In Paris, Cavour had occasion to meet and appraise the stature of Europe's most capable diplomats and to examine the reasons behind the policies of the great powers. He knew full well that it was illusory to hope for the disinterested assistance of Europe in the Italian cause; nevertheless, with his tireless energy and unlimited capacity to take advantage of the most adverse situations, he finally succeeded in winning Napoleon III over to his side. His trump card was the proposition to re-establish France as the leading power on the Continent by an expedition into Italy that would replace Austrian domination of the Peninsula with French rule. Cavour knew that times were changing and that once the flame of national feeling was kindled in Italy, it would no longer be possible to extinguish it. He received unexpected help from the Italian Republicans by their attempt, led by Felice Orsini, on the lives of Napoleon III and the empress Eugenie, a plot which almost succeeded. The attempted assassinations seemed to confirm what Cavour had maintained for a long time—that Italy was a powder magazine, which, if suitable precautions were not taken, would cause a major explosion throughout the Continent.

Meeting with Napoleon III at Plombières

The war of 1859. At a secret meeting at Plombières in July 1858, Napoleon III and Cavour agreed to provoke a European war against Austria in the following year. At the first suspicions of a secret agreement, the European powers—especially England—began a campaign to prevent the French and Piedmontese from carrying out their intentions, a campaign so intense that Cavour saw himself being dragged toward the brink of personal and national catastrophe. In vain he had persuaded a reluctant Victor Emmanuel II to permit the marriage of his young daughter Maria Clotilde of Savoy to Napoleon's middle-aged cousin Prince Jérôme. In vain he had accepted, between January and April 1859, all of Napoleon's conditions—even the most humiliating ones—in order not to appear as the aggressor against Austria but as the injured party, thus providing the *casus bellis* that Napoleon III required to persuade France to accept the war and Europe to remain neutral. All these efforts seemed to have been wasted when an order from Paris commanded Cavour in April to demobilize the troops and dismiss the volunteers. According to several historians and biographers, he was on the point of committing suicide. He was saved by an incredible blunder on the part of Austria, which sent an ultimatum threatening war unless Piedmont disarmed at once. The Franco-Piedmontese alliance accordingly came into force, and this time, Austria's superior military power was counterbalanced by the French contribution. Franco-Piedmontese victories followed one after another until Napoleon signed an armistice with Emperor Francis Joseph I at Villafranca in July 1859.

The war had unleashed revolutionary movements in Tuscany, in the duchies of Modena and Parma, and in the papal states between the Po and the Apennines, from Bologna to Cattolica; the ducal rulers had been expelled, as had the papal legates. The armistice seemed to call everything into question, except for Victor Emmanuel's acquisition of Lombardy, which was a minimal gain compared with Cavour's dreams of liberating Italy from the Alps to the Adriatic. At Villafranca, Cavour vented his rage and frustration on the King and resigned his office. Victor Emmanuel, who for some time had found it difficult to tolerate his prime minister, accepted his resignation.

Cavour's character had always shown a strongly contradictory combination of two elements: a calculating logic, capable of rapidly absorbing and evaluating the complexities of political reality, and an extreme, almost irrational, irrascibility (which at Villafranca endangered the results of the most sophisticated political reasoning). Contrary to his usual perception, he realized only later the advantages to be derived from the armistice. The revolutionary landslide in Italy could no longer be checked, nor could the French emperor withdraw from his position as protector of Italian self-determination.

Return to power

After being returned to power by the reluctant King in January 1860, Cavour worked for the annexation of the central duchies that had formerly belonged to the ancient rulers of Piedmont; he was able to do this only by ceding Savoy and Nice to France. This action, while alarming England, tied the hands of Napoleon, who henceforward had to accept the fact that, as an accomplice, he could oppose Turin's policy of annexation only within certain limits.

Unification of Italy. The surrender of Nice to France vastly sharpened the conflict between Cavour and Giuseppe Garibaldi, for Nice was the popular hero's birthplace. The surrender of Piedmont's Alpine bulwark could be compensated for only by territorial expansion into Central Italy (at the pope's expense) and into the Kingdom of the Two Sicilies. But Cavour, by now the black sheep of European diplomacy for having disturbed its tranquillity too often, was not in a position to take the initiative, even though England now favoured his policy.

It was Garibaldi who resolved the stalemate caused by Cavour's enforced inactivity. Sailing with his famous Thousand to Sicily, he destroyed Bourbon rule there and in the south. The daring diplomacy of Piedmont and Cavour seemed momentarily to be eclipsed by the military exploits of the red-shirted hero, but more important, there now appeared the first outlines of rivalry between a moderate, monarchist Italy and a revolutionary, republican Italy. The danger of a rupture was averted by the good sense and magnanimity of Garibaldi and by a diplomatic strategem of Cavour. Cavour, taking up his stance before Europe as the defender of law and order against revolutionary excesses, and before Napoleon as the defender of the last strip of papal territory against attack by Garibaldi, sent an army under Victor Emmanuel across Marche and Umbria in order to check the "hero of the two worlds" and to weld the two Italies into one united kingdom.

There still remained the problem of establishing a capital. Turin had to be ruled out because of its location at the extreme northwest corner of the country. Cavour felt that only Rome could be the capital of the new state; but that meant he had to face the most complex problem of his life—that of the position to be assigned to the pope, the head of Catholicism, once Rome had become the capital of Italy.

He turned once more to the political and religious convictions that had developed since his youth through the lively discussions held in Geneva with his relatives and

through his meetings with brilliant minds in Paris and London. Cavour wholeheartedly accepted the concept of the separation of church and state, according to the ideas formulated above all in Geneva. In his negotiations with the papacy he became a passionate supporter of the idea. He maintained that the liberty of the church was to be the fulcrum of the renewal of the world, even though this involved the renunciation of its temporal power and the surrender of Rome to the Italian nation. An entirely spiritual church and papacy, he asserted, would revive mankind. Pius IX's answer to these proposals was negative; but while Cavour was still vigorously promoting his formula of "a free church in a free state," he fell seriously ill and died on June 6, 1861, after having formed a nation in ten years of impassioned and restless activity.

BIBLIOGRAPHY. P. MATTER, *Cavour et l'unité italienne*, 3 vol. (1922–27), is the most complete biography in existence today. A.J. WHITE, *The Early Life and Letters of Cavour, 1810–1848* (1925) and *The Political Life and Letters of Cavour, 1848–1861* (1930), are the best documented works available in English. W. ROSCOE THAYER, *The Life and Times of Cavour*, 2 vol. (1911), with a full bibliography, is at times somewhat sketchy. H. VON TREITSCHKE, *Cavour* (1869, reprinted 1939), depicts Cavour as an exponent of *Realpolitik*. R. ROMEO, *Cavour e il suo tempo*, vol. 1 (1969), promises, when completed, to be the definitive work on Cavour. DENIS MACK SMITH, *Cavour and Garibaldi, 1860: A Study in Political Conflict* (1954), is strongly adverse to Cavour.

(U.M.)

Cayley, Arthur

Arthur Cayley ranks high among 19th-century mathematicians for his analytical power and the originality of the concepts he pioneered. He played a great part in founding the modern British school of pure mathematics.

Cayley was born at Richmond, in Surrey, on August 16, 1821, during a periodic visit of his talented merchant family to England from Russia, where his father was engaged in trade. Cayley's remarkable mathematical ability became apparent by his skill as a child in doing complex calculations for amusement. On the advice of school authorities, his father, who had by then settled in England, enrolled him in May 1839 at Trinity College, University of Cambridge, where he mastered several languages—Greek, French, German, and Italian—and distinguished himself in mathematics.

Cayley, oil painting by W.H. Longmaid, 1884. In the collection of Trinity College, University of Cambridge, England.

Following his graduation in 1842, he obtained a three-year appointment at Trinity, which allowed him to begin work on the problems in mathematics that occupied his attention for the next 50 years. During this extremely productive period, he also began a lifelong interest in mountaineering, painting, and travel. Because no positions in mathematics were open to him when his term ended in 1845, he entered Lincoln's Inn, London, to prepare for a legal career. Admitted to the bar in 1849, Cayley earned just enough by practicing law during the next 14 years to allow him to pursue his real interest in mathematics. During this time, Cayley wrote his brilliant mathematical papers. In 1850 he met James Joseph Sylvester, a fellow lawyer and mathematician; and the two henceforth spent much time in enthusiastic collaboration.

Cayley's work treated nearly every subject of pure mathematics. The concept that the order of points formed by intersecting lines is always invariant, regardless of spatial transformations, is an application of the theory of algebraic invariance, which he originated and developed with encouragement from Sylvester. This concept is of importance in working out space–time relationships in physics. Cayley's development of *n*-dimensional geometry is also significant in conceptualizing four dimensions (space–time) in relativity and in going beyond the dependence on points and lines as elements by which geometric space is constructed. Cayley also developed the algebra of matrices, which are arrays of numbers in rows and columns, in which the order and direction of multiplication determines the quantitative result. This tool was used by the German physicist Werner Heisenberg in 1925 for his work in quantum mechanics. Cayley also prepared the way for the idea that Euclidean and non-Euclidean geometries are special cases of the same kind of geometry. He did this by devising a means of uniting projective geometry, which is dependent on invariant properties of figures, and metrical geometry, which is dependent on sizes of angles and lengths of lines. He also prepared two British Association for the Advancement of Science reports (1857, 1862) on theoretical dynamics and on the Moon's mean motion.

Development of *n*-dimensional geometry

Cayley practiced law until 1863, when he was elected to the new Sadlerian chair of pure mathematics at Cambridge. He married Susan Moline the same year. From the time of his arrival at Cambridge until his death he constantly engaged in mathematical investigation. He was also influential in assisting women to be admitted as students for the first time. His lectures at Cambridge attracted very few students; among them, however, was A.R. Forsyth, who succeeded him in the Sadlerian chair, and who, by introducing the new theory of functions that had been making progress in France and Germany, helped to bring English mathematics back into the mainstream of European trends.

In 1881–82 Cayley lectured at Johns Hopkins University in Baltimore on Abelian functions—a means of combining numbers such that the result of mathematical treatment is independent of the order. At Johns Hopkins he again met his friend Sylvester, who had become professor there in 1876. Cayley's more than 900 mathematical notes and papers were published in Cambridge in 1889–98 in 14 volumes of his *The Collected Mathematical Papers*.

Honours

Cayley was the recipient of nearly every academic distinction that can be conferred upon an eminent man of science: honorary degrees from Oxford, Dublin, Edinburgh, Göttingen, Heidelberg, Leiden, and Bologna; and election as fellow or foreign corresponding member of the French National Institute, and of the academies in Berlin, Göttingen, St. Petersburg, Milan, Rome, Leiden, Uppsala, and Budapest; and recipient of the Copley Medal in 1883 from the Royal Society of London. At various times he was president of the Cambridge Philosophical Society, of the London Mathematical Society, and of the Royal Astronomical Society.

He died at Cambridge on January 26, 1895.

Soc.*, 58:1–43 (1895), and is reprinted, with slight changes, in vol. 8 of *The Collected Mathematical Papers of Arthur Cayley*, 13 vol. (1889–97). For other biographical studies, see GANESH PRASAD, *Some Great Mathematicians of the Nineteenth Century*, vol. 2, ch. 1 (1934); ALEXANDER MACFARLANE, *Lectures on Ten British Mathematicians of the Nineteenth Century*, pp. 64–77 (1916); and E.T. BELL, *Men of Mathematics* (1937, reprinted 1961).

Ceará

Ceará, a primarily agricultural state (*estado*) in northeastern Brazil, is bounded on the north by the Atlantic Ocean, on the east by the Atlantic and the states of Rio Grande do Norte and Paraíba, on the south by the state of Pernambuco, and on the west by the state of Piauí. It covers an area of 57,149 square miles (148,016 square kilometres), and its population in the early 1970s was nearly 4,500,000—about 40 percent of it urban. The capital, Fortaleza, is the principal cultural, commercial, and seaboard shipping centre, with a population of over 520,000. Other principal towns are Juazeiro do Norte, Sobral, Crato, Iguatu, and Crateus. The seaboard, the mountains and mesas, and the backlands are the main regional settings of the state. Each has a population reflecting different ways of life: the *jangadeiro*, or raftsman, living near the seashore and engaged in fishing; the *vaqueiro*, or cowboy, employed on the farms and ranches; and the *morador*, or subsistence farmer, along the littoral and upcountry.

Physical features

The state lies partly upon the northeast slope of the great Brazilian Highlands and partly upon the sandy coastal plain. Its surface is a succession of great terraces, facing north and northeast, formed by the erosion of an ancient sandstone plateau; the terraces are seamed by watercourses, and their valleys are broken by hills and ranges of highlands. The sandy coastal plain is nearly bare of vegetation; behind it is an elevated region with sandy soil that is amenable to cultivation and produces fruit, cotton, and many tropical products. The soil of the backlands is thin and porous.

The long dry season turns this part of the country into a barren wasteland, or *sertão*, relieved by vegetation only along riverbanks and on mountains; spiny, stunted groves of *caatinga*, or scrub forest, the trees of which lose all their leaves in the dry season and turn gray, are typical.

Ceará is semi-arid, precipitation ranging from 63 inches (1,600 millimetres) on the seaboard and in the mountains to 16 inches (406 millimetres) in the backlands; regardless of the amount, it is almost wholly concentrated in the three months of March, April, and May, so that there is a long dry period during which all rivers and streams eventually become dry beds. Although in some years the rains may fall torrentially for days on end, occasionally they may fail altogether. Severe droughts cause famine and pestilence, economic disruption, and migrations of rural peoples; a drought and accompanying plague in 1877 took 57,000 lives. Average temperatures year-round range from 79° to 82° F (26° to 28° C) but may peak to 86° or 90° F (30° or 32° C) in the backlands during the dry season, thus aggravating the aridity. The problem of drought, however, is only partly a result of the workings of nature. Man himself, by stripping away the cover of natural vegetation and subjecting the land to intensive and careless use, has destroyed much of the soil's capacity to retain moisture.

Economy

Like other states of the Northeast, Ceará was settled as a "captaincy," or fiefdom, of the Portuguese crown, its economy in the 18th century centring on sugar plantations worked by Negro slaves. Slavery, indeed, persisted in Brazil until the late 19th century; Ceará in 1884 became the first state to free all its slaves. As early as the 18th century cattle were introduced to the *sertões*, and in the 19th century long-staple cotton was planted and thrived. Today Ceará is the third largest producer of cotton in Brazil (after São Paulo and Paraná), with about 350,000 tons annually. With more than 2,000,000 head of cattle, it has the third largest herd in the Northeast (after Bahia and Maranhão). Sugarcane, though now less important, is still grown, largely for manufacturing brown sugar and spirits; other commercial crops include cashew nuts, cassava, carnauba wax, oiticica oil, fruits, and vegetables. Cotton and other commercial crops and cattle are grown on the great estates, which include sharecroppers, whereas the large population of smallholders are restricted to the hard life of subsistence farming. Generally, the possibilities of improving agriculture and the lives of farmers are limited by climatic conditions, lack of capital, and antiquated technology.

Though the federal government has fostered the building of numerous dams, there has been no comparable development of irrigation networks. Rural life remains primitive.

There are indications of mineral resources in the state, but prospecting and research have not proceeded far enough to establish their economic potential. Gypsum and limestone are being produced, however, and the possibilities for future production of iron, copper, manganese, and graphite seem encouraging.

The cities of Ceará have developed as centres for collecting, processing, and marketing the regional products, particularly cotton. Trade has been accompanied by inchoate industrial activity, involving the production of textiles, food, chemicals, and pharmaceuticals. Fortaleza is not only the commercial and metropolitan centre of the state but also the seat of its administrative life, with the governor and the state assembly at its head. The capital city is also the site of the Federal University of Ceará.

Cecil, William, Lord Burghley

William Cecil, Lord Burghley, has enjoyed fame as a great Elizabethan statesman and a master of Renaissance statecraft. Elizabeth I's trust in him made his a persistent if not always decisive voice in her counsels for nearly 40 years. His talents as a diplomat, politician, and administrator won him high office and a peerage.

Cecil, oil painting on panel attributed to M. Gheeraerts. In the National Portrait Gallery, London.

Early life. William was born on September 13, 1520, at Bourne, Lincolnshire. His grandfather David left the Welsh border to follow Henry Tudor to victory at Bosworth in 1485. His rewards established him at Stamford, and by service to the Tudors and marriage to local heiresses David and his son, Richard, acquired wealth, office, and the status of gentry. Richard educated his only son, William, at schools in Grantham and Stamford. In childhood William served as a page of the robes at court, where his father was a groom of the wardrobe. In 1535 he entered St. John's College, Cambridge, where he studied classics under the versatile Humanist John Cheke and came under Protestant influence. At the age of 20 he

fell in love with Cheke's sister, Mary; family disapproval of his unambitious attachment may have precipitated William's move in 1541 to Gray's Inn, London, to study law. William married Mary later in 1541; but she died in 1543, leaving him a son, Thomas.

In 1542, for defending royal policy, William was rewarded by Henry VIII with a place in the Court of Common Pleas. A year later he first entered Parliament. Through his second marriage, to the learned and pious Mildred Cooke in 1545, he joined an influential Protestant circle at court; it included his father-in-law, Sir Anthony Cooke, his former brother-in-law, John Cheke, the future protector, Edward Seymour (Lord Hertford and duke of Somerset), and the queen consort Catherine Parr, for whom Cecil edited a devotional tract. When Edward VI succeeded, Cecil joined the protector Somerset's household, accompanied him on a Scottish campaign of 1547, and became his master of requests and, in 1548, his secretary. On Somerset's first fall from power, in 1549, Cecil was briefly imprisoned in the Tower of London. By acting as go-between for Somerset and his rival, John Dudley, earl of Warwick, Cecil regained favour and became in 1550 a councillor and one of the two secretaries to the king, alongside William Petre. After Somerset's final fall, in 1551, Cecil was knighted by the victorious Warwick, who assumed the dukedom of Northumberland. Cecil was committed to Northumberland; but, when the Duke proposed to alter the succession, Cecil, though fearing for his life and contemplating flight, sided with the judges in opposition. He capitulated to Northumberland only on royal command. Ever loyal to the Tudors, Cecil deserted Northumberland after Edward VI's death. He approached the triumphant Mary Tudor as representative of the council, winning her approval as "a very honest man."

Influential friends at court

As junior secretary, Cecil had had little scope under Edward VI. He shared neither the social idealism nor the iconoclastic urge of the more extreme reformists at court. He did share in the spoils of a corrupt government; but he established himself as an able bureaucrat, a moderate with a sense of legal propriety, and, like his ally the archbishop of Canterbury Thomas Cranmer, a gradualist in religious reform. Yet, although offered employment on Mary's accession, he, unlike most of his colleagues, withdrew from the Catholic court. His concept of a subject's duty persuaded him to conform outwardly as a Catholic, while remaining inwardly Protestant, to serve in local government, and to undertake two missions, his only visits to the Continent. In Parliament in 1555 he incurred suspicion by defending the property rights of exiles and by entertaining disaffected members; but he was acquitted. He lay low and cultivated Elizabeth Tudor, for whom he had acted as surveyor since 1550.

Career under Elizabeth I. On Elizabeth's accession, in 1558, Cecil was appointed her sole secretary. His first major diplomatic achievement was to persuade a reluctant queen to intervene in Scotland and conclude the Treaty of Edinburgh (1560), which removed French forces from Scotland. His gift for compromise facilitated the church settlement in 1559; his financial sense, the recoinage in 1561. Elizabeth's flirtation with John Dudley's son Robert, however, weakened Cecil's position. Despite threats of resignation and opposition to Robert Dudley, Cecil retained Elizabeth's trust and was rewarded with the lucrative mastership of the Court of Wards in 1561.

Rivalry with Robert Dudley

Decision on the succession was necessary to settle policies. While Cecil intrigued to thwart Dudley, he sympathized with Protestant efforts in Parliament to make Elizabeth marry. He resisted Mary Stuart's claims to succeed but recommended the Habsburg suitor, the archduke Charles. Dudley, capturing the initiative, backed an ill-fated expedition to France to aid the Huguenots, which ended the Treaty of Troyes, became a councillor, and in 1564 became earl of Leicester. On the defensive, Cecil restored the balance by introducing Thomas Howard, 4th duke of Norfolk, into the council. But the consequences of Mary Stuart's marriage to Lord Darnley in 1565 worked to Cecil's disadvantage; Cecil's hopes of drawing England and Scotland together were threatened. While Elizabeth prevaricated with Parliament in 1567 over the succession, Mary Stuart, with an heir, James, was attracting an English following.

Mary Stuart's flight to England in 1568 embarrassed Cecil; although it opened diplomatic opportunities in Scotland, it led to Norfolk's plan to marry the widowed Queen of Scots. Norfolk opposed Cecil over Mary's fate, over secret aid to the Huguenots, and over policy toward Spain. Resenting the threat of the Duke of Alba's Spanish army in the Netherlands, Cecil nearly precipitated war in December 1568 by instigating the seizure of ships carrying bullion to Alba, who retaliated by closing Antwerp to English trade. Leicester joined Norfolk, and they prepared to oust Cecil; but they faltered before the Queen's support for her secretary. A consequence of Norfolk's opposition was an avowedly Catholic rebellion of the northern earls in 1569; but again Cecil survived to punish the rebels.

His challengers defeated, Cecil was created a peer, 1st Baron Burghley, in 1571, and in 1572 he became a knight of the Garter and lord treasurer; he now shared royal favour on equal terms with Leicester. Meanwhile, the papal bull of 1570, deposing Elizabeth, confirmed Cecil in his defense of the Elizabethan church, in which he cooperated with his nominee, Archbishop Matthew Parker. The intrigue called the Ridolfi Plot, a planned Spanish invasion of England to put Mary Stuart on the throne, led to Norfolk's execution in 1572 and discredited Mary Stuart and the pro-Spanish interest. Burghley's rebuff to Spain was underlined by the Treaty of Blois with France in 1572. Neither French influence in the Netherlands nor the St. Bartholomew's Day Massacre (1572) deterred Burghley from the French alliance; but he also soothed Spain, and the embargo on trade with Antwerp was lifted. In Scotland he settled the regency; but he failed to persuade the Scots to try and depose their queen, who remained a focus of Catholic intrigue in her English prison.

In the 1570s Leicester, supported by Francis Walsingham, who became a secretary in 1573, courted Puritan support; agitated for aid to William of Orange, Protestant leader of the rebels in the Netherlands; and favoured negotiations with France. Burghley, restraining the French and trying to avoid open commitment to the rebels, pursued a policy that, in advocating nominal Spanish suzerainty over a Netherlands enjoying its traditional liberties, ignored Philip II's obvious intentions. Failing to gain a settlement in 1576, Burghley finally joined Leicester in urging Elizabeth to act an behalf of Orange. Rather than fight openly, Elizabeth tried to utilize French influence in the Netherlands by marriage negotiations with the Duke of Anjou. Burghley accepted royal policy, but Puritan opposition prevented a definite conclusion to the Anjou affair.

Support of William of Orange

Burghley's moderation in politics and church reform was overtaken by Puritan extremists who, in Parliament and in the church under the patronage of aristocrats such as Leicester, attacked episcopacy, advocated presbyterianism, and urged anti-Catholic measures. Although his hopes for moderate reform collapsed when his chosen archbishop, Edmund Grindal, was made powerless following a quarrel with the Queen, Burghley could not afford to weaken the Puritan militants against aggressive Catholicism. A Jesuit mission and papal intervention in Ireland in 1580 roused Burghley to anti-Catholic action and to alarm over the intentions of Catholic Spain. The assassination of William of Orange in 1584 and the knowledge of a planned French landing at Arundel led Burghley to take measures to protect the Queen's life and to incline toward war against Spain. His hesitation over the costs of war and the peace feelers he extended to Alessandro Farnese, the 3rd duke of Parma, the Spanish commander in the Netherlands, created ill will with Leicester. But by 1585 Burghley supported Leicester's expedition to the Netherlands and Sir Francis Drake's voyage to the Caribbean. In 1586, on Walsingham's revelation of the Babington plot—a plan by Anthony Babington, once page to Mary Stuart, to assassinate Elizabeth

—Burghley pressed to ensure the trial of Mary Stuart and her execution in 1587. His initiative put him in brief disgrace with the diplomatically outraged Elizabeth. Under the growing threat of the Spanish Armada in 1587, Burghley parleyed with Parma, courted Henry of Navarre and James VI of Scotland, and kept a sharp eye on the Irish and English Catholics. His diplomatic, military, naval, and financial preparations proved just adequate in 1588 to defeat the Armada. He exploited victory with propaganda, and his fame as principal councillor of Elizabeth spread through Europe.

Policies during his last years

After the failure of the Armada, Leicester died (1588), but Burghley survived to preside over the politics of a new generation. He strove to contain the new royal favourite, the Earl of Essex, and to recreate a stable balance of faction. But Essex's desire to dominate drove the Queen to counter him by giving patronage to Burghley. Burghley coached his son Robert, born in 1563, for the secretaryship, which he obtained for him in 1596; Robert had taken over its responsibilities after Walsingham's death in 1590. Despite ill health, Burghley remained active, performing his official duties, writing memorandums, and dealing with suits. But he devised no new policies to check declining prosperity. Instead, he intensified a program of retrenchment and pressed the Commons for grants. His attitude toward Puritans and sectaries hardened after pamphlets, secretly printed and signed by "Martin Marprelate," ridiculed the bishops (1588–90). In foreign affairs he supported campaigns waged against Spain in France and the Netherlands and naval expeditions by Drake and Essex. But finally he urged peace with Spain, fearing a Franco-Spanish settlement and the strain of prolonged war. In the midst of negotiations and still in office, Burghley died in his house in the Strand on August 4, 1598.

