings. There is evidence to suggest that the *Aṣṭasāhasrikā* ("In 8,000 *Ślokas*," *ślokas* in the context of a prose work meaning a unit of 32 syllables) is the oldest and most basic text, from which there have been such expansions as the *Śatasāhasrikā* ("In 100,000 *Ślokas*") and the *Pañcaviṃśatisāhasrikā* ("In 25,000 *Ślokas*") and abridgements, the *Saptaśatikā* ("In 700 *Ślokas*"), *Adhyardhaśataka* ("In 150 *Ślokas*"), *Vajracchedika* ("Diamond Cutter"), and even the *Prajñapāramitāhṛdayasūtra* ("The Essence of the Perfection of Wisdom"), which consists of only a few lines. In this literature a philosophical absolutism expressed through the dialectics of negation (*śūnyatā*) of all empirical notions and speculations is established. While in earlier Buddhism it was shown that the notion of a self was untenable, here the same critique is applied to those elements of reality other than the self. The origin of this literature falls into the period of the 1st century BC, if not earlier; by the second century AD it was sufficiently famous to be translated, the earliest translation into Chinese of the *Aṣṭasāhasrikā* having been made by the Yüeh-chih (Indo-Scythian) Lokarakṣa in AD 172.

Mādhyamika texts. The Mādhyamika ("middle way") system—which held both subject and object to be unreal—is the systematized form of the doctrine of *śūnyatā* (cosmic emptiness) contained in the *Prajñāpāramitā* literature. The most famous exponent of this system was the Indian philosopher Nāgārjuna, author of the voluminous *Mahā-prajñāpāramitā-śāstrā* ("The Great Treatise on the Perfection of Wisdom"), preserved in its Chinese translation (402-05) by Kumārajīva; of the *Mūlamadhyamakakārikā* ("The Basic Memorial Verses of the Middle Doctrine"), which is the Mādhyamika work par excellence; of the *Śūnyatā-saptati*, expounding the unreality of all elements of reality; of the *Vigrahavyāvartanī*, a refutation of possible objections to the doctrine of *śūnyatā*; of the *Vyavahārasiddhi*, teaching that absoluteness and relativity can coexist in practice; and of the *Yukti-ṣaṣṭika*, dealing with relativity. It is likely that Nāgārjuna is also the author of the *Ratnāvalī*, of the *Pratītyasamutpādahṛdaya*, and of the *Sūtrasamuccaya*, besides many other works attributed to him. Nāgārjuna's chief pupil was Āryadeva. His main work, the *Catuḥśataka*, not only criticizes the early form of Buddhism but also the classical Sanskrit philosophical systems. Together with his teacher Nāgārjuna, Āryadeva is the real founder of the Mādhyamika system.

Works of Nāgārjuna and Āryadeva

A new phase in this system was initiated during the 5th–6th century by Buddhapālita and Bhāvaviveka, the founder of a subschool that sought to prove the correctness of Mādhyamika doctrines by means of independent arguments. The former, commenting on the *Mādhyamikaśāstra*, developed the method of reducing to absurdity the arguments of an opponent on principles acceptable to him; the latter, author of the philosophical work *Tarkajvālā* ("Firebrand of Logical Investigation"), the *Mādhyamikārthasamgraha* ("Summary of the Mādhyamika Doctrine"), and the *Mādhyamikāvatārapradīpa* ("Lamp of the Mādhyamika Descent"), as well as the *Karatalaratna* ("Jewel in the Hand"), was a more liberal philosopher, and his works, now lost in the original, have been extremely influential. The Buddhist logician Candrakīrti (6th- or 7th-century-AD), author of the *Prasannapadā* ("The Clear-Worded"), a commentary on the *Mādhyamika Kārika*, and of the *Mādhyamikāvatāra* ("Descent of the Mādhyamika Teaching"), and Śāntideva, author of the *Śikṣā-samuccaya* ("Summary of Training") and the *Bodhicaryāvatāra* ("The Coming of the *Bodhisattva* Way of Life"), two of the most popular works in the whole Mahāyāna literature, continued the orthodox line of the Mādhyamika system; while Śāntirakṣita, a celebrated Indian teacher, who visited Tibet (8th century AD), author of the *Tattvasaṃgraha* ("Summary of the Essentials"), and the *Mādhyamikālaṅkāra Kārikā* ("Verses on the Ornament of the Mādhyamika Teaching"), on which his disciple Kamalaśīla wrote a commentary, represents the liberal line, which had great impact on Tibetan Buddhism.

The strict orthodox line is continued in such *sūtras* as the *Samādhirāja-sūtra*, in which *śūnyatā* is explained in *samatā* (self-sameness), and the *Suvarṇabhāsottama-sūtra*, of which various versions existed and which introduced significant ideas concerning the *Buddhakāyas*—the various "bodies" of the Buddha.

The Mādhyamika system must be viewed in relation to the mentalistic philosophy of the Yogācāras, who held that only consciousness itself is real and who, too, accepted the *śūnyatā* of the *Prajñāpāramitās* but interpreted it experientially rather than primarily metaphysically. Their leading exponent is Maitreyanātha (270–350), represented by his illustrious disciple Asaṅga (*c.* 350), author of the *Mahāyāna-sūtrālaṅkāra, the Dharmadharmatā-vibhaṅga*, and the *Madhyānta-vibhāga.* Important for the development of Japanese Zen Buddhism—a meditative school that emphasizes sudden enlightenment—was the *Laṅkāvatāra-sūtra* ("The Buddha's Descent on Ceylon *Sūtra*"), which combines both the absolutism of the Mādhyamikas and the mentalism of the Yogācāras (see also BUDDHIST PHILOSOPHY; NAGARJUNA).

Avataṃsaka-sūtra. There exists a vast collection of Buddhist scriptures known as the *Mahāvaipulya-Buddhāvataṃsaka-sūtra* ("The Great and Vast Buddha Garland *Sūtra*"), or, briefly, as the *Avataṃsaka-sūtra.* The only part that has been studied in detail is the *Daśabhūmika-sūtra* ("The *Sūtra* on the Ten Spiritual Levels"), dealing with the ten stages of a *bodhisattva;* another part is the *Gaṇḍavyūha-sūtra* ("The Compact Display *Sūtra*"). The latter dates back to the 1st century AD, and the text is probably of South Indian origin. The important centre of *Avataṃsaka* Buddhism, where the process of accretion and combination of various texts took place, was, however, in Central Asia, particularly Khotan. The *Avataṃsaka-sūtra* already existed in parts in China before the first complete translation was finished (AD 418–420). Among the early translations, a work called *Tou-shaching* ("Tuṣita [Heaven] *Sūtra*"), a somewhat shorter version of the *Ju-lai ming hao p'in* ("Section on the Tathāgata's [Buddha's] Names") of the later *Avataṃsaka* translation, has been attributed to Lokakṣema (AD 168–188). A fragmentary translation of the *Gaṇḍavyūha*, attributed to the monk Sheng-chien, belongs to the period of the reign of the emperor Hsiao-wu (AD 373–385) of the Eastern Chin dynasty. Between 418 and 421 the North Indian

Central Asian translations

monk Buddhabhadra made the first translation of the entire text, which had been imported from Khotan in 60 volumes (*chüan*). In AD 680 the monk Divākara retranslated a small part of the *Gaṇḍavyūha* in order to fill a gap in Buddhabhadra's work. In 699 a second translation was completed under the direction of the Khotanese monk Śīkṣānanda. This new translation in 80 *chüan* was also made from a text imported from Khotan. In AD 796–798 the monk Prajña translated a *Gaṇḍavyūha* manuscript in 40 *chüan*. The central theme of the *Avataṃsaka-sūtra* is the meaning of true enlightenment. Since the *Gaṇḍavyūha*, which relates the travels of the youth Sudhana in search of enlightenment (assisted by numerous spiritual friends, all of whom belong to different walks of life), is an integral part of the *Avataṃsaka-sūtra*, the elucidation of the complicated system of different stages of spiritual attainment is the secondary theme. The end of the *Gaṇḍavyūha* is formed by the *Samantabhadracarī-praṇidhāna-gāthā*, or, briefly, *Bhadracaryā*. In 62 verses the devotee makes a pious vow to follow the exemplary conduct of the *bodhisattva* Samantabhadra. From the available evidence of different translations, the incorporation of the *Bhadracaryā* into the *Gaṇḍavyūha* came at a later date. The *Avataṃsaka-sūtra* is the basic work of the Hua-yen (Japanese Kegon) school, with its theory of universal causation and its belief that there is a universal, immutable mind that is the basis of all phenomena.

Saddharmapuṇḍarīka-sūtra. One of the most popular early texts of the Mahāyānists is the *Saddharmapuṇḍarīka-sūtra* ("The Lotus of the Good Law")—popularly known as the *Lotus Sūtra*—which is the basic text of the Tendai (Chinese T'ien-t'ai) sect—which emphasized the possibility of universal salvation and the Buddha-nature that is inherent in all beings—and the Nichiren sect (founded by the 13th-century prophetic reformer Nichiren) in Japan. The *Lotus Sūtra* is also recited in the temples of the Zen sect of Japan. Manuscripts have been found in Nepal, Central Asia, and Gilgit (Kashmir). The earliest Chinese translation (AD 286) is by Dharmarakṣa (a Yüeh-chih), born in Kansu but educated farther west. The text was next translated by Kumārajīva, a Buddhist missionary from Kucha (an oasis on the northern trade route through Central Asia) to China, in AD 406. A third translation (AD 601) by Jñānagupta and Dharmagupta follows the Nepalese version. In the 4th century AD a commentary in four volumes had already been completed by Chu Fa-ch'ung, a learned Chinese monk. Kumārajīva's translation had 27 chapters (as has the extant Sanskrit version), but the Chinese Buddhist monk and traveller Fa-hsien (flourished AD 399–414) found in Khotan another chapter, which he had translated by Fa-i, an Indian. This chapter deals with Devadatta, Buddha's cousin and enemy, and was added to the 27-chapter version in the Chinese rendering.

Purpose of the work

The aim and object of the work is to establish the "one spiritual pursuit" (*ekāyāna*). There are three successive stages, or "vehicles," in the attainment of *ekāyāna:* (1) the Śrāvakayāna, the vehicle for disciples (*Śrāvaka*s) who become saints through hearing the teachings of the Buddha and are unconcerned with the salvation or enlightenment of others; (2) *Pratyekabuddhayāna*, the vehicle for those who attain salvation or enlightenment by themselves and are unconcerned with the salvation of others; (3) *Bodhisattvayāna*, the vehicle for those who are ready to become enlightened but postpone their enlightenment in order to save all other beings first. The work also contains the Buddha's plans for imparting training to those having different mental capacities and inclinations due to their past deeds. Another point is the emphasis on the immense merit a person derives from reading, copying, or propagating this *sūtra*. Being mainly devotional, this text avoids the philosophical aspects of Buddhism; but when they are touched upon, they are the same as those expounded in the other Mahāyāna *sūtra*s that deal with *śūnyatā*. The ultimate aim is Buddhahood, and for its attainment the practice of the six *pāramitā*s, or perfections (liberality, morality, patience, energy, concentration, and wisdom), is recommended; the sixth, the *Prajñāpāramitā* (perfection of wisdom), is identical with omniscience. Along with the practice of the *pāramitā*s the *bodhisattva* must lead a well-controlled life, showing kindness and compassion. This practice is not restricted to monks and nuns but can be performed equally well by householders. It is in this work that are found the famous parables of the burning house (from which the father lured his children by promising them toys and different carriages, but when they came out they saw there was only one carriage), the rich man's son (who, having returned home destitute, does not recognize his father, but whose inheritance is revealed at the end of his father's life), and the wise caravan leader (who lets his travellers rest before leading them on to the final destination).

Sukhāvatī-vyūha-sūtra. Of purely devotional character is the *Sukhāvatī-vyūha-sūtra* ("Pure Land *Sūtra*"), which exists in two versions, a larger and a smaller one. It was translated into Chinese by Lokarakṣa (a Yüeh-chih) in the latter half of the 2nd century, by Chih-ch'ien (also a Yüeh-chih) in the second half of the 3rd century, by Saṅghavarman (from Sogdiana, in Central Asia, shortly after 250), and by Kumārajīva around 400. The first three translations closely resemble each other and the larger *Sukhāvatīvyūha*, while Kumārajīva's version corresponds to the smaller *Sukhāvatīvyūha*. Apart from these important works, a number of other translations are still extant. In these texts the Buddha reigning over the Western Paradise is called Amitābha ("of measureless light") to denote his character of infinite light and Amitāyus ("of measureless life") to indicate his infinite life. His paradise, Sukhāvatī ("Pure Land"), is the most beautiful one. Those who have lived in purity or have called on his name he will welcome to his paradise at the moment of their death. This work is basic to the most widespread form of Buddhism, the Pure Land school (Ch'ing t'u) in China—characterized by the belief that salvation consisted in attaining the Pure Land or Western Paradise of the Buddha Amitābha and is attainable through faith in Amitābha—and the Jōdo schools (Amidism) in Japan (Japanese Pure Land schools).

Other Mahāyāna texts. As early as the 1st century AD, the *Lalitavistara* ("The Detailed Narration of the Sport [Play] of the Buddha"), in mixed Sanskrit and Sanskritized vernacular, telling the life story of the Buddha up to his first discourse, was translated into Chinese and followed by other translations. The *Kāśyapa-Parivarta-sūtra* ("Kāśyapa's Discourse *Sūtra*"), existing before AD 200, contributed much to the development of the Mādhyamika system; while the *Śrīmālādevī-siṃhanāda-sūtra* ("*Sūtra* of Srīmālādevī Whose Discourse is Like the Roaring of a Lion") emphasizes the "one spiritual pursuit" and the *bodhisattva* ideal, thus being close to the *Saddharmapuṇḍarīka-sūtra*. The *Daśabhūmika-sūtra*, in particular, deals with the stages of development of the *bodhisattva* ideal. The *Amitāyurdhyāna-sūtra* ("*Sūtra* on the Meditation on Amitāyus") has been influential for meditation on the celestial Buddha Amitābha-Amitāyus. The *Vimalakīrtinirdeśa-sūtra*, explaining Ultimate Enlightenment by a householder and containing a subtle satire on those who avoided involvement in daily life, has been popular even in Zen circles. Lastly, the 2nd-century Buddhist saint and scholar Aśvaghoṣa's *Buddhacarita* ("The Life of the Buddha"), the life story of the Buddha, and his *Saundarānanda-kāvya* ("The Poetic Narration of Sundarī and Nanda"), having the Buddha's disciple Nanda's infatuation with women's beauty as its theme—both in highly poetic style—must be mentioned. The *Divyāvadāna* ("Heavenly Heroic Deeds") is a collection of narratives extolling the Buddhist virtues of sacrifice and kindness, the *Avadāna-śataka* ("A Hundred Stories of Heroic Deeds") is a collection of edifying tales, and Āryaśūra's *Jātakamālā* ("Garland of *Jātaka*s [Birth Stories]") is a poetic treatment of some of the stories of the Buddha's previous lives.

Works of Aśvaghoṣa

TANTRIC AND TIBETAN TEXTS

While the *sūtra*s cannot be underestimated in the development of Buddhist thought and of the various philosophical systems, there exists another kind of literature

that is concerned with the inner experience of the Buddhist ideas and ideals. The *sūtras*, therefore, can be said to represent the theoretical and speculative aspect of Buddhism; while the *Tantras* ("Treatises"), written in a highly figurative language, express Buddhism as individually lived. The *Tantras* are essentially individual works that apply to larger groups of persons because of the similarity of the experiences described in them. The individual spiritual development occurs through symbols that must not be reduced to signs; a symbol always points beyond itself. Because of this symbolic character, the *Tantras* have usually been kept secret, and a literalist interpretation of such texts has usually failed to make any sense out of them.

Tantras. The *Guhyasamāja-tantra* ("Treatise on the Sum Total of Mysteries"), also known as the *Tathāgataguhyaka* ("The Mystery of Tathāgatahood [Buddhahood]"), is the earliest known written *Tantra*. It is by tradition ascribed to the renowned Indian scholar Asaṅga (*c.* 4th century AD), the propounder of the Yogācāra philosophy. Usually the *Tantras* do not give an explanation of the technical or symbolic terms, as this explanation is left to the teacher, but the *Guhyasamāja-tantra* devotes a very long chapter to the elucidation of these terms. An important feature of all *Tantras* is a polarity symbolism, which on the physical level appears as the union of male and female, on the ethical level appears as beneficial activity and insight into and appreciation of what there is as it is, and on the philosophical level appears as the dynamic aspect of enlightenment as absolute Being and absolute compassion. It is to be noted that in Buddhist *Tantras* the female component in the nature of reality is an appreciative awareness (*prajñā*), an inspiration, not a power (*śakti*) through which a male superbeing attempts to dominate, as in Hinduism. Another feature is the idea of the *maṇḍala* (ritual drawing), which is both a projection of an ordering and a visual aid to the psychological orientation process, which is a kind of seeing the world and oneself in transfiguration. While the *sūtras* often create the impression of a negative approach to life, the *Tantras* insist on the absolute value of what there is. In order to realize this value, a strict discipline is demanded. The rich symbolism of the *Tantras* is already indicated in the opening of the *Guhyasamāja*, when the absolute in its polarity symbolism manifests itself in various *maṇḍalas*, each related to one of the celestial, meditational Buddhas—Akṣobhya, Vairocana, Ratnasambhava, Amitābha, and Amoghasiddhi—each of whom again represents a polarity, portrayed in iconographic works as being in union with their female consorts (see BUDDHIST MYTHOLOGY). The symbolism involved is further elaborated by the development of the idea that spirituality is existentiality and vice versa and that spirituality and existentiality are also communication.

Tantric symbolism

The ideas presented in the *Guhyasamāja-tantra* became in the course of time more and more clearly elaborated. Because the *Tantras* reflect an individual process of growth, the centre toward which this process gravitates and from which it is also fed appears in various symbols given various designations. Thus, there is the *Hevajra-tantra*, in which the sustaining life force is called *Hevajra*, and the *Mahā-Vairocana-tantra*, in which it is Mahā-Vairocana ("The Great Resplendent One"; in Japan, identified with the Sun) as distinguished from Vairocana belonging to a lower level.

In view of the fact that the *Tantras* may emphasize either "beneficial activity" or "appreciative awareness" or their "unity," the Tantric literature has been divided into the so-called *Father Tantra* (emphasizing activity), the *Mother Tantra* (emphasizing appreciation), and the *Nondual Tantra* (dealing with both aspects unitively). Almost all these works have been lost in their original Sanskrit versions, but their influence is noticeable in such works as the great Tantric teacher Indrabhūti's (*c.* 687–717) *Jñānasiddhi* ("Attainment of Knowledge"), the 8th-century Indian writer Anaṅgavajra's *Prajñopāyaviniścayasiddhi* ("The Realization of the Certitude of Appreciative Awareness, and Ethical Action"), and the songs of the 84 *mahāsiddhas* ("great accomplished ones," who were spiritual adepts). One of the last Sanskrit works to have been written in Central Asia is the *Kālacakra-tantra*. Its penetration into India may be dated AD 966. The central theme is the Ādi-Buddha—primeval Buddhahood—manifesting itself as a continuum of time (*kāla*) and space (*cakra*).

Tibetan literature. The vast mass of Buddhist literature, mostly lost in India, has been preserved in its Tibetan and Chinese translations, from which many translations into other Asian languages have been made. The translation techniques varied; first the attempt was made to render the spirit of the texts rather than their exact words. This technique was employed by the Chinese under the influence of Kumārajīva. The Tibetans, too, first rendered the spirit of the texts, but these early translations are not found in the standard collection, which utilized only those translations of texts that had been made under the influence of the translator Rin-chen bzang-po (11th century). This later translation technique was more concerned with the exact words of the original. The earlier version, still very little known, is of much greater importance for the study of the history of the development of Buddhist thought, while the later translation reflects the final stage of Buddhism. It is important to remember that there are more texts than the number contained in the Tibetan collections, known as the *Bka'-'gyur* ("Translation of the Buddha-Word") and *Bstan-'gyur* ("Translation of Teachings"). There are different editions, mostly differing in the arrangement of the texts; the oldest edition is the so-called Cone edition, which was the prototype for the Derge edition, on which, in turn, the Peking edition of 1411 is based. These are very good editions. The Narthang edition (printed by Tibetan monks in the 18th century) was made in a hurry and is full of mistakes. The following analysis follows the arrangement of the Peking edition.

Classification of Tibetan texts

Bka'-'gyur ("Translation of the Buddha-Word"). This collection, containing the works that are supposed to represent the Buddha's words, is divided into six sections, containing 1,055 titles in 92 volumes. The arrangement is (1) *Tantra;* (2) *Prajñāpāramitā;* (3) *Ratnakūṭa*, a collection of 49 small Mahāyāna texts; (4) *Avataṃsaka;* (5) *Sūtra*, mostly Mahāyāna *sūtras* but also a number of Hīnayāna ones; and (6) *Vinaya.*

Bstan-'gyur ("Translation of Teachings"). This collection of 224 volumes with 3,626 texts is divided into three major groups: (1) *Stotras* (hymns of praise) in one volume, including 64 texts; (2) commentaries on *Tantras* in 86 volumes, including 3,055 texts; and (3) commentaries on *sūtras* in 137 volumes, including 567 texts.

Commentaries on the *sūtras* include *Prajñāpāramitā* commentaries (16 volumes), Mādhyamika treatises (17 volumes), Yogācāra treatises (29 volumes), *Abhidharma* (eight volumes), miscellaneous (four volumes), *Vinaya* commentaries (16 volumes), narrative literature and drama (four volumes), and technical works—logic (21 volumes), grammar (one volume), lexicography and poetics (one volume), medicine (five volumes), chemistry and sundry other "sciences" (one volume), and a supplement (old and recent translations, indices, 14 volumes).

Other Tibetan texts. Tibetan Buddhist literature developed in intimate relationship with the translation work that brought new ideas and interpretations to a people who were singularly gifted at assimilating and developing. By the time that the Indian texts became widely available, Buddhism in India was on the wane, but it found new life with the Tibetans, who disseminated Buddhist ideas into Mongolia, which, in turn, contributed to the flowering of Buddhist thought. Perhaps the greatest stimulus to this development was the arrival of the great Indian teacher Atīśa in Gu-ge, an ancient kingdom in western Tibet, in AD 1042. Although his favourite disciple, 'Brom-ston (1008–64), avoided publicity of all kinds, even refraining from giving instruction, the strictness of his conduct and his earnest attention to the Buddhist axioms of transitoriness, frustration (resulting from believing that something would last forever when it may break at any moment), and the ethical obligations that derive from seeing the world in its true light left an in-

delible impression on his followers, who became known as the Bka'-gdams-pa, "those bound by command." The *Bka'-gdams gces-bsdus* ("Collection of the Sayings of the Bka'-gdams-pa Saints") has preserved their utterances, which often are of high poetic quality. In this religiously saturated climate, the first school, or order, to be established was the Sa-skya-pa, named after the monastery of Sa-skya, which had been founded in AD 1073 by Dkon-mchog rgyal-po, a disciple of 'Brog-mi, an eccentric mystic. It was Dkon-mchog rgyal-po's son and successor, the great Sa-skya-pa Kun-dga' snying-po (1092–1158), who formulated the teachings received. His *Legs-bshad* ("A Treasury of Aphoristic Jewels"), a collection of maxims, is one of the most famous works, also highly appreciated by other Tibetan schools. The indigenous contributions to Buddhist thought were contained in the *gsung-'bum* (collected works) of the great lamas. They are of prime importance for evaluating the Tibetan and Mongolian achievement in every field of knowledge. It is not possible, however, to deal with these works exhaustively because no systematic survey has been made as yet. The topics that are dealt with in these collected works range from explanations of the *Prajñāpāramitā*, *Mādhyamika*, *Vinaya*, and *Abhidharma* to contributions to epistemology, *Tantra*, ritual, and philosophical surveys. The latter present the whole of Buddhism as a gradation and are known under the name *Lam-rim* ("Stages on the Path"). One of the earliest works of this kind is Sgam-po-pa's (1079–1153) *Thar-rgyan* ("Jewel Ornament of Liberation"), in which he embodied teachings of religious practices of his master Mi-la ras-pa (Milarepa). It has become the manual of the Bka'-brgyud-pa ("those who transmit the Buddha-Word") order. Mi-la ras-pa (1040–1123) himself is known from his beautiful songs expounding his religious experiences.

Writings of Tsong-kha-pa

Widely known for his learning was Tsong-kha-pa (1357–1419), founder of the Dge-lugs-pa order—the dominant order of Tibetan Buddhists, who wear yellow hats. His religious views seem to have taken their final form when at the age of 40 he joined the great Bka'-gdams-pa monastery of Ra-sgreng. There he wrote his voluminous *Lam-rim chen-mo* ("The Great Account of the Stages on the Path"), which he later supplemented by the *Sngags-rim chen-mo* ("The Great Account of the Stages on the Tantric Path"), a highly technical work of ritual and mystical practices. His *Lam-rim chen-mo* became the pattern after which subsequent lamas molded their accounts of the Buddhist Path, such as the *Myur-lam* ("Quick Path") by the third Dalai Lama (1543–88) —Dalai Lamas were spiritual and temporal rulers of Tibet before 1959—on which countless commentaries were written.

A famous writer and historian was Tāranātha (born AD 1575). He belonged to the Jo-nang-pa school, a sect whose monasteries were eventually destroyed and whose books were burned by the Dge-lugs-pas. Tāranātha's writings are still extant, however, and his *Rgya-gar chos-'byung* ("History of Buddhism in India") has been highly appreciated even by modern scholars.

Padma dkar-po is the main representative of the 'Brug-pa suborder of the Bka'-brgyud-pa. His systematic approach to all aspects of Buddhism makes him one of the greatest scholars.

Outstanding among the rNying-ma-pa ("The Old Order")—followers of the earliest Tibetan Buddhist traditions—are Klong-chen rab-'byams-pa (1308–63), whose *Klong-chen-mdzod-bdun* ("Seven Treasures of Klong-chen") reflects the profoundest thought of Tibet, and Mi-'pham of Khams (1846–1914), who wrote elaborate commentaries on the canonical texts.

Thu-kwan Blo-bzang chos-kyi nyi-ma (1737–1802) is the author of a history of the doctrines of the various Buddhist and other heterodox schools in India, Tibet, China, and Mongolia.

A very erudite work is the *Grub-mtha'shel-gyi me-long* ("History of the rNying-ma-pa") by Dudjom Tulku Rimpoche (1964).

Mongolian texts. In Mongolia there have been three propagations of Buddhism, the earliest through Li-yul (Khotan, Sogdiana, or the Tocharian kingdom), the middle and later ones through Tibet. The contribution of the Mongols to Buddhism has been enormous, both as regards the *Lam-rim* literature and the *Tantras*. Lcang-skya qutuγtu Ngag-dbang blo-bzang chos-ldan (1642–1714) and Lcang-skya qutuγtu Rol-pa'i rdo-rje (1717–86) were both prodigious scholars, the latter making a fundamental contribution toward the creation of a classical Mongolian language into which to translate Buddhist texts.

The masterly manuals by 'Jam-dbyangs-bzhad-pa I, Ngag-dbang-brtson-'grus (1648–1721), are highly esteemed by the Dge-lugs-pa and studied in Tibet and Inner and Outer Mongolia by the Buryats and Kalmuks. 'Jam-dbyangs-bzhad-pa II, Dkon-mchog-'jigs-med dbang-po (1728–81), is noted for his concise exposition of philosophical systems. The many works in the Tibetan language composed by the Mongols have been acclaimed even in Tibet and are testimony to the rich literary activity inspired by Buddhism.

CHINESE AND JAPANESE TEXTS

By the end of the T'ang dynasty (618–907), the composition of the Chinese *Tripiṭaka* (*Ta-ts'ang Ching*, "Great Scripture Store") was practically completed. Sporadic translations were still made during the Sung period (960–1279), but they did not add anything new. The standard modern edition, *Taishō Shinshū Daizōkyō*, contains 2,184 texts arranged in 24 sections as follows: (1) *Āgama* section, containing the Long, Medium, Kindred, and Item-More (*i.e.*, numerically graded) *Āgamas*, as well as some individual texts corresponding to sections of the Pāli *Khuddaka Nikāya;* (2) story section—*Jātakas*, lives of various Buddhas, fables, and parables; (3) *Prajñā-pāramitā* section; (4) *Saddharmapuṇḍarīka* section, three complete versions of this famous *sūtra* together with some doctrinally related *sūtras*; (5) *Avataṃsaka* section; (6) *Ratnakūṭa* section, 49 Mahāyāna *sūtras*, some in more than one translation; (7) *Mahāparinirvāṇa* section, the Mahāyāna version of the Buddha's last days; (8) Great Assembly section, containing texts similar to the *Ratna-kūṭa* section but more varied in content; (9) *sūtra*-collection section, a miscellany of *sūtras*, mostly Mahāyāna; (10) *Tantra* section; (11) *Vinaya* section, the disciplinary codes of various early Buddhist groups (some texts deal with the *bodhisattva* discipline); (12) commentaries on *sūtras* by Indian authors; (13) *Abhidharma* section, scholastic works of various early Buddhist groups; (14) Mādhyamika section; (15) Yogācāra section; (16) collection of *śāstras*; (17) commentaries on *sūtras* by Chinese authors; (18) commentaries on the *Vinaya* by Chinese authors; (19) commentaries on *śāstras* by Chinese authors; (20) Chinese sectarian writings; (21) history and biography; (22) encyclopaedias and dictionaries; (23) non-Buddhist doctrines, including non-Buddhist philosophies of India and Manichaean and Nestorian Christian writings; and (24) catalogs of earlier compilations.

Early Chinese writers

As Buddhism permeated the way of thinking of the peoples of the Far East, the tendency to concentrate on the study of one particular scripture or group of scriptures led to significant contributions by the most brilliant minds of China, Japan, and Korea. Apart from such early scholars as Seng-chao (AD 384–414), Tao-sheng (5th century AD), and Tao-an (AD 312–385), Chi-tsang (549–623), who had a Parthian father and a Chinese mother, greatly elaborated and systematized the Mahāyāna teachings. His influence extended to the 8th century, after which his school rapidly declined. Of more lasting fame was the Chinese development of the Indian Yogācāra school by Hsüan-tsang (596–664), who, in his *Ch'eng wei-shih lun* ("Dissertation on Consciousness-Only"), selected, summarized, and systematized the ideas of ten great philosophers of India. Although this school also declined after the 9th century, it is on these ideas that such modern philosophers as Hsiung Shih-li (1885–1968) and T'ang Chün-i (1907–) base their own philosophies. Chih-k'ai (or Chih-i, 538–597), a southerner with a distinctly intellectual background, under the influence of his teacher the monk Hui-ssu (*c.* 514–577), gave both a con-

templative and an intellectual interpretation of the *Saddharmapuṇḍarīka-sūtra*. *Ta-ch'eng chih-kuan fa-men* ("The Method of Concentration and Insight in the Mahāyāna"), by Hui-ssu, and *Fa-hua Hsuan-i* ("The Profound Meaning of the *Saddharmapuṇḍarīka*"), by Chih-k'ai, are important works for the T'ien-t'ai school, characterized by the belief that all men can become the Buddha, since all men possess the Buddha nature. Significant contributions to the development of the Hua-yen (Japanese Kegon; Sanskrit Avataṃsaka) school—which stresses the doctrine that all things in the universe are representations of the same supreme mind—were made by Tu-shun (557–640), the nominal founder, and Fa-tsang (643–712), who is considered to be the real founder and whose treatise *Chin shih-tzu chang* ("The Golden Lion") is one of the most lucid expositions of the Hua-yen philosophy. Tsung-mi (780–841), revered as the fifth and last patriarch of both the Hua-yen school and the Ho-tse branch of the Southern school of Ch'an (Zen) Buddhism (see below), was the author of the *Yüan jen lun* ("Treatise on the Original Nature of Man"). In this work his own spiritual development—early training in classical Chinese studies, conversion to Ch'an Buddhism in his early twenties, and introduction in his early 30s to Hua-yen philosophy by Ch'eng-kuan, the fourth patriarch of the school—as well as his critical evaluation of the principal schools of thought of his time is clearly reflected. The Pure Land Buddhism found able interpreters in T'an-luan (476–542), commenting on the *Sukhāvatīvyūha;* in Tao-ch'o (died AD 645), a T'ien-t'ai monk, in his *Ching t'u lun* ("Compendium on the Happy Land"); and in Shan-tao (613–681), who is known for his pietism and the influence he exerted on the Pure Land schools in Japan. Among the works of the Ch'an school, which began with the study of the *Laṅkāvatāra-sūtra* but gradually split into a Northern school stressing gradual enlightenment and Southern school advocating sudden enlightenment, *T'an Ching* ("The Platform Scripture") of the sixth patriarch, Hui-neng (died AD 713), is a highly esteemed work said to represent a collection of sermons and the autobiography of Hui-neng as transmitted by his disciple Fa-hai. It is the only Chinese noncanonical work called a *sūtra* (*ching*). The original version, found at Tun-huang in northwest Kansu, is rather primitive, while the current one has been greatly extended and revised. The stories of the Ch'an masters, recording their sayings and short paradoxical stories about them, which are said to indicate the depth of their understanding, are collected in the *Ching-te ch'uan-teng lü* ("Records of the Transmission of the Lamp"), AD 1004.

Works of Ch'an school

In Japan, Saichō (or Dengyō Daishi, 767–822), of Chinese descent, based his teaching on the *Lotus Sūtra*, which he had studied in China; and the Tendai sect, founded by him, upheld the "one spiritual pursuit" idea as the real meaning of Mahāyāna Buddhism. His writings, undistinguished in style, reveal his earnestness and sincerity. At first he was on friendly terms with Kūkai (Kōbō-daishi, 774–835), but a rift occurred when the latter asked Saichō to become his regular disciple, if he wanted to study the esoteric form of Buddhism. Kūkai's first major work was *Sangō-shiiki* ("The Indications to the Three Teachings"), in which he treats Confucianism, Taoism, and Buddhism in a somewhat superficial way. In AD 804 Kūkai sailed for China, where he met the great master Hui-kuo (746–805), who took him as his chosen disciple. His greatest contribution is the systematization of esoteric "True Word" (Shingon) Buddhism—which considered the cosmic Buddha Mahā-Vairocana to be the source of the whole universe. His *Jūju shinron* ("The Ten Stages of Consciousness") was written entirely in Chinese in an ornate poetical style.

Writings of Saichō and Kūkai

The sudden collapse of the Kyōto court in the 12th century coincided with a crisis in the religious life of the Japanese, which found its expression in the growth and spread of Pure Land Buddhism. Forerunners of this movement had been Kūya (903–972), the "saint of the streets"; Ryōnin (1072–1132), who promulgated the *nembutsu*—the constant repetition of Amida Buddha's name—through popular songs; and Ippen (1239–89), who believed that the grace of Amida was found everywhere. The popularization of this faith owes much to Genshin (942–1017) through his famous work *Ōjō-yōshū* ("Essentials of Salvation"), in which he describes the torments of hell and the bliss of the Pure Land of Amida Buddha. The Pure Land Buddhism as a separate school owes its existence to Hōnen (1133–1212) through his epoch-making *Senchaku-shū* ("Original Vow of Amida") and to Shinran (1173–1262), who later claimed to be Hōnen's true disciple. The writings of the prophetic reformer Nichiren (1222–82) introduce a rather militant tone. The writings of Dōgen (1200–53) are important for the Sōtō school of Zen, as are the writings of Hakuin (1685–1768) for the modern Rinzai school of Zen.

OTHER IMPORTANT TEXTS

A unique work that has often been quoted and that played an important role in the formulation of Hua-yen thought is the *Mahāyāna-Śraddhotpāda* ("The Awakening of Faith in Mahāyāna"). Its one-time attribution to the famous Indian poet and dramatist Aśvaghoṣa is certainly wrong. Since the philosophical ideas so clearly presented in it are rather an amalgamation of Buddhist and Taoist ideas, a Central Asian or Chinese origin is more likely. The *Sādhanamālā* ("Garland of Successful Visualizations") contains more than 300 visualizations —prescriptions for both mental images and actual temple images—of Buddhist deities and is invaluable for the study of Buddhist iconography. A favourite of Zen scholars has been the *Pi-yen lu* (Japanese *Hekigan-roku*, "Blue Cliff Records"), a collection of one hundred short stories of Zen teachers who had lived and taught in various parts of China for over 400 years.

III. Ritual use and influence of Buddhist texts

Because the practice of Buddhism has demanded detachment from the turmoil of daily life and has insisted on disciplined study, any use of the Buddhist texts for non-study purposes is purely incidental and a concession to popular demand. The Buddhist monks officiate at funerals, perform ceremonies in the monastery temples, and instruct the young. Each ceremony, whether in Hīnayāna or Mahāyāna countries, begins with the invocation of the Three Jewels (the Buddha, the *dharma*—the law—and the *saṅgha*—the monastic order or community) and what follows varies with the wealth and the piety of the person asking for a recitation of the sacred texts or arranging a specific ceremony. In Tantric ceremonies the choice of texts that are recited depends not only on the occasion and the nature of the ceremony but also on the tradition a particular monastery follows.

Buddhist sacred literature has had a lasting influence on the fine arts, which, in the case of painting, were applied to illustrate the manuscripts. The overwhelming majority of works of Buddhist art are cult images, representing sacred figures either individually or in groups. It is the nature of the cult image that it signifies the absolute as revealed to the observer; at the same time it is at the service of Buddhahood, goodness, and salvation. The simplest form of the cult image is the Buddha either in his shape as the Enlightened One or as the *bodhisattva*. When the psychological process of enlightenment became the focus of attention, since everyone is capable in principle of attaining Buddhahood, it was only natural that this process, manifesting itself in symbolic forms, was made visible in the many Tantric deities who are but formulated psychic energies, incorporated in the texts dealing with them as visual aids. As cult images there must also be counted the many representations of the Pure Land of Amitābha, whose description is found in the *Sukhāvatīvyūha*. In contrast to the cult images, the narrative image depicts the ordinary world in such a way that the beholder is reminded of the fact that the world can be overcome. The most frequent themes in telling a tale are taken from the *Jātaka*s, as can be seen in the illustrative paintings in the Ajantā caves of India. A specifically favoured theme in China and Japan was the *bodhisattva*'s self-sacrifice to save a starving tigress and her cubs. This scene is found in the cave temples of

Mai chi shan and on the Tamamushi Shrine in the Hōryūji. From among the *sūtra*s it was the *Vimalakīrtinirdeśa-sūtra* that stimulated the artists to paint the domestic scene in which the rich householder Vimalakīrti discourses with the *bodhisattva* Mañjuśrī on the central subject of the Mādhyamika system.

Illustration of texts

Just as the sacred Buddhist texts inspired artists to paint and carve cult images and narrative images, the texts themselves are also illustrated. The most famous texts to be illustrated were the *Saddharmapuṇḍarīka-sūtra* and the *Avataṃsaka-sūtra*, the last part of which, the *Gaṇḍavyūha*, inspired the Borobuḍur temple complex in Java. Other famous *sūtra*s that were illustrated were the *Sanzen Butsu-myō-kyō* ("*Sūtra* of the Three Thousand Names of the Buddha"), the *Prajñāpāramitā-sūtra*, and, in Japan, the *Yakushi hongan-kyō* ("The *Sūtra* of the Original Vow of Bhaiṣajyaguru [Buddha of Healing]"). A special illustrative method, which was also applied to secular subjects, is the Japanese hand scroll, *emaki* or *emakimono*. Here the pictorial part is not merely a short illustration interspersed in the texts but is itself a narrative. Portraits of priests frequently were used to illustrate the texts they wrote or to whose development they contributed.

BIBLIOGRAPHY. MORIZ WINTERNITZ, *Geschichte der indischen Litteratur*, vol. 2 (1913; Eng. trans., *A History of Indian Literature*, vol. 2, 1933), still the only general survey of Buddhist sacred literature in Sanskrit and Pāli; LOKESH CHANDRA (ed.), *Materials for a History of Tibetan Literature*, 3 vol. (1963), a valuable beginning for assessing the voluminous Tibetan literature; and LOKESH CHANDRA, *Eminent Tibetan Polymaths of Mongolia* (1961).

Budgets, Governmental

A governmental budget is the forecast by a government of its expenditures and revenues for a specific period of time. In national finance, the period covered by a budget is usually a year, known as a financial or fiscal year, which may or may not correspond with the calendar year. The word budget is derived from the Old French *bougette* ("little bag"). When the British chancellor of the exchequer makes his annual financial statement, he is said to "open" his budget or receptacle of documents and accounts.

Budgeting and control

Government budgetary institutions in the West grew up largely as a result of the struggle for power between the legislative and executive branches of government. With the decline of the feudal system, it became necessary for kings and princes to obtain resources for their ventures from taxation rather than dues. The disappearance of the old feudal bonds meant that taxpayers demanded to be consulted before they paid. In England this was written into Magna Carta (1216), which stated:

> No scutage or aid shall be imposed in the Kingdom unless by the common council of the realm, except for the purpose of ransoming the King's person, making his first-born son a knight, and marrying his eldest daughter once, and the aids for this purpose shall be reasonable in amount.

This related to taxes; the control of expenditures came much later. For centuries, Parliament seemed content to restrict the amounts that the sovereign levied while letting him spend the money as he pleases. Only after the controversies of the 17th century culminated in the Revolution of 1688 and the Bill of Rights did Parliament extend its concern to the question of expenditure control. The tradition grew up that expenditures must flow from appropriations, and appropriations were to be made for specific purposes.

In France, the struggle between the monarchy and the nobility over control of tax revenues was one of the causes of the Revolution of 1789 that led to the overthrow of both the monarchy and the nobility. Financial crises have been turning points in the history of many other countries.

The United States budget system also evolved out of controversy. In the early days of the republic there was a famous dispute between Alexander Hamilton and Thomas Jefferson as to the amount of discretion that the executive branch should exercise in the spending of public funds. Jefferson's victory enabled Congress to assert its authority by making appropriations so highly specific as to hinder efficient executive action. Had Hamilton won, the treasury would have attained extraordinary power in relation both to Congress and to the president. As it was, Congress assumed authority with respect to both expenditures and revenue.

A budget in the 20th century, however, is not simply a matter of raising money to pay for government expenditures. In many countries budget policy has become an important part of general economic policy. With the great increase in government expenditures, raising and spending money have come to have a significant impact on the functioning of the national economy. A deficit or a surplus in the government budget may have inflationary or deflationary consequences; it may even mean the difference between prosperity and recession (see FISCAL AND MONETARY POLICY).

BUDGETS AND THE REDISTRIBUTION OF INCOME

Impact of budgets on different groups

Government budgets almost inevitably affect the distribution of income—that is, the purchasing power of different sections of the population. The very act of transferring resources from the private sector to the public sector has a different impact on some groups than on others. In many cases the redistribution of income is one of the goals of public policy. For example, payments to the poor, the sick, or the aged are generally financed through taxes that bear more heavily on those with higher incomes. But the budget may redistribute income indirectly through taxes and subsidies that bear differentially on different sectors of the economy. A protective tariff redistributes income in favour of protected industries at the expense of those that remain exposed to the competition of the world market. Subsidies to miners or farmers redistribute income in their favour. Such measures may bear little relation to personal need, and in many cases they result in greater personal inequality.

A third type of redistribution is regional. Most governments are exposed to strong pressures to give economic support to poorer regions of the country through grants-in-aid, government contracts, or public works. Regions like the South of the United States or the Northeast of Brazil thus receive very favourable treatment in their national budgets, though income disparities may remain wide.

PROGRAM BUDGETING

Budgeting and the allocation of resources

A relatively new development in budgeting is the attempt to use the budgetary process as a method of achieving an allocation of national resources that is efficient in the economic sense. This has come along with the great expansion in the economic role of most governments since World War II, and the enormous increase in the size of government budgets relative to the national product. As budgets rose, so did political and economic expectations. Governments were faced with multiple demands upon their resources, ranging from social welfare to foreign aid, and from the building of schools to vast military expenditures. No budget can please everyone. Good budgeting, it may be said, should result not in general contentment but in equally distributed discontent among rival groups. The more efficiently resources can be allocated among competing uses, the more nearly everyone can be satisfied. The need for economizing in this sense gave rise to the program budgeting movement, which originated in the United States in the area of military planning.

Program budgeting (or so-called systems analysis) is an attempt to apply the economics of choice to public decision making. Its basic assumption is that explicit choice among alternative courses of action leads to better results than do other methods of decision making. At the highest governmental levels difficult choices must be made that involve the use of a portion of the nation's resources. But the same principles apply to decision making at lower levels. The problem of allocating resources within a specific field, such as health or education, are

conceptually similar to those faced in drawing up the national budget.

Program budgeting also takes account of the time dimension in many government programs. New undertakings often take time to come into operation. A typical new program may have to pass through a research and development phase and an investment or construction phase before it reaches the operating phase. Alternative programs may differ considerably in this respect. The process of choosing among alternatives frequently involves trading the present against the future. One alternative may require ten years before it yields results; another may yield smaller results but more quickly. The kinds of choices made in government often involve alternatives that cannot be measured in terms of market value. For this reason governmental decisions involve much more uncertainty than do most business decisions.

A governmental program must therefore be frequently revised in the light of unfolding circumstances. Indeed, every year should be thought of as the first year of a new program. Pervasive uncertainty also requires a high degree of flexibility and a capacity for program revision. A number of options should be held open, particularly in the development phase. Even though this may appear costly, it is less costly than commitment to a design that proves to be inappropriate because of circumstances that could not be foreseen in the early stages.

Program budgeting should be thought of not as a method of reaching definitive conclusions but rather as a method of organizing discussion and marshalling evidence. The situation is analogous to that of a legal trial, in which, if the rules of evidence are followed and both sides are well represented, the decision is more likely to be good than bad.

This is admittedly imprecise. Various efforts have been made to provide more specific criteria for choosing among programs. One of the best known approaches is that of cost-benefit analysis.

Cost-benefit analysis. This attempts to do for government programs what the forces of the marketplace do for business programs: to measure, and compare in terms of money, the discounted streams of future benefits and future costs associated with a proposed project. If the ratio of benefits to costs is considered satisfactory, the project should be undertaken. "Satisfactory" means, among other things, that the project is superior to any available public or private alternative. Or, if funds are limited, public investment projects may be assigned priorities according to their cost-benefit ratios.

Criteria for choosing among programs

One difficulty with cost-benefit analysis is that every government agency has an incentive to estimate favourable ratios for its own projects. It must, after all, compete with other agencies for funds. No one can be certain as to the returns to be expected from an irrigation canal or a highway. Private investors have also been known to exaggerate their claims in appealing to stockholders, but they are generally subject to market sanctions that encourage them to err on the side of caution. It is only human for estimators to be optimistic—however professionally competent they are.

The most important difficulty, however, is that in public undertakings some of the expected benefits are likely not to be measurable in money. Water projects, for example, are designed to produce a variety of benefits ranging from electric power and irrigation to employment and recreation. The cost of training a high school dropout is not to be measured only against the income he will earn but also against the social benefits of making him a productive member of society. In other areas, such as defense and conservation, economic standards are applicable either not at all or only to a small extent.

The theory of public goods. Economists have sought to provide objective criteria for public expenditures through the so-called theory of public goods. It is generally recognized that some goods needed by the public cannot be provided through the private market (lighthouses are a classic example). While everyone wants such goods, everyone has an incentive to let someone else pay for them. Consequently, government action is required. Economists have tried to devise voting procedures that would guide the public authorities in providing these goods in the desired quantities.

The difficulty with this approach is that it rests on the assumption of fixed consumers' tastes and holds that the function of government is to give effect to those fixed tastes. But the private economy is actively engaged in changing individual tastes; and the government is similarly engaged, whether or not it ought to be. It would be absurd to say that the consumer has a taste for national defense and that it is the job of the government to satisfy it. The task of national leaders is to evolve a defense policy and persuade the public to accept it. Similarly, conservationists must attempt to awaken the public to the importance of parks and wildlife. In the context of public policy, the efficient allocation of resources consists not merely of distributing funds in the pursuit of given objectives but involves determining the objectives themselves. For this reason budgeting has become an essential component of the decision-making process.

ALTERNATIVE APPROACHES TO THE BUDGET

The various forms a budget may take

In order to deal with the problems discussed above, most countries have experimented with various kinds of budgets for different purposes. In the current American terminology these are: the administrative budget, the cash budget, the capital budget, the national income accounts budget, the unified budget, the full-employment budget, and the program budget.

Administrative budget. The administrative budget is the traditional one. It contains the executive's recommendations concerning the raising of what the Magna Carta referred to as "scutage or aid," and the disposal of it for purposes of government. This kind of budget is designed to control expenditure; accordingly, it emphasizes the salaries and tasks of civil servants rather than the results that they are supposed to achieve.

The objective of control naturally gives rise to the doctrine that the administrative budget should be balanced. Deficits imply irresponsibility. Surpluses imply the imposition of unwarranted tax burdens on the public.

The limitations of the administrative budget are that some important items receive less than adequate attention or are excluded from it entirely. Military procurement is one example. Neither budget offices nor appropriations committees are well equipped to scrutinize the actual procurement of ships or aircraft. Consequently, in most countries large expenditures on military items are often treated perfunctorily while the activities of civil servants receive an inordinate amount of attention.

The administrative budget generally does not include all governmental receipts and expenditures. Those of trust funds are often excluded. Trust funds are used to finance contributory old age and unemployment insurance; taxes are paid directly into the funds and disbursements made out of them. The theory is that the government acts as trustee for the public and that the public is protected by having its social security taxes put in a separate fund. (The same idea has been used to ensure that gasoline and highway taxes are used for highway construction.)

Other items may be included in the budget on a net rather than a gross basis. For instance, the total receipts and expenditures of the post office usually do not appear, only the postal deficit or surplus. The theory justifying this treatment is, first, that business management is not well performed by legislative committees and, second, that so long as a business undertaking pays its way, its conduct is not a matter of public concern.

Capital budget. In many countries, some items are regarded as inappropriate for the administrative budget and are included "below the line." The rule of budget balance is not applied to them; instead, it is permissible to finance them by borrowing.

In the United Kingdom, all government loans to other public bodies and to nationalized industries are included below the line on the ground that since the loans are repayable they need not be covered by current taxation. The government's own borrowing can be repaid out of the loan repayments it receives.

By similar reasoning, direct public works are regarded by most countries as suitable for loan financing on the ground that they are productive assets that will yield a revenue sufficient to cover their cost. They may do so either directly, as in the case of a toll highway, or indirectly by increasing the general economic welfare, as in the case of a free highway. In many cases, however, governments succumb to the temptation of including in their capital budgets items such as free playgrounds, which, however socially desirable, are not productive in the economic sense.

Another reason for loan financing is that some expenditures are so "lumpy" that it is neither feasible nor equitable to saddle the contemporary taxpayer with the full costs of the undertaking. This applies particularly to war expenditures, but the same is true of the construction of schools and hospitals by local governments.

The federal government of the United States has resisted the idea of a capital budget, even though there was strong pressure for one in the 1930s when economists and politicians wanted to legitimize the government deficit. Among U.S. state and municipal governments, however, loan financing of public works is the regular practice, for two reasons. First, those bodies are usually unable to finance their projects by current taxation; second, they do not want to because the projects are generally of a long-term nature.

Most national governments have now become accustomed to thinking in terms of national economic policies in which the amount of borrowing to be undertaken depends on current requirements for stability and growth. This makes capital budgeting less attractive, particularly if the government wishes to use the budget to supplement the national flow of savings. The more need there is to increase saving the smaller should be the amount of government borrowing. On the other hand, government borrowing is justified when private savings tend to exceed private capital requirements.

Cash budget. The consolidated cash budget has the merits of simplicity and comprehensiveness. As used in the United States, it presents total payments by the federal government to and from the public (including other levels of government). It is thus similar to the cash flow account of a modern business. Trust fund expenditures and receipts are included, as well as cash payments and receipts involved in loan transactions. Government business undertakings such as the post office, however, are still included on a net basis.

The cash budget suffers from the defect that it is not directly tied to government decision making. Liabilities incurred do not synchronize completely with payments. This is because government expenditures result from appropriations and other forms of commitments; cash expenditures may follow appropriations and other commitments of money only after a considerable lag, notably in the case of construction and procurement. Appropriations relate to actions in the future. Expenditures result from past decisions. Both kinds of information are needed for a complete appraisal.

National accounts budget. It is useful to have a budget that is constructed in terms of the national income accounts. From the point of view of aggregate economic analysis, the accounts of the public sector should mesh with those of the private sector. The "national accounts budget" differs from the cash budget principally by excluding loans made by the government and also repayments to the government. While this is justified by the need for consistency with the national income accounts, which do not consider lending as an expenditure or a receipt, the total exclusion of government loans does not make much sense from the point of view of analyzing government operations. In terms of its effects on the economy, an excess of loans over repayments in a government lending agency cannot readily be distinguished from an excess of expenditures over receipts of other types of government business organization.

Unified budget. The United States government, in an effort to reduce public confusion over the foregoing array of concepts, has adopted a so-called unified budget concept that is more logical than the cash budget but differs from it only in some details that do not materially affect the budget aggregates.

Full-employment budget. A concept that is gradually seeping into budget discussions is that of the receipts and expenditures that would prevail under conditions of full employment. This approach views the actual expenditures and receipts for the coming year as of secondary importance; it assigns primary importance to the influence of the budget on the national economy. In time of recession a budget deficit may thus be presented as a necessary step toward achieving a balanced budget at full employment. Ideally, the budget should include estimates of expenditures and revenues at full employment, and also estimates of the same items at the anticipated level of employment. These ideas have been extensively used in the United States by the Council of Economic Advisers.

An analogous procedure could be used with respect to inflation. Expenditures and receipts would then be estimated on the assumption of little or no inflation, and supplementary estimates would show the effects on the budget of the amount of inflation actually expected. This idea is still far from acceptance, since governments are no less reluctant to anticipate inflation than they are to budget for unemployment.

Program budget. Traditionally, government expenditures have been considered as inputs rather than outputs. This is because, in the classical 19th-century conception, the well-run government does not produce a marketable output. The program budget is a new departure; it attempts to classify expenditures in terms of the outputs to which they are devoted. For example, a traditional school budget would categorize expenditures in terms of teachers, books, and buildings, and what came out of the process would be left to the reader's intuition or experience. The program budget, in contrast, attempts to assign expenditures to specific outputs, categorizing them according to numbers of children completing various programs.

In government, budgets have traditionally been constructed according to departments and agencies of government. This may be justified on historical or administrative grounds, but it does not necessarily correspond to the structure of activity. Every country organizes the civilian and military components of its foreign policy in separate departments—but this is frequently a serious obstacle to effective policy making. Again, the requirements of good administration suggest that there should be a single department of agriculture. But that department's activities impinge on those of others, both in domestic and foreign policy. A budget constructed according to actual programs would cut across departmental boundaries.

Difficulties in defining output, and the obvious conflicts with organizational structure, suggest that program budgets of governmental scope will never fully replace the traditional administrative approach.

THE BUDGETARY PROCESS

The United States. Since 1921 the budget of the United States has been the responsibility of the president. It is prepared under his direct authority by the Office of Management and Budget (OMB). The process begins when the various departments and agencies prepare their appropriation requests, based on expenditures required under existing law and those estimated under new legislation to be proposed by the president. These requests are carefully scrutinized by the OMB. In case of disagreement, cabinet officers negotiate directly with the president, who is ultimately responsible.

Unlike the budgets of many countries, that of the U.S. deals mainly with expenditures. Revenue is covered in much less detail. Great significance is ascribed to the size of the expected deficit or surplus, even though there is no legal requirement that the budget be in balance.

The budget is submitted in January and normally applies to appropriations for the fiscal year beginning July 1. These must normally be spent in the following two years. For some items, such as construction or procure-

ment of military hardware, appropriations are made to cover expenditures for the whole construction period.

The Appropriations Committees of Congress

When the budget reaches the House of Representatives, it is distributed among the subcommittees of the Appropriations Committee. Each subcommittee is concerned with a particular organizational unit. There is virtually no consideration of the budget as a whole by the committee as a whole. Revenues fall under the jurisdiction of the Ways and Means Committee of the House and are considered separately and possibly even at a different time from appropriations. The upper house of Congress, the Senate, plays a secondary role with respect to the budget. Its Appropriations Committee acts as a kind of court of appeal from the House Appropriations Committee. These procedures allow more coordination than appearance would suggest. The committee chairmen are among the most influential members of Congress, and the committee staffs are very experienced and skillful.

Economic impact of the budget. The president sends three documents to Congress in January: the State of the Union Message, the Budget, and the Economic Report. The first is addressed to broad national policy, whereas the Economic Report is concerned with economic policy alone. In particular, it seeks to assess the economic impact of the budget and its effect on employment and prices. The Economic Report was instituted by the Employment Act of 1946, which requires the president to report to Congress on the state of the economy and to recommend policies to promote "maximum employment, production and purchasing power."

The record in this respect is a mixed one. The most serious problems stem from inflation, which in turn is the result of governmental budget deficits incurred during periods when the economy is at a high level of activity. Once inflation is allowed to get under way, attempts to correct it seem to result in high levels of unemployment.

Budget makers in the U.S. must also consider the international balance of payments. This is a relatively new problem for the United States, which historically enjoyed a balance-of-payments surplus until the 1960s. A declining trade balance, coupled with heavy military commitments abroad, now requires that budgetary and other economic measures be designed with international as well as national economic balance in mind.

Effect of the budget on resource allocation. There is no formal machinery for ensuring that the budget strikes a satisfactory balance among the different programs contained in it. But the alternatives receive a good deal of scrutiny. Cabinet officers have their clienteles in the public and in Congress and through them can bring political power to bear in the competition for funds. Similarly, the congressional committees are able to exert some influence on the budget during its preparation. The president for his part is not passive; he has a political position of his own that permits him to assert his conception of the national interest. Other pressures come from the taxpayers, who are able to express their stand on expenditures both to Congress and to the president.

A satisfactory outcome for the allocative process depends on the evenness with which these competing forces are balanced. Opinions will differ. It can be said that the process of decision making is at least an open one, even though vested interests have entrenched themselves in particular areas.

Even though amendments to the budget are usually minor, the influence of Congress is not negligible. The prospect of facing Congress is a sobering one to the officers of government. And departmental budget recommendations are often strongly influenced by the views of congressional committees. The secretary of agriculture, for example, often has a relationship with the Agricultural Committees of Congress that is friendlier and more intimate than his relationship with the president.

The United Kingdom. The British budget is submitted to Parliament by the chancellor of the exchequer, who is responsible for its preparation. The emphasis of the chancellor's budget speech is on taxation and the state of the economy, rather than on the detail of expenditures; public discussion likewise is devoted mainly to the chancellor's tax proposals. The estimates of expenditures are sent to Parliament with less fanfare, where they are reviewed by the select committee on estimates of the House of Commons. The review of the committee hardly touches matters of policy. While the committee does not amend the budget, it is influential through its criticism and advice.

Britain: the power of the treasury

In the preparation of the budget, the treasury appears to have virtually complete authority over the government departments on matters of detail. Major issues are settled in Cabinet discussions, the records of which are not available. The British system thus vests extensive controls in the treasury bureaucracy.

A major part of the budget speech by the chancellor of the exchequer is addressed to forecasts of employment, prices, and the balance of payments, together with a discussion of fiscal and monetary policies. Economic analysis is a continuing preoccupation of the Treasury. Forecasts are prepared three times a year; a budget committee composed of important financial and economic officials meets continously to discuss policy matters. Their attention, however, is focused on tax, borrowing, and monetary policies rather than on the details of government spending.

In the 1960s the attempt was made to plan government expenditures on a long-term basis. Emphasis was placed on the predetermination of expenditures, over a five-year period, in accordance with the expected (or desired) rate of growth of the economy. Planned expenditures are broken down by major functional categories such as defense, education, health and welfare, housing, and so forth, which are to serve as guides in the preparation of annual budgets. The functional breakdown is also intended to assist legislative discussion.

Japan. Under Japan's 1947 constitution the Cabinet has the responsibility of preparing the national budget, which must then be submitted to the lower house of the Diet. Taxes can be imposed or modified only as prescribed by laws enacted by the Diet.

The budget is prepared on a fiscal-year basis by the budget division of the Ministry of Finance. The centre of the budget system is the general account, which theoretically includes all revenue and expenditure directly applicable to the overall fiscal operation of the government. There is also a system of special accounts for the operation of government enterprises and other special aspects of government finance. Theoretically, each special account is self-balancing. In actual practice, however, there have at times been substantial deficits in the special accounts that have had to be covered by direct government appropriations, borrowings, and transfers of funds from one account to another.

Under the Public Finance Law of 1947, the general account of the national budget must be either balanced or in surplus. The government cannot increase its net long-term debt without special legislation, and then the increase must be tied to some specific investment use.

The budget under central planning

Soviet budgeting practices. In the Soviet Union and some other countries having Communist governments, economic activity is either carried on by state enterprises or is subject to central control. The national budgets therefore have a much broader scope than in countries where most economic activity is in the private sphere. In the Soviet Union well over 90 percent of capital investment is financed by the government; in the United States the corresponding figure is less than 25 percent, and in Great Britain it is less than 50 percent. There are two main sources of revenue: the profits of state-owned enterprises and the turnover tax on the sales of enterprises. The relative proportions of the funds drawn from enterprises under these two headings vary; there has been a long-term tendency for the share of the turnover tax to decline and for profit transfers to increase.

The budget is essentially a part of the national economic plan. It is drawn up by the Ministry of Finance and presented to the Supreme Soviet for consideration and approval every calendar year. Revenues and expenditures are usually in close balance. The budget is implemented by the Ministry of Finance, which scrutinizes the opera-

tions of the state enterprises in accordance with the economic plan.

Buenos Aires

Buenos Aires, the capital of Argentina, is the largest city in the Southern Hemisphere and the sixth-largest in the world. Located on the western shore of the Río de la Plata, the city proper, which is also the federal district, covers an area of 77 square miles (200 square kilometres) and has a population of about 3,000,000. The total metropolitan area, however, extends over 1,500 square miles and has about 8,400,000 inhabitants. According to tradition, 16th-century Spanish sailors named the port for their patron saint, St. María del Buen Aire (St. Mary of Good Air). Today, the citizens of Buenos Aires call themselves *porteños* ("people of the port").

The city is the national centre of commerce, industry, politics, and culture. Its wealth and influence overshadow the life of the rest of the nation and confront Argentina with its greatest economic and social problems. Since its nomination as the head city of the Río de la Plata government (a dependent of the viceroyalty of Peru) in the 18th century, Buenos Aires has been the region's administrative and financial capital; in addition, because of its location, it has also often been a focus for political and social unrest outside of its borders. The Argentine poet and philosopher Martínez Estrada has called the city "The Head of Goliath," a metaphor that illustrates its imbalance in relation to the rest of the country, much like a large-headed giant with a feeble body.

Buenos Aires is beset with the same problems encountered by other large cities. Increased industry is causing increased pollution; limited land area in the city proper has led to the construction of high-rise buildings with resultant congestion; rapid expansion is hampered by inadequate public services; increased migration from the countryside is creating a growing urban population composed of the poor and unskilled. There is at the same time, however, a feeling of progress and burgeoning strength. (For an associated physical feature, see PLATA, RIO DE LA.)

HISTORY

Foundation of the city

Pedro de Mendoza—the first Spanish governor general of the Río de la Plata region—established a *real*, or provisionary settlement, at the mouth of the Riachuelo River in 1536. The poorly fortified settlement was soon besieged by the surrounding Indian population, and the settlers were forced to flee northward up the Río de la Plata to Asunción. From there, Juan de Garay led an expedition back to the original site and founded the Ciudad de la Trinidad (Trinity City) and the Puerto de Santa María de Buen Aire in 1580. Streets and city blocks were laid out on a rectilinear plan, urban and rural lands were granted to the expedition's members, and the conquered Indians were divided as slaves among the larger landholders.

For two centuries Buenos Aires was a poor city in the extreme south of the opulent viceroyalty of Peru. Since Spanish policy decreed that all trade be carried out through the Pacific Ocean port of Lima, Buenos Aires was not able to engage in direct commerce with Europe or North America. There was, however, an active trade in all manner of contraband. In 1776 the viceroyalty of the Río de la Plata was created, with its seat in Buenos Aires, after which the city began to grow.

After fighting off several attacks by pirates in the 18th century, the city's population defended itself against British attacks in 1806 and 1807 without any help from the Spanish government. In 1810, when Napoleon invaded Spain and placed his brother, Joseph Bonaparte, on the Spanish throne, the city felt little allegiance toward the new government. It therefore deposed the viceroy and established its own government in the name of the deposed Spanish king. A constitutional congress subsequently met in San Miguel de Tucumán and, in 1816, declared independence from Spain. A Directory, or provisional government, was created, and Buenos Aires was named the capital of the United Provinces of the Río de la Plata. Ten years later, the presidential republic was formed, and the capital district of Buenos Aires came into existence. After much political wrangling, interspersed with threats of secession, the state was reconstituted in 1860 and consolidated in 1880 as the Argentine Republic with Buenos Aires as its capital. The towns of San José de Flores and Belgrano were added to the federal district in 1887, bringing it to its present size.

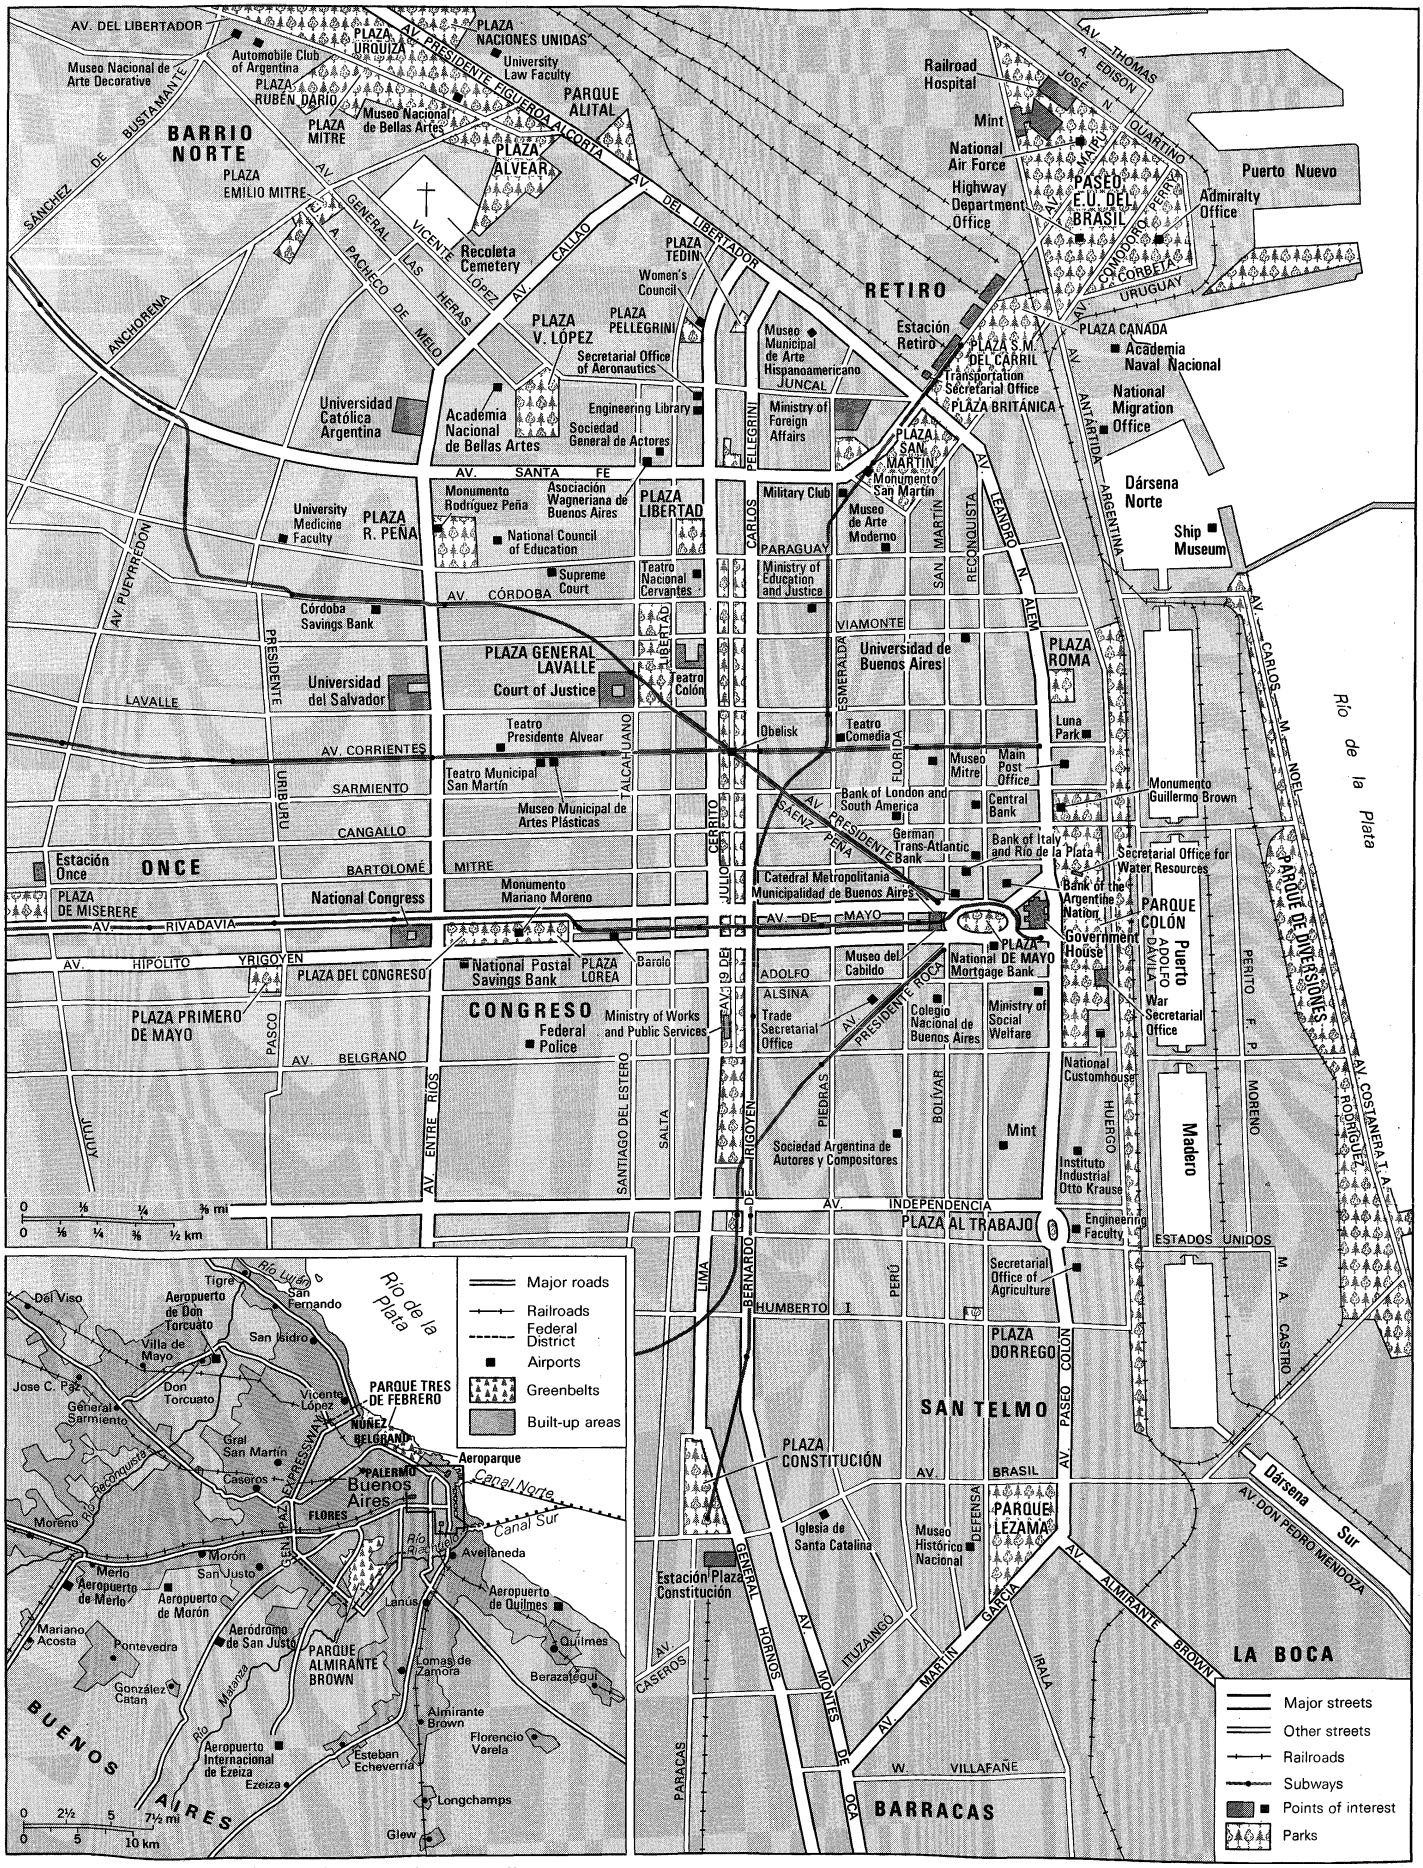
The city's development

In the mid-1800s Buenos Aires was more an overgrown village than a city. Houses were low built and widely spaced, and public utilities were at a minimum. The population was almost totally Spanish. Between 1860 and the outbreak of World War I, however, the city received a continuous influx of European immigrants, largely from Italy and Spain. During that period the population grew by about 500 percent. Because land was inexpensive and readily available in all directions except the east, the newcomers spread out in barrios, or self-contained neighbourhoods, that were usually identified with a particular ethnic group. Some barrios were located outside the federal district and formed part of what later became Gran (Greater) Buenos Aires. The original site became dotted with collective houses known as *conventillos*, where the poor lived under slum conditions in tiny rooms connected by long open corridors.

The expansion of the city was accompanied by a program of beautification and improvement without a proper city plan. Trees were planted in the squares, streets were paved and lighted, and old buildings were replaced with new until little remained of the original city. Buenos Aires also developed as the political, cultural, and economic centre of the country, completely overshadowing other Argentine cities. Rapid industrialization after World War II increased the city's attraction for immigrants from abroad, as well as for migrants from within the country. Buenos Aires is now a cosmopolitan, sprawling megalopolis, faced with a problem of economic and social imbalance.

THE CITY SITE

Location and natural environment. The federal district is located mostly on the southeastern corner of the plain that stretches between the Río Reconquista to the west and the Riachuelo (Matanza) River to the southeast; it is bordered by the Río de la Plata to the east, the Riachuelo River to the southeast, and the Province of Buenos Aires to the west and north. The city slopes eastward from its centre at Villa Ortúzar, which is 82 feet above sea level, to the *barrancas*, or ravines, which rise to 15 feet above sea level. Between the ravines and the Río de la Plata are two large coastal zones in the flat Matanza River Valley and the estuary margin. The areas are flooded during abnormally high tides; they have been partially reclaimed with landfill and developed as residential and recreational areas. Gran Buenos Aires is composed of the federal district and 22 adjacent municipalities in the Province of Buenos Aires.



Central Buenos Aires and (inset) its metropolitan area.

Soil and water. The soils of the urban region are composed of loess (a brownish mixture of clay, silt, and sand deposited by the wind) in the plains area and marine sands in the river valleys. The granite base is covered by compacted layers of clay to a depth of 1,000 feet. Subterranean water is found at various depths; most of it is potable and is used in industry. Numerous streams flow beneath the city; some of the plazas and public gardens were once lagoons or water-filled depressions.

Underground water

Climate. The temperate climate of the Pampas (the vast Argentinian plain) that is characteristic of the Río de la Plata's coastal area is marked by a long summer (December–March) and abrupt temperature changes in autumn (March–June) and spring (September–December). Temperature differences within a 24-hour period can be as great as 22° F (12° C). The average annual temperature is slightly higher than 60° F (16° C); frosts occur from May to September. June and July are the coldest months, with mean temperatures of 52° F (11° C), and January the warmest, with a mean temperature of 75° F (24° C). Winds are generally of low velocity and are more frequent during the electrical storm season between September and March. Humid southeastern ocean winds bring the rains, accompanied by occasional windstorms, that result in a prodigious rise in the Río de la Plata, and northeastern winds bring warm air from Brazil. The northern winds are suffocatingly hot; those from the east are relatively fresh. The rare southwestern winds, or *pamperos*, may occur at any time of the year and usually follow winds from the north. They cool the air and clear it of humidity. Rainfall is greatest during March; the average annual rainfall is about 37 inches. The relative humidity is high throughout the year and averages 76 percent.

Vegetation and animal life. The original vegetation of the coastal forests has been practically eliminated and replaced by foreign and domestic exotic plants. The city is dotted with trees, including the jacaranda, the large-coned araucaria, the caranday palm, and the foreign eucalyptus. Various species of birds live in the city parks and along the coast. The coastal waters abound in edible fish such as the pejerrey, or silversides, which is related to the gray mullet.

Pollution. Air and water pollution have not yet reached serious proportions, but the tributaries of the Río de la Plata contain increasing amounts of urban and industrial waste. The air is also affected by automobile exhaust and domestic and industrial smoke.

The plan of the city. Buenos Aires has expanded without the benefit of urban planning, and its growth patterns have been determined largely by real-estate values. Zoning laws have been subject to constant modification. There is progressive congestion in the centre of the city, as well as in those areas reached by railroad, bus, or subway. Older *barrios jardines* ("garden neighbourhoods") are being replaced by high-rise apartment buildings.

The overall layout of the city corresponds to the quadrangular pattern decreed by the laws of the Indies—a body of legislation codified in 1680 for all the Spanish colonies. The streets run at right angles to one another and enclose city blocks that are, on the average, 330 feet square.

The centro. The *centro*, or the city centre, coincides with the original settlement. The streets are narrow, running from north to south and from east to west. Beginning in 1826, every fourth street was widened to form larger quadrangles of avenues enclosing groups of 16 city blocks. The widest avenue in Buenos Aires, the Nueve de Julio (9th of July), runs from north to south and helps to alleviate traffic congestion.

The capital zone

Part of the *centro* is known as the capital zone, because it contains the Government House (Casa de Gobierno), the National Congress (Congreso Nacional), the Palace of Justice, and other government buildings, as well as the official banks, the city cathedral, the Museo del Cabildo, and the larger newspapers and commercial concerns. This area developed along the Avenida de Mayo from east to west and along the Paseo Colón and Leandro N. Alem from north to south. These streets and the diagonal ones nearby converge on a wide, green space composed of the Plaza de Mayo and the Parque Colón, which comprise the urban core.

The barrios. There are more than 50 distinguishable barrios in the city, most of which were founded in the 19th century. The two oldest—the cathedral barrio and San Telmo, in the *centro*—coincide with Juan de Garay's original city. La Boca, on the waterfront, is largely an Italian community; Flores was originally a country village founded in 1804. Other barrios of importance include Barracas, Concepción, Montserrat, Balvanera, and Retiro, all of which surround the *centro* and originally formed the outskirts, or *orillas*, of the viceregal city. Their inhabitants were called *orilleros* to distinguish them from the original port settlers, the *porteños*. Belgrano (originally La Calera), Once, Almagro, Caballito, Floresta, Liniers, Colegiales, Ortúzar, Coghlan, Núñez, Saavedra, Urquiza, and Villa del Parque grew up in the last half of the 19th century around rail and tram lines. La Recoleta, or Barrio Norte, became a focus for the upper-income group, as it moved out of the *centro;* since the 1960s, however, the wealthier families have left the city proper to settle farther north along the Río de la Plata in provincial municipalities.

Gran Buenos Aires. There are numerous towns within the greater metropolitan area. Those with more than 100,000 inhabitants include Matanza (San Justo) and Morón to the west; Lanús, Lomas de Zamora, and Almirante Brown to the south; Avellaneda and Quilmes to the east; Vicente Lopez, San Isidro, and San Fernando to the north; and San Martín and General Sarmiento to the northwest. There are also six smaller towns within the area.

THE PEOPLE

Demography. The dominant feature of the city's development has been its rapid population growth since the end of the 19th century. In 1855 there were 100,000 inhabitants, and by 1862 the population doubled to 200,000. By 1905 the city had outgrown its boundaries, and 15 percent of its 1,000,000 citizens lived in adjacent communities. By 1927 the metropolitan area included 2,000,000 people, and by 1947 it had grown to about 4,700,000, of whom less than 3,000,000 lived within the federal district. By 1960 the city proper housed nearly 3,000,000 people, about two-thirds of whom were native-born. By 1970, 5,400,000 people lived in the suburbs, while the population of the city itself remained constant, bringing the total metropolitan population to 8,400,000.

Population growth

Between 1860 and 1900, this prodigious growth was due to a large European migration. The city's position as the national political, commercial, and industrial centre attracted migrants from other parts of Argentina, which resulted in further expansion. New arrivals moved into existing population centres and also settled on small rural subdivisions known as *loteos*, as well as on public and private lands, thereby creating *villas miserías* (slum districts).

The demographic composition of the city is similar to that of other large cities. There are more women than men and more adults than children. The average family is small; almost half the population is employed.

Ethnic composition. The population is almost entirely European. Spanish and Italians predominate, but there are also sizable English, French, and German communities. There are smaller groups of Poles, Russians, Portuguese, Syrians, and Turks; and the Negro and mulatto population is negligible in size. Although some ethnic groups tend to congregate in particular areas of the city, strictly defined or officially sanctioned ghettos do not exist. The Argentine identity tends to override specific cultural loyalties but is flexible enough to allow ethnocentric mutual-aid societies and social clubs to emerge. Even the dominant Spanish language has been affected by the acceptance of other European cultures and has undergone pronunciation and grammatical changes; in the slums and waterfront districts an italianized dialect has emerged. Italian cuisine is popular in the city, and pasta dishes appear on almost all restaurant menus.

Cultural and linguistic influences

Buenos Aires, with the Congreso Nacional building and the Plaza de Mayo in the foreground.
Carl Frank

Perhaps the most important social difference is that between the *porteños* and the *orilleros*. Since the city's inception, the established families of the original town site have retained political and social power; they are still identified with the federal-district area, even though some are now moving to northern residential suburbs. The *porteño* identification has also been expanded to include all those born in the city, as opposed to immigrants or visitors. The *orilleros*, now suburbanites, often belong to the lower income groups living in the industrialized communities that surround the city.

Housing. *Building types.* The one-family home of one or two stories, with an interior patio and a garden, predominates. In the *centro* and in the centres of the barrios, apartment buildings ranging from five to 20 stories are common and result in congestion and insufficient services. Large, one-family dwellings or apartments, built according to official plans, are found throughout the city and contrast with the congested buildings around them. In old Flores, the municipal government is developing a large area where homes in the form of large flats are interspersed with public parks. In areas not developed under municipal guidance, the construction code permits the building of compact apartment buildings on small lots of land. Skyscrapers are permitted on slightly larger lots, thus improving hygienic conditions, although at the cost of an extremely high population density. Older barrios—such as Belgrano, Palermo, and Núñez—are conglomerations of multistoried buildings, many of which are of excellent architectural quality; they are raised above the ground and have ample gardens at street level.

Rents have been fixed by law since 1943. This has resulted in a large quantity of low-rent apartments being made available but has also bankrupted some building owners and discouraged building improvement. Many streets appear to be run-down even though they are not old. Since 1948, however, the Horizontal Property Law has stimulated the renovation of entire urban areas with thousands of new apartment flats financed by private banks.

Architecture. In the coastal barrios of Barracas and La Boca, the one- and two-story buildings are made of wood and corrugated-metal roofing and are almost all over 100 years old. They are painted in various primary colours and are graced with flower-laden patios. Caminito Street, in La Boca, is maintained by the municipal government as an example of late-19th- and early-20th-century prefabricated architecture. By contrast, the Barrio Norte contains luxurious palaces from the same era, many of which have been converted into embassies, museums, elegant clubs, and public institutions. Among these are the Chancellory (formerly Anchorena Palace), the Military Club (formerly Paz Palace), and the Museo Nacional de Arte Decorativo (National Museum of Decorative Arts, formerly Errazuriz Palace).

Buildings of the Spanish period

Almost all of the few remaining relics of the Spanish viceregal period are churches, convents, and religious schools found in the *centro* and its surrounding barrios. The best architectural examples from this period are the Cabildo, or Town Hall, and the Metropolitan Cathedral. In San Telmo and Centro Sur barrios are old tiled homes, one of which served as the residence of viceroy Santiago Liniers and is now a national historic monument.

Buildings of the 20th century are interspersed with those from earlier years. New buildings are usually eclectic in design, are sometimes capricious in conception, and can be of debatable functional or aesthetic value. Within the banking zone of the *centro*, Neoclassical bank buildings are crowded together with the Bank of London and South America, a structure of painted, reinforced concrete with vast windows and exposed gas and water pipes built in 1969. There are many notable examples of functional, high-quality architecture in the city, including the numerous office and apartment "towers" built during the 1960s and large housing units called monoblocks, scattered about the *centro* area.

THE ECONOMY

Industry. Gran Buenos Aires represents about 80 percent of Argentina's investment in industry, labour, and business. Industrial establishments are usually large factories with modern equipment, although smaller units do exist. During the 1950s, there was great emphasis on the production of consumer goods, and the city now meets its own needs. Main industries include food processing (meat, fish, grain), metalworks, automobile assembly, and oil refining, as well as printing, and the manufacture of textiles, beverages, paper, paint, and chemicals. Service industries are important, especially in the suburban areas, and the metropolitan area consumes more than half of all the electric and natural gas energy produced in the country. Inside the city proper are many larger

Industrial and commercial trends

industrial and manufacturing establishments, mostly in the barrio of Barracas.

Commerce. The national banking system is controlled by the Banco Central de la República Argentina (Central Bank of the Argentine Republic). Five government banks represent the official banking board, to which all private banks are responsible. Many of the private banks are associated with foreign banks or are subsidiaries of provincial banks. Numerous credit corporations provide funds for small businesses, while larger credit organizations are concerned with national and international enterprises. Federally controlled savings and loan associations finance home building.

Financial quotations are available from the stock exchange and the stock market. There are also specialized markets for meat, cattle, fruit, and grain. Insurance companies are backed by the Instituto Nacional de Reaseguros (National Re-insurance Institute).

More than 40 percent of all imports and 30 percent of all exports in Argentina pass through the port of Buenos Aires. Large warehouses and *barracas* ("huts") store the goods and act as national distributing houses. The administrative centres of the country's large agricultural, industrial, and mining enterprises are located in the city.

Transportation. *Roads.* The highway system is composed of five expressways that radiate out from the *centro* to connect it with the General Paz Expressway, which circles most of the city, thus forming a pattern resembling the sticks of a fan. Since 1886, the Riachuelo River and Avenida General Paz have defined the city's inland limits. Other main avenues penetrate to the Plaza de Mayo, in the heart of the city.

Railways and subways. The city is the terminus of every major railway in the country. There are four main railway stations within the urban area—Constitución, Once, Federico Lacroze, and Retiro. There are also two electric lines connecting the city with the towns of Tigre and Moreno. The city's five subway lines are interconnected and also connect the railway stations. They run for a total distance of 22 miles through tunnels decorated with murals made of multicoloured tiles.

Air services. The two international airports of Ezeiza and Don Torcuato, as well as the military airport, are respectively located outside the city limits in the municipalities of Matanza, Tigre, and Morón. They are connected to the city by expressways. The Buenos Aires City Airport lies within the federal district and services all the domestic airlines, as well as those that operate to and from Chile, Uruguay, and Paraguay.

The port of Buenos Aires

Port facilities. Buenos Aires is one of the world's largest ports, and its harbour is entirely man-made. Ships reach the port facilities through a twisting channel in the Río de la Plata, which must be continuously dredged because of shifting sand. The port stretches for five miles along the city's waterfront in a series of five interlocking basins and docks, which are connected to the main channel by smaller branch channels with a maximum depth of 30 feet. Puerto Nuevo (New Port) contains six open docks. It is the main passenger port and an important freight centre because of its large grain elevators and its proximity to the railway yards of Retiro. Located between Puerto Nuevo and Puerto Madero, the other major port facility, is Dársena Norte (North Dock), the naval operations base. Southward along the waterfront are Puerto Madero, which accommodates the river trade; Dársena Sur (South Dock), which handles all combustible materials; and two miles of wharves at the mouth of the Riachuelo, the original anchorage site for sail ships, called "la Boca."

Traffic. Though most city traffic is regulated by automatic traffic lights, the city's residents are notorious for ignoring them. Since the early 20th century, two major streets have been closed to motorized traffic during part of the day to allow for a free flow of pedestrians. More than 400,000 automobiles are registered in the city, and thousands of other vehicles enter and leave the city daily. Since trams were eliminated in the 1950s, *colectivos* (microbuses) and taxis have added to the steady flow of traffic.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Political and governmental institutions. Buenos Aires, as mentioned, is the national capital, and the city proper is the federal district. The seven main national parties maintain their headquarters in the city. The president of the republic controls the municipality, and the National Congress is responsible for all legislation pertaining to it. The president appoints the mayor, who is his official representative. Over the years an elected city council has functioned only intermittently.

The administrative districts

The city territory is divided into 46 administrative districts, which coincide approximately with the traditional barrios. Each district has a neighbourhood junta, or council, composed of representatives from institutions such as the Lions and Rotary clubs, trade and industry groups, and workers' syndicates, who deal with various problems of public concern.

Many of the provincial governments maintain provincial houses in the city, which act as information and promotion centres; most of these are also concerned with relations between province and capital.

Public utilities. *Organization of services.* Almost all public-service facilities are in the hands of nonmunicipal organizations, functioning independently of the city administration. The municipal government is in charge only of the construction and maintenance of pavements and sidewalks, and parks. Because of population growth and uncontrolled building, the public services are severely overtaxed. There is also a lack of cooperation among individual public services, although the municipality indirectly exercises a coordinating role.

Types of services. Sanitary facilities—water supply, drainage, sewers—are the responsibility of the General Administration of Sanitary Works of the Nation (OSN), which services the greater part of Gran Buenos Aires. The large water-purification plant in Palermo Park treats water from the Río de la Plata and sends it underground through tunnels to four reservoirs in different parts of the city. This water is used for drinking, bathing, laundry, irrigation, fire fighting, public fountains, and industry. Electricity is provided by the Stock Company of Electrical Services of Gran Buenos Aires (SEGBA) and the Italian–Argentine Electrical Company (CIAE). Four main thermal centres are located in the port area with other stations in the urban area. These are fuelled by nationally produced oil, coal, and natural gas. All are interconnected with the thermic centre of San Nicolás and the nuclear centre of Atucha, both on the Paraná River coast. The National Tele-Communications Enterprise (ENTEL) operates about 70 centres and provides telephone service for the capital and its surrounding areas. International service is operated via satellite and national intercommunication by microwave. Natural gas is provided for all of Gran Buenos Aires by the State Gas Corporation from oil fields to the north, south, and west of Argentina through gas ducts and pipelines.

Health and security. *Public health.* The city has almost 600 municipal and private hospitals, as well as numerous dispensaries, pharmacies, and social hygiene centres in the various barrios. A relatively high number of hospital beds are maintained in order to accommodate the many patients from other parts of Argentina who travel to Buenos Aires for specialized treatment.

The waste-disposal system includes garbage-burning centres, but most wastes are used to fill lowlands along the Río de la Plata. The reclaimed areas are converted into parks, sports areas, and construction sites.

Safety. The federal police are responsible for maintaining public order and ensuring personal safety; the force is administered by the National Ministry of Internal Affairs. The police control traffic and regulate parking; traffic infractions are referred to the municipal tribunal. There are 50 district police stations in the capital's barrios, the central office is in the *centro*, and the mounted police headquarters is in Barrio Norte.

The fire department is under the jurisdiction of the federal police. There are several volunteer-firemen groups in the different barrios.

The military

The headquarters of the National Military Defense system is in Buenos Aires, as are the main offices of the Defense Ministry's navy, army, and airforce secretariats. The chiefs of staff of the coast guard and the frontier (national) guard are also located in the city, as are the barracks of the *patricios* and *granaderos*. The *granaderos*, a regiment created in 1812 by General San Martín, constitute the President's guard and cavalry. The *patricios*, created in 1810 by General Cornelio Saavedra, is the first army national corps.

Education. *Administration.* Educational institutions at all levels—nursery, primary, secondary, and university—are under the jurisdiction of the National Council of Education. The municipal government is in charge of a few nursery schools and some trade schools. Public schools are administered by the National Council of Education; and private schools are under the jurisdiction of an inspection department of the Secretariat of Culture and Education.

The school system. Primary education is obligatory and uniform for children in both public and private schools; it lasts for seven years. There are over 1,000 primary schools, with an attendance of about 290,000 students, as well as almost 600 nursery schools.

Secondary education is mandatory for three out of a possible five years. More than 450 secondary schools either prepare future teachers or serve as college-preparatory schools. The public schools are not usually coeducational, although most private schools are. The boys' schools are called *colegios nacionales* and the girls', *liceos*. Several secondary schools specialize in such subjects as fine arts, languages, or technical training. The University of Buenos Aires (Universidad de Buenos Aires) runs two preparatory schools—the Carlos Pellegrini Commercial School (Escuela Superior de Comercio "Carlos Pellegrini"), which is affiliated with the Faculty of Economics, and the Colegio Nacional de Buenos Aires (National College), both coeducational since 1965.

The universities

There are more than 40 universities in the city. The University of Buenos Aires, the principal university in the country, was founded in 1821. The Universidad Tecnológica Nacional (National Technological University) was founded in 1959 and offers courses in construction, engineering, and metallurgy. Important private universities include the Universidad Católica Argentina (Catholic University of Argentina), the Universidad del Salvador (University of Salvador), the Universidad de Belgrano, and the Universidad del Museo Social Argentino. Several faculties of the National University have been moved to an area on the Río de la Plata in an attempt to create a university campus. The Universidad Católica Argentina is located on the Riachuelo River at the opposite end of Buenos Aires, in Almirante Brown Park. The armed forces operate several technical schools and institutes, such as the Military Geographical Institute, which specializes in cartography.

CULTURAL LIFE

Buenos Aires has an active cultural life. The major newspapers and magazines publish cultural supplements, and numerous institutes, sports clubs, and labour unions offer cultural and recreational programs.

The arts. *Music and literature.* Varied activities include performances given by the Wagnerian Association and the Argentine Mozart Society, as well as literary presentations by the Writer's House and the Theatre House. Performances of folk songs and dances, known as *peñas*, are extremely popular. The tango originated in the city's ancient barrios "orilleros."

Entertainment. The most important of the city's 40 theatres is the Teatro Colón opera house, which attracts famous artists during its June to August season. It is also the headquarters of the national ballet and the national symphony. The Teatro San Martín houses three simultaneously available stages as well as an art gallery; the Teatro Alvear offers performances almost daily. Another theatre of note is the Teatro Nacional Cervantes. Amateur theatre groups present their works in rooms donated by businesses or labour organizations, and there is an open-air stage in the Boca barrio.

The city offers numerous tea rooms and cabarets. Along one of the streets in La Boca, dozens of Italian cantinas specialize in pasta and fish dishes and offer music and singing in which the clients merrily participate. Most of the modern nightclubs are located along the roads leading into the city. There are also more than 100 commercial movie houses.

Museums. The city's 16 museums—six of which are run by the municipal government—house varied collections. The Argentine Museum of Natural Sciences possesses an exceptionally rich fossil collection and runs a scientific institute. The National Museum of Fine Arts contains collections of world masters and of Argentine painters and sculptors, while the National Museum of Decorative Arts houses tapestries and antiques. The Museum of Spanish-American Art contains antique silver objects in a replica of a colonial home. Other art collections include Spanish, Italian, and modern works, and there are several historical museums and documentary centres. Museums of lesser importance are annexed to various public and private institutes, and there are 11 national academies of arts and sciences.

Libraries. The public municipal libraries, distributed throughout the city, are complemented by larger scholastic and institutionally sponsored libraries. The largest is the National Library, and others of importance include those of the Mitre Museum, the National College, the National Congress, the Women's Council, the National Council of Education, the Central Bank, and the Argentine Centre of Engineering. All of the universities maintain libraries, and numerous private foundations present public scientific and cultural programs.

The media. *The press.* The press includes hundreds of daily newspapers edited in Buenos Aires. Morning papers of long standing and of national importance are *La Prensa*, *La Nación*, and the country's oldest English-language paper, *The Standard*. The *Clarín* is also an important morning paper, and *La Razón* and *La Crónica* are published in the evening. Numerous others are published by professional groups, unions, and associations.

Television. All television stations are commercial. There are four local television stations, and the city also receives broadcasts from La Plata.

Radio. There are 13 local radio stations, two of which belong to the government. The most important commercial stations are Radio El Mundo, Radio Argentina, Radio Belgrano, Radio Splendid, Radio Excelsior, and Radio Mitre. Programs from Uruguayan stations are also received.

Recreation. *Parks.* The city is ringed with *espacios verdes* ("green areas"), which include plazas, parks, and tree-lined boulevards. Two extensive parks that were built on reclaimed floodlands are the Almirante Brown Park in the Riachuelo Valley, and the Parque Tres de Febrero, on the Río de la Plata. Palermo, the oldest park, has an area of 1,500 acres and contains Bosque de Palermo, or Palermo Forest.

Nueve de Julio Avenue, which is about 460 feet wide and has a strip of grass and trees down its centre, forms, in effect, a mile-long park running through the city centre. In general, however, available public recreational space has been reduced by the use of a large portion of the marginal parks for sports installations and other municipal development.

Sports facilities. The Club River Plate has built a gigantic stadium in Parque Tres de Febrero, where the Riding School of the Argentine Equestrian Club is also located. Other facilities include the National Race Track, the zoological and botanical gardens, the National University campus, the public baths, various nautical and sports clubs, the planetarium, the Lago Theatre, the Rose Walk of Palermo, and the northern coastal highway, which is lined with small restaurants, or *carritos*, specializing in steaks.

In Almirante Brown Park is the Autodromo Municipal —the city automobile race track—as well as a vast reservoir, used for boating, and a public recreation area.

In Costanera Park, near the port, reclaimed land is used for a football stadium, for exhibitions, and for a public park. Other sports clubs have their headquarters and stadiums in the urban area proper.

Gardens. Buenos Aires is one of the most tree-filled cities in the world, and the fondness of the population for flowers and plants is evident from the aspect of patios, balconies, and flower-covered terraces.

BIBLIOGRAPHY. DIRECCION NACIONAL DE ESTADISTICA Y CENSO, various statistical publications with census figures from 1869, 1895, 1914, 1947, and 1960; also provisional census figures from 1970 dealing with population, housing, and education; the Municipality of Buenos Aires City, various publications on historic and present development; IPRU (Institute of Regional and Urban Planning of Buenos Aires), various publications dealing with urban development and land use, particularly for the years 1950 to 1965; JUAN AGUSTIN GARCIA, *La ciudad indiana*, 2nd ed. (1909), a description of 19th-century Buenos Aires; BERNARDO CANAL FEIJOO, *Teoría de la ciudad argentina* (1951), a penetrating discussion of the role of Greater Buenos Aires within the country's structure; EZEQUIEL MARTINEZ ESTRADA, *La cabeza de Goliath* (1940, various editions), an explanation of the difference between Buenos Aires and other Argentinian cities.

(J.M.F.P./Jo.B.)

Buffon, Georges-Louis Leclerc, Comte de

Buffon was a French naturalist famous for his comprehensive work on natural history. He is also remembered for his celebrated *Discours sur le style* (1753), in which he said, "Le style c'est l'homme même" ("The style is the man himself").

Buffon, engraving by C. Baron, 1761, after a painting.
By courtesy of the Hunt Botanical Library, Carnegie-Mellon University, Pittsburgh, Pennsylvania

Early years

He was born Georges-Louis Leclerc on September 7, 1707, at Montbard in Burgundy. The name Buffon came from an estate that he inherited from his mother at about the age of 25. His father, Benjamin Leclerc, was a state official in Burgundy; his mother was a woman of spirit and learning, and he was fond of saying that he got his intelligence from her.

Beginning his studies at the College of Godrans in Dijon, which was run by the Jesuits, he seems now to have been only an average student but with a marked taste for mathematics. His father wanted him to have a legal career, and in 1723 he began the study of law. In 1728, however, he went to Angers, where he seems to have studied medicine and botany as well as mathematics.

He was forced to leave Angers after a duel and took refuge at Nantes, where he lived with a young Englishman, the Duke of Kingston. In his correspondence he gives an impression of the town, where "one lives very well and drinks excellent wine." The two young men travelled to Italy, arriving in Rome at the beginning of 1732. They also visited England, and while there Buffon was elected a member of the Royal Society.

The death of his mother called him back to France. He settled down on the family estate at Montbard, where he undertook his first research in the calculus of probability and in the physical sciences. Buffon at that time was particularly interested in questions of plant physiology. In 1735 he published a translation of Stephen Hales's *Vegetable Staticks*, in the preface of which he developed his conception of scientific method. Maintaining an interest in mathematics, in 1740 he published a translation of Sir Isaac Newton's *Fluxions*. In his preface to this work he discussed the history of the differences between Newton and Leibniz over the discovery of the infinitesimal calculus. He also made researches on the properties of timbers and their improvement in his forests in Burgundy.

In 1739, at the age of 32, he was appointed keeper of the Jardin du Roi and of the museum that formed part of it through the patronage of the minister of marine, J.-F.-P. de Maurepas, who realized the importance of science and was anxious to use Buffon's knowledge of timber for the shipbuilding projects of the French government. Maurepas also charged Buffon to undertake a catalog of the king's museum, which Buffon's ambition transformed into an undertaking to produce an account of the whole of nature. This became his great work, *Histoire naturelle, générale et particulière.*

The *Histoire naturelle*

Though he laboured arduously on it—he spent eight months of the year on his estate at Montbard, working up to 12 hours a day—he was able to publish only 36 of the proposed 50 volumes before his death. He had several collaborators. In the preparation of the first 15 volumes, which appeared in the years 1749–67, he was assisted by several associates. The next seven volumes formed a supplement to the preceding and appeared in 1774–89, the most famous section, *Époques de la nature* (1778), being contained in the fifth of them. They were succeeded by nine volumes on birds (1770–83), and these again by five volumes on minerals (1783–88). The remaining eight volumes, which complete the first edition, appeared after Buffon's death; they covered reptiles, fishes, and cetaceans. To keep the descriptions of the animals from becoming monotonous, Buffon interspersed them with philosophic discussions on nature, the degeneration of animals, the nature of birds, and so forth.

He was elected to the Académie Française, where he delivered his *Discours sur le style* on August 25, 1753. He was also treasurer to the Académie des Sciences. During the brief trips he made each year to Paris, he frequented the literary and philosophical salons. Though he was a friend of Diderot and d'Alembert, he did not collaborate on their *Encyclopédie*. He enjoyed his life at Montbard, living in contact with nature and the peasants and managing his properties himself. He built a menagerie and a large aviary there. He also transformed one of his outbuildings into a laboratory, with a furnace large enough to conduct experiments on the nature of fire.

Buffon's wife died in 1769, leaving him with a five-year-old son. The boy showed signs of brilliance; and when he was 17 Buffon asked the naturalist J.-B. Lamarck to take him along on his botanical travels across Europe. But the younger Buffon was not interested in study. He developed into a spendthrift, and his imprudences were to lead him to the guillotine during the Revolution (1794).

In 1785 Buffon's health began to decline. To his physical disabilities were added family cares, particularly the public liaison between his son's wife and the Duc d'Orléans. At the beginning of 1788, feeling his end near, he returned to Paris. Unable to leave his room, he was visited each day by his "sublime friend" Mme Necker, the wife of the finance minister Jacques Necker. He died on April 16. Mme Necker, who was with him to the very end, is said to have understood him to murmur, "I declare that I die in the religion in which I was born. . . . I declare publicly that I believe in it."

Buffon's position and influence

Buffon's position among his contemporaries was by no means assured. Though the public was nearly unanimous in its admiration of him, he met with numerous detractors among the learned. The theologians were aroused by his conceptions of geological history; others criticized his views on classification; the philosopher Étienne de Con-

dillac disputed his views on the faculties of animals; and many took from his work only some general philosophical ideas about nature that were not faithful to what he had written. Voltaire did not appreciate his style, and d'Alembert called him "the great phrasemonger." According to the writer J.-F. Marmontel, Buffon had to put up with snubs from the mathematicians, chemists, and astronomers, while the naturalists themselves gave him little support and some even reproached him for writing ostentatiously in a subject that required a simple and natural style. He was even accused of plagiarism but made no reply to his detractors, writing to a friend that "I shall keep absolute silence . . . and let their attacks fall upon themselves."

In some areas of natural science Buffon had a lasting influence. He was the first to reconstruct geological history in a series of stages, in *Époques de la nature* (1778). With his notion of lost species he opened the way to the development of paleontology. He was the first to propose the theory that the planets had been created in a collision between the Sun and a comet. While his great project opened up vast areas of knowledge that were beyond his powers to encompass, his *Histoire naturelle* was the first work to present the previously isolated and apparently disconnected facts of natural history in a generally intelligible form.

BIBLIOGRAPHY. Buffon's collected writings are in *Oeuvres complètes de Buffon*, 12 vol. (1853–55), rev. and annotated by PIERRE FLOURENS; *Oeuvres philosophiques de Buffon*, ed. by JEAN PIVETEAU (1954), including a detailed bibliography; and *Histoire naturelle, générale et particulière*, 44 vol. (1749–1804; Eng. trans., *Natural History, General and Particular*, 20 vol., 1781–1812).

Evaluations of his work are in E. GEOFFROY SAINT-HILAIRE, *Fragments biographiques, précédés d'études sur la vie, les ouvrages, et les doctrines de Buffon* (1838, Pillot edition); PIERRE FLOURENS, *Buffon: histoire de ses travaux et de ses idées* (1844); F. GOHIN (ed.), *Buffon: discours et vues générales* (1905); D. MORNET, *Les Sciences de la nature en France au XVIII^e siècle* (1911), essential to the study of Buffon, particularly the bibliography and the chapter on the controversial Buffon; L. ROULE, *Buffon et la description de la nature* (1924), emphasizes the scientific value of his work and the introduction of the idea of time into the study of nature; and EMILE GUYENOT, *Les Sciences de la vie aux XVII^e et XVIII^e siècles: l'idée d'évolution* (1941), which contains lengthy passages on Buffon, notably on the origin of the idea of evolution, the idea of transformism in Buffon, and Buffon as the precursor of Lamarck. For an analysis of the contribution of Buffon's thought to the doctrine of evolution, see A.O. LOVEJOY, "Buffon and the Problem of Species," *Pop. Sci. Mon.* 79:464–473, 554–567 (1911); and J.S. WILKIE, "Buffon, Lamarck and Darwin: The Originality of Darwin's Theory of Evolution," in P.R. BELL (ed.), *Darwin's Biological Work* (1964).

Building Construction

Protection from inclement weather, human enemies, and animals has always been one of man's basic needs. His first attempts to provide such shelter were crude, involving such primitive constructions as screens and windbreaks made of interwoven branches, reeds, and animal skins. Man seems always to have understood the elementary principles of building and to have been blessed with a sense of structure; with similar raw materials—mud, stone, and timber—widely scattered groups often built the same type of structure. As time passed, man refined his knowledge through practical experience; advances in structural techniques roughly paralleled those in industrialization and mathematics.

This article is divided into the following sections:

I. History of construction
  Ancient construction materials and methods
    Reed and straw construction
    Thatching
    Wood construction
    Masonry construction
  The development of modern materials and methods
    Metal construction
    Concrete construction
    Building systems
II. Modern building construction
  Preconstruction planning
    Design programming

    Finish hardware
    Auxiliary systems

I. History of construction

ANCIENT CONSTRUCTION MATERIALS AND METHODS

Reed and straw construction. Before the ancient Egyptians began to quarry stone, little material was available for building other than the reeds, rushes, and mud of the Nile Valley. In a few cases, date-palm stems were used. In building reed houses (Figure 1), the reeds, which grew

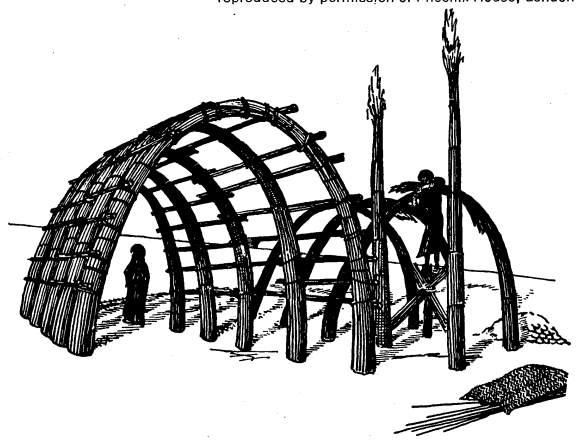

Figure 1: Reed dwellings under construction.

up to 20 feet (six metres) in height, were cut and tightly bound into bundles to form long tapering pillars that were set vertically in two parallel rows of holes about two and a half feet (75 centimetres) deep. Next, a tripod five to six feet (150 to 180 centimetres) high was made from cut and bound reed bundles. Standing on this rigid structure, a man would reach up, bring the tops of two parallel reed columns together and bind the ends securely with the twisted edges of a sedge leaf. The tripod was then moved to the next pair of columns, and the process was repeated until a series of high parabolic arches had been made. When the arches were complete, slender bundles of reeds were tied horizontally to them, and the entire structure was covered with reed matting. Finally, other tapered pillars were set up at the ends of the structure to support an end wall of alternating matting and trelliswork. This construction principle has survived for 6,000 years and can be seen in the modern reed dwellings in the Mesopotamian marshes of southern Iraq.

Use of reed ceilings

Reeds have also been used for reinforcing and constructing roofs, floors, and ceilings. A flat ceiling in a house at Eutresis in ancient Greece was made by placing a layer of clay reinforced with reeds upon closely spaced timbers spanning the main beams. Matting was then laid over the secondary beams, followed by a layer of reed, a second layer of matting, and a mixture of mud and chopped straw. These materials were made watertight by applying bitumen. According to Vitruvius, the Roman architect and engineer, the Romans used reeds in constructing curved ceilings. Parallel laths of cypress wood were placed not more than two feet (60 centimetres) apart and bent to the shape of an arch. Reeds were then bound to the ribs with cords of Spanish broom. After completion of the arches and their interweaving with reeds, the undersurface was finished with mortar (made with sand and hair) or marble.