Assessment. As a statesman Burghley saw that his duty was to give the Queen his best advice and then to carry out whatever policy seemed expedient to her. His loyalty in this task won Elizabeth's confidence. A master of discretion, Burghley as a royal servant assumed an official mask and learned "to walk invisible." His contribution to policy making was his intuitive appreciation of the national interest, which he strove to convey to the Queen. The inspiration of the "common cause" of European Protestantism did not lead him to subordinate insular national interests; he reduced the ideological ends of international Protestantism to the more practical aims of secular patriotism. Preferring diplomacy to war on practical grounds, he exploited informal contacts, rebels, and factions among foreign enemies. In economic affairs he tried to maintain England's security by conventional statecraft. In agriculture and industry he encouraged self-sufficiency; in commerce, those trades that amassed bullion. His pragmatism as an administrator usually overcame any tendency as an intellectual and lawyer to indulge in balanced appreciations and legalistic argument rather than in action.

When there was a threat to England's independence he acted boldly. His Treaty of Edinburgh (1560) closed England's "postern gate" to France and drew Protestant Scotland to England. His opportunist seizure of Alba's treasure broke English dependence on Spain and Antwerp, leading temporarily to greater flexibility in diplomacy and commerce. His removal of Mary Stuart, the Catholic pretender, secured the Protestant succession. His preparations enabled England to survive the Armada. But he failed to induce Elizabeth to marry or to reform her church; and his policy over the Netherlands was unrealistic and in the end led to open conflict with Spain. Often Burghley was frustrated by the equivocations of the Queen, but he came to accept her good fortune as the care of Providence for Protestant England.

Administrative diligence and competence

Burghley's recommendation was his diligence and competence in handling the administration. No eager innovator, he fought corruption and made the existing system work. His patronage in church and state enabled him to harness the clergy, the gentry, and the nobility to the tasks of administration. His attendance in council and Parliament was constant, and he understood how to manage both. He directed censorship, propaganda, and an intelligence network at home and abroad.

As lord treasurer he maintained solvency until the overwhelming war expenditure of the late 1580s. Convinced of the damaging political and constitutional effects of heavy taxation on the Queen's relations with her people and on Parliment, he pursued retrenchment and economy rather than expansion of revenues. Through financial control of the royal household and of the military and naval establishments, he increased their efficiency. In the conciliar and departmental courts he gained a reputation for probity as a judge. His handling of royal finance and justice was scrupulous. His personal fortune derived from the unofficial opportunities for profit that attached to office in the 16th century; but in exploiting fees and gifts Burghley was careful not to go beyond the limits of contemporary public morality. He presided over one of the least oppressive and most efficient administrations in 16th-century Europe.

Elizabeth's determination to rule through faction forced Burghley to protect his interests by maintaining a following. But he was a reluctant faction leader, because his real aim was to find an acceptable official policy and to manipulate the balance of faction rather than to dominate too obviously as an overmighty minister. Despite the impressive portraits of him, Burghley, although he had dignity, was not an imperious or heroic personality. He practiced patience and persistence, argued, and induced. His reputation for wisdom won him respect and influence. His caution, pessimism, awareness of limited national resources, and bureaucratic professionalism brought him into opposition with the optimistic belligerence and courtly amateurism of Leicester and then of Essex. Minimizing personal antagonisms and avoiding violence, Burghley helped to civilize Elizabethan politics and to preserve the domestic peace. Only once, in 1569, did he lose control of the faction balance, but even then he was not isolated from the Queen. His realization of the central position of the monarch in the constitution and in society gave him security and a focus for his sense of the national interest. Responsible to the crown alone, he understood that neither council nor Parliament nor faction provided an alternative basis for legal power.

Loyalty to the crown

For him there could be no divided loyalties even in the name of religion. Burghley did not allow that obedience to a pope or to a Puritan Providence might override allegiance to the sovereign and supreme governor. His patriotism, loyalty to the Tudors, and religious convictions were fused into one by his belief that church and state were but two aspects of one body politic. In his eyes Protestantism was the guarantee of England's independence, which, in its turn, ensured the survival of Protestantism in Europe. He defended the Church of England and upheld its middle way between Catholicism and Calvinism. He could permit only one public practice of religion.

Burghley tolerated variety in private beliefs, provided that it caused no political disturbance. He demanded outward conformity and punished recusants, sectaries, and separatists. His sympathy for the Puritan movement extended to its emphasis upon pious private conduct, evangelical preaching, and antipopery but not to its attack upon established ecclesiastical government. Because the papal bull of 1570 allowed Catholics to withdraw allegiance from the Queen, he treated activist Catholics as political offenders and had such men as the Jesuit Edmund Campion executed for treason.

To Calvinists and Catholics who assumed the separation of church and state, Burghley's unitary concept of church and state appeared as Politique, and his concentration upon the political implications of dissent seemed to be Machiavellian. Burghley answered such charges in *The Execution of Justice in England* (1583). He justified himself in intellectual argument, and his theological learning was respected by theologians.

Burghley was modest about his learning. He was trained in common law and was conversant with Roman law. Expert in Greek and Latin, he possessed a knowledge of French, Italian, and Spanish. His library, rich in manu-

scripts and maps, reflected his wide acquaintance with Renaissance learning. Among his interests was genealogy, history, topography, and cartography. He was knowledgeable in mathematics and cosmography and about the skills of artisans and men of mechanical trades. If his patronage of music and vernacular drama and poetry was minimal, he did encourage his favoured studies.

As chancellor of the University of Cambridge from 1559, he influenced discipline rather than the curriculum, but he made his household a resort of scholars and an educational centre for the Queen's wards and the young aristocracy. His intellectual interests, like his italic handwriting, were formed in the advanced humanist circle of John Cheke. His artistic eclecticism, developed under Somerset and Northumberland, was revealed in his personal planning for his three houses—Burghley House at Stamford, Cecil House in the Strand, and Theobalds in Hertfordshire; their decoration, furnishings, collections of pictures, coins, and "things of workmanship," and their gardens, supervised by the botanist John Gerard, won universal admiration. Burghley made a creative contribution to the Elizabethan architectural achievement.

Home and family life

Burghley's home life was disciplined by the pious routine of Bible reading and prayer and enlivened by the hospitality that he extended to friends and suitors. He entertained the Queen some dozen times. At his gates was charity for the poor. He was considered a good landlord. Belief in hierarchical society made him study to live like a lord, to cultivate his family tree, and to indulge in the ostentation expected of his rank. But his Puritan conscience made him thrifty in management and frugal in personal living. He did not allow ambition to ruin him. In his conduct was emerging the ideal of a gentleman whose personal virtues of humility, moderation, and moral rectitude were coming to count for as much as the traditional standards of aristocratic behaviour.

In his family life the early deaths of his first wife and of his daughters Anne and Elizabeth, the youthful escapades of his son Thomas, the unhappy marriage of Anne to Edward de Vere, 17th earl of Oxford, and the physical frailty of Robert were Burghley's personal griefs and anxieties. Gout from his youth and deafness in old age were his afflictions. But he enjoyed the adoration of his mother until 1588 and the spiritual support of his accomplished and high-minded second wife, Mildred, until 1589. In moments of relaxation his favoured pastime was reading or learned discourse at table. He loved horses and dogs. He practiced archery, went hunting, and trotted through his gardens on his mule. As a dynast he could rejoice in having married his family among the nobility. Late in life he delighted in his grandchildren—and had the satisfaction of endowing two dynasties—Thomas became earl of Exeter with his seat at Burghley House; Robert was made earl of Salisbury, installed first at Theobalds and then at Hatfield House. Burghley's descendants still reside in the houses once occupied by his sons. Burghley's remains lie in his canopied tomb, probably designed by Cornelius Cure, in St. Martin's Church, Stamford.

Burghley has always been a controversial figure. The hostility of his Catholic victims, foreign ambassadors, disappointed suitors, and rivals started a critical tradition that was perpetuated by Catholic historians. The favourable treatment of Lord Burghley by Protestant historians was begun by Francis Bacon and William Camden. Inevitably, religious partisanship affected Burghley's reputation as a statesman and as a man. The estimates of his responsibility for policy have depended on the roles in government assigned by historians to the Queen and to his colleagues. The assessments of his professional competence have emerged from studies of Elizabethan administration, finance, faction politics, and diplomacy. The lineaments of Burghley's public role and of his characteristics as a man of his time are becoming clearer, but the depths of his individuality remain difficult to probe.

BIBLIOGRAPHY. The main sources for Burghley's life are the Hatfield Manuscripts at Hatfield House, the Lansdowne Manuscripts at the British Museum Library and the State Papers at the Public Record Office. The most useful biography is B.W. BECKINGSALE, *Burghley: Tudor Statesman, 1520–1598* (1967). CONYERS READ, *Mr. Secretary Cecil and Queen Elizabeth* (1955) and *Lord Burghley and Queen Elizabeth* (1960), provide a detailed survey, especially of diplomacy. On Cecil in faction politics to 1572, see W.T. MACCAFFREY, *The Shaping of the Elizabethan Regime* (1968); on Burghley in administration, see J. HURSTFIELD, *The Queen's Wards: Wardship and Marriage Under Elizabeth I* (1958); and A.G.R. SMITH, "The Secretariats of the Cecils, Circa 1580–1612," *English Historical Review*, 83:481–504 (1968). On his parliamentary activities, see J.E. NEALE, *Elizabeth I and Her Parliaments*, 2 vol. (1953–57, reprinted 1966); on his family origins, see A.L. ROWSE, "Alltyrynys and the Cecils," *English Historical Review*, 75:54–76 (1960). On his artistic patronage, see J. SUMMERSON, "The Building of Theobalds, 1564–1585," *Archaeologia*, 97:107–126 (1959); J.A. VAN DORSTEN, "Mr. Secretary Cecil, Patron of Letters," *English Studies*, 50:545–553 (1969); and ROY C. STRONG, *Tudor and Jacobean Portraits* (1969).

(B.W.B.)

Celastrales

The Celastrales is a moderately sized order of flowering plants composed of 12 families containing about 147 genera and 2,000 species. The four major families (Celastraceae, the staff-tree family; Aquifoliaceae, the holly family; Hippocrateaceae, the Hippocratea family; and Icacinaceae, the Icacina family) contain well over 90 percent of the total genera and species. The holly family, the best known in the order, is widely cultivated and economically important as an ornamental.

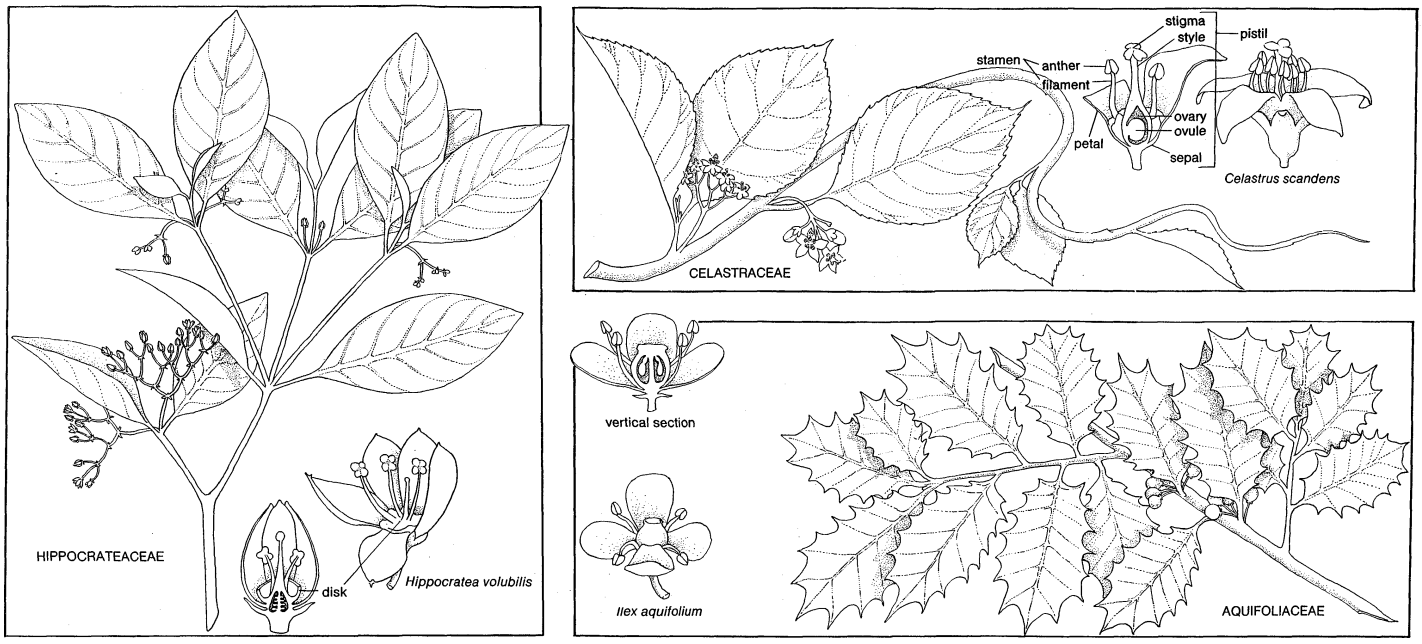
General features. *Distribution.* The families of the order Celastrales are primarily tropical and subtropical; only the Celastraceae and the Aquifoliaceae occur to any degree in the temperate zones. The larger families have a broad distribution in their climatic range; the smaller have relatively limited ranges.

Size range and diversity of structure. Most members of the order are either trees or shrubs; a few occur as herbs. The family Hippocrateaceae is somewhat unusual within the order in that it is composed primarily of woody vines, but shrubs and slender trees also occur within this family. Members of the family Celastraceae often are characterized by a scandent mode of growth—climbing or twining in other vegetation without the aid of tendrils. *Celastrus scandens*, the American bittersweet, is a familiar native shrub of the northeastern United States that exhibits this mode of growth, often reaching with long whiplike shoots to the tops of tall trees. The family Stackhousiaceae is unique within the order because all of its members are herbs.

Economic importance. The economic importance of this order can be attributed primarily to one genus in the family Aquifoliaceae—the genus *Ilex*, which is composed of species of the well-known holly. The use of the holly plant dates back many centuries. European pagans brought holly sprays into their homes, offering them to the fairy people of the forests as refuges from the harsh winter weather. During the Saturnalia, the Roman winter festival, branches of holly were exchanged as tokens of friendship. The earliest Roman Christians apparently used holly as a decoration at the Christmas season. Despite its past and present association with holy seasons, however, the root of the term holly is *holen* (*holegn*), an old English word meaning holly; holly has no etymological connection with the word holy.

Place of holly plants in history

Holly now is grown commercially for use as Christmas decorations. The red berries and shiny green foliage make it an ideal decoration, and, as it is an evergreen, it possesses excellent lasting qualities. Hollies are also cultivated extensively as ornamentals, and numerous horticultural varieties have been bred. The attributes that give this group such ornamental appeal include hardiness, long life, beauty of form and colour, considerable variation in berry colour (there are red-, black-, and yellow-berried varieties), and variation in leaf form. In addition, hollies can be adapted to a wide range of uses—as accent trees, driveway plantings, hedges, foundation plantings, bonsai, topiary, and even as ground covers.



Representative plants from three of the largest families of the order Celastrales.
Drawing by M. Moran

Holly also has other important economic values. It has been used for centuries as a hot drink, in the same manner as tea or coffee. Spanish explorers in 1542 commented on the use of yaupon holly (*Ilex vomitoria*) as a ceremonial and medicinal drink of the coastal Indians of the southeastern United States. In South America, particularly in Brazil, Paraguay, and Argentina, a drink called *yerba maté* enjoys a wide popularity; it is made from a native holly, *Ilex paraguariensis*. The best *yerba maté* is made from wild trees, although they are also cultivated for this purpose. The leaves are dried, ideally first in the sun and then over wood fires, after which they are steeped in hot water as in tea making. The active ingredient is the stimulant caffeine, whose content in the leaves approximates that of tea leaves.

The wood of holly, particularly that of the American holly (*Ilex opaca*), is also of some commercial importance. Small ornamental objects, inlay, and extremely fine furniture are made of its wood. The honey of holly has an extremely delicate flavour.

Although hollies are the commercially dominant group in the order Celastrales, several other plants also have economic value. A few members of the family Icacinaceae are raised domestically as garden ornamentals. In the family Celastraceae, the American and the oriental bittersweet are grown as ornamentals and are noted for their brightly coloured fruits. Several other members of the Celastraceae are also grown as ornamentals; particularly *Euonymus* species. In the Soviet Union two species of this genus, *E. verrucosus* and *E. europaeus*, are cultivated as sources of gutta-percha, a resinous, rubberlike substance that is used principally as an electric insulator and in temporary fillings for teeth.

Natural history. *Specialized reproductive systems.* The order Celastrales does not possess any unique feature that clearly delineates it from other orders; rather, it is classified on the basis of a number of unifying morphological characters. There are, however, within some families in the order, two particularly relevant features. The first is the frequent occurrence of a nectar-producing disk of tissue either to the inside or to the outside of the whorl of stamens (male reproductive structures) in the flower. This disk, which is a reduced whorl of stamens, serves as a means of attracting pollinators, such as bees, to the flower.

Multiple embryos in seeds

The second feature is the presence of polyembryony (more than one embryo in a seed) in some members of the family Celastraceae, especially in the genus *Euonymus* and in *Celastrus scandens* (American bittersweet). The polyembryony is a somatic type—the extra embryos developing from vegetative cells rather than from sex cells—known as adventitious embryony, in which the adventive, or extra, embryo originates from the inner integument, or covering, of the egg-containing body (ovule). A relatively uncommon phenomenon, polyembryony most frequently occurs in species of plants that are native to warm temperate or tropical climates. Further research may well reveal other examples of polyembryony within the order.

Ecology. Beyond a general adaption to tropical and subtropical climates, the order Celastrales possesses no unusual ecological characteristics and no particular adaptations to special habitats or modes of life. A few families within the order, however, have some interesting ecological characteristics. The family Celastraceae often shows a scandent mode of growth, enabling shrubby plants to attain a considerable height by climbing and twining up neighbouring trees. The family Hippocrateaceae often includes woody vines that can also reach considerable heights. Three families exhibit an adaptation to xerophytic (hot and dry, often arid) conditions: the Stackhousiaceae to a limited degree, the Geissolomataceae, and the Salvadoraceae. Species of the family Salvadoraceae are often adapted to very salty coastal regions; such habitats require considerable morphological and physiological modifications for survival.

Form and function. The Celastrales is an order of primarily woody plants, usually shrubs or trees but occasionally vines or herbs. The leaves are consistently simple throughout the order and can be either alternate or opposite in arrangement. The flowers are usually perfect (both sexes in one flower) but are sometimes unisexual. They typically have only one cycle of stamens alternating with the petals and frequently a nectar-producing disk inside or outside the whorl of stamens. Several types of fruits occur within the order, but they all characteristically have only one or two ovules per locule (compartment within the fruit).

Evolution. *Fossil record.* Three families—the Aquifoliaceae, the Celastraceae, and the Icacinaceae—are reasonably well documented in the fossil record. The Wilcox flora of the early part of the Eocene Epoch (38,000,000 to 54,000,000 years ago), found in about 130 localities in the southeastern United States, has many records of the Celastraceae, as does the Paleocene (54,000,000 to 65,000,000 years ago) flora of northeastern France. The London Clay flora, also Eocene, has members of the Icacinaceae, and the Aquifoliaceae and Ce-

lastraceae are well recorded in the boreal (northern) flora of the Tertiary (beginning 65,000,000 years ago) and in the excellent amber fossils of the late Eocene Baltic flora.

The genus *Celastrus*, in the family Celastraceae, is of particular interest because fossil members are well represented in many localities. In strata from the Cretaceous (about 125,000,000 years ago) fossil records from such disparate places as the northeastern region of China, Greenland, and Alaska have been found. The majority of records for this genus are from the central European floras of the Eocene and Miocene (7,000,000 to 26,000,000 years ago), from the Wilcox flora localities, and from the western United States.

Phylogeny. The phylogenetic (evolutionary) relationships of this order are not clear. The fossil record has not yet yielded much definitive information, and there is disagreement among the leading authorities; according to one of them, the order Celastrales is thought to be closely related to the Saxifragales—apparently derived from the common ancestors of some families within that order. The orders Oleales, Santalales, and Elaeagnales appear to share a common origin with the Celastrales; they are also particularly closely associated with three Celastrales families: Icacinaceae, Aquifoliaceae, and Salvadoraceae.

Classification. *Distinguishing taxonomic features.* The families have several common features: simple leaves; stamens alternating with the petals, with the exception of the Corynocarpaceae, a family of somewhat doubtful affinities; and usually one to two ovules in a locule. In addition, the nectar-producing disk is an important diagnostic character for seven of the families—the Celastraceae, Hippocrateaceae, Siphonodontaceae, Goupiaceae, Corynocarpaceae, Aextoxicaceae, and occasionally the Icacinaceae. The absence of the disk separates the Aquifoliaceae from the families most closely related to it. If the disk is present, its position inside or outside the whorl of stamens is of importance in further delineating families. Among the major criteria for delineating families within the order are: the presence or absence of stipules (leaflike appendages at the bases of leafstalks); the type of inflorescence, or arrangement of flowers; the presence of the lianous, or climbing, habit; the polygamodioecious state (male and female flowers on different plants but with a few flowers of the opposite sex or a few bisexual flowers on all plants at flowering time); the structure of the gynoecium (female parts); the curvature of the ovule; and seed characteristics.

Presence of the nectar-producing disk

Annotated classification. The order Celastrales is given here in accordance with one modern taxonomic authority. Most present-day taxonomists would agree that the following families should be classified together: Aquifoliaceae, Celastraceae, Hippocrateaceae, Siphonodontaceae, Stackhousiaceae, Salvadoraceae, Icacinaceae, and Geissolomataceae. The family Phellineaceae is sometimes included within the Aquifoliaceae but is considered here as a separate family on several characteristics: its valvate petals (those that touch at the edges), its inflorescence, the position of the ovules, the wood anatomy, and the pollen-grain morphology.

The relationships of the families Goupiaceae and Corynocarpaceae are not completely clear; in both cases the presence of the disk offers support for including them in this order. Taxonomic research could cause their status to be revised in the future, however. The family Aextoxicaceae has an even more uncertain position, but it does exhibit the following characteristics of the order: simple leaves, a nectar-secreting disk, and two ovules per locule.

The following descriptions give a wide range of characters which, taken as a whole, serve to delineate each family. Anomalous members also exist within most families of flowering plants, so that a familial description can be only a general one to which most members of that family adhere.

ORDER CELASTRALES

Woody plants: shrubs, trees, or vines; occasionally herbs. Leaves simple, alternate or opposite. Flowers usually bisexual, occasionally unisexual; hypogynous to perigynous (attachment of other floral parts either beneath the ovary or around it but not above it). Petals separate from each other. Stamens in a single cycle alternating with the petals; often a nectar-secreting disk of tissue inside or outside the whorl of stamens. Ovules typically 1 or 2 in a locule (compartment of an ovary or fruit). Twelve families, 147 genera, 2,000 species. Distribution pantropical and subtropical, with centres of distribution in Southeast Asia and South America.

Family Aquifoliaceae (holly family)

Trees or shrubs, typically with leathery alternate (rarely opposite) leaves. Flowers bisexual or unisexual. If unisexual then dioecious (sexes on different plants) or polygamodioecious (a few bisexual flowers or flowers of the opposite sex on all plants at flowering time). Flowers symmetrical, small and greenish, 1 to a few in small close clusters or cymes (more or less flat-topped flower cluster with central flowers opening first) located in axils. Sepals 3 to 6, joined basally and overlapping. Petals 4 or 5, free or only somewhat joined basally and overlapping, with point of attachment under the ovary (superior ovary). Stamens 4 or 5, distinct, alternating with the petals and sometimes fused with them. Nectar-secreting disk absent. Female flowers usually with anther-bearing staminodes (sterile stamens); male flowers usually with a rudimentary pistil (female structure). Pistil 1, style (elongated upper part of pistil) short or absent, stigma (pollen-receiving region at tip of style) lobed or capitate. Ovary with 3 to many locules. Ovules 1 or 2 per locule, hanging downward and anatropous (the opening near the point of attachment to placenta); placenta located at the centre of the ovary; fruit a berry; seeds with small straight embryo and copious endosperm (nutrient tissue for developing embryo). Three genera, 300 species, approximately 295 of which are in the genus *Ilex* (holly). Major centre of distribution is in Central and South America, with a secondary distribution in Asia. *Nemopanthus*, a genus of northeastern North America; *Byronia* a genus of Polynesia and Australia.

Family Icacinaceae (Icacina family)

Trees or shrubs, often vines, rarely herbs. Leaves leathery, simple, usually alternate. Flowers bisexual (occasionally unisexual through abortion), symmetrical, usually in panicles (many-branched inflorescences with stalked flowers). Sepals 4 or 5, small. Petals 4 or 5, usually free, meeting at their edges without overlapping. Stamens 4 or 5, distinct, alternating with the petals. Nectar-secreting disk rarely present. Pistil 1, ovary superior, with 3 to 5 carpels (structural segments), one locule each. Ovules 2 per locule, hanging from top of locule, anatropous. Style 1, usually with 3 stigmas. Fruit usually a drupe or occasionally a samara (indehiscent, winged fruit). Seeds with straight or curved embryo; endosperm typically absent. Fifty-eight genera and 400 species distributed throughout the tropics but more abundant in the Southern Hemisphere than in the Northern Hemisphere.