Reeds were used in England until about 1850 in plaster

floor construction (Figure 2). A layer of reeds or straw was placed across floor joists, secured with batten strips (light strips of wood), and covered with about three

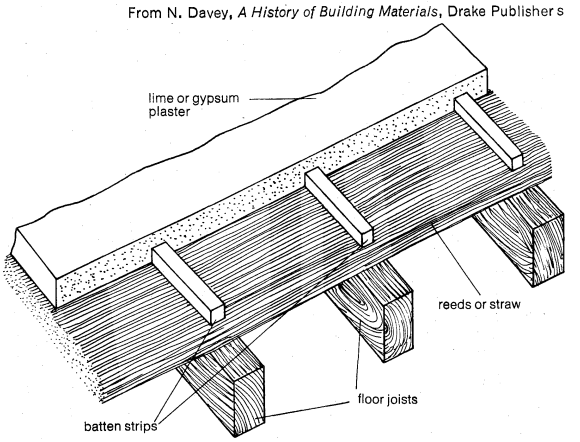

Figure 2: Lime or gypsum over reed or straw floor construction in England about 1850 (see text).

inches (75 millimetres) of lime or gypsum plaster. In some cases, ashes, sand, or crushed brick were included in the mix. Reeds and straw have also been employed in wall construction; the reeds were placed vertically, staggered, and tied to horizontal ribs about two inches (five centimetres) in diameter. A mixture of clay and chopped straw was then pressed into the voids and the wall surface finished with a clay coating.

Thatching. Thatching involves covering the rafters or beams of flat roofs with some vegetable material held in place by various methods. Depending upon locality, brushwood, grass, broom, bracken, or heather may serve as thatch; it may be sewn direct to the battens, nailed to the rafters, held down with rods secured by ropes stretched over the surface with ends tied and weighted, held by ropes fixed by pegs; or held by knotting the ends of the sheaves or bundles and thrusting them into or between turves (bundles of turf). Layers of mud or a straw-mud mixture may be used to fill any voids.

Where turves were used, as in Ireland, they were cut in long strips, sometimes 20 feet (six metres) or more in length and up to two feet (60 centimetres) in width, and about two to three inches (50–75 millimetres) thick. They were sewn with grass upward onto the battens and purlins (horizontal timbers supporting the rafters) of the roof structure. Where there were no battens or purlins, a layer of straw, woven to form a mat, was used, and the sheaves or bundles of thatch were attached.

Rope thatching methods

Rope thatching is still done in Scotland and Ireland. The straw, which in these countries may be heather, flax, or rye straw, is placed in layers on a sloped roof and held down by ropes. The ropes are sometimes tied to stones projecting from the wall at the eave, or they may be weighted by stones. In the Soviet Union, particularly in the Ukraine, the roof is covered with small bound sheaves or bundles of straw placed with the ears downward, except at the eaves, where the sheaves are placed with the ears upward. The sheaves are then tied to the battens with twisted straw.

Wood construction. *Trunks and staves.* During the period of reed and straw construction (about 5500–2500 BC), men in warmer climates where timber was plentiful (Britain, for example), began to construct rectangular dwellings with single or multiple rows of posts to support the roof. Interiors were often subdivided by partitions into compartments or rooms, whereas the floors were often covered with roughhewn timber planking, and occasionally with birch bark. From about 2500 to 1500 BC, walls in Europe were built of split trunks or planks. A variation of this type of construction, which included upright planks or staves embedded in a wall trench, was later found in Danish fortresses and churches such as the 11th-century AD St. Maria Minor at Stavkyrkaus. In this structure timbers were grooved along their sides, and tongues of wood were let in. One of the few remaining stave churches (built about AD 1013) stands near Ongar, Essex, in England.

Logs. Where straight-trunked trees, such as pine, fir, and beech, were available, as in Scandinavia, the French and Swiss Alps, northern Italy, Czechoslovakia, the Soviet Union, and the Himalayas, log-cabin-type construction began to appear. Gaps between the timbers were filled with wood chips and mud. In a dwelling of this type near Stockholm, the roof at the eave has a special board that projects above the roof line to retain the heavy snow and thus to provide additional insulation in the winter. Log cabins in the Ukraine consisted of roughly squared full logs coated with clay both on the interior and exterior. In another Russian method, the underside of the log was hollowed over its entire length so that it rested on the log beneath. Moss was then stuffed into the joists.

Wood frames. Since log cabins used large amounts of timber, a wood frame or structure with a wattle and clay daub in-fill was more economical in areas where timber was scarce. Chopped straw or grass was often added to the clay daub to act as a binder and lessen the effects of shrinkage cracking. By the 16th century this had evolved into half-timber construction, in which the timber was vertical, closely spaced, and mortised into horizontal wall plates and sills. Uprights were grooved from top to bottom; split oak lath was wedged into these grooves. In other cases, square-panelled construction was preferred. The uprights were more widely spaced and horizontal timbers were introduced. Since durability was a problem with wattle and clay daub, a good roof overhang was required; in the case of a two-story dwelling, the second-floor beams and walls overhung the wall of the first story. For a complete description of wood frame construction, including the various joints used, see CARPENTRY. Wooden bridges and their construction are described in BRIDGES, CONSTRUCTION AND HISTORY OF.

Roofs. During the late 17th century, four major types of roofs—the gable, gambrel, hipped, and rainbow—were in use. The gable roof, which was the simplest, consisted of two planes sloped on each side of a ridge, usually but not always centred on the short dimension of the dwelling. The gambrel was a gable roof in which one plane broke about half-way down from the ridge to slope at a steeper pitch. The hipped roof sloped to all four sides of the dwelling; and in the rainbow roof, the side planes normally bowed out in a convex curve. Another rather common type of roof, found in the New England region of America, was the single-pitch or lean-to, typically used to cover an extension to the house.

Masonry construction. *Egypt.* Though brick and stone, or masonry, construction can be traced as far back as the 3rd millennium BC, it did not achieve real development until the Middle Ages. The earliest stone buildings—palaces, temples, tombs, and monuments—are recorded in Egypt during the 4th millennium BC. Cut slabs of limestones were used for lining and roofing of small chambers. Probably the earliest complete stone building that can be dated accurately is the pit chamber of the tomb of King Khasekhemui of the 2nd dynasty (*c.* 2890–*c.* 2686 BC). Sandstone was also used in ancient Egypt but in no great quantity until the 18th dynasty (1567–1320 BC); granite, alabaster, basalt, and quartzite were reserved mainly for monumental and decorative purposes. The most remarkable of Egyptian masonry constructions were the pyramids, made mostly of rough-dressed limestone cased with fine white limestone.

Greece. The ancient Greeks demonstrated considerable versatility in masonry construction, fitting blocks together with remarkable precision and artistry. Early types of stone walling used by the Greeks were built with very large and heavy pieces, irregular in shape, roughly trimmed, piled skillfully, and wedged together by filling the interstices with smaller pieces of stone, sometimes bedded in clay. With the development of mortar that attained considerable strength on hardening, it became possible to construct walls with a concrete core capable of taking most of the load and to face them with stones

Development of mortar

smaller than those used previously. This was done mainly for appearance and convenience. Later, the Greeks constructed concrete walls by placing stones in layers inside formwork, pouring mortar over each layer, and inserting string courses (narrow layers of stone or tile at the same height in a wall) every three or four feet (90 to 120 centimetres) to improve stability. By the 2nd century BC, concrete was being produced by incorporating stone in a mortar mix.

Brick. Bricks came into use because of their strength and durability, ease of production from readily obtainable clays, and lower cost in comparison to stone. In some areas, builders were compelled to use small units of material such as bricks because the local geology did not supply stone in blocks sufficiently large. The Chaldeans, for example, developed brick arches for the openings in their buildings, whereas the Greeks and Egyptians were able to find large blocks of stone to span wide openings. Modern brick construction had its most rapid development in the American colony of Virginia in the 17th century. The most skilled brick masons in the colony were the Dutch, who became the first to use and build with glazed brick and tile. Their work is exemplified by Bacon's Castle, a monumental house built about 1655 in Surry County, Virginia.

Arch, vault, and dome. The arch is primarily used for spanning intervals of space in one major vertical plane by means of inclined or curved masonry, as opposed to horizontal beams. When masonry forms based on the arch are used to cover extended spatial compartments, the result is a vault. Within the limits of masonry construction, arches have two advantages over horizontal beams: they can span much greater distances and they can carry much greater loads. In all likelihood, the arch was conceived by accident when a lack of large stones compelled builders to use bricks and other small units of material. The true or radiating arch, in which each voussoir (wedge-shaped piece) is stepped upward and outward (corbelled) away from its support, dates from the period of Etruscan architecture, about 750 BC. It was in Roman Italy during the late republican period that the arch was first exploited on a grand scale both as a structural device (in aqueducts) and as a symbolic form (in triumphal arches).

The arch in Gothic buildings

During the four and a half centuries from 1100 to 1550 arches were most widely used in European architecture, especially in churches and monastic buildings whose ribbed vaults and flying buttresses reveal the arch as the first principle of Gothic structural engineering. Churches of that period became veritable systems of arches in which walls, windows, and roofs served only as screens against the weather. Though the arch was undoubtedly used during this period for its structural advantages, its symbolic value in making churches splendid structures was important as well.

A dome is an ovoidal or hemispherical vault, or a vault of polygonal plan that resembles the round dome in shape. Masonry dome construction was important during Roman times; the Pantheon, built under Hadrian between AD 120 and 124, with a diameter of about 125 feet (38 metres), displayed a masterful command of large-scale domical construction in brick, with an intricate system of built-in relieving arches. The construction was heavy, the only opening being a great "eye" at the top. A great advance in domical construction was made by Byzantine architects when they developed the pendentive (a triangular segment of a spherical surface filling in the upper corners of a room in order to form, at the top, a circular support for a dome), enabling them to dome over a plan of any shape. The greatest Byzantine dome was that over the basilica-plan church of Hagia Sophia at Constantinople (originally built 532–537). So skillfully and subtly was the weight of this 100-foot-wide, 180-foot-high (30 by 55 metres) dome transferred through pendentives to side walls and buttresses, that on the interior it gave what a contemporary described as the effect of being "suspended on a golden cord from heaven." Muslim builders, under Byzantine influence, used the dome in a lavish form but on a small scale in Spain and North Africa, and they developed it along Byzantine lines in Egypt, Persia, India, and Turkey.

THE DEVELOPMENT OF MODERN MATERIALS AND METHODS

Metal construction. The adoption of iron as a structural material, the most far-reaching revolution in the history of building, resulted from that material's desirable physical properties such as strength and incombustibility and from a new scientific approach to building construction.

Though the use of iron in details of construction (*e.g.*, for clamps in masonry) can be traced back to classical antiquity, the material did not come into its own until the Industrial Revolution of the 18th century. The earliest employment of primary structural elements made of iron came with the construction of St. Anne's Church in Liverpool, England (1772), which was built of cast-iron columns and wood beams. The first industrial structure of iron was a calico mill at Derby, England, in 1792–93. The collapse of many iron structures, however, is clear evidence that iron was little understood and that scientific investigation was needed. Iron structural members for buildings were introduced in the United States in Philadelphia and New York. Though iron-fronted and iron-framed buildings continued to be erected through the 19th century, their number dwindled after the American Civil War.

Growth of the railroads created a demand for fire-resistant bridges capable of spanning relatively large distances and carrying substantial loads; iron met these requirements. The iron arch was created, followed by the iron truss, which first appeared in a railroad bridge built in Manayunk, Pennsylvania, in 1845. A truss is an assemblage of members such as beams in triangular combinations to form a rigid framework; adoption of the iron truss in railroad bridges spurred experimentation with this new device, leading to several different designs and the use of the truss in iron-framed buildings.

First use of iron truss

The forms and techniques of the new large-scale urban building were largely developed in Chicago, where the Auditorium Building of 1889 employed elliptical trusses with a maximum span of 117 feet (36 metres) to carry its ceiling and flat trusses to support the roof over the theatre, the ceilings of the main dining room and banquet hall of the former hotel (now a university building), and the ceiling of the rehearsal hall above the theatre. The remainder of the hotel and office areas were framed in iron within the granite and limestone piers of the exterior walls. The final step in the creation of the framing that made the modern skyscraper possible came with the Home Insurance Company Building (1885) erected in Chicago, in which an internal skeleton and curtain wall were used for the first time in a rigorously functional high office building. The most advanced features of the framing system in this building were the method of supporting each bay of the wall on a shelf angle and the introduction of steel into the building frame. Four years after the Home Insurance Company Building was complete, the steel-framed skyscraper had totally evolved in Chicago. The final step in the creation of the modern skyscraper came with the construction of the second Rand McNally Building in 1890. The frame of this high office building was wholly freed from its masonry parts and built entirely of steel.

By 1894, the problem of foundations had been solved with the placing of concrete caissons extending to bedrock. The structural culmination was reached with the Reliance Building (1895), erected in Chicago, which was braced by 24-inch- (60-centimetre-) deep girders, supporting exterior panels (spandrels), to provide portal bracing, and two-story columns erected with staggered joints to increase the rigidity of the vertical members.

A rigid frame is one that has triangularly arranged members and moment-resisting joints; *i.e.*, they resist tendencies to produce motion. Such a frame can be designed so that under a vertical load the tensile and compressive stresses arising from the deflection of a beam are distributed equally among three members rather than concentrated in the horizontal member. Though originally used

in bridges, the rigid frame was adopted for buildings in the early 1930s. A three-dimensional arrangement of trusses is known as a space frame; an early structure with such a frame, designed for maximum rigidity and minimum weight, was the George Washington Bridge (1927–31) in New York City. Another important innovation in steel construction was welding, used to its greatest potential in the Inland Steel Building (1955–57) of Chicago, in which all the floors and roof loads are carried by 58-foot (18-metre) transverse girders to seven pairs of columns outside the wall planes of the long elevations.

Although the dome had disappeared for the most part as an element in building construction, it reappeared in the 20th century in a number of functional designs to shelter the maximum area at the least cost. The idea of metal shells and stretched membrane, or stressed skin, found its way into specialized construction; this technique combined curtain wall and roof in a single continuous enclosure by stretching a thin aluminum skin over a framework of ribs.

Invention of the geodesic dome

Perhaps the most heralded structural invention of the 20th century is the geodesic dome, patented by R. Buckminster Fuller in 1947. Fuller's primary intention was to substitute a great number of light, mass-produced, hand-assembled elements for the heavy ribs and purlins of the conventional steel-framed dome. The dome is a thin cover of aluminum or plastic pinned to a framework of steel or aluminum tubing arranged in a pattern of triangles or hexagons. By the nature of triangles and hexagons, the structure is a rigid framework theoretically limited to compressive stresses. In 1958, an immense geodesic dome was designed to house the car-repair facilities of the Union Tank Car Company at Baton Rouge, Louisiana. The first use of a plastic skin was at a botanical conservatory built in St. Louis between 1961 and 1962.

Concrete construction. Though concrete is the oldest synthetic material used in building construction, there was a period of about 13 centuries when knowledge of it was wholly lost in Europe. The Romans were known to have employed concrete made from pozzolana, a clean, sandy earth, to construct domes, vaults, and walls; these were faced with brick, stone, alabaster, porphyry, and other marbles. In conjunction with brick and stone casing, concrete gave uniformity of style to Roman architecture. Concrete was used by Mayan builders as early as the 11th century, but this work had no influence on later building in the New World.

Not until the late 16th century was concrete rediscovered as a result of systematic investigations carried on by the English civil engineer John Smeaton preceding the reconstruction of the Eddystone Lighthouse off the Plymouth coast. Though concrete was used in construction from that time, the modern scientific age of concrete did not begin until 1871, when the American David O. Saylor patented an equivalent of Portland cement, built a production centre, and studied its physical properties and structural behaviour in a systematic manner. By 1880, concrete, either poured in place or cast as blocks, had come to be used for a wide variety of simple structural elements such as piers, walls, and footings. The pioneer concrete multistory building was the Ponce de Leon Hotel (1886–88), in St. Augustine, Florida. The footings, foundations, main exterior walls, and some interior walls were monolithic concrete with a shell aggregate. Concrete was also applied successfully to bridges and dams.

Unlike iron construction, the technology of reinforced concrete developed rather rapidly. Reinforced masonry had spread from France to England and the United States in the early half of the 19th century. Not until 1854 did the idea arise of strengthening concrete in a similar manner; in 1867, concrete was first reinforced with iron bars. The first building constructed of reinforced concrete was a residence in Port Chester, New York, erected between 1871 and 1876. With such progress in reinforced concrete construction, engineers, especially in France and Germany, began adapting the new techniques to arch bridges. A more efficient design was now possible because the reinforcing metal could do the work formerly done by large volumes of concrete.

The first skyscraper of reinforced concrete was the 16-story Ingalls Building in Cincinnati, Ohio, erected between 1902 and 1903. The main tendency in American concrete construction was to meet larger loads simply by increasing the size of structural members. Employing reinforced concrete made it possible to eliminate long beams and trusses, an important advantage in warehouses and freight-handling facilities where overhead space is quite valuable. Known as flat-slab construction, this technique eventually reached the point of maximum simplicity, marked by slabs of uniform depth and columns of uniform section, that freed the vertical space entirely of beams, capitals, and other structural details.

Building systems. Though the construction industry constantly innovates, changes tend to be incremental and evolutionary rather than revolutionary. Perhaps the greatest change in recent years has been the emergence of building systems (mass production of prefabricated buildings) immediately following the end of World War II in Europe. Among the most important contributing causes to the replacement of traditional hand methods by industrialized building systems were the shortage of manpower, especially skilled craftsmen; the extensive demand for housing units due to bombing destruction; the need to reduce costs while erecting buildings rapidly; and the participation of national governments in public housing programs. Generally speaking, industrialized building systems have made their swiftest progress in countries such as France and the United Kingdom, where a large percentage of the total construction program is financed by the national government; slower progress has been made in such nations as Germany and Italy, where the private sector is stronger. About 25 percent of new construction in western Europe employs building systems, whereas for eastern Europe, approximately 60 percent is estimated.

Currently, hundreds of specific systems are available for use throughout Europe, differing in details such as materials used, dimensions of panels, and intended end use (*e.g.*, single story, multi-story; residential, school). Development of a building system is commonly initiated by contractors, engineers, clients, or manufacturers. To date, contractors and engineering organizations dominate the field.

Open and closed systems

A system may be either open or closed. In an open system, the components are interchangeable with those of other systems with which they are dimensionally coordinated. Conversely, a closed system is one in which the components are designed and coordinated only for that system. The trend today is toward open systems, which offer the architect greater flexibility.

Though building systems are widely used in the United States, they are usually not so identified. All home manufacturers, metal-building producers, mobile-home manufacturers, and some industrial firms, for example, have their own building systems encompassing design, manufacture, transportation of components, erection, and finishing. Generally speaking, United States systems employ lighter building materials than their European counterparts and emphasize single-family dwelling units and other low-rise structures rather than medium and high-rise structures.

Box systems. Basically a modular volumetric unit composed of some combination of walls, roof, and/or floor, the box system is usually prefabricated in a plant; its degree of factory finish and the extent of mechanical services included varies considerably among manufacturers. The box can be transported to a site and stacked, hung, inserted, or grouped according to project requirements. The system is relatively new; considerable interest was stirred by the Canadian government's Habitat, a box system displayed at Montreal in 1967.

Panel systems. The panel system utilizes either load-bearing exterior walls, load-bearing cross-wall construction, or a combination of exterior and interior load-bearing panels. Basic sizes of these panels vary considerably from small sections to room size. The lower cost, cross-wall type of construction is currently quite popular; its major advantage is that since the interior walls, floors,

and roofs resist both vertical and lateral loads, a non-load-bearing facade panel can be used that permits exterior design flexibility.

Frame systems. Almost any curtain-wall building can be classified as a frame-system building; this system is used more than any other. Pre-engineered frame-system buildings can be used for dormitories, apartments, and industrial or commercial structures.

II. Modern building construction

PRECONSTRUCTION PLANNING

Before any building project can be undertaken, numerous decisions must be made. The design program must be resolved. The site must be chosen and economic feasibility determined. Finally, a completed design for the building must be made. Each of these elements is important; none can be considered in isolation of the others.

Design programming. Frequently a decision is made to construct a building before much has been determined about its function. In the case of a residence, little information is needed to make the decision to build. In the case of other buildings, such as offices or retail stores, questions of actual need may arise, and a market analysis (see below) may be performed. Once need has been determined, it is necessary to develop guidelines for designing and building the structure. The first step in this process is to determine how the building is to be used—its overall function and the purposes various spaces within it must serve. In a residence, for example, the potential occupant must determine his needs: living, sleeping, food preparation, dining, bathroom, storage areas, and special design features, such as a fireplace, wood panelling, and air conditioning. Typically, a residence does not require very comprehensive programming or study. The potential owner or occupant may do nothing more than describe his desires to an architect or builder, who then translates them into design sketches.

Larger buildings, such as offices, schools, and industrial buildings, require more comprehensive programming.

Determination of future needs

School planners, for example, may attempt to project future student population in order to determine the size of the building. Present and future curricula may be analyzed before a specific design program, including classrooms, gymnasium, library, etc., is drawn up.

In most countries, if a project under development is to be sold or leased, the ability of the owner to market the project at a reasonable return will be critical in determining the project's feasibility. Marketing analysis is undertaken for projects such as multifamily housing, office, commercial, and selected industrial buildings, and even new towns. The method used can be either simple or comprehensive and complex. The approach will vary with the type of construction. In determining the market for a housing project, for example, analysts may examine the supply of housing in the area, projected population and employment, and the levels of income expected by future residents. In this way both the extent and market value of housing demand can be estimated. The extent of market competition is usually also analyzed.

Site selection and land acquisition. Before the market analysis can be completed, there must be a decision on the approximate geographic location of the project. To make this decision, specific information is needed on such points as land value; tax rates; availability of utilities; drainage; relationship to the transportation network; zoning, if any; and number of workers in the immediate area of the site. This kind of information is typically obtained and organized in map form. Another important map tool is a diagram showing areas of accessibility to home, to work, or to a shopping centre. In considering a shopping centre, for example, the distance of the site from potential shoppers is of major importance. In a project such as a general office building, the distance of the site from major transportation lines is usually a consideration.

Maps used in planning

As the market analysis progresses, various site advantages and disadvantages can be considered. Finally, one site is given priority over others under consideration. Final site selection is generally delayed until the financial feasibility study is well underway.

Architectural design, specifications, and bidding. *Schematic design.* During financial-feasibility analysis, and before any construction-cost analysis is made, simple schematic design sketches are prepared to illustrate the design-program requirements. Generally, these sketches as well as the more detailed design, construction drawings, and specifications are prepared by an architect.

The purpose of schematic design sketches is to assist the client in his understanding of the design program, to illustrate possible solutions within the shortest possible time and at a minimum expense, and to assist the client in determining the feasibility of the project. A series of sketches, sometimes a long series, is made in the process of studying the possibilities of the problem and in attempting to find an acceptable solution within the imposed financial limits. Schematic sketches include building plans, elevations, perspectives, and site utilization. Three-dimensional models can facilitate the study of mass, proportion, scale, and the relation of parts. When the project is a part of a larger development, such as a master plan of a downtown area or a university, the relationship should be indicated and explained.

Besides the sketches, other information is developed by the architect, such as the ratio of the gross floor area to the area to be used for the purpose of the building. For some types of building, calculations of floor area per occupant or per unit of production are useful. In addition, a preliminary cost estimate is prepared by taking data available from recent similar projects and applying unit costs (*e.g.*, per square foot or metre, per cubic foot or metre, per bed, per student) to the proposed project to determine the estimated cost. If there is a variance in number of stories, type of construction or finish, mechanical equipment, labour or material costs, the unit cost is modified.

At the time the schematics are being developed, the architect considers applicable zoning restrictions. In most countries, zoning controls are regulatory tools used by local governments to guide land-use development. Typically, a zoning ordinance prescribes how each parcel of land in a community may be used and covers land use, population density, and building bulk. Many zoning regulations divide uses into three categories: residential, commercial, and industrial. Population density is also controlled by setting a minimum required size for each lot. In other cases, the number of families per acre or hectare may be limited. Building bulk is limited by limiting building height, the proportion of lot area that may be covered by buildings, and open spaces along lot boundaries. The architect is expected to take these and other requirements into consideration during the design stages.

Building codes

National or local building codes are also important at this stage of planning. A building code is a series of standards and specifications designed to establish minimum safeguards in the erection and construction of buildings, to protect against fire and other hazards, and to establish regulations to further protect the health and safety of the public.

Detailed design development. Once the schematic design has been approved by the client, detailed design development goes forward, comprising drawings of plans, elevations, building cross sections, perspectives, and in some cases three-dimensional models. This stage includes illustration and description of the site development, materials, structural system, mechanical equipment, and even interior furnishings. In studying and developing the design for these components, it is necessary to have at least tentative data concerning the location, kind, and size of structural members (*e.g.*, wood, steel, or concrete); location and size of heating and air-conditioning components; elevators and moving stairways; plumbing; illumination; acoustical system (*e.g.*, acoustical ceiling and materials in theatres); and general colour scheme.

During the design-development stage, the architect typically collaborates with other consultants, such as a landscape architect, structural engineers, mechanical engineers, and cost consultants. Also during this stage, outline specifications are prepared. Thus, a more definite basis is provided for a more detailed cost estimate, which

should also be prepared. The method used for preparing this cost estimate is similar to that employed in preparing the cost estimate during the schematic-design stage. It is based upon unit cost per square foot or metre, unit cost per cubic foot or metre, or cost per occupancy unit.

Working drawings and specifications. Once the detailed design has been approved by the client, the architect may move into the development of working drawings and specifications. These are essentially the contract documents, upon which depend exactness in construction-cost estimating and the effectiveness of the contractor to determine the current market price by competitive bidding. A good set of working drawings is clear and simple, arranged in an orderly and readable manner on the sheet, and accurately drawn, so that scaled measurements agree with the illustrations. In general, the working drawings include the design, location, and dimensions of the elements of the building.

The plans and elevations prepared during the design development can be used for the working drawings if they are at the same scale. As the working drawings develop, details of parts of the building are made at large scale (in some cases full scale) to indicate how the various materials and parts fit together. Dimensions are established as soon as possible, so that those working on other phases of the project can use them.

In addition, schedules included on the working drawings present information on room finishes, wall finishes, floor finishes, hardware, opening lintels and arches, columns and footings, doors and frames, lighting fixtures, kitchen equipment, and laboratory equipment.

During the development of the working drawings, a detailed set of specifications is prepared. Specifications, the written description of the work to be done, form part of the contract and describe the quality of materials, workmanship, and the scope of the work to be performed in constructing the building. Typically, the sections are arranged in the order in which the respective building trades normally begin their work. Specifications also facilitate the assignment of the work to subcontractors and separate contractors; for example, for special equipment to be installed in a hospital or laboratory. Each section includes a description of the scope of the work and a description of the various categories of material and labour.

Arrangement of specifications

After the award of the contract, the construction phase begins, and a list of subcontractors and a cost breakdown are furnished by the successful contractor. At this point the contractor becomes a part of the team with the owner and the architect; one of the first tasks during the construction phase is the preparation of the necessary formal agreements among the different parties and supplying of bonds to guarantee performance of work.

ELEMENTS OF BUILDING CONSTRUCTION

Surveying procedures. The first step in beginning any actual building at the site is either a land survey or laying out the building foundation on the site. If a large parcel of land is involved in a proposed development and it is necessary to establish new boundaries or if it is necessary to establish subboundaries inside the land acquired for the project, a land survey is undertaken. Laying out the building on the site is done by marking each corner of the proposed building and running string lines from corner to corner.

In laying out a building foundation, the first step is to locate one corner of the building. This first corner can be located by measuring a specified distance from a curb or other given point, depending upon the site layout in the architectural drawings. At this point a stake can be driven. A transit or level can then be set up over the first stake and the building lines set. Once the lines are set, wood batter boards (two horizontal boards nailed to stakes approximately 4 to 10 feet [one to three metres] outside the corners of the building) may be erected. The actual excavation line may then be laid out using string with the ends tied to the batter boards. At this point the site is ready for excavation.

Foundations and footings. Those portions of a building resting upon the earth or rock are known as the foundations or footings. The foundation is closely dependent upon the design and weight of the building and on the conditions and behaviour of the subsoils involved. As a result, detailed study must be given to calculating the size of the foundation and its strength as well as determining the characteristics and resistance of the earth or bed upon which they rest. Thus, the two sets of forces—those applied by the structure itself and those applied by the subsoil beneath the structure—must balance with each other. If the subsoil is unable to develop the needed forces of resistance to the forces of the building, functional failure will occur in the form of excessive or unequal settlement.

Three methods are employed to achieve the proper size of foundation for supporting a building. In the first, foundations may be spread to distribute the load over the earth or bed so that the safe bearing capacity of the bed per square foot is not exceeded. Alternatively, excavations can be made through unstable materials until a stratum of soil or bed of rock is reached, the bearing power of which is sufficient to carry the loads. The foundations as a whole or the footings under individual walls and columns are then built upon this base. These footings may also be spread to distribute the load. In the third method, long shafts of wood or concrete known as piles are driven into the ground until they are sufficiently embedded to carry the loads without further sinkage or until their lower ends rest upon rock. The footings and column bases are then built upon the tops of these piles.

Testing the earth under a structure

The first element of foundation construction is to test the strength of the material upon which the proposed foundation is to sit. Several methods of testing in common use involve determining not only the nature of the materials that might be encountered but also what underlies them and at what depths water or rock might be encountered. The four typical methods of testing are test pits, auger borings, wash borings, and core borings. Test pits may be dug in the ground to explore the actual conditions. Auger borings are made with an ordinary two-inch or 2½-inch auger fastened to a pipe or rod. The auger may be removed after a few turns, exposing samples of the strata. A wash boring may be used when the material is too compact for good results with an auger. The equipment for a wash boring consists of a pipe, two to four inches (five to ten centimetres) in diameter, driven into the soil and containing a smaller jet pipe through which water is forced. The flow of the water washes the material at the bottom up to the surface, where it is collected and examined. Core borings, however, are probably the most dependable. These can penetrate to great depths, through all materials, including rock, and bring up complete cores of the material they pass through.

Footings and foundations for light buildings. Probably the simplest and most common foundation is the masonry-wall foundation, used under light wood-frame construction in such buildings as residences and apartment houses. The foundation can be rather shallow, extending only to below the frost line, or quite deep, acting as the basement wall. It must be of sufficient thickness to carry the imposed loads of the structure above and must also resist the lateral forces of the earth that push on the outside face. The footing for such a wall foundation is usually plain concrete when the loads are small or reinforced concrete when the loads become heavier. Often a rectangular section having a depth of twice the projection from the face of the wall is adequate. Concrete masonry units of eight or 12 inches (20 or 30 centimetres) in thickness are then laid on top of the footing. Often the concrete masonry is reinforced with metal bars spaced 12 feet (3.7 metres) on centres and running from the footing to the top of the foundation wall.

When girders or roof trusses are supported on a wall, it is often necessary to thicken the wall, the foundation wall, and the footing to provide sufficient strength to carry the concentrated loads. In other cases a wide footing may be required to distribute the load from a wall so that the bearing capacity of the soil per square foot or metre is not exceeded. To save concrete and reinforcement the footing may be stepped from the width of the wall to the width required for the footing.

Footings for heavy buildings. Whenever a building—through its walls, piers, or columns—transmits such loads to the foundations that it is not economical or practical to use plain concrete footings, these may be combined or counterbalanced, and steel beams or reinforced concrete must be used. Although walls may at times be so loaded as to require reinforcement in the wall footings, heavy buildings are generally constructed so that they transmit their loads to the foundations through columns. These columns may be supported by a slab footing, a spread footing, a mat, or raft, foundation, or a pier. The slab footing and the spread footing are similar to that described above for light buildings. Of mat, or raft, foundation, there are two types—the beam-and-slab type and the flat-slab type. The beam-and-slab type is composed of beams running from column to column in both directions and slabs spanning from beam to beam; it is similar to a beam-and-slab floor construction except that the forces are inverted. The slabs lie on the underside of the beams and may be calculated as flanges of inverted T beams. An additional slab is constructed over the beams to provide a basement floor. The flat slab is similar to an inverted flat-slab floor construction except that a drop or slab thickening is placed under the slab at the column. The advantage of such a foundation is that the building will settle more uniformly. If the columns rested upon independent footings, some of which sank farther than others, severe cracking might occur throughout the structure.

Where piles are used, timber, precast or prestressed reinforced-concrete, or steel bearing piles are driven into the ground by a single-acting hammer or a drop hammer. The pile is driven down to a depth at which the soil resistance is adequate to resist the forces of the structure. The individual piles are designed to have the capability of transferring the load down to the point of sufficient soil resistance. Cast-in-place pier systems are excavated by the use of a mechanical auger in which concrete is placed. The Fondedile pile (Figure 3) is very much the same in

From R. Hammond, *Modern Foundation Methods;* Applied Science Publisher

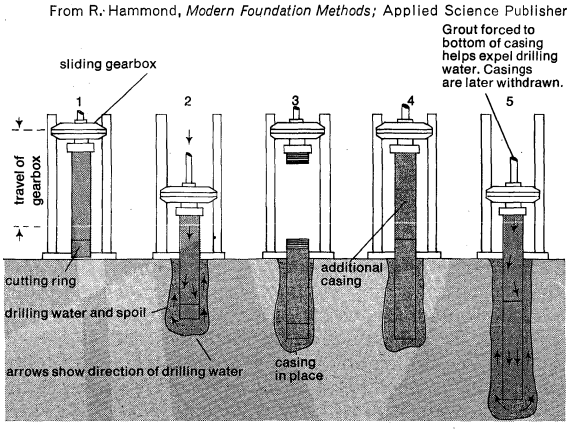

Figure 3: Sequence of operations for boring Fondedile pile in planting building foundations (see text).

principle. Here, a cutting ring is attached to a length of casing. The casing is then fed down to cut through the soil. Unlike ordinary cast-in-place piling, the Fondedile pile can reach to great depths by simply adding length of casing. The necessary reinforcing is then lowered into place and grout (waterproof cement) is forced to the bottom of the casing by pressure. As the grout rises, the drilling water also rises until it is expelled when the grout reaches the surface. The casings are then withdrawn one by one.

Floating or caisson foundation

In areas where the soil condition is poor, a floating foundation or caisson foundation is used. There large areas are excavated in relatively deep positions. The floating foundation, or caisson, can be sufficiently rigid to resist all moments (tendencies toward movement) applied by the distribution of concentrated loads over its surface. Its function is to reduce the overall loading at any given point by relieving the weight of soil originally lying above such point and then replacing the soil by a structure of approximately the same weight or slightly more. The result is that the soil is in the same condition as before excavation began and settlement is greatly diminished.

The structural frame. The selection of one particular structural frame system over another is determined by consideration of the many elements that prevail in the basic design of any building. Understanding the primary uses of the structure will obviously determine the required clear distances between supporting walls or columns and the necessary live and dead loads that are imparted.

For small structures, such as residences, a 12- to 20-foot (3.7- to 6-metre) clear span may be common. In a two- or three-story office building, spans may commonly approach 25 feet (eight metres). Because these types of structures carry a relatively light load, the design may call for a wall-bearing (weight-carrying) structure, either masonry or wood, with the interior bearing on light steel columns or masonry walls. If the structure is to be a warehouse or one where machinery is housed, it may be necessary to design a reinforced concrete or steel frame, even if there are only two or three stories, because of the large concentration of load. In one-story structures in which the structural frame is not required to carry a heavy load, long-span light steel or laminated-wood roof supports bearing on masonry walls or steel columns may be used. In certain instances, fireproofing and soundproofing of the structural frame may be needed, in which case a light steel frame may not be adequate.

Though building codes often restrict the designer to a limited number of structural approaches, many systems are available; one must be selected that will most closely fit requirements of strength, economy, and quality of design. The availability and cost of materials and labour, and the efficiency of the frame in regard to the architectural concept are other important considerations that must be made in selecting the structural frame.

Wood frame. The wood frame, being light and simple, is most common in residences, apartments, and other small structures. The first step in wood-frame construction is a solid concrete or masonry foundation. On top of the foundation wall or basement wall rests a wood member called the sill, usually a nominal two inches (five centimetres) thick and having approximately the same width as the supporting foundation wall. It is bolted into the wall at equal intervals to prevent it and the members it supports from pulling away.

Balloon and platform frames

There are two common methods of constructing the exterior walls of a wood-frame building: the balloon frame and the platform frame. The essential characteristics of the balloon frame—a less rigid system than the platform but one that saves in labour and materials—are the studs (vertical framing members) that rest on the sill and extend in one piece from it to the top plate, regardless of whether it is one story or two. Studs are usually two inches thick by four inches wide (five by ten centimetres) spaced at intervals of 12, 16, or 24 inches (30, 40, or 60 centimetres). At the upper ends of the studs is the horizontal plate, which supports the ends of the roof rafters. The first-floor joists rest on the sill, and the upper floor joists rest on one- by six-inch (25- by 150-millimetre) ribbon boards that are placed, horizontally, between the inner faces of the studs and the corner posts. The top plate is a four- by four-inch (ten- by ten-centimetre) member and carries the roof rafters. The exterior wall is usually covered with some type of sheathing material such as insulation board or plywood, which is, in turn, covered with a finished surface such as wood siding, stucco, or brick veneer. The interior surface is usually covered with plaster or wood panelling. The roof rafters are covered with a roof decking, consisting of a plywood sheathing, and a finished material such as asphalt or wood shingles, tile, or metal. The floor joists are covered first by a subflooring material such as plywood or particle board and then by a finished flooring. The primary advantage of the balloon frame is its relatively smaller vertical shrinkage.

The main feature of the platform frame is that the entire first-floor construction can be completed before work

is started on the framing for the first-story exterior walls and the interior partitions. This condition is achieved by first placing the floor joists on the sill and covering them with a sheathing material such as wood or plywood. The first-floor wall studs are then placed, including a top and bottom two- by four-inch plate. The second-floor platform can then be constructed before the second-story studs and roof rafters are raised. The primary advantage of the platform frame over the balloon frame is that it provides a work platform. Both the balloon frame and the platform frame can be modified to meet special conditions.

For more elaborate residences and small office buildings, a light steel frame or a structural masonry exterior wall is often used. These support open-web steel joists on which the roof or floor rests.

Steel frame. For many years, building codes limited tall structures over a certain height to steel frames. Although there have been many advances in concrete design and changes in codes allowing the use of the concrete frame for tall structures, there are still many advantages to steel construction. First, steel is easily and quickly assembled. Second, steel is physically less bulky than concrete. Third, steel is lighter in weight than concrete, an advantage in areas of poor soil bearing conditions.

The I beam

The most common structural-steel shapes used in building construction are wide flange beams, I beams, channels, T beams, angles, and plates. Of these, the I-shaped form is the most popular. It is economical for its weight because a large proportion of the steel is concentrated in the top and bottom flanges at which points the greatest stresses occur and can be resisted. Steel channels are convenient in certain locations in which design considerations are limited to size or in which overall strength can be reduced. Steel angles—which may be used as beams for short spans and light loads and especially as lintels over openings supporting brick, concrete block, or stone masonry—are also important as members of built-up sections such as columns, trusses, and girders and as connection members. Steel T sections are often used as top and bottom chords of welded steel trusses and as framing members for roof systems. Steel plates are used for webs of built-up girders and columns and as flange and web reinforcement. There are two general forms of wide-flange shapes. The narrow and deep forms are more suitable for beams and girders, and the nearly square forms for column sections. These various shapes are fabricated in the shop by rivetting and welding when a desired built-up section is needed. Each member is cut to the proper dimension and shape and fastened together to form a complete member.

A structural-steel building frame consists of a series of columns, girders, and beams. The column is a vertical support while the girders and beams are horizontal members. Thus, the column supports the weight transferred to it from the girders and any other materials attached directly to it such as masonry, precast concrete, or metal panels. The girders in turn support the beams that carry the floor loads, including interior partitions, ceiling systems, and mechanical systems, the interior live load including the building occupants and furnishings, and such added loads as wind or snow. The sizes and spacing of these members are dependent upon engineering calculations that take all of the load factors into consideration. In order to minimize total cost and to have an efficient floor plan, the size and spacing of these members are maximized in terms of the building's function and cost.

In wall-bearing construction, the exterior and interior walls serve as the end support for the steel beams that carry the weight of the subfloors, finish floors, interior partitions, ceiling systems, mechanical systems, building occupants, and interior furnishings, as well as the roof deck and finish roofing membrane. In such cases, the bearing walls eliminate the necessity for columns and girders.

Field erection of these steel members is accomplished by raising them into position by a crane and temporarily bolting them. Once these members are finally positioned, final rivetting, bolting, or welding can take place. As the framing progresses upward, other required secondary steel framing members are attached, such as the subfloor, exterior wall system, roof system, ceiling system, finish floor, and interior partitions.

Lift-slab system

Probably one of the most unique forms of steel-frame construction is the lift-slab system, a combination of steel frame and concrete flooring. The steel columns are first erected, and the floor slabs are cast on the ground, one on top of the other, separated by a membrane of melted paraffin. At each column location, a steel collar is integrally cast with the slab as a means of securing the floor slab to the column when it has been lifted to its permanent position. When the floor slabs have been cured (set) sufficiently, usually 10 to 14 days, they are individually lifted into position by means of a hydraulic jack placed on top of each column. The last slab cast is the first to be raised, and when it reaches its proper height, the steel collar in the slab is welded to the column. The remaining slabs are then raised and secured in the same manner. Column spacing of 20 to 24 feet (six to seven metres) is the most economical and should not exceed 12 columns for any one lift.

Concrete frame. For a long time the design of concrete structures imitated the typical steel design of column, girder, and beam. With technological advances in structural concrete, however, its own form began to evolve. Concrete has the advantages of lower cost than steel, of not requiring fireproofing, and of its plasticity, a quality that lends itself to free flowing or boldly massive architectural concepts. On the other hand, structural concrete, though quite capable of carrying almost any compressive (vertical) load, is extremely weak in carrying significant tensile loads. It becomes necessary, therefore, to add steel bars, called reinforcement, to concrete, thus allowing the concrete to carry the compressive forces and the steel to carry the tensile (horizontal) forces.

Reinforced-concrete framing

Structures of reinforced concrete may be constructed with load-bearing walls, but this method does not use the full potentialities of the concrete. The skeleton frame, in which the floors and roofs rest directly on exterior and interior reinforced-concrete columns, has proven to be most economical and popular. Reinforced-concrete framing is seemingly a quite simple form of construction. First, wood or steel forms are constructed in the sizes, positions, and shapes called for by engineering and design requirements. The steel reinforcing is then placed and held in position by wires at its intersections. Devices known as chairs and spacers are used to keep the reinforcing bars apart and raised off the formwork. The size and number of the steel bars depends completely on the imposed loads and the need to transfer these loads evenly throughout the building and down to the foundation. After the reinforcing is set in place, the concrete, a mixture of water, cement, sand, and stone or aggregate of proportions calculated to produce the required strength, is placed, care being taken to prevent voids or honeycombs.

Building codes require that test samples of the concrete that is used in every placement be made so that the actual strength of the concrete is determined and compared to the required strength needed to carry the imposed loads. After the concrete has set and cured for a specified period of time, the forms may be removed and moved to a new location for the next placement. As the finished frame moves upward, the exterior walls on the lower floors may be erected. These walls may be placed between or over the face of the exterior columns and are non-load-bearing. They are often concrete or masonry panels or even glass and metal curtain-wall systems. The interior partitions, also non-load-bearing, can then be erected. The floor and roof are integral parts of the building frame and need only to receive the finish materials.

One of the simplest designs in concrete frame is the beam and slab. This system follows ordinary steel design but uses concrete beams that are cast integrally with the floor slabs. The beam-and-slab system is often used in apartment buildings and other structures where the beams are not visually objectionable and can be hidden. The reinforcement is simple, and the forms for casting

can be utilized over and over for the same shape. The system, therefore, produces an economically viable structure.

With the development of flat-slab construction, exposed beams can be eliminated. In this system reinforcing bars are projected at right angles and in two directions from every column supporting flat slabs spanning 12 or 15 feet (four or five metres) in both directions.

Prestressing and posttensioning

Reinforced concrete reaches its highest potentialities when it is used in prestressed or posttensioned members. Spans as great as 100 feet (30 metres) can be attained in members as deep as three feet (90 centimetres) for roof loads. The basic principle is simple. In prestressing, reinforcing rods or high tensile strength wires are stretched to a certain determined limit and then high-strength concrete is placed around them. When the concrete has set, it holds the steel in a tight grip, preventing slippage or sagging. Posttensioning follows the same principle but the reinforcing is held loosely in place while the concrete is placed around it. The reinforcing is then stretched by hydraulic jacks and securely anchored into place. Prestressing is done on individual members in the shop and posttensioning as part of the structure on the site.

In some instances in which long clear spans must be met, heavy wood construction offers advantages. A heavy post-and-beam frame may hold up two- or three-ply laminated-wood floors. Another important use of wood is in the laminated-wood arch or truss. The arch is made up of several thicknesses of wood glued together and shaped into the required form. All shapes and sizes are possible and spans of 120 feet (40 metres) can be achieved. One of the greatest advantages of the heavy wood arch is its resistance to heat as compared to that of steel. In extreme heat, steel loses its strength quickly, and the possibility of its collapse increases. Wood, however, chars slowly and therefore loses its strength slowly.

Other frame systems. There are also other structural frame systems, which, although they differ in appearance from the wood, steel, or concrete frames, use many of the same principles. Framing methods such as the dome, the arch, and the vault are most common. Domes are frequently used as roofs for structures requiring large circular floor areas. They are constructed of self-supporting reinforced-concrete shells or may be made of various types of wood, steel, and aluminum sections arranged in a great variety of patterns. A dome exerts a force outward around its entire perimeter. These forces are resisted by what is known as a tension ring. The dome and tension ring are usually supported on columns spaced around the perimeter and braced to add lateral stability.

The arch is a common system used to span openings in walls or areas in square or rectilinear buildings. The concept of the arch is to transfer overhead loads down on either side of the opening or clear area. Masonry components of brick or stone are used to span door or window openings; and wood, steel, or reinforced concrete are used to span large clear areas. Arches may be formed in many shapes (Figure 4) and hinged in many ways to carry the imposed loads. A vault, an arch that runs continuously from one end of the roofed area to the other, is usually constructed of reinforced concrete, solid-arch ribs, or trussed-arch ribs of steel or wood.

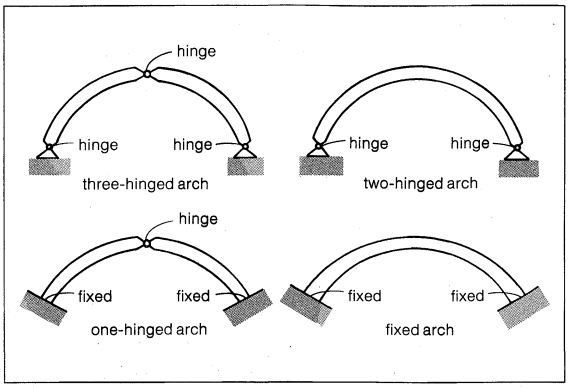

Figure 4: Selected types of arches.

Floor systems. The primary purpose of the floor system in any building is to support the weight of the functions and activities to be carried out there. Thus, the floor system must be capable of supporting the occupants; the interior furnishings and equipment; and the weight of the materials in the floor system itself and of other interior partitions. In addition to this function a floor system must work together with the structural frame to stiffen the structure and to help the frame resist the loads placed upon it. Before the design of a floor system can be finally determined, several factors must be considered.

Requirements for a good floor system

Besides being able to support the imposed loads and providing stiffness to the structural frame, a floor system must be capable of transmitting its load to the structural frame; must meet the code requirements concerning fire resistance and strength; must lend itself to the placing of any auxiliary systems such as elevators, stairs, or electrical and plumbing systems; and must meet certain cost limitations imposed by the building budget.

Wood floor systems. For light frame construction such as residences or apartments, the most common floor system consists of wood or steel joists supporting both subflooring and finish flooring. The joists are usually nominal two-inch- (five-centimetre-) thick wood members, the depth depending on their span, but spaced 12, 16, or 24 inches (30, 40, or 60 centimetres) apart. In heavy wood construction, joists may be three or four inches (75 or 100 millimetres) in thickness. In other cases open-web steel joists may be used. Their actual dimensions may vary from the wood joist dimensions but the spacing may be similar.

The subflooring first provides a working surface during construction and later provides support for the finish floor, which is typically thinner and considerably more expensive than the subfloor. The subfloor may also be more fire-resistant and provide additional soundproofing. It may be ordinary wood sheathing in nominal one-inch- (25-millimetre-) thick boards or plywood panels in four- by eight-foot (1.2- by 2.4-metre) sheets.

Just as the floor system provides lateral stiffness to the frame, cross bridging (*i.e.*, nailing small diagonal crosspieces between joists) provides stiffness to the floor joists. Cross bridging also helps in distributing loads over the entire floor.

Steel or composite floor systems. In steel-framed buildings the floor system is typically supported by open-web steel bar joists or steel beams. The spacing of these members is dependent upon the same factors described above for steel frames. A variety of floor decks may be placed over the bar joists or beams. This deck is typically ribbed or cellular and varies in depth from 1½ to 7½ inches (40 to 190 millimetres). In the erection process it follows the placement of the bar joists or steel beams with the advantage that it can be used as a working platform during construction and can serve as the formwork for the finish concrete. It is also capable of carrying electrical wiring and can act as an air duct if its rib is deep enough. The most common metal deck is the cellular floor section. It is typically 1½ or three inches (40 or 75 millimetres) in depth and may be covered on the bottom by sheet metal. As a result, an open channel is formed inside the panel. Although the deck comes in various lengths, it is most economical in relation to span and thickness at about ten feet (three metres) in length. Once the deck is in place and all work in relation to it is completed, the deck is covered with concrete.

Use of precast concrete slabs

Besides the steel deck, a precast concrete slab or precast hollow-core concrete slab may be used. The precast concrete slab may be relatively small in dimension (two-foot [60-centimetre] widths) and supported by the steel joists or beams at the ends. The longitudinal joists between the slabs are usually filled with a high-strength grout. As a result, the concrete panels accept a superimposed load more uniformly.

Similar to the concrete panel is the precast hollow-core concrete slab, six or eight inches (15 or 20 centimetres) in

depth and 16 or 24 inches in width. The length varies according to the span. Hollow cores that run the length of the panel tend to lighten the dead load and also provide a conduit for electrical wiring or heat. Similar to their precast-concrete counterpart, these panels are supported by the steel beams, and, because of a metal plate cast into the ends of the panels, they can be tack welded to the steel beams to prevent shifting during construction.

Reinforced-concrete floor systems. The floor system in a reinforced structure is commonly constructed in a monolithic manner with the framing system. In buildings with heavy floor loads, a system known as flat-slab construction is common, in which a concrete slab is reinforced in two directions and supported only by the structural columns. It becomes practical in systems in which the floor panels, as defined by the location of the columns, are approximately square. The tops of the columns may be built up with a capital and a drop panel that help transfer the floor loads down the column (Figure 5).

From W.C. Huntington, *Building Construction: Materials and Types of Construction*, 3rd ed., Copyright 1929, 1941 by Whitney C. Huntington, Copyright © 1963 by John Wiley & Sons, Inc.; reprinted by permission

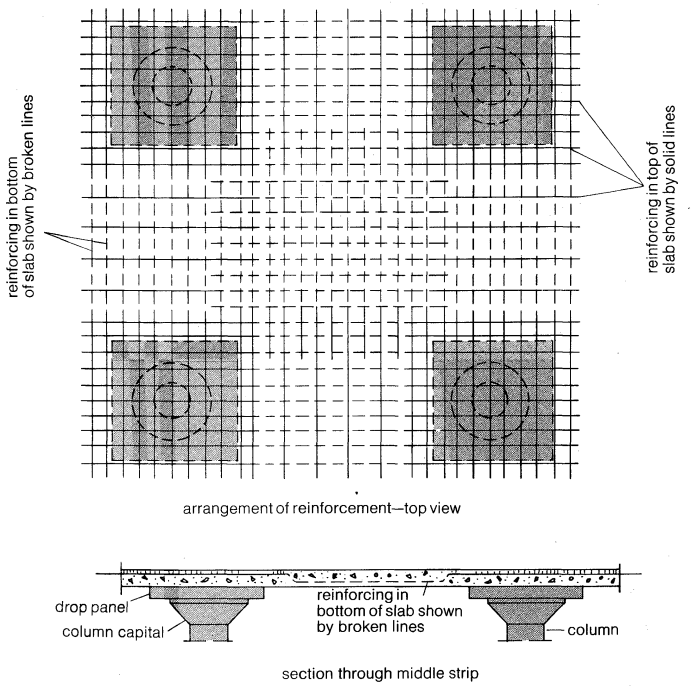

Figure 5: Two-way flat-slab construction with capital and drop panel (see text).

In structures with lighter loads, a flat-plate floor system is often used, similar to the flat-slab system except that the capital and drop panel are removed and the underside of the floor slab is uninterrupted. Its advantage is that for the same ceiling height in any other system, flat-plate construction results in a much lower story height. Another type of floor system is the slab band, which employs the wide and shallow beam that runs continuously over each row of columns. It is placed in a monolithic manner with the slabs that span between.

In the flat-slab, flat-plate, and slab-band systems, a large part of the concrete on the lower side is unnecessary; to save on concrete and reinforcing steel and in effect reduce the weight of the slab, ribbed-slab systems have been developed that remove this material. These ribs are made wide enough to resist the shearing stresses and to carry the necessary tensile steel. If it becomes necessary to support the slab on all four sides, ribs are placed in two directions. The ribbed-slab system is appropriate for spans of ten to 35 feet (three to 11 metres) but can be used for longer spans. As with the steel-deck system, these ribbed slabs can help carry wiring and air-conditioning and heating ducts.

Floor finishes. A variety of materials are available for the floor finish or wearing surface. This surface is applied over the wood or concrete subfloor. The most popular materials for light frame construction are wood, tile, terrazzo, and resilient tile or sheet. Typical materials for commercial and industrial building construction are resilient tile or sheet, concrete, terrazzo, and tile.

Flooring materials

Oak, yellow pine, and maple are the woods most generally used, for they have the highest resistance to wear in comparison to other woods. Matched flooring, plank-finished flooring, parquet flooring, and wood-block flooring are the most common shapes and finishes of wood flooring used. The most common resilient floorings are asphalt tile, linoleum, and vinyl or rubber tile or sheet. Asphalt tile is made from asphalt or resinous binders, asbestos fibre, mineral pigments, and inert fillers by combining them under heat and pressure. The sheets are then cut into tiles that are resilient, nonabsorbent, reasonably stain proof and acid proof, moisture proof, and relatively inexpensive. Linoleum is composed of oxidized linseed oil, ground cork, wood flour, and a colouring material pressed to a burlap back at great pressure. Linoleum may be plain or solid in colour or may be stamped or printed with a pattern on the surface. It is sanitary, easily cleaned, resilient, and inexpensive. Rubber tile is made of synthetic rubber combined with fillers such as cotton fibre, various minerals, and colour pigments at high temperatures. Rubber tile is attractive, elastic, noiseless, durable, easily cleaned, but more expensive than asphalt tile or linoleum. Vinyl asbestos tile has asbestos fibres added to the combination of materials. Vinyl sheet is composed of thermoplastic binders, plasticizers, and granular mineral fillers and pigments in the required proportions to give the desired properties and colours. Vinyl tile is wear resistant, impervious, resilient, easily maintained, and attractive. The method of securing all these materials is by cementing directly to the wood or concrete floor.