Family Celastraceae (staff-tree family)

Usually smooth-surfaced trees or shrubs, often twining (but rarely vines). Leaves simple, opposite or alternate, deciduous or persistent. Inflorescences axillary or terminal or flowers solitary or clustered in leaf axils. Flowers small, symmetrical, bisexual or unisexual on same or different plants (if on different plants, then polygamodioecious). Sepals 4 or 5, small, joined half their length or more, usually overlapping. Petals 4 or 5, small, free, usually overlapping and inserted under the disk. Stamens 4 or 5 (rarely 8 to 10), distinct, alternating with petals, inserted on or under disk. Usually a conspicuous nectar-secreting disk between the stamens. Ovary superior or with other floral parts arising from around ovary; carpels 2 to 5 (rudimentary in male flowers); stigma 1, style single and short or lacking. Ovules 2 (rarely 1 or 4 to 6), erect and anatropous. Fruit a capsule, drupe, berry, or samara. Seeds characteristically with a conspicuous brightly coloured, pulpy outer covering. Endosperm usually present. Fifty-five genera and 850 species, widely distributed throughout the world except for Arctic regions.

Family Hippocrateaceae (Hippocratea family)

Woody vines, shrubs, or slender trees; frequently with latex (milky sap) ducts in all parts of the plant. Leaves simple, opposite (occasionally alternate). Flowers bisexual, symmetrical, usually small, with bracts (leaflike structures located just below flowers), often with abundant mucilaginous fibres. Sepals 5, free, overlapping, persistent. Petals 5 free, overlapping or touching at edges. Stamens 3 (rarely 2, 4, or 5), inserted in the disk. Disk in a usually continuous ring forming pockets; pistil 1; ovary superior, sometimes joined to disk and concealed by it; locules 3 (rarely 5); carpels 3; style short and 3-parted (occasionally absent); stigmas usually 3. Ovules 2 to 14 per locule, anatropous. Fruit a schizocarp (dry fruit that splits into two halves), berry, or unusual capsule—3-locular and deeply 3-parted with a large flattened segment containing seeds. Seeds compressed or, if in capsule, then winged from base. Twenty-one genera and 400 species, with a main centre of distribution in South America and a minor one in Africa.

Family Phellineaceae

Trees or shrubs. Leaves simple, alternate, persistent, and membranous or leathery. Inflorescence a solitary raceme (simple, elongated cluster with stalked flowers) in axils of leaves. Flowers dioecious. Sepals minute or lacking. Petals 4 to 6, free, meeting at edges without overlapping. Stamens 4 to 6, free, reduced staminodes present in female flowers. Ovary with 1 pistil, 2 to 5 locules, and 1 ovule per locule. Ovules weakly campylotropous (curved by uneven growth, with axis nearly at right angles to stalk of ovule) or hemitropous (partly campylotropous). Fruit a drupe. Seeds with copious endosperm. One genus (*Phelline*) and 10 species, endemic (restricted) to New Caledonia.

Family Stackhousiaceae

Annual or perennial herbs, somewhat xerophytic, with rhizomes (underground stems). Leaves simple, entire. Flowers bisexual, symmetrical, with bracts, in simple, unbranched, elongated spikes. Sepals 5, overlapping. Petals 5, arising from around the ovary, possessing long claws joined in their middle portions, lobes of petals overlapping. Stamens 5, 3 long and 2 short. Pistil with 2 to 5 free or joined styles. Ovary with 2 to 5 carpels and 2 to 5 locules. Ovules 1 per carpel, erect, anatropous. Fruit a schizocarp with 2 to 5 parts, each with 1 seed. Endosperm present. Three genera (*Stackhousia*, *Macgregoria*, and *Tripterococcia*) and 27 species, distributed in Australia, Tasmania, New Zealand, and the Philippines.

Family Salvadoraceae

Trees, shrubs, or scramblers, occasionally spiny. Entire plant usually of an olive-gray colour. Leaves opposite, entire. Flowers bisexual or polygamodioecious. Sepals 2 to 4, overlapping or meeting at the edges. Petals 4 or 5, overlapping or contorted, and usually with teeth or glands on the inner side. Anthers 4 or 5, alternating with the petals, free or arising from the petals and occasionally with the filaments connected into a tube. Ovary superior consisting of 2 carpels, each with 1 or 2 locules containing 1 or 2 erect ovules. Style short and usually 2-cleft. Fruit a 1-seeded berry or drupe. Endosperm absent. Three genera and 12 species, distributed in the hot and dry regions of Africa, Madagascar, and Asia (also often along salty coasts).

Family Siphonodontaceae

Trees or climbing shrubs. Leaves simple, entire, alternate. Sepals 5; petals 5; stamens 5. Ovary superior, usually of 10 united carpels. Floral structure unique: each locule partitioned horizontally into two parts; upper ovule ascending from partition, lower hanging; the whole embedded in a disk having a central channel lined with five grooves or stigmatic lines that end in 5 tufts (serving as stigmas) and filled by a column resembling a style and barely reaching the opening of the disk; stamens bent and pressed to the disk so that anthers form a 5-rayed star at the top of the disk. Large fruit pear-shaped to globose, usually with 20 radiating bony pyrenes (single seeds with a hard outer covering). Embryo with large cotyledons (seed leaves) in bony endosperm. One genus (*Siphonodon*) and 5 species distributed from Southeast Asia to Australia.

Family Geissolomataceae

Small, xerophytic shrubs. Leaves simple, opposite, entire, evergreen; stipules present. Flowers bisexual, symmetrical, solitary in leaf axils, subtended by 6 persistent bracts. Sepals 4, resembling petals, overlapping, persistent. Petals absent. Stamens 8, free, 4 opposite the sepals and 4 alternating with the sepals. Ovary superior; styles 4, tapering from base to apex, free at base but coherent above (touching adhesively but not actually fused); carpels 4; locules 4, ovules 2 per locule, hanging. Fruit a capsule. One genus and 1 species (*Geissoloma marginata*) endemic to South Africa.

Family Goupiaceae

Trees or shrubs. Leaves simple, entire, alternate, with stipules; with 3 main veins extending the length of the leaf and with transverse veins. Flowers bisexual, symmetrical, stalked in false umbels (flat-topped inflorescence that mature from the margin inward). Sepals 5, overlapping, small. Petals 5, awl-shaped, meeting at the edges and rolled inward; yellow with red base; the top one-third strongly inflexed in the bud and remaining curved upon opening. Stamens 5 arising from edge of cup-shaped disk. Pistil with 5 short, free styles. Ovary superior, with 5 carpels and many ascending ovules. Fruit a globose drupelike berry, small, hard, with 2 or 3 locules and many seeds. Fleshy endosperm present. One genus (*Goupia*) and 3 species distributed in South America.

Family Aextoxicaceae

Large trees. Leaves simple, opposite or nearly so, nearly entire (smooth-margined), lepidote (with small scurfy scales on the surface). Inflorescences in axils of leaves, lepidote, in racemes. Flowers symmetrical, unisexual, enveloped in bud by bracts. Sepals 5, overlapping. Petals 5, overlapping, broadly clawed with a thick midvein and spreading at the apex. Female flower also with 5 broadly linear, fleshy staminodes. Stamens 5, alternating with 5 disk glands. Pistil lepidote with recurved, 2-cleft style. Ovary superior, with 2 carpels and 2 hanging ovules in only 1 locule. Fruit a small, dry drupe. Seed with mottled endosperm. One genus and 1 species (*Aextoxican punctatum*) endemic to Chile.

Family Corynocarpaceae

Trees or shrubs. Leaves simple, entire, alternate, lacking stipules. Inflorescence a terminal panicle. Sepals 5, overlapping. Petals 5, overlapping, joined to the base of the whorl of sepals. Stamens 5, opposite petals and epipetalous (arising from the petals); alternating with 5 petallike staminodes. Disk of 5 large glands opposite staminodes. Pistil with 1 or 2 free styles. Ovary superior with 1 or 2 carpels; 1 fertile locule with one hanging ovule, 1 sterile locule. Fruit a drupe, globose, fleshy. Endosperm absent. One genus (*Corynocarpus*) and 5 species with centre of distribution in the southwest Pacific.

Critical appraisal. Many taxonomic questions are yet to be resolved in this order. Some present-day taxonomists would consider various other families to be part of the Celastrales and would exclude some that are discussed here. Most authorities agree, however, that there is a solid core of distinct families that definitely belong in the Celastrales: Aquifoliaceae, Icacinaceae, Celastraceae, and Hippocrateaceae. The Geissolomataceae, Stackhousiaceae, Salvadoraceae, and Siphonodontaceae are accepted to a lesser degree as being definite members of the order, but some taxonomists would place them elsewhere. The members of the family Phellineaceae clearly belong in the Celastrales, but the one genus of the family (*Phelline*) often is considered as part of the Aquifoliaceae and not as comprising a separate family. The remaining three small families of the order—Goupiaceae, Aextoxicaceae, and Corynocarpaceae—generally are considered to have rather unclear relationships. Their placement in the Celastrales can be contested on the basis of present knowledge, but the problem cannot be resolved until more information is gathered both about these families and about the groups to which they appear to have affinities.

Other taxonomic schemes

BIBLIOGRAPHY. H. HAROLD HUME, *Hollies* (1953), a well-written, authoritative, and interesting book giving considerable background information on hollies in general, as well as detailed information about particular species and varieties; *American Horticultural Magazine* (Fall 1970), a special issue devoted entirely to hollies with well-written and extremely interesting articles on almost every aspect of the genus, from folklore and legends to holly propagation and varieties of hollies now commercially available; E. BERKELEY, "Morphological Studies in the Celastraceae," *J. Elisha Mitchell Scient. Soc.*, 69:185–208 (1953), a detailed anatomical floral study investigating the relationships of several genera within the family, fairly difficult for the non-botanist; R.A. HOWARD, "Studies of the Icacinaceae, I. Preliminary Taxonomic Notes," *J. Arnold Arbor.*, 21:461–489 (1940), a discussion of the historical taxonomic problems in the family Icacinaceae, and an interesting preliminary report on the nature of the research to be done to resolve these problems; I.W. BAILEY and R.A. HOWARD, "The Comparative Morphology of the Icacinaceae," 4 pt., *ibid.*, 22:125–568 (1941), an excellent, thorough study of several morphological structures, clarifying trends of specialization and relationships of genera within the family—requires a botanical background.

Celibacy

Though the term celibacy refers simply to the state of being unmarried, it is usually used in connection with the celibate individual's role as a religious official, specialist, or devotee. Not all persons in a religious vocation, or calling, who happen to be unmarried are technically celibate; the term celibate applies only to those for whom the unmarried state is the result of a sacred vow or act of renunciation or of a belief that it is preferable for a person because of his religious position or his degree of religious seriousness.

Celibacy has existed in some form or another throughout man's religious history and has appeared in virtually all the major religious traditions of the world. A distinction, however, could be made between those tradi-

tions in which celibacy has had a great and continuing prestige and is considered to be the preferred state of most spiritual leaders (*e.g.*, Hinduism, Buddhism, Taoism, Roman Catholicism, and Eastern Orthodoxy) and those in which it is only an occasional and often suspect deviation from a norm that gives marriage greater honour, for spiritual leaders as well as for the laity (*e.g.*, Judaism, Islām, Confucianism, and Protestantism).

Wherever celibacy has appeared, it has generally accompanied an emphasis that views the religious life as essentially different or even alienated from the normal structures of society and the normal drives of human nature. On the other hand, the religious style that disparages celibacy gives priority to the role of religion as employing and sanctifying the "natural" states of life: sexuality, family, and work. While the religions that encourage celibacy in leaders and devotees may not neglect the sanctification of the natural states, they stress the importance of certain symbols of separation, even of polarization, between the life of the person who has a sacred vocation and that of the ordinary man. They emphasize the difference between the religious and the natural life.

FUNCTIONS OF CELIBACY

Symbolism of celibacy

The basic function of celibacy is to establish a symbol of the sacred or holy within the life of an individual and make him its living, objective image. The priest or monk is to have the internal wholeness and self-sufficiency of God, of Christ, of the Buddha, or of other sacred beings. He is to be spiritually hermaphroditic, not needing the other sex for completeness, because he is an image in the world of men of the sacred, the ultimate reality which is beyond external needs. The celibate also demonstrates before men an utter dependency on the sacred.

Ritual purification. More specifically, however, celibacy functions in the history of religion as a means of ritual purification. In archaic religion (the religions of early and primitive cultures), the whole area of sexuality is commonly pervaded by negative taboo. Women in menstruation are to be avoided; sexual activity is forbidden before the hunt, war, or religious ceremonial. Celibacy serves as a permanent extension of this sort of preparedness for sacred and special activity. The celibate priest also serves as a pure *representative* of the community; he is viewed by the community as it would like to be seen by the gods.

Institutional control. A celibate class is created when the permanent celibate state becomes "routinized" into a regular, necessary qualification for those performing sacred activities. Some celibates have simply made a total withdrawal (*e.g.*, the "holy man," the hermit) and do not exercise sacerdotal powers. But if celibacy is a necessary qualification for priesthood, as in traditional Buddhism and Roman Catholicism, then it may functionally serve to demarcate and perpetuate a special group that possesses greater or lesser control of religious institutions. Ideally, it releases this group for more than ordinary expenditures of time and energy on behalf of their purposes.

Moral or spiritual advancement. At the same time, within the celibate community, celibacy is taught with the view that it contributes to the moral or spiritual advancement of individuals. According to such teachings, those in the married state can attain a positive balance of good over bad in their lives, and hence a favourable judgment on the last day or a desirable reincarnation. Nevertheless, the life of exemplary supernatural perfection, and of those advanced mystical states that give one a direct experience of the spiritual absolute, is held to be compatible only with the celibate state.

Other functions. Celibacy also functions as an example within a society, constantly suggesting the possibility of a life directed to more than natural ends; in other words, that continence is possible and the marital state a relative rather than an absolute end.

TYPES OF CELIBACY

Sacerdotal. Parallel to the diverse functions that celibacy plays in the religious life of man is a diversity of types. One type is sacerdotal celibacy, the celibacy of priests and priestesses. A priest may be defined as one who, as a mediator, performs the sacred function of communicating through rites the needs of the people to heaven and the sacred power and presence from heaven to the congregation. His function is objective. Its efficacy is assured if the priest knows and does the proper rite and has the proper qualifications of ordination and, perhaps, of ritual purity, regardless of whether he is particularly moral or fervent. Celibacy, if required for the priesthood, would be such an objective mark of special state and ritual purity. Celibacy probably is derived from taboos that regarded sexual power as a rival to religious power, and the sexuality of the opposite sex as a polluting factor, especially in sacred or crisis situations.

Monastic. Another type of celibacy is the monastic. While the monk may (or may not) also be a priest, his main motive will be moral and spiritual advancement, not the ritual purity required for sacerdotal rites. To this end the interior freedom, the opportunity for asceticism and meditation, and perhaps the "new family" of the religious community, all contribute to a sense of separation from the ordinary that releases the monk for religious growth. Types of monasticism range from the solitary—the hermit in the woods or desert, the anchorite living in isolation in a church or monastery—through the cenobite living a stabilized monastic life in community, to the mendicant ascetic who, either alone or with a band of friars, wanders from place to place gathering alms. In any case, the celibate state is viewed as an inseparable part of his way of life.

Anchorites, cenobites, and mendicants

Institutional (nonsacerdotal). Mention must be made also of states of institutional celibacy for women. Very frequently this life has no connection with sacerdotalism and is rather designed to aid spiritual advancement. Virginity and celibacy are considered to be assets in the attainment of spiritual goals. Generally, institutional female celibates are nuns in residential cloisters, although occasional solitaries, like the anchoress (lady hermit) Dame Julian of Norwich (14th–15th century) may be noted. Orders of nuns often perform important social service functions and in traditional societies may provide refuges for orphans, widows, and other women without family support.

Individual (noninstitutional, nonsacerdotal). Individual noninstitutional and nonsacerdotal religious celibacy is normally the state of the lay celibate or the occasional clergyman in a faith not requiring celibacy, who makes a vow to remain unmarried out of devotion or to allow the performance of some special religious service. Often these persons make their commitments in connection with a special relationship to a monastic order, as in the case of Catholic oblates (a lay person who unites with a religious order) or devout Buddhist laymen. Sometimes, as often obtains with high-caste Hindus, private vows of this type may be taken late in life, after an individual has been married and a householder. Even in these cases, however, the vow of celibacy is made in the presence of another: the abbott of the order or one's guru (spiritual guide).

Other types. There may also be cases of what might be called spontaneous or unofficial celibacy, especially in faiths in which the celibate state has no regularized standing. An individual may find his religious enthusiasm so all-consuming or his vocation so demanding that marriage can find no place in his life, and it is thereby consciously or unconsciously rejected for religious reasons. A good example of this type was John Chapman, "Johnny Appleseed," the Protestant mystic and wanderer of the American frontier. Islāmic mysticism also offers examples of this type.

CELIBACY IN THE RELIGIONS OF THE WORLD

Primitive religions. Among primitive peoples, the celibate state is chiefly connected with shamans and ritual purity. The shaman is an ecstatic who speaks to and from the gods or spirits on behalf of the people. Not all shamans are unmarried. But because the shaman has undergone a profound initiatory experience and has had a quite

The shaman

extraordinary calling, the prototype of the celibate may be found among his ranks. Some shamans, for example in the Goldi tribe of Siberia, "marry" initiatory female spirits at the time of their call. In other cultures, such as in that of ancient Japan, the female shaman was often the spouse of the god of whom she was the medium. Other shamans have been transvestite or homosexual. Priests also have been celibate in some archaic societies; *e.g.*, among the Aztec.

Ancient peoples and civilizations. With the rise of the great civilizations of antiquity, celibacy emerged in various contexts. The requirements for the famous Vestal Virgins of Rome, celibate for at least the thirty years of their service, indicate that celibacy had some place in a very ancient stratum of Roman religion. As classical civilization developed, two types of religious styles involving masculine celibacy appeared, that of the ascetic philosopher and that of the priest of the mystery religions. The Pythagoreans, perhaps influenced by the mysteries of Orpheus, are an excellent example of the former. Pythagoras himself established a small community at Croton in southern Italy (*c.* 529 BC). The community life was one of study, vegetarianism, and sexual restraint or abstinence. Later philosophers, including the well-traveled Neo-Pythagorean Apollonius of Tyana (1st century AD), under the influence of this tradition believed that celibacy would be conducive to the detachment and equilibrium required by the philosopher's calling. The Stoic philosopher Epictetus (born *c.* AD 50) taught that the ideal teacher would be unmarried and that his task required a calm freedom from family care. As a celibate teacher, the philosopher would make a far greater contribution to the world than that of bringing into being a few more children, and the single state could justifiably be substituted for the latter duty (*Discourses*, III, 22).

Priests of the mystery religions

A different mood was set by the celibate priests of the mysteries. Celibacy was especially characteristic of priest-devotees of the Great Mother cults. The Syrian goddess, for example, was described by Apuleius as being served by eunuchs who, in their zeal, would dance and lacerate their bodies with knives before her image. In contrast, the well-organized priesthood of the religion of Isis represented serene sacerdotalism. Sexual abstinence was an absolute requirement of those who celebrated her holy mysteries. Tertullian (the 2nd-century Christian rigorist) held up their continence as a reproachful example to Christians. He likewise noted that the sect of the Mithraists had "their virgins and their continents."

Similarly, the increasing number of cults—*e.g.*, Manichaeans (Iranian-based religion flourishing in the 3rd to 5th century that upheld the dualism of spirit and matter), Gnostics (early Christian heretics who believed that matter was evil and spirit good), and Hermeticists (Hellenistic believers in the occult and astrology)—influenced by the Platonic and Neoplatonic quest for the One through contemplation, esoteric knowledge, or theurgy (the art of influencing gods), typically had an inner or esoteric circle requiring strict continence. Thus, almost all important religious movements in the classical world show a strong drift in the direction of continence as an ideal and set the stage for Christian celibacy and monasticism.

Religions of the East. *Hinduism.* The ideal of the celibate state is also important in religions of the East. In Hinduism, celibacy is divorced from the priesthood, which is hereditary. Prominent, however, among the religious personages of India are the *sādhus*, "holy men," who live a life free of possessions and family obligation. They may be *sannyāsins*, devotees of Śiva (Shiva); *bairāgis*, devotees of Viṣṇu (Vishnu); or *yogins*, practitioners of yogic techniques. The *sādhus* have no organization or corporate discipline. Many *sādhus*, male and female, become celibates after marriage or widowhood; others early in life. The *sādhu* is one who has left the type of life ruled by the order of *dharma* (cosmic and societal law; *i.e.*, of caste, family, money, state, and all their responsibilities and privileges) in order to seek *mokṣa* (final liberation). Worldly involvements are believed to increase one's activities and distractions and hence militate against attainment of a life of controlled equilibrium or devotional ecstasy that is the goal of the spiritual techniques. Certain schools of yoga teach continence so that sexual energy may be redirected toward the opening of psychic and enlightenment centres in the body.

Buddhism. Buddhism began as a celibate order in India dedicated to the attainment of the *arhat* state, which is one of enlightenment. The *arhat* is a person who has attained enlightenment, also called the nirvanic consciousness, through the control of the passions and the withdrawal of the senses from attachment to external objects. Buddhism has both monks and nuns. As Buddhism became a world religion, certain variations arose: in Southeast Asia, most young men spent only a year in the order; in Tibet, Tantric monks were married; in Japan, the large Jōdo Shinshū denomination dispensed with the celibacy ideal altogether. At its core, however, Buddhism is a faith that teaches that all suffering is caused by particularized attachment to objects perceived by the senses, and that this desire is overcome best by meditative states of consciousness. Thus the image of the detached monk, an emulator of the Buddha himself who gave full priority to the meditative task of analysis and self-transcendence, remains at the centre of the Buddhist road to salvation.

The *arhat*

Jainism. The Jain religion arose in India about the same time as Buddhism. Its monastic groups were marked by an even greater austerity than that of Buddhism. Those of the Digambara school go about entirely naked after being fully initiated. All Jain monks are to avoid even looking at women, for, according to a Jain source, "they are to monks what a cat is to a chicken" (S.B. Deo, *History of Jaina Monachism*, p. 208).

Other religions of the East. Chinese Taoism has moastics and independent celibate adepts. Originally the tradition was probably derived from shamanism, but now the Taoist monasticism and priesthood is modelled on the Buddhist. Shintō in Japan has no monks or celibate priesthood; it has embraced shamanesses "married" to the shrine god and celibate priestesses in major shrines, especially in premodern times.

Religions of the West. *Islām.* Celibacy was not part of the original practices of Islām. But after the faith of Muḥammad had conquered vast stretches of the world, mystical movements, particularly Ṣūfism (Islāmic mysticism), arose and sometimes produced celibates. Islāmic celibacy was a matter of personal spiritual advancement or enthusiasm rather than of sacerdotal purity or institutional control, and most of the famous saints were married. In various places, bands or fraternities of Ṣūfī mystics, such as the dervishes, developed out of a need for rigorous training or practice. Celibacy was exceptional even among members of these mystical orders, however, except for the Bektāshīyah of Turkey and Albania, which had a celibate wing. Religious celibacy, together with the traditional practice of Ṣūfī mysticism, seems to be on the decline in the Islāmic world today.

Ṣūfism

Judaism. Celibacy has had little part in normative Judaism. The creation accounts in Genesis 1 and 2 in the Old Testament present the marriage relationship as a good and natural one. "Any Jew who has no wife is no man," said Rabbi Eleazar (3rd century AD). The single, dramatic exception in the Old Testament is that of the prophet Jeremiah.

There were, however, prescribed periods of sexual abstinence in connection with rituals and sacrifices, and while engaging in holy wars.

Celibacy does appear, however, in sectarian Judaism in post-Old Testament times. Some members of the Essene sect, as described by Pliny, Philo, and Josephus, rejected marriage. The Qumrān community near the Dead Sea apparently was Essene, but there is some uncertainty as to just what part celibacy played in its life. One manuscript makes a note of women and children in the Qumrān community; however, a holy war was believed to be imminent; and to be ready for this apocalyptic conflict, ritual purity, including sexual abstinence, was necessary.

Christianity. Celibacy first appears in Christianity out of similar apocalyptic expectations. It was believed

among the original Christians that the present age was ending and that the Kingdom of God was at hand, and that in the new age there would be no marriage, since all would be like angels. Some of the followers of Jesus gave up family life in order to devote themselves to proclaiming the Kingdom. St. Paul commended celibacy but insisted that he, like the other Apostles, had the right to be married if he so desired.

In the subapostolic period (late 1st and early 2nd centuries), discussion and practice of celibacy varied. Some took the extreme view that all Christians should renounce marriage. Middle positions were developed to defend marriage in opposition to Encratic (heretical ascetic) and Gnostic (heretical ascetic or libertarian) views that the flesh and all matter were evil and to defend celibacy in opposition to the widespread sexual license and chaos of the times. Many writers held that marriage was good, but that celibacy was better.

As time passed and expectations of the consummation of history dimmed, a belief that sexual intercourse was defiling and incompatible with holiness emerged as the dominant motivation for the practice of celibacy. Some persons dedicated themselves to lifelong virginity. Others, already married when converted, separated from their spouses from the time of their Baptisms or practiced continence within marriage; some became celibate after being widowed. The pre-Christian idea that sexual activity was particularly wrong for those who officiated at the altar was assimilated by Christians, and it became the custom for ordained men to give up sexual relations with their wives, but there was no uniformity on the matter. The regional Council of Elvira in Spain (*c.* AD 306), decreed that all priests and bishops, married or not, should abstain from sexual relations. On the other hand, the ecumenical Council of Nicaea (AD 325) declined to make such a prohibition. The council condemned the practice in which supposedly celibate priests kept a "subintroduced woman" in their households in order to test and prove their moral strength.

Beginnings of clerical celibacy

The position of the Eastern churches was made clear by the time of the decrees of the Council in Trullo in Constantinople in 691. Bishops must be celibate, but ordained priests, deacons, and subdeacons could continue already-established marriages.

In the West, a series of popes and regional councils in the 4th and 5th centuries confirmed the general position taken at Elvira requiring clergy in various places to be celibate or, if married, continent.

The social chaos caused by the breakup of the Roman Empire had the effect of extending the practice of celibacy among the laity. Lay persons fleeing the cities to live as hermits or to form monastic communities sought safety as well as purity.

In the 10th and 11th centuries a crisis in the practice of clerical celibacy resulted from the decline of the Carolingian Empire and the Norse (Viking) invasions. Churches were destroyed, church lands secularized, and many priests married or lived in concubinage. Not only the practice but also the principles of clerical celibacy were challenged. Popes and councils reacted strongly with reassertions of the traditional law.

The first and second Lateran Councils (1123 and 1139) put an end to the legality of theoretically continent clerical marriages. They declared priestly orders an impediment to valid marriage and vice versa. This is still the official position of the Roman Catholic Church, although occasionally exceptions are made.

The churches of the Reformation (Lutheran, Anglican, Reformed, and others) discontinued the requirement of clerical celibacy. Lay celibacy was also discontinued, but about 1845 monastic orders began to reappear in the Church of England. About the time of World War II, small Protestant monastic groups (*e.g.*, Taizé community) were founded on the continent of Europe.

Debates on clerical celibacy

In connection with the second Vatican Council (1962–65) clerical celibacy has once again become a cause of ferment in the Roman Church. The council permitted a married diaconate. Subsequent to the council, the number of priests seeking to leave the priesthood and marry has vastly increased.

A substantial number of European and American Catholics began to urge that celibacy be made optional for priests. The National Association for Pastoral Renewal was formed in St. Louis and New York, 1966–67, to work toward this change. A survey carried out by the association revealed that 62 percent of lower echelon American priests favoured optional celibacy.

Pope Paul VI, however, issued an encyclical, *Sacerdotalis Caelibatus* (June 23, 1967), reaffirming the traditional law on celibacy. The pope and those who are in agreement with his position tend, in their defense of the present practice, to pass over the antisexual writings of early centuries and to return to the New Testament texts. Thus, in this view, for the sake of Christ and the coming Kingdom of Heaven, the priest must be totally available and free of domestic responsibilities; he must witness by his way of life to the transcendent reality that fills and grips him.

In general those who urge change indicate that they hold celibacy in high regard and want it to continue both among laity and some priests. Making it voluntary should, they believe, actually enrich and strengthen it. They refer to New Testament practice of freedom in this area, and they also point out that in present practice many men are not motivated by the exalted New Testament reasons when they take on celibacy. To insist that the two vocations of celibacy and priesthood must necessarily coexist in the same person at the same time, they claim, is arbitrary and is contradicted by centuries of Orthodox and Protestant experience.

The Roman Catholic law of clerical celibacy is of ecclesiastical origin; it is not considered by either side to be infallible or divine, and thus theoretically it can be changed. The issue may thus be seen in large measure as a crisis of authority.

(R.S.E.)

Cell and Cell Division

Cells are the units of life; they survive and conserve their kind by reproduction. The distinction between the two main designs of cells, procaryotic and eucaryotic, is that between life-forms that appeared on the Earth 3,000,000,000 years ago and relative newcomers that date back no more than 2,000,000,000 years.

In the following discussion of the designs and workings of cells, molecules are distinguished from the structures and mechanisms in which they participate. The interpretation of life processes as chemical processes has answered some of the most important biological questions. The answers to others involve considerations of the ways in which molecules are organized because, ultimately, it

is the organization of molecules that is responsible for the coordination of activities in the cell.

This article is divided into the following major sections:

I. The designs of cells
The cell as a molecular system
Cell morphology—form and structure
Procaryotic and eucaryotic cells
II. Functional aspects of cells in life
The internal environment and the cell matrix
Living membranes
Interplay of nucleus and cytoplasm
Cells in societies
III. The cell cycle—growth and division
Cell growth
Mitosis
Meiosis

I. The designs of cells

Two basic cell designs

Two quite distinct designs of cells are recognized. One, the procaryotic plan, is found in all bacteria and blue-green algae. The second, the eucaryotic plan, occurs in the true algae, the fungi, the protozoans, and the cells of multicellular plants and animals. The same principles of reproduction, inheritance, molecular composition, and metabolism apply to both kinds of cells; the differences between them are dealt with below (see below *Procaryotic and eucaryotic cells*).

THE CELL AS A MOLECULAR SYSTEM

The same kinds of molecules are found in all types of living cells. The following is a catalog and evaluation of the important classes of molecules found in cells.

Macromolecules in cells. Macromolecules can be defined arbitrarily as molecules of molecular weight greater than 10,000 daltons (10,000 times the weight of a hydrogen atom). They are characteristic of living things and are not found in nature except as components or products of organisms. In all cases, the molecules are polymers; *i.e.*, they consist of chains of smaller units called monomers. Much of biochemistry is a description of two processes: the synthesis of monomers and the polymerization, or joining, of monomers to form macromolecules. Each of the kinds of macromolecules—proteins, nucleic acids, or polysaccharides—is assembled from one class of monomers. Proteins are polymers of amino acids, molecules characterized by the presence of a nitrogen-containing amine group, NH_2, attached to the carbon atom adjacent to the organic carboxyl acid group, COOH. Nucleic acids are polymers of units known as nucleotides, each of which is composed of a specific sugar molecule (deoxyribose or ribose), a molecule of phosphoric acid, and a molecule of one of four organic bases (adenine, guanine, cytosine, or thymine). Polysaccharides are polymers of carbohydrates, which are molecules composed of carbon, hydrogen, and oxygen atoms. In the cell, these polymers are generally heteropolymers; *i.e.*, the monomers that comprise them belong to the same chemical class (*e.g.*, amino acids in proteins), but they are not all identical in structure—there are about 20 different amino acids. The term sequence refers to the order in which the different monomers of one class appear in the polymer.

Nucleic acids and genetic conservation. Deoxyribonucleic acid (DNA) is literally the substance of heredity; it carries the essence, or character, of an organism from generation to generation. DNA is a heteropolymer of four types of monomers, called deoxyribonucleotides because they contain deoxyribose. The inherited character of every organism is encoded in the sequences of these four nucleotides; thus the ultimate basis of reproduction lies in the exact replication of these sequences. The basis of evolution involves occasional modification of them.

Another group of nucleic acids, ribonucleic acids (RNA), consists of sequences of four types of monomers called ribonucleotides because they contain ribose. RNA's that can copy sequences of deoxyribonucleotides in DNA are called messenger RNA's or mRNA's; they function in the expression of the genetic code contained in the DNA. The most immediate expression of the genetic code is the synthesis of proteins (see NUCLEIC ACID; GENE).

The roles of proteins. Proteins are heteropolymers of about 20 kinds of amino acids. The functioning of a protein depends on its structure; the three levels of structural complexity that are recognized are primary, secondary, and tertiary. The primary structure of proteins is described by the sequences of the amino acids, which are polymerized in chains. The terms secondary and tertiary structure are used to describe the coiling of the polypeptide chains into helices (secondary structure) and the further folding of the helices into three-dimensional shapes, the conformations and surface features of which are important for the biological activities of the proteins (tertiary structure). The conformation of protein molecules is important because their activities involve the way in which they "fit" with other molecules; the two molecules must fit together very exactly because any distortion in the conformation affects the functioning of the protein molecule.

Several distinct roles of proteins can be recognized in the operations of the cell; for example, catalysis, transport, structure, and regulation (all treated below) are some of the principal functional processes in which proteins are important.

The chemical reactions in the cell are catalyzed (*i.e.*, assisted so that the rate of reaction is increased) by enzymes, and all enzymes are proteins. Each kind of reaction is catalyzed by a different enzyme. It is estimated that as many as several thousand different enzymes are contained in certain cells.

Certain proteins are found in the cell membranes, where they function as transport proteins. Each transport protein recognizes a specific molecule, combines with it, and carries it across the membrane into the cell.

Structural proteins

Proteins are responsible for the properties of cells—their form, structure, and movements. The existence of a class of structural proteins is recognized, although less is known about them than is known about enzymes. Such proteins are present in cells in large amounts because they build massive structures rather than serve catalytic functions.

Procaryotic cells contain a class of proteins called repressors, which are agents of genetic regulation. They function as genetic valves by combining with specific genes to turn off their activity. In eucaryotic cells, protein components of chromosomes are thought to serve similar functions, although the case is far less clear (see PROTEIN; ENZYME).

The role of polysaccharides. The polysaccharides, polymers of various sugars, are prominent in functions that occur at the outer face of the cell but have few functions inside the cell. Bacterial cells are encased in cell walls the most prominent components of which are polysaccharides; frequently they are associated with proteins and lipids. The walls surrounding plant cells are composed of cellulose, a polymer of the sugar glucose. Animal cells do not have walls, but an important compound of their outer face is a polysaccharide containing sialic acid (see CARBOHYDRATE).

Small molecules in the cell. An inventory of the small molecules of cells, those smaller than macromolecules, would be immense. Those groups—lipids, nucleotides, porphyrins, and water—that are central to the concept of the cell as a molecular system are described below.

Lipids. The term lipid lumps together a variety of fatty molecules that are insoluble in water but soluble in organic solvents (*e.g.*, ether); lipids comprise about 10 to 20 percent of the dry weight of a typical cell and are major components of all cell membranes. They constitute about 50 percent of the material of cell membranes and account for a number of their important properties. Functionally, layers of lipids are effective in separating water regions from one another (*e.g.*, cell interiors from their environments) in such a way that their components do not mix freely (see LIPID; MEMBRANE, BIOLOGICAL).

Nucleotides. Nucleotides, the monomeric units of nucleic acids, contain a nitrogenous base; a sugar, generally either ribose or deoxyribose; and one or more phosphate groups. It is remarkable that one type of molecule plays such a variety of roles. In the respiration of all

cells, for example, certain of the key compounds involved are nucleotides combined with proteins. In most chemical reactions of all cells in which a transfer of energy occurs, the nucleotide adenosine triphosphate (ATP) is involved.

The cyclic adenosine monophosphate (cyclic AMP or cAMP) molecule is a nucleotide that functions as a major communicator molecule in cells. In both procaryotic and eucaryotic organisms it has been shown that cells respond to various stimuli (*e.g.*, hormones, events at junctions between nerves, substances that induce enzyme synthesis in bacteria) by producing cyclic AMP, which then plays an essential part in turning on the necessary activity (*e.g.*, enzyme synthesis; see METABOLISM).

Porphyrin derivatives. Porphyrins are widely distributed in plant and animal cells. Certain porphyrin derivatives, the cytochromes, are essential for oxidative processes, especially in cells that utilize oxygen. Other porphyrin derivatives, the chlorophylls, are responsible for the utilization of light energy in photosynthesis.

Water. Water, the simplest and most abundant of all the molecules, is also the most mysterious. Cells contain 70 to 80 percent water. If the water content of a cell falls much below about 50 percent, life processes stop, sometimes irreversibly. Cell chemistry involves the study of reactions in aqueous solutions. But much of the water in cells is not ordinary water; rather it is structured in shells surrounding macromolecules, especially proteins. In fact, it has been suggested that most of the water in cells is structured and that the reactions of aqueous solutions in test tubes are not synonymous with the chemistry of the living cell.

The unique role of water in cells

CELL MORPHOLOGY—FORM AND STRUCTURE

It is possible to make generalizations about the structure of eucaryotic cells because all are built of a relatively small number of similar structural elements; each kind of cell thus can be considered as a variant of a basic plan.

Sizes and shapes of cells. All eucaryotic cells can be thought of as spheres with diameters ranging from about ten to 100 microns (1 micron = 0.001 millimetre [0.0004 inch]). Few are smaller. Larger ones can be considered as specialized cases—cells that contain many nuclei can be regarded as several cells sharing the same skin (*e.g.*, giant amoebas and slime molds); cells that include an exceptionally large amount of storage material (*e.g.*, eggs); cells in which a large part of the volume is occupied by vacuoles (cavities) rather than by active cytoplasm (*e.g.*, many specialized cells of plants).

Most cells are not actually spherical in shape but can be converted to spheres. The deviation from the spherical form depends on supporting structures. In animal cells, for example, the supporting structure, sometimes called the cytoskeleton, is an internal one; it contains fibrous elements, of which the most prominent is the microtubule system (see below *Microtubules*). Many animal cells, which assume a flat shape by adhering to a solid surface, assume a spherical form when they are detached from the surfaces. The shapes of many protozoans are determined by an external rigid covering, or pellicle. Plant cells are encased in cellulose walls of definite shapes. There are many other kinds of cell walls—*e.g.*, the siliceous walls of diatoms. Plant cells and other cells contained in cell walls form spherical bodies called protoplasts when the walls are removed.

Morphological elements—parts of cells. *The cell membrane.* The cell membrane, or plasma membrane, is the boundary between the external environment and the internal environment; it can be defined functionally as the barrier to the free passage of molecules. Structurally, it is recognized as a layer 60 to 100 angstroms (one angstrom = 0.0001 micron) thick and is thus visible only with the electron microscope. It has a trilayered appearance after treatment by certain electron microscopic techniques. Because the appearance of the surface membrane is much the same in all kinds of cells—procaryotic and eucaryotic—and similar to that of internal membranes of eucaryotic cells, the term unit membrane is widely used. It should be made clear, however, that the term is morphological and that the chemistry and functions of various unit membranes differ greatly.

Chemically, all unit membranes consist of lipid and protein, the protein representing 50 to 75 percent of the material. The major classes of lipids prominent in most membranes are the phospholipids and cholesterols, which are present in varying proportions. Proteins found at the outer surface of membranes differ from those found at the inner surface. Those at the outer surface include prominent amounts of glycoproteins—*i.e.*, proteins combined with polysaccharides; in animal cells, the conspicuous carbohydrate component is sialic acid. Less is known about the proteins of the inner membrane face, but it is thought that they are not glycoproteins. In the case of the mammalian red blood cell, the best studied membrane, the number of structural proteins is not extremely large, there being perhaps three major kinds and five or six smaller components.

Chemical composition of membranes

Physically, the outstanding characteristic of cell membranes is their extremely high electrical resistance, in the range of 1,000 to 10,000 ohms per square centimetre. This resistance is consistent with the presence of a continuous layer of lipid, which has only a few channels for the passage of ions (charged particles). The negative charge at the surface of cell membranes is attributed to the negatively charged sialic acid groups in the glycoproteins of the outer layer.

There is no accepted molecular model of a cell membrane at present. A classical "sandwich" model, in which a continuous inner layer of lipids two molecules thick is sandwiched between two layers of protein, has served very well to account for many properties of membranes. Its validity is questionable, however, in view of evidence from the freeze-fracture method of electron microscopy, in which the membrane appears to be peelable into two layers with particles dispersed between them. It has been proposed that the membrane consists of particles of both lipids and proteins rather than a distinct double layer of lipids and outer and inner layers of proteins (see MEMBRANE, BIOLOGICAL).

Extracellular coats. Many, if not all, animal cells have structures that lie outside the cell membrane as it has been defined above. A common feature is that of hairlike projections, which give the cell a fuzzy appearance. At the places where cells come together, as in tissues, layers of a cement-like substance are laid down outside the cell membrane. These surface layers play an extremely important part in the attachment of cells to solid surfaces and to each other. Since freely suspended cells can be obtained from tissues or from cells growing on surfaces by treating them either with a protein-digesting enzyme, with a reagent that removes calcium ions, or both, it seems probable that the extracellular coats are composed of proteins—in some cases they have been identified as glycoproteins—the adhesive properties of which depend on calcium ions.

Intracellular membrane system. The intracellular membrane system of eucaryotic cells consists of structures inside the cell membrane that are bounded by unit membranes. Membranes are employed in a variety of functions to sequester some of the material of the cell. The endoplasmic reticulum, for example, is a complex network of sacs, sometimes flattened, that are enclosed by unit membranes. The Golgi apparatus is a stack of very flattened vesicles (dictyosomes); the vesicles are one to two microns in diameter and have an inner space 100 to 200 angstrom units thick. The lysosomes, little round vesicles about 0.5 micron in diameter, contain a variety of digestive enzymes.

Mitochondria. Mitochondria are typically sausage-shaped particles about 0.5 to one micron wide and five to ten microns long; they are surrounded by an outer unit membrane that is separated by about 70 angstroms from an inner membrane. The outer membrane is comparable to other cell membranes in that it controls the passage of material into and out of the mitochondrion and governs its internal environment. The inner membrane is the site of the respiratory functions that make the mitochondrion the so-called powerhouse of the cell.

The study of mitochondria has focussed on the enzymes and on their relation to mitochondrial structure. The membranes consist of about 30 percent lipids; a considerable proportion of the proteins are thought to be enzymes involved in respiration and the phosphorylation—the addition of phosphate groups—of ATP.

Mitochondrial activities

Mitochondrial membranes not only contain the respiratory enzymes but are also active in controlling the inward and outward passage of ions, especially those of calcium, and molecules. Further, they may be active in a "contractile" way; *i.e.*, expansions and contractions of the mitochondrial surfaces are correlated with decreasing and increasing respiratory activity. In general, mitochondria provide the best examples within the cell of correlations between structure and activity.

The mitochondrion has a degree of autonomy that makes it quite unlike the other components of cells. It contains DNA in the form of a "chromosome" resembling that of a procaryotic cell; this chromosome carries the genes for some of the enzymes found in mitochondria. Thus the mitochondrion can synthesize some of its own proteins and can reproduce itself. In one respect the mitochondrion is a part of the eucaryotic cell; in another, it is an independent organism.

Ribosomes. Ribosomes are particles about 200 angstrom units in diameter consisting of about 40 percent protein and 60 percent RNA. Very numerous in a cell, they may account for 40 to 60 percent of its total RNA. In typical eucaryotic cells, ribosomes may occur both as free particles and as particles attached to the membranes of the endoplasmic reticulum.

Ribosomes are so small that it has not yet been possible to determine fine details of their structure, even with the electron microscope; it is known, however, that they are composed of two subunits, one larger and different in shape from the other. Although they are usually described as macromolecules, their chemistry in fact is quite complex; they contain 20 or more different kinds of proteins.

Microtubules. To account for the forms of cells and for certain processes such as cell division, the existence of fibrillar elements was long postulated; their existence was proved in the late 1950s using the electron microscope. The discovery of microtubules provided an explanation for many problems of cell structure.

Microtubules are about 200 angstroms in diameter; their length ranges from ten to hundreds of microns; and they have the appearance of straight, unbranched tubes. The tubules appear as cylindrical arrays of filaments about 35 to 40 angstroms in diameter; typically there are 12 or 13 such apparent filaments. The filaments are rows of particles about 35 to 40 angstroms in diameter; this diameter corresponds to that of a protein molecule of 50,000 to 100,000 molecular weight.

Chemically, the microtubules are composed of protein molecules, each with a molecular weight of about 100,000; the protein molecules in turn consist of two subunits of slightly different structure, each with a molecular weight of about 50,000. The proteins of microtubules combine with the drug colchicine, a characteristic that is often used to identify existing microtubules or to prevent the formation of new ones; both are important in establishing relationships between microtubules and various cell functions.

The microtubules often provide the structural frame for cell shapes. The shapes of many cells—for example, cells such as the protozoan *Actinospherium*, the surface of which is extended in long spikes—are the result of the disposition of microtubules; the cells revert to a spherical form if the microtubules are broken down. The structure of cilia and flagella, short and stiff or long and whiplike organs of locomotion, respectively, is accounted for by an arrangement of microtubules.

Microfilaments. Only in the late 1960s were microfilaments perceived as a universal element of cell structure—one especially involved in the motility of cells. Microfilaments, about 40 to 50 angstroms in diameter and of indefinite length, are composed of a protein with general properties similar to actin, the protein of the thin filaments of muscle, which was intensively studied long before it was realized that such filaments are universal components of eucaryotic cells.

Functional aspects of microfilaments

Microfilaments are involved in many kinds of cell motility; the evidence showing the equivalence of the thin actin filaments of all kinds of muscle and microfilaments is quite strong. Microfilaments are associated with cytoplasmic streaming movements in plant and animal cells, with amoeboid movement, and with the "ruffling" movements so characteristic of the surfaces of animal cells when grown in culture. Microfilaments have not been found, however, in association with flagella, cilia, or the mitotic apparatus (*i.e.*, the spindle-shaped structure evident in cells during cell division). Microfilaments are the supporting structures of microvilli, fingerlike outward extensions covering many kinds of cells, and the inward cuplike extensions of many cell surfaces when they take up large molecules and particles by the processes of pinocytosis and phagocytosis—intaking of water drops or solid particles at the membrane surface of the cell.

The nuclear envelope. In all eucaryotic cells, the chromosomes are contained within a nuclear envelope during at least a large part of the cell cycle; this interval, called interphase, is the period between cell divisions. In most single-celled eucaryotes (fungi, protozoans, and algae) the chromosomes are encased by the nuclear envelope at all times; in cells of multicellular plants and animals, the nuclear envelope breaks down during mitosis (cell division).

The nuclear envelope has a characteristic structure, consisting of two unit membranes separated by about 200 angstroms. The membranes appear to be perforated by pores, which are about 500 angstroms in diameter and which occupy 10 to 20 percent of the cell surface. It has not yet been established with certainty whether these pores actually are open passages between the nucleus and cytoplasm. Although they can always be seen under the electron microscope, other kinds of evidence suggest that the nuclear envelope is sometimes open and sometimes closed to the passage of ions, molecules, and particles.

In any case, the pores are not regarded as mere perforations; rather, they are quite elaborate structures, called annuli, that persist after the rest of the membrane has been destroyed experimentally. Moreover, there is now good evidence that the annuli are the sites at which chromosome threads attach to the nuclear surface, and they

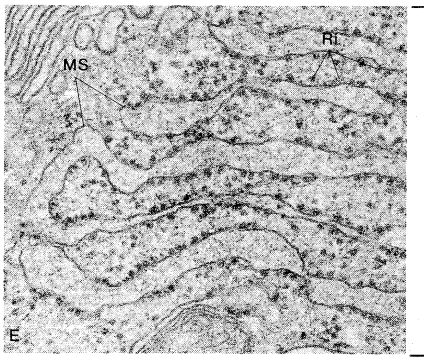
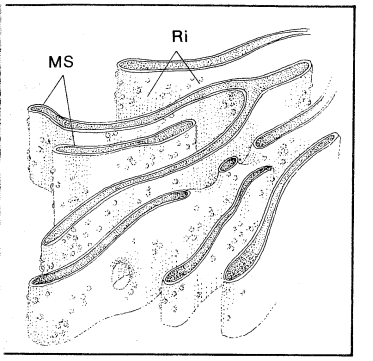
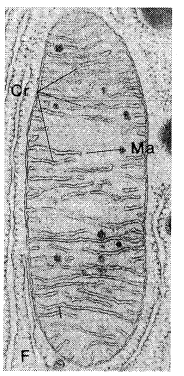
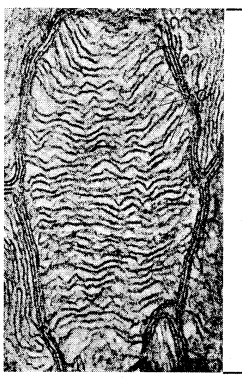
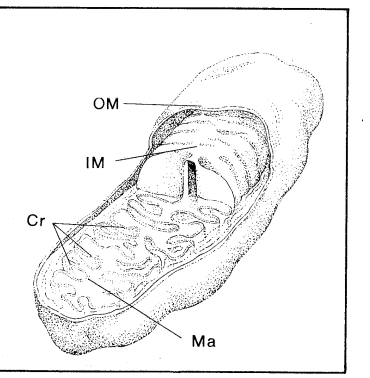
GENERALIZED ANIMAL CELL

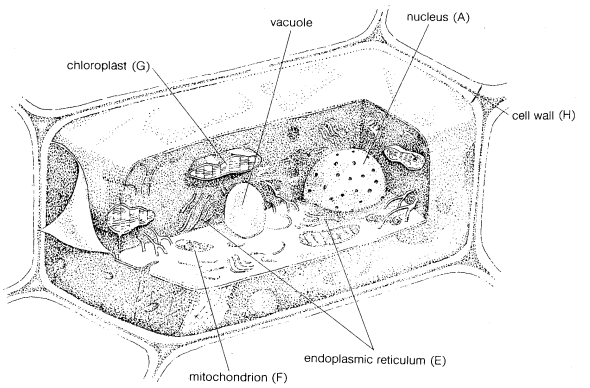




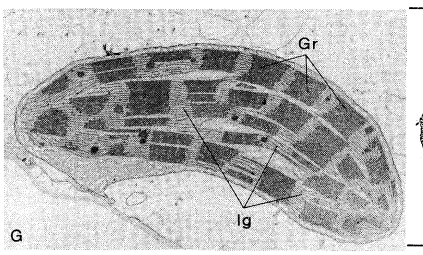


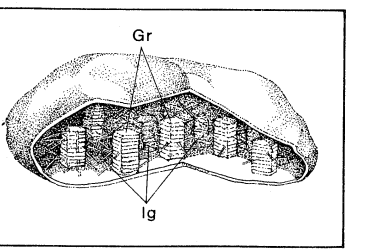


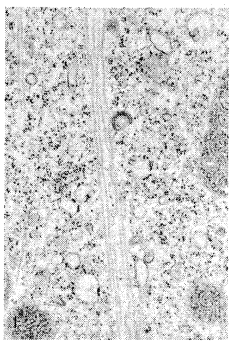


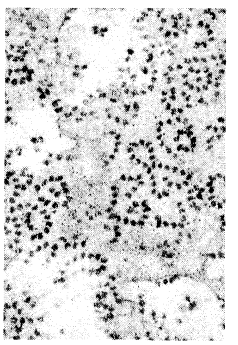


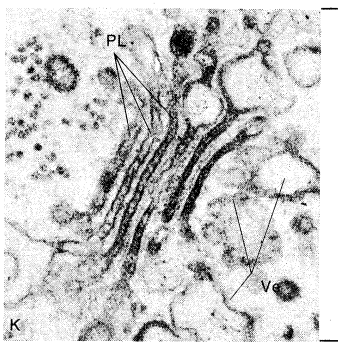
GENERALIZED PLANT CELL

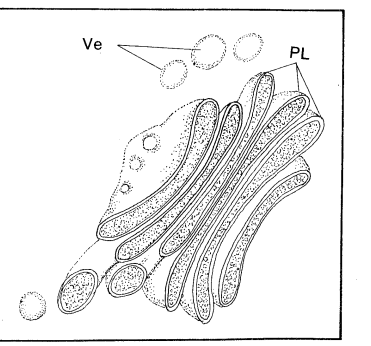












may be involved in the positioning of the chromosomes relative to each other in the nucleus.