Where moisture and dirt collection is a problem, finish floor materials such as terrazzo and glazed or unglazed ceramic tile may be used. Terrazzo consists of a mixture of cement, sand, and marble chips applied in a two-inch (five-centimetre) thickness over a concrete slab. To minimize possible cracking over a large area, small metal divider strips are inserted in the terrazzo finish every 24 to 30 inches (60 to 75 centimetres). Both glazed and unglazed tile, also frequently used, are made in many different colours and are quite wear resistant. Common styles of floor tile are semivitreous quarry tile, ceramic mosaic tile, and glazed tile. If these materials are applied on the floor, adhesive may be used. A thin set method consists of applying an adhesive to the concrete or wood, placing the tile, and filling the joints between the tile with a mortar. Another technique consists of applying a cement mortar bed over the concrete, placing the tile, and filling the joints between the tiles with a grout. Wall application of these tiles is similar.

Roof systems. Roof systems have the same type of structural support as floor systems: wood, steel, concrete. In addition, roof systems may be classified by their pitched or flat slope. Typical roof types are flat with wood rafters, flat with steel framing, flat with concrete framing, pitched with wood rafters, and pitched with steel framing. Flat roofs are used extensively on nonresidential buildings; these are sloped only slightly to insure drainage. Pitched roofs are used more frequently on residences and apartments. Common pitched roofs—such as shed, lean-to, gable, hip, gambrel, mansard, and deck—are illustrated in Figure 6. In selecting a particular roof system, the primary considerations are the materials used as the structural framing; the character and amount of the loads; the span; the degree of fire resistance; and the general character employed to meet economically the requirements of the entire building.

Wood roof systems. Many of the small structures being built today, such as houses and apartments, have wood framing. Loads are light; the frame is composed of many light members spaced close together, each carrying a relatively small load. The roof framing is supported on members (rafters) two inches (five centimetres) thick

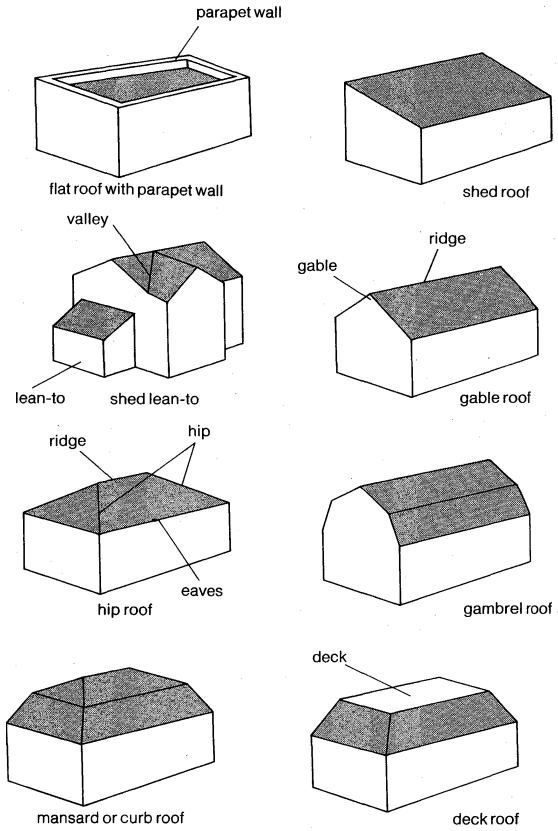

Figure 6: Common roof types.

by four to 14 inches (ten to 35 centimetres) deep, usually spaced 12 to 24 inches (30 to 60 centimetres) apart, depending upon the imposed load. The rafters rest on the top wall plate and meet opposing rafters at the ridge (centre line of a house) or valley rafter. The outward thrust imposed on the rafters by the loads that each carries is counteracted by the ceiling joists that act as ties or collar beams. For great spans, it may be necessary to support the rafters to help carry the added loads. In many cases attic partitions or posts may be adequate for support. More frequently, trusses are used.

Wooden trusses

Trusses are composed of a number of triangles framed together. A triangle cannot change its shape without a change in the length of one of its sides. Therefore, in the truss composed of many triangles, every member is pulling or pushing against another—*i.e.*, is in tension or compression. In analyzing the loads imposed on a given truss, these individual members can be sized accordingly and be so made to keep the truss from failing or collapsing. There are many types of trusses; the proper one is determined by the length of span, the material of which it is constructed, and the manner of loading (Figure 7). Another important point about truss construction is that the truss is always designed so that the end reactions are vertical upon the supporting members. Horizontal movement may take place by sliding or rolling on the bearing plate. If the truss is designed so that the loads are transmitted in the direction of the slope of the truss, horizontal movement is restricted and causes the bearing structures to lean in an outward direction and the truss to act in the same manner as an arch. These considerations are common for both wood and steel trusses.

The usual method of constructing roofs with trusses is to space the trusses at regular intervals and to accommodate the loading and the particular size of the roofing material. Support between trusses is accomplished by purlins (horizontal members) that run from truss to truss.

A new development in spanning clear areas is the trussed rafter. Here, a truss of light material, usually wood two inches thick by four inches wide or two inches thick by six inches wide, is placed two feet apart and the roofing material is nailed directly to it. These trusses can be fabricated on the ground, in a shop, or on the site and then erected as a whole. They eliminate the need for interior bearing walls, thus considerably reducing labour and material costs. Trussed rafters have become ideal for spans of 20 to 40 feet.

Reinforced-concrete roof systems. A reinforced-concrete roof system is similar to the reinforced-concrete floor system, as described above. Typically, a reinforced-concrete roof system is a basic part of a total concrete structural frame. The roof system consists of a roof slab that is either flat or with ribs or joists underneath. A one- or 1½-inch- (25- or 40-millimetre-) thick insulation board, together with a built-up roof, is laid over the roof slab.

As well as a poured-in-place concrete roof system, a series of precast prestressed concrete T sections may be used, particularly for a one- or two-story building. These units may be single T or double T cross sections capable of spanning sizable distances. The sections provide a flat roof surface capable of carrying one- to 1½-inch-thick insulation board as well as a built-up roof membrane. To prevent the sections from appearing to give under the weight, a camber, or slight rise, is built into it. In this case the T section bows upward. Once installed on the roof, the weight of the T section and the added weight of the other roofing materials causes the T section to level out but not sag.

Steel roof systems. When the spans between supporting walls increase and the imposed load increases, the capabilities of wood joists become limited. It therefore may be economical to use steel joists. For extremely heavy loads, steel I beams can be used, but for somewhat lighter loads, lightweight joists called junior beams are used. A junior beam is of similar shape to the I beam but is manufactured in thinner sections, with the sections ranging from six inches deep with a weight of 4.4 pounds per foot (6.5 kilograms per metre) to 12 inches deep with a weight of 11.8 pounds per foot.

Another form of the steel joist is the open-web, or trussed, joist (Figure 8), built up of steel bars or rods welded between flat bars, channels, or T sections; such a roof system is light and strong and permits me-

chanical systems to occupy its open spaces. These are commonly called bar joists. Bar joists placed 12 to 30 inches (30 to 75 centimetres) apart are braced laterally to prevent them from twisting and often support a thin concrete slab reinforced in both directions. Wood nailing strips running perpendicular to the joists can be fastened on to permit laying of the finish roofing material.

Finish roof materials. A roof is covered with a finished material to provide protection from the elements. Many materials have proved to be satisfactory. The most generally approved types of materials are shingles of wood, asphalt, or asbestos; slate; tile; glass and sheet metal including tin, copper, lead, zinc, aluminum, steel, Monel metal, stainless steel; and built-up roofing (see below).

Wood shingles, used primarily in residential construction, vary in lengths and have random widths. They are laid horizontally, each row overlapping the preceding row and nailed to wood slats four or five inches apart.

Asbestos shingles

Asphalt shingles (made of asphalt-impregnated felt covered with crushed slate of various colours) are commonly used in residential construction because they frequently cost less and are more fire-resistant. Because the butt ends are relatively thin, a roof covered with this material gives a flat appearance.

Asbestos shingles, also used primarily in residential construction, are made to imitate wood shingles in shape and size and, to a slight degree, in appearance. Very durable and very fire-resistant because they are formed under great pressure and composed of about 15 percent asbestos fibre and 85 percent cement, these are nailed to plywood sheathing covered with felt or waterproof paper.

Slate, because of its very marked layers, is easily split into thin sheets. The slate sheets are drilled so that they may be nailed to felt covered sheathing. Slate is fire-resistant and durable but very heavy, so that the roof rafters or trusses must be designed to carry the additional load.

Clay roofing tile is made of wet clay pressed in molds and fired in kilns. It is fastened with copper nails to the roof surface, which is covered with an asphalt felt. Quarry tile, a large, red, unglazed rectangular or square tile, is laid in a bed of cement mortar spread over the top layer of built-up roofing.

Tin, copper, zinc, and lead have been used as roofing materials for many years. They are especially useful on flat roofs with too little slope for conventional shingles and on curved roofs. Tin roofing is made by coating sheets of iron or steel with tin, the sheets being laid over felt covered sheathing and the joints, either flat or standing seams, soldered tight. If tin roofing is kept well painted, it can successfully resist corrosion for as long as 50 years.

Probably the most popular of the metal roofing materials is copper. Although initially more expensive than tin, it requires no maintenance after installation because when it oxidizes it thus provides a protective coating for itself. Laid much as tin roofing, its seams are not soldered because the copper expands and contracts.

Lead roofing, long an accepted roofing material, is quite pliable and can be stretched to meet any surface requirements without being cut or soldered. Its weight and tendency to creep have long been disadvantages, but in the 1960s hard lead was developed with more tenacity and less expansion, reviving interest in lead roofing. Lead is also laid in much the same manner as tin and copper.

Flat glass is used for roofing greenhouses, and ribbed or prism glass may be inserted in domes or on the roofs of public buildings. Corrugated glass is often adapted to industrial buildings. When strength is required, wire glass is employed. High strength polyester plastic sheets have been developed for roofing: flat or corrugated; transparent, translucent, or opaque; in a wide variety of colours; and readily formed into many shapes.

Other roofing materials

Built-up roofing, which has been proved best adapted to flat roofs having great open areas, adjusts well to expansion and contraction, is considerably less expensive than sheet-metal roofing, and when properly laid may last for many years. It is composed of three to five layers of felt saturated with coal-tar pitch or with asphalt, each layer set in tar or asphalt. The top layer is finished with a covering of crushed slag or clean gravel or with a layer of flat quarry tile. It may be laid on wood-plank roof, concrete slabs, or cinder-concrete roof fill.

Space-enclosure systems. Space-enclosure systems are the exterior or interior walls or panels used in a structure to delineate the interior space; they may be classified as load-bearing or non-load-bearing. Load-bearing walls are capable of carrying structural loads imposed by the floor or roof, while non-load-bearing walls do not carry any additional load imposed by the structure. As a result, load-bearing walls can be used on the exterior to support the ends of the floor or roof joists or on the interior, if it is more economical than having the floor or roof joists span the entire width of the building. Non-load-bearing walls may also be used interchangeably. When non-load-bearing walls are used on the exterior, however, they either cover the face of the structural frame and are supported by the structural frame or they are in-fill panels that bear on the floor.

Load bearing and non-load bearing walls

Wood. Wood wall systems can be either load-bearing or non-load bearing and, thus, can be used either on the exterior or interior. They typically consist of two- by four-inch (five- by ten-centimetre) studs, 16 inches (40 centimetres) on centre, which bear on a sill and are capped by a wood top plate. In the case of exterior walls, an insulation bat or blanket is used to fill a portion of the void between the studs to provide adequate insulation, particularly in northern climates. The exterior finish consists of one or more materials such as insulation board, wood or plywood siding, cement plaster or stucco, aluminum siding, brick, stone, or plastic siding or panelling. The interior finish of the exterior wall typically consists of gypsum drywall, plywood, or plaster. These same finishes are also usually applied to the interior walls (Figure 9A). If it is necessary to minimize the amount of floor area consumed by interior partitions, the wood stud

may be turned so that its narrower dimension is used for the wall thickness. To cover any construction joints which typically occur at the floor, at doors, and at windows, wood trim is most often used. At the floor, however, a rubber or vinyl base approximately four inches high may be employed, particularly in kitchens and bathrooms, in which water and moisture might be splashed against the base.

Masonry. Masonry walls may be either load-bearing or non-load-bearing. If the walls are load-bearing, they should be thick enough to support loads without exceeding the compressive strength of the masonry units. If the wall is non-load-bearing, the thickness should be related

to the unsupported height of the wall. In either case, there should be sufficient lateral support and, if necessary, wire-mesh reinforcing added to maintain wall integrity and strength. The masonry units most often used, individually or in combination, are brick, concrete block, structural clay tile, glazed tile, gypsum block, and stone, including granite and marble. If these materials are used in combination in the same wall, it is necessary to connect them, often by interlocking one material, such as brick, with a back-up material, such as concrete block or structural clay tile, a system that bonds the materials together. Sometimes a mechanical bond such as a wire or thin piece of metal is employed. If wood panelling, gypsum drywall, or plaster is applied over the masonry, a thin wood strip is attached to the masonry and the wood panelling or gypsum drywall is fastened to the strip. Plaster may be applied to a gypsum lath board in the same manner or directly to the masonry.

Metal. In modern architectural design, the desire for large glass areas in the exterior wall has stimulated the use of prefabricated panels in curtain walls that are simply building skins with no load-bearing characteristics. Extruded aluminum or steel sections (called mullions) similar to I beams are placed over the frame. Between these mullions, windows and spandrel panels of aluminum, structural glass, marble, or precast concrete are attached. The spandrel panel is located between the head of one window and the sill of the window above. Great care must be taken by the contractor to make this system airtight and watertight.

Use of mullions

The three basic types of curtain-wall systems are custom walls, commercial walls, and industrial walls. Custom walls are designed specifically for one building. Commercial walls are made up of members standardized by a manufacturer and assembled in stock patterns. In industrial walls, preformed sheets in stock sizes are used for the major surfaces along with standard metal windows.

For interior wall use, steel studs have become popular. These bear on galvanized runners at both the floor and ceiling and are spaced at 16-inch (40-centimetre) intervals. Four- by eight-foot (1.2- by 2.4-metre) sheets of gypsum drywall are fastened to the metal studs by concealed clips. Just as in the wood stud partition, the gypsum drywall is taped and covered with a joint compound or covered with decorative battens. In some cases, particularly in office buildings, metal panels are applied over the steel studs. These panels are typically designed so that they can be dismounted, moved, and reassembled in a new location. The concept is to provide a flexible interior and a low-cost wall system.

Another means of saving floor area is through the use of solid plaster partitions (Figure 9B). These non-load-bearing partitions are built of ¾-inch (19-millimetre) steel channel studs or metal lath, set vertically. Plaster is applied to metal lath on both sides of the channel forming a reinforced wall two to 2½ inches (50 to 65 millimetres) thick.

Concrete. Concrete panels can be either load-bearing or non-load-bearing. Most frequently, they are used as non-load-bearing panels and attached to the structural frame. Thickness depends upon panel size, loads, amount of insulation, and type of concrete. Typically, these panels are precast off site, shipped to the project, and raised in place by a crane. In relatively small structures, these precast concrete panels can be tilted into position—a method known as tilt-up construction. The panels in many cases are cast on site.

Surface treatment may consist of various forms of texturing or, in some cases, application of an aggregate to provide an even coarser texture. Where insulation is included in the precast concrete panel, the insulation material may be a polystyrene or polyurethane foam or cellular glass.

Ceiling systems. A finished ceiling is often hung at some distance below the underside of the floor system. In accomplishing this, a 1½-inch (40-millimetre) metal channel, called the runner channel, is hung from the floor system by rods, bars, or wires. This system has become quite popular, particularly in commercial buildings, because of its adaptability to supporting various components included in the ceiling, such as acoustical tile or panels, lighting fixtures, and air-handling systems.

It may be desirable in some buildings to forego the suspended ceiling and attach the finished ceiling directly to the underside of the floor or roof deck. To do so, either metal or wood strips can be attached to the floor deck, and the appropriate ceiling finish such as plaster or gypsum drywall is attached. The disadvantage of this method is that any deep girders or beams will project below the ceiling line and lighting fixtures must be suspended from the ceiling. Most designers prefer to conceal structural members, lighting fixtures, and mechanical equipment by suspending the ceiling or finishing around them.

Finish hardware. Hardware, an important aspect of the finish of any building, includes door knobs, locks, hinges, door closers and stops, push bars and plates, kick plates, thresholds, and door openers. Because these materials are in constant use and contact by the occupants, the designer chooses the hardware that will reflect and conform to the overall design of the structure. Hardware is made of materials that withstand a great deal of abuse and wear—such as stainless steel, chrome plating, aluminum, and bronze. Usually door knobs, lock face plates, strike plates, and cylinder faces are of noncorrosive metal. Hinges on the interior of the building are usually cold-rolled wrought steel, while on the exterior they are a noncorrosive metal with nonremovable pins. Automatic door-opening devices may be operated electrically, pneumatically, or hydraulically. An actuating mechanism starts a hydraulic or air pump or an electric motor that opens the door. The same type of device or a spring may shut the door.

Auxiliary systems. Another important element in building design and construction is the mechanical, or auxiliary, system—plumbing; heating, ventilating, and air conditioning; electrical wiring; vertical transportation; and chimneys and flues.

Plumbing systems. The purpose of the plumbing system in any building, whether residential, commercial, or industrial, is to provide clean water for drinking, cleaning, washing, and sanitary facilities and to remove and dispose of wastes. Governments long ago recognized the importance of plumbing and have taken steps to insure proper facilities through building codes. As a result, the codes are very specific as to the design and installation of the system. Pipe sizes, materials, connections, number of fixtures for both sexes, sewer lines, septic tanks, and drain or leaching fields are covered in great detail for all buildings and their type of occupancy.

In structures such as auditoriums, theatres, plants, and office buildings, sanitary facilities are based on the number of occupants expected to use the building in relation to the total usable floor area. In multifamily dwellings, facilities are determined by the number of families housed and the amenities demanded. In addition to providing water supply and liquid waste disposal for the occupants, it is also important to provide for cleaning facilities for both interior and exterior areas, air-conditioning equipment and heating systems, and for fire fighting.

Plumbing system planning

In designing plumbing facilities for any one building, the designer, besides considering the convenience of the occupants and the codes, must always keep the flexibility of the system in mind. Allowances must often be made for expansion to meet the requirements of an increasing need and use. These allowances are usually made by oversizing the initial equipment. Such advanced planning is valuable when expansion of the building is made or if the type of occupancy changes. These considerations can add to the resale or leasing value of the building.

In a sanitary waste system, it has been good practice to use extra heavy cast-iron soil pipe above and below the ground inside the building and to a point approximately five feet (1.5 metres) outside the building. From that point extra strength vitrified clay pipe may be used outside the building. Galvanized-iron, copper, or plastic pipe is typically used inside the building. Plastic pipe has become popular, however, because of its lower cost, limited

maintenance, and resistance to corrosion. Horizontal sanitary pipes are laid at a slope, usually ⅛ inch per foot (about one centimetre per metre), to insure proper drainage and to prevent backup. Sanitary lines or drain lines have traps incorporated in the line to prevent the backup of unwanted gases into the building. These gases are vented through pipes that run vertically through the building and discharge through the roof to the outside. Vent pipe is usually galvanized iron, copper, or plastic. Codes are very specific about vents and vent sizes and how they are to be connected to various fixtures to help prevent gas and sewerage backup in the main sewerage lines.

Although storm water is also a form of waste, storm water and sanitary drains are kept separate. If the two are connected, the line may become overloaded during a heavy rainstorm thus overflowing, and bringing both storm water and sewage back into the building. Consideration is also being given to the size of the storm drain required in the particular geographic area in which the building is located. If the area is one of heavy rainfall, the lines are sized accordingly. Storm drains are usually galvanized or cast iron.

In buildings that have drains below the city's sanitary and storm sewer lines, sewage ejectors and sump pumps are employed. These are actuated by float valves that activate the motor when the collection of water and sewage has reached a certain level. The pumps, with waterproof motors, are capable of disposing all the waste and storm water into the city's lines. These pumps are usually made of special iron or bronze, ideal materials for such equipment in heavy use areas.

Cold-water supply systems usually use bituminous-coated cast-iron piping for the service between the street mains and the building. Inside the building, the distribution piping is usually galvanized iron, copper piping or tubing, or 85 percent red brass.

The hot-water system parallels the cold-water system except that a heat exchanger or a hot-water tank is used to warm the water. In some cases the system may be designed in a loop and a circulating pump used. Such a system returns the water to the generator to be reheated to provide hot water at the outlets. The hot-water tank is usually steel lined with a noncorroding coating. It contains controls that regulate the flow of the heating medium that in turn heats the surrounding water. The hot-water distribution piping is galvanized iron, copper, or red brass.

Though galvanized piping has been extensively employed in hot- and cold-water supply systems, the corrosive action of hard water on it has led to a preference for copper pipe or to treatment (softening) facilities or to both. Hard water contains a great quantity of dissolved minerals that deposit and collect on the walls of iron or steel pipe, as well as carbon dioxide that combines with water to form carbonic acid, the cause of most corrosion in iron or steel piping. Water can be softened at a centralized water-treatment plant or at the individual building with special equipment.

Necessity of system testing

In all the systems mentioned above, tests must be conducted before the system is closed in or covered over during construction. Water supply lines, for example, may be placed under abnormally high pressure to test strength and tightness. Waste and vent lines are filled with water or a pungent odor; lowering of the water level or the detection of the strong odor will indicate a leak. All water supply systems are tested to determine the actual flow rate as compared to the required flow rate.

Codes also require the installation of water systems for fire-fighting purposes in buildings having a high concentration of occupants or valuable contents. These systems are completely independent from the regular plumbing system. A common fire-fighting installation is the standpipe that consists of a vertical riser of black iron pipe, the size of which is determined by code according to the height of the building. The standpipe is connected to a permanent source of water and has an outlet at every floor. The number of standpipes, also set by code, is determined by the total floor area and building dimensions. The sources of permanent water are rooftop tanks or pumps connected to an outside main or other source.

For positive fire protection in high-risk areas, sprinkler systems are designed so that they may discharge water in spray form directly into the fire from outlets located in the ceiling. The spray outlets are opened when a small metal plug that holds the outlet closed is melted away by the heat. These plugs melt at temperatures from 135° to 165° F (57° to 74° C) and are often connected to an alarm system so that when the outlet is opened it will actuate a fire alarm (see also FIRE PREVENTION AND CONTROL).

Heating, ventilation, and air conditioning. Almost every modern building receives some form of heating, ventilation, and air conditioning, depending on the climate, the size of the building, and the availability and comparative cost of various fuels. To determine the proper system, the designer considers several factors. Of primary importance is the use of the building and the location and climate of the site. Based upon these factors the designer determines the desired inside temperature and the maximum variations in outside temperatures. Through the use of established equations and tabular data, the designer can determine the amount of heating or cooling needed to sustain such an inside temperature. Of course, consideration is given to the materials used and the quality and quantity of insulating material.

Central heating systems

In northern climates a central heating plant is generally used. In residences, apartment buildings, or small commercial buildings, the heating plant can be either a hot-water or steam boiler, or a forced-warm-air plant. In a hot-water system, hot water is circulated through either wall or baseboard convectors. These units are designed to transmit heat by moving air over and through their warm surfaces and are thermostatically controlled, and, as a result, the entire heating system can be adapted to zone heating, in which different areas can receive different amounts of heat.

In radiant heating, hot water is circulated in pipe coils placed in a concrete floor slab or in the ceiling. This system involves a danger of pipe leakage, however, and the difficulty and expense of repair.

In steam heating, steam is generated in a centrally placed boiler and transported through pipes to various locations in the building. Heat transfer then takes place in a manner similar to the hot-water system. As the heat is withdrawn from the steam, the steam condenses to water and flows back to the boiler.

A forced-air heating unit heats the surrounding air. The air is forced by a fan through ducts to the individual rooms. Cooled air is then returned to the plant through cold-air return ducts for reheating, thus keeping the air circulating. Fresh air is added directly from the outside or by air that infiltrates around windows and doors. Warm air from a forced-air system can be humidified by passing it through water. Furthermore, the system can be readily adapted to receive air conditioning. If the required heating load is low, floor furnaces, which are self-contained heating units installed under the floors, can be used.

For the small multiple-dwelling or business buildings, the calculation of heat load is the same in principle as that for a residence. The choice of the heating unit is, to some extent, dependent on whether or not the building is air conditioned. In general, an oil- or gas-fired hot-water or low-pressure steam boiler is used. Large areas are often heated by unit heaters in which air is blown by fans through coils which carry the hot water or steam.

In large office buildings, design of the heating unit is tied in with the ventilating and cooling systems. The basic calculations for heat loads are the same, but consideration is also given to prevailing winds and sun. Because the heating is closely associated with the ventilating and cooling systems, the heat is always transmitted by means of air that is warmed by passing over warm surfaces and blown into the desired spaces. The air is then recirculated and fresh air added mechanically. The heating plant can be a low-pressure hot-water or steam boiler, a heat exchanger, or a high-pressure steam plant that supplies steam for turbine-driven compressors for air conditioning

and uses the "left over" low-pressure steam for heating. If electrical energy is economical, a low-pressure boiler is most practical. These systems are usually prefabricated units that are ready to install. If electrical energy is not economical and other fuels are, a high-pressure steam plant may be used that runs the air-conditioning compressors and heats the building. The distribution of the heat depends on the total design of the air-conditioning systems. In some instances the hot water or steam is sent to a series of window units around the perimeter of the building. These units then force air over the warmed surfaces. In other instances, the hot water or steam is supplied to coils located at central fan systems that blow air over the coils and then force the warm air through ducts to the desired areas.

Air-conditioning factors

Air-conditioning plants vary in size and capacity but all work on the same principle (for a detailed description of various systems, see HEATING, VENTILATING, AND AIR CONDITIONING).

In large buildings, certain areas may require heat while others require cooling. To supply each properly, the designer divides the building into zones and provides individual heating and cooling units for each zone. The number of zones required is determined by the climate, the orientation of the building, and the amount of wind.

Air conditioning also raises the problem of location of the plant in the building. It may conveniently be sited on the basement level or on the roof. If it is placed in the basement the structural frame does not need to be strengthened to carry the additional load, and installation and service are easier. The boiler stack and condenser lines, however, must carry to the roof, thus eliminating valuable space, and there may be basement waterproofing problems. Among the advantages of roof placement are the fact that the condenser water and the chilled water lines are at a minimum because the cooling tower and the fan units are close by and that centralized maintenance and controls are facilitated. Utility lines must be extended to the roof, however, and the structural frame and floors must be completed before installation. An increasing number of new high-rise buildings are placing their air-conditioning plants on the roof.

Air-distribution methods

There are four methods of distributing air that are generally used. The first is the high- and low-pressure system. Here, small diameter air ducts are run up the perimeter of the building along the exterior columns. The ducts carry warm or cool air at a fairly high velocity. The air is carried to induction perimeter units that further heat or cool the air and then release it into the space. For interior conditions, large ducts carry air at low velocity to ceiling louvres or diffusers. A single-duct system is often used in small buildings. The air is distributed to the floors by means of two vertical ducts, sent through a tempering coil, and distributed into every space by ceiling diffusers. A third system is the double-duct, a complex of main vertical and branch horizontal ducts that carry high-pressure warm air and a parallel series carrying high-pressure cool air. The horizontal ducts end in mixing boxes located in the ceilings in every area that is controlled by a thermostat. Fourth, is the perimeter window unit. These units consist of a series of coils that carry either hot or cold water. Thin metal fins are bonded to these coils so that the maximum metal surface is presented to the air that flows over them. The air that comes from the vertical high-pressure riser ducts enters a large chamber under the coils where its pressure is reduced. As the fresh warm or cool air blows over the coils, its velocity induces room air to enter the chamber and mix with it.

The entrance of fresh air is provided by a ceiling plenum reinforced by exhaust ducts running in the hung ceiling space. A ceiling plenum is the space between the underside of the floor and the top of the hung ceiling. The exhaust air moves into this space through ceiling exhaust louvres. It is pushed in by the incoming conditioned air and is circulated by fans to vertical risers that empty into the outside air.

Other important factors supplemental to the total design of the heating and cooling systems are sound abatement, water treatment, and the control system. The control systems are the most important, because they must be able to maintain predetermined temperatures and humidities during all seasons and for every work activity. The system performs this task by first measuring the changes in temperature and humidity in the various areas or zones. It then must convert the observed changes into energy impulses, either pneumatic or electrical, and, finally, correct the system by means of the controlling devices.

Electrical systems. An electric current in buildings typically is carried by a wire of copper, aluminum, or other metal, but liquid or gas may also conduct electricity. To provide for interchangeability of electrical appliances and devices and for low cost, voltage ratings have been standardized, though the standards vary in the United States, western Europe, and elsewhere. Higher voltages are required for air-conditioning systems, pumps, fans, and elevators than for lighting.

Electrical services may be as simple as those installed in a single-family residence or as complicated as those that are installed in hospitals or nuclear power plants. Whatever the installation, the designer should always make provisions for expansion of the system. Even in the single-family residence, with its increasing number of electrical appliances, it is difficult for a designer to predict the extent of any future expansion.

Electrical service is delivered to a building by dropping service wires to a meter, usually outside the building. Wiring fed through the wall to the panel box is distributed to the various circuits through circuit breakers or fuses, the function of which is to prevent overload. In office buildings the designer must consider the many machines that will be used in great quantities, such as typewriters and calculators, or devices that draw an extremely large load, such as computers. In manufacturing plants such equipment demands heavy electrical loads. By determining a total electrical load for the building, the designer can make the necessary provisions for installing transformers of the proper size. These transformers will carry the total load and reduce it to the required service load needed. The basic theory behind the reduction in current by the transformer is that the higher the voltage coming into the transformer the more efficient the transmission of electricity to the various outlets. From the transformer the electrical service is brought to panel boxes similar to those used in residential construction but providing many more circuits. The circuits are fused and distributed to the area where the service is needed.

Circuit wiring

Circuit wiring can be brought to the area between the suspended ceiling and the structural floor or it can even be brought through the floor itself if it is composed of a steel deck or concrete components with sufficient cell space. Wiring can also be brought through the interior partitions if there is a hollow base suitable for distributing the wire. Where a heavy use of electrical current is needed, provisions may be made for under-floor raceways that may be tapped at desired locations. The raceway can be incorporated in the floor system, or it can be a separate duct laid over the structural floor. Bus ducts are sometimes used that contain four copper or aluminum bus bars—rectangular, round or tubular—used as conductors for very high currents. The bus ducts are prefabricated and can be bolted together to form any length.

Interior illumination of a building is often the most important consideration in designing the electrical service. An office or industrial building requires nonglare, evenly distributed lighting. Lighting level requirements vary for many reasons, but a level of 65 to 85 footcandles of illumination is usually adequate for office buildings. Drafting or design work areas require higher levels. Illumination levels must be analyzed for every situation and designed to fit the need. Important considerations are: the type of work performed, ceiling height, spacing of fixtures, the quality of light, and the size of the fixture. Other considerations such as the design of the fixture and the lens and its maintenance factor are also important. Well-proven formulas and tabulated data have been prepared to help the designer study these factors and make a

decision that will be advantageous to the owner and those who live or work in the building (see also LIGHTING AND LIGHTING DEVICES).

Vertical transportation systems. The two most common types of vertical public transportation are the passenger elevator and the escalator. The freight elevator and the dumbwaiter are the primary types used for materials handling. The need for elevators became evident when high-rise buildings began; advances in elevator design have enhanced the flexibility of multistory buildings.

The essential characteristics of an ideal vertical transportation system are prompt availability of cars at any level and in either direction; minimum delay in starting; rapid and comfortable acceleration; constant high speed after acceleration; rapid and comfortable deceleration; quick levelling at the landing; and rapid opening of the doors. All this should be achieved with smoothness, quietness, and complete safety to passengers.

Elevator handling capacity

An initial consideration in the design stage is the handling capacity per elevator. The elevators must be capable of transporting a certain percentage of the total occupancy of a building at peak travelling times within a certain time span. The designer must also determine the number of passengers the elevators are likely to carry and the round trip time of the elevators. It has been determined that the number of passengers per trip never normally exceeds 80 percent of the carrying capacity of the elevator, because many passengers alight at intermediate floors. Given the rate of speed of the needed elevator, the designer can calculate that 80 percent of the capacity of that elevator will be carried in the time it takes for a total round trip, or x amount of people in the assumed time span. If a certain percentage of the total occupancy is to be transported in this assumed time span, he can, therefore, determine the number of elevators required. By dividing the round trip time of the elevator by the number of elevators, the designer can determine the waiting interval between elevators. A specification for a 20- to 30-story high-rise building may call for: as many as six cars with 3,500-pound (1,600-kilogram) capacity travelling at 1,000 feet (300 metres) per minute. Such a specification provides much flexibility for shifting floor occupancies.

The requirements for a freight elevator differ. Freight elevators are used primarily for transporting office supplies, janitorial equipment and personnel, and heavy or bulky loads. A single freight elevator, consisting of a 4,000-pound (1,800-kilogram) car travelling at 500 feet (150 metres) per minute, is generally adequate for a multistory office building of about 600,000 square feet. A freight elevator must be much larger in physical dimensions and total carrying capacity, however, than the passenger elevator.

The mechanical equipment used for elevators in high-rise buildings are the geared traction machine or the gearless traction machine. The geared traction machine consists of a high-speed electric motor that drives a hoisting sheave by means of a worm-and-gear reduction unit. It is run on alternating current (ac) which comes directly from the power lines. Alternating current, though economical, causes a jerky ride, and levelling the car is difficult, creating a hazard to the occupants. A direct current (dc) motor provides flexibility in speeds and a smooth ride. The gearless traction machine consists of an ac–dc motor generator that drives the dc hoisting motor. The hoisting motor is directly connected to a sheave over which hoisting cables travel to raise and lower the car and counterweight. Such machines can easily handle elevators of 10,000-pound (5,000-kilogram) capacity and 1,800-feet- (550-metre-) per-minute travelling speed. The gearless traction machine gives a great flexibility in speed and smooth operation. It is advantageous in handling large numbers of passengers in a short period of time. Freight elevators are always operated by geared traction because of their heavy use.

Elevators are always equipped with safety devices that are positive and "failsafe." No car can start unless the outer and inner doors are closed, thereby closing the operating circuit. If a person or object is in the door opening, an electric eye or a pressure-activated door edge reverses the motion of the door and causes it to open again. This device provides added safety for the individual passenger. The cables are of special steel designed to take continual bending and stretching. They are wrapped around both a primary and secondary sheave to prevent slippage. The counterweight is usually equal to the weight of the car plus 40 percent of the car capacity. It helps in relieving the motor of the full load, and if the motor does fail with a less than 40 percent load, it carries the car to its uppermost point. Limit switches, governor cables, and brakes control the speed of the car if it starts to travel faster than its present speed. An additional safety measure is hydraulic or heavy spring bumpers placed in the elevator pit that can absorb much of the force of a falling car.

The overall speed of the elevator service depends in great part on the operation of the door mechanisms. Door speeds of seven seconds for opening and closing time are usually accepted for a good operating system. A dc motor drives both doors through a gear reduction unit that enables the doors to open or close smoothly and completely. The doors are supported by rigid door hangers and move on sheave wheels; as they close, a projecting vane on the inner doors disengages, actuating the interlock mechanism which closes the electrical circuit and permits the car to proceed.

In modern elevators the pushbutton calling devices indicate the floor called until it has been reached and the direction in which the car is moving. Audible signalling devices are also sometimes used to indicate that the car is stopping.

The escalator

The escalator has become an increasingly valuable means of vertical circulation. It involves no waiting time, and a great number of people can be continually moved. A 48-inch- (1.2-metre-) wide escalator moving at 120 feet (40 metres) per minute can move between 6,700 and 10,700 people per hour. Escalators can be placed in a variety of patterns, depending on available space, the desired direction of circulation, and economics.

The mechanism is composed of a running gear or moving steps that carry the passengers. On either side is a fixed balustrade with a handrail on top that moves at the same speed as the steps. The equipment is supported on a track and a steel truss. Movement is supplied by a dc motor that provides a smooth and even ride. Since the escalator is continually moving, the electrical consumption is much lower than that of the elevator. There are basically two types of escalators, the flat-step and the cleat-step type. Both operate in the same manner, but the difference is in the method of entering and leaving. The flat step consists of a number of steps which are held flat forming a moving platform. The passenger enters on the platform and gradually the steps are formed as the escalator moves upward. At the top, this pattern is reversed. This type requires added floor area at the top and bottom. The cleat step has longitudinal cleats, and by a combing action, they appear and disappear without the use of a platform. This enables the passenger to step directly on and off the escalator with greater ease and safety and eliminates the need for additional floor area.

Chimney and flues. To produce a given amount of heat in a building, fuel must be burned at a given rate. To do this a definite weight of air must be supplied for combustion. In this process air must flow through the fuel bed. The force causing the air flow in a natural draft plant is the chimney. It is capable of producing a draft that is caused by the difference between the atmospheric pressure and the pressure existing at any point in the furnace or in the flue. The intensity of draft that a chimney is capable of producing at the base is a function of its height, temperature of the flue gas, and the outside air temperature.

In designing a chimney several factors are considered —grate surface area, size of breeching (smoke pipe), and the rate of combustion. By using selected formulas, the flue area can be calculated. Height of the flue should be sufficient to prevent any downdrafts through the flue caused by adjacent roofs at the same height.

Chimneys may be constructed from concrete, masonry, or steel. Masonry chimneys, particularly for smaller buildings, such as residences, should be lined with a terra-cotta flue liner to prevent combustion fumes from penetrating the building through cracks in the mortar. The chimney for a high-rise building is a special case. Available formulas or manufacturers' recommendations, especially in the case of prefabricated chimneys, should be used to design them.

BIBLIOGRAPHY. The early history of building materials and building techniques is best covered by NORMAN DAVEY, *A History of Building Materials* (1961); and RENE ALLEAU, *Histoire des grandes constructions* (1966; Eng. trans., *History of the Great Building Constructions*, 1967). BANISTER FLETCHER, *A History of Architecture (on the Comparative Method)*, 18th ed. (1975), characterizes the many architectural styles through time and describes many of their influential factors; while SIGFRIED GIEDION, *Space, Time, and Architecture*, 5th ed., rev. and enlarged (1967), contrasts architectural styles and building techniques with an incisive analysis. CARL CONDIT, *American Building* (1968), narrates the history of building materials and techniques in the United States from the beginning of the Colonies. ROLLAND B. GUY *et al.*, *The State of the Art of Prefabrication in the Construction Industry* (1968), describes the trends toward prefabrication and the potential for building systems in the United States. Other references describing the history of construction are HENRY COWAN, *An Historical Outline of Architectural Science* (1966); GAVIN MAXWELL, *A Reed Shaken by the Wind* (1957); A.W. LAWRENCE, *Greek Architecture*, rev. ed. (1975); VITRUVIUS, *Ten Books on Architecture* (Eng. trans. 1914); JOHN H. BATEMAN, *Materials of Construction* (1950); and DON A. HALPERIN, *Building with Steel*, 2nd ed. (1966). LAURENCE E. REINER, *Methods and Materials of Construction* (1970); HARRY PARKER, CHARLES M. GAY, and JOHN W. MACGUIRE, *Materials and Methods of Architectural Construction*, 3rd ed. (1958); and JOHN L. SCHMIDT, WALTER H. LEWIS, and HAROLD B. OLIN, *Construction: Principles, Materials and Methods* (1970), present a description of materials and techniques currently used in the various functional areas (*e.g.*, foundations, structural frames, roofs, floors, space enclosure, and finishes) in residential and nonresidential construction. WILLIAM J. MCGUINESS *et al.*, *Mechanical and Electrical Equipment for Buildings*, 5th ed. (1975), provides the same type of detailed analysis relative to auxiliary systems, such as plumbing, electrical heating, ventilating, and air conditioning, as well as vertical transportation. PHILIP KISSAM, *Surveying*, 2nd ed. (1956); LOUIS C. RIPA, *Surveying Manual* (1964); W. FISHER CASSIE, *Fundamental Foundations* (1968); W.H. ELGAR, *Foundations for Houses and Other Small Structures* (1951); ROLT HAMMOND, *Modern Foundation Methods* (1967); LEONARD MICHAELS, *Contemporary Structure in Architecture* (1950); WHITNEY C. HUNTINGTON, *Building Construction*, 4th ed. (1975); THEODORE CRANE, *Architectural Construction*, 2nd ed. (1956); and T. BAUMEISTER and LIONEL MARKS, *Standard Handbook for Mechanical Engineers*, 8th ed. (1977), treat individual elements of construction (*e.g.*, surveying, foundations, and structural frame) in considerable detail. Structures with special construction problems are discussed in PETER BLAKE, "Cape Kennedy," *Architectural Forum*, 126:58–59 (1967); HARRY A. KULJIAN, *Nuclear Power Plant Design* (1968); and J.F. MUNCE, *The Architect in the Nuclear Age* (1964). The role of the architect and the design professions is well described in the AMERICAN INSTITUTE OF ARCHITECTS, *Handbook of Architectural Practice*, latest ed.; and *Comprehensive Architectural Services: General Principles and Practice* (1965). The role of the contractor and subcontractor, as well as the bidding process, is described in RICHARD H. CLOUGH, *Construction Contracting*, 3rd ed. (1975).

(J.R.Ha./D.C.Hu.)

Bulgaria

A Communist country of southeastern Europe, the People's Republic of Bulgaria occupies the eastern portion of the Balkan Peninsula, crossed by historically important routes from northern and eastern Europe to the Mediterranean Basin and from western and central Europe to the Middle East. The home of some 8,730,000 people at the time of the census of 1975, Bulgaria is remarkable for its variety of scenery, its rugged mountains and modern Black Sea resorts alike attracting an increasing flow of tourists from other countries. Historical, cultural, and political ties connect the republic with the Soviet Union, and long-term alliances also bind Bulgaria to other Soviet-bloc countries that are members of Comecon, the east European mutual economic development program, and the Warsaw Treaty Organization.

A nation of some 43,000 square miles (111,000 square kilometres), Bulgaria is bounded by Romania on the north, the border being marked by the Lower Danube River. The Black Sea lies to the east, Turkey and Greece to the south, and Yugoslavia to the west. The capital, Sofia, lies in a mountainous basin in the west, commanding important trans-European routes and near the geographical centre of the whole Balkan region.

This article is concerned with the contemporary country Bulgaria. For historical aspects, see BALKANS, HISTORY OF THE; see also DANUBE RIVER and SOFIA.

THE LAND

Topography. Within a relatively small compass, the Bulgarian landscape exhibits striking topographic variety. Open expanses of lowland alternate with broken mountain country, cut by deep river gorges and harbouring, often unexpectedly, such upland basins as that in which Sofia lies. The bewildering detail tends to conceal a series of crescent-shaped basic structural and physiographic divisions that run east–west. Topographic variety

The Danubian Plain. All but a small section of the northern frontier of Bulgaria is marked by the Lower Danube, the abrupt and often steep Bulgarian bank contrasting with the swamps and lagoons of the Romanian side. A fertile, hilly plain, with rivers flowing northward from the Balkan Mountains to join the Danube, borders the river. The average altitude of the region is 584 feet (178 metres), and it covers 12,171 square miles (31,523 square kilometres).

The Balkan Mountains. The Balkan Mountains border the Danubian Plain on the south, their rounded summits having an average height of 2,368 feet and rising to 7,795 feet (2,376 metres) in Botev, the highest peak. Parallel to this main chain (its Bulgarian name, Stara planina, means Old Mountains, "old" signifying its greater extent compared to the adjacent ranges) lies a transitional region of very complex relief. Block faulting—the raising or lowering of great structural segments along regular lines of crustal weakness—has produced here the Sredna gora (*gora* means "hill" and *planina* means "mountain," or "mountain range"), Vitosha Mountains, Lisa planina, a number of sheltered structural basins, and the Upper Thracian and Tundzha lowlands.

The Rila–Rhodope massif. Another mountain mass covers southern Bulgaria. This includes the alpine Rhodope (Rodopi in Bulgarian, Rodhópis in Greek) Mountains, which rise to 7,188 feet (2,191 metres) in Golyam Perelik Peak; the Rila Mountains, rising to Musala Peak, at 9,596 feet (2,925 metres) the highest in the country and indeed in the whole Balkan Peninsula; the Pirin Mountains, with Vikhren Peak reaching 9,560 feet (2,914 metres); and a frontier mountain range known as the Belasitsa.

These majestic ranges discharge meltwater from montane glaciers throughout the summer, and their sharp outlines, pine-clad slopes, and, in the Rila and Pirin ranges, several hundred glacial lakes combine to form some of the most beautiful of Bulgarian landscapes.

The Black Sea coast. Trending north–south at the eastern fringe of the other regions, the narrow Black Sea coastal region has few bays (exceptions being the fine harbours of Varna and Burgas) but does have extensive stretches of sandy beach that have led to the growth of a number of picturesque seaside resorts.

Drainage. Bulgaria has a complex drainage pattern characterized, with the notable exception of the Danube, by relatively short rivers. The major rivers are the Maritsa (Marica), draining the lowlands to the north of the Rila–Rhodope massif before turning away southward at the Greek–Bulgarian–Turkish frontier; the Iskŭr (Iskâr), draining the Sofia Basin before turning northward toward the Danube in a deep gorge through the Balkan Mountains; the Struma, running southward toward the Aegean through a valley paralleling Bulgaria's western frontier; the Arda, of the central Rhodope; the Tundzha, running Rivers

east along the southern flank of the Balkan Mountains; and the Yantra, flowing north to the Danube.

Overall, 57 percent of the runoff drains to the Black Sea and 43 percent to the Aegean. Northern areas subject to continental influences have a spring runoff maximum, while transitional Mediterranean influences give a winter runoff maximum farther south. Bulgaria's numerous lakes may be coastal (as the large lakes around Varna and Burgas), glacial (as in the southern mountains), structural, or karst in origin. A distinctive feature is the 500 or so mineral springs, half of which are warm or hot (reaching 215° F [101° C] at Sapareva Banya), which are used for bathing or drinking or both, the waters being considered healthful. Many dams have been constructed in the mountains.

Soils. The varied Bulgarian natural environment has produced about 20 soil types and subtypes, which may be grouped into three main regions. Northern Bulgaria is characterized by the fertile black-earth soils known as chernozems and also by gray soils of forest origin. Southern Bulgaria has forest soils with acidic (cinnamonic) traces—by far the most extensive single category—as well as the modified chernozems known as chernozem-smolnitzas (a dark-coloured zonal soil with a deep and rich humus horizon). Finally, the rugged high mountain regions have brown forest, dark mountain forest, and mountain meadow soils.

Climate. The greater part of Bulgaria has a moderate continental climate, which is tempered by Mediterranean influences in the south. The average annual temperature is 51° F (10.5° C), but this conceals a wide variation; temperatures as low as —37° F (—38° C) and as high as 113° F (45° C) have been recorded. Mean annual precipitation ranges from about 18 inches (450 millimetres) in the northeast to more than 47 inches (1,200 millimetres) in the highest mountains. This abundant rainfall is brought by thunderstorms in the spring and summer, and damaging hailstorms are also common.

Precipitation

Five climatic regions may be broadly distinguished. The north and northwest have a moderately continental climate, with cold winter winds from the European interior and the northeast sweeping over the Danubian Plain. A transitional version of this climate, with continental extremes moderated somewhat, affects the west, southwest, and central regions.

A 25-mile-wide belt on the Black Sea coast has a warmer winter but a cooler summer. The Mesta and Struma river valleys and the southeast have a transitionally Mediterranean climate, often with summer drought. Finally, regions above about 3,000 feet have a severer mountain climate.

Vegetation and animal life. The relatively large number of Bulgarian plant and animal species reflects the country's border situation adjoining several of the great Eurasian biogeographical zones. During the Ice Age, life in the region was not destroyed by advancing glaciers as occurred in much of Europe; it was actually enriched by the immigration of species from the north, some of which still survive. Influences from the steppes of western Asia also penetrated the region at that time. Nonetheless, the greater part of the plant and animal life is central European, mixed with a type that blends Arctic and alpine characteristics in the high mountains. Steppe species are most characteristic of the northeast and southeast, while the south is rich in sub-Mediterranean and Mediterranean species. To the east, the organisms of the Black Sea coastal fringe are of the steppe type along with some thermophilic, or heat-loving, species, while the Black Sea waters contain chiefly Mediterranean elements combined with some from the Caspian Sea.

In keeping with an awakening worldwide interest in the natural environment, the Bulgarian government has introduced a number of conservation measures, including steps to protect soil, water, and air from pollution and to establish protected areas of outstanding interest to naturalists. A council for the protection of the natural environment was set up in 1971, and 81 recreational areas, seven national parks, and 39 places of special interest were designated for protection in 1973.

Conservation

The human imprint. The natural environment of Bulgaria falls into three basic regions: North Bulgaria, including the Danubian Plain and the Balkan Mountains; South Bulgaria, including the Rila–Rhodope massif; and a transitional area between them. Each of these traditional regions over the centuries has been subjected to the actions of man, whether in the remoter mountains, where national culture was cherished and the seeds of nationalism were sown during the long Ottoman domination; or in the Danubian Plain, where agriculture has been practiced from ancient times. By the mid-1970s, Bulgarian settlements had been officially classified into 214 urban areas and some 5,441 villages, the latter including more than 500 small hamlets, about 350 clusters of farmsteads, and, deep in the mountains, a handful of historic monasteries.

Urban settlement patterns. Bulgarian towns have roots in the Middle Ages and in remotest antiquity, although new, modern settlements are being created each year; the urban population overtook the rural for the first time in 1969. Contemporary towns can best be classified according to their economic functions; thus, Sofia, Dimitrovgrad, and Pernik have a preponderance of industry, while other towns specialize in transportation or services.

The rapid urbanization now transforming much of the Bulgarian landscape is planned, each new or modernized town having its own development plan. The neighbourhood unit is a characteristic feature of this process. The rapid increase in the population of the capital and the largest towns has created a severe housing shortage, which the government did not seriously attack till 1970. The average size of a town increased from just over 16,000 people in 1946 to more than 26,000 by the early 1970s, when there were 14 towns with populations of more than 50,000, including seven major cities with more than 100,000 inhabitants. In spite of this transformation, many Bulgarian towns preserve their ancient charm and are rich in cultural monuments; in the remoter areas, they offer a slower pace of life than can be found in the cities.

Major cities

Sofia, the capital, is the largest city; with almost 1,000,000 people in its built-up area, it dominates the national economic and cultural life. Plovdiv, with more than 300,000 inhabitants, enjoys a scenic location on the Maritsa River and is another major industrial and cultural centre, where an international trade fair is held annually. Varna (ancient Odessus), with 252,000 inhabitants, is a resort on the shores of the Black Sea. The newer seaside resort of Zlatni Pyassŭtsi (Golden Sands), nearby, is attracting an increasing international tourist trade. On the Danube, Ruse, with more than 150,000 inhabitants, is the largest Bulgarian river port; there the Friendship Bridge leads to the Romanian city of Giurgiu. Burgas, with a population of well over 130,000, is Bulgaria's largest Black Sea port and a major industrial (petrochemicals), cultural, and resort centre. Stara Zagora, the Roman Augusta Trajana, lies on the southern flanks of the central Sredna gora, is the home of more than 110,000 persons, and is famous for its archaeological and architectural remains.

Rural settlement patterns. The numerous contemporary Bulgarian villages are either compactly clustered or relatively scattered. Since World War II, they have undergone a radical transformation from the sleepy, backward, and poverty-stricken settlements that typified much of the region for centuries. By the early 1970s, 90 percent of the rural population was living in villages with a water supply, and electricity was available to virtually all communities; from 70 to 75 percent of the houses were recent constructions, replacing the older lath and plaster structures. Most of the villages have paved and asphalted streets and new community centres. Industrial plants have been set up in the larger villages, and the agro-industrial economic complexes and detailed regional planning that is a part of government policy helps relate these developments to the needs of specific areas. Smaller villages (fewer than 500 inhabitants) nevertheless form nearly half of the total, although less than 7 percent of the rural population is found there. Administratively, the villages have undergone extensive amalgamation.

THE PEOPLE

Ethnic, religious, and linguistic background. Ethnically, the population is fairly homogeneous, Bulgarians making up more than 88 percent of the total.

The origins of the Bulgarians

The Slav tribes that settled in the eastern part of the Balkan Peninsula in the 6th and 7th centuries AD, thereby assimilating the local Thracian tribes, formed a basic ethnic group. The group known as the proto-Bulgarians, who, together with the Slavs, formed the Slav-Bulgarian state in 681, formed another component. With the gradual obliteration of fragmented Slav tribes and also of the ethnic differences in the territory of the first Bulgarian state (covering Moesia, Thrace, and Macedonia) in the 9th and 10th centuries, proto-Bulgarians and Slavs consolidated into a unified Slav people who thence retained the name of Bulgarians. This national unity, present in embryonic form during the long Ottoman domination, flowered in the independence struggles of the 19th century, and the Bulgarians today share a unity unassailed by either ethnographic or linguistic differences.

The majority of religious Bulgarians (the church is separate from the state) are Eastern Orthodox, with small numbers of Catholics, Protestants, and Muslims, the latter including those Muslim Bulgarians who were forced to adopt Islām in the 16th and 17th centuries but who have nevertheless retained Bulgarian language and customs. The Turks, Bulgaria's largest minority, live in some regions of the northeast and in the eastern Rhodope. Gypsies and Macedonians are two other sizable minorities (though the government does not consider Macedonians as such, regarding them as ethnically Bulgarian), and there are a few thousand Russians, Armenians, and Greeks (mostly in the towns) and Romanians and Tatars (mostly in the villages).

Minorities

The Bulgarian language belongs to the South Slavic group, along with Serbo-Croatian, Slovene, and Macedonian (the last, however, considered to be a dialect of Bulgarian by the Bulgarian government). A number of dialects remain in the common speech.

Contemporary demography. *Birth and death rates.* As a result of social and economic changes after World War II, notably the introduction of free medical care and the improvement of working conditions, Bulgaria's mortality rate dropped from 13.4 per 1,000 in 1939 to 10.3 in 1975, with infant mortality dropping from 139 to 23.1 per 1,000 over the same period. The birth rate dropped from 21.4 per 1,000 in 1939 to 16 in 1970, rising to 16.6 in 1975, and was about the same in town and country. Nat-

ural growth followed the same trends but declined after 1968, reaching 6.3 per 1,000 by 1975.

Emigration and immigration. Emigration since World War II has mostly affected non-Bulgarians. Some 190,000 Turks left the country, 155,000 having been expelled in 1949–51. Almost all Czechs and Slovaks returned to their homelands, as did large numbers of Russians and Armenians (to the Soviet Union) and Jews (to Israel). About 35,000 others, mostly Bulgarians, returned from North America and from European countries. Internally, the movement of population has been from rural areas to larger towns and cities. Between 1946 and 1968 the population of Sofia doubled and the populations of Varna and Ruse were multiplied by 2.7.