Chromosomes. The chromosomes are the residences of the genetic material of the cell. They are best known from their behaviour in cell division because it is in that part of the life history of the cell that they are in a condensed state and thus visible. A characteristic set, or karyotype, of chromosomes is recognized for each species.

In the cell that is not dividing, the individual chromosomes are difficult to see, although it is not true that they are dispersed in a chaotic tangle of threads. It is more useful to think of the chromosomes in a nondividing cell as retaining their discreteness while being in an expanded, open state. There is reason to believe that individual chromosomes have definite positions in the interphase (*i.e.*, the time between successive cell divisions) nucleus and are attached to the nuclear membrane.

Apart from DNA, the most characteristic constituent of chromosomes is a class of proteins called histones, of which five kinds are found in most cells. Chromosomes also contain "nonhistone proteins," about which little is yet known. They also contain RNA. The few published analyses suggest that chromosomes contain 60 to 70 percent protein, of which half or more is histone; 15 to 30 percent DNA; and varying amounts of RNA, most of which is of the same kind as the RNA of ribosomes.

If all the DNA of a chromosome of a plant or animal cell were in the extended form, it would extend for several centimetres. At mitosis (cell division), the fully condensed chromosomes are thick elongated bodies only a few microns long. The packing of the very long genetic thread can be described in terms of a primary, secondary, and tertiary structure of the chromosome. The primary structure is that of extended DNA combined with proteins in threads 50 to 100 angstroms in diameter. The primary thread is tightly packed, perhaps by tight coiling but not necessarily so, to form thick threads about 200 to 300 angstroms in diameter. Such threads are commonly seen with the electron microscope. Further condensation involves folding or coiling the 200- to 300-angstrom threads into the forms recognized in the observation of condensed chromosomes with the light microscope; there is disagreement, however, as to whether folding or coiling occurs.

Chromosome condensation

The nucleolus. In many eucaryotic cells, especially those of higher plants and animals, the nucleoli are easily observed and were noted by the earliest microscopists. The nucleoli are best understood as parts of chromosomes and appendages to chromosomes. They are associated with definite regions of certain chromosomes in any given kind of cell; these regions are called nucleolus organizers. Structurally, the nucleoli are differentiated into a core containing a threadlike mass called the nucleonema and a peripheral zone full of particles. Chemically, the most conspicuous nucleolar constituent is RNA, which is in the process of being converted to ribosomal RNA.

PROCARYOTIC AND EUCARYOTIC CELLS

The distinctions between procaryotic cells and eucaryotic cells are morphological and became firm only when the electron microscope provided a sufficient picture of cell structure. Before that time, the existence of a procaryotic type of cell emerged from a nagging unease about the failure of microscopy to find a membrane-bounded nucleus and recognizable chromosomes in certain microorganisms.

Distinguishing features of procaryotic cells. As mentioned previously, the typical groups of procaryotic organisms are the bacteria, the mycoplasmas (minute organisms lacking the cell walls characteristic of bacteria), and the blue-green algae. All procaryotic cells are small, typically having linear dimensions below ten microns.

Procaryotic cells lack the internal components described above for eucaryotic cells, with the exception of the ribosomes. There is neither an internal membrane system nor mitochondria; the components are built into or attached to the surface membrane.

When viewed with the electron microscope, the surface membrane does not differ appreciably from the unit membrane of eucaryotic cells. Masses called mesosomes, which are inrolled extensions of the surface, are sometimes visible. The respiratory enzymes found in mitochondrial membranes of eucaryotic cells are located in the surface membranes of procaryotic cells, as are many of the other enzymes normally found in the interior of eucaryotic cells. It is of evolutionary interest that the cells considered to be the most primitive have so many components packed into a single membrane.

The motile flagella of procaryotic cells are molecular threads that extend outward from the cell surface. The flagella and cilia of eucaryotic cells, in contrast, are actually internal structures, consisting of the cell membrane and microtubules.

The procaryotic cell is so named because it lacks a distinct nucleus; it also lacks a nuclear membrane and a set of chromosomes. All of the genetic material is contained in a single circular molecule of DNA, about one millimetre long but densely packed. It is attached to the cell surface at the sites of the mesosomes. Cell division in procaryotes does not require an internal mitotic apparatus unless the cell surface is said to function as a mitotic apparatus. Procaryotic cells do not associate to form multicellular systems, and they lack the cytoplasmic bridging structures necessary for communication between cells, such as are found among eucaryotic cells.

The differences between the two kinds of cells are fundamental differences in design. Both carry out many of the same functions, however, and each is superior to the other in some respects; for example, no eucaryotic cell attains the rates of growth and reproduction of a procaryotic cell, which can double every 20 minutes. If the procaryotic cell is regarded as the more primitive, the argument must be based on evolutionary age; *i.e.*, procaryotic cells are believed to have appeared on the earth 1,000,000,000 years before eucaryotic cells.

Evolution of eucaryotic cells. Concerning the evolution of cell types, it has been suggested that eucaryotes—typified by internal membranes—may have originated with the enclosure of one procaryotic cell by another. There is one solid line of evidence: the fact that mitochondria and the plastids (small membrane-bound structures usually containing pigments) of plant cells retain many features of a procaryotic cell. The inner membrane of the mitochondrion and its contents is considered to be the evolutionary remnant of the original procaryotic surface membrane. There is some evidence that the chemical composition of the inner mitochondrial membrane is similar to that of the membranes of procaryotic cells. The interior of the mitochondrion contains ribosomes with the properties of those found in procaryotic cells; *i.e.*, procaryotic cells and mitochondria of eucaryotic cells contain smaller ribosomes with smaller subunits than are found in eucaryotic cells.

Procaryotic basis of cellular evolution

It is impressive that mitochondria contain DNA arranged in a ring and not combined with protein, as in the chromosomes of procaryotic cells. Another possible relict of a procaryotic origin of eucaryotic cells is the presence in dinoflagellates, a group of eucaryotic single-celled swimming protozoans, of chromosomes that resemble those of procaryotic cells.

Other arguments for the origin of eucaryotic cells from procaryotic cells are interesting and imaginative but are not factual. In fact, the molecular aspects of the two kinds of cells are astonishingly similar, but the structural designs are different in almost all important aspects. Common evolutionary origin of procaryotes and eucaryotes is not questioned, only the point of divergence between the two lines.

II. Functional aspects of cells in life

Contemplation of the living cell leads to the recognition that it exhibits behaviour and is a wiggling, streaming, growing, dividing thing capable of adapting to extraordinary conditions by responding to various stimuli. It recognizes other cells, communicates with other cells, and, in multicellular plants and animals, transforms it-

self according to genetic directions from the organism of which it is a part.

THE INTERNAL ENVIRONMENT AND THE CELL MATRIX

The conceptual image of the cell has passed between two extremes. On the one hand there has long existed the idea of a "protoplasm," implying the existence of a unique complex of matter—in effect, a supermolecule, in which are embodied the properties of life. At the other extreme is the idea that the cell is a "bag" containing a water solution of molecules or a bag containing a suspension of particles, such as mitochondria, ribosomes, and others, in an aqueous solution variously called the "soluble fraction" or cytosol.

If the latter image is considered, the nature of the internal environment can be described as follows. The cell water would contain a fair amount of macromolecular material; since about 50 percent of the proteins are soluble by conventional criteria, the cell water would be about a 10 percent solution of free macromolecules. From the analyses of the whole cell, it can be calculated that the internal environment would contain 0.1 to 0.2 molar—moles per litre of solution; each mole contains about 6.024×10^{23} atoms, ions, or molecules—potassium ions (K^+), 0.02 to 0.05 molar sodium ions (Na^+), 0.01 to 0.05 molar magnesium ions (Mg^{++}), and about 0.001 to 0.0001 molar calcium ions (Ca^{++}). There are some chloride ions (Cl^-), some sulfate ions (SO_4^-), and some phosphate ions (PO_4^{3-}); but most of the negatively charged ions (anions) would be organic acids. The pH (acidity, a measure of the hydrogen ion concentration) would be 6.9 to 7.2 (7 is neutral, lower numbers are acidic, higher ones basic). Some of these figures are misleading in one important way; for example, because much of the internal calcium is sequestered within internal membranes, the concentration prevailing throughout the cell is far lower than that measured by whole-cell analysis. In fact, the concept of "compartments" dominates much thought about the cell; figures such as the averages given above, therefore, do not necessarily reveal anything about the local environment in the living cell.

When the idea of a "protoplasm" was more prevalent than now, it was supposed that the matrix of the cell must have a characteristic structure. The physical properties of that structure were thought to be capable of definition by study of intracellular viscosity. If the matrix of the cell were an aqueous solution containing various proteins and ions, the viscosity should not be much greater than that of water; yet early work showed that the viscosity of "protoplasm" is highly variable; that, in different states of activity, the cell substance can behave as a watery fluid or as a fairly rigid substance (gel). Modern techniques have provided more substantial information about the cellular matrix; its viscosity has been found to be rather high—about 20 times that of water. The mechanical properties of the whole cell contents (called visco-elastic properties) have also been studied: the movement in a magnetic field of a small iron ball introduced into the cell and its recoil after the field has been removed reveal that the cell contents do have a relatively high viscosity—about 100 times that of water. The viscosity can be even higher; for example, the contents of a sea urchin egg become a very viscous gel at the time of fertilization. These results have led to the belief that there may be an as yet unexplored level of cell structure, indeed a structured matrix.

Mechanical properties of cell contents

The contents of the cell are variable; for example, internal membranes appear and disappear readily, as do microtubules. The molecular principle by which the formation of such structures is described is called the assembly principle. It is postulated that the cell contains a pool of free-floating molecules, which, under suitable circumstances, fall together spontaneously to form a structure. A conceivable alternative is that the molecules are not free-floating but already assembled and need only to assume the correct geometric order; in this case, the formation of a structure would be a transfiguration rather than an assembly. Such latent structure would be part of the underlying structure of the cell and thus would not be observed by present microscopic methods.

LIVING MEMBRANES

The surface membrane accounts for fundamental properties of the cell, the interior of which is never in equilibrium with the environment; in fact, an immediate sign of the death of a cell is the penetration of molecules that could not enter the living cell. If a nontoxic dye that does not penetrate living cells is added to a population of cells, for example, the number of cells that become coloured is the number of dead cells.

Membranes as barriers. The passive permeability properties of cells—their ability to take up certain substances without the expenditure of energy—have been well studied. The penetration of water is retarded, compared with free diffusion, as would be expected of a lipid layer; on the other hand, molecules soluble in lipids penetrate readily, independently of their size. Molecules soluble in water but insoluble in lipids, however, penetrate only if they are small; a molecular weight of about 100 is about the upper limit. Salts do not penetrate the membrane, which may be permeable to positively or negatively charged ions but not to both. These properties are exploited practically, as in the design of drugs that will enter cells or of blood plasma additives that will not.

Membranes and transport. The cell is not at the mercy of the passive properties of the membranes, however; it regulates the passage of molecules by the mechanism of active transport, employing a specific transport protein for each kind of molecule pumped into or out of the cell (see MEMBRANE, BIOLOGICAL). One important discovery of recent years has been that transport proteins (*e.g.*, sodium-potassium ATPase) may also be enzymes (biological catalysts) that split ATP (adenosine triphosphate); since the inside of cells is high in potassium but low in sodium and their environment is high in sodium but low in potassium, the cell must pump potassium inward and sodium outward.

Membranes and endocytosis. Most eucaryotic cells take up not only molecules but droplets of liquid (pinocytosis) and solid particles (phagocytosis); collectively these processes are termed endocytosis. During endocytosis, the cell membrane bends itself into a cup or channel, surrounding the droplet or particle; this piece of membrane is pinched off, forming a vacuole, which then passes to the cell interior. This process enables molecules and particles too large to pass through the membrane to enter the cell. The contents of the vacuole, however, cannot be used by the cell until the enclosing membrane has been broken down. The vacuole becomes a digestive vacuole, or phagosome, by fusion with lysosomes, particles that carry digestive enzymes.

Lysosomes

The lysosomes contain enzymes within their membranes that can digest such large molecules as proteins, nucleic acids, lipids, and carbohydrates; in fact, these enzymes destroy the cell if set free. Accordingly lysosomes are sometimes called "suicide bags." Within the digestive vacuoles (phagosomes), the enzymes of the lysosomes break down the material taken in by endocytosis, setting the products free for use by the cell. The used digestive vacuole may then pass to the cell surface, fuse with it, and eject undigested material outward.

Membranes and export. The internal membrane system often serves as a channel between the cell and the outer world. The endoplasmic reticulum, which often is associated with ribosomes, takes up proteins that are to be delivered to the outside. Proteins are made on the ribosomes, pass into the cavities of the endoplasmic reticulum, and are passed to the surface in vacuoles that fuse with the surface membrane. The Golgi apparatus plays a similar role but is thought to specialize in the formation and export of the polysaccharide-containing proteins that are important components of the outer coats of the cell. Cells that are very specialized for the movement of water and solutes into and out of organisms—such as cells of the gills of fish—undergo extensive development of internal vacuoles that sequester the water and ions on one side of the cell and carry them to the other for ejection.

Membranes have been imaginatively described as undergoing movements such as bending, engulfing, fusing,

pinching off, and migrating. Some of these processes, such as fusion, can be understood in terms of the physical properties of membranes themselves; others involve different intracellular mechanisms. Extensions of the cell surface in fingerlike processes called microvilli, which increase the surface area of a cell, are supported by microfilaments inside the microvilli. Similarly, the formation of the vacuole during endocytosis depends on microfilaments, as does the active ruffling, wavelike motions of cell surfaces. The projection of the surface membrane to form a cilium of flagellum, the length of which can be greater than the diameter of the cell, is supported by microtubules.

Membranes and the generation of electricity. The generation of electric currents by cells depends on the properties of the surface membrane. There is a bioelectric potential—a voltage drop caused by biological processes—across the cell surface, typically about 0.06 volt (60 millivolts), with the inside of the cell negative. This potential depends on the concentration differences of ions across the surface and sometimes on the active pumping of ions. Electric potentials occur in all cells studied thus far, although their biological importance is recognized in only a few cases. The properties of membranes have been extensively developed in nerve cells, making possible the conduction of nerve impulses.

Responses to stimuli. Responses to stimuli involve changes of state in cells, and such responses are purposeful in the sense that they serve survival in some way; for example, it was proposed some decades ago that one of the first responses to a stimulus is the release of calcium ions (Ca^{++}) within the cell. In the case of muscle, it is now known that most of the calcium ions within a muscle cell are sequestered in the internal membrane system (sarcoplasmic reticulum) that surrounds the contractile fibrils. The concentration of calcium ions near the fibrils of a resting muscle is very low; when the muscle cell is stimulated, the sarcoplasmic reticulum releases calcium ions to the fibrils. The ions are required for the activity of the enzyme (calcium-sensitive ATPase) that catalyzes the breakdown of ATP during the contraction of the fibrils. Relaxation involves the rapid pumping of calcium ions back into the sarcoplasmic reticulum.

Reception of stimuli by cells

The initial reception of the stimulus is also a membrane event. It is signalled by a wave of depolarization—a change of the electrical potential across the cell surface—that reflects an increase in the penetrability of sodium ions followed by an active pumping out of sodium ions (see MUSCLE CONTRACTION; NERVE IMPULSE).

INTERPLAY OF NUCLEUS AND CYTOPLASM

Overall function of the nucleus. In the eucaryotic cell, most of the genetic information resides in the nucleus. Because the existence of the nucleus was recognized from the early days of microscopy, there were many speculations as to its functions. One basic experiment was to remove the nucleus and to observe the enucleated cell; invariably the cell lived more or less normally for a while and then died. If a nucleus was restored in time, the cell revived. The main function of the nucleus is to make gene products called messenger RNA (mRNA), which pass into the cytoplasm and there direct the synthesis of new proteins. The cytoplasm of a cell deprived of its nucleus survives for a while because it can function with existing proteins until they have to be replaced. Some mRNA molecules remain active for extended periods of time (hours or days) in some eucaryotic cells, although this is not the case in procaryotic cells. In such eucaryotic cells, therefore, the proteins can be replaced until the mRNA no longer functions, and the cell can live for days or weeks—but not indefinitely—without a nucleus.

Most of the many enzymes in the nucleus are found in even larger amounts in the cytoplasm. The nucleus is, however, the main site for a relatively few enzymes concerned with such processes as the making of the nucleotides of which the nucleic acids are composed; the replication of DNA; the transcription of DNA into RNA; and the regulation of these processes. The proteins associated with DNA (histones) are formed in the cytoplasm.

Exchange between nucleus and cytoplasm. Among the substances shuttled between nucleus and cytoplasm are proteins. Although it has been established that certain proteins pass back and forth through the nuclear membrane, their function is not clear. It has long been inferred, but could not be proved, that nucleus-cytoplasm interaction is a two-way process and that the cytoplasm does more than transfer raw materials and ATP into the nucleus for purposes of synthesis. Now the problem has been studied by using certain viruses (Sendai viruses) that change cell membranes so that adjacent cells fuse; as a result, their nuclei share a common cytoplasm. The fusion of a growing cell (the nucleus of which is making RNA) with a nongrowing cell (the nucleus of which is not making RNA) will turn on RNA synthesis in the latter. It has been shown that signals to or between nuclei can pass through the cytoplasm. Apparently, some of the signals are not very specific, since the same results are obtained when cells from quite unrelated organisms are fused. The molecular nature of the signal has not yet been established.

The effect of the cytoplasm on the nucleus can be summarized by the following generalization: whenever several nuclei share the same cytoplasm, their activities tend to become synchronized.

CELLS IN SOCIETIES

The evolution of multicellular life, as it occurs in higher plants and animals, requires the extension of the cell concept to include means by which cells can combine, communicate, contribute to the survival of the collective society, and respond to the regulatory actions of the organism as a whole. The organism as a whole is a society of cells, all of which possess the same genes. In the society different cells acquire different structures and functions in a process called differentiation; in each kind of cell, some genes are active, others not. The life-span of the organism is limited, so that most of the cells ultimately die; but the organism is propagated in kind by reproduction through germ cells, ova (eggs) and spermatozoa, which initiate the development of succeeding generations of the same kind of organism. Some diseases—of which cancer is an example—can be described as the escape of cells from the rule of the organism.

The organism level of cellular organization

Individuality of cells. The idealized cell, as so far described, is very much insulated from other cells. It can maintain its own internal environment; it can proceed on its own timetable, its processes not in synchrony with those of its neighbours; and it can be different morphologically and functionally from neighbouring cells. Although fusion of membranes within the cell is common, cells normally do not fuse to other cells, probably because of some property, perhaps involving the polysaccharides, of the outer surfaces of membranes.

Cells in culture. Cells can be taken out of organisms and grown as individual cells in culture. One observation noted from isolating cells in this way is that many that do not divide when in the organism do divide when grown as individuals in cultures. Equally impressive is the fact that the cells quickly—after a few generations of cell division—lose their distinctive structures and revert to a few general types. Specialized animal cells, for example, revert to elongated, spindle-shaped cells called fibroblasts; or to bricklike epithelioid forms (*i.e.*, that resemble the cells of cavity linings such as the inside of the mouth). It has been observed, however, that the fibroblastic form is maintained by microtubules and can be converted to an epithelioid form by the action of the microtubule-attacking drug colchicine. In studies of the biochemical rather than the morphological characteristics, it has been found that the distinctive synthetic abilities of cells within the original organism are often lost; *e.g.*, cells cultured from mammary glands no longer make the milk-producing enzymes, but cells derived from the retina of the eye may retain the ability to make pigments. Such evidence demonstrates the rule of the organism over the character of cells.

When cells derived from multicellular organisms are cultured for many generations, they undergo a kind of

evolution. The chromosome set (karyotype) tends to change; *i.e.*, the numbers and kinds of chromosomes are no longer the same as in the original organism. Certain karyotypes, presumably those best adapted to life independent of the organism, survive in culture and become cell lines, which are populations of cells capable of indefinite propagation. In some cases it is possible to maintain diploid cell lines—that is, cells that maintain the original chromosome set. Such lines tend to die out after a certain number of generations, however—about 50 in some cases. It is as if aging is built into body cells (but not germ cells) and is overcome when cells are grown in culture by modifications of the chromosome set.

Cell cultures are now a widely used tool in research on the cellular problems of higher organisms, especially mammals—differentiation, effects of the environment, cancer, immunity, and especially heredity are studied (see TISSUE CULTURE).

Cell junctions. Cells in the organism are not walled off from each other. In many groupings of cells in tissues, cell junctions can be detected by a physical method or by electron-microscopic observation. The physical method draws on the fact that cell membranes have a very high electrical resistance. If two unjoined cells are placed side by side, an electrode is put inside each, and an electrical potential imposed, there is an extremely high resistance to the passage of current across the two membranes. The electrical resistance between two cells in a tissue—in fact among all the cells of a tissue—however, may be quite low. Some low-resistance channel therefore exists at the apposed membranes; such channels are called junctions, and cells joined by them are said to be electrically coupled. The structure of cell junctions has been studied extensively. Cell membranes, even in a densely packed tissue such as epithelium, normally do not touch each other but are separated by about 150–200 angstroms of intercellular space. This space contains the extracellular cementing material, which is rich in polysaccharides. At the site of junctions, the membranes come very close and, in some cases, may even appear to fuse in rather elaborate structures called desmosomes. In other cases, the two membranes may seem to be held together by cross-connections in a configuration called a septate junction. The exact nature of the substances that pass across the junctions has not yet been established, although it is known that they permit the passage of ions and small molecules.

Structural features of cell junctions

The ability to form junctions is a general property of membranes of cells that normally live in an organism. Cells grown in culture will also form junctions if their numbers become so great that they are pressed against each other. Moreover, junctions may be formed in culture between cells of quite different kinds; such cells would not be joined in an organism.

Recognition and association among cells. Cells in tissues may be experimentally separated from each other in various ways: by procedures that dissolve the intercellular cements; by the use of proteolytic—protein-attacking—enzymes; and by the removal of calcium ions from the environment. Remarkably, cells in tissues can reassociate when returned to a normal medium. Such experiments are most successful when cells from embryos are used. In such cases not only do the cells join but they organize themselves—outside the organism—into excellent facsimiles of normal tissue organization. If two kinds of cells are used (*e.g.*, kidney cells and retinal cells) they sort out to form groupings resembling the two original tissues. If the same kind of cells, but from different species, are mixed, they form a tissue consisting of a mixture of cells of the two species; that is, they organize according to the functional kind of cells they are, not according to the species from which they came.

Some research has been done on the molecules that guide such recognition and association. The molecules are proteins, probably those of the outer coats of cells.

III. The cell cycle—growth and division

Cells have short lives as individuals, but they reproduce. The cell cycle—doubling of a cell in size by growth, then division into two cells, which double in size and divide—guarantees survival of the species if, during division, the daughter cells obtain a set of genes identical to those of the mother cell.

CELL GROWTH

Doubling. During interphase, the period from the "birth" of a cell to the time when it divides, a cell duplicates itself. Experimentally, the doubling may be followed as an increase in volume, mass, or protein content.

The duplication process, or doubling, is relatively exact; careful measurements have shown that the cell stops growing when its mass is twice that at birth with a variation of only about 10 to 15 percent. (Exceptions are micro-organisms grown in very rich conditions; they may divide before they have doubled.) Cells that will not divide again sometimes grow to be more than twice their birth size.

Attention has been devoted to the growth curves (*i.e.*, plots or graphs) of cells as they double; such curves reveal whether growth is linear, exponential (*i.e.*, an accelerating growth rate), or follows some other path. The genetic functions of the growth period involve the readout of the genes—the conversion of the information contained in a gene to a chemical structure—that results in the synthesis of enzymes. It is known that some genes are read out continuously during the period of growth; others are read out in a specific sequence. An increase in the rate of growth depends on the production of enzymes involved in protein synthesis; if production increases continuously, the growth rate increases continuously. Both linear and exponential growth curves—and some that show sudden changes in the rate of growth—have been found in different cells.

Explanation of growth rates in cells

Genetic replication. Cell division is the equipartition of replicated (doubled) chromosomes, but the replication process (*i.e.*, duplication of chromosomes) takes place in anticipation of division. After the replication of chromosomes begins, it goes to completion, and the cell is committed to divide. The chromosomes of differentiated cells that never divide do not replicate. The replication of chromosomes is measured experimentally as the appearance of "new" DNA, detectable by using radioactive isotopes of substances that are incorporated in the new DNA.

In the typical eucaryotic cell (*i.e.*, in most plant and animal cells) the period of chromosome replication is a so-called *S* period, which takes place about the middle of interphase (the phase of growth between successive cell divisions). The period of interphase preceding the *S* period is generally called *G1*, and the period from the end of the *S* period until the onset of mitosis is called *G2*. The whole of interphase is longer than the period of division; typical schedules of the cell cycle, using the *S* period as the reference point, are shown in the Table. Cells of plants and animals require about 12 to 24 hours to complete their cycle, and the replication of the chromosomes generally takes several hours. Within a species, there can be great uniformity of the duration of the *S* phase from cell to cell. The *G1* period, which is not yet completely understood, is the most variable; it must include processes that decide the future division of the cell; if the transition from *G1* to *S* takes place, the cell is committed to divide.

Typical Schedules of the Cell Cycle

phase	duration (in hours)	
	in a mouse fibroblast	in a bean root cell
G1	6	10
S	8	7
G2	5	6
Mitosis	1	1

Many unicellular eucaryotes double in a few hours; many procaryotes, however, double in less than an hour. In procaryotes there is no *G1* or *G2;* chromosome repli-

cation occupies the whole of interphase. Some kinds of eucaryotic cells, such as many kinds of eggs in the early stages of division (cleavage) or in plasmodial slime molds, have no *G1; S* begins at the end of division and may require only ten to 15 minutes. In animal tissues, some cells remain in *G2* for a long time but enter mitosis immediately upon injury to the tissue. Thus these "*G2* populations" represent an immediate reserve of cells ready to divide for healing processes, without the need to wait for cells to go through the full 24-hour cycle.

Replication of chromosomes

The typical long *S* period involves chromosomal replication, which occurs according to a specific program. Although the DNA in an individual chromosome is physically continuous, it is not continuous for the purposes of replication; instead there are replicating units, regions of the DNA at which replication can be initiated and proceed. A reasonable estimate of the number of replicating units in the chromosomes of a plant or an animal is about 1,000. Replication begins earlier in some chromosomes than in others; however, some chromosomes—the sex chromosomes, for example—typically replicate later than the others. On a given chromosome, different replicating units replicate in a definite order, not necessarily in sequence from one end of the chromosome to the other. In summary, the *S* period is a time during which the replicating units complete the program—each makes one copy of itself. At the end of the *S* period there are two sets of chromosomes, which will become visible after the *G2* events have been completed.

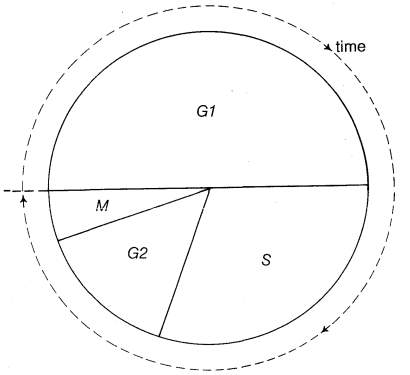

Figure 2: The time course of the cell cycle, showing the relative amount of time a cell spends in each of the phases of growth and division. *M*, time of mitosis; *G1*, interval between end of mitosis and onset of DNA synthesis; *S*, DNA synthetic phase; *G2*, phase between DNA doubling and onset of next mitosis (see text).

When cells whose chromosomes have different durations for the *S* period are fused, both nuclei enter *S* at the same time but need not complete it at the same time. This is because the initiation of the *S* period is a distinct event of the cell; the completion of *S* is determined by the chromosomes.

Preparations for mitosis. Certain events of interphase involve preparations for division; the distinction is meaningful since such events need not take place in cells that grow but will not divide. One of the obvious preparations is the replication of the chromosomes. Another is the replication of the centrioles, bodies that (in animal cells and some others) determine the poles to which the chromosomes will move. The mitotic apparatus, a spindle-shaped structure in the cytoplasm, consists of proteins; the best known are those forming the microtubules of the mitotic spindle. Evidence indicates that a cell will not enter division if the synthesis of proteins is interrupted during interphase, even if the interruption occurs shortly before division. It has also been established that microtubule proteins are synthesized before division.

MITOSIS

Mitosis in eucaryotic cells can be defined as the separation of sister chromosomes to the opposite poles of the mitotic apparatus. Procaryotic cells have no mitotic apparatus unless special devices in the cell membrane, not yet discovered, move chromosomes; it will be recalled that the chromosomes are attached to the membrane at sites called mesosomes (see above *Distinguishing features of procaryotic cells*). Apparently, growth of the membrane between the attachment points of sister chromosomes moves them apart. Separation of chromosomes is part of growth in procaryotic cells; the eucaryotic cell ceases to grow during mitosis.

The typical mitosis sequence of a eucaryotic cell can be displayed in a diagram (see Figure 3). The major events are the chromosome cycle and the alignment and deployment of the chromosomes by the mitotic apparatus in the cytoplasm. The nuclear membrane breaks down when the chromosomes are engaged by the mitotic apparatus. Chromosomes make attachments to the poles in such a way that each sister chromosome is attached to a different pole. The attachments, seen as spindle fibres, appear to draw the sister chromosomes to opposite poles. At the end, the chromosomes are no longer condensed, and a new nuclear membrane forms around each group of chromosomes. Then the cell divides in two.

Variations in the pattern of mitosis

Observation of more primitive and smaller eucaryotic cells using electron microscopy has resulted in the recognition that this generalized pattern of mitosis applies mainly to multicellular plants and animals. In many unicellular eucaryotic cells, the nuclear membrane does not break down. In cases in which the mitotic apparatus is inside the nucleus, elongation of microtubules results in elongation of the nucleus, which pinches in two after the chromosomes have separated. In other unicellular forms (*e.g.*, the flagellated protozoan *Barbalunympha*, found in termites and related forms), a spindle forms in the cytoplasm but the nuclear membrane does not break down. The spindle fibres connect to the chromosomes at the nuclear membrane, separating them as the spindle elongates. In the unusual case of the dinoflagellate protozoans, in which the chromosomes resemble those of procaryotic cells, the spindles consist of bundles of microtubules that run through "tunnels" in the nucleus and attach to the chromosomes, which remain inside the nuclear membrane. In most of the following discussion, mitosis is treated as it is seen in multicellular plants and animals.

Special structures in mitosis. *Centrioles.* Centrioles are bodies that define the poles of mitosis in animal cells, some plant cells, and some lower forms; they are not seen as such in the cells of higher plants. Poles can be identified by the presence of visible particles whose behaviour reveals something about important mitotic events. Even though visible centrioles are lacking in plant cells, there are no good reasons to propose different mechanisms of mitosis. It may be assumed that the true pole is some part of the centriole that can be recognized and that an equivalent body will eventually be found in cells in which the poles are apparently not marked by particles. The idea of the poles themselves is unambiguous: they determine the axes of the spindle and of the spindle fibres, and they are the points toward which chromosomes separate. The cell usually divides in a plane midway between the poles and at right angles to the axis connecting them.

The animal centriole has a well-defined structure; typically, it is a cylinder about 0.5 micron long or longer and 0.5 micron in diameter; the centriole can be resolved into nine groups of short microtubules arranged as cylinders. Each group consists of three microtubules, each of which is slightly different in length. Particles may be arrayed around the centriole. The kinetosomes, which organize the microtubules of cilia and flagella at cell surfaces, are similar in structure and derive from centrioles.

In yeasts, definite centrioles with a different morphology from that of the animal centriole are found. Some flagellate protozoans have structures that have been called centrioles by virtue of their functions.

The centrioles are regarded as self-replicating bodies. Even though there is as yet no good evidence that they contain DNA, it is significant that they can be seen to re-

produce during the *S* period of the cell. The centriole does not divide, but a daughter centriole, a procentriole, grows out from one end—almost always at right angles to the axis of the mother centriole. This generative form of reproduction suggests that somewhere in the centriole is a seed that replicates to produce a daughter, which can then organize another centriole. In most cases centrioles occur as pairs, a mother and a daughter at right angles to each other. The mitotic poles are normally observed as such pairs, but it is known that each member of the pair, given time to separate, can form a pole.

Kinetochores. The kinetochores, also called centromeres, are regions of condensed chromosomes that attach to spindle fibres and thus to the poles. Their positions on the chromosomes are so well defined that the shapes of chromosomes are accounted for by the positions of the kinetochores, which act as bending points or constrictions. If a chromosome loses the part containing the kinetochore, as can occur after radiation, it cannot attach to the mitotic apparatus and will be ejected and lost at mitosis.

When viewed with the electron microscope, kinetochores appear as a region denser than the rest of the chromosome, sometimes layered, at the points of attachment of the microtubules of the mitotic spindle. The kinetochores as structures have been seen only in condensed mitotic chromosomes. Evidence indicates that they are attached to the nuclear membrane before it breaks down.

Chromosome behaviour at the beginning of mitosis

The chromosome cycle. In mitosis, the tertiary or highly condensed structure of chromosomes develops. In light microscopy, thin, long threads that define the early prophase stage of mitosis become resolvable, and they soon became shorter and thicker. There is increasing evidence that the chromosomes occupy definite positions in relation to each other: the kinetochores are near the nuclear membrane; the ends of the chromosome arms attach at early prophase to form a chain of chromosomes; and homologous chromosomes—chromosomes of the same kind but from different parents—are next to each other. The condensation does not depend on the mitotic apparatus; it goes to completion even in the presence of colchicine, which prevents the formation of a mitotic apparatus. The condensation proceeds past the time of the breakdown of the nuclear membrane and even past metaphase (the stage of mitosis at which all the chromosomes are aligned on the plane of cell division); maximum condensation is seen at anaphase (the stage of mitosis when the chromosomes are separated and are approaching the poles of the mitotic apparatus).

It is known that condensation is a distinct event, elicited by a specific cytoplasmic signal. Mitosis can be delayed by small doses of irradiation, and it has been proved that the delay is accounted for by a delay in the onset of prophase condensation of the chromosomes; whatever invokes condensation is sensitive to radiation. If a cell in mitosis, with condensed chromosomes, is fused with a cell in any other phase of the cell cycle, the chromosomes of the latter cell condense. If these chromosomes happen to be in the *S* period of interphase, they condense in fragments, as though the chromosome were not physically continuous during its replication period.

Early stages of the formation of the mitotic apparatus. Even as the chromosomes are condensing within the still-intact nuclear membrane, the mitotic apparatus may begin to assemble and to form poles. In the light microscope the assembly may be seen as the formation of a clear zone near or around the nucleus. The clarity of the developing mitotic apparatus is significant; as its constituents are assembling in a dense mass, larger particles of the cytoplasm, such as mitochondria, are ejected. The focus of the assembly is seen to be the centriole—more accurately, the two centrioles, each consisting of a fully grown centriole and a procentriole growing at right angles from it. The material being assembled consists of a matrix of densely packed vesicles, which sometimes extend radially from the centrioles, and microtubules, which radiate from the centrioles. In many cases, in both plants and animals, the developing mitotic apparatus polarizes even before the breakdown of the nuclear membrane, and it can be determined where the chromosomes will go even before they are committed. There are even cases in which the early spindle passes right through the still-intact nucleus, which has the conformation of a doughnut.

The cell is thus polarized for mitosis, and the direction of movement of the chromosomes is determined, as is the plane of cell division. The two poles, each defined by a pair of centrioles in the animal cell, are connected by the spindle, which contains bundles of microtubules running from pole to pole. Although the pole-to-pole microtubules are described as "continuous," evidence indicates that they consist of tubules coming from the two poles and joining at overlapping ends. It is not known how the poles move apart; perhaps they are "pushed" apart by the growth of the microtubules between them. The separation of poles has not yet received serious study.

Engagement of chromosomes and metakinesis. The breakdown of the nuclear membrane is another important mitotic event that has not yet been studied intensively. The kinetochores are engaged to the poles by spindle fibres composed of microtubules (chromosome-to-pole fibres). Other parts of the chromosomes do not make connections to the poles, and kinetochores still function if chromosome arms are lost. The connections, if broken, are remade. If a chromosome is pulled away from the forming mitotic apparatus and its connections severed,

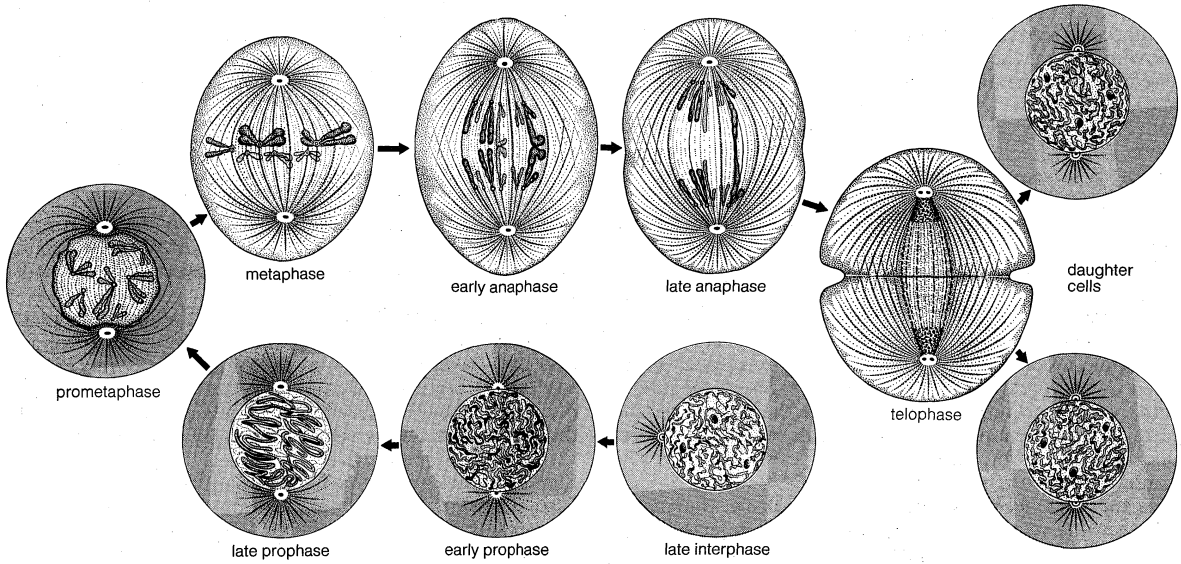

Figure 3: Stages of mitosis.

the connections reform, and the chromosome is moved back into position.

Determination of the direction of chromosome migration

The great mystery of the engagement of the chromosomes is the exclusion principle, according to which sister chromosomes must attach to different poles; there are almost no exceptions. It is as if both sister chromosomes and sister poles could join in no other way.

In some kinds of cells, the engagement of the chromosomes to the mitotic apparatus is not simply a question of attachment of kinetochores to poles. In the cells of craneflies, for example, the microtubules running from pole to pole pass right through the chromosomes, which appear to be threaded by the continuous spindle fibres rather than attached to the ends of chromosome-to-pole fibres.

Once the connections are made, the chromosomes begin to move in the process called metakinesis, the termination of which is the disposition of the chromosomes in a plane midway between the poles; this forms the equatorial plate or metaphase plate of the cell. Whatever the path followed by a chromosome, its movement is accounted for by the movement of the kinetochore. The process requires a mitotic apparatus and, in that sense, is executed by mechanisms similar to those that later move the chromosomes to the poles. However the movement is generated, it is best describable as the attainment of an equilibrium in which the chromosomes lie on the equator because the force imposed from the two poles is equal. More difficult to explain is the fact that individual chromosomes in the metaphase plate can have definite positions relative to each other, the same in every cell. Sometimes the smaller chromosomes are closest to the central axis, the larger on the circumference of the plate. In other cases, such as plant cells with large chromosomes, the kinetochores are arrayed around the circumference of the equatorial plate with the arms of the chromosomes dangling outside the spindle.

The duration of metaphase is the time during which the chromosomes lie on a metaphase plate (oscillating a bit back and forth across the equator) before they begin to separate toward the poles.

Anaphase movement. The separation of sister chromosomes is an event in that it involves a definite signal or process, all of the sister pairs separating at the same time. If fragments of chromosomes lie outside the mitotic apparatus, as occurs in radiation-damaged cells, they also split at the same time; the event thus is broadcast through the whole cell.

Anaphase movement, the actual separation of sister chromosomes to the poles, is regular in that chromosomes of a set usually move at nearly the same speed. The speed is not related to the size of the chromosomes; in fact, the speeds of anaphase movement are remarkably similar in many kinds of cells—about one micron per minute.

Anaphase separation of chromosomes not only involves movements of the chromosomes to the poles but also movement of the poles further apart—*i.e.*, elongation of the whole spindle. Although both processes take place in most cells, they usually do not occur simultaneously. In some kinds of cells, elongation of the spindle is the main factor in increasing the distance between sister chromosome sets; in other cells, the decrease of the chromosome-to-pole distance accounts for most of the separation.

Structural aspects of the mitotic apparatus. The structures corresponding to the spindle fibres of classical microscopy are bundles of microtubules. Two kinds exist: pole-to-pole fibres and chromosome-to-pole fibres. Neither pole-to-pole fibres nor chromosome-to-pole fibres need be continuous; the former may represent the lateral joining of microtubules coming from the two poles, the latter the lateral joining of microtubules from the kinetochore with microtubules from the poles, although the configurations are not yet established.

As the chromosomes separate in anaphase, the region between the two groups of chromosomes (interzonal region) has a different structure and fewer microtubules than the regions poleward from the chromosomes (half spindles). Between chromosomes and poles, the matrix in which the microtubules lie is a dense mass of vesicles, excluding mitochondria and larger particles. The structure of the microtubules does not change during anaphase—they may grow shorter or longer but not thicker or thinner.

Mechanisms of chromosome movement. Most earlier theories of chromosome movement—those that invoked electrical or magnetic attractions, jet propulsion, tactoid bodies (spindle-shaped colloidal particles), autonomous migration of chromosomes, and others—have been discarded in their original form. Current theories are devoted to microtubules and appeal to contractile mechanisms, following the visual indications that spindle fibres grow longer and shorter. One view is that the fibres (microtubules) are in a dynamic state of assembly and disassembly, in equilibrium with a pool of unassembled molecular units. The shortening of a microtubule would be explained by a return of some of its molecules to the pool, a "degrowth," so to speak. The elongation of a microtubule would be explained by the insertion of molecules from the pool; the inherent structure of a microtubule would demand that such growth could be only an elongation.

An explanation of microtubule shortening

Another more recent view draws on the sliding filament mechanism of contraction that has been successful in explaining muscle contraction. In such a mechanism, two filaments slide past each other; shortening is seen as increasing overlap. In muscle the sliding depends on structural bridges between parallel filaments. Such bridges have been observed between microtubules of the mitotic apparatus. If microtubules from kinetochores slide toward the poles along microtubules from the poles, the span of the overlap should increase, and the number of tubules seen in cross sections of the poleward halves of the spindle should increase; data suggest that this occurs.

Descriptively, the exactness of chromosome separation does depend on the shortening of the distance between chromosomes and poles, although it is achieved in some cells by the lengthening of the distance. Several theories deal with these changes in terms of microtubules. It has been asked, however, if it is possible that the behaviour of the microtubules represents the guidance system without necessarily being the motor.

Metabolic aspects of mitosis. In eucaryotic cells, growth stops during mitosis; in procaryotic cells, there is no interruption of growth during the cell cycle. The arrest of growth in the eucaryotic cell is associated with the condensation of the chromosomes. In early prophase, however, there is still RNA synthesis on the chromosomes; and DNA synthesis for repair, but not for replication, is observed. During mitosis, a residual synthesis of proteins occurs; it may be important but is not massive enough to be measured as growth. The composition of the chromosomes themselves changes. During condensation, the nucleolus—which is a body in which ribosomal RNA is being processed at certain genetic sites—breaks down. By various criteria, all components of the chromosome reflecting the nucleolar function are shed during mitosis and recaptured at the end of mitosis. More generally, there is a loss of nuclear RNA early in mitosis and a recapture of it at the end of anaphase. The enzyme presumably responsible for the replication of DNA (a chromosomal DNA polymerase) is shed in chromosome condensation and restored to the chromosomes at the end of mitosis.

Metabolism other than the synthesis of macromolecules continues through mitosis. Some fluctuations of respiration have been described, but the mitotic cell can make ATP. ATP is required for mitosis, either as an energy supply or as a reagent serving some other function. When the production of ATP is arrested, as by removal of oxygen, mitosis stops (at least in the sea urchin egg) when the ATP content of the cell falls to half its original level. This is surprising because the requirements of mitotic movements for energy are very small; it has been calculated that a minute fraction of the energy available to the cell suffices for chromosome movement. Part of the

requirement is not for movement but for the maintenance of structure; that is, if the ATP level falls too low, the mitotic apparatus disorients and perhaps disassembles. The mitotic apparatus thus is a dynamic structure, requiring ATP to hold together.

Telophase—restoration of nuclei. After chromosomes have completed their poleward movement, they decondense and surround themselves with a nuclear membrane. The telophase process is best described by considering a rather atypical case in which it is rapid and foreshortened. In many cleaving egg cells, for example, each chromosome begins to decondense as soon as it reaches the pole. As the chromosome reaches the pole, it surrounds itself with a double membrane with pores, a typical nuclear membrane. Early in the process the nuclear membrane can be seen forming in patches over a chromosome before it covers it entirely. Such a process of forming karyomeres, or individual membranes around each chromosome, is possible in any cell if a given chromosome is far from the others; each chromosome can lay down nuclear membrane. In the egg cell, the karyomeres fuse, so that all the chromosomes are finally contained within a common nuclear membrane. In more typical cases, the chromosomes decondense more slowly, and the group is surrounded by a nuclear membrane. If the chromosomes are associated with the "pores," it can be imagined that the chromosomes are the sites of formation of these annuli, which in turn determine the pattern of assembly of the two membranes.

Reformation of the nuclear membrane

The other remarkable event of telophase is the recapture of nuclear constituents that were lost in prophase. Not only do the nucleoli reconstitute, but they regain some of the molecules that were lost earlier. Generally, RNA that was lost from the mother nucleus is recaptured by the daughter nuclei. It is a puzzle how they return to the nucleus if these molecules were scattered through the cell.

Cytokinesis—division of the cell body. Superficially, the division of typical animal cells is seen as a pinching of a sphere into two spheres by constriction in the plane of the mitotic apparatus. The obvious hypothesis, that there is in fact a contractile ring around the belly of the dividing cell, was advocated through a period when other alternatives were prominent. The subjective impression was confirmed objectively only when, with electron microscopy, microfilaments were identified; more recently, the drug cytochalasin has become available to intervene in the functions of microfilaments. In fact, there is a contractile ring of microfilaments underlying the surface of dividing cells at the equator, and cytochalasin prevents the division of the cell body. The mechanism of cell division in animal cells thus becomes part of the more general problem of cell movements involving microfilaments. The ring of microfilaments, however, forms only around the equator defined by the poles of the mitotic apparatus; therefore it must be determined by these poles. It is not known if this determination is an event that takes place sometime earlier in mitosis. Beyond a certain point (metaphase or early anaphase), the mitotic apparatus may be removed and the cell will still divide in its now-predestined plane. Experiments support the idea that some determinant of the formation of the division furrow passes from the poles to the surface; even fragments of cells containing a piece of the surface so determined will constrict.

Cell division in plants

Plant cells, confined in cell walls, do not divide by constriction; new membranes form across the equatorial plane of the mitotic spindle. The movement of microtubules toward the equator after chromosome separation has been completed is prominent and must be an important part of the process of building partitions between the sister nuclei. The other conspicuous part of the process, one that is also seen in animal cells, is the aggregation of internal membrane components (or vesicles) along the equatorial plane. These gather and fuse to make the two membranes separating the sister cells. In plant cells, the plane of division can be predetermined; there are cases in which, after the nuclei have been displaced in a cell, it will divide along the somehow-established plane to produce one cell with two nuclei and another without a nucleus. From the standpoint of the plant, true cell division as the partitioning of each nucleus within a separate cell membrane is only the first step. The next is the laying down of a phragmoplast, a surface layer that will develop into a cellulose wall.

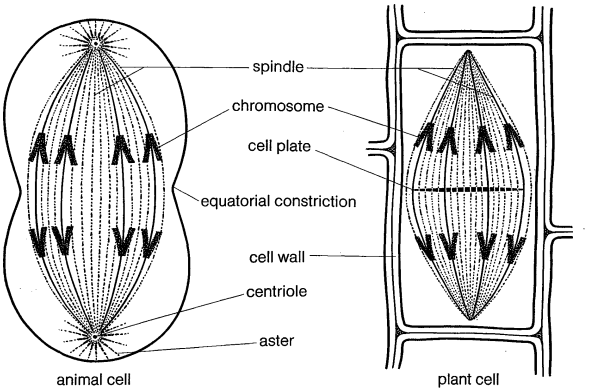

Figure 4: Comparison of cell division in a generalized animal cell and a generalized plant cell.

In procaryotic cells, cell division is less rigidly linked to the procaryotic equivalent of mitosis. It has been shown that certain cells incapable of replicating their chromosomes will nevertheless divide, producing some cells lacking DNA entirely; despite the absence of DNA, the coordination between chromosome separation and cell division in normal procaryotic cells assures that daughter chromosomes will be segregated into daughter cells.