Bulgaria, Area and Population

	area		population

Source: Official government figures.

Population distribution. Bulgaria's geographical variety is reflected in the distribution of its population. The most densely populated areas are the Danubian Plain, the Upper Thracian Basin, the Burgas plain, and the intermontane basins of southwestern Bulgaria. Areas of lowest density are the east and southeast of the country, the Strandzha and Dobruja regions, and the higher mountain areas. Of a total population of more than 8,700,000 in 1975, just over half lived in cities, as compared to a quarter in 1946 (see above *The human imprint: Urban settlement patterns*).

Demographic trends. Urbanization continues to have an effect on the demographic structure; a large segment of the urban population is of a young working age, and this has an effect on the rising birth rates of the 1970s and the natural growth of the towns. Because relatively more older adults remain in the villages, the birth rate there continues to be lower and the mortality rate higher.

Birth and death rates

THE NATIONAL ECONOMY

The Bulgarian economy is based on the premise that all means of production should be owned by the state. Economic activities are centrally planned and supervised by the Council of Ministers—assisted by several ministries for specific aspects of the economy—along lines indicated by the Bŭlgarska Komunisticheska Partiya (Bulgarian Communist Party). Industry is almost wholly state owned, though private artisans were tolerated, and even encouraged, till 1968, after which increasingly severe restrictions were placed on their activities. By 1975, 83 percent of national income was generated by state-owned enterprises; the proportion generated by collectives had fallen to 12 percent and that of private enterprises to 5 percent.

Statistics issued by the government are not comparable with those issued by the United Nations or the United States, because of differences in concept and coverage, and are sometimes mutually contradictory. Thus it is difficult to speak of the growth of the Bulgarian economy in Western terms.

The extent and distribution of resources. Bulgaria is not rich in natural resources. Deposits of bituminous and anthracite coal have been almost exhausted, but large reserves of lignite (said to amount to about 3,000,000,000 tons) are found in the Maritsa Basin near Stara Zagora, and there are promising deposits of coking coal in the Dobruja region. Oil and gas are produced in small quantities in the Danubian Plain. Iron comes mainly from Kremikovtsi, northeast of Sofia. Government reports indicate mining of the important steel-alloying minerals (manganese, chromium, and molybdenum), but imports of these are also reported. Nonferrous metals—particularly copper, lead, and zinc—are apparently more extensive than ferrous.

Coals

Biological resources include the forests, meadow vegetation, edible mushrooms and the fruits of other plants, plant products used in the pharmaceutical industry, and fish, game, and mussels and oysters.

Lignite provides the basic local source for power requirements and feeds most of the power stations. Hydroelectric resources are limited in comparison.

Sources of national income. *Mining and quarrying.* Coal output—mostly lignite, with a large content of ash and moisture—was around 34,097,000 tons in the mid-1970s, more than meeting Bulgaria's own requirements. About 20 quarrying enterprises provide chiefly materials for production of cement and other building materials; there are also eight marble and granite quarries.

Manufacturing. Before World War II, industries were of minor importance in Bulgaria. Under the Communist system, industrialization became one of the principal aims of economic policy, with particular emphasis on basic industries such as electric power, ferrous and nonferrous metallurgy, and chemicals. Central planning of management, production, and investment channelled into industry a steadily increasing part of the national resources, and by 1975 industrial output was 55 times as great as before World War II and accounted for 66 percent of the national income. Industrial expansion was slowing, however.

Before the war, shipbuilding at Varna and foundries at Sofia, Plovdiv, Ruse, and Pernik were the most important metallurgical industries. Those developed after the war include iron and steel works at Pernik, based upon local brown coal and iron ore from the Sofia district; a large steel project at Kremikovtsi; a lead and zinc works at Kŭrdzhali; and a copper and sulfuric acid plant at Pirdop. A chemical industry has developed at Dimitrovgrad, and chemical plants were also built at Stara Zagora, Vratsa, Devnya, and Vidin, and a petrochemical plant at Burgas. Machine building is a priority branch of the national economy. Its relative share of industrial production jumped from 2.4 percent in 1939 to 17.8 in 1966 and to 25 in 1975.

Postwar industrialization

Textile industries before World War II were mainly to be found in the central part of the country—*e.g.*, Gabrovo, Sliven, Kazanlŭk, Khaskovo—together with Sofia, Varna, and Ruse. These used locally produced wool, cotton, or silk. Under the five-year plans, large new mills were built at Sofia, Sliven, and Plovdiv, and the total output of textile fabrics by 1966 rose to 16 times what it was in 1939. Other industries that have increased since World War II are food processing and consumer goods industries such as footwear, pottery, and furniture.

Energy. The major source of energy in Bulgaria is the Maritsa lignite field, which serves large thermoelectric plants at Dimitrovgrad and Maritsa-Iztok; there are thermal power stations also at Pernik, Sofia, Plovdiv,

and Burgas. About 90 hydroelectric stations generate about 9 percent of the total electricity output, but planners are giving considerable emphasis to developing the quite substantial potential power in the country's rivers, particularly in the Rhodope Mountains. Nuclear energy is provided from a station at Kozloduy (constructed with Soviet aid), which began operation in 1974 and has a capacity of 1,760,000 kilowatts. Transmission lines serve most parts of the country.

Agriculture, forestry, and fishing. A cooperative movement developed in Bulgaria before World War II, and after the war it spread further, until probably more than 80 percent of the arable land was in cooperative farms. In 1957 there were 3,202 cooperative and state farms, which by 1970 had been merged into about 1,000 large state and collective units. Agriculture had grown unevenly, however, and in that year these were consolidated into 170 large agro-industrial complexes (later consolidated still further) to take better advantage of mechanization, including automation, supply, etc. Agriculture accounts for about 18 percent of the national income.

Crops

Cereal crops are grown on almost three-fifths of the sown land. Wheat is by far the most important (32 percent of sown land), followed by corn (maize) with nearly 15 percent and barley with 11 percent; rye, oats, and rice are also grown. Other food crops are varied, as farmers produce most of their own vegetables and fruits.

Industrial crops are important, especially tobacco, a good-quality Oriental type grown mainly in the south. Sunflower seed is the chief (about 90 percent) oil-seed crop; after extraction of the oil, the pulp is made into cattle feed. Sunflowers, like sugar beets, grow mainly in the north and were introduced after 1918. Bulgaria has become a leading exporter of grapes and tomatoes. Animal husbandry accounts for about 43 percent of the agricultural output.

Financial services. About half of the national expenditure goes toward financing the economy and about a quarter for education, science, culture, and social services. Around three-quarters of the budget is financed from the profits of the state-owned economy. The Bulgarian National Bank (Bŭlgarska Narodna Banka) is the principal banking institution, although a Bulgarian Foreign Trade Bank (Bŭlgarskata Vŭnshnotrgovska Banka) was set up in 1964, and the State Saving Bank (Dŭrzhavna spestovna kasa) and the State Insurance Institute (Dŭrzhaven zastrakhovatelen institut) are also incorporated into the financial and credit system.

Imports and exports

Foreign trade is a state monopoly. Capital goods make up some 47 percent and consumer goods (a large proportion of agricultural origin) 53 percent of the export total, while for imports the corresponding figures are 87.5 and 12.5 percent. The export of machinery and equipment is rising and accounts for more than a quarter of the value of all exports. About 70 percent of foreign trade is with Comecon member countries (half of the total foreign trade being with the Soviet Union) and 17 percent with the developed capitalist countries.

Management of the economy. *The state role.* The national economy is managed by the state, as noted above. The drafts of the five-year plans and of the budgets (including the budgets for local governments) are worked out by the Council of Ministers (the government) and approved by the National Assembly. The Council of Ministers organizes, directs, and controls the implementation of plan and budget, with the National Assembly regularly receiving progress reports on the work done.

Taxation. The main sources of revenue are the turnover tax and deductions made from the profits produced by public enterprises. The turnover tax is based on a fixed rate and goes immediately into the budget after the sale of products by state enterprises. In this way the state budget is ensured a regular and uniform source of revenue to finance the undertakings called for in the economic plan. The turnover tax is dependent on the size, variety, and sale of manufactured products; ultimately it is passed on to the consumer. The profit deduction tax from state enterprises, unlike the turnover tax, is not at a fixed rate. It comes from each enterprise's net income after deduction of the turnover tax. The profit shown by an enterprise is the difference between income and maintenance expenses. In the mid-1970s, 42 percent of an enterprise's profit was left for its own disposal after subtracting the two taxes.

Budget. The size of the state budget increased nearly eightfold between 1949 and 1969. Some of this was accounted for by loans from the Soviet Union, but the size of these loans is not generally known; they must be large enough to suggest that the deferred repayment for Bulgaria's industrialization policy will be the responsibility of several generations of Bulgarians in the future. The national budget finances most capital investments, enterprises under direct central management, and a number of social and cultural needs (*e.g.*, higher educational institutions, research institutes, etc.). It also covers defense and the central government departments. People's council budgets—those of the district, municipality, and village people's councils—maintain a variety of educational, health, and cultural institutions, urban development and planning, and various other services. The state social insurance budget covers expenditure for employees' pensions, temporary incapacity to work, maternity leave, maintenance of rest homes, family allowances, etc.

State loans

The national budget allots around 50 percent of its revenues to developing the national economy, a large portion of this going to development of heavy industry. It also provides funds for capital investment in industrial enterprises and provides them with turnover funds. Large credits are allocated to agricultural development and the supply of farm equipment. Budgetary credits are also used to finance long-term investment projects (*e.g.*, power generation, forestry, ferrous metallurgy, and land improvement and water conservation projects). About a third of all investment comes from state budgetary credits, and two-thirds is covered by local enterprises' funds and bank credits. About 30 percent of the budgetary expenditure goes to social services and about 2 percent to administration.

The role of trade unions. The Dimitrov Constitution of 1947 proclaimed the trade unions to be "mass, nonparty public organizations of the workers and employees." In fact, however, the trade unions all belong to one organization, the Central Council of Trade Unions (Tsentralen sŭvet na profesionalnite sŭyuzi), founded in 1944 with 264,000 members; by the mid-1970s, it had some 3,324,000. The whole of Bulgaria's labour force is under state control and theoretically not allowed to strike or to disobey the government. Evidence suggests that theory and practice sometimes differ; worker discontent and strikes occurring during early 1971 were followed by a broad purge of the top leadership of the Central Council of Trade Unions. Such administrative response to workers' discontent may not be effective in the long term; the workers' dislike for totally dependent bureaucratic organizations that in their view have done little to protect their interests tends to refute the official line that "the trade union is the chief organizer of the working people in the struggle for fulfilling the economic plan [and it is its duty to] see to labour safety and do its best to improve and meet the working people's social and communal needs, defending and representing their interests in the conclusion of labour contracts."

Transportation. The development of the Bulgarian economy has required the expansion of the transportation system. The relationship among the various components of the system is changing rapidly; by the mid-1970s, road transport accounted for 88 percent of all the freight carried (on a tonnage basis) and for about five-sixths of all passenger traffic.

Roads and railways. Roads and railways together account for all but a small fraction of both freight and passengers carried. Road mileage by the 1970s was more than double that before World War II. An expressway ring linking Sofia–Plovdiv–Burgas–Varna and Sofia–Pleven–Varna was under construction, and the E-5 European International Highway, crossing the country toward Istanbul, had been thoroughly reconstructed in the Kalotina–Kapitan Andreevo section.

By the mid-1970s, railway track mileage was only a fifth that of roads, though half as much again as the pre-World War II total. The main lines connect Sofia with the Black Sea coast, and electrification is underway.

Water and air transport. The Danube is used for both internal and international traffic, Ruse and Lom being the main river ports. The chief seaports are Varna and Burgas, and there is a regular international merchant service on the Black Sea. Bulgaria has international airports at Sofia, Varna, and Burgas, and internal air services are growing; scheduled international service showed a considerable increase during the 1960s and '70s.

Airports

ADMINISTRATION AND SOCIAL CONDITIONS

The constitutional framework. The People's Republic of Bulgaria is one of the states of the Communist bloc of eastern Europe. Power in this people's democracy, according to the constitution of May 18, 1971 (which replaced the so-called Dimitrov Constitution of 1947), resides in "the working people in town and countryside," and the Bulgarian Communist Party is "the leading force in society and in the state" ("leading" is permissible, since one other party is tolerated). The nominal supreme organ of power is the one-chamber National Assembly (Narodno Sŭbranie), which consists of 400 representatives elected for five-year terms from constituencies with equal numbers of inhabitants and which meets for very short sessions three times a year. The highest constantly functioning organ of state power is the State Council (Ministerski Sŭvet), theoretically responsible to the National Assembly, which has both legislative and executive functions. The Council of Ministers is the official executive and administrative organ.

The country is divided into 28 districts (*okrŭzi*, singular *okrŭg*), which are subdivided into municipalities (further divided, if large, into urban constituencies, or *rayoni*) and villages (grouped together to form rural constituencies, or *obshtini*). Organs of government paralleling those at the national level exist at the local levels.

In practice, the Bulgarian Communist Party exercises legislative and executive control at all levels of government.

The political process. Elections to the various representative bodies are open to all citizens who have attained the age of 18, and representatives are theoretically accountable to the electorate. There are two political parties. The ruling party is the Bulgarian Communist Party (Bŭlgarska Komunisticheska Partiya, or BKP), founded in 1891 as the Bulgarian Social Democratic Party, with about 790,000 members by 1976. The other party that is permitted to function is the Bulgarian Agrarian Union (Bŭlgarski Zemedelski Sŭyuz, or BZS), founded as a peasant organization in 1899, with some 120,000 members in the mid-1970s. The Fatherland Front (Otechestvenofront), founded in 1942 by several political parties and some independents, was transformed in 1948 into the largest mass organization, with some 3,770,000 members in the mid-1970s. The Dimitrov Young Communist League has a membership of about 1,300,000.

Bulgarian Communist Party

Justice and the armed forces. The judiciary is part of the government structure, ranking below the executive and legislative branches. The system of court organization distinguishes between general (district) courts, special courts (for the armed forces and transport facilities), and a Supreme Court. Supreme Court judges are elected by the National Assembly for terms of five years, judges of district courts for three years; judges of people's courts, on the lowest level, are elected by the general electorate for the same three-year period. All judges are subject to removal by the agency that elected them.

Individual court decisions (apart from those of the Supreme Court) are not a source of law and are binding only in the case for which they are rendered. Even judicial practice does not constitute a source of law. Decisions are important only for the elucidation of the contents of law and its application. A decision of the Supreme Court, however, taken at its civil, criminal, or military division, is considered binding upon the lower courts and a source of Bulgarian law.

According to a ruling of 1953, "the courts correctly understand and carry out the policy of the Bulgarian Communist Party and people's democratic power [*i.e.*, government] for a merciless struggle against the crimes as defined in the Criminal Code."

Bulgarian military forces are made up of the Bulgarian People's Army and the troops of the Ministry of the Interior, both under the State Council; the Bulgarian People's Army is under the immediate command of the Ministry of National Defense, most of whose members are military officers. The term of obligatory national service is two years, except in the naval forces, in which it is three. The army is well equipped with modern weapons and integrated with the forces of other Warsaw Treaty Organization member countries.

Military forces

Also under the Ministry of National Defense are the Border Troops, responsible for the integrity of the frontiers. The Construction Troops, which provide labour under military discipline and organization, are directly under the Council of Ministers. The Ministry of Internal Affairs supervises the activities of the People's Militia, who act as local police, and the state security police, who deal with crimes against national security or those presenting a threat to society.

Services. *Education.* Education is the responsibility of a government ministry and of the educational councils of local people's councils, while higher education is supervised by a special state committee. Education is free for all types and levels (for financing, see above *The economy: Management of the economy: Taxation*) and is obligatory for children from seven to 16 years of age. Since 1959, general education includes polytechnical subjects and vocational training. There are 21 semi-higher institutions and more than 30 higher institutions. The Sofiiski Universitet "Kliment Ohridski" (founded in 1888 as the Sofia Higher Institute) is the oldest body of higher learning and was the only university till 1971, when two teacher-training institutes in Plovdiv and Veliko Tŭrnovo were elevated to university status. There is a ratio of 1,800 students to 10,000 inhabitants, and the educational system compares well with other countries of Europe.

Health and welfare services. The health service, directed by a health ministry, provides free medical assistance of all types. By the mid-1970s there were more than 180 hospitals, with one bed per 130 inhabitants. In addition, a number of specialized establishments took care of tuberculosis patients and children. Medical social services are supported by an insurance plan that consists of a consolidated fund of contributions from state and cooperative enterprises and institutions and similar bodies. It is directed by the Central Council of Trade Unions and covers practically all of the working population.

Housing. Some 15 percent of the total capital investment in Bulgaria in the mid-1970s was going into housing, reflecting a program adopted in 1970 to try to alleviate the severe housing shortage caused by rapid urbanization. An amount equal to about 10 percent of the capital investment program is spent on individual housing construction, with the state granting to individuals loans that can be repaid over periods of up to 25 years.

Urban housing shortage

Social conditions. Since both wages and retail prices are controlled by the government, they are kept relatively stable in relation to one another. The highest annual wages are those in the building trades, lowest in agriculture. Monthly children's allowances, pensions, and sick pay in some cases add considerably to the income from wages alone.

Industrialization is having its effect on the socio-economic categories of the population: some 33.5 percent were engaged in industry in 1975, compared with 21.9 percent in 1960 (and 7.8 percent in 1934), while the share of agriculture declined from 54.7 to 27.6 percent over the same period. There has also been a rise in the numbers employed in education, culture, and art (from 3.4 percent in 1960 to 6.1 percent in 1975) and in the health services (1.6 percent to 3.6 percent). The percentage of women workers continues to rise, having reached 47.4 percent overall by 1975 and as high as 73.2 percent in finance, banking, and insurance.

CULTURAL LIFE AND INSTITUTIONS

Contemporary Bulgarian culture is a lively blend of the millennium-old folk traditions of the region; a more formal culture, which played a vital role in the emergence of national consciousness and the development of a modern state; and, since World War II, the development of a strong Communist element.

Socialist Realism

The fine and decorative arts and architecture. Socialist Realism now dominates Bulgarian painting, with its theme of building Communism. There is, nevertheless, much variety in individual forms and styles, ranging from satirical drawings and cartoons to portrait painting, genre pictures, and woodcuts. In applied arts—wood carving, ceramics, textiles, wrought iron, and embroidery—a number of artists are striving to blend contemporary artistic requirements with the old national traditions.

A new content has imbued architecture as a result of housing and public building programs and the development of professional and experienced architects. Many communities are changing their appearance, with well-planned housing developments replacing the often dilapidated older structures. The Black Sea coast has seen some of the more spectacular vacation and health resort developments, notably those of Zlatni Pyassŭtsi (Golden Sands) and Slunchev Bryag (Sunny Beach). Modern industrial architecture has also made headway, succeeding a rigid, monumental style imposed in the 1940s and '50s. The new industrial towns of Dimitrovgrad, Madan, and Rudozem are cited as examples of all-round planning.

Folklore and literature. Bulgaria is a country of rich, orally disseminated folklore; contemporary folklore, while preserving its old forms, is being enriched with a new content reflecting both the guerrilla movement of World War II and ensuing programs of reconstruction. There is a noticeable coming together of folklore and the general body of literature: folklore authors master the techniques and forms of personal poetry, while the contemporary writer is enriched by the poetic folklore heritage. Folklore is widely disseminated by books, radio, television, folk song and dance ensembles, and amateur folklore groups.

Bulgarian written literature dates from the 9th century AD, when SS. Cyril and Methodius created alphabets for Old Bulgarian (or Old Church Slavonic) and translated the Bible into that language. Their disciples created a literature that influenced the writers of Serbia, Russia, and Romania. From the 15th to the 18th century, Bulgarian literature suffered under Ottoman oppression. The literature of the ensuing Bulgarian revival was characterized by a democratic and realistic spirit and served the cause of national awakening and general cultural advance. It reached its climax in the poetry of Khristo Botev. After the liberation from the Turks in 1878 came the period of Critical Realism, of which Elin Pelin was probably the best example. The novels and poems of Ivan Vazov spanned the period before and after liberation, and the poetry of Pencho Slaveykov and Peyo Yavorov is also regarded as being of very high standard. The 1930s and '40s saw a number of anti-Fascist and antimilitarist works joining a growing undercurrent of working class and Marxist literature and criticism. Socialist Realism dominated the scene after World War II, and historical themes, as well as the anti-Fascist struggle, were accorded much attention by writers and critics. Among the writers should be mentioned the poets Elisaveta Bagryana and Valery Petrov and the prose writers Dimitr Talev, Dimitr Dimov, Emilian Stanev, and Nikolay Khaytov, as well as the humorist Yordan Radichkov and Blaga Dimitrova, author of both poetry and prose.

Bulgarian revival

Music and the theatre. By 1975 there were seven state opera houses, a number of orchestras, an operetta theatre, and state choreographic schools. Choir singing, instrumental music, and amateur activities are particularly developed, with such groups as the S. Obretenov Choir, the State Folk and Dance Ensemble, and the Bodra Smyana pioneer children's choir achieving international reputations. The two basses Boris Khristov and Nikolay Ghiaurov are probably the singers best known in the West.

The theatre has always had a strong tradition of Realism, and its principles were consolidated by N.O. Massalitinov, who studied at the Moscow Art Theatre and exerted a powerful influence as head of the Ivan Vazov National Theatre from 1925 to 1944. The "Krastju Sarafov" Higher Institute of Dramatic Art was set up in Sofia in 1948, and there are some three dozen state drama theatres, a dozen or so puppet theatres, and three Turkish variety theatres active in the country.

The cinema and the mass media. Prior to 1944, motion-picture production was limited, but during the ensuing decade a number of films were produced by a highly talented group. Major productions ranged from *Alert* (1951), concerning the problem of an individual person's neutrality in World War II, to *Farewell Friends* (1970), which was about the education of young people in a Communist society. The popularity of film going is reflected in high attendance rates.

By the mid-1970s some 498 newspapers, 830 periodicals, and 3,700 book titles were coming out regularly each year, and circulation figures reflected the high readership interest. Most of the newspapers are issued rather infrequently, however; only 13, for example, are dailies, all of them published in Sofia and all reflecting official views in their treatment of the news. Radio and television broadcasting—all operated by the state—by the mid-1970s reached, respectively, 262 and 168 persons per 1,000 population.

Institutions. There are some 10,500 libraries, with a total holding of about 59,460,000 volumes, and more than 180 museums. There are an additional 4,270 *chitalishchas*, which resemble reading rooms, found in even the smallest villages, that are a special Bulgarian form of cultural and educational activity. It first emerged in 1856 in Svishtov during Turkish bondage and has a very fine record in broadening the consciousness of a wide cross section of the community.

THE OUTLOOK

By the early 1970s, the question of improving the technical and organizational standards of production, labour, and management was being raised with the greatest urgency. In this connection, automated managerial systems began to appear as early as 1968, and within a few years a number of electronic computer centres were under construction. One of Bulgaria's basic problems has been the lack of raw materials, and efforts have been directed toward increasing local supplies, which accounted for only half the total by the 1970s. An extended long-term forecast for power generation and an improvement of the national fuel and energy balance envisages heavy dependence on nuclear power plants (about a quarter of total electricity production by 1980).

Technocratic management

Underproduction by workers, a consequence of lack of incentive, is considered by Western observers to be a serious problem. Continued urbanization will have marked effects on the demography of the country and the provision of social services. Overall coordination of all aspects of economic and social life will continue to be controlled by the state planning apparatus. It is hoped that the process will take into account the need for safeguarding the national heritage of a rich and distinctive culture.

Bullfighting

Bullfighting is the Spanish national spectacle. It developed in Spain, the country that still is the hub of *la fiesta brava*, but there is also keen interest in it in Mexico, Peru, Colombia, and Venezuela. The Spanish name is *corrida de toros*, from the Latin *currere*, "to run," and *taurus*, "bull." Bulls used in *corridas de toros* are not the commonly known variety of meat or milk cattle, which are basically domesticated, but a distinctly savage breed.

Combats and spectacles with bulls were common in ancient Crete, Thessaly, and imperial Rome but depended on the inherent trait of domesticated cattle to flee their attackers; the distinguishing trait of savage Iberian stock is its spirited and continuous attack without the slightest provocation.

Iberia's savage horned beasts

History. Even before the Punic Wars the Celtiberian people knew the peculiarities of the savage cattle that inhabited their forests, having developed their hunt into a game and also having used them as an auxiliary in war. Thus, when in 228 BC the Carthaginian Hamilcar Barca marched on Ilici and blockaded the city, the defenders gathered a great herd of the beasts, attached wagons loaded with resinous wood to them, which they lighted with torches, and drove them at the enemy. In the ensuing battle Hamilcar was killed and his army annihilated. Carthaginians and Romans, disputing the known world between them, were astounded by accounts of Barca's annihilation. They were equally amazed at subsequent tales of games held in Baetica (the Spanish province of Andalusia) in which men exhibited dexterity and valour before dealing the death blow with ax or lance to a savage horned beast. The Iberians were reported to use skins or cloaks to avoid the repeated attacks of their savage bulls before killing them.

Conquest of the Iberian Peninsula by Vandals, Swabians (Sueves or Suebi), and Visigoths modified the customs of the people. Three centuries of Visigoth rule (AD 415–711) evolved a spectacle featuring brute strength of men over bulls (*forcados* or *pegadores*), later adopted by the Lusitanos (Portuguese) and still retained as one of their specialties. The Muslims from Africa who overran Andalusia in AD 711 gradually modified the existing games. As the Muslims were great horsemen, their dignity demanded that they take the lance from their vassals, relegating the peons to the inferior position of simply manoeuvring the animals on foot so that their mounted masters might perform to better advantage. The crumbling Roman amphitheatres of Seville, Cordova, Toledo, Tarragona, Mérida, and Cádiz were rebuilt and embellished. Tournaments developed as a result of the rivalry between Moorish chieftains and Christian Iberian knights, and, except in large cities that boasted amphitheatres, most festive occasions were held in the city square or plaza, from which all bullrings derive their names, or in the open fields outside the town.

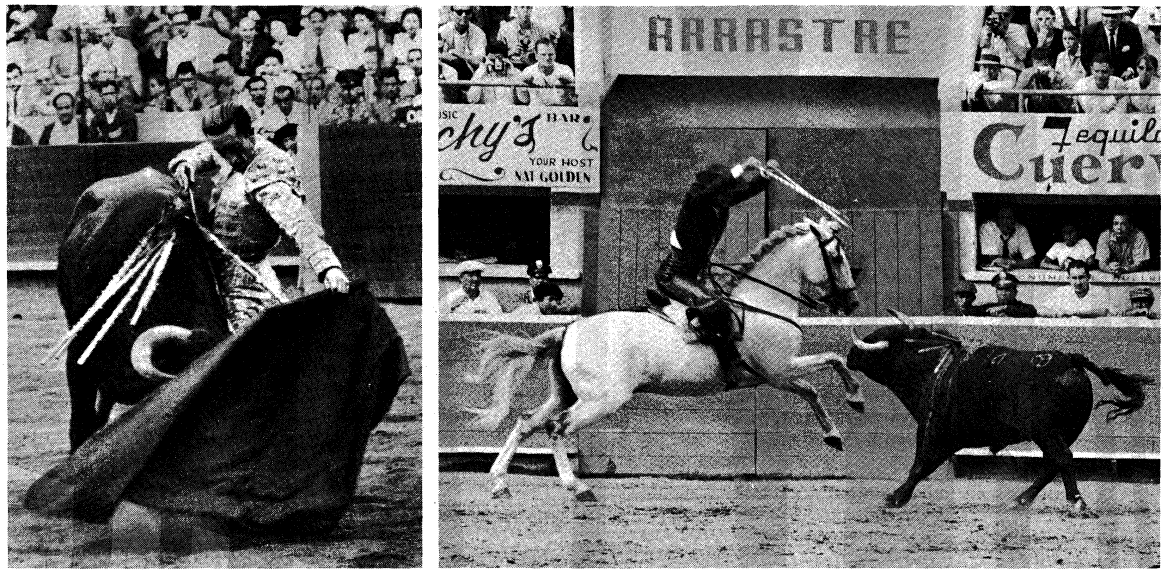
The first Castilian to lance a bull from horseback is thought to have been Rodrigo Díaz de Vivar, "El Cid Campeador" (1043–99). After the Muslims were driven from Spain in the 15th century, bull-lancing tournaments continued to be the favourite sport of the aristocracy. By the time of the Austrian accession it had become an indispensable accessory of every court function, and Charles V endeared himself to his subjects by lancing a bull on the birthday of his son Philip II. During the reign of Philip IV the lance was discarded in favour of the *rejoncillo* (short spear) and the leg armour (still worn by the picadors) was introduced. As knowledge of the nobles' prowess spread, they were invited to competitive jousts in provincial tournaments. The nobles' unfamiliarity with the spirit of bulls other than their own caused the vassals to gain greater experience and fame than their masters. By 1700 they were performing on foot and had relegated their peons to a subordinate role on horseback (picador). By the early 1700s bull breeding had become financially profitable, and herds were bred for specific characteristics. The royal houses of Spain, France, Portugal, Italy, and even the Roman Catholic Church in Spain competed to present the best specimens in the ring.

First professional bullfighters: introduction of the sword

Papal threats of excommunication gradually wrought a radical transformation in the character of the *lidia* (bull joust), forcing the nobles to relinquish their role to professional subordinates who, because of class consciousness, discarded the lance in favour of the sword. One of the first great professional *espadas—i.e.*, the man who actually kills the bull—was Francisco Romero of Ronda in Andalusia (about 1700), who introduced the *estoque* (the sword still used to kill the bull) and the muleta (small, heart-shaped red worsted serge-type cloth cape folded lengthwise over a 56-cm staff), used in conjunction with the *estoque*. At the height of his fame, the artist Francisco José de Goya y Lucientes (1746–1828) designed a distinctive professional uniform (worn only on commemorative gala occasions in Goya-style *corridas* or *corridas goyescas*). Performers began using a net to hold back their shoulder-length hair, later tying it in a knot at the base of the skull for protection in falls when tossed by the bull, just as, before the innovation of the helmet, football players used their hair to protect the head. This hair style later developed into the *moña y coleta*, the satin-covered semispherical cork headpiece and short queue that became the distinguishing mark of the profession. Expense and lack of native spirited stock prevented bullfighting from taking root in France proper (though *corridas* are held in southern France) and Italy. Portugal retained the *rejoneadores* or *cabaleiros en praça* (lancers mounted on highly trained horses) who, with the *forcados* or *pegadores* and *salteadores* (men who pole-vault over a charging bull), comprise what is known as Portugal's *corridas* in which the bull's horns are padded or brass-ball tipped; thus the horses and bulls are rarely killed. After the introduction of railways, the *plazas de toros* in Spain, Portugal, and Latin America (where the conquistadors introduced *corridas* in the early 1500s) greatly multiplied. Spain in the second half of the 20th century had about 400 *plazas de toros* of all sizes, from those of Madrid and Barcelona, seating about 20,000 spectators each, to those of the small towns accommodating 1,500. The arena floor never varies more than several metres, those at higher altitudes being smaller than those at sea level to help compensate for altitude fatigue. The *plaza de toros* in Mexico City, inaugurated during the 1945–46 season, seats approximately 50,000.

Bull breeding. The bulls used in *corridas* are invariably of pedigreed lineage reared on special ranches (*ganaderías*), the most celebrated being those of Miura, from Seville, which have killed more famous matadors, including the great Manolete, than any others. Shortly after weaning, vaccinating, and branding, the yearling males are tested in the open fields (*tienta de acoso y derribo*, hazing and tumbling), and only those displaying the proper spirit are retained for future *corridas*. Some yearlings of remarkable pedigree, true coloration, and fine physical construction are separated and when three years old are put through a series of tests (*tentadero de sementales*, stud tests) designed to prove the animal's spirit beyond a doubt. If acceptable, such bulls are then used exclusively at stud, usually 15 years; if not, they are sent to the slaughterhouse. At two to three years the heifers are tested in a small ring at the ranch (*tentadero de vaquillas*, test of heifers to be used for breeding) through all the phases of the *corrida* and only those acceptable are used; the rejects or culls go to the slaughterhouse. Royalty attended these tests, which became fortnightly social events at which famous matadors practiced new manoeuvres.

Bulls are never used a second time in the *corrida*. First, their memory is remarkable and former experience would not permit the type of performance expected; and second, to be acceptable for a *corrida*, they must be physically virgin as well as virgin of contact with any phase of the *corrida*. All cattle are colour blind. The colour red has been adopted for the work cape and muleta since it minimizes the sight of blood and other



(Left) Manolete (Manuel Rodríguez) executes a natural, a close *pase* with the muleta in the left hand. (Right) Matador Carlos Arruza places *banderillas* from horseback.
(Left) Barnaby Conrad, (right) C. Don Mengason

stains and produces a more colourful spectacle; the inside of the cape is yellow and the bulls charge just as readily at it as they do the red.

Performers. *Toreros* or professional bull men consist of matadors; *banderilleros*, assistants on foot who work with the cape and also place *banderillas*; and picadors, mounted assistants with pike poles, or lances. Six bulls usually are killed during one *corrida*, the matadors, whose *cuadrillas* or troupes consist of two or three *banderilleros* and two or three picadors to each, alternating in the performance according to seniority in the profession. Matadors must pass through a trying novitiate as *novilleros* (professional novices) before receiving the *alternativa*, the ritualistic ceremony in which the senior matador confers on the novice professional status and acceptance as a professional equal, capable of dispatching any bull properly.

The ceremony. The *corrida* begins with the grand entry procession of the *cuadrillas* led by one or two mounted *alguaciles* (bailiffs in 16th-century costume). The matadors wear short jackets, waistcoats, and knee-length, skintight trousers of silk and satin, richly embroidered in gold, silver, and silk; dress capes of satin, heavily embroidered in gold, silver, and silk, or combinations of them, worn only during the entry procession; handdrawn linen lace shirtwaists: coral-pink heavy silk stockings; flat, heelless black slippers; and *monteras* or hats made of tiny black silk chenille balls hand sewn in special designs on heavy buckram. *Banderilleros* wear similar garments, lacking only the gold embroidery, which is reserved exclusively for the matadors. Picadors wear broad-brimmed, low-crowned, heavy, beige-coloured hats called *castoreños*, jackets and waistcoats similar to those of the matadors but not as ornate, hip-to-ankle armour of steel one-eighth inch thick on the right leg, and knee-length left-leg armour covered by tightly fitting trousers of heavy cream-coloured chamois and heavily protected chamois ankle boots.

Opening ceremonies

After the opening procession has crossed the arena, the *presidente municipal* (the mayor or his legal representative) throws down to one of the *alguaciles* the key to the *toriles* or bull pens. When the *cuadrillas* not performing with this bull have left the arena and the others have taken their respective positions, the *toril* door is opened. As the bull passes through the *toril* door, an attendant perched above attaches a silken rosette made of the ranch colours into the shoulder muscles of the bull. A *banderillero* capes the bull with one hand only, so that the matador may judge whether the bull shows marked preference in the use of either horn or attacks equally from both sides. Then the matador goes into the arena and performs the initial passes, usually the basic *verónica*, working as gracefully and as close to the horns as possible. During the cape work, a bugle signals the entrance of the picadors, the beginning of the first of the three main divisions or acts (*tercios*) that constitute the fight—the *pic*-ing, the planting of the *banderillas*, and the kill. The picadors move into position, and when the bull charges the horse it is the picador's duty to fend off the attack by the use of his pike pole, planting the point in the bull at the junction of the neck and shoulder blades. Because of shocking and unnecessary disembowelment of the horses, complete protective armour made of three-inch thick compressed cotton encased in leather and canvas, encouraged by Sidney Franklin, the first U.S.-born professional matador, was officially adopted in March 1930, thus virtually eliminating harm to the horses.

The three matadors vie in series of passes (*quites*) as gracefully as possible, taking turns in order of seniority (the matador performing with this bull coming first, the others following in turn). This is done a minimum of two times and a maximum of four, stamina and spirit of the bull dictating the number. A bugle call announces the *tercio de banderillas*, and the picadors retire from the arena. *Banderilleros* alternate in planting two to four pairs of *banderillas* (72-centimetre staves decorated with coloured paper and with a 3-centimetre barb at one end) in the bull's shoulders at the junction with the neck. This is done by attracting the bull's attention with violent gestures and shouts from a distance of 20 to 30 yards. As the bull charges, the *banderillero* runs forward and slightly to one side, and as both come together, the *banderillas* are deftly planted, the man spins away to safety, and the bull's momentum takes it out of goring range. The basic object of both the *banderillas* and the picador's use of the pike pole is to weaken the great neck muscle of the bull so that his head will be low enough at the end of the fight for the matador to kill him with the sword. Some matadors, especially the Mexicans, are highly skilled with the *banderillas* and plant their own.

The Hour of Truth

Another trumpet call signals the third and final *tercio*, the killing, known as the Hour of Truth. This is done by the matador alone, his *banderilleros* being present only in case of emergency or should he request their assistance. The matador takes a position below the *presidente's* box and with *montera* held aloft in his right hand, muleta and *estoque* in his left, he formally requests permission to *brindar* (dedicate) the bull to some

personage or friend to whom he tosses his *montera*. After the matador has performed many dangerous and graceful passes with the bull to prove complete mastery (using only the muleta, which may be spread wider with the *estoque*), he prepares for the kill. This is done *al volapié*, or "fleet-foot," in which man and bull attack each other from a standstill position; or *recibiendo*, in which the man stands still and receives the bull. The latter is rarely done because of the great precision and courage required for its successful completion. At no time is the matador permitted to touch the bull with the *estoque* except for the kill. Improper ethics on the part of any *torero* during a *corrida* may result in heavy fines or jail sentences, or both.

The kill

The kill is executed by the matador thrusting forward the muleta with his left hand, causing the bull to lower his head in quest of his adversary, while with his right hand the matador sinks the *estoque* between the bull's shoulder blades at the junction with the neck. The blade should penetrate diagonally, severing the aorta, or great artery; the thrust, if well executed, causes almost instant death.

After the kill the matador, if acclaimed, circles the arena with his *banderilleros* to the applause of the spectators. Then he returns to the person honoured by his *brindis* to retrieve his *montera*, which invariably is returned with money or a gift. If the performance has been excellent the matador receives, as a token of popular esteem, one ear of the bull. If it has been exceptional he receives two ears. If his success should be extravagant, he receives both ears and the tail. While the matador is being acclaimed, a *puntillero* (an attendant armed with a short blade) severs the bull's spinal cord at the base of the skull, and the carcass is dragged from the arena, quartered, and dressed. Sometimes the bull's meat is given to the poor, but usually it is sold right at the *plaza de toros*. The ring is raked over, the next bull is introduced, and the spectacle begins anew.

A specific and colourful vocabulary has evolved to describe each of the actions and manoeuvres of the participants, the performance of the bull, and other aspects of the spectacle. Many of the terms, which are Spanish, derive from slang used by Gypsies (*caló*). Glossaries of bullfighting terms may be found in the references cited in the bibliography, below.

Great matadors. The star performer of this spectacle, the matador, can be and often is a wealthy man. When Manolete was killed at the age of 30 in 1947, he had made the equivalent of $4,000,000 U.S. Many *toreros* (never "toreadors," a word popularized by the French composer Georges Bizet in his opera *Carmen*) risk their lives for 10 years or so, amass a fortune, and then retire to a large ranch where they raise bulls for younger men to fight, as Juan Belmonte did.

Juan Belmonte

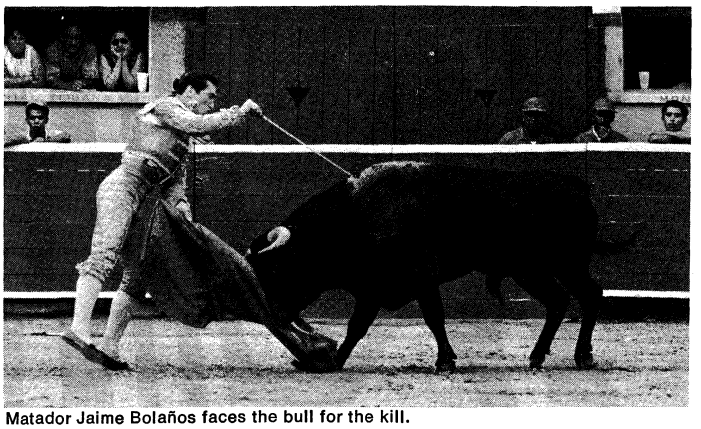
It was Belmonte who truly revolutionized the ancient spectacle about 1914. Formerly, the main object of the fight had been only to prepare the bull for the sword thrust; Belmonte, a small, frail Andalusian, emphasized the danger to the man by close and graceful capework, and the kill became secondary. He worked closer to the horns than people had ever believed possible and became an overnight sensation. The crowd does not actually wish to see a man killed, but the possibility of death and the man's disdain of it and his skillful avoidance of injury thrills a crowd.

The audience is not interested in simply seeing a man go into an arena, kill an animal in the safest manner, and emerge unscathed; they want to see skill, grace, and daring. Therefore a *corrida* is not really a struggle between a man and a bull but rather the struggle of a man with himself: how close will he dare to let the horns come, how far will he go to please the crowd?

Joselito (José Gómez), Belmonte's great friend and rival, considered the greatest bullfighter of all time, gave his life for the crowds in 1920, as have many men. Virtually every matador is gored at least once a season in varying degrees of severity. Belmonte was gored more than 50 times. Of the approximately 125 major matadors (since 1700), more than 40 have been killed in the ring; this figure does not include beginning matadors, *banderilleros*, and picadors who have been killed.

The greatest matadors of the 20th century have been the Mexicans Rodolfo Gaona, Armillita Chico (Fermín Espinosa), and Carlos Arruza; and the Spaniards Belmonte, Joselito, Domingo Ortega, and Manolete (Manuel Rodríguez). Perhaps the man who made the largest sum of money was El Cordobés (Manuel Benítez), who dominated bullfighting from 1963 until his retirement.

C. Don Mengason



Matador Jaime Bolaños faces the bull for the kill.

Women bullfighters

There have been several women bullfighters but no great ones. The first mention of a *torera* occurred in 1654. Later, one of Goya's etchings depicted "the manly courage of La Pajuelera" as she performed in the arena at Zaragoza. Even a nun, Doña María de Gaucín, supposedly left a convent in an unknown year to become a *torera*. Around the turn of the 20th century, "La Reverte" became famous as a *señorita matadora*, but in 1908 the government of Spain declared it illegal for women to perform in bullrings, so that "La Reverte" was forced to doff his wig and reveal himself as a man. In modern times two young American women, Bette Ford and Patricia McCormick, attracted publicity by fighting as *novilleras* with a modicum of success. The finest female bullfighter, however, is generally agreed to have been Conchita Cintrón, who achieved great success in Peru, Mexico, and Spain in the late 1930s and early '40s, fighting both on horseback in the Portuguese style and on foot. She was the only woman of any nationality to be taken seriously by both spectators and fellow bullfighters. While women are allowed to fight bulls on foot in Latin America, such practice is prohibited on the Iberian Peninsula, where, however, they may still perform on horseback.

Bultmann, Rudolf

Perhaps the leading New Testament scholar of the 20th century and certainly the one who occasioned the most controversy, Rudolf Bultmann was best known for his program to "demythologize" the New Testament. He held that its essential message was expressed in mythical terms derived from the mythological context of its time and place, and he proposed to interpret these "myths" (*e.g.*, virgin birth, incarnation, Resurrection) in terms of the categories of 20th-century Existentialist philosophy in order to give meaning to the message for modern man. Both his view of the New Testament texts as essentially mythical rather than historical and his explicit use of

Existentialist philosophy to interpret them aroused intense discussion. Bultmann was also a major figure in the general theological field, one of the giants of the period between the two World Wars. His theological position also aroused controversy, because he claimed, following his interpretation of Paul the Apostle and John the Evangelist, that Christian faith is, and should be, comparatively uninterested in the historical Jesus and centred instead on the transcendent Christ. Christian faith, he asserted, is faith in the *kērygma* ("proclamation") of the church, into which Jesus may be said to be risen (Bultmann's understanding of the Resurrection), and not faith in the historical Jesus.

Rudolf Karl Bultmann was born on August 20, 1884, at Wiefelstede, Germany, the son of a Lutheran pastor and the grandson of a missionary. He always intended to follow an academic theological career, and at 19 he began his theological studies at the University of Tübingen. By 1912 he had completed his qualifying studies and was appointed a lecturer at the University of Marburg. There followed appointments at Breslau (1916) and Giessen (1920). In 1921 he was appointed professor of New Testament at Marburg, where he remained until his retirement in 1951. He continued his residence in Marburg after his retirement.

Rudolf Bultmann.

Early works

In 1921 Bultmann published his *Geschichte der synoptischen Tradition* (*History of the Synoptic Tradition*), an analysis of the traditional material used by the Evangelists Matthew, Mark, and Luke and an attempt to trace its history in the tradition of the church prior to their use of it. This proved to be a seminal work, and it established Bultmann's reputation as a scholar. He followed it with a book on Jesus (*Jesus*, 1926; English translation, *Jesus and the Word*, 1934), in which the beginning of his own theological position can be traced. Between 1922 and 1928 he had as a colleague at Marburg the German Existentialist philosopher Martin Heidegger, whose *Sein und Zeit* (*Being and Time*) was published in 1927. Heidegger was enormously influential upon Bultmann, in part because Bultmann felt that he was developing, in philosophical terms, an analysis of human existence that was strikingly parallel to the understanding of human existence implied by the theologies of Paul and John, as Bultmann interpreted them. It was during these years of discussion with Heidegger that Bultmann developed his own theological position, which found its earliest expression in two essays, "Der Begriff der Offenbarung im Neuen Testament" ("The Concept of Revelation in the New Testament"), written in 1929, and "Die Geschichtlichkeit des Daseins und der Glaube" ("The Historicity of Man and Faith"), written in 1930. His position was to remain constant thereafter, and all his subsequent work, including his demythologizing proposal made in 1941, developed consistently out of it.

During the Hitler years in Germany, Bultmann refused to modify his teaching in any way to suit Nazi ideology, and he supported the Confessing Church, the German Protestant movement organized to resist Nazi church policy. But, in his own words, he "never directly and actively participated in political affairs"; *i.e.*, he did not directly oppose the Nazi regime. With the resumption of contacts between the German universities and the rest of the world after World War II, Bultmann became a major international academic figure. His pupils came to occupy leading positions in German universities, and his views were the subject of discussion around the world. All New Testament scholars found themselves in dialogue with him, and among theologians his position became the point of departure for major developments in both Germany and the United States. He himself gave an extremely influential series of lectures in Britain in 1955 (*History and Eschatology: The Presence of Eternity*) and in the United States in 1958 (*Jesus Christ and Mythology*), and his demythologizing program became the subject of a multivolume series with the title *Kerygma und Mythos* (*Kerygma and Myth*).

Assessment

Bultmann was an outstanding teacher, and he encouraged independence of mind among his students. The result was two major developments within the "Bultmann school." In 1954 Ernst Käsemann raised "the question of the historical Jesus" (*i.e.*, the question of the significance of knowledge of the historical Jesus for Christian faith), and a number of Bultmann's pupils developed a position independent of their teacher's on the matter. Then Ernst Fuchs and Gerhard Ebeling, building on Bultmann's Existentialist analysis, developed a method of interpreting the New Testament that emphasized the linguistic mode of human existence. This is the so-called new hermeneutic.

Bultmann himself took part in these discussions among his pupils for as long as his health permitted, later living quietly in Marburg, where he died on July 30, 1976.

BIBLIOGRAPHY. There is no formal biography of Bultmann, although some discussions of his theology include a biographical sketch and there is "Autobiographical Reflections" in C.W. KEGLEY (ed.), *The Theology of Rudolf Bultmann* (1966), in itself a series of dialogues between Bultmann and other scholars. Collections of essays by and about Bultmann include H.W. BARTSCH (ed.), *Kerygma und Mythos*, 4th rev. ed. (1960; Eng. trans., *Kerygma and Myth I*, 1961, and . . . *II*, 1962); C.E. BRAATEN and R.A. HARRISVILLE (eds.), *Kerygma and History* (1962), and *The Historical Jesus and the Kerygmatic Christ* (1964), and SCHUBERT M. OGDEN (ed.), *Existence and Faith* (1973), a collection of Bultmann's shorter writings. Important discussions of his theology are found in SCHUBERT M. OGDEN, *Christ Without Myth* (1961); R. MARLE, *Bultmann et l'interprétation du Nouveau Testament* (1956); W. SCHMITHALS, *Die Theologie Rudolf Bultmanns: Eine Einführung* (1967; Eng. trans., *An Introduction to the Theology of Rudolf Bultmann*, 1968); and G. HASENHUTTL, *Der Glaubenvollzug* (1963). Popularly written are N. PERRIN, *The Promise of Bultmann* (1969), J.M. ROBINSON, *A New Quest of the Historical Jesus* (1959; there are important changes in the German versions *Kerygma und historischer Jesus*, 1960; rev. ed., 1967); and J.M. ROBINSON and J.B. COBB (eds.), *The New Hermeneutic* (1964), details the developments within the "Bultmann school."

(N.P.)

Buñuel, Luis

Probably the most controversial of film makers, Luis Buñuel owes his fame to his absolute sincerity. Ignoring fashions and conventions, he has pursued his career in his native Spain, in France, in the United States, and in Mexico for a half century, mostly working within the limitations of the film industry. Yet, no other film maker has been more personal, more frank in expressing his continuing obsessions with social injustice, religious excess, gratuitous cruelty, and eroticism—themes as evident in his first film, the avant-garde Surrealist classic *Un Chien andalou* (1928; *An Andalusian Dog*), as in his greatest international success, *Tristana* (1970).

Buñuel.
Camera Press—Publix

The eldest of seven children, Buñuel was born on February 22, 1900, at Calanda, in northeastern Spain. From his father, Leonardo Buñuel, a businessman, who had left home at the age of 14 to join the army and fight in Cuba in the Spanish-American War (1898), Luis inherited an adventurous spirit. He excelled at school, in Saragossa, spending only his holidays in Calanda. He was also good at sports, such as boxing, and in playing the violin. He attended a Jesuit college in Saragossa, until at 17 he entered the University of Madrid, where he became a friend of the painter Salvador Dalí and the poet Federico García Lorca. In 1920 Buñuel founded the first Spanish movie club and wrote critiques of the films shown there.

Early interest in film

Having discovered Freudian psychoanalysis and having broken away from religion, he went to Paris in 1925 and entered film-producing circles, feeling that films would become his true medium of expression.

In 1926 he became an assistant director, and in 1928 he directed his first picture, *Un Chien andalou*, in collaboration with Dalí. It created a sensation: at a time when movies tended to be dominated by the natural and the literal, Buñuel discovered the cinema of instinct, which issued through him from the Surrealist movement. Spain always remained the background of his films, the moral and poetical content of which was expressed in terms of Surrealism.

His next two films—*L'Age d'or* (1930; *The Golden Age*), a radically anticlerical and antibourgeois film made in France, and *Las Hurdes* (1932; English title, *Land Without Bread*), a documentary about a particularly wretched region of Spain—asserted his concern with the freedom to dream and to imagine, his revolutionary attitude toward social problems, his aggressive sense of humour, and his contempt for traditional logic.

Exile from Spain

In Spain, Buñuel acted as producer of a number of commercial films in an attempt to build a native industry. When the Spanish Civil War began in 1936, he volunteered to the republican government in Paris, and in 1938, he acted as a technical adviser for two Hollywood films about the Spanish Republic. In the United States he experienced his greatest difficulties. He did some film editing and worked briefly for the Museum of Modern Art, in New York City, until it became known that he had directed the atheistic *L'Age d'or*, and he was allegedly forced to resign. In 1947 he settled in Mexico with his wife and two sons.

There he began a new career, directing pictures designed to have box-office appeal, into which he introduced one or two freely creative sequences. The success of one of these, *El gran calavera* (1949; *The Great Madcap*), allowed him to make a personal film, *Los olvidados* (1950; *The Young and the Damned*), a fascinating argument in favour of juvenile offenders.

Buñuel exercised more and more freedom in allowing the "free" sequences to invade otherwise conventional films, and his own blasphemous but tender world reappeared more often. Soon all his films, even those imposed upon him by producers, such as *Robinson Crusoe* (1952), rendered the Buñuelian universe—a dreamland in which strange and unwonted happenings occur. The most sincere poetry is combined with an aggressiveness, born of tenderness, in his work. His great films from this Mexican period include *Ensayo de un crimen* (1955; *The Criminal Life of Archibald de la Cruz*) and *Nazarin* (1958), about an unworldly priest.

In 1960 Buñuel was allowed to return to Spain to make *Viridiana;* the Spanish authorities, however, found the completed film to be anticlerical and tried to suppress it. Nonetheless, it was smuggled out to be shown at the Cannes Festival, where it was awarded the top prize. In 1962, in Mexico, he made another major work, *El ángel exterminador* (*The Exterminating Angel*), about a formal dinner party from which the guests find themselves powerless to depart; it too was interpreted as having powerful anticlerical connotations.

Implications of Buñuel's success

Now acclaimed throughout the world, Buñuel was again free to make films as he chose, as he had not been since his first period in France. Critics everywhere declared him to be among the authentic creative geniuses in film, one of the few capable of achieving popular as well as critical success.

Buñuel's late films offer a remarkable diversity of themes: *Le Journal d'une femme de chambre* (1964; *The Diary of a Chambermaid*) deals with problems of social status; the 42-minute *Simón del desierto* (1965; *Simon of the Desert*) and *La Voie lactée* (1969; *The Milky Way*) contain humorous reflections on religion; and *Belle de jour* (1966) and *Tristana* show the destruction of dream and reality, the confusion of true and false, of the rational and the imaginary. Buñuel's late works are increasingly calm and serene, avoiding all spectacular technical effects in favour of clear and simple expression that is still surprising and complex in its inner meaning.

MAJOR WORKS

Un Chien andalou (1928; *An Andalusian Dog*); *L'Age d'or* (1930; *The Age of Gold*); *Las Hurdes* (1932; *Land Without Bread*); *Los olvidados* (1950; *The Young and the Damned*); *Robinson Crusoe* (1952); *El* (1952); *Ensayo de un crimen* (1955; *The Criminal Life of Archibaldo de La Cruz*); *Nazarin* (1958); *Viridiana* (1961); *El ángel exterminador* (1962; *The Exterminating Angel*); *Le Journal d'une femme de chambre* (1964; *The Dairy of a Chambermaid*); *Simon del desierto* (1965; *Simon of the Desert*); *Belle de jour* (1966); *Tristana* (1970).

BIBLIOGRAPHY. The most complete monographs are ADONIS KYROU, *Luis Buñuel*, 4th French ed. (1970; Eng. trans., 1963); FRANCISCO ARANDA, *Luis Buñuel* (1969), in Spanish; RAYMOND DURGNAT, *Buñuel* (1967); and FREDDY BUACHE, *Luis Buñuel* (1970), in French. Buñuel's works have amply been studied in general publications dealing with different aspects of the cinema. His Surrealist character is analyzed by J.B. BRUNIUS, Buñuel's assistant in the production of *The Age of Gold*, in *En Marge du cinéma français* (1954). ADONIS KYROU, *Le Surréalisme au cinéma* (1963), places Buñuel's works in the Surrealist context of the 1920s and 1930s. Buñuel wrote fascinating film reviews in the periodical *Cahiers d'Art* in 1927, and poetical texts by him appeared in Surrealist magazines of that time: "Une Girafe," a poem in prose, in *Le Surréalisme au Service de la Révolution* (May 15, 1933), and "Réponse à un questionnaire sur l'amour," in *La Révolution Surréaliste* (December 15, 1929).

(A.Ky.)

Bunyan, John

John Bunyan, English Puritan minister and preacher, was the author of *The Pilgrim's Progress*, a work of universal appeal and the most characteristic expression of the Puritan religious outlook. Born in November 1628, at Elstow near Bedford, in the heart of the agricultural midlands, he declared that he had been brought up "among a multitude of poor plowmen's children"; his father Thomas Bunyan was a brazier, or travelling tinker. He learned to read and write at a local grammar school, but he probably left school early to learn the family trade.

Early life. Bunyan's mind and imagination were formed in these early days by influences other than those of formal education. He absorbed with delight the popular tales of adventure that appeared in chapbooks and were sold at fairs like the great one held at Stourbridge near Cambridge (it provided the inspiration for Vanity Fair in *The Pilgrim's Progress*). In these works, such as *Bevis of Hampton* and *The Seven Champions of Christendom*, the heroes of medieval romance entered the lives

Influences on Bunyan

of the common people. He also became acquainted with the varied popular literature of the English Puritans: plain-speaking sermons, homely moral dialogues, books of melodramatic judgments and acts of divine guidance, and Foxe's *Book of Martyrs* with the fearsome woodcuts of the Elizabethan edition. Above all he steeped himself in the English Bible; the Authorized Version was but 30 years old when he was a boy of 12. As a child whose parents were "of the national church," he was not cut off by a narrow piety but brought up on the general store of

Bunyan, pencil drawing on vellum by Robert White (1645–1704). In the British Museum.

country lore and tradition. He had seen the shot bird tumble headlong from the tree; his mind was stocked with proverbs: both visual experience and popular saying were to go into his later works.

Bunyan speaks in his autobiography of being troubled by terrifying dreams. It may be that there was a pathological side to the nervous intensity of these fears; in the religious crisis of his early manhood his sense of guilt took the form of delusions. But it seems to have been abnormal sensitiveness combined with the tendency to exaggeration that caused him to look back on himself in youth as "the very ringleader of all . . . that kept me company into all manner of vice and ungodliness."

In 1644 a series of misfortunes separated the country boy from his family and drove him into the world. His mother died in June, his younger sister Margaret in July; in August his father married a third wife. The Civil War had broken out, and in November he was mustered in a parliamentary levy and sent to reinforce the garrison at Newport Pagnell. The governor was Sir Samuel Luke, immortalized as the Presbyterian knight of the title in Samuel Butler's *Hudibras*. In Newport Bunyan remained till July 1647; it is likely that he saw little fighting, though once when he was "drawn out to go to such a place to besiege it" (probably Leicester), a comrade took his place and was shot, so that later he felt he had been preserved by divine providence.

His military service, even if uneventful, brought him in touch with the seething religious life of the left-wing sects within Cromwell's army, the preaching captains, and those Quakers, Seekers, and Ranters who were beginning to question all authority except that of the individual conscience. Luke had trouble with many such religious agitators passing through his garrison; in this atmosphere Bunyan became acquainted with the leading ideas of the Puritan sectaries, shared alike by Cromwell and his meanest trooper. They believed that the striving for religious truth meant an obstinate search, often from sect to sect, relying on free grace revealed to the individual, and condemning all forms of public organization as "legal and dark." The devotion of the New Model Army both in prayer and action left an indelible impression on him; it is recalled in *The Holy War* in the preaching, drilling captains of Emanuel's army, Credence and Boanerges.

Some time after his discharge from the Army (in July 1647) and before 1649, Bunyan married. He says in his autobiography *Grace Abounding* that he and his first wife "came together as poor as poor might be, not having so much household-stuff as a dish or spoon betwixt us both." His wife came from a godly family and she brought to him as her dowry two evangelical books, Arthur Dent's *The Plain Man's Path-way to Heaven* and Lewis Bayly's *The Practice of Piety;* the former taught him that even a religious tract could employ racy colloquialisms and salt its precepts with homely proverbs. Their first child, a blind daughter Mary, was baptized in July 1650. Three more children, Elizabeth, John, and Thomas, were born to Bunyan's first wife before her death in 1658. The record of Elizabeth's birth in the transcript register of Elstow shows that she, too, was baptized in the parish church there in 1654, though by that time her father had been baptized by immersion as a member of the Bedford separatist church.

Bunyan's family

Conversion and ministry. Bunyan's conversion was a gradual process in the years following his marriage (1650–55); it is dramatically described in his autobiography. After an initial period of legal conformity in which he went regularly to church and looked with awe at the "priest" and his "vestments" (probably at this period a plain Geneva gown), he gave up, slowly and grudgingly, his favourite recreations of dancing and bell ringing and sports on the village green, and began to concentrate solely on his inner life. Then came agonizing temptations to spiritual despair lasting for several years. The "storms" of temptation, as he calls them, buffeted him with almost physical violence; voices urged him to blaspheme; the texts of scriptures, which seemed to him to threaten damnation, took on personal shape and "did" pinch him very sore." Finally one morning he believed that he had surrendered to these voices of Satan and had betrayed Christ: "Down I fell as a bird that is shot from the tree." In his psychopathic isolation and despair he presents all the features of the divided mind of the maladjusted as they have been analyzed in the 20th century; Bunyan, however, had a contemporary psychological instrument for the diagnosis of his condition, the pastoral theology of 17th-century Calvinism, which interpreted the grim doctrine of election and predestination in terms of the real needs of souls, the evidence of spiritual progress in them, and the covenant of God's grace. Both techniques, that of the modern analyst and that of the Puritan preacher, have in common the aim of recovering the integrity of the self; and this was what Bunyan achieved as he emerged, slowly and painfully, from his period of spiritual darkness, gradually beginning to feel that his sin was "not unto death" and that there were texts to comfort as well as to terrify. He was aided in his recovery by association with the Bedford separatist church and its dynamic leader John Gifford. He entered into full communion with this church about 1655.

The Bedford community practiced adult baptism by immersion but unlike the strict Baptists it did not insist on this as a condition of church membership; its position was closer to that of modern Congregationalists: it was an open-communion church, admitting all who professed "faith in Christ and holiness of life."

Bunyan as preacher

Bunyan soon proved his talents as a rousing lay preacher. Fresh from his own spiritual troubles, he was fitted to warn and console others: "I went myself in Chains to preach to them in Chains, and carried that Fire in my own Conscience that I persuaded them to beware of." He was also active in visiting and exhorting church members, but his main activity in 1655–60 was in controversy with the early Quakers, both in public debate up and down the market towns of Bedfordshire and in his first printed works, *Some Gospel Truths Opened* (1656) and *A Vindication of Some Gospel Truths Opened* (1657). The Quakers and the open-communion Baptists were rivals for the religious allegiance of the "mechanics" or small tradesmen and artificers in town and country; much alike in class attitude, stress on salvation by free grace, and separation from the world, they were divided,

apart from the strains of evangelical competition, by the Friends' doctrine of the inner light. Bunyan's passionate conviction was always expressed in an orthodox, objective theology with a clear frontier drawn between the realms of God and man. This explains the violence of his protest against what seemed to him the dangerously blurred and self-centred mysticism of the Quaker preacher Edward Burrough. He soon became recognized as a leader among the sectaries. Already in 1659 a letter to George Fox speaks of "Bunyan and his people."

The Restoration of Charles II brought to an end the 20 years in which the separated churches had enjoyed freedom of worship and exercised some influence on government policy. On Nov. 12, 1660, at Lower Samsell in South Bedfordshire, Bunyan was brought before a local magistrate and, under an old Elizabethan act, charged with holding a service not in conformity with those of the Church of England. He refused to give an assurance that he would not repeat the offense, was condemned at the assizes in January 1661, and imprisoned in the county jail in Bedford. In spite of the courageous efforts of his second wife (he had married again in 1659) to have his case brought up at the assizes, he remained in prison for 12 years. A late-17th-century biography, added to the early editions of *Grace Abounding*, reveals that he relieved his family by making and selling "many hundred gross of long Tagg'd laces"; prison conditions were lenient enough for him to be let out at times to visit friends and family and even to address meetings.

Bunyan's imprisonment

Literary activity. During this imprisonment Bunyan wrote and published his spiritual autobiography (*Grace Abounding*, 1666). In the effort to recall the state of his soul with complete accuracy and absolute honesty he achieved a remarkable prose instrument for subjective analysis. He describes his inner life in a style rich in powerful physical imagery; the text that seemed to spell out his damnation "stood like a mill-post at my back." The imaginative vitality of his subsequent work, *The Pilgrim's Progess*, springs from a blending of the musical flow of this dreamlike, introspective style with the popular sermon style of the "mechanic preacher," which draws on the common life and culture of the countryside; his comparisons always appeal to common experience, as witness the rustic reality of his portraits of hypocrites:

> His house is as empty of Religion as the white of an egg is of savour . . . a saint abroad and a devil at home.

Bunyan's release from prison came in March 1672 under Charles II's Declaration of Indulgence to the Nonconformists. The Bedford community had already chosen him as their pastor in January, "after much seeking God by prayer" (Bedford Church Book) and a new meeting-house was obtained. In May he received a license to preach together with 25 other Nonconformist ministers in Bedfordshire and the surrounding counties. His nickname "Bishop Bunyan" suggests that he became the organizing genius in the area. When persecution was renewed he was again imprisoned for illegal preaching; the circumstances of this imprisonment have remained more obscure than those of the first, though it does not appear to have lasted longer than six months. A bond of surety for his release, dated June 1677, has survived, so it is likely that this second detention was in the first half of that year. Since *The Pilgrim's Progress* was published soon after this, in February 1678, it is probable that he had begun to write it not in the second imprisonment but in the first, soon after the composition of *Grace Abounding*, and when the examination of his inner life contained in that book was still strong upon him.

The Pilgrim's Progress

The Pilgrim's Progress was published by Nathaniel Ponder in 1678. There is an intense life-or-death quality about the story of Christian's pilgrimage through danger and distraction to the Celestial City in this first part of the allegory. Personal experience has been translated into solid characters and presences, the pompous snob Worldly Wiseman, Apollyon the demon, Vanity Fair, the Valley of the Shadow of Death, the smug young man Ignorance, the Delectable Mountains where the pilgrims rest before the final crossing of the River of death—all these creations have entered fully into the mainstream of the English imagination because they are observed from life with a sharp objective eye, as well as having been germinated in the depths of personal spiritual growth. The book was instantly popular with all classes, though it was perhaps the last great expression of the folk tradition of the common people before the divisive effects of modern enlightened education began to be felt. It may in the present age seem a paradox that Bunyan wrote simply as a physician of souls and yet created a work of art, but this is a measure of his wholeness as a human being.

Bunyan continued to tend the needs of the Bedford church and the widening group of East Anglian churches associated with it. As his fame as a preacher increased with his literary reputation, he also preached in Congregational churches in London. In 1672–73 he entered into controversy with William Kiffin and other London Baptists for his open-communion principles. *The Life and Death of Mr. Badman* (1680) is more like a realistic novel than an allegory, giving an insight into the problems of money and marriage when the Puritans were settling down after the age of persecution and beginning to find their social role as an urban middle class. Some of the strongest writing in the book is found in the short anecdotes related by Wiseman, the narrator, to illustrate particular vices.

Later writings

The Holy War (1682), Bunyan's second allegory, has a carefully wrought epic structure and is correspondingly lacking in the spontaneous inward note of *The Pilgrim's Progress*. The town of Mansoul is besieged by the hosts of the devil, relieved by the army of Emanuel, and later undermined by further diabolic attacks and plots against his rule. The metaphor works on several levels; it represents the conversion and backslidings of the individual soul, as well as the story of mankind from the Fall through to the Redemption and the Last Judgment; there is even a more precise historical level of allegory relating to the persecution of Nonconformists under Charles II.

The Pilgrim's Progress, Second Part (1684), tells the story of the pilgrimage of Christian's wife, Christiana, accompanied by her children. It gives on the whole a more social and humorous picture of the Christian life than the First Part, but the great concluding passage on the summoning of the pilgrims to cross the River of death is perhaps the finest single thing in Bunyan.

In spite of his ministerial responsibilities Bunyan found time to publish a large number of doctrinal and controversial works in the last ten years of his life. He also composed rough but workmanlike verse of religious exhortation; one of his most interesting later volumes is the children's book *A Book for Boys and Girls* (1686), vigorous poems serving as comments on emblematic pictures.

Under James II, when there was a renewal of the persecution of dissenters, Bunyan protected his family by a deed of gift transferring all his property to "my well-beloved wife, Elizabeth Bunyan" (December 1685). When the Protestant dissenters were being wooed in order that James might obtain toleration for Roman Catholics, Bunyan shrewdly resisted the blandishments of the royal agent Lord Aylesbury, who offered him an official position; at the same time he secured seats for members of his church on the reorganized corporation of Bedford. He died on Aug. 31, 1688, in London, after one of his preaching visits; he had ridden out of his way through heavy rain to Reading to settle a quarrel between father and son and contracted a fever (probably pneumonia). He was buried in Bunhill Fields, the Nonconformists' traditional burying ground.

Reputation. Until the decline of religious faith and the great increase in books of popular instruction in the 19th century, Bunyan, like the Bible, was to be found in every English home and was known to every ordinary reader. In literary estimation, however, he remained beyond the pale of polite literature during the 18th century, though his greatness was acknowledged by Swift and Johnson. After the Romantic movement he was recognized as a type of the natural genius and placed along-

side Homer and Robert Burns. Twentieth-century scholarship has made it possible to see how much he owed to the tradition of homiletic prose and to Puritan literary genres already developed when he began to write. But the sublime tinker remains sublime, if less isolated from his fellows than was formerly thought; the genius of *The Pilgrim's Progress* remains valid. Nothing illustrates better the profound symbolic truth of this noted work than its continuing ability, even in translation, to evoke responses in readers belonging to widely separated cultural traditions.

MAJOR WORKS

RELIGIOUS ALLEGORIES: *The Pilgrim's Progress*, 1678, and *The Pilgrim's Progress, . . . The Second Part*, 1684 (published together in modern editions); *The Life and Death of Mr. Badman*, 1680; *The Holy War . . . for . . . Mansoul*, 1682.

AUTOBIOGRAPHY: *Grace Abounding to the Chief of Sinners*, 1666; *A Relation of the Imprisonment of Mr. John Bunyan* (included in later editions of *Grace Abounding*), 1765.

THEOLOGICAL PAMPHLETS AND DEVOTIONAL WORKS: *Some Gospel-truths Opened*, 1656; *Profitable Meditations*, 1661?; *The Barren Fig-tree*, 1673?; *Instruction for the Ignorant*, 1675; *Come and Welcome, to Jesus Christ*, 1678; *Solomon's Temple Spiritualiz'd*, 1688; *Mr. John Bunyan's Last Sermon* (included in later editions of *The Holy War*), 1689; *An Exposition of the First Ten Chapters of Genesis*, 1692.

VERSE: *A Book for Boys and Girls* (retitled *Divine Emblems, or, Temporal Things Spiritualized*, 1724 onward), 1686.

BIBLIOGRAPHY

Editions: The first collected edition of his works was *The Works of that Eminent Servant of Christ, Mr. John Bunyan*, ed. by C. DOE (1692). Because of copyright difficulties, only vol. 1 of what was to have been a complete edition appeared; 2nd ed., 2 vol. (1736). The standard complete edition is still that by G. OFFOR, *The Works of John Bunyan*, 3 vol. (1853, 1862). Editions of single works include: *The Pilgrim's Progress*, ed. by J.B. WHAREY, rev. by R. SHARROCK (1960, rev. ed. 1968); *Grace Abounding*, ed. by R. SHARROCK (1962); *The Life and Death of Mr. Badman*, ed. by G.B. HARRISON (1928); *The Holy War*, ed. by J.F. FORREST (1967).

Bibliography: F.M. HARRISON, *A Bibliography of the Works of John Bunyan*, suppl. to the *Transactions of the Bibliographical Society*, no. 6 (1932).

Biography and Criticism: LORD MACAULAY in *Critical and Historical Essays*, vol. 1 (1843), a general and biographical essay; J. BROWN, *John Bunyan, His Life, Times and Work* (1885; rev. by F.M. HARRISON, 1928), a heavily documented life; W.Y. TINDALL, *John Bunyan, Mechanick Preacher* (1934), on the background of the sects; H.A. TALON, *John Bunyan (1628–1688) l'homme et l'oeuvre* (1948; Eng. trans., 1951), a French critic's view; R. GREAVES, *John Bunyan* (1969), on Bunyan's theology; R. SHARROCK, *John Bunyan*, rev. ed. (1968), a concise critical account; R.M. FRYE, *God, Man and Satan* (1960), theological comparison of Milton and Bunyan. O.E. WINSLOW, *John Bunyan* (1961), a straightforward and readable biography; R. SHARROCK, *John Bunyan: "The Pilgrim's Progress"* (1966), a critical study.

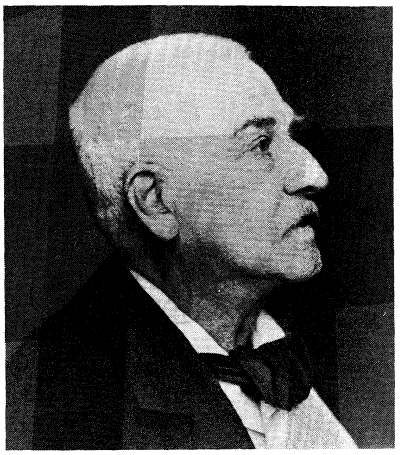
(R.S.)

Burckhardt, Jacob

One of the first great historians of art and culture, Jacob Burckhardt was an outstanding representative of historical scholarship in the classical period of that discipline, around the middle of the 19th century. After much controversy, his general concept of an original European culture in the age of the Renaissance and much of his philosophy about the course of world history have been absorbed into the basic outlook of the present generation of historians. In the German originals the literary style of his works remains masterly and inimitable.

Jacob Christopher Burckhardt was born in Basel, Switzerland, on May 25, 1818, the son of a Protestant clergyman. The thriving Burckhardt family was among the most respected in town. For three centuries some of its members had earned wealth in international trade and the manufacture of silk and with their wealth had gained political power, while others had served the community as professors and pastors. Basel's excellent grammar school provided Burckhardt with a humanistic education. His first studies at the local university, supplemented by a stay in Neuchâtel, were dominated by a devotion to Greek. But, before the philological and increasingly historical orientation of his interests could fully assert itself, Burckhardt spent three years in the study of formal theology. Although he never regretted this concession to the professional traditions of his father and grandfather, Burckhardt took up divinity without a calling and after a prolonged crisis abandoned it, together with the explicit profession of Christian faith. Henceforth, he was always to avoid clarification of his religious position, which may be described as a kind of pantheism. Markedly romantic at first, in later years Burckhardt's religious ideas revealed their classical inspiration and, evincing a profound respect for human destiny, came to underlie his concept of history.

Education



Burckhardt, 1892.
By courtesy of the Universitats-Bibliothek Basel

From 1839 to 1843 Burckhardt studied at the University of Berlin, where his talents were acknowledged by two eminent teachers of ancient history, August Boeckh and Johann Gustav Droysen. But it was under the influence of two other professors—Franz Kugler and Leopold von Ranke—that his appreciation of ancient and modern history came into balance in his efforts to comprehend the past as a whole. Art and architecture had fascinated Burckhardt from childhood. Now Franz Kugler provided a formal introduction to the fledging discipline of art history, which profoundly appealed to the German Romantics. The achievements of painters and architects not only directed Burckhardt's attention toward Italy and the Renaissance; they also helped to reduce law, politics, and diplomacy to a somewhat inferior status in his concept of the past. At Berlin, Burckhardt's developing priorities accounted for an ambiguous relationship with the most famous among all his teachers, Leopold von Ranke. Ranke, the master of diplomatic history, assigned an autonomous and exalted function to statehood and nationhood and consequently cast his lot with Prussian and German nationalism, forces that Burckhardt would later denounce with growing violence. Since Ranke and Burckhardt are often used to illustrate diametrically different approaches to historiography, it is important to note that Burckhardt respected the scholarly achievements of his great teacher, and Ranke recognized and commended the ability of his student. Burckhardt was later offered a chair at Berlin, but he declined it.

After the chill of two Berlin winters, Burckhardt permitted himself a summer term at the young and modest University of Bonn, where he passed many of his most romantic and imaginative hours among the circle that met in the home of Gottfried Kinkel, a fellow art historian who had in the past, like Burckhardt, given up theology but would, unlike his Swiss friend, become a leader in the unsuccessful liberal revolution that erupted in Germany in 1848–49, by which time their friendship had cooled completely. Burckhardt's political creed is as hard to define as his religious one. The spirit of his hometown and upbringing was democratic, although tempered with patrician arrogance. His love of freedom was supreme, but he soon came to despise the aspirations of political liberalism in Switzerland and Germany. For

Burckhardt 1848–49 was a turning point. Romantic indulgence and political hopes were now dead; his German friends were almost forgotten. With complete concentration he turned to his studies and his teaching. He was a conservative by now, but his conservatism was cultural rather than political. His own time was, he thought, hopelessly superficial. He felt increasingly out of touch with it and concentrated all his energies on reclaiming a past that seemed incomparably deeper and richer. Also in 1849, Margarethe Stehlin, the only woman for whom he ever seems to have had any deep affection, married a Basel banker. He suppressed his feelings without too much difficulty and never again considered marriage, stating that he had no wish to beget children "who would be tutored by a proletarian."

University career

The University of Basel awarded Burckhardt the degree of Ph.D. *in absentia*, and after his return from Berlin in 1843 he was quickly authorized to give private lectures. Lecture he did, but for two years he had to earn his living as the editor of the *Basler Zeitung*, a conservative daily. In 1846–47 he returned to Berlin to prepare, in conjunction with his friend and teacher Kugler, substantially enlarged new editions of Kugler's two textbooks of art history. The winter of 1847–48 was spent in Rome. Thereafter he resumed his teaching at Basel. The university was small and, on the whole, undistinguished. Burckhardt's lectures, by far the largest component of his life's work and also the most accomplished, were normally delivered before a mere handful of students. Never did his academic audience reach 50; only when he addressed the Basel public at large, as he often did with series of evening lectures, was the attendance more substantial. In 1855 Burckhardt left Basel to teach art history at the newly founded Federal Institute of Technology in Zürich, but in 1858 he returned to his home university and henceforward occupied Basel's only chair of history. For another 20 years, however, he also had to teach in his former grammar school. Only from 1874 could he divide his time evenly between his university lectures in history and art history. From 1886 until his retirement in 1893 he taught art history exclusively. In his courses he covered the entire range of European civilization from ancient Greece to the French Revolution.

Burckhardt, who had learned Italian, in 1837 first crossed the southern frontier of his country, hiking all the way from Basel and back. In the following summer he returned for a month-long tour of northern and central Italy. Thereafter and until 1883, travel in Italy and elsewhere was a regular feature of Burckhardt's bachelor life.

Burckhardt's most successful books are unthinkable without his familiarity with the historical sites and art treasures of Europe. His first important work, however, like the last, attested to his deep interest in ancient civilization. In *Die Zeit Konstantins des Grossen* (1853; Eng. trans., *The Age of Constantine the Great*, 1949) Burckhardt presented a picture of a transitional age, unhealthy and immoral but teeming with religious and cultural activity. While he recognized that the rise of Christianity was inevitable and that it was necessary for the development of an original culture during the Middle Ages, his sympathies lay clearly with the waning forces of the ancient world. *Der Cicerone* (1855; Eng. trans. 1873) is a comprehensive study of Italian art, geographically arranged in the form of a travel guide. It went through many editions, but Burckhardt reacted to the popularity of his work with growing aloofness.

Burckhardt's concept of the Renaissance

Burckhardt's next book, *Die Kultur der Renaissance in Italien* (1860; Eng. trans., *The Civilization of the Renaissance in Italy*, 1878), is the major source of his fame. Using programmatic subheadings (the discovery of world and man; the development of individuality; the state as a work of art; the modern sense of humour), Burckhardt deftly analyzed the daily life of Renaissance Italy, its political climate, and the thought of its outstanding minds. His sources—often contemporary chronicles and tales—were in print and readily available yet frequently ignored by historians. He approached them with newly conceived questions in mind. Although Burckhardt emphasized many contrasts between the Middle Ages and the Renaissance, he did not underrate medieval achievements. His concept of history left no room for the idea that the Renaissance or any other period was characterized by general progress over the preceding epoch. If Raphael's art presented the Renaissance at its best, the ingenious and ruthless mechanism of Renaissance politics reminded Burckhardt of "the works of a clock." Here he perceived the beginnings of the modern state, a precision instrument of mass control, without consideration for the creative freedom of individuals and minorities.

Art was to Burckhardt the saving grace of the Renaissance, but in his *Die Kultur* this vital subject was not treated. Burckhardt hoped to cover it in a separate monograph, but that hope found only partial fulfillment in *Die Geschichte der Renaissance in Italien* (1867), which deals with architecture only. If eventually Burckhardt's study of the Renaissance provided a basic model for the treatment of cultural history in general, the implications for art history were best realized by his pupil and successor Heinrich Wölfflin. Styles of art followed one another as did historical periods. They were determined by common features derived from the general character of a period and in turn helped to define the period's culture. Among Burckhardt's minor publications, a small but precious collection of poetry in the Alemannic dialect may be noted: *E Hämpfeli Lieder* (1853).

Burckhardt died at Basel on August 8, 1897. Friends edited his last great work, four volumes of an uncompleted survey of Greek civilization—*Griechische Kulturgeschichte* (1898–1902; abridgment in Eng. trans., *History of Greek Culture*, 1963)—and some essays in art history: *Erinnerungen aus Rubens* (1898), *Beiträge zur Kunstgeschichte von Italien* (1898). Of particular significance are two later posthumous publications. *Weltgeschichtliche Betrachtungen* (1905; Eng. trans., *Force and Freedom: Reflections on History*, 1943) epitomizes his philosophy of history. *Historische Fragmente* (1929 in *Gesamtausgabe*; Eng. trans., *Judgments on History and Historians*, 1958) selects highlights from his lecture manuscripts and demonstrates impressively Burckhardt's gift for visualizing history as a whole. Both books contain passages that can be interpreted as prophetic visions of the violent totalitarian states of the 20th century; but more important than Burckhardt's prophecies of the future is his vision of the past, which offers, he said, "experience to make us, not shrewder (for the next time), but wiser (for ever)."

BIBLIOGRAPHY. A critical edition of Burckhardt's collected works, *Gesamtausgabe*, 14 vol., ed. by E. DURR *et al.* (1929–34), is now being followed by a critical edition of his letters, *Briefe*, ed. by MAX BURCKHARDT, 7 vol. (1949–). See also WERNER KAEGI, *Jacob Burckhardt, eine Biographie*, 4 vol. (1947–67); WALLACE K. FERGUSON, *The Renaissance in Historical Thought* (1948); and *Jacob Burckhardt and the Renaissance, 100 Years After* (1960), papers read at a meeting of the Central Renaissance Conference.

(P.G.B.)

Bureaucracy

In everyday usage the term bureaucracy connotes the "red tape" and inefficiency that one often experiences in dealings with large-scale organizations, especially with a state administration. As a sociological concept, the term has a less pejorative, a more "neutral" meaning. It simply refers to a type of formal organization. By formal organization is meant a social unit that is established in a more or less deliberate manner for the attainment of a specific goal (in contrast to such social units as a friendship group or a neighbourhood that seem to emerge in a spontaneous, unplanned manner). Thus *purposive design* and *goal specificity* seem to be the two crucial criteria differentiating formal organizations from other types of social groupings. A business firm, a modern political party, and a trade union, for instance, are typical examples of formal organizations, and all such organizations coordinate their activities and other resources in a highly deliberate manner in order to achieve a number of specific goals.

This article is divided into the following sections:

I. The character of bureaucracy and bureaucratization
The classical or "ideal" conception of bureaucracy
The bureaucratization of the state in western Europe
Differentiation between state and royal household administration
The expansion of the state administration
The aristocratization and commercialization of office
Further bureaucratization
II. Theories of bureaucracy
Classical theories of bureaucracy
The Marxist theories
The Weberian theories
Oligarchic theories of bureaucracy
The classical theories in review
Managerial theories of organization
The scientific management movement
Formal theories of administration
The human relations school
The decision-making approach
Converging trends
Functionalist theories
Conflict theories
General conclusion

I. The character of bureaucracy and bureaucratization

THE CLASSICAL OR "IDEAL" CONCEPTION OF BUREAUCRACY

Not all formal organizations are bureaucratic. Bureaucracy refers to a special type of formal organization whose structure has a number of specific characteristics. These characteristics were first formulated in a systematic manner by the German sociologist Max Weber (1864–1920), whose definition and theories on bureaucracy have set the foundations for all subsequent work on the subject. They refer to (1) the division of labour in the organization, (2) its authority structure, (3) the position and role of the individual member, and (4) the type of rules that regulate the relations between organizational members.

Division of labour

A highly developed division of labour and specialization of tasks is one of the most fundamental features of bureaucracy. This is achieved by a precise and detailed definition of the duties and responsibilities of each position or office. The allocation of a limited number of tasks to each office operates according to the principle of fixed jurisdictional areas that are determined by administrative regulations.

The bureaucratic organization is characterized by a "rational" and impersonal regulation of inferior-superior relationships. In traditional types of administration (feudal, patrimonial), the inferior-superior relationship is personal, and the legitimation of authority is based on a belief in the sacredness of tradition. In a bureaucracy, on the other hand, authority is legitimized by a belief in the correctness of the process by which administrative rules were enacted; and the loyalty of the bureaucrat is oriented to an impersonal order, to a superior position, not to the specific person who holds it.

When one shifts the focus of attention from the organization as a whole to the role and status of the individual member, the following features characterize the bureaucrat's position. Starting with the mode of recruitment, the bureaucrat is not selected on the basis of such particularistic considerations as family position or political loyalties. His recruitment is based on formal qualifications (diplomas, university degrees) that testify that the applicant has the necessary knowledge to accomplish effectively his specialized duties. Once a candidate enters the bureaucratic organization, his office is his sole—or at least his primary—occupation. It constitutes a *career*. That is to say, it is not accepted on an honorary or short-term basis; it implies stability and continuity, a "life's work." Moreover, there is usually an elaborate system of promotion based on the principles of both seniority and achievement.

Insofar as the mode of remuneration is concerned, the bureaucrat usually receives a salary based not so much on his productivity performance as on the status of his position. Contrary to some forms of traditional administration, in the bureaucratic case the civil servant cannot sell his position or pass it on to his sons. There is a clear-cut separation between the *private* and the *public* sphere of the bureaucrat's life. His private property is sharply distinguished from the "means of administration" that do not belong to him.

Rational rules

The most important and pervasive characteristic of bureaucracy (one that to some extent explains all the others) is the existence of a system of control based on rational rules—that is, rules meant to design and regulate the whole organization on the basis of technical knowledge and with the aim of achieving maximum efficiency. According to Max Weber, "Bureaucratic administration means fundamentally the exercise of control on the basis of knowledge. This is the feature of it which makes it specifically rational" (*The Theory of Social and Economic Organization*, 1947, p. 339).

These are briefly the major features of Weber's ideal type of bureaucracy. The type is "ideal" in the sense that the characteristics included in it are not to be found, in their extreme form, in all concrete bureaucracies. Real organizations can be more or less bureaucratic according to their degree of proximity to their ideal formulation.

THE BUREAUCRATIZATION OF THE STATE IN WESTERN EUROPE

Although the ideal type refers to all types of formal organizations (religious, political, economic), Weber formulated this concept having in mind mainly the administrative apparatus of the modern state. Being primarily concerned with explaining the unique features of Western civilization, he wanted to examine the processes that made the state apparatus of western European societies approach so closely his ideal type of bureaucracy. For Weber thought that although bureaucratic administrative systems existed in many state societies of the past, only in western Europe did the bureaucratization of the state apparatus reach its fullest form. For this reason, the concept of bureaucracy can perhaps be best understood if seen comparatively and within a context of long-term historical developments. Such a historical examination can be important not only for a better comprehension of the notion of bureaucracy itself but also for an understanding that the bureaucratization of the state set the initial and fundamental framework for further bureaucratization in all other institutional areas. Although such bureaucratic organizations as the Roman Catholic Church and the political organization of medieval cities did exist in Europe before the emergence of the modern state, it was only after a strong bureaucratic state had established a unified and centralized political community over an extended territory that bureaucracy, as a form of organization, could spread and prevail in all spheres of social life.

Political origins of bureaucracy

Differentiation between state and royal household administration. The origin of the main administrative departments in western European countries is to be found in the royal household. Initially there was no differentiation between state activities and the administration of the king's court. Royal income and expenses, for instance, were hardly distinguished from state finances, and all public officials were household dependents directly supported from the king's stores. In a typically nonbureaucratic manner, the administration of the realm was discharged by the same people who were in charge of the main functions of the household.

The gradual ascendancy of the crown and the ensuing increasing volume and complexity of administrative tasks initiated a process of differentiation between household and state administration. To take England as an example, the first major department to be separated from the royal court was the treasury in the 12th century. Because at that time the royal household still had an itinerant character, it was becoming increasingly difficult—even from a purely physical point of view—for the moving court to carry the treasury with it. Thus its headquarters were fixed at Westminster, and clergymen, leading a communal life under the leadership of the Exchequer, were its first officials.

The chancery, originally in charge of the king's correspondence, was the second important department that "went out of court." This development, which started under Henry III (reigned 1216–72), was completed only with the administrative reforms of Edward II (reigned 1307–27), when the accounts of the chancery were finally separated from the king's accounts.

A similar process of differentiation took place in continental countries. With the extension of royal authority, administrative tasks became more numerous and complex and royal officials increased in number; hence it became more and more difficult for the royal household to provide for the needs of such a large population of officials; officials had gradually to establish their own households.

The expansion of the state administration. If the emergence of the state administration out of the royal household constitutes the first big step toward bureaucratization, the subsequent spectacular expansion of the state administration, and its continuous acquisition of new functions by its encroachment on local self-government, contributed greatly to further bureaucratization in the administrative field.

In England this process was very slow, especially after the failure of the Tudor and Stuart dynasties to establish an absolutist system of rule in the 16th and 17th centuries. The powerful nobility managed through Parliament to check effectively the state administration's expansive tendencies. Thus English local government remained for a long time in the hands of nonprofessional noblemen, the justices of the peace. It was on the Continent that administrative expansion reached impressive dimensions quite early. This expansion was linked with the rise of royal absolutism and the gradual curbing of the political autonomy of the nobility and of the towns. The French monarchy and its administration, as it was finally shaped under Louis XIV (reigned 1643–1715), has been the prototype of European absolutist rule, a model imitated all over Europe. Until the 17th century the French nobility managed to maintain some political functions by exercising constitutional opposition to the crown through the States General and the local *parlements*. But the Bourbons, unlike the English kings of the time, managed gradually to reduce the nobles' power. The provincial governing positions ceased to be the hereditary fiefs of the nobility, and by the Edict of 1641 the autonomy of the local *parlements* was destroyed, their powers being relegated to the Royal Council. The famous *intendants*, the crown representatives to the provinces, first appeared in the 16th century. After their powers were extended by cardinal de Richelieu in the 1620s and '30s, they gradually managed to weaken self-government until they became the effective masters of all local affairs. Town autonomy disappeared in a similar fashion under Louis XIV.

Influence of absolutism on bureaucratization

The continual expansion of the French state apparatus was temporarily checked toward the end of the 18th century with the weakening of royal power. During the so-called feudal reaction after the death of Louis XIV, an attempt was made to revive the local *parlements*. But the revival was both partial and short-lived. The French Revolution and later Napoleonic rule (1789–1815), with its hostility to all "intermediate powers," promoted and consolidated a political system in which the central state apparatus was all dominant—all local self-governing bodies being considered an interference to the direct relationship that the state should have with its citizens.

In Prussia the process of bureaucratic expansion followed essentially similar lines. The ruling Great Elector —or king, as he was later titled—managed to build up a strong state administration by curbing the power of the nobility and their representative bodies. The *Regierungen*, the equivalent of the French *parlements*, were reduced to insignificance as most of their functions were gradually absorbed by the central administration. This process was momentarily arrested by Frederick the Great (reigned 1740–86), who, in his attempt to reinvigorate the Prussian nobility and to fight the increasing dominance of the state bureaucracy, tried to revive the local *Regierungen*. But the attempt, as in France, was short-lived and basically unsuccessful.

The aristocratization and commercialization of office. In many ways administrative expansion meant bureaucratization: the increasing complexity and volume of administrative tasks made a minimum of rationalization imperative. Spheres of competence had to be more rigorously defined; specialization within and between departments was becoming more necessary; and at least a partial opening of posts to professionally trained people had to be effected. But if the process of administrative growth was fairly continuous, the process of bureaucratization, at least in terms of some Weberian characteristics of bureaucracy, was less so. In fact, following Weber, it is more precise to say that the public administrations of the *ancien régime* were "patrimonial" bureaucracies because they were characterized by a peculiar mixture of patrimonial and bureaucratic elements. Of course, in the long term, the patrimonial elements were declining in importance and bureaucratic ones were becoming more dominant. But this process of bureaucratization was never a unilinear, direct movement. Drawbacks and temporary processes of debureaucratization were both numerous and persistent.

The entry of aristocrats into bureaucratic government

In order to understand such processes, one must examine the relationship of the public administration both to the upper classes and to its royal head. If the nobility failed in resisting the growth of the central authority and administration, it was much more successful, once this growth was consolidated, in advancing its own interests within the new bureaucratic framework of the central state. The destruction of the aristocratic self-governing bodies by no means implied the destruction of the nobility as a class. Despite the loss of their political autonomy, European aristocracies proved flexible and remarkably resilient. For a very long time they managed to maintain their economic advantages and even to exercise effective political power—not anymore by opposing the state administration but by occupying the top positions within it.

This partial aristocratization of the state administration, though a common feature of all *ancien régime* European societies, is nowhere more clearly seen than in the administrative development of Prussia. During the initial stage of administrative expansion, the Great Elector, facing serious aristocratic opposition to centralizing policies, had to open the gates of the growing administration to commoners, especially to those having a legal training. Talented officials of common origin could reach top administrative positions and exercise great influence in the formation of policy. Of course noblemen who were prepared to change camps and to join forces with the king also were welcomed. Thus a delicate balance between aristocrats and commoners, between a nonbureaucratic inheritance system and a bureaucratic merit system of recruitment, was achieved.

The three forces of king, aristocracy, bureaucracy

At a later stage of development, however, when the state administration had been well established and the aristocratic opposition had started to wane, the administration rather than the aristocracy started to create problems for the king: the entrenched bureaucrats became as difficult to control as the previously recalcitrant aristocracy. Thus Frederick the Great, in his frantic attempts to exercise effective control over the state bureaucracy, resorted to the aristocracy. He made it a policy to reserve all the key administrative positions for noblemen. This policy was never completely realized, because certain positions required trained skills not always easy to find among those of noble birth. Moreover, restrictions were watered down by the process of ennoblement: successful officials of common origin aspired to and often achieved aristocratic status. Nevertheless, despite these reservations, the process of debureaucratization temporarily succeeded and was even reinforced after Frederick's death, as the sponsors of the Prussian Legal Code of 1794 tried to "improve" the merit system of recruitment by setting aside all important state positions for the aris-

tocracy. These legal restrictions were abolished during the great administrative reforms at the beginning of the 19th century. Ultimately, the highest ranking Prussian bureaucrats, whether of noble or common origin, developed into a self-conscious, self-recruiting status group striving to promote its own interests and achieving considerable autonomy vis-à-vis both the various social strata (including the "nonbureaucratic" aristocracy) and their royal master. In the long drawn-out triangular contest between the aristocracy, the king, and the bureaucracy, the bureaucrats were the ultimate victors. Although some of these developments were indeed peculiar to Prussia, the mixture of the ascriptive and merit system of recruitment was a common feature of all European bureaucracies up to the 18th and even into the 19th century.

Apart from aristocratization, the commercialization of offices was another "nonbureaucratic" feature that persisted for a long time in the public administrations of western Europe. Although in England the practice lasted longer, it was in France that the system of buying and selling of public offices reached extraordinary dimensions and with quite disastrous consequences. Francis I systematized the sale of offices by establishing in 1522 the Bureau des Parties Casuelles, which was literally an "office-selling" bureau. At the beginning, attempts were made to limit the sales to financial posts only. Gradually, however, judicial as well as most other offices of the royal administration could be bought. Such offices could become hereditary through payment of an annual fee. Moreover, at times of financial crisis, offices were created en masse for the sole purpose of raising additional funds. Office selling became at certain periods the main source of state revenues. Thus between 1620 and 1632, for instance, one third of the French state's income came from office transactions.

Looking at the aristocratization and commercialization of the public office in power terms, one can say that both phenomena enhance the autonomy of the officials vis-à-vis their royal master (although this type of autonomy, based on status and money, is quite different from the "contractual" autonomy that the modern bureaucrat enjoys vis-à-vis his superiors). Consequently they impose a certain rigidity on the administrative structure because the ruler cannot rely on the continuous cooperation and obedience of his officials in the policies that he wants to pursue. Of course, this situation varied according to the relative power of the king. In England, where the crown was never as powerful as in some continental countries, the autonomy of a sinecure owner was considerable. In France, before the weakening of royal authority in the 18th century, the situation was quite different. Proprietorship rights were no full guarantee against royal arbitrariness. At times of grave financial crisis, the crown often arbitrarily abolished sinecure rights or refused to pay the holders of sinecures; often the latter were forced to provide loans to the government or to pay for their office a second and third time.

Despite these variations in the power relationships between officials and their rulers, one could risk the generalization that *ancien régime* European administrations enjoyed a relatively high degree of autonomy vis-à-vis their rulers. This becomes obvious if one compares them with certain cases of oriental rule (as among the Ottomans or Mongols), in which officials were subjugated to a despotic ruler. On the other hand, this administrative autonomy in Europe did not reach the point of jeopardizing the whole political framework of society. In that sense European administrations never went through the "feudalization" processes that typically occur during the decline of highly centralized empires—that is, such processes as the total paralysis of the ruler's power and the usurpation of the means of administration by various local officials who become totally autonomous.

Further bureaucratization. The sales of offices and the various other types of ascriptive recruitment started to decline at the end of the 18th century. As a result of revolution (as in France) or of various reform movements initiated by officials striving for more autonomy and self-regulation and by extrabureaucratic groups fighting against the privileged access to public office, public administration in western Europe gradually took a more rational-bureaucratic character. The purchase of sinecures was abolished; examinations as well as the systematic requirement of formal qualifications for office became the standard mode of selection; and departmental divisions were established on a more rational basis.

Formalizing the selection and tenure of bureaucrats

Moreover, as the nation-state developed further and as *subjects* became *citizens* and as more and more people were actively drawn into the political process, public administration ceased to be an instrument at the personal service of a king or a privileged group. It became, at least in the minds of the people, a service rendering "neutral" organization at the service of all citizens. As such, it had to be protected and "insulated" from all pressures that might attempt to divert the bureaucrat from the professional and disinterested performance of his task. As a matter of fact, the gradual establishment of various legal guarantees (such as tenure for life under "civil service" rules) has succeeded in protecting the bureaucrat against his master's arbitrariness and against powerful external groups, which, in their efforts to promote their narrow interests, might put pressure on the public official to abandon his "neutral" position.

Thus public officials, as a group, managed to achieve a relatively high degree of autonomy and self-regulation, though this autonomy, in contrast to the *ancien régime* patrimonial bureaucracies, is based neither on aristocratic status nor on the strong economic position of the bureaucrat. It is mainly based on the general developments mentioned above and on the fact that the bureaucrat's expertise and administrative experience place him in a position of strength vis-à-vis his master, who has increasingly become simply a high-level decision maker in administrative matters.

For some theorists of bureaucracy this autonomy and "insulation" of modern bureaucracy has gone too far—in the sense that the public bureaucracy, instead of being a neutral tool at the service of the people and its legitimate leaders, has become itself the real master. The problem of the position of the state administrative apparatus in the power structure of modern society requires an examination of the classical theories of bureaucracy that placed this problem at the centre of their preoccupations.

II. Theories of bureaucracy

CLASSICAL THEORIES OF BUREAUCRACY

Despite the variety of sources from which the classical writings in bureaucracy have sprung, it is possible to identify in all of them a recurrent theme: the impact of large-scale organizations on the power structure of society. In what way does "big" government or "big" business influence the political institutions of modern industrial societies? Or, on the level of the individual, in what ways do such developments affect man's chances for a free and meaningful existence? In other terms the problem is to find out whether bureaucracy, despite its dimensions, is still an administrative apparatus for the implementation of socially useful goals or whether it has lost its neutral and instrumental character; whether from a tool in the hands of the legitimate policy-making body it has become itself the master dictating policies of narrow self-interest.

In a way, most students of modern society deal directly or indirectly with such problems. Among the various writings, it is possible to identify three major perspectives, three outstanding contributions, that constitute the key elements in the development of the classical literature of bureaucracy: the Marxist, the Weberian, and what may be called the oligarchic theories.

The Marxist theories. Although the concept of class rather than the concept of bureaucracy is at the centre of Karl Marx's work, his theory of the state bureaucracy is a crucial starting point for understanding future debates on the problem of bureaucratization in modern so-

ciety. Marx studied bureaucracy in the context of the capitalist state and its administrative apparatus. His main thesis about the nature and development of modern bureaucracy derives from his general theory on the dynamics and future of the class struggle in capitalist society.

The withering away of bureaucracy under communism

For Marx, the state, with its bureaucratic administration, is a mere instrument in the hands of the dominant social class. It is the division of society into classes that explains the existence and growth of the state apparatus. More specifically, the bureaucracy of the state is one of the main means by which the exploiting class manages to consolidate and perpetuate its domination over the masses. The greater the divisions and the interclass struggles in society, the more oppressive the state apparatus becomes. In fact, according to Marx, the increasing bureaucratization of the state in capitalist societies is a reflection of increasing tension in the sphere of production, of the mounting intensity of the class struggle.

It follows, according to Marxists, that with the advent of socialism and the gradual abolition of class divisions, a process of debureaucratization will gradually take place. The state and its oppressive apparatus will ultimately wither away in the communist classless society of the future. For in such a society, since there will be no oppressors and no oppressed, the state apparatus will become superfluous.

The Weberian theories. For Max Weber bureaucracy rather than class becomes the key concept of modern society. Weber elaborated his concept of bureaucracy within the context of his political sociology—in discussing ideal types of domination. According to him, a system of domination is mainly characterized by (1) a number of beliefs that legitimize the exercise of power and (2) an administrative apparatus that operates as a bridge between the ruler and the ruled. Weber distinguishes three types of domination: the charismatic, the traditional, and the legal.

Charismatic domination

Types of domination. Charisma, from the Greek, means literally "gift of grace." A leader with charisma is someone who has, or is believed to have, extraordinary personal qualities that become the basis of his domination. Thus beliefs in the extraordinary capacities of the ruler legitimize power in the charismatic type of domination. The administrative apparatus, whenever it exists, consists simply of the leader's immediate disciples.

Belief in the sacredness of tradition, respect for the old and established ways of doing things, is the basis of legitimation in the traditional type of domination. The traditional ruler commands by virtue of his inherited status. His orders are personal and arbitrary but within limits fixed by custom. His subjects obey out of personal loyalty to him or out of respect for his traditional status. When this type of domination, typical in the patriarchal household, is extended over many people and a wide territory, the ensuing administrative apparatus ideally can take the *patrimonial* or the *feudal* form. In the patrimonial administration the officials are personal retainers (servants, relatives, favourites), usually dependent on their master for remuneration. On the other hand, the feudal apparatus has a greater degree of autonomy for the officials in relation to the master. The feudal officials are not personal dependents but allies giving an oath of fealty to their lord. By virtue of this type of contract they exercise independent jurisdiction, they usually own their administrative domain, and they are not dependent on their superior for remuneration and subsistence.

Finally, belief in the rightness of law constitutes the basis for legitimation in the legal type of domination. Here the ruled obey the ruler not because he possesses exceptional qualities or hereditary status but because he came to occupy his position by following certain properly enacted rules to which both the ruler and the ruled adhere. Bureaucracy is the typical administrative apparatus in the legal type of domination.

Weber's "ideal" bureaucrat

The power position of the bureaucrat. In a typically bureaucratic administration a ruler's arbitrariness is seriously curtailed by the existence of legal norms that regulate in great detail the relations between him and the bureaucratic officials. Thus for instance, with the acquisition of tenure it is very difficult, if not impossible, to dismiss a recalcitrant bureaucrat. Dismissal is only possible in exceptional circumstances, and such circumstances are stipulated by impersonal regulations, not by any superior official. The bureaucrat, moreover, can refuse to obey orders that go against some generally accepted rules or professional standards of job performance. He can equally refuse commands that directly impinge on his private sphere of existence, for a superior's authority is to be strictly limited to the office situation.

If, however, the bureaucrat is enjoying a high degree of autonomy vis-à-vis his superior in terms of job security and the application of professional standards, in all other respects he is supposed to follow faithfully orders coming from above, even if such orders go against his personal opinions and beliefs. In other terms, insofar as general policy making is concerned, the bureaucrat should be a mere tool; he should put aside his own preferences and execute in a highly "neutral" manner his master's will.

This delicate balance between professional autonomy and political neutrality is, of course, an ideal formulation; it refers to things as they ought to be, not to things as they actually are. Weber saw clearly that such a balance could easily be shattered in actual situations. As a matter of fact, in the legal type of domination there is a built-in tension between the bureaucrat and his legitimate ruler: as the complexity of administrative problems increases and as their solution requires more expert knowledge, it becomes increasingly difficult for the ruler, usually a nonexpert in administrative matters, to exercise effective control. The expert bureaucrat can easily boycott the ruler's policies by withholding information or by judging any undesirable policy as technically unfeasible.

On the other hand, in this struggle between the ruler and his administrative apparatus, the ruler is not always at the complete mercy of his "servants." His position is strengthened by the internal struggles between bureaucrats. Their intensive competition for promotion often enables the ruler to control an obstructive bureaucrat with the help of his antagonistic colleagues. Thus, although not an expert, the ruler can use the rivalries between experts in order to check the concealment or distortion of facts. In many cases such collegiate bodies as state councils or ministerial cabinets can be used as a forum in which rival experts express their opinions, thus enabling the ruler to get a more balanced view on a problem.

In conclusion, according to Weber, inherent in the legal type of domination are tendencies that could destroy the ideal balance of professional autonomy and political neutrality between bureaucracy and its master. This balance can be shattered either by way of a total subjugation of the bureaucracy to its master or by way of its total dominance. Whether the balance shall be maintained or not and whether it will tip on the side of the master or of the bureaucrat depends on the specific configuration of forces surrounding the bureaucracy in each actual situation.

The bureaucratization of all spheres of life

The future of bureaucracy. Although the power position of bureaucracy can vary from case to case, according to Weber, its permanence and technical indispensability in modern society is beyond doubt. Revolutions in modern times can change radically the power position of various groups, including the bureaucracy, but they can never abolish it. Whatever the political regime and whatever the sociopolitical changes in modern society, bureaucracy is here to stay. Thus Weber did not agree with Marx's prediction of the eventual disappearance of bureaucracy. According to Weber, not only will the state bureaucracy not wither away but the bureaucratic form of organization will spread and become dominant in all spheres of life. Whether in the religious, educational, or economic domain, Weber predicted the proliferation of large-scale organizations, the concentration of the means of administration at the top of the hier-

archy, and generally the adoption of the bureaucratic type of organization. The modern army, the church, the university, and other institutions are gradually losing their traditional aspects. They are increasingly administered by impersonal and rational rules aiming at maximum efficiency.

But if Weber did not share Marx's optimism, neither did he share the pessimism of subsequent writers (see below) who have predicted the inevitability of the bureaucrat's political dominance as a result of the spreading and technical indispensability of bureaucracy in modern society. For Weber bureaucratic indispensability does not automatically imply political dominance. The slaves also were technically indispensable in some ancient societies, but they had no political power whatsoever. Bureaucracy's impersonality makes it a tool that can serve many masters.

Oligarchic theories of bureaucracy. If for Marx bureaucracy was an oppressive tool in the hands of the dominant class and for Weber an efficient one in the hands of whoever knows how to control it, subsequent writers, impressed by the increasing bureaucratization of modern society and by the rise of totalitarian regimes in East and West, have seen bureaucracy as an oligarchic system of political domination: bureaucracy ceases to be a tool; it becomes the master, the politically dominant group in a new type of society that is neither capitalist nor socialist. If for Weber the political domination of bureaucracy was problematic, for the German sociologist Robert Michels (1876–1936) and other writers having a similar orientation it became an inevitable outcome, inherent in the internal dynamics of bureaucracy.

Michels' "iron law of oligarchy." Michels was one of the first theorists who tried systematically to link increasing bureaucratization with the oligarchic tendencies in modern society. He focussed his attention primarily on the internal political structure of large-scale organizations. His main thesis, the famous "iron law of oligarchy," postulates that with the increasing complexity and bureaucratization of modern organizations all power is concentrated at the top, in the hands of an organizational elite that rules in a dictatorial manner. This is so even if oligarchy, as in the German Socialist party, which he extensively studied, runs against the ideals and intentions of both rulers and ruled.

In fact, the increasing size of modern organizations and the increasing complexity of the problems with which they have to deal makes technically impossible the participation of the rank and file in the taking of decisions. Moreover, given the ensuing apathy of the members and the increasing concentration of the means of communication at the top, the power position of the leader becomes impregnable. Not only can the leader manipulate information and use the communication network against any potential rival but also, by the exercise of his functions, he acquires specialized knowledge and political skills that make him almost irreplaceable to the organization. In this way both the structural position of the rulers and the ruled lead to a political system that perpetuates the leadership of the person in power and alienates the rank and file from the political process.

Once in control, according to Michels, the organizational oligarchy always has as its primary aim the consolidation of its own power position. Whenever this aim clashes with the more general aims of the rank and file, the elite will sacrifice the latter rather than jeopardize its own privileges. It is in this way that Michels explains the decline in radicalism of the established Socialist parties whose bureaucratic conservatism serves more the interests of the leaders and less the masses whose interests they are supposed to represent.

Finally, for Michels, organizational oligarchy brings societal oligarchy. If the political systems of such voluntary organizations as trade unions and political parties cannot work democratically, then the democratic institutions of the whole society are undermined at their very roots. Indeed, a society dominated by large-scale oligarchic organizations eventually develops an oligarchic political regime. Organizational elites, together with other social elites, having a common interest in the maintenance of the status quo, form a strong power group determined to oppose any demand for change coming from the masses.

Other oligarchic theories. Michels' theory focusses mainly on the bureaucratization of "voluntary" organizations, such as political parties. Other theorists, sharing his pessimism about the future of democracy, point more to the increasing size and bureaucratization of the state administration or of the capitalist enterprise as the main threats to the parliamentary institutions of Western societies.