MEIOSIS

The events and significance of meiosis. The meaning of meiosis, cell division that produces daughter cells with half the number of chromosomes of the parent cells, relates not to the everyday life of the cell but to genetics and evolution. As a process that involves halving of the chromosome number, its events differ in important respects from those of the somatic cell cycle; in addition, the homology of chromosomes (*i.e.*, their similarities and origins) becomes important. The diploid or double set of chromosomes in ordinary cells consists of two haploid or single sets, one from each parent; the members of each pair (homologues) are identical in appearance and contain the same kinds of genes in allelic, or different, forms. The pairing of the homologous chromosomes in the preliminary prophase of meiosis divides the number of chromosomes in half; a pair of homologues behaves as one chromosome. Each homologue has replicated before the pairing; after pairing, the chromosomes are bivalents, structures consisting of two parts (homologues), each of which is a pair of sister chromosome strands. With the number of chromosomes now reduced by pairing, the cell undergoes two divisions. The first meiotic division separates the homologues; the daughter cells receive half the number of chromosomes characteristic of the organism, and the two are not genetically identical. Each kind of chromosome is represented in this haploid set, however. Because the separation of homologues is random, each daughter cell can have any permutation of chromosomes of maternal or paternal origin. The second meiotic division merely separates the already-doubled sister chromosomes. The genetic recombination—literally the random sorting of maternal and paternal genes in one chromosome set—is enhanced by the fact that crossing over—the homologues exchanging pieces of chromosomes—between paired maternal and paternal chromosomes had taken place at the time of pairing. Thus the combination at fertilization of male and female germ cells, each having an haploid set of chromosomes, assures that individuals of successive generations of sexually reproducing organisms will have the same chromosome complement: one haploid set from each parent. From an evolutionary standpoint (otherwise there would be no real significance to sexual reproduction), it

assures that all possible combinations and recombinations of genes can be realized.

Differences between meiosis and mitosis. Meiosis differs from mitosis in a few important respects. There is no pairing of homologous chromosomes in mitosis, but evidence indicates that they are in propinquity even in ordinary cells. Somatograms, pictures that describe the arrangements of mitotic chromosomes in mitotic prophase, show that all the chromosomes are attached end-to-end in a chain and that homologues are attached to each other. It has been shown that homologues lie side by side in metaphase plates. If these findings are general, the problem is not so much how homologues find each other but how they pair so closely and exactly. Homologous genetic regions come together and can be exchanged by crossing over. At least a structural basis has been found; chromosomes pairing in the zygotene stage (one of the stages of the meiotic prophase) do not merely lie side by side; they are firmly joined by a structure, the synaptinemal complex, which is not seen in mitotic prophase. Overall, the synaptinemal complex is a ribbon-like structure about 1500 to 2000 angstroms wide running between the opposing faces of the homologous chromosomes. It resolves into a central element running down the middle of the space between the chromosomes, with dense lateral elements along the faces of the chromosomes and fibres running across the space.

Structural basis of meiotic chromosome pairing

The orientation of kinetochores in meiotic chromosomes differs in an instructive way from that in mitosis. In mitosis, in which the sister chromosomes will move in opposite directions, the kinetochores lie on opposite sides of the pair, facing in opposite directions. In the first meiotic division, which separates homologues but moves sister chromosome units to the same pole, the sister kinetochores lie side by side in the four-part chromosome, facing in the same direction.

A great deal of attention has been devoted to DNA synthesis in meiosis because it was theoretically attractive to attribute crossing over to events that took place during the replication of chromosomes and correspondingly difficult to imagine how condensed chromosomes could break at several places, exchange pieces, and rejoin. Nevertheless, most of the DNA is replicated before meiotic prophase, and crossing over does seem to be a process of breaking and rejoining segments of condensed chromosomes. It is known that a small amount of DNA is synthesized during meiotic prophase, long after the *S* period, during which most of the chromosomal material is replicated in anticipation of meiosis. The relation between this delayed replication and the singularities of meiosis is not known. It is also a fact that the histone content of chromosomes changes during meiosis; in the preparations for ordinary mitosis the increase in histone parallels the increase in DNA, and the ratio of the two remains constant.

Although these special features of chromosomes in meiosis are known, there are no known fundamental differences in the spindle apparatus or in the mechanisms of chromosome separation. There are a few singularities in the behaviour of the meiotic spindle; for example, in many animals the ovum is arrested in the metaphase of the first meiotic division and does not proceed further through meiosis until it is fertilized. Such long and stable metaphases are not known in mitosis.

BIBLIOGRAPHY. The current perspectives of cell science are made accessible to the general reader in three recent textbooks: E.J. AMBROSE and DOROTHY M. EASTY, *Cell Biology* (1970); E.D.P. DE ROBERTIS, W.W. NOWINSKI, and F.A. SAER, *Cell Biology*, 5th ed. (1970); and ARIEL G. LOEWY and PHILIP SIEKEVITZ, *Cell Structure and Function*, 2nd ed. (1969). These volumes supply the introductory chemical background in graphic form. The first two are more complete on morphological and genetic aspects of the subject, while the last work stresses the molecular basis of cell functions. A larger text by H. ROTHSTEIN, *General Physiology: The Cellular and Molecular Basis* (1971), treats the physiological ramifications of cell biology more completely, and traces the history of the major discoveries in a successful way. A thorough presentation of the cell as a molecular system is found in E.J. DUPRAW, *Cell and Molecular Biology* (1968).

The reader interested in the historical development of cell biology will find that some of the classics are much more than archives; rather, they record the recurrence of certain constant themes, enriched in each cycle. The outlook on the cell at the turn of the century may be recaptured in MAX VERWORN, *Allgemeine Physiologie*, 2nd ed. (1897; Eng. trans., *General Physiology*, 1899). The brilliance of classical microscopy and especially the excitement about the revelation of the chromosome is recaptured in E.B. WILSON, *The Cell in Development and Heredity*, 3rd ed. (1925). Two important texts trace the development of the study of cell function in the 20th century: W.M. BAYLISS, *Principles of General Physiology*, 4th ed. (1924); and L.V. HEILBRUNN, *An Outline of General Physiology*, 3rd ed. (1952). J. BRACHET and A.E. MIRSKY (eds.), *The Cell*, 5 vol. (1959–61), is the major treatise and most of the contents are still valuable to the contemporary reader. Volume 3 includes a monograph by D. MAZIA on "Mitosis and the Physiology of Cell Division," which can serve as a starting point for the literature on cell division.

A few monographs for the reader who would extend his reading on matters stressed in the present article include: A.B. NOVIKOFF and E. HOLTZMAN, *Cells and Organelles* (1970), an outstandingly lucid and beautifully illustrated summary of the present knowledge of cell structure, with emphasis on animal cells and tissues; E.J. DUPRAW, *DNA and Chromosomes* (1970), which treats problems of nuclei and chromo-

somes in depth in a concise way; and A.L. LEHNINGER, *Bioenergetics* (1965), an excellent source of information on the energetic problems of the cell and the complexities of mitochondria. The series *Protoplasmatologia*, which is published in the form of monographs at irregular intervals, has now accumulated useful summaries of a considerable variety of topics in cell biology.

Up-to-date summaries of most of the topics covered in this article may be found by scanning the following annual review publications: *The International Review of Cytology*, *Annual Review of Biochemistry*, *Annual Review of Physiology*, and *Annual Review of Genetics*.

The rate of progress of cell studies is so rapid that the student or general reader, as well as the specialist, will have occasion to consult the research journals for information more recent than that contained in reviews and monographs. Major advances are reported in summary form in *Nature* and in *Science* (both issued weekly). Reports of exceptional significance often appear in the *Proceedings of the National Academy of Sciences*. Most of the primary literature of the field is published in the following journals, which are available in most biological and medical libraries: *Caryologia* (Italy); *Chromosoma* and *Zeitschrift für Zellforschung* (Germany); *Experimental Cell Research* (international); *Journal of Cell Biology*, *Journal of Cellular Physiology*, and *Journal of General Physiology* (United States); *Journal of Cell Science* and *Journal of Molecular Biology* (United Kingdom); *Journal de Microscopie* (France); *The Nucleus* (India); *Tsitologiya* (U.S.S.R.); and *Protoplasmatologia* (Austria).

Cellini, Benvenuto

The fame of Florentine goldsmith and sculptor Benvenuto Cellini is due more to his record of his own life than it is to his work as an artist. First printed in Italy in 1728, Cellini's autobiography was translated into English (1771), German (1796), and French (1822) and, launched on the tide of the Romantic movement, gained immediate popularity. Dictated to a secretary, it is composed in colloquial language with no literary artifice and gives a firsthand account of the writer's experience in the Rome of Clement VII, the France of Francis I, and the Florence of Cosimo de' Medici. Despite its manifest exaggerations and its often boastful tone, it is a human document of surprising frankness and incomparable authenticity and thanks to it Cellini's character is more intimately known than that of any other figure of his time.

As an artist, however, Cellini was not only a craftsman of surpassing taste and skill but a sculptor of great significance, enjoying a position of importance both in France and in Florence, where he executed all but one of his large-scale works. He declared in his "Treatise on Sculpture" (*Tratto della scultura*) that he "always had a desire to do some great works in marble," and the tone of frustration and disappointment that runs through his autobiography is due in the main to the failure of his contemporaries to supply scope for his transcendent gifts. His "Perseus" (1545–54) is perhaps the greatest statue produced in Florence by any member of the generation after Michelangelo's, and the scene of "Perseus Rescuing Andromeda" originally in its base (now in the Bargello, Florence) leaves no doubt of his talent as an artist in relief.

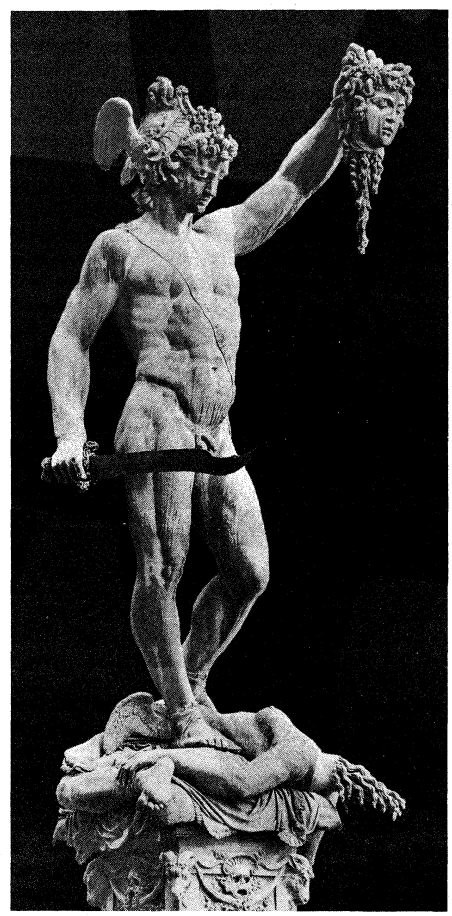
Early career

Cellini was born in Florence on November 1, 1500. Resisting the efforts of his father to train him as a musician, he was apprenticed as a metalworker in the studio of the Florentine goldsmith Andrea di Sandro Marcone. Banished to Siena as a result of a brawl in 1516, he returned to Florence during 1517–19 and then moved to Rome. Prosecuted for fighting in Florence in 1523 and condemned to death, he fled again to Rome, where he worked for the bishop of Salamanca, Sigismondo Chigi, and Pope Clement VII. Cellini participated in the defense of Rome in 1527, during which, by his own account, he shot the constable of Bourbon as well as the Prince of Orange.

After the sack of Rome he returned to Florence and in 1528 worked in Mantua, making a seal for Cardinal Gonzaga (Episcopal Archives of the City of Mantua). Moving back to Rome in 1529, he was appointed *maestro delle stampe* ("stamp master") at the papal mint and in 1530–31 executed a celebrated morse (clasp) for Clement VII. Like so many of Cellini's works in precious metals, this was melted down, but its design is recorded in three 18th-century drawings in the British Museum, London. The only survivors of the many works he prepared for the Pope are two medals made in 1534 (Uffizi, Florence).

Guilty of killing a rival goldsmith, Cellini was absolved by Pope Paul III; but in the following year, having wounded a notary, he fled from Rome and settled in Florence, where he executed a number of coins for Alessandro de' Medici (now in the Cabinet of Coins, France). After a further year in Rome, he paid a brief visit to France, where he was received by Francis I, a portrait medal of whom (1538; Bargello, Florence) is the sole relic of the journey. On his return to Rome in 1537, he

Alinari



"Perseus," bronze sculpture by Benvenuto Cellini, 1545–54. In the Loggia dei Lanzi, Florence, Italy. Height 3.2 m.

was accused of embezzlement and imprisoned. He escaped, was once more imprisoned, and was finally released in 1539 at the insistence of Cardinal d'Este of Ferrara, for whom he executed a seal (*c.* 1540; original lost; lead impression in Lyon). Again invited to France by Francis I, he arrived at Fontainebleau in 1540, carrying with him an unfinished saltcellar, which he completed in gold for the King in 1540. This, Cellini's only fully authenticated work in precious metal (Kunsthistorisches Museum, Vienna), is the supreme example of the Renaissance goldsmith's work. In 1542 Cellini was granted letters of naturalization by the King and in 1544 received a royal commission for 12 silver candlesticks decorated with figures from mythology. The design of one of these, representing Juno, is recorded in a drawing in the Louvre, Paris. Also in 1543–44 he modelled and cast a large bronze lunette of the Nymph of Fontainebleau for the entrance to the palace (Louvre). For a projected fountain at Fontainebleau he prepared a model in 1543 for a colossal figure of Mars (lost).

Later years in Florence and Venice

In 1545 Cellini left Paris precipitately and returned to Florence, where he was welcomed by Cosimo de' Medici and entrusted with the commissions for his best known sculpture, the bronze "Perseus" in Florence's Loggia dei Lanzi, where it still stands, and for a colossal bust of the Grand Duke of Tuscany (Bargello, Florence). Fleeing to Venice in 1546 to escape charges of immorality, Cellini completed the bust by 1548. In the same period he restored an antique torso from Palestrina as "Ganymede" (1546–47; Uffizi, Florence) and carved his marble figures of "Apollo" and "Hyacinth" (1546) and of "Narcissus" (1546–47); all three works are now in the Bargello in Florence, as is a small relief of a greyhound made as a trial cast for the "Perseus" (1545). A bronze bust of a banker and patron of the arts, Bindo Altoviti (*c.* 1550; Isabella Stewart Gardner Museum, Boston), was executed by Cellini in Florence, probably in 1550. After the unveiling of the "Perseus" (1554), he began work on a marble crucifix originally destined for his own tomb in the Florentine church of SS. Annunziata; this is now in the church of the royal monastery of the Escorial (Spain). The "Escorial Crucifix" (1556) exemplifies the superiority of Cellini's art to the works of his rivals Bartolommeo Ammanati and Baccio Bandinelli. Two designs for the seal of the Academy of Florence (British Museum and Graphische Sammlung, Munich) date from 1563. His autobiography was begun in 1558 and completed in 1562; and in 1565 he began work on his important treatises dealing with goldsmiths' work and sculpture, the *Trattato dell'oreficeria* and the *Trattato della scultura*. Cellini died in Florence on February 13, 1571.

BIBLIOGRAPHY. The best Italian edition of Cellini's autobiography is that of ORAZIO BACCI, *Vita di Benvenuto Cellini* (1901); the standard Eng. trans. is by JOHN A. SYMONDS (2 vol., 1888; reprinted with notes and bibliography as *The Life of Benvenuto Cellini Written by Himself*, 1949 and 1968). On Cellini's works see EUGENE PLON, *Benvenuto Cellini, orfèvre, médailleur, sculpteur*, 2 vol. (1883); and ETTORE CAMESASCA, *Tutta l'opera del Cellini* (1955). For the *Trattati* see CARLO MILANESI, *I Trattati dell'oreficeria e della scultura di Benvenuto Cellini* (1857); C.R. ASHBEE, *The Treatises of Benvenuto Cellini on Goldsmithing and Sculpture* (1898, reprinted 1967); and JOHN POPE-HENNESSY, *An Introduction to Italian Sculpture* (1963).

(J.W.P.-H.)

Cell Theory and Classification

The cell theory is not as much a theory in the conventional sense as it is a statement of fact: life is manifest only through the functioning of intact cells, never in their absence. A cell and even some of its isolated parts are capable of growth and reproduction as a result of the assimilation of substances drawn from the environment; but an intact cell is the simplest structure that displays all of the characteristics of life. The similarity of structure and function in all cells, although modified by evolution to produce the great diversity that occurs in living things, results from the fact that the molecules and processes responsible for energy manipulation, growth, and reproduction are basically similar in all cell types. The differences among the cells of plants, animals, and microorganisms mostly represent specialized features that permit a cell to adapt to a particular way of life.

This article is divided into the following sections:

The cell theory
- Historical background
- The protoplasm concept
- Evolution of the cell theory
- Critique of the cell theory

Classification of cells
- General features
  - Cells and viruses
  - Procaryotic and eucaryotic cells
  - Tissues: a functional classification of cells
- Animal tissues
  - Absorptive cells
  - Secretory cells
  - Nerve cells
  - Sensory cells
  - Muscle cells
  - Cells in supporting tissues
  - Circulating cells
  - Reproductive cells: gametes
- Cells and tissues of higher plants
  - The plant cell
  - Cell types
- Summary

The features of cells mentioned in this article are described in greater detail in the article CELL AND CELL DIVISION.

THE CELL THEORY

Historical background. The history of the cell theory is a history of the actual observation of cells, because early prediction and speculation about the nature of the cell were generally unsuccessful. The decisive event that allowed the observation of cells was the invention of the microscope in the 17th century, after which interest in the new invisible world was stimulated. Robert Hooke, who described cork and other plant tissues in 1665, introduced the term cell because the cellulose walls of dead cork cells reminded him of the blocks of cells occupied by the monks of that period. Even after the publication in 1672 of excellent pictures of plant tissues, no significance was attached to the contents within the cell walls.

The role of microscopy

The magnifying powers of the microscope and the inadequacy of techniques for preparing cells for observation precluded a study of the intimate details of the cell contents. The inspired amateur of early microscopy Antonie van Leeuwenhoek, beginning in 1673, discovered blood cells, spermatozoa, and a lively world of "animalcules." A new world of unicellular organisms was opened up. Such discoveries extended the known variety of living things but did not bring insight into their basic uniformity. Moreover, when Leeuwenhoek observed the swarming of his animalcules but failed to observe their division, he could only reinforce the idea that they arose spontaneously.

The cell theory was not formulated for nearly 200 years after the introduction of microscopy. Explanations for this delay range from the poor quality of the microscopes to the persistence of ancient ideas concerning the definition of a fundamental living unit. Historians of this period have chronicled many observations of cells, but apparently none of the observers was able to assert forcefully that cells were the units of biological structure and function.

Three critical discoveries made during the 1830s, when improved microscopes with suitable lenses, higher powers of magnification without aberration, and more satisfactory illumination became available, were decisive events in the early development of the cell theory. First, the nucleus was observed by Robert Brown in 1833 as a constant component of plant cells. Soon nuclei were also observed and recognized as such in some animal cells, even though they were not surrounded by the cellulose walls found in plants. Last, a living substance called protoplasm was recognized within cells, its vitality made evident by its active streaming, or flowing, movements, especially in plant cells. After these three discoveries, cells, previously considered as mere pores in plant tissue, could no longer be thought of as empty, because they contained living material.

Two German biologists, Theodore Schwann and Matthias Schleiden, clearly stated in 1839 that cells are the "elementary particles of organisms" in both plants and animals and recognized that some organisms are unicellular and others multicellular. This statement was made in 1839 in a book by Schwann entitled *Microscopic Researches into the Accordance in the Structure and Growth of Animals and Plants*. Schleiden's contributions on plants, which had appeared in 1838, were acknowledged by Schwann as the basis for his comparison of animal and plant structure.

Schleiden and Schwann's descriptive statements concerning the cellular basis of biological structure are straightforward and acceptable to modern thought. They recognized the common features of cells to be membrane, nucleus, and cell body and described them in comparisons of various animal and plant tissues. A state-

ment by Schleiden pointed toward the future direction of cell studies:

> Each cell leads a double life: an independent one, pertaining to its own development alone; and another incidental, insofar as it has become an integral part of a plant. It is, however, easy to perceive that the vital process of the individual cells must form the first, absolutely indispensable fundamental basis, both as regards vegetable physiology and comparative physiology in general; and therefore, in the very first instance, this question especially presents itself: how does this peculiar little organism, the cell, originate?

Historians point out, however, that Schwann and Schleiden were not alone in contributing to this great generalization of natural science—strong intimations of the cell theory occur in the work of their predecessors. Recognizing that the basic problem was the origin of cells, these early investigators invented a hypothesis of "free cell formation," according to which cells developed *de novo* out of an unformed substance, a "cytoblastema," by a sequence of events in which first the nucleolus develops, then the nucleus, the cell body, and finally the cell membrane. The best physical model of the generation of formed bodies then available was crystallization, and their theory was inspired by that model. In retrospect, the hypothesis of free cell formation would not seem to have been justified, however, since cell division, a feature not characteristic of crystallization processes, had frequently been observed by earlier microscopists, especially among single-celled organisms. Even though cell division was observed repeatedly in the following decades, the theory of free cell formation lingered throughout most of the 19th century; however, it came to be thought of more and more as a possible exception to the general principle of the reproduction of cells by division. The principle of division of cells was affirmed in 1855 by a German biologist of great prestige: Rudolph Virchow asserted that "omnis cellula e cellula" ("all cells come from cells"); but doubt remained.

The hypothesis of "free cell formation"

The inherently complex events of cell division prevented a quick resolution of the complete sequence of changes that occur during the process. First, it was noted that a cell with a nucleus divides into two cells, each having a nucleus; hence, it was concluded that the nucleus must divide, and direct division of nuclei was duly described by some. Better techniques served to create perplexity, because it was found that, during cell division, the nucleus as such disappears. Moreover, at the time of division, dimly discerned masses, now recognized as chromosomes, were seen to appear temporarily. Observations in the 1870s culminated in the highly accurate description and interpretation of cell division (mitosis) by Walther Flemming in 1882. His advanced techniques of fixing and staining cells enabled him to see that cell reproduction involves the transmission of chromosomes from the parent to daughter cells by the process of mitosis and that the division of the cell body is the terminal event of that reproduction.

The discovery that the number of chromosomes remains constant from one generation to the next resulted in the full description of the process of meiosis. The description of meiosis combined with the observation that fertilization is fundamentally the union of maternal and paternal sets of chromosomes culminated in the understanding of the physical basis of reproduction and heredity. Meiosis and fertilization are therefore complementary events in the life cycle of organisms: meiosis halves the number of chromosomes in the formation of spores (plants) or gametes (animals), while fertilization restores the number through the union of gametes. By the 1890s "life" in all of its manifestations could be thought of as an expression of cells.

Protoplasm as the living substance of the cell

The protoplasm concept. As the concept that the cell is the elementary particle of life developed during the 19th century, it was paralleled by the "protoplasm" concept—the idea that the protoplasm within the cell is responsible for life. Protoplasm had been defined in 1835 as the ground substance of living material and hence responsible for all living processes. That life is an activity of an elementary particle, the cell, can be contrasted with the view that it is the expression of a living complex substance—even a supermolecule—called a protoplasm. The protoplasm concept was supported by observations of the streaming movements of the apparently slimy contents of living cells.

Advocates of the protoplasm concept implied that cells were either fragments or containers of protoplasm. This interpretation threw doubt on the existence of a cell membrane as a defining characteristic of cells; its supposed absence from some cells was considered to be a refutation of the cell theory. The doubt, though unproductive, was justified, since the existence of the cell membrane, which lies below the limits of resolution of the light microscope, was based on indirect evidence and was experimentally demonstrated only after the introduction of advanced techniques such as electron microscopy. The weakness of the protoplasm concept was its inability to account for the origin of formed structures within the cell, especially the nucleus. The existence of a nucleus in all cells could be denied as long as microscopic techniques were incapable of demonstrating one in all cells, and the importance of the nucleus could be ignored until the discovery of the chromosomal basis of reproduction was established.

In retrospect, those who stressed the protoplasm concept and those who stressed the cell theory converged. The preoccupation with protoplasm resulted from research on intact living cells and provided much information about cells. Advocates of the protoplasm concept, suspicious and often contemptuous of information obtained from dead and stained cells, discovered most of the basic information on the physical properties—mechanical, optical, electrical, and contractile properties—of the living cell. It was also a matter of concern that observed structures might not be actual cell components but extraneous changes caused by experimental techniques (artifacts); as a result, the development of important methods for studying cell components was delayed. An assessment of the usefulness of the concept is difficult. It was not wholly false; on the one hand, it encouraged the study of the chemical and mechanical properties of cell contents, but it also generated a resistance, evident as late as the 1930s, to the realization that very large molecules (macromolecules) could be cellular constituents.

As the cell has become fractionated into its component parts, protoplasm, as a term, no longer has meaning in a modern sense. The word protoplasm is still used, however, in describing the phenomenon of protoplasmic streaming—the phenomenon from which the protoplasm concept originally emerged.

Evolution of the cell theory. Appreciation of the cell as the unit of life has accrued from important sources other than microscopy; perhaps the most important is microbiology. Even though the small size of micro-organisms prohibited much observation of their detailed structure until the advent of electron microscopy, they could be grown easily and rapidly. Thus it was that the studies of microbes by Louis Pasteur, published in 1861, helped to establish the principle of biogenesis, namely, that organisms arise only by the reproduction of other organisms. Fundamental ideas regarding the metabolic attributes of cells—that is, their ability to transform simple nutritional substances into cell substance and utilizable energy—came from microbiology. Pasteur perhaps overplayed the relation between catalysis and the living state of cells in considering enzymatic action to be an attribute of the living cell rather than of the catalytic molecules (enzymes) contained in the cell; it is a fact, however, that much of cell chemistry is enzyme chemistry—and that enzymes are one defining attribute of cells. The techniques of microbiology eventually opened the way for microbial genetics, which, in turn, provided the means for solving the fundamental problems of molecular biology that were inaccessible at first to direct attack by biochemical methods.