On the one hand, such liberal German economists as Ludwig von Mises and Friedrich von Hayek are alarmed at the proportions of the state bureaucracy and its increasing intervention in the economic sphere. For them, it is the government's "levelling" tendencies, its insatiable appetite for expansion that gradually destroys free enterprise and undermines democratic institutions.

Alleged effects of expanding government

On the other hand, there are those who attribute increasing bureaucratization and the decline of democracy not to the state's interference but to the internal dynamics of the capitalist economic system. According to this view, the technological changes under a capitalist system necessitate the formation of huge corporations that dominate the market and destroy any kind of competition. Under such circumstances, economic power is concentrated in the hands of a few monopolists who become a "state within a state." Thus, there is an opinion, for instance, that extreme monopolization of the German economy was responsible for bringing the Nazis to power (Franz Neumann, *Behemoth*, 1942). A similar opinion holds that business concentration favours totalitarianism and that, because economic concentration is as strong in some democratic states (Great Britain, United States) as it has been in totalitarian ones (prewar Japan, Germany, Italy), democracy is endangered in the Anglo-Saxon countries (Robert A. Brady, *Business as a System of Power*, 1943).

The other centre of similar debates has been among Marxists trying to understand the nature of the increasingly bureaucratized Soviet society and its deviance, not from democratic but from Marxist principles. What all Marxists now accept is that instead of the withering away of the bureaucratic state predicted by Marx, in the newly founded socialist order one witnesses the exact opposite: the state and its apparatus have expanded in an unprecedented manner.

Theories on the nature of Soviet bureaucratization

For Lenin the increasing bureaucratization of the Soviet state was seen as a sign of the "immaturity of socialism." The civil war and the ensuing chaotic state of the economy, the persistence of internal and external foes of the regime, were used to explain to a great extent the increasing bureaucratization of the state. But such a trend, in Lenin's view, was bound to be a transient phenomenon. As soon as industrialization had transformed the infrastructure and consolidated the regime, debureaucratization would set in and Marx's prediction would come true. Leon Trotsky, who wrote later, at a time when bureaucratization had reached its peak under the dictatorship of Joseph Stalin, explained bureaucratization by the fact that the Soviet economy, being predominantly agricultural, was totally inimical to a socialist regime. This did not mean that the Russian revolution was premature. It simply meant that it had to be expanded in other more industrialized countries through permanent, worldwide revolution. Stalin's policy to build socialism in one country only and his attempt to impose a socialist superstructure on a non-industrial society explained both the expansion and the increasing oppression of the party and the state bureaucracy.

For Trotsky, as for Lenin, bureaucratization had a transient character. The bureaucrats did not constitute a new social class, since they did not directly own the means of production. Their position in the productive process was not "organic" and permanent as was that of a "real" class. If they regulated the production and distribution of goods, it was by *delegation*, not by direct

ownership. Therefore, Trotsky believed, as had Lenin, in their eventual decline and loss of power. For Lenin this could come about through intensive industrialization; for Trotsky a new proletarian revolution was needed for the overthrow of the bureaucrats.

Whereas Lenin and Trotsky could not admit that bureaucracy had a permanent and "organic" position in the Soviet system, other Marxists have thought that it was at its centre and that it defined more than anything else the very nature of the regime. Thus if the former tried to accommodate Soviet reality to Marx's specific predictions about the withering away of the state, the latter dismissed such predictions and tried to analyze the Soviet reality by using a fundamentally Marxist conceptual framework. From their point of view, bureaucracy is not only a privileged oppressive group but a new exploiting class, a class characterized by a new type of oligarchic regime that is neither socialist nor capitalist and that is rapidly spreading both in the East and in the West.

The first systematic elaboration of this position was attempted by the Italian Marxist Bruno Rizzi in *The Bureaucratisation of the World* (1939). For Rizzi the Soviet bureaucracy constituted a new ruling class that exploited the proletariat as much as the capitalists had in the past. It differed from capitalism only in that the new type of domination was based not on individual but on group ownership of the means of production. In fact, in the Soviet system the means of production represent not "socialism" but "stateism." They do not belong to the whole collectivity but to the state and to the bureaucrats who control it. In the last analysis, it is these bureaucrats —the technicians, directors, and specialists holding key positions in the party and state administration—who exploit the proletarians and steal the surplus value of work. According to Rizzi this new type of regime, which he called bureaucratic collectivism, was not limited to the Soviet Union. Similar tendencies could be discerned in fascist countries and even in the "welfare state" type of capitalist democracies. The Yugoslav Communist Milovan Djilas in *The New Class* (1957), a later criticism of the Yugoslav Socialist regime, used arguments similar to Rizzi's.

The managerial revolution

The American philosopher and critic James Burnham proposed a theory of the "managerial revolution" that was more or less an elaboration of Rizzi's ideas. According to his theory, technological progress and the growth of large-scale economic as well as political bureaucracies deprived the old capitalist class of the control of the means of production. The effective control of the economy and of political power had passed to the managers —that is, to the production executives and to the administrators of the state bureaucracy. He predicted that at a later stage of development, private ownership would be abolished and the bureaucrats would appropriate collectively, through the state, the means of production. Thus, according to Burnham, both in the East and the West the managers would impose a new type of oligarchic order.

The classical theories in review. The classical writings on bureaucracy constitute a coherent body of thought with a well-defined pattern of development—a pattern that reflects the changing character of the problems posed by the increasing spread of large-scale organizations in modern society. Indeed, the Marxist, Weberian, and oligarchic theories of bureaucracy could be placed along an optimism-pessimism continuum.

For Marx, bureaucratization was a transient phenomenon, to disappear with the advent of socialism-communism. Marx's optimism and his faith in a classless society prevented him from identifying organizational problems that are common in all advanced industrial societies, whether capitalist or not. In this sense the subsequent analysis of Weber is complementary to the Marxist critique of the strictly capitalist aspects of modern society that come to the fore. Weber saw clearly the permanence and indispensability of the state bureaucracy in modern society without, however, deducing from this indispensability its ultimate political dominance.

Finally, such writers as Michels, Rizzi, and Burnham saw bureaucracy as a system of political domination arising from a shift of power from the legitimate sources of authority to those officeholders (whether in the big corporation or in the government) who achieve de facto dominance because of their strategic position and their acquisition of specialized knowledge.

Merits and defects of the classical theories of bureaucracy

If one tries to identify common elements among the classical theories of bureaucracy, the most basic one is the broad scope attempted by all of them. Their analysis of bureaucracy was not placed, as in many modern studies, in a political and social vacuum. It was systematically linked with the social structure as a whole. Moreover, most of the classical writers had a broad historical perspective. In dealing with the problems of bureaucracy and bureaucratization, they were fully aware that such problems can be understood only when the societies within which they arise are studied dynamically in their long-term historical development and change.

Of course, the broadness of scope or the all-inclusiveness of the classical approach has its shortcomings. By attempting to embrace all the aspects of the problem, the classical theorists offered analyses that often lacked the rigour and precision that can be achieved by a more limited, less ambitious approach. Thus, sometimes they formulated sweeping generalizations that clearly are half-truths or that are valid only under certain conditions that remain unspecified by classical theory. From this point of view, more recent writers, preoccupied with the same problems, try to refine these generalizations by examining in a more limited and empirical manner the specific conditions under which classical statements hold true.

Such a re-examination has, on the whole, dispelled some of the "gloom" characterizing the oligarchic theories of bureaucracy. Michels' law of oligarchy, for instance, was empirically re-examined by a group of American sociologists (Seymour M. Lipset, Martin A. Trow, and James S. Coleman, *Union Democracy*, 1956). In an intensive study of the International Typographical Union, a voluntary organization effectively run in a democratic manner, they tried to identify the conditions accounting for the initiation and maintenance of the union's two-party political system. Among other factors, they found that the relatively high autonomy of the local branches of the union was one of the most relevant conditions. As a matter of fact, a decentralized system of authority increased the power of the locals and thus constituted the basis of a pluralistic system of power. Another important factor was the degree of participation and interest of the rank and file in union affairs. Such an interest was enhanced in the union by the existence of a strong occupational "community" that provided members with many occasions for meeting and discussing union problems.

Such a study challenges effectively the overly deterministic character of Michels' theory. It shows clearly that under certain conditions increasing bureaucratization does not inevitably lead to organizational oligarchy. In defense of Michels, however, it must be mentioned that most empirical studies do support his theory. Thus not only most trade unions and political parties but even such voluntary organizations as cooperatives, professional associations, and churches are oligarchically run.

Nevertheless, in spite of the undeniable fact that large-scale organizations do have an oligarchic political system, many modern writers refuse, simply because of this fact, to accept Michels' pessimistic conclusions as to the meagre chances of democratic institutions in modern society. They argue that such oligarchic large-scale organizations as unions and even political parties can very well constitute autonomous and antagonistic centres of power. Such forces, in the pursuit of their particular interests, sustain the pluralistic system of democratic regimes.

It is because of this pluralistic system of power, indeed, that the structural differentiation (accentuated by the growth of large bureaucracies) between masses and elites does not necessarily lead to the unlimited manipulation of the former by the latter. The so-called elitist theory of democracy maintains that even though the masses do not

actively participate in the political process, competing elites do need electoral support and are forced to take into consideration interests other than their own.

The debate does not end here. "Democratic pluralism" is attacked by those who think that a multiplicity of centres of power is an insufficient condition for democracy. As one critic put it, "It is one of the political myths of our age that democracy is protected and sustained principally or solely by the competition between elites, which balance and limit each other's power." (From T.B. Bottomore, *Elites and Society*, 1964.) Democracy, according to such an argument, is meaningful only if decisions are *not* taken at the top by a unified or a pluralistic establishment and only if an environment is created in which the people can effectively participate in all decisions concerning their daily life.

MANAGERIAL THEORIES OF ORGANIZATION

"Taylorism," or scientific management

The second major tradition of organization writings starts with the American engineer Frederic W. Taylor (1856–1915) and the movement of "scientific management." Here the problem of productivity rather than the problem of power is the dominant preoccupation. If the classical theorists were worried about the impact of large-scale organizations on the power structure of society, writers in the managerial tradition are much more concerned with finding out ways of running such organizations in the most efficient manner. What is problematic here is not the chances of freedom in an increasingly bureaucratized environment but whether the environment can be made even more rational and bureaucratic in the interests of increased productivity. As the problems change so does the basic conceptual framework underlying such theories: Taylor's main unit of analysis is not society as a whole but the individual at the workplace. In fact, Taylor is concerned with the individual more as an isolated unit than as an organizational member. A brief examination of his theories and their organizational implications, however, is necessary for understanding subsequent theoretical developments that try to support or refute Taylorism.

The scientific management movement. The basic aim of Taylorism is the more rational utilization of human and material resources at the workplace. In order to realize this goal, Taylor advocated the empirical and experimental approach to the problems of workshop management. He believed that for every process, every task in industry, there is one best way of doing it. In order to discover this unique way, one has to study work in a "scientific" way: one has to examine in a highly detailed and objective manner the actual ways in which workers were working. On the basis of such an examination, a more rational method of doing the job can be found. In this way, Taylor thought that scientific knowledge could replace intuition and the rule-of-thumb method in organizations.

Time-and-motion studies

It is this basic drive of rationalization that underlies such well-known techniques of scientific management as the time-and-motion study. Very briefly, such a technique consists in the following processes. By the detailed analysis and registration of a worker's movements, the whole working process is broken down to simple operations, all operations being timed. Then, by a systematic analysis of the data thus obtained, the unnecessary movements are corrected and the whole work process is reconstructed in a more simplified and rational manner. Finally, the standard time of the new way of doing the job is calculated by adding up the time units of each operation and the "idle" times (rest and other unavoidable delays). Once the "best way" of doing the job is discovered, the next step is to teach the new work method to the workers. For Taylor, this can easily be achieved by an incentive system that rewards the fast and pliant workers and penalizes the slow or recalcitrant ones.

Taylor and most of his followers, being engineers, approached the organization mechanistically. In analyzing the organization member at work and in building up standard procedures, they concentrated on the instrumental aspects of human behaviour. Indeed, the organization member was conceived as an instrument of production to be handled as easily as any other tool (provided that one knows the laws of scientific management). In such a conception there is no consideration of the feelings, attitudes, and private goals of the individual; neither is there any realization that the worker is a social being influenced by his colleagues and by the social structure and culture of the groups within which he finds himself. Briefly, Taylorism neglected the psychological and sociological variables of organizational action.

Formal theories of administration. Despite Taylor's concern with spreading the methods of scientific management throughout the whole organization, the workshop remained his chief field of investigation. Formal theories of administration are in many ways complementary to Taylorism. They shift the concern for rationalization and efficiency from the shop floor to the administrative problems of management. The aim of such theories is the discovery of principles enabling the manager to build up and administer an organization in the most efficient manner.

The design of organizational networks

Formal theories of administration conceive the structure of the organization in terms of the rights and responsibilities attached to each position and in terms of the prescribed ways by which various positions are linked with one another. On the basis of such a conception of structure, the problem is (given the goals of the organization) to find the best way of designing the organizational blueprint, and principles are sought that can help the manager in this task. The principle of a "flat" hierarchy, for instance, suggests that levels of authority should be kept at a minimum so that communications are facilitated. Another well-known principle suggests that the number of people under the control of a superior should be quite small for the supervision to be effective. Similar principles are formulated insofar as the general process of management is concerned. Their aim is to help the manager at his everyday work by rationalizing such managerial activities as coordination, planning, control, and so forth.

Administrative theories of this type concentrate on the formal aspects of the organization. The emphasis is not on actual relations between groups or individuals but on prescribed relations. It is not on actual behaviour and motivation but on design and rules to be recorded in an organizational chart or manual. One is not concerned with how actual managers are acting and trying to solve problems but with the "best" ways of acting, which are exclusively related to the formal goals and functions of the organization. This highly formalistic perspective explains to a great extent why such theories of administration have failed in their major endeavour of formulating universally valid principles of management. The principles, and more generally the whole literature of this school, do not give the impression of a growing body of knowledge; they give more the image of a mosaic of definitions and redefinitions and of common-sense formulations of rules that make little significant contribution to knowledge of how real organizations function.

The human relations school. The "human relations school," by introducing the social sciences in the study of the workplace, can be seen as a reaction both to Taylor's mechanistic approach and to the sterile formalism of those who tried to discover universal principles of management.

Informal organization

The comprehensive approach. The school has its starting point in studies undertaken in 1927 at the Hawthorne Western Electric plant in Cicero, Illinois. The chief objective of this research was the examination of work conditions and their relevance to workers' performance on the job. At the beginning the approach was not very different from Taylor's. The investigators tried to relate the workers' performance to such variables as illumination, ventilation, fatigue, and so forth. Because the results were inconclusive and confusing, the Hawthorne researchers started gradually to realize that such variables as illumination or humidity cannot be treated separately from the meaning that individuals assign to them or from

their attitudes and preoccupations about them. This insight made the investigators turn their attention to the psychological and finally to the sociological determinants of the work situation. Indeed, at the last stage of their long research, they realized that they must look for the explanation of workers' behaviour in the social organization of the plant. Thus, they started examining, by direct observation and through interviews, a group of operators at work. They soon found out that workers' activities were not regulated by formal managerial policies and directives but by a system of informal norms that were in direct opposition to management's rules and objectives. There were rules, for instance, regulating the pace of work with informal sanctions against any worker producing above a stipulated maximum.

Such rules and patterns of behaviour, emerging spontaneously through the daily interaction of people working together, constitute the informal organization of a plant. This new concept has far-reaching implications for the study of organizations. The worker is no longer perceived as an isolated unit of production but as a social being, as a group member whose actions are very much influenced by the social organization of the workplace. According to the Hawthorne students, this new perspective also has important implications for the practical theory of management. Usually management operates on the basis of assumptions not far removed from those of Taylor and the formalists. The informal organization is ignored, and workers are seen as isolated production units, solely motivated by economic rewards. Management's logic of economic rationality, because it does not take into consideration the psychological and sociological dimensions of the situation, clashes with the workers' "logic of sentiments." As a result, communications break down and industrial conflict becomes inevitable. The remedy for such a situation should be a radical reorientation of managerial conceptions and attitudes toward the workers. Once managers cease to see the worker as a *Homo oeconomicus* and once they turn their attention to the informal organization of work groups, they will be more capable of bringing the informal aims of workers and the formal goals of the firm closer together.

The approach adopted at the final stage of the Hawthorne investigations has been followed by many subsequent studies that attempt to account, in the most detailed and comprehensive way, for the patterns of relations and norms that emerge spontaneously in the work situation. Because such informal patterns are not immediately visible to an outsider, their study necessitates an intimate and long-term acquaintance with the persons and events involved. For this reason, researchers usually limit themselves to the study of a restricted area within an organization (such as a work group). Within this limited context, the informal organization is studied as a social system, as a whole of interdependent parts that emerges within the formal framework of the larger organization.

The "abstractive" phase. The exhaustive study of a single work group, even though it gives insights into the unobtrusive workings of an organization, nevertheless has serious limitations, too—the most important being that the findings in one such case cannot be generalized. One cannot be sure about their applicability and relevance in other cases. For such reasons, human relations students at a later stage abandoned the comprehensive one-case approach and attempted, by abstracting a few variables from the group situation, to examine the relations of these variables in many organizational settings. They hoped that the loss in comprehensiveness could be compensated by findings that would be more valid.

Styles of bureaucratic leadership

Thus an attempt was made to establish correlations between productivity and such variables as characteristics of the worker (*e.g.*, age, sex, social background) or characteristics of the work group (cohesion, type of supervision). The most representative writings of this type were concerned with the relation between the supervisor's style of leadership and group productivity. Their conclusions were that a "democratic," nonauthoritarian style of supervision was positively correlated with high productivity and morale. Strict "punishment-oriented" supervision was conducive to poor work performance. On the basis of such findings human relations students started advocating the training of supervisors in social skills as a solution to the problems and conflicts arising at work.

Such optimism was short-lived. Not only did training schemes for foremen not have the anticipated results, but also correlations between styles of supervision and productivity were put in doubt by subsequent studies that found no consistent relations between them. It was shown, for example, that technology may influence the type of leadership style that will be more effective. When the technological setting involves repetitive and routine tasks, strict rather than permissive supervision seems to be more conducive to high productivity. It was also realized that in order to understand the relation between style of leadership and productivity, one should focus not only on the work group; wider organizational factors also must be taken into account. It was found, for instance, that the supervisor's position within the managerial hierarchy is very important in understanding his effectiveness as a leader. Only the supervisor having a certain influence with his superiors can effectively adopt a permissive style of leadership; without such influence, permissive leadership fails.

As a result of such developments, it was gradually realized that it was not possible to establish valid generalizations by abstracting a few variables and studying their relations in a number of organizations—ignoring, thus, the organizational and group context in which such variables are embedded.

Return to a more comprehensive approach. Thus at a third stage of the development of the human relations school, there was a return to the more inclusive approach of the Hawthorne studies. Moreover, with the new emphasis on technology and with the gradual shifting of attention to organizational variables, human relations writings started to lose their distinctive character. They gradually became indistinguishable from post-Weberian bureaucracy studies (see below *Converging trends*) or from other writings in industrial sociology that are not in the human relations tradition. The fundamental weakness of the human relations approach is its narrow focus. Human relations students, wishing to avoid the vagueness and imprecision of broader theories, concentrated their attention on the individual and the small group. Such an emphasis on the individual and the group, however, prevented them from taking into consideration certain crucial aspects of industrial organizations that can be clearly seen only if one shifts the focus to the organization as a whole and to the wider societal context in which organizations are embedded. This is apparent if one examines the way in which human relations students have studied organizational conflict. By studying it on the individual and group level, they have stressed mainly its psychological dimensions. They have viewed it as bad interpersonal relations or as misunderstandings arising out of bad leadership. In this way conflict became a technical problem that allegedly could be solved by human relations training in social skills. Social conflict—the conflict of different interests arising out of the structure of work organizations and the wider society—was ignored.

Criticism of the human relations approach

Not surprisingly, therefore, the various remedies that the human relations people proposed have not always been effective. Neither better knowledge of the informal organization nor more skillful supervision can alter the fundamental fact that workers and managers in advanced industrial societies have conflicting interests arising ultimately from the general distribution of power in such societies. If this fundamental proposition is accepted, it becomes clear that methods of conflict resolution, which might be partially effective on the individual and group level, cannot work on the organizational and societal level. A permanent resolution of conflict on those higher levels, if at all possible, would certainly require a radical redistribution of power in modern societies. Of course

such ideas are completely alien to human relations writers who accept the status quo.

The criticism above does not invalidate all human relations research. Although human relations students have not given definite answers to the problems they posed, they have introduced the social and psychological sciences to the study of work organizations and have thus broken through the mechanistic and formalistic approach of previous theories.

The decision-making approach. Decision-making theory, as applied to the study of bureaucracies or formal organizations, constitutes a distinct development and must be seen as a reaction to the shortcomings and opposing perspectives of the human relations school, the formal administration theories, and some economic theories of the firm. Its leading exponent is the American social scientist Herbert Simon.

According to this approach, human relations students, by emphasizing the importance of the informal organization, have neglected what is most distinctive about formal organizations—their "formalness," the fact that they are set up in a highly purposive manner for the attainment of specified objectives. By their emphasis on "sentiments," human relations students have completely underrated the fact that people in organizations, whatever their feelings, must solve problems and make rational decisions in their day-to-day work. On the other hand, those disciplines that focus strongly on the rational aspects of action, usually go to the other extreme. They build up ideal models of a perfectly rational man with unlimited capacities for computation and prediction. Thus, for example, in economic theory, economic man, when faced with a problem, is supposed (1) to know in an omniscient way all the alternative courses of action, (2) to predict all ensuing consequences, and (3) to rank automatically all consequences from the least to the most desired according to a system of preferences. In this way economic man always makes optimal choices. This model, of course, does not tell us anything about how real people make decisions. It tells us only how people should decide if they were perfectly rational and omniscient beings. As for the formal theories of administration, they have a similar bias. In trying to formulate principles of good management, they are more concerned with how managers ought to decide and less with how managers actually decide and solve problems.

Decision-making theory represents an attempt to bridge the gap between the extreme positions by formulating a framework of organizational action that can effectively integrate all previous approaches to the study of organizations.

The social psychology of organizational decision making. The decision maker's environment can be seen as a set of premises upon which his decision can be based. There are *factual* premises, subject to empirical testing for their vadility, and *value* premises, which (because they do not refer to what *is* but what *ought* to be) are not subject to such tests. From this point of view, a rational decision can be seen as the right conclusion reached from these two kinds of premises.

In economic theory, the decision maker is supposed to have all factual premises (complete knowledge of alternatives and consequences) and value premises (preference ordering) that are relevant to his problem. In real situations these premises are not given. He has to search for them. In the search process, there are all sorts of limitations reducing both the quantity and the quality of such premises. Thus the habits, skills, and reflexes of the decision maker, his feelings and value orientations, as well as his basic knowledge and available information, will limit seriously the "rationality" of his decisions. In fact, because of such limitations, he will not achieve or seek an optimal but a satisfactory solution. He is not the *maximizing* man of economics but the *satisfying* man; that is to say, as soon as he finds a satisfactory solution, he will stop the search for alternatives.

The search for solutions in decision making

As soon as the organizational decision maker joins the organization, his decisional autonomy is reduced. The organization shapes and limits his decision-making environment in a way that both simplifies problem solving and ensures the general coordination of all decision making activities. Thus the division of labour, by assigning to each member a limited area of responsibility, limits the problems for which he must make a decision. The organizational hierarchy is another crucial factor in structuring the decision maker's environment. The broad and crucial policy decisions are taken at the top. They are subsequently transmitted to the lower echelons and become the value premises that the subordinate will use in making decisions of a more detailed and procedural character.

Thus the division of labour, the authority structure, and other organizational features shape the decisional environment of the individual. They do not necessarily deprive him of all initiative, rather they determine some of the value and factual premises of his environment.

Decision making and organizational structure. When decision-making theorists shift the focus of analysis from the individual problem solver to the organization as a whole, they usually conceptualize it in two ways.

In the first way, attention is paid to the relation of the organization to its external environment. The total organization is seen as a decision maker that tries to give "satisfactory" solutions to organizational problems. As in economics, an attempt is made to build up models of how economic organizations behave in different market situations. But in contrast to the ideal models of economics, decision making theorists attempt to build "realistic" models of how organizations, given the limitations imposed by their own structure and environment, actually take major decisions about such matters as prices and output.

In the second way of conceptualizing the whole organization, the focus shifts more to internal structure. The organization is seen not as a decision-making *unit* but as a decision-making *system*—as a network of decision centres linked together through communications channels. Here cybernetic concepts are used. The organization is seen as a self-controlled communication system with feedback mechanisms. These ensure that whenever a deviation occurs (that is, whenever decisions taken by individuals are not promoting organization goals), information is fed back to the centres and corrective decisions are taken and then implemented.

Criticism of decision-making theory

Decision-making theory, by re-emphasizing formal structure and the rational problem-solving aspects of organizations, has definitely made a significant contribution. It was a healthy reaction against all those psychologically oriented students who were considering the formal structure as something unreal or irrelevant in contrast to the "real" feelings and relations arising spontaneously at work. Moreover, being highly empirical, it has shown the sterility and formalism of those management theories that try to elaborate principles of formal structure without any previous research on how formal organizations are actually structured.

When decision-making theorists claim that they have a conceptual framework within which all previous approaches to the study of organizations can be accommodated, however, their claims are not well founded. It is true that it is somewhat possible to fit all sorts of variables into their decision-making framework when a single individual is making decisions. On the level of the individual, informal values, technology, elements of the formal structure, interest groups, and even societal institutions can be accounted for as premises limiting or expanding the decisional environment of the organizational member. But when the focus becomes broader and shifts from the individual to the organization as a whole, the conceptual framework loses its "integrative" capacity. In fact, when the organization is seen as a system of decision centres and when a vocabulary borrowed from cybernetics is used to account for processes common to all kinds of self-regulated systems (machines, biological organisms, etc.), then the specifically sociological dimensions of organizations are lost.

Problems in communication theory

This does not mean that, on the organizational level, the approach is useless. It can be fruitful insofar as one does not accept in an uncritical manner analogies between self-controlled machines, organisms, and organizations and insofar as one does not forget its partiality and limitations. Otherwise it might lead to gross misrepresentations. There is a tendency among "communication" theorists (especially in industrial contexts), for instance, to reduce all difficulties and troubles in an organization to communication problems, which could supposedly be solved by improving communication channels, correcting "feedback" procedures, and so forth. Although such techniques may be successful in some cases, they are not effective whenever the real trouble lies not in bad communication engineering but elsewhere—for instance, in the rivalry of different departments or bureaus. In such a case, the eventual breakdown in communications is a result, not the cause of the trouble. Under such circumstances, the solution of the conflict (if a solution is possible) is not technical, as would be a problem in communication engineering, but is primarily political, and the political solution will improve communications, rather than the other way round. Consequently, if one wants to discover the organizational conditions under which communication engineering is effective and those under which it is irrelevant, one certainly needs an organizational model that is more inclusive than the "cybernetic" one.

CONVERGING TRENDS

Classical and managerial theories compared

The two lines of organizational writings so far examined have diametrically opposed starting points. Classical theories of bureaucracy, by focussing on the whole social structure, are meant to reveal the impact of increasing bureaucratization on the power structure of modern societies. Managerial theories have relegated the problems of power and social conflict to the background and have tended to look at the industrial organization as a basically harmonious unit whose efficiency one should improve.

As already suggested, however, certain developments on both sides have narrowed the gap between the two different lines of thought. As more and more social scientists become interested in organizational problems, and as they freely choose their conceptual tools from a variety of sources, boundaries between schools become increasingly uncertain; an interchange of ideas and methods constitutes a distinctive feature of recent organization theory. Thus, for instance, post-Weberian theories of bureaucracy use extensively informal organization concepts (a distinctive contribution of the human relations school) in order to challenge Weber's assumption about the rationality of bureaucratic organizations. Moreover, most writings seem to avoid both the shortsighted focus of the social-psychological studies and the all-inclusive society-wide framework of classical theories. Increasingly, the main focus of analysis becomes the organization itself, as a whole.

The problem then is how one sees this whole. Some writers, putting more emphasis on the systemic and integrative aspects of the organization, see it as a system having to fulfill certain functions or needs in order to survive; they examine organizational parts and try to see to what extent various processes inhibit or promote the fulfillment of organizational goals. Other writers, emphasizing organizational conflict, are interested not so much in how an organization solves its systemic problems but, rather, in the configuration of groups within an organization and in the strategies by which they try to promote their usually conflicting interests.

Functionalist theories. Weber's ideal type of bureaucracy has been the starting point of many modern functionalist theories of bureaucracy. Weber argued that the bureaucratic type of organization is technically the most efficient mode of administration. Indeed, the closer that an organization can approach the ideal characteristics of bureaucracy (impersonality, concentration of the means of administration at the top, etc.), the more efficient it will become. In a way, a large part of the post-Weberian literature on bureaucracy tries to show that this hypothesis does not always hold—that very often an accentuation of bureaucratic elements makes an organization not more but less efficient.

(In fairness to Weber, it must be pointed out that many of these criticisms may be misplaced. Weber used a very broad historical perspective and tried to contrast bureaucracy with other types of state administrations. On such a level of analysis, bureaucracy is probably the most rational and efficient organizational instrument ever invented by man. And such a position does not deny that in viewing single bureaucratic organizations one can find and acknowledge bureaucratic inefficiencies.)

The "red tape" image of bureaucracy

Dysfunctional aspects of bureaucracy. The American Robert K. Merton was among the first sociologists to emphasize systematically the other side of the bureaucratic picture—its red tape and inefficiency. According to Merton, if, as Weber thought, the predominance of rational rules and their close control of all actions favours the reliability and predictability of the bureaucrat's behaviour, it also accounts for his lack of flexibility and his tendency to turn means into ends. Indeed, the emphasis on conformity and strict observance of the rules induces the individual to internalize them. Instead of simply means, procedural rules become ends in themselves. Thus a kind of "goal displacement" occurs. The instrumental and formalistic aspect of the bureaucratic role becomes more important than the substantive one, the achievement of the main organizational goals. According to Merton, when one leaves the sphere of the ideal and studies a real organization, one can see that a certain bureaucratic characteristic (such as strict control by rules) can both promote and hinder organizational efficiency; it can have both functional effects (predictability, precision) and dysfunctional effects (rigidity).

Many writers after Merton have tried to study these inefficient, "nonrational" aspects not portrayed in the ideal type of organization. This emphasis on dysfunctions is strongly linked with the key concepts elaborated by the human relations school—that of the formal and the informal organization. Within a formal framework, informal arrangements among workers can go against the fulfillment of organizational goals and, from that point of view, are dysfunctional. Or at least they are dysfunctional from the point of view of management; from the point of view of the workers the informal organization can be functional, since it increases their degree of autonomy and self-regulation. Thus what is functional for one group can be dysfunctional for another group, in the same way that policies promoting one type of goal can hinder the fulfillment of other organizational goals.

The unanticipated consequences of formal controls. Another concept central to functionalist theories of bureaucracy and linked with the formal-informal, functional-dysfunctional concepts is that of the unintended consequences of purposive action. People consciously coordinate their activities in order to achieve specific goals, and the existence of a formal structure clearly reflects purposiveness. But purposive action can have unpredicted consequences. Although formal rules are designed to control everyone's activities in the interest of organizational productivity, they apply not to inert materials or tools but to human beings and thus can never succeed in controlling a situation completely. Contrary to the hopes of Taylorism, human beings can never be turned into perfect machines. They have goals of their own that do not always coincide with the formally prescribed organizational objectives.

The humanness of human beings

The recalcitrance of human beings reluctant to accept full bureaucratic control generates unanticipated "informal" consequences, which in their turn bring forth a renewed attempt to control the situation by additional formal rules. Thus, in a schematic way, the following dialectic pattern seems to be present in many bureaucratic situations: formal control by bureaucratic rules leads to unanticipated consequences of action that in turn lead to renewed formal control.

In one study of a U.S. employment agency, for instance

(reported in Peter Blau, *The Dynamics of Bureaucracy*, 1955), there was an example of an attempt to increase organizational productivity by introducing statistical records of the daily quantity of work of each employee. This formal attempt to control work behaviour had unanticipated consequences. Although productivity was increased, the quality of the work performance deteriorated. Employees were so keen on showing a good record of performance, dealing with as many cases as possible every day, that they ceased giving adequate attention to the case of each particular client. This unanticipated event created the need for a further elaboration of formal controls to change the quality of services. New rules modified the statistical records to take into consideration the nonquantitative aspects of an employee's performance.

The imposition of rules has another dysfunctional aspect: as A. Gouldner has pointed out in his *Patterns of Industrial Bureaucracy*, the detailed definition of unacceptable behaviour in lists of rules increases the employee's knowledge about what behaviour of his is minimally acceptable. This may tend to incite the bureaucrat to accomplish the minimum work required. Such an attitude of course is detrimental to the productivity of the organization. One consequence may be that supervisors will increase their activities and controls and thus increase interpersonal conflict and tension.

Some sociologists believe that the central dilemma in bureaucracy arises out of the need to delegate power to organizational subsystems. The increasing complexity of organizational tasks makes decentralization and the delegation of responsibility to intermediaries inevitable. But such a measure can bring forth a divergence of interests between the central system and its decentralized subunits. There is a tendency for the subunits to neglect the overall organizational goals in favour of their limited subgoals. In this way subgoals become ends in themselves rather than simply means. This situation makes the need for centralized control stronger, and the circle may start all over again. (This circular pattern of rationalization in bureaucracy may be merely a tendency that can be more or less checked by countervailing forces.)

The Parsonian theory of organizations. The formal-informal dialectic outlined above helps the student to study the organization dynamically, as a "going concern," as a system of tensions that produce short-term change. As a conceptual framework, however, it is too simplistic. It cannot in itself account in a thorough and systematic manner for all the complex aspects of an organization. Within the context of functionalist theories, the American sociologist Talcott Parsons has attempted to provide a more comprehensive framework. In applying his general sociological theories to the field of formal organizations, he has attempted to account systematically for the various organizational processes and for the ways in which such processes are linked with one another and with the larger society.

Parsons has seen the organization as a system made up of various subsystems (groups, departments) and embedded in larger systems (community, society). The point of departure and the main emphasis in his theory of organizations is on values. Primarily, organizational values legitimize the major goals of the organization. At a lower level of generality, these values are differentiated and institutionalized in the form of more detailed norms that regulate the various organizational activities. More precisely, these norms regulate the processes that carry out the functions of the organization. According to Parsons, as in every other social system, an organization has four functional requirements or problems that it has to cope with if it wants to survive. These are the problems of adaptation, goal achievement, integration, and latency.

Adaptation, goal achievement, integration, and latency

The adaptation problem points to every organization's need to acquire all the material and human resources necessary for its proper functioning. The institutionalized norms and processes designed to cope with this problem constitute the adaptation sector of the organization. Thus, for instance, norms regulating personnel recruitment will be placed within the adaptation sector.

The goal-achievement sector refers to all norms that contribute to the mobilization of resources to achieve organizational goals. This is basically the problem of fitting means (resources provided by the adaptation sector) to ends. It is in this sector that Parsons places the major power aspects of the organization; in this sector are found the norms regulating the crucial decision-making processes that set the major goals and policies for the organization.

Integration, the third functional problem, refers to the need of every organization to coordinate and keep together its various subsystems (groups, departments). The latency problem, finally, is basically one of "socialization." The latency sector contains all the processes designed to ensure that individual members have adequate training and a motivational commitment for the performance of organizational tasks.

All organizations have the same four functional problems, according to Parsons. What differentiates one from another is that, depending on their goals, they solve these problems in different ways, and the systematic study of such different institutionalized solutions should be one of the major aims of organization theory.

In another context Parsons has been less concerned with functional problems and has paid more attention to the hierarchical structure of an organization. In this respect he distinguishes three subsystems: the technical, the managerial, and the institutional. The technical is concerned with all those activities that contribute directly to the achievement of the organization's goal—such as the processing of raw material in a factory or the actual teaching in a school. The managerial system administers the internal affairs of the organization and mediates between the technical subsystem and outsiders by procuring the necessary resources and by finding "customers" for the disposal of organizational products. The institutional subsystem operates as a link between the technical-managerial subsystem and the larger society. Thus, for instance, in a business bureaucracy the plant would correspond to the technical subsystem, the office or administration to the managerial, and the board of directors to the institutional.

Criticisms of the Parsonian approach

Although Parsons' conceptual framework helps one to understand the system of norms that maintain an organization as a functioning whole, it does not help one to understand how these norms came about nor how they can change. It says little about the concrete actors, collective or individual, who actually create and transform such norms. In fact, in talking continuously about values and norms as regulating processes and solving problems, Parsons gives the impression that such values exist in a social vacuum. His approach, for instance, does not acknowledge that norms regulating the remuneration of personnel are often a reflection of the power position of various groups within an organization. As the power of such groups changes, so do the remuneration norms. To speak of norms without reference to the distribution of power and other scarce resources among organizational groups not only gives a partial view of an organization but also makes impossible the study of organizational change.

Conflict theories. A group of theorists has rejected the functional approach and contended that organizations must be seen as configurations of antagonistic groups that aim, through various strategies, to promote their conflicting interests. Although these theorists do view the organization "as a whole," they see that the parts of the whole are not institutional norms but instead are groups that, according to their power position, can influence policies. Obviously such an approach can deal more easily with social conflict and change than the previous one, which emphasizes integration or equilibrium.

This emphasis on organizational conflict, being a relatively recent development, is far from having a conceptual framework that can be compared with the Parsonian one in thoroughness and sophistication. Nevertheless, some of the recent work on the problems of power and conflict provides useful insights that may constitute a

basis for the elaboration of a more general theory. Thus the American sociologist Melville Dalton, in a book based on his long experience as a participant and observer in six business firms (*Men Who Manage*, 1959), offered a revealing picture of organizational structure in terms of conflicting cliques and their interminable struggles for gaining more power and ensuring a greater share of organizational rewards. Even if sometimes exaggerated, this analysis showed in a striking way to what extent organizational members and groups can be primarily interested in the pursuit of their narrow interests and the consolidation and improvement of their own power position, even at the expense of wider organizational interests. Moreover, it showed the pervasiveness of the ensuing struggles and their impact on every aspect of organizational life. It showed, too, how this intense political activity can be scrupulously and skillfully camouflaged so that the resulting policies appear to be in harmony with the official ideology.

Organizations as networks of cliques and power-seeking groups

This emphasis on the "dirty linen" aspect of the organization, its incessant intricacies and petty struggles, caused Dalton to assign less importance to such larger antagonisms as "staff versus line" or "management versus workers." According to Dalton, although such broad divisions can be identified in the organizational structure, neat lines of demarcation are blurred because numerous cliques within and across the major blocks emerge and fight each other—without regard to abstract ideologies overall. Thus the organizational image that finally emerges from such an analysis is a bewildering kaleidoscope of swiftly changing and conflicting cliques, which cut across departmental and other traditional loyalties and which ultimately account for organizational order or disorder.

The French sociologist Michel Crozier's study of two French government agencies (*The Bureaucratic Phenomenon*, 1963; Eng. trans. 1964) was another important step in the analysis of organizational power and conflict. In Crozier's analysis, the social structure consists of highly cohesive occupational groups, each presenting a unified and rather hostile front toward the others. (Contrary to Dalton, Crozier ignores the existence of cliques within and across these occupational groupings.) Each group's strategy consists in manipulating the rules in order to enhance its own prerogatives and secure its independence from every direct and arbitrary interference by those higher up. Because rules obviously can never cover everything, "areas of uncertainty" always emerge that constitute the focal points around which collective conflicts become acute and instances of direct dominance and subordination develop. The group that, by its position in the occupational structure, can control the "unregulated" area, has a great strategic advantage that it naturally uses in order to improve its power position and to ensure a greater share of organizational rewards.

Conflict studies, as illustrated by the work of Dalton and Crozier, point to the central importance of an organization's political structure and thus open a new perspective in the analysis of bureaucracy. To the image of the organization man as a person of sentiments seeking friendship and emotional security and to the image of the problem solver and decision maker is added the new image of a "political man" primarily interested in the collective and individual pursuit of power for the promotion of his own interests. So long as it is not followed single-mindedly, this new dimension should contribute to a more inclusive and realistic approach to the study of organizations.

Finally, insofar as conflict theories emphasize concrete *actors* and their strategies rather than *systems* and their impersonal functioning, they come close to such new trends in sociological theory as phenomenology and symbolic interactionism. These trends have already had a limited impact on organization theory. Symbolic interactionists reject the functionalist approach which views organizational processes and activities in terms of system needs. For them to speak of system or organizational needs, as distinct from the needs of concrete social actors, is to postulate a mystical social entity over and above the existence of organizational members. Thus, for instance, the English sociologist David Silverman in his book *The Theory of Organisations* (1970) placed social actors rather than system parts as the centre of organizational analysis. According to him, organizational order as well as disorder can only be understood if one refers to the meaningful activities of concrete individuals and groups interacting with each other. In fact, social actors, in attaching meanings to their own actions and to the actions of others and in pursuing various strategies for the achievement of their goals, create, sustain, and change social reality. The action frame of reference has been implicit, at least partly, in many organization writings; but its clear theoretical formulation is a useful, although somewhat exaggerated, reaction against those system theorists who tend to dissociate the study of social reality from the human beings who are involved.

Symbolic interaction

General conclusion. On the level of a general theory of organizations, what is needed most at the present time is a synthesis of the integration-functionalist and the conflict-action frames of reference—a conceptual framework that would help the student to study as *inseparably interrelated phenomena* both normative integration and the conflict of interests, both system requirements and actors' orientations. It has become clear in general sociological theory that one cannot deal adequately with social conflict without considering normative arrangements that limit and regulate it. Inversely, one cannot understand system formation and change without reference to group strategies and conflicts, to the contests of power that determine to a great extent the concrete ways in which norms are institutionalized and de-institutionalized.

(N.P.M.)

Burgundy, History of

The name of Burgundy (French Bourgogne) has designated several political formations that have at various times occupied the region of the Rhône and Saône rivers in eastern France. In modern times the name has been limited to the region lying between the Saône, the Loire, and the upper Seine—that is, to the former duchy of Burgundy (see below)—but in the Middle Ages the name was applied to a Burgundian kingdom later called the kingdom of Arles, and to the countship of Burgundy, later known as the Franche-Comté.

Early kingdoms. The Burgundians were a Scandinavian people whose original homeland lay on the southern shores of the Baltic, where the island of Bornholm (Burgundarholm, in the Middle Ages) still bears their name. About the 1st century AD they moved into the lower valley of the Vistula, but, unable to defend themselves there against the Gepidae, they migrated westward to the borders of the Roman Empire. There, serving as *foederati*, or auxiliaries, in the Roman army, they established a powerful kingdom, which by the early 5th century extended to the west bank of the Rhine. Their king Gundahar (Gundicar or Gunther), who seems to have had his capital at Worms, became involved in hostilities with the Romans about 435. The Roman general Aetius, using the Huns as allies, nearly annihilated the Burgundians the following year. The massacre of the royal family by the Huns is recounted in the great medieval German epic, the *Nibelungenlied*. In 443 Aetius transferred the surviving Burgundians to Sapaudia (Savoy) in the vicinity of Lake Geneva.

As Rome's hold over its Western Empire declined in the second half of the 5th century, the Burgundians gradually spread their control over areas to the north and west of Savoy, and then throughout the Rhône and Saône valleys. This second Burgundian kingdom reached its zenith under the lawgiver and king Gundobad (474–516), who promulgated a written code of laws, the Lex Gundobada, for the Burgundians and a separate code, the Lex Romana Burgundionum, for his Gallo-Roman subjects. Although Gundobad was a Christian of the heretical Arian sect, he and his people lived on good terms with the Gallo-Roman bishops. Gundobad's son Sigismund, who was later canonized, converted to Catholicism and founded the monastery of Saint-Maurice d'Agaune. Under Sigismund the Burgundians were attacked by the powerful Frankish kingdom founded by Clovis to the north and east of Burgundy. Sigismund was killed by Chlodomer, son of Clovis, in 524, but Burgundy remained independent under his brother Gundomar until 534, when the Franks occupied the kingdom, extinguishing the royal dynasty.

Conquest by the Franks

With the death of Clotaire I in 561, however, the Frankish kingdom was partitioned among members of the Merovingian dynasty, and one of Clotaire's sons, Guntram, secured the *regnum Burgundiae*, or kingdom of Burgundy. This *regnum* eventually included not only all the former Burgundian lands but also the diocese of Arles in Provence, the Val d'Aosta east of the Alps, and even extensive territory in north central France. It remained a separate Merovingian kingdom until Charles Martel, the grandfather of Charlemagne, subjugated it to Frankish Austrasia early in the 8th century.

The Carolingians made several partitions of Burgundy before Boso, ruler of the Viennois, had himself proclaimed king of all Burgundy from Autun to the Mediterranean in 879. The French Carolingians later recovered the country west of the Saône and north of Lyons from him, and the German Carolingians recovered Jurane, or Upper, Burgundy (*i.e.*, Transjurane Burgundy, or the country between the Jura and the Alps, together with Cisjurane Burgundy, or the Franche-Comté). Boso and his successors, however, were able to maintain themselves in the kingdom of Provence, or Lower Burgundy—sometimes also, rather misleadingly, called Cisjurane Burgundy—until about 933.

Creation of the last Burgundian kingdom

In 888 Rudolf I (died 912) of the German Welf family was recognized as king of Jurane (Upper) Burgundy, including much territory in what is now Switzerland. His son and successor Rudolf II was able in *c.* 931 to conclude a treaty with Hugh of Provence, the successor of Boso's son Louis the Blind, whereby he extended his rule over the entire *regnum Burgundiae* except the areas to the west of the Saône. This union of Upper and Lower Burgundy was bequeathed in 1032 to the German king and emperor Conrad II and became known from the 13th century as the kingdom of Arles (the name Burgundy being increasingly reserved for the county and for the duchy of Burgundy).

Burgundy in the 11th century.

The county of Burgundy to 1335. The rulers of the kingdom of Burgundy had little control over the local counts in Cisjurane Burgundy, where effective authority passed more and more into the hands of the counts of Mâcon. In 1127 the new count Raynald III refused to do homage to the German king Lothair III. Lothair then tried to set up Conrad of Zähringen in Raynald's place, but after ten years of conflict Raynald was victorious. Thereafter he was the *franc-comte* ("free count"), and his territory known as the Franche-Comté.

The emperor Frederick I (Barbarossa) married Raynald's heiress, Béatrix, in 1146, hoping that the possession of the countship would strengthen his influence in Germany. The countship, however, passed on Béatrix's death to her third son, Otto I (died 1200), then to his daughter Béatrix and her husband Otto II (died 1234) of the house of Meran. Their son Otto III was succeeded in 1248 by his sister Alix, whose husband, Hugh, of the house of Chalôn, was descended from a brother of Raynald III. Their son, Otto IV, heavily in debt after a long conflict with the Emperor, agreed in two treaties (1291 and 1295) with the French king Philip IV to surrender the county to the French crown. Otto's daughter married the future Philip V of France, and their daughter's mar-

riage to the Burgundian duke Eudes IV in 1335 temporarily succeeded in reuniting the duchy and the county of Burgundy.

The duchy of Burgundy to 1335. The duchy of Burgundy was that part of the *regnum Burgundiae* west of the Saône that was recovered from Boso by the French Carolingians and remained a part of the kingdom of France. Boso's brother Richard, called the Justiciar, count of Autun, was invested with a command against the Norman invaders who devastated the duchy in 888–889. Richard expelled them and then organized the greater part of the territory under his own authority. His son Rudolph (Raoul), who succeeded him in 921, was elected king of France in 923. On Rudolph's death in 936 the Carolingian king Louis IV and Hugh the Great, duke of the Franks, detached Sens, Troyes, and Langres from Burgundy, and Hugh secured the succession to the duchy for his two sons. The younger of these, Henry I (Eudes-Henry), who died without issue in 1002, had adopted his stepson Otto William, but the king of France, the Capetian Robert II, who was Henry's nephew, refused to acknowledge Otto William as heir to Burgundy and conquered the duchy (1003–06). Robert made his son Henry duke of Burgundy, to which Dijon (separated from the duchy with Langres) was restored in 1016, though the countships of Nevers and Auxerre were detached from it. In 1032, after Henry's accession to the French crown, his brother became duke as Robert I (died 1075).

The duchy under the Capetians

The duchy formed in 1016, though smaller than its 10th-century predecessor, was stronger and remained in the Capetian family until 1361. In their foreign policy the Capetian dukes adhered loyally to their cousins the kings of France and in internal affairs enlarged their domain and enforced obedience from their vassals. Burgundy came to be recognized as the premier peerage of the French kingdom. Hugh III (died 1192) commanded the French forces in the Holy Land in the Third Crusade after King Philip II Augustus returned home. His successor, Eudes III (duke 1192–1218), fought against the Albigensian heretics and supported Philip Augustus against John of England. Hugh IV was prominent in the reign of St. Louis. Robert II (duke 1272–1306) and Eudes IV (duke 1315–49) were the most powerful French barons of their time, being allied by marriage to the royal house and often directing royal policy.

The development of feudal institutions within the two Burgundies proceeded at an unequal pace. Central authority over the vassals was much stronger in the duchy than in the county, which had been plagued by dynastic rivalry, and judicial institutions such as the *grand jours* (ducal assizes) and courts of appeal were organized sooner and more thoroughly within the duchy. The towns prospered: Dijon became an important market town; a fair was held at Chalon-sur-Saône, where merchants from the south of France met northern traders; and Italian merchants came to Burgundy to buy its wool, which rivalled that of England. Pilgrims flocked to Vézelay and Autun, where in 1146 a magnificent church was built around the tomb of St. Lazare. Burgundian monasteries were famous: Cluny (founded 910) became the centre of an order of monks extending from England to Spain; and in 1098 the monastery of Cîteaux was founded and with it a new religious order, the Cistercian.

Growth of towns

Unification under the Valois dukes. The reunification of the two Burgundies effected in 1335 was ended in 1361 with the death of Eudes IV's grandson Philip of Rouvre. The king of France, John II the Good, reunited the duchy to the domain of the crown, while Franche-Comté went to the Count of Flanders. A new period of Burgundian history opened under King John, who in 1363 granted the duchy to his son Philip the Bold; then in 1369 Philip married the heiress of the county, Margaret of Flanders. In 1384, when his father-in-law died, Philip inherited Nevers, Rethel, Artois, and Flanders, as well as the Franche-Comté. The two Burgundies formed the southern part of a state, the northern possessions of which extended over the Netherlands, the valley of the Meuse, and the Ardennes. In the north expansion was to continue (Hainaut, 1428: Brabant, 1430; Luxembourg, 1443), but the south, from which Nevers was again detached in 1404, became less and less important. Philip the Bold, however, who lived in Burgundy, built the monastery Chartreuse de Champmol at Dijon. He also purchased the southern territory of Charolais in 1390.

John the Fearless succeeded Philip in 1404 and devoted most of his energies to the struggle with his rival Louis, duc d'Orleans, and with Louis' supporters under the Count of Armagnac, who devastated the southern borders of Burgundy between 1412 and 1435. John was assassinated in 1419, and his son Philip the Good continued the struggle against the Armagnacs and threw his support to the English during the Hundred Years' War. The Treaty of Arras (1435), which established peace between Burgundy and Charles VII, added greatly to the Burgundian domain. Even so, mercenary bands continued their depredations in Burgundy until 1445, after which the duchy enjoyed peace until Philip's death in 1467.

The next duke, Charles the Bold, was constantly in conflict with the French king Louis XI. Charles's aim was to unite the northern and southern sections of the kingdom by annexing Lorraine, and he demanded from the Emperor the title of king of Burgundy. Charles was thwarted in these efforts by the persistent efforts of Louis XI, who conducted several campaigns against him and subjected Burgundy to an economic blockade.

Economic decline

The two Burgundies suffered from the ravages of the Black Death in 1348 and from the mercenaries' bands of the Hundred Years' War. The population declined perceptibly and put a heavy strain on production in the 15th century. The lucrative trade in grain, wines, and finished wool was threatened, and the market-fairs lost some of their importance. But on the whole the two Burgundies seem to have enjoyed more security than much of Europe during the 14th and 15th centuries. The Valois dukes (1363–1477) introduced new institutions into the Burgundies: in the duchy the Chambre des Comptes ("chamber

of accounts") was organized in Dijon in 1386, and the *grand jours* were transformed by Charles the Bold as a *parlement*, or permanent court, which met alternately at Beaune and at Dôle (which also became the meeting place for the estates of the Franche-Comté). The "lands of Burgundy" were administered by a single governor but remained separate in fiscal matters. The Burgundian nobility profited from the rule of the Valois dukes as state servants.

Later history. After the death of Charles the Bold in 1477, his heiress married the Austrian archduke Maximilian of Habsburg (later Holy Roman emperor), thus disappointing French hopes that she would marry Louis XI's son Charles, the future Charles VIII of France. The Treaty of Arras (1482), however, ceded the Franche-Comté to Charles on his betrothal to Mary's daughter Margaret of Austria. When he broke this engagement, he had to cede the Franche-Comté to Austria by the Treaty of Senlis in 1493.

The Franche-Comté. For the next 185 years the Franche-Comté was a possession of the Habsburgs. By the Treaty of St. Jean-de-Losne (1522) with France, the neutrality of the county was ensured during the wars between the Habsburgs and the last French kings of the Valois line. Its ensuing prosperity, enhanced by industrial development, can be judged by the splendid Renaissance architecture of its towns. Civil disturbances, however, came with the Reformation, when bands of Protestants entered the predominantly Catholic county from Germany and Switzerland. The Franche-Comté passed to the Spanish Habsburgs through the emperor Charles V's partition of his dominions in 1556. Under Philip II of Spain a forceful repression of Protestants took place, and Henry IV of France, in his war with Philip, violated the Franche-Comté's neutrality. From 1598 to 1635 peace was maintained, but French fear of Habsburg encirclement led Louis XIII to attempt to annex the county. He invaded and ravaged the area annually from 1636 to 1639, but the Peace of Westphalia (1648) confirmed Habsburg control.

Annexation by the French

Conquered in 1668 by the prince de Condé during the War of Devolution but returned to Spain by the Peace of Aix-la-Chapelle (Aachen; May 2, 1668), the Franche-Comté was finally conquered for France by Condé in the last of the so-called Dutch Wars, the French annexation being recognized by the Peace of Nijmegen in 1678. Louis XIV transferred the capital of the new province to the former imperial city of Besançon. In 1790, along with the rest of France, the Franche-Comté was divided into three separate *départements* of Jura, Doubs, and Haute-Saône.

The province of Burgundy. After the death of Charles the Bold (1477), the duchy was annexed by the French crown. During the 16th century it was devastated by the Wars of Religion. The towns had to be fortified, and mercenaries roamed the country. As Catholic supporters of the Holy League during the wars, the towns did not recognize the former Protestant Henry IV as king until 1595. The duchy was again ravaged in the Thirty Years' War, and also during the aristocratic revolt known as the Fronde (1648–53) led by the great Condé. Not until the French annexation of the Franche-Comté in 1678 were peace and security restored. From 1631 to 1789 the duchy was governed by the princes de Condé. After the French Revolution the province of Burgundy disappeared, divided into the *départements* of Côte-d'Or, Saône-et-Loire, and Yonne.

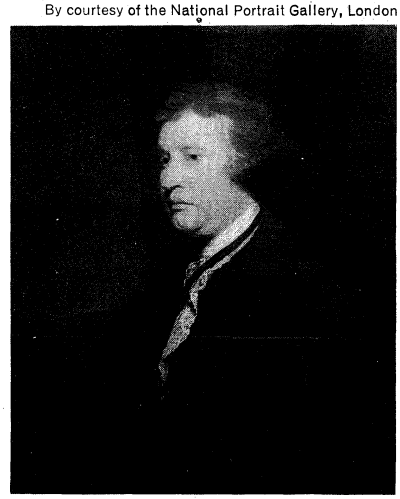
BIBLIOGRAPHY. Although the history of the Burgundian lands has been the subject of several general works, including A. KLEINCLAUSZ, *Histoire de Bourgogne*, 2nd rev. ed. (1924); J. RICHARD, *Histoire de la Bourgogne* (1957); and E. PRECLIN, *Histoire de la Franche-Comté* (1947), none of these works satisfies the demands of present research. Major works have been devoted to different periods of Burgundian history. M. CHAUME, *Les origines du duché de Bourgogne*, 4 vol. (1925–37), covers the Roman period to the end of the 11th century. This may be supplemented by R. GUICHARD, *Essai sur l'histoire du peuple burgonde* (1965); R. POUPARDIN, *Le royaume de Bourgogne* (1907); and on ducal Burgundy, J. RICHARD, *Les ducs de Bourgogne et la formation du duché du XI^e au XIV^e siècle* (1954). The Valois dukes and the formation of their state is the subject of R. VAUGHAN, *Philip the Bold: The Formation of the Burgundian State* (1962), *John the Fearless: The Growth of Burgundian Power* (1966), *Philip the Good: The Apogee of Burgundy* (1970); and J. BARTIER, *Charles le Téméraire* (1970), all of which give references to additional studies. The history of Burgundy and Franche-Comté in the 16th century has been studied by L. FEBVRE, *Philippe II et la Franche-Comté* (1911); and H. DROUOT, *Mayenne et la Ligue en la Bourgogne*, 2 vol. (1937). For a discussion of the crisis of the 17th century, see G. ROUPNEL, *La Ville et la campagne au XVII^e siècle* (1922), a study of the ascendancy of Dijon over the surrounding countryside. A good city history is C. FOHLEN (ed.), *Histoire de Besançon*, 2 vol. (1964–65). Essential material is furnished by numerous critical articles and reviews, recorded in the *Bibliographie bourguignonne* (annual); and in C. FOHLEN (ed.), *Bibliographie franc-comtoise, 1940–1960* (1961).

(J.B.R.)

Burke, Edmund

British statesman, parliamentary orator, and political thinker, Edmund Burke played a prominent part in all major political issues from 1765 to his death in 1797 and remains an important figure in the history of political theory.

By courtesy of the National Portrait Gallery, London



Burke, oil painting from the studio of Sir Joshua Reynolds, 1771. In the National Portrait Gallery, London.

Early life and career. Burke was Irish, born in Dublin probably on January 12 (January 1, old style), 1729. His father, a solicitor, was Protestant, his mother Roman Catholic. He encountered a third religious tradition at his boarding school, run by a Yorkshire Quaker. He entered Trinity College, Dublin, in 1744 and moved to London in 1750 to begin his studies at the Middle Temple. There follows an obscure period in which Burke lost interest in his legal studies, was estranged from his father, and spent some time wandering about England and France. In 1756, he published anonymously and in the style of the statesman and man of letters Viscount Bolingbroke *A Vindication of Natural Society in a Letter to Lord . . ., by a Late Noble Writer*, a satire aimed at both the destructive criticism of revealed religion and the contemporary vogue of "return to Nature." A contribution to new trends in aesthetic theory, *A Philosophical Enquiry into the Origin of Our Ideas of the Sublime and Beautiful*, which appeared in 1757, gave him some reputation in England and was noticed abroad, among others by Denis Diderot, Immanuel Kant, and G.E. Lessing, the German dramatist and man of letters. In agreement with the publisher Robert Dodsley, Burke initiated *The Annual Register* as a yearly survey of world affairs; the first volume appeared in 1758 under his (unacknowledged) editorship, and he retained his connection with it for about 30 years.

In 1757 Burke married Jane Nugent, the daughter of an Irish Catholic doctor. From this period also date his

numerous literary and artistic friendships, including those with Dr. Samuel Johnson, Oliver Goldsmith, Sir Joshua Reynolds, and David Garrick.

Secretary to Marquess of Rockingham

After a first unsuccessful venture into politics, Burke was appointed secretary, in 1765, to the Marquess of Rockingham, leader of one of the Whig groups, the largely liberal faction in Parliament, and entered the House of Commons. Burke remained Rockingham's secretary until the latter's death in 1782, exercising great influence on his upright and disinterested, if not very forceful, patron. He worked with some success to inspire with a sense of unity and common principle the group that formed round Rockingham. Mostly in opposition, this group was to be the vehicle of Burke's parliamentary career.

Political life. Burke soon took an active part in the domestic constitutional controversy of George III's reign. The revolution settlement after the accession of William and Mary to the throne in 1689 had enlarged the role of Parliament, but while placing specific limitations on the royal prerogative it had left many aspects of constitutional practice undefined. The main problem during the 18th century was whether king or Parliament controlled the executive. George III was seeking to reassert a more active role for the crown, which had lost some influence in the reigns of the first two Georges, without infringing the revolution settlement. Burke's chief comment on this issue is his pamphlet "Thoughts on the Cause of the Present Discontents" (1770). He argued that George's actions were against not the letter but the spirit of the constitution. Choice of ministers purely on personal grounds was favouritism; public approbation by the people through Parliament should determine their selection. The community and its accredited representatives must be presumed capable of rational choice, provided that the independence of the House of Commons was maintained. But changed circumstances of government meant that a restoration of the past, such as a return to triennial Parliaments, was no remedy; what was needed was a more active intervention of the electorate in defense of its powers. The pamphlet includes Burke's famous, and new, justification of party, defined as a body of men united on public principle, which could act as a constitutional link between king and Parliament, providing consistency and strength in administration, or principled criticism in opposition.

Member of Parliament

In 1774 Burke was elected a member of Parliament for Bristol, then the second city of the kingdom and an open constituency requiring a genuine election contest. He held this seat for six years but failed to retain the confidence of his constituents. For the rest of his parliamentary career he was member for Malton, a pocket borough of Lord Rockingham's. It was at Bristol that he made the well-known statement on the role of the member of Parliament. The elected member should be representative, not delegate. The electors are capable of judging his integrity, and he should attend to their interest; but, more importantly, he must address himself to the general good of the whole community, acting according to his own judgment and conscience, unfettered by mandates or prior instructions from those he represents.

Burke gave only qualified support to the parliamentary reform movements, his main concern being curtailment of the crown's powers. However, he accepted the possibility of widening political participation, provided that there was evidence of rationality, restraint of aggressive partiality, and dedication to the common good; he rejected any doctrine of mere rule of numbers. Apart from holding general principles on this subject, Burke made a practical attempt to reduce the influence of the crown as one of the leaders of the movement for economical reform, which pressed for parliamentary control of royal patronage and expenditure. When the Rockingham Whigs took office in 1782, bills were passed reducing pensions and emoluments of offices, including Burke's own. Burke was specifically connected with an act regulating the civil list, the amount voted by Parliament for the personal and household expenses of the sovereign.

Views on American policy

Colonial policies. A second great issue that confronted Burke in 1765 was the quarrel with the American colonies. Their prodigious development in the 18th century had produced strains in the system of imperial political and economic regulation that came to a head after the Seven Years' War. The imposition of a stamp duty by George Grenville in 1765, along with other measures, provoked unrest and opposition, which soon swelled into disobedience, conflict, and secession. English policy was vacillating; determination to maintain imperial control ended in coercion, repression, and unsuccessful war. The Rockingham group opposed coercion, basing their American policy on their actions in their short administration of 1765–66 when they repealed the Stamp Act, while asserting the imperial right to impose taxation by the Declaratory Act.

Burke's best known statements on this issue are two parliamentary speeches, "On American Taxation" (1774) and "On Moving His Resolutions for Conciliation with the Colonies" (1775), and "A Letter to . . . the Sheriffs of Bristol, on the Affairs of America" (1777). British policy, he argued, had been both imprudent and inconsistent, but above all legalistic and intransigent, in the assertion of imperial rights. Authority must be exercised with respect for the temper of those subject to it, if there was not to be collision of power and opinion. This truth was being ignored in the imperial quarrel; it was absurd to treat universal disobedience as criminal: the revolt of a whole people argued serious misgovernment. Burke made a wide historical survey of the growth of the Colonies, the special traditions and circumstances that had formed their character, the revolutionary changes in the recent past, and their economic problems. In the place of narrow legalism he called for "legislative reason," an imaginative reinterpretation of the values enshrined in the imperial relation in the light of these new factors. The claims of circumstance, utility, and moral principle should be considered, as well as precedent. And as a prerequisite of reconciliation, a conciliatory temper must be shown by the imperial Parliament with readiness to meet American complaints and measures to restore colonial confidence. His proposal was an extension of the forms of the British constitution to the imperial relation, so far as circumstances allowed it.

In view of the magnitude of the problem, the adequacy of Burke's specific remedies is questionable, but the principles on which he was basing his argument were the same as those underlying his "Present Discontents": government should ideally be a cooperative, mutually restraining relation of rulers and subjects; there must be attachment to tradition and the ways of the past, wherever possible, but equally, recognition of the fact of change and the need for a comprehensive and discriminating response to it, reaffirming the values embodied in tradition in new circumstances.

Ireland was a special problem in imperial regulation. It was in strict political dependency on England and internally subject to the ascendancy of an Anglo-Irish Protestant minority, owning the bulk of the land. Roman Catholics were excluded by a penal code from political participation and public office. To these oppressions were added widespread rural poverty and a backward economic life aggravated by commercial restrictions resulting from English commercial jealousy. Burke was always concerned to ease the burdens of his native country. He consistently advocated relaxation of the economic and penal regulations, and steps toward legislative independence, at the cost of alienating his Bristol constituents and of incurring suspicions of Catholicism and charges of partiality.

The remaining imperial issue, to which he devoted many years, and which he ranked as the most worthy of his labours, was that of India. The commercial activities of a chartered trading concern, the British East India Company, had created an extensive empire. Burke in the 1760s and 1770s opposed interference by the English government in the company's affairs as a violation of chartered rights. However, he learned a great deal about

the state of the company's government as the most active member of a select committee that was appointed in 1781 to investigate the administration of justice in India but which soon widened its field to that of a general inquiry. Burke concluded that the corrupt state of Indian government could be remedied only if the vast patronage it was bound to dispose of was in the hands neither of a company nor of the crown. He drafted the East India Bill of 1783 (of which the Whig statesman Charles James Fox was the nominal author), which proposed that India should be governed by a board of independent commissioners in London. Two of Burke's best known speeches were on Indian affairs, "On Mr. Fox's East India Bill" (1783) and "On a Motion Made for the Papers Relative to the Nabob of Arcot's Debts" (1785). After the defeat of the bill, Burke's indignation came to centre on Warren Hastings, governor-general of Bengal from 1772 to 1785. It was at Burke's instigation that Hastings was impeached in 1787 and he challenged Hastings' claim that it was impossible to apply Western standards of authority and legality to government in the East. He appealed to the concept of the Law of Nature, the moral principles rooted in the universal order of things, to which all conditions and races of men were subject. The impeachment dragged on for eight years and ended with Hastings' acquittal on all charges. The proceedings resulted in an authoritative statement of the principle of responsible rule in imperial affairs; but it is generally regarded as an act of injustice to Hastings, who had been, despite questionable methods, a disinterested servant of the company and the British name in India.

Hastings impeached

Burke's political judgment. The impeachment is the most conspicuous illustration of the failings to which Burke was liable throughout his public life, including his brief periods in office as paymaster general of the forces in 1782 and 1783. His political positions were sometimes marred by gross distortions and errors of judgment. His Indian speeches fall at times into a violence of emotion and abuse, lacking restraint and proportion. His reliance on the opinions of Sir Philip Francis, one of Hastings' most pertinacious enemies, illustrates his inability to accurately judge personality. His parliamentary activities were at times irresponsible or factious. Nor did he escape the charge, in Indian affairs, of personal interest. Throughout his career he was associated financially and politically with his brother Richard and a putative kinsman William Burke, both doubtful characters known to be unsuccessfully speculating in East India stock. The Burkes' joint finances were indeed always in a precarious state, and as Edmund was ever eager to forward his kinsmen's political fortunes it is understandable that he appeared in some hostile eyes as hardly more than one of a clan of Irish adventurers.

It can plausibly be argued that these failings were defects of Burke's virtues rather than an impurity in those virtues themselves. It has not been shown that he himself was a speculator in company stock; it seems rather that he was rendered blind or oblivious to the nature of his relatives' proceedings by family partiality. Nor do his political lapses, even at their worst, appear to spring from self-interest or unworthy motives but from his failure to control and balance his unusually sensitive and powerful emotional nature. Burke's weaknesses therefore lie close to what is best in his character and career: the capacity to illuminate practical politics by general principles in a synthesis at once intellectual and emotive, the intensity of his dedication and industry in public affairs, the constancy of his humanitarian struggle against injustice and suffering, the readiness and generosity of his help in need (of which the poet George Crabbe and painter James Barry are the best known recipients), the distinction of his numerous literary and political friendships, and the happiness of his family life and kinship ties.

Writings on French Revolution. The outbreak of the French Revolution in 1789 was initially greeted in England with much enthusiasm. Burke, after a brief suspension of judgment, was both hostile to it and alarmed by this favourable English reaction. He was provoked into writing his *Reflections on the Revolution in France* (1790) by a sermon of the Protestant dissenter Richard Price welcoming the Revolution. Burke's deeply felt antagonism to the new movement propelled him to the plane of general political thought; it provoked a host of English replies, of which the best known is Thomas Paine's *The Rights of Man* (1791–92).

Reflections on the Revolution in France

In the first instance Burke discussed the actual course of the Revolution, examining the personalities, motives, and policies of its leaders. More profoundly, he attempted to analyze the fundamental ideas animating the movement and, fastening on the Revolutionary concepts of "the rights of man" and popular sovereignty, emphasized the dangers of democracy in the abstract and the mere rule of numbers when unrestrained and unguided by the responsible leadership of a hereditary aristocracy. Further, he challenged the whole rationalist and idealist temper of the movement. It was not merely that the old social order was being pulled down. He argued, further, that the moral fervour of the Revolution, and its vast speculative schemes of political reconstruction, were causing a devaluation of tradition and inherited values and a thoughtless destruction of the painfully acquired material and spiritual resources of society. Against all this, he appealed to the example and the virtues of the English constitution: its concern for continuity and unorganized growth, its respect for traditional wisdom and usage rather than speculative innovation, for prescriptive, rather than abstract, rights, its acceptance of a hierarchy of rank and property, its religious consecration of secular authority and recognition of the radical imperfection of all human contrivances.

As an analysis and prediction of the course of the movement, Burke's French writings, though frequently intemperate and uncontrolled, were in some ways strikingly acute; but his lack of sympathy with its positive ideals concealed from him its more fruitful and permanent potentialities. It is for the criticism and affirmation of fundamental political attitudes that the *Reflections* and *An Appeal from the New to the Old Whigs* (1791) retain their freshness, relevance, and force.

Appeal from the New to the Old Whigs

Burke opposed the French Revolution to the end of his life, demanding war against the new state, and gaining a European reputation and influence. But his hostility to the Revolution went beyond that of most of his party and in particular was challenged by Fox. Burke's long friendship with Fox came to a dramatic end in a parliamentary debate (May 1791). Ultimately the majority of the party passed with Burke into support of William Pitt's government. In 1794, at the conclusion of Hastings' impeachment, Burke retired from Parliament. His last years were clouded by the death of his only son, on whom his political ambitions had come to centre. He continued to write, defending himself from his critics, deploring the condition of Ireland, and opposing any recognition of the French government (notably in "Three Letters Addressed to a Member of the Present Parliament on the Proposals for Peace, with the Regicide Directory of France" (1796–97). Burke died at Beaconsfield, Buckinghamshire, on July 9, 1797.

Burke's political thought. Burke's writings on France, though the most profound of his works, cannot be read as a complete statement of his views on politics. Burke, in fact, never gave a systematic exposition of his fundamental beliefs but appealed to them always in relation to specific issues. His consistency during his political career has therefore been debated. He himself repudiated the charge of inconsistency, and it is possible to regard his writings as an integrated whole in terms of constant principles underlying his practical positions.

Those principles are, in essence, an exploration of the concept of "Nature." Burke conceives the life of feeling and the spiritual life of man as a harmony within the larger order of the universe. Natural impulse, that is, contains within itself self-restraint and self-criticism; the moral and spiritual life is continuous with it, generated from it and essentially sympathetic to it. It follows that society and state make possible the full realization of

human potentiality, embody a common good, and represent a tacit or explicit agreement on norms and ends. The political community acts ideally as a unity. Political participation will naturally differ from one part of society to another, and from period to period, but it should always exclude aggressive self-interest and allow expression of rational self-interest compatible with the good of the whole. Burke therefore does not reject the concept of natural right, but he does not give it any simple or direct political implication.

This interpretation of nature and the natural order implies deep respect for the historical process and the usages and social achievements built up in time. Therefore, social change is not merely possible but inevitable and desirable. But the scope and the role of thought operating as a reforming instrument on society as a whole is limited. It should act under the promptings of specific tensions or specific possibilities, in close union with the detailed process of change, rather than in large speculative schemes involving extensive interference with the stable, habitual life of society. Also, it ought not to place excessive emphasis on some ends at the expense of others; in particular, it should not give rein to a moral idealism that sets itself in radical opposition to the existing order. Such attempts cut across the natural processes of social development, initiating uncontrollable forces or provoking a dialectical reaction of excluded factors. Burke's hope, in effect, is not a realization of particular ends, such as the "liberty" and "equality" of the French Revolution, but an intensification and reconciliation of the multifarious elements of the good life that community exists to forward.

Assessment and influence. Burke's system is in essence a defense of God's goodness and omnipotence in the face of the existence of evil. Burke is not a Christian political thinker in the sense that the tenets of Christian faith, or unity of Christian worship, are integral elements in his political thought, as is the case with Richard Hooker. But of all earlier English political thinkers, his closest affiliations, in historical situation, in tone, and in many details of thought, are with Hooker; and both belong to the tradition of political thought whose greatest figures are St. Thomas Aquinas and Aristotle.

In his own day, Burke's writings on France were an important inspiration to German and French counter-revolutionary thought. His influence in England has been more diffuse, more balanced, and more durable. He stands as the original exponent of long-lived constitutional conventions, the idea of party, and the role of the member of Parliament as free representative, not delegate. More generally, his remains the most persuasive statement of certain inarticulate political and social principles long and widely held in England: the validity of status and hierarchy and the limited role of politics in the life of society. As for the contemporary relevance and ultimate validity of his thought, this hinges on the question as to how far his particular conception of "nature" can still be found consonant with subsequent social experience and speculation.

BIBLIOGRAPHY. There are 19th-century editions of Burke's *Works* but no modern edition. The most recent edition of *Reflections* is that of C.C. O'BRIEN (1969), using the critical edition of W.B. TODD (1959). The most detailed up-to-date biography is C.B. CONE, *Burke and the Nature of Politics*, 2 vol. (1957–64). Discussions of Burke's thought, or phases of it, in relation to the political issues of his career are J. MORLEY, *Edmund Burke: A Historical Study* (1867); G.W. CHAPMAN, *Edmund Burke: The Practical Imagination* (1967); H.C. MANSFIELD, JR., *Statesmanship and Party Government: A Study of Burke and Bolingbroke* (1965); and R.R. FENNESSY, *Burke, Paine, and the Rights of Man* (1963). Attempts to restate Burke's ideas as a systematic political philosophy in the tradition of Natural Law are: C.W. PARKIN, *The Moral Basis of Burke's Political Thought* (1956); P.J. STANLIS, *Edmund Burke and the Natural Law* (1958); and F.P. CANAVAN, *The Political Reason of Edmund Burke* (1960). A. COBBAN, *Edmund Burke and the Revolt Against the Eighteenth Century*, 2nd ed. (1960), is an interpretation of Burke's place in intellectual history. J.T. BOULTON, *The Language of Politics in the Age of Wilkes and Burke* (1963), is a special study analyzing the relation of style and content in the political writings of Burke and his contemporaries.

(C.W.Pa.)

Burma

Burma is an independent republic in Southeast Asia, with an area of 261,789 square miles (678,034 square kilometres) and, early in the 1970s, a population of some 27,000,000. It is bordered by Thailand and Laos on the east, by China (the autonomous region of Tibet and the province of Yunnan) on the north and northeast, by India on the northwest, on the west by Bangladesh and the Bay of Bengal, and on the southwest and south by the Gulf of Martaban and the Andaman Sea.

Burma stretches from latitude 10° N to about 28° 30′ N; almost half the country is, therefore, situated outside the tropics, but, because of its configuration, it is generally considered to be a primarily tropical country. The country is in the shape of a diamond, with a long tail—running south along the Malay Peninsula—attached to it. Its total length from north to south is 1,300 miles; its width, at the widest part, is 575 miles from east to west.

Burma's historic tradition

In ancient and medieval times, Burma was regarded as a gateway to the Indochinese Peninsula, as well as to China; it was known as the Golden Land, because of its abundant natural resources and the wealth that its control of trade routes generated. In the 11th century it became the homeland of Theravāda Buddhism (one of the two great schools of Buddhism, the other being Mahāyāna) at a time when that faith was being suppressed in other countries. After being annexed by the British in 1886, it fell under Japanese rule for a period during World War II; British rule ended in 1948, when Burma regained its sovereign independence.

Burma is individualistic in its social structure and nationalistic in its outlook. As one of the original nonaligned countries—maintaining independence from both Eastern and Western power blocs—Burma achieved some international importance in the first decade after its independence; in the early 1970s, however, it had for some years tended to remain aloof and isolated from the international community. The land and air battles that were waged throughout the country during World War II destroyed many towns and villages and dislocated the economy. In the early 1970s Burma still exported rice but was no longer, as it once was, the foremost rice-exporting country in the world. The wounds of war had not completely healed, partly because of lack of capital and partly because of insurgency and political unrest. Since independence, some modest industrialization programs have been embarked upon, but the country remains primarily agricultural. (See the city article RANGOON; for associated physical features, see ANDAMAN SEA; BENGAL, BAY OF; IRRAWADDY RIVER; MEKONG RIVER; and YANGTZE RIVER; for historical aspects, see BURMA, HISTORY OF.)

THE LANDSCAPE

The natural environment. *Relief.* The country slopes from north to south, from an elevation of 19,578 feet (5,967 metres) at Hkakabo Razi peak in the extreme north to sea level at the Irrawaddy and Sittang deltas. The mountain ranges are longitudinal, running from north to south. The country as a whole can be divided into five landscape regions—the northern mountains, the western mountains, the eastern plateau, the central basin, and the coastal strips.

The five landscape regions

The northern mountains consist of a series of ranges forming a complex knot, with peaks of nearly 20,000 feet. It is in this region that the sources of such great rivers as the Irrawaddy, Salween, Mekong, and Yangtze arise in swirling torrents. They flow through deep gorges within a few miles of each other, separated by peaks rising sheer into the sky. It was across this wild and forbidding region that the ancestors of the present-day Burmese travelled from their original homeland in Tibet.

The western ranges, which originate in the northern mountain knot, continue southward as far as Cape Negrais, the southern tip of the Arakan Peninsula, where they run under the sea, reappearing as the Andaman

Islands. Their average height is about 6,000 feet, although some peaks rise to 10,000 feet and more. They are folded mid-Tertiary ranges (formed about 20,000,000 to 40,000,000 years ago), with a core of old crystalline rocks surrounded by hard, tightly folded sedimentary rocks on either side. Forming the border between India and Burma, they are given different names according to locality—being known successively as the Patkoi, Lushai, Naga, Manipur, and Chin hills. The southern portion of these mountains lies entirely within Burma, forming the Arakan Yoma (*yoma* in Burmese means "main bone"). They separate the Arakan coastal strip from the central plain.

The Shan Plateau in the east rises abruptly from the central basin, often in a single step of 2,000 feet. Occupying the whole of the east of the country, it is deeply dissected, with an average height of 3,000 feet. The plateau was formed during the Mesozoic Era (65,000,000–225,000,000 years ago) and thus is much older than the western mountains. But the plateau also shows intensive folding, with north–south longitudinal ranges with heights of 6,000 to 8,600 feet, rising abruptly from the plateau surface. Northward, the plateau merges into the northern ranges, and southward it continues into the Tenasserim Yoma, a series of parallel ranges with narrow valleys. The central basin, lying between the Arakan Yoma and the Shan Plateau, is structurally connected with the folding of the western mountains. The basin was deeply excavated by the predecessors of the Irrawaddy, Chindwin, and Sittang rivers; the ancient valleys are now occupied by these rivers, which cover the ancient soft sandstones, shales, and clays with their new alluvial deposits. In the deltaic regions formed by the Irrawaddy and Sittang (total area 12,000 square miles), the landscape is absolutely flat, and the monotony is relieved only by a few blocks of erosion-resistant rocks, never more than 60 feet high. The basin is cut into two unequal halves, the larger Irrawaddy Valley and the smaller Sittang Valley, by the complex folded range of Pegu Yoma.

In the centre of the basin and structurally connected with the Pegu Yoma and its northern extension is a line of extinct volcanoes with small crater lakes and eroded cones, the most impressive being Popa Hill, 4,984 feet (1,519 metres).

The coastal strips consist of the narrow Arakan and Tenasserim coastal plains, which are backed by the high ranges of the Arakan Yoma and Tenasserim Yoma and are fringed with numerous islands of varying sizes.

Drainage and soil. Like the mountains, the rivers run from north to south. About two-thirds of Burma's surface is drained by the Irrawaddy (*q.v.*) and its tributaries.

The rivers

Flowing through the entire length of Burma, it is 1,300 miles long and is navigable for 872 miles. At the apex of its delta, it breaks up into a network of streams and empties into the Andaman Sea through nine mouths. Its great tributary, the Chindwin, drains the western region. The Bassein River drains the southern Arakan Yoma, and the Rangoon River drains the Pegu Yoma, both entering the Irrawaddy at the delta. The Sittang flows into the Gulf of Martaban of the Andaman Sea and, in spite of its comparative shortness, has a large valley and a huge delta. The Shan Plateau is drained by the Salween, which enters Burma from Yunnan in China and empties into the Gulf of Martaban south of the Sittang. It is deeply entrenched and crosses the plateau in a series of deep gorges. Many of its tributaries are more than 300 miles long and enter the Salween in cascades. The Arakan coastal plains are drained by short, rapid streams, which, after forming broad deltas, flow into the Bay of Bengal. The Tenasserim plains are drained also by short and rapid rivers, which make right-angled turns to enter the Gulf of Martaban.

The highland regions of Burma are covered with laterite (red soil, leached of silica and containing iron oxides and hydroxide of aluminum). Protected by the forest cover, it absorbs heavy rain, but, once the forest is cleared, it erodes quickly. The lowland regions are covered with alluvial soil—mainly silt and clay. Low in potash, lime, and organic matter, it is improved by fertilizers. In the central-region dry belt, the alluvial soil develops into a black soil rich in calcium and magnesium. In the same region, however, when the soil has a low clay content, it becomes saline under high evaporation and is recognizable by its yellow or brown colour.

Climate. Burma belongs to the monsoon (rain-bearing wind) region of Asia, but its climate is greatly modified by its geographical position and its relief. Although the cold-air masses of Central Asia bring snow to the northern tip for two months of the year, the mountain wall prevents them from moving farther south, so that Burma lies primarily under the influence of the monsoon winds. The north and south alignment of ranges and valleys forces the northeast monsoon to blow from the north. When the southwest monsoon winds blow from the Indian Ocean, this alignment of ranges and valleys creates alternate zones of heavy and scanty rainfall.

Elevation and distance from the sea affect both the temperature and the rainfall; although a tropical country, temperatures are not high. Daily range of temperature is negligible everywhere, and no locality in Burma has a continental type of climate. Even at Mandalay, in the centre of the dry belt, the annual range is only 22° F (12° C) compared with 11° F (6° C) at Rangoon and 7° F (about 4° C) at Moulmein; the average temperature is 82° F (28° C) compared to 81° F (27° C) at Rangoon, 79° F (26° C) at Sittwe (Akyab) in Arakan, and 71° F (22° C) at Lashio on the Shan Plateau.

There are three seasons: the cool dry season, from October to February; the hot dry season, from March to the middle of May; and the rainy season, from May to October. The coastal regions and the mountains receive annually 200 inches of rain, while the delta regions receive nearly 100. The central region is not only away from the sea but also in the rain shadow of the Arakan Yoma. Rainfall gradually decreases northward until in the dry zone it is only between 20 and 40 inches. The Shan Plateau, because of its elevation, receives about 65 inches.

Vegetation and animal life. Even after centuries of rice cultivation involving clearing of forest, 67 percent of Burma is covered with forests of various types, depending on elevation and the amount of rainfall. Above the frost line at 3,000 feet, evergreen forests of oak and pine are to be found. In the northern mountains at heights above 6,000 feet are forests of rhododendrons. In regions with more than 80 inches of rainfall, there occur evergreen tropical forests. The trees are of hardwood but of little commercial value. In regions where the rainfall is between 40 and 80 inches, there appear monsoon forests, the trees of which shed their leaves in the hot season. They produce valuable cabinet wood, including teak. Where rainfall is less than 40 inches, the forests gradually merge into scrubland. There are no real grasslands, but, when a patch of forest has been cleared, bamboo, bracken, and coarse grass grow. In the Irrawaddy and Sittang deltas are tidal forests of mangrove trees, growing as high as 100 feet and supplying firewood and charcoal, as well as bark for tanning.

The forests

In the jungles of Burma are the homes of pheasants, parrots, peacocks, wild fowl, and grouse. The Asiatic two-horned rhinoceros, wild buffalo, bison, and various kinds of deer were once plentiful but are now reduced in numbers and protected. Elephants are numerous, a number of them being caught annually to be trained to work. Tigers, leopards, and wild cats are still common. Bears are found in hilly regions, and gibbons and monkeys of various kinds inhabit the thicker parts of the forests. Snakes include pythons, cobras, and vipers, and crocodiles are found in the deltas. Turtles live in coastal regions, and edible fishes abound in every stream.

The landscape under human settlement. *Traditional regions.* The Burmese live in the plains and the tribal peoples in the hills. In the plains, the division between Upper and Lower Burma dates from early history, not only because of differences in the geography but also because the Mons, now a small minority, lived in Lower Burma. The division became more marked during the period from 1852 to 1885, when Lower Burma became British Burma. The Arakan and Tenasserim coastal

plains are traditional regions; the people there speak Burmese in a dialect retaining archaic features.

Urban and rural settlement. Burma is a land of villages. Except for Rangoon (*q.v.*), which has 2,449,000 people, Mandalay, which has 473,000, and Moulmein, 295,000, there are few large cities, and the towns are merely overgrown villages. The hill peoples, although practicing a shifting agriculture, have settled in villages perched near the tops of mountains and at some distance from the fields. On the Shan Plateau and the plains, the fields adjoin the villages. Older villages are circular in shape, but along the banks of the delta streams and along the railway line the villages are rectangular. Burmese houses are built of timber and bamboo, the roofs thatched or tiled. Typical Burmese houses were built on piles, the original purpose being protection from wild animals or floods. The style persists in many villages, especially those on the hills, and farm animals are kept under the houses at night. In small towns the piles have given way to a supporting brick structure with cement flooring, the upper story still being made of timber. Houses entirely of brick were few in number before 1942, but many have since sprung up in Rangoon, Mandalay, and larger towns on the rubble of buildings destroyed during World War II. Life in villages and towns is still communal because of tribal custom, the influence of Buddhism, and the "classless" nature of Burmese society. Even once-cosmopolitan Rangoon regained its Burmese atmosphere after independence.

The villages

PEOPLE AND POPULATION

Linguistic and other groups. More than 100 indigenous languages—as distinct from mere dialects—are spoken in Burma, most of them by the hill peoples. The common language is Burmese, spoken by both the people of the plains and the hill peoples. All of these languages belong to only three groups. The Burmese language itself, and most of the other languages, belong to the Tibeto-Burman subfamily of the Sino-Tibetan family. The Shan language belongs to the Tai family. Languages spoken by the Mons of Lower Burma and by the Was and Palaungs of the Shan Plateau are members of the Mon-Khmer subfamily of the Austro-Asiatic family.

Language groups

Until colonial times, only the Burmese, Mons, and Shans had written languages, and, even today, writing systems for Karen, Kachin, and Chin are still being developed. The archaic Burmese spoken in Arakan and Tenasserim, when written down, shows no difference from the Burmese spoken in the plains. To the majority of the hill peoples, Burmese is the second mother tongue.

During the colonial period, English became the official language, but Burmese survived as the second official language. Both English and Burmese were made compulsory subjects in schools and colleges, and although a knowledge of English became an asset, and many learned to speak it, no English-speaking elite emerged. Burmese remained the language of commerce, and Burmese literature also survived. After independence, English ceased to be the official language and lost its importance in

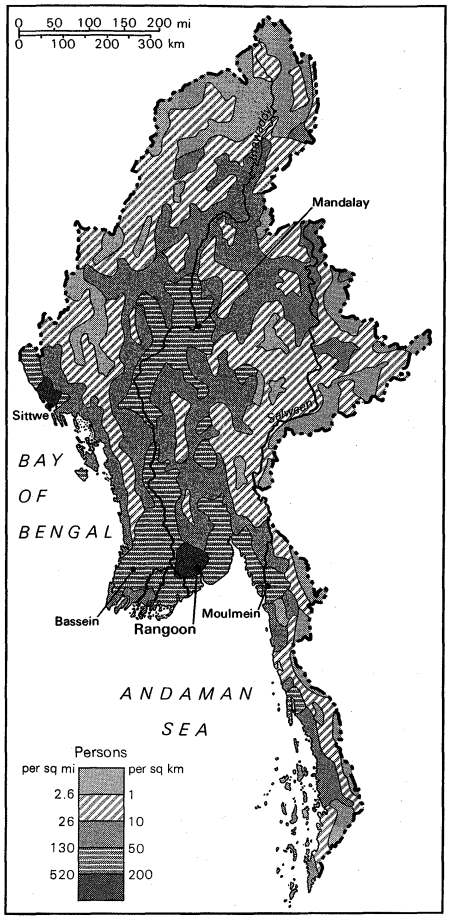
Elevations in metres



Population density of Burma.

schools and colleges, although an elementary knowledge of English is still required.

Ethnic groups. The original home of the Burmese in the dry zone established the ethnic character of the entire Irrawaddy Valley and the coastal strips. These areas hold three-fourths of the population.

The Irrawaddy and Sittang deltas were once peopled by the Mons, who entered the country from their kingdoms in the Chao Phraya River Valley in Thailand. They were conquered in the 11th century by the Burmese, a less cultured race at the time. The Mons attempted from time to time to throw off the Burmese yoke, but by the end of the 18th century they had been largely absorbed by the Burmese, mainly through intermarriage but partly through suppression. A few hundred thousand still remain in the Sittang Valley and in Tenasserim; although they still call themselves Mon, many of them have Burmese blood and no longer speak their original language.

The tribal peoples

In the western hills and the valley of the Chindwin are various tribes called by the comprehensive name of Chin. The Upper Irrawaddy Valley and the northern hills are occupied by tribal groups under the comprehensive name of Kachin. The names Chin and Kachin are Burmese and indicate, respectively, "friend and companion" and "dancing friend and companion." These tribal peoples were indeed friends and companions, for they lived with the Burmese on the southeastern slopes of Tibet and followed the Burmese on the long migration into Burma.

The Shans of the Shan Plateau have no racial affinity with the Burmese, and their society, unlike that of the Tibeto-Burman peoples, was not democratic.

The Was and the Palaungs are probably Mon-Khmer by race, but, because of the smallness of their numbers and because of their long residency on the plateau, they are usually classified with the Shans. In the same way, the Nāgas on the Burmese side of the Indo-Burmese frontier are classified with the Chins, and the Lolo-Muhsos in the northeast are grouped with the Kachins.

The Karens are the only hill people who have come down to the plains. Although racially and linguistically they are Tibeto-Burman, they were closely associated with the Mons. They are found in the deltas among the Burmese, on the Pegu Yoma, and along both sides of the lower Salween River.

The Kayahs, who live on the southern edge of the Shan Plateau, were known as Red Karens, or Karenni, from their red robes. Although racially and linguistically Karens, they tend to have their own identity.

In the mid-1970s there were estimated to be about 3,000,000 Karens, some 1,500,000 Shans, about 1,000,000 Chins and Kachins, and 100,000 Kayahs. These were unofficial estimates, made in the absence of any published official figures. The number of Indians and Chinese decreased as a result of an exodus at the outbreak of World War II and of a second exodus in 1963, when commerce and industry were nationalized. There are now about 120,000 Indians, Pakistanis, and Bengalis and some 400,000 Chinese.

Buddhist population

Religious groups. About 85 percent of the population is Buddhist. The Burmese are Buddhists except for minimal numbers of Christians and Muslims; the Shans are also Buddhists. Among the Karens, there are twice as many Buddhists as Christians, and the remainder are animists. All of the other hill peoples are animists except a few Kayah Buddhists and Kachin and Chin Christians.

Demography. The density of population in each region depends upon its suitability for agriculture. The most thickly populated regions are therefore the Irrawaddy Delta and the dry zone, which have 126 to 200 persons per square mile (49 to 77 per square kilometre); in the upper delta, between Rangoon and Henzada, the density reaches 250 (97). The Sittang Delta, the sedimented hinterland of Akyab, and the regions of both sides of the lower Chindwin have densities ranging from 76 to 125 (29 to 48). Arakan (except the Sittwe [Akyab] region), the west bank of the Irrawaddy behind Arakan Yoma, and Tenasserim are all sparsely populated, with densities of 26 to 75 (10 to 29). The more inaccessible parts of the western and northern mountains and the Shan Plateau have a density of less than 25 (10).

Burma is underpopulated as compared with other Asian countries. Its overall density at the census of 1973 was only 110 persons per square mile (43 per square kilometre), and its density per cultivated square mile was only about 500 (190). Only 16 percent of the people lived in urban areas. Since independence, government policy has been to preserve these density and distribution patterns. Immigration and emigration are restricted, so that the population remains indigenous. As an increase in the indigenous population is desired, special attention is given to public health. The mortality rate, which was about 19 per 1,000 in 1964, decreased to 12 in 1972, and the birth rate, which was about 37 per 1,000, increased to 39. The population (30,310,000 in 1974) showed a growth rate estimated at 2.4 percent per year during the period 1970–75.

Birth and death rates

THE NATIONAL ECONOMY

Agriculture. The economy of Burma is basically agricultural; more than two-thirds of its people derive their livelihoods directly from agricultural pursuits; of the nonagricultural workers who are employed in the more modern sectors of the economy, many are indirectly involved in agriculture through activities such as transportation, processing, marketing, and exporting of agricultural goods.

Burmese planners must emphasize agriculture because an estimated 60 percent of the raw materials utilized by industry originates in agriculture; failure to attain planned goals in agriculture during the early 1970s contributed to a severe inflation and cutbacks in related industries, although both these problems were exacerbated by inefficiency and corruption in state-managed economic enterprises.

Burmese agriculture may be considered to consist of three realms: the delta, where paddy rice culture predominates; the dry zone, an area of mixed agriculture;

and the hill country, where forestry and shifting agriculture have been the rule.

Although the agriculture of the dry zone has been most typically Burmese in the past, it is the rice culture of the delta that now provides from 40 to 50 percent of the country's export earnings and the staple diet of the country's people and on which the short- and long-term health of the economy depends. About 60 percent of the land in agricultural use is devoted to rice culture, and despite a climate that would permit much more extensive double cropping, only about 10 percent of the land is actually so managed. The delta's traditional agriculture consisted primarily of rice in normal years, with the substitution of millet in drier years when there was insufficient moisture for rice; both grains yielded good returns on the alluvial soils of the delta. After Burma was officially annexed to British India in 1886, colonial policy called for a more commercially oriented and extensive cultivation of rice; since the indigenous Burmese labour force was insufficient to support this new economy, officially encouraged immigration of Indian and Chinese labourers and their families took place during the early decades of the 20th century. By 1942, first-generation immigrants composed about 13 percent of the total population. Despite relatively low growth in rice production since World War II, it still remains both the basic food and the basic export of Burma.

Agriculture in the dry zone is much more diversified than that of the delta. Its major products include, in addition to rice, other grains (wheat, millet, and corn, or maize), peanuts (groundnuts), sesame, legumes, tea, and rubber. However, to cultivate much of this land successfully, irrigation is required. The construction of the earliest known Burmese irrigation works, in Kyaukse and Minbu districts, can be dated from the 11th century, and although their maintenance has not been a continuing concern of governments throughout Burmese history, many are still in active service. As in the delta, the arrival of the British led to increased commercial and public works activities; British authorities renewed and extended many of these ancient systems and, in addition, built new ones during the early years of the 20th century, including the Mandalay (1903), Shwebo (1906–12), Mon (1912), and Salin (1926). About five-sixths of Burma's irrigated land is in the dry zone, and even here about 90 percent is cultivated in rice. The portions of the dry zone that are not irrigated are utilized for the production of crops that are less sensitive to the seasonality or irregularity of rainfall than rice. In addition to the crops mentioned above, cotton and sugarcane are cultivated in this zone, although neither is of considerable significance. Cattle are also raised in the dry zone.

Irrigation

The third zone of agriculture, the hill country, occupies perhaps two-thirds of the area of Burma, and, although it is of much less economic significance than the other two, it is the home of many of the non-Burmese peoples of the country. Their agriculture has been, and to a considerable extent still is, a type of slash-and-burn agriculture called *taungya*, although more sedentary traditional modes also exist and others are imposed with the advance of agricultural technology and central planning. Outside the forest areas of these highlands, the principal foods raised are rice, yams, millet, with swine and poultry ubiquitous. Possibilities, largely unrealized, exist for commercial agriculture in the more fertile river and lake basins.

Bullocks and buffalo are used as beasts of burden, and goats, pigs, and poultry are raised for food in all parts of the country.

Fisheries. The second most important element in the Burmese diet after rice is fish—fresh, preserved, or prepared as *ngapi*, a sort of paste that is eaten with rice. Marine fisheries are not well developed, although the reported commercial catch of 320,000 metric tons is more than twice as great as the reported catch from inland waters. The latter, however, provide much private, noncommercial fishing in virtually every type of permanent, seasonal, or artificial body of water of any size. Two nonindigenous fish, the European carp and the tilapia of Thailand, have been imported and breed very well in impounded waters.

Forestry. Forestry is particularly important to economic planners, since exports of teak yield more than a quarter of all export earnings. Burma has been estimated to contain up to three-quarters of the world's exploitable teak supplies. The trees are found in the mixed deciduous forests of the hills and commonly comprise about 12 percent of forests of which they are a part. The forests are state-owned, and the responsibility for their management and exploitation belongs to the State Timber Board.

Minerals. Burma's rich mineral deposits are not fully exploited. Deposits of silver, lead, and zinc are located in the northern Shan Plateau; tin and tungsten are found in Tenasserim. Ruby mines in the northern Shan Plateau were worked to exhaustion during colonial times. Jade is found in the northern mountains, but for some years the output has been negligible. There are petroleum fields in the dry zone; installations and several surveys for offshore oil deposits have been undertaken. Coal of an inferior quality is found in the upper Chindwin Valley.

Manufacturing and power. There was little industrialization until after independence, when a limited program began. Rangoon, Myingyan (in the dry zone), and Arakan division (now state) were selected to become the new industrial centres. There are textile factories at Rangoon and Myingyan and one near Paleik in the central region. Rangoon also has steel-processing and pharmaceutical plants, and there is a paper mill in Arakan. Existing food-processing plants (mainly rice mills) and lumber mills have been improved and expanded. Cottage industries are encouraged by subsidies.

After independence the government built a large thermal power plant in Rangoon and undertook the development of hydroelectric power plants on the Balu Chaung, a tributary of the Salween; at Taikkyi near Pegu; and in northern Arakan. The Balu Chaung plant serves Rangoon and many surrounding villages.

Trade. In the first few years of independence, trade, which had been totally abandoned during the Japanese occupation, showed definite signs of revival; after 1963, however, a steady decline occurred, partly because of inexperience after nationalization but mainly because of the virtual collapse of the international rice market. In 1974 the chief items of export by value were rice (41 percent), teak (26 percent), and oil cake (5 percent). The exports have been fairly evenly distributed among India, Sri Lanka, the People's Republic of China, Japan, Indonesia, West Germany, Singapore, the United Kingdom, Hong Kong, and Malaysia. Imports were mainly machines and spare parts, defense stores, industrial raw materials, and consumer goods from the United States, Japan, the United Kingdom, the People's Republic of China, India, France, West Germany, the Soviet Union, and Australia. Because of the shortage of foreign exchange, imports were balanced against exports.

Trading partners

Management of the economy. All large industrial enterprises, the banking system, insurance, foreign trade, domestic wholesale trade, and 90 percent of the retail trade were nationalized in 1962 and 1963. Small-scale industry (consisting mainly of food and beverage processing, miscellaneous manufacturing, and cottage industries), agriculture, and fishing were left in the private sector. Further nationalization, however, took place in medium-sized industries in the late 1960s and early '70s.

Enterprises remaining in the private sector after nationalization account for only about 10 percent of the nation's tax income. The balance is collected from the public sector. The principal sources of revenue are income, customs, and commercial taxes. There is also a land tax, applicable to the private sector only, and, applicable to both, excise, forest, mineral, fishery, and miscellaneous taxes.

There are no trade unions or employer associations. Strikes are not permitted; labour disputes are submitted to local conciliation committees consisting of labour officers and selected workers. A network of workers'

councils has been formed to complement the conciliation committees in the implementation of general government policy toward workers that includes a wage policy.

The overall economic objective is the establishment of a fully socialized state. Policy measures include the diversification of agricultural production to promote exports; the substitution, wherever feasible, of essential commodities for imports; the utilization of existing industrial plants to full capacity by providing spare parts and adequate raw materials; and the assignment of priority to mining and petroleum exploration both on land and offshore. The pace of development is based on the availability of foreign exchange.

The problems of the economy, which are both structural and serious, arise from lack of experience. Inefficiency in the nationalized sectors is apparent in both production and distribution; allocation is often inequitable, and pricing policies are sometimes artificial. There are deficits in the balance of payments and a sharp decline in foreign reserves, and the international rice market has deteriorated.

TRANSPORTATION

River transport. The Irrawaddy River is the backbone of the transport system. Trade in rice, which is still the basis of the country's economy despite the decline in exports, is dependent on water transport. There has never been any need for grain elevators, as small country boats can reach any rice field that has surplus rice to sell.

Navigable streams

The Irrawaddy is navigable up to Bhamo, a distance of some 900 miles (1,450 kilometres) from the sea; the next stretch of another 90 miles to Myitkyina is navigable only during the dry season when there are no rapids. The Chindwin is navigable for 380 miles (610 kilometres) from its confluence with the Irrawaddy below Mandalay. The many streams of the Irrawaddy Delta, with a total length of 2,000 miles (3,200 kilometres), are navigable, and there is a system of connecting canals with a total length of 60 miles (97 kilometres). The Sittang, in spite of its silt, is usable by country boats; the Salween, in spite of its rapids, is navigable up to 74 miles (119 kilometres) from the sea. Small steamers and country boats also serve the coasts of Arakan and Tenasserim.

Railways. The first railway line, running from Rangoon to Pye (Prome) and built in 1877, followed the Irrawaddy Valley. At that time Upper Burma was still a kingdom, and Pye was just a few miles from the frontier between British Burma and the Kingdom of Burma. The line was not extended to Mandalay; instead, after 1886 a new railway from Rangoon up the Sittang Valley was constructed, meeting the Irrawaddy at Mandalay. From Mandalay it crosses the river and, avoiding the Irrawaddy Valley, goes up the Mu Valley to connect with the Irrawaddy again at Myitkyina. A short branch line connects Naba to Katha on the Irrawaddy below Bhamo.

The Rangoon–Mandalay–Myitkyina railway is the main artery, and from it there are branch lines connecting the northern and central Shan Plateau with the Irrawaddy. Other branches run from Pyinmana across the Pegu Yoma to Kyaukpadaung, which in the early 1970s was being extended to the oil fields on the Irrawaddy River, and from Pegu to Moulmein to Ye. The Pye–Rangoon railway has a branch line crossing the apex of the delta to Henzada and Bassein. There are no railways in Arakan and Tenasserim. The entire railway system had 2,400 miles (3,860 kilometres) of narrow-gauge track in the mid-1970s.

Roads. The road system was built without plan or policy, and, until independence, it was confined to the Irrawaddy and Sittang valleys, duplicating the railway route. A road goes from Pye along the Irrawaddy to the oil fields. Government policy is to improve and extend existing highways and to construct new ones connecting Burma proper with its six sister states.

There were originally three international roads in use during World War II—the road from Lashio to K'unming in China, the road between Myitkyina and Assam in India, and the road between Kentung in the southern Shan Plateau and northern Thailand. The road between Assam and Myitkyina has now disappeared, and the other two roads have been neglected and are only in partial use.

Airways and ports. The Union of Burma Airways runs frequent domestic flights from Rangoon to some 50 towns and regular flights to Hong Kong, Bangkok, Dacca, Calcutta, and Kāthmāndu. Rangoon and Mandalay have international airports. Rangoon, as the terminus of road, rail, and river transport systems, is an international port with up-to-date equipment and facilities. Bassein, Moulmein, and Sittwe are also international ports.

ADMINISTRATION AND SOCIAL CONDITIONS

Constitution of 1974. A new constitution was approved by a referendum in December 1973 and came into force on January 4, 1974, the 26th anniversary of Burmese independence. The country also assumed a new official name, the Socialist Republic of the Union of Burma. General elections were held in January and February, and a new government was established on March 2, 1974, the 12th anniversary of the coup that had established a military government.

The new constitution provides for seven states (Arakan, Chin, Kachin, Kawthule, Kayah, Mon, and Shan) and seven divisions of Burma proper (Irrawaddy, Magwe, Mandalay, Pegu, Rangoon, Sagaing, and Tenasserim), with "local autonomy under central leadership." The supreme power is the Pyithu Hlutdaw, which exercises legislative, executive, and judicial authority. The adoption of the name Hlutdaw (or Hluttaw; literally "place of release") is significant. Under the Burmese kings the Hlutdaw was a supreme council discharging legislative, executive, and judicial functions, but as the historical Hlutdaw was a royal institution the new designation is Pyithu ("People's") Hlutdaw. Thus, Pyithu Hlutdaw is the People's Council at the national level as distinct from the People's Council at the division or state, township, and ward or village levels. Elections to the Hlutdaw and to the local council are held simultaneously, members being elected for four-year terms.

Pyithu Hlutdaw

Central government structure. The organs of the 450-member Pyithu Hlutdaw are the Council of State, the Council of Ministers, the Council of People's Justices, the Council of People's Attorneys, and the Council of People's Inspectors. The Council of State consists of an elected representative from each state and division, an equal number elected by the Pyithu Hlutdaw as a whole, and the prime minister as an ex-officio member. The Council of State elects its own chairman, who is ex-officio president of the republic, and its own secretary. The president, Ne Win, and the secretary, Gen. San Yu, are also, respectively, the chairman and the secretary general of the Burma Socialist Programme Party. The Council of State appoints senior civil servants and deputy ministers and submits lists of names for election by the Hlutdaw of the prime minister, his Cabinet, and the councils of justices, attorneys, and inspectors. The number of ministers can fluctuate, but the three councils have five members each. The Council of People's Justices is the equivalent of a supreme court in a parliamentary democracy; the Council of People's Attorneys is comparable to an attorney general (but members do not need legal qualifications or experience) and the Council of People's Inspectors to an auditor general.

Local government structure. The local People's Council follows the pattern of the Hlutdaw; every council has an Executive Committee and a Judicial Committee. All but the village or ward councils also have a Committee of Inspectors. The Committee of Judges, not necessarily composed of lawyers, sits as the local court, exercising criminal and civil jurisdiction.

Civil service and political parties. There is a civil service, and military officers are drafted into it. All political parties are illegal except the official party, the Burma Socialist Programme Party. Membership is by election after preliminary service as a "friend of the party" and then as an "auxiliary." It was at first restricted to cadres, but the party held its first national assembly in 1971, when its membership was widened so that it be-

One-party system

came a national party. Civil servants and members of the armed forces, as well as workers and peasants, are members, and senior military officials and civil servants are included in the party's hierarchy.

Armed forces. The Burmese fighting forces consist of a trained and well-equipped army, a small navy, and a small air force. The Defense Service Academy is located at Maymyo. The police force, although armed and equipped and often used as a branch of the army in emergencies, remains essentially civilian in character and regional in organization; it deals with the day-to-day maintenance of law and order.

Public welfare. In social welfare measures, the government has given special attention to workers and peasants and to the hill peoples. The National Housing Board was retained after the coup in 1962, and, in spite of a shortage of imported building materials, the housing problem is not acute. A high mortality rate, especially among infants, has been lowered substantially, and every village has a health unit and access to a hospital.

Education. The literacy rate has always been at a high level and continues to improve. Education is free in the primary schools, and in secondary schools and universities fees are nominal. The number of children attending school doubled between 1960 and 1970, and the number of students attending universities and institutions of equivalent status tripled in the same period. The University of Rangoon and its branch at Mandalay were separated in 1958 into autonomous units now known as the Rangoon Arts and Science University and the Mandalay Arts and Science University. Various institutes and colleges teach medicine, technology, agriculture, economics, etc.

Burmese folk culture

Cultural life and institutions. Burmese culture is essentially a folk culture. Buddhism, which originated in a rural setting such as that of Burma, has pervaded Burmese life since the 11th century and has blended harmoniously with folk culture. The emphasis given by Buddhism to equality among all men and women and to the liberty and dignity of the individual fits in with Tibeto-Burman social tradition. The Feast of Merit in Chin animism, for example, has the same folk background as that of a Buddhist Burmese alms-giving ceremony; the dancing, singing, music, and general gaiety of a Kachin sacrificial celebration are reflected in the Burmese ceremony initiating a boy as a novice in the Buddhist order of monks; and the animals, monsters, trees, flowers, and abstract designs carved on the central post of a Kachin men's club are similar to those carved on the doors of the palace of the kings. Some observers maintain that Burmese culture is animistic; others, that it is Buddhist; but all agree that it is Burmese.

Burmese dancers performing in traditional costume.

Burmese drama in 1886 appeared to be dying with the passing of the old kingdom. As it was essentially a folk drama, however, it survived and with the regaining of independence gathered new strength.

Wood-carving, lacquerwork, goldwork, and silverwork, the sculpture of Buddhist images and mythological figures, and temple architecture also survived under colonial rule; there has been a revival of these indigenous art traditions under the patronage of the Ministry of Culture. The arts of bronze casting among the Burmese and of making bronze drums among the Karens, however, both disappeared. The Burmese puppet show also declined, although occasionally there are attempts to revive it. The cinema is the one Western art form that has been accepted in the cultural life of the Burmese people.