The role of microbiology

The science of molecular biology would be most capable of overthrowing the cell theory if the latter were an exaggerated generalization. On the contrary, molecular

biology has become the foundation of cell science, for it has demonstrated not only that basic processes such as the genetic code and protein synthesis are similar in all living systems but also that they are referrable to the same cell components in living things—*e.g.*, chromosomes, ribosomes, and membranes.

In the overlapping histories of cell biology and medicine, two events are especially important. One, the identification in 1827 by Karl Ernst von Baer of the ovum (unfertilized egg) as a cell, was important considering the many ways it often differs from other cells; von Baer not only laid the foundations for reproductive biology but also provided important evidence for the cell theory at a critical time. The second important event was the promotion in 1855 of the concept of "cellular pathology" by Rudolph Virchow. His idea that human diseases are diseases of cells and can be identified and understood as such gave the cell theory an authority not easily undermined by deficiencies in the theory.

Although biochemistry might have made considerable progress without the cell theory, each influenced the other almost from the start. When it was established that most biochemical phenomena are shared by all cells, the cell could be defined by its metabolism as well as by its structure. Cytochemistry, or histochemistry, made a brilliant start in 1869, when a Swiss biochemist, Friedrich Miescher, postulated that the nucleus must have a characteristic chemistry and then went on to discover the nucleic acids, which have since been shown to be the crucial molecules of inheritance and metabolism.

Critique of the cell theory. The cell theory has been subject to remarkably little debate. Disputes have arisen about the validity of various generalizations—whether all cells possess membranes and nuclei; whether cells can reproduce other than by mitosis; and whether chromosomes are the bearers of heredity. And at times the cell has moved into the background when the existence of more fundamental living units in cells has been postulated; indeed, the first crystallization of a virus, in 1935, pointed to the existence of molecules endowed with life. But none of these doubts or findings questioned the validity of the cell theory as a general statement.

Inadequacies of the cell theory

Nevertheless, several difficulties requiring a broadened view of the cell theory may be mentioned. The existence of syncytial forms of life (*i.e.*, many nuclei sharing the same cytoplasm) certainly detracts from the precision of the cell theory; in certain giant plant cells (*e.g.*, the common pond plant *Nitella*), for example, many nuclei share the same cytoplasm. The so-called acellular slime molds are living masses of indefinite size and contain many nuclei. In animals, such important tissues as skeletal muscle are syncytial in nature; all such apparent acellular organisms, however, arise from cells, either by the absence of division of the cell body following nuclear division or by the fusion of cells. These are thus special cases in which individual nuclei are not separated from each other by cell membranes but are contained within a common membrane.

A seemingly more serious extension of the cell theory is required by the existence of unicellular organisms, especially certain protozoans, which show remarkable complexity as free-living organisms. They have well-differentiated structures for the capture and digestion of food, for coordinated movement, for reception of stimuli, and for purposeful behaviour of the kind usually associated with multicellular animals. All this complexity results from the remarkable flexibility of the cell membrane in producing a variety of subcellular organelles. Such organisms express the potential of the cell for internal differentiation; modern techniques (*e.g.*, electron microscopy) sustain this opinion by revealing that these complex protozoans have the same structural elements—microtubules, microfilaments, membranes, centrioles—as are responsible for differentiation in plant and animal cells.

The most serious difficulty of the cell theory is that it cannot explain the development and unity of the multicellular organism; a cell is not necessarily an independently functioning unit. A plant or an animal is not merely a congeries of individual cells; fortunately, however, the controversy centring on the individuality and separateness of cells has ended. Cell biology of the 1960s and 1970s focussed on the interactions and communications between cells, as well as on the analysis of the single cell; and the exchanges of materials between cells, contact phenomena, and cell junctions have all become important aspects in the study of the cell (see CELL AND CELL DIVISION). The influence of the environment on the cell has aways been important; now it has been recognized that one very important part of the environment of a cell is other cells—recognition, association, and cooperation between cells have become observational and experimental questions.

The importance to cells of other cells

The cell theory thus is not so comprehensive as to eliminate the concept of the organism as a whole. But the study of a particular organism requires the investigation of cells as both individuals and groups. The cancer problem is an example: a plant or animal governs the division of its own cells; the right cells must divide, be differentiated, and then integrated into the proper organ system at the right time and place. Breakdown results in a variety of abnormalities, one of which is cancer. When the cell biologist studies the problem of the regulation of cell division, his ultimate objective is to understand the effect of the whole organism on an individual cell.

CLASSIFICATION OF CELLS

A taxonomy of cells does not play a large part in modern biological thought. In the preceding section, convincing evidence of the fundamental similarities among cells was presented. It can be plausibly argued, in fact, that all cells that have ever existed have had a common origin. Cells are classified by types for purposes of discourse and to study the diversification and specialization of common designs.

General features. *Cells and viruses.* Viruses are small masses of material that can enter and reproduce in cells. They are organisms only in a limited sense—whatever can survive and reproduce itself indefinitely possesses the most essential attribute of an organism. The propagation of a virus requires the internal environment of a complete cell, including its biochemical machinery. A nonviral organism, however, can reproduce in a nonliving external environment, from which it draws only simple nutrients and energy sources while maintaining its own internal environment; it possesses the biochemical machinery for transforming the matter it captures into living matter.

Viruses are not merely pieces of nucleic acid and may be rather complex. Complexity is expressed in the protein coat, which contains and thus protects the genetic material before it enters a cell (infectious phase). In the infectious phase the virus does not reproduce. The structure of the complete infectious virus (*e.g.*, the bacteriophages that infect bacteria) thus is concerned both with the survival of the virus outside a cell and with the mechanisms by which it enters the cell. The virus loses the protein coat upon entry into a cell, after which the genetic material of the virus reproduces, using materials made by the host cell. The virus leaves the host cell surrounded by the protein coat; the characteristics of these proteins are determined by genes in the virus, but the proteins are made within the host. It might be supposed that viruses are the ultimate parasites—"naked genes," as they were once designated—which have discarded all the other attributes of complete cells. But the idea is difficult to sustain, since the genetic material of so many viruses is RNA, whereas that of true cells is DNA.

Procaryotic and eucaryotic cells. Cells can be placed in one of two groups on the basis of whether or not they have a membrane-bound nucleus; those with a membrane-bound nucleus are called eucaryotic cells, and those lacking this structure but containing nuclear material are called procaryotic cells. As recently as 1941 the difference could be expressed only in negative terms: the failure to find certain features (*e.g.*, a distinct nucleus surrounded by a nuclear membrane) of a "typical" cell in certain micro-organisms (procaryotes). Detection of the

numerous distinctions that exist between procaryotic and eucaryotic cells depends on techniques that were not available before the 1950s. These distinctions are elaborated upon in CELL AND CELL DIVISION.

Most procaryotic cells, such as bacteria and blue-green algae, appear to have very little internal structure when viewed through the light microscope. Simple eucaryotes, such as the yeasts and many unicellular algae, have more complex internal structure than the procaryotes but live under conditions similar to those of the procaryotes, drawing upon the same simple nutrients and energy sources.

After the discovery of the differences between procaryotes and eucaryotes, impressive similarities between simple eucaryotic organisms (*e.g.*, yeasts) and the eucaryotic cells of higher organisms were found—a yeast cell is probably more similar to a mammalian cell than it is to a bacterial cell. It has been of value to examine the differences between simple eucaryotes and the always eucaryotic cells of higher organisms. Unicellularity and multicellularity are important because the multicellularity found in higher organisms is accompanied by definite capabilities for differentiation. Differentiation in turn depends on communications between cells; such communication is not seen in unicellular organisms. In addition, the chemistry of the chromosomes of multicellular plants and animals differs from that of unicellular organisms; those of the former always contain proteins called histones, which apparently are not found in a number of simple eucaryotic organisms.

Unicellularity and multicellularity

The mechanisms of mitosis also differ. In the typical mitosis that occurs in plant and animal cells, the nuclear membrane breaks down; in some unicellular eucaryotes, mitosis takes place within the nucleus. In both cases, however, chromosome movements depend on structures called microtubules, which are not seen in procaryotic cells. Finally, it is suspected that the mechanisms of genetic regulation—the determination of which genes are active in a given cell at a given time—may differ in cells of multicellular and unicellular eucaryotes. It would seem that this is likely, since, in the case of multicellular eucaryotes, cells with the same genes must differentiate into many types, so that complex control mechanisms are essential; in the case of unicellular eucaryotes, such differentiation does not occur; hence, elaborate controls are not necessary.

Tissues: a functional classification of cells. The tissue concept preceded the cell theory. As developed in the early 19th century, the theory of tissues proposed that the organs known to gross anatomy could be analyzed in terms of tissues. The tissue was said to be defined by a characteristic structure and texture, and membranes and "vessels" were emphasized rather than fluids. Tissues were said to represent the level of organization intermediate between unorganized matter and the functional organ; *i.e.*, the existence of cells was not anticipated. When the cell theory was expressed, tissues were redescribed in terms of cells.

Modification of the definition of a tissue

The study of tissues, the science of histology, is a well-developed discipline in both plant and animal science. In the following section, comments are limited to representative cell types in order to illustrate the ways in which the basic design of eucaryotic cells has been modified to serve the specialized functions of tissues and organs.

Animal tissues. *Absorptive cells.* In animals, layers of cells covering an organ (epithelia) may serve the function of exchanging material between the environment and the body fluids of the organism, as well as having a supportive role to play. A common modification of this cell type is the fingerlike projections of the cell membrane, called microvilli, which increase the total area of the absorptive surface. Another modification may occur at the cell surface, so that specific transport processes are located on the outer surface or inner surface of the membranes or, in some instances, within the mosaic structure of the membrane itself. In many cases, such as in the cells of gills that transport salts into or out of the blood and body fluids of aquatic animals, the internal membrane system is conspicuous as pockets called vesicles, in which the substances being transported are sequestered. The cells forming an absorptive surface are very often united at cell junctions.

Secretory cells. Well-developed in glandular tissues, secretory cells are adapted to synthesize molecules not used by the cells themselves but exported from them. Outstanding is their extensively developed internal membrane system, the components of which include the endoplasmic reticulum and the Golgi apparatus, both of which are present in all eucaryotic cells. The accumulation of secretory products may be massive, often occurring as secretory droplets.

Nerve cells. In nerve cells (neurons), most cellular functions occur in a cell body containing the nucleus. The specialized function of the neuron—conduction of impulses—is performed by extensions of the cell body: short dendrites, at which chemical or electrical transmissions from other neurons are received, and very long axons, which conduct impulses to other neurons, muscles, or glands. Biosynthesis occurs in the cytoplasm of the cell body. The axon contains many small filaments called neurofilaments and small tubes called neurotubules along its length; materials synthesized in the cell body may be transported along these structures to the end of the axon. The ends of the axons may be highly differentiated as bulbous structures at the surfaces of which vesicles of substances, made in the cell body and transported down the axon, are secreted when impulses arrive. These secretions stimulate the next neuron in the nerve circuit or some effector cell, such as a muscle.

An extreme example of cell differentiation is the Schwann cell. It develops extensive surface membranes and wraps itself around the membrane of the neuron, providing an insulating sheath (called the myelin sheath).

Sensory cells. Sensory cells, which transduce stimuli such as light, touch, and the "tastes" of chemicals so that they set off impulses in adjacent neurons, show unexpected adaptations of typical cells. In cells adapted to respond to mechanical stimuli (touch or bending, for example), the receptor is provided with a modified hairlike projection (cilium). More remarkably, animal evolution has produced photoceptors (rods and cones), which also contain an array of membranes in which the light-receiving pigments are incorporated. Although receptive processes, in which the energy in stimuli is received, are fairly well understood, much less is known about the way in which the receptor cell triggers an impulse in an adjoining neuron.

Muscle cells. Muscle cells, though specialized, have been derived from a typical cell. Contractility is a function of arrays of filaments, which, in the case of skeletal and heart muscle, are collected into bundles called myofibrils. In smooth muscle, the filaments are not associated so definitely into bundles. All kinds of muscle contain thin filaments composed of the protein actin. Heart and skeletal muscle contain arrays of thick filaments, which are composed of the protein myosin and spaced at regular intervals along the thin filaments, accounting for the striated appearance of the cells. Smooth muscles also contain myosin but not in the form of thick filaments. The modified internal membrane system of a muscle cell, called a sarcoplasmic reticulum, sometimes has many vesicles; in skeletal muscle it consists of an array of sacs investing the myofibrils. The surface membrane of skeletal muscle is highly and regularly involuted to "connect" the surface with the contractile fibrils, thus conducting the effects of stimuli to the vicinity of the contractile elements. Skeletal and smooth muscles consist of very large cells containing many nuclei and produced by the fusion of single cells to form a syncytium. Heart muscle is composed of single cells, richly provided with cell junctions in order that their contraction can be coordinated as the beat of the whole tissue. The consistency between the general design of the eucaryotic cell and the extreme specialization of muscle is an example of the interpretive power possible with the cell theory.

Types of muscle

Cells in supporting tissues. Although, in a histological survey, connective tissue, bone, and cartilage deserve

a detailed treatment, only the features common to these very different tissues are noted below. The cells comprising them show no great structural deviation from that of a typical cell, but they are specialized for large-scale production of the protein collagen and, in bone, for the laying down of mineral crystals of definite structure. The role of certain cells in providing the body with supporting structures is a fundamental expression of the differentiation of animal cells; a comparable expression is even more important in plants (see below *Cells and tissues of higher plants*).

Circulating cells. The red blood cells of mammals may be considered the ultimate simplification (or degeneracy) of cells or the best example of the adaptive subordination of the cell to the requirements of the organism as a whole. They have, in their final state of differentiation, neither nuclei (and thus cannot divide) nor the other components typical of eucaryotic cells and can be regarded as bags containing a concentrated solution of the iron-containing protein hemoglobin, which carries oxygen and carbon dioxide. On the other hand, their membranes are highly developed to control the internal environment in which the hemoglobin is dissolved. The regulatory devices in the membranes of red blood cells enable them to pick up a maximum load of oxygen in the lung and release it with great efficiency in the tissues.

White blood cells (leucocytes) utilize the capacity of many cells to engulf and digest particles, including bacteria and the debris of injured tissue (phagocytosis). The production of antibodies in the immune response is the result of the cooperation of specialized cells derived from certain white cells called lymphocytes (*i.e.*, macrophages and plasma cells). None of these types of leucocytes is organized into tissues; since their structures resemble that of a typical eucaryotic cell, these cells give no clues to the several important and specialized functions they perform in the animal.

Reproductive cells: gametes. Although the gametes—ovum and spermatozoon—contribute an equal set of genes to the new individual, the contribution of each to the success of the reproductive process is quite different. The ovum of an animal is adapted to meet the nutritional requirements of the early developmental stages of the embryo. It is always a large cell because it contains sufficient cytoplasmic substance for the development of a self-sufficient embryo. Some of the substance, which is packaged in yolk particles, contains cell components; typically, an ovum contains sufficient quantities of components for many cells. Thus, the ovum need not grow as it divides—as the nuclei divide, the cytoplasm subdivides until the ovum consists of a large number of normal-sized cells. Perhaps a remarkable adaptation of the ovum involves fertilization: the cell surface is specialized to receive and engulf sperm at the time of fertilization and to reject all but one sperm. By contrast, spermatozoa are motile cells that contain very little cytoplasm, have a short life, and cannot divide. Typically, a spermatozoon has a small head and a long motile tail (flagellum), but many variations occur. The head contains the nucleus and a complex structure, the acrosome, which is responsible for the attachment of the spermatozoon to the surface of the egg.

Cellulose walls and vacuoles

Cells and tissues of higher plants. *The plant cell.* The outstanding features of plant cells, as compared with animal cells, are the rigid cellulose walls external to the cell membranes and the cavities (vacuoles) within the cell. Both cellulose walls and vacuoles are intimately involved in the life of the plant and constitute the main reference points for the diversification of plant cells.

Because the cellulose walls provide mechanical support, there is no need for an internal skeleton or an external shell. At the cellular level, cell walls permit cells to function in an environment dilute with regard to salts and other molecules. The tendency for water to enter the cell is translated into a pressure by the cells against the walls, a turgor that contributes to the rigidity of the plant. In fact, plants wilt in the environments required by animal cells.

The internal vacuoles of plant cells—typically a single vacuole surrounded by a membane, or tonoplast—may occupy most of the volume of the cell; the cytoplasm is a thin layer immediately beneath the cell membrane. The vacuoles are filled with an aqueous solution consisting mostly of small molecules, such as organic acids and pigments; some very large molecules (macromolecules); and, often, metabolic end products in the form of crystals. Growth in plants is, to a large extent, an increase in the size of the vacuoles without a corresponding increase in other cytoplasmic structures and often occurs by an increase in cell length with little increase in width. Thus, the control of cell elongation by the lengthwise deposition of cellulose walls, with a corresponding expansion of the vacuoles, is a major difference between plant cells and animal cells. Remarkable regulatory substances, notably the auxins, control these processes.

The most conspicuous structures found only in plant cells are chloroplasts, the sites of photosynthesis (*q.v.*). These structures are bounded by double membranes; the inner one is modified to form stacks of flattened vesicles, which contain chlorophyll, other photosynthetic pigments, and photosynthetic enzymes. The chloroplasts contain deoxyribonucleic acid (DNA) and, as semi-independent, self-reproducing parts of plant cells, behave much as does another component, mitochondria, of all eucaryotic cells. In fact, the similarities between chloroplasts and mitochondria exemplify the unities of cellular organization. Their structures have uncertain origins in the evolution of cells, but both perform the same fundamental process: the mobilization of energy for the cell by the synthesis of the energy-rich compound adenosine triphosphate (ATP). The chloroplasts convert the energy of light into energy-rich ATP and use the ATP to convert carbon to specific organic substances. In turn, mitochondria oxidize carbon-containing compounds, thereby recovering the ATP energy stored in them.

Remarkably few other structures in the cytoplasm of plant and animal cells differ, and the nuclei of the two are similar. The components of plant cells that deposit cellulose on the cell surface are called dictyosomes; their structure resembles other membrane-bound structures found in cells (*e.g.*, the Golgi apparatus); the dictyosomes, which are stacks of flattened vesicles, apparently concentrate the compounds from which cellulose is formed and deposit them on the outer surface of the cell.

Intercellular channels of communication in plants

Cytoplasmic connections between plant cells are common. Called plasmodesmata, they are thin bridges of cytoplasm (containing few or no components) covered by the cell membrane, which is thus continuous from one cell to the next, and pass through very small holes in the cellulose wall. It has not yet been established whether or not these intercellular channels of communication have different significance in animals and in plants, because the study of intercellular junctions between animal cells—quite different in structure from plasmodesmata—is a comparatively new one.

Another characteristic of plant cells, apart from photosynthesis and the incorporation of cellulose into the cell wall, is the production of a great variety of useful end products, such as oils, resins, pigments, drugs, latexes, and tannins, as well as substances incorporated into perfumes and flavourings. Noncellulose components of cell walls, such as pectins and lignins, also are used by man. Production of such substances requires elaborate synthetic mechanisms that are not found in animal cells.

Differentiation of plant cells, though simple to describe, is less easy to explain. It begins with cell divisions, which produce not identical daughter cells but cells the different destinies of which are recognizable at the time of division. In higher plants, cells capable of division are usually concentrated in tissues called apical or lateral meristems, such as are found at root and shoot tips and at the outer edge of woody plants beneath the bark. When meristematic cells divide, one daughter cell remains a meristematic cell, and the other differentiates; *i.e.*, it elongates, and a vacuole develops. In some cases of differentiation, the plane of division determines the properties of the daughter cell: a long cell may divide crosswide into two short cells, lengthwise to form two thin cells, or unequally to produce one large and one small daughter cell. As men-

tioned, the main expressions of further differentiation are not modifications of basic cell structure but modifications of the cell wall and the vacuole.

Cell types. Despite concern with the classification of plant cells, tissues, and tissue systems, there is as yet no agreement as to how they should be classified. The difficulty for the botanist in classifying plant cells lies in the extreme modifications of the typical cell structure.

Diversity of plant cells

At one extreme are cells that are no longer alive; in this case, arrangements of the cell walls serve the plant in important ways. Examples of nonliving plant cells include the phellem (cork) cells, which provide mechanical protection and insulation; fibre cells of various kinds, which provide mechanical support; and cells of the vascular tissues, which conduct water and nutrients in the plant. It is remarkable that living cells lacking striking internal peculiarities associate with each other at the right place and time, grow by the formation of walls made of cellulose and other molecules (lignins of wood, for example), and then cease to live as cells while they serve the organism.

At the other extreme, the meristem cells at the tips of roots and the apexes of shoots are a major source of new cells in the plant. Initials are cells that divide to produce one cell that retains the properties of an initial and another that differentiates; thus, a small population of initials can be the long-term source of cells for extensive growth and differentiation. Daughter cells that differentiate may divide several times. Structurally, the initials of meristems are typical eucaryotic cells, except for their cellulose walls. The counterpart in animals to these cells, which remain capable indefinitely of generating and regenerating complex tissues and organs, are those found in the blood- and skin-forming areas of the body.

Between the extremes of the meristematic cell and the nonliving plant cell are many types, the walls and vacuoles of which are specialized. Although the epidermal cells of leaves, for example, contain a nucleus and cytoplasm, their main specialization is the elaboration of a waxy outer cover (cuticle) that is impervious to water. In contrast, the mesophyll cells of leaves, which contain chloroplasts and carry out photosynthesis, make cellulose walls that are especially permeable to water and gases—a striking adaptive contrast to the epidermal cells, the thick walls and cuticle of which are a barrier to water and gases. Some epidermal cells secrete substances responsible for the tastes and odours of plants; as in secretory cells of animals, the internal membrane system is well developed. Epidermal cells of flowers concentrate pigments in their vacuoles.

The most active organs of the higher plant are the stomata, which open and close to adjust the movement of gases and water vapour into and out of the leaf. The opening is controlled by two curved, sausage-shaped guard cells; they change the aperture by changing their shape. The changes of shape result from changes in the water content of the cells and are not the result of any active contractile process.

Summary. The bases for the differentiation and hence the classification of animal and plant cells are quite different. In the case of animal cells, diversity results from modification of the internal structural components of the typical cell. In the case of plant cells, modifications of internal structure are not as important as differences in cell walls and vacuoles. Even in extreme cases, however, the fundamental unity of the cell concept is upheld. All plant and animal cells result from reproduction and differentiation of cells that are rather similar in both groups. Each structure within a living animal cell has its counterpart in a living plant cell. Each structure within plant cells, with the possible exception of the chloroplasts, has its counterpart in animal cells. Differences result from the elaboration of one or another part of a cell. Even the production of cellulose walls in plant cells is similar to the production of surface coats in animal cells. The important difference is that cellulose, a large molecule containing the sugar glucose, which is found in all cells, has special mechanical properties. Since many types of plant cells do not carry out photosynthesis, the presence or absence of chloroplasts is not a very good criterion for distinguishing a plant cell from an animal cell, although it is a most important distinction between a plant and an animal.

BIBLIOGRAPHY

Cell theory: The historical setting of the cell theory is found in the exposition by FRANCOIS JACOB, *La Logique du vivant* (1970). In a work demanding little technical background, Jacob describes historical changes in attitudes toward the nature of life, views that prevailed before the advent of theories on the cell and evolution, and the contemporary outlook that would resolve the major problems in terms of molecular biology. As a comprehensive reference work, E. NORDENSKIOLD, *The History of Biology* (1935), has not been superseded. An important series of articles on cell theory is J.R. BAKER, "The Cell Theory: A Restatement, History and Critique," *Q. Jl. Microsc. Sci.*, vol. 89 (1948), vol. 90 (1949), and vol. 93 (1952). ARTHUR HUGHES, *The History of Cytology* (1959), is a vivid and thoughtful account of that large part of the history and criticism of cell biology involved with observations using light microscopy. Hughes' book was published at the time when the major advances in electron microscopy had only begun. An evaluation of the precursors of the cell theory, somewhat downgrading the contribution of Schwann and Schleiden, is given by E.G. CONKLIN in a collective work *The Cell and Protoplasm* (1940). The original work of Schwann and Schleiden was published in English translation under the title of *Microscopical Researches into the Accordance in the Structure and Growth of the Animals and Plants* (1847). The German text of Schwann's work, *Mikroskopische Untersuchungen über die Übereinstimmung in der Struktur und dem Wachstum der Tiere und Pflanzen*, was reprinted in 1910. A culminating event in the history of the subject, the elucidation of mitosis, is described in the publications of W. FLEMMING. The original papers, "Beiträge zur Kenntniss der Zelle und ihrer Lebenserscheinungen" ("Contributions to the Knowledge of the Cell and Its Vital Processes"), were published in the journal, *Archiv für mikroskopische Anatomie*, vol. 16 (1878) and vol. 18 (1880). An English translation of the second and definitive article appeared in the *Journal of Cell Biology*, vol. 25 (1965). In his book *Zellsubstanz, Kern- und Zelltheilung* (1882), Flemming summarized a great deal of what was known about the cell at that time and the historical development of the field. All the further developments of classical cell biology are summarized in E.B. WILSON, *The Cell in Development and Heredity*, 3rd ed. (1924), which, still being read and useful, defies the usual implications of the term "classical." MAX VERWORN, *Allegemeine Physiologie*, 2nd ed. (1897; Eng. trans., *General Physiology*, 1899), marks a turning point in which the cell theory became a major force in physiology as well as in microscopic anatomy. The protoplasm concept is developed from different standpoints in L.V. HEILBRUNN, *The Colloid Chemistry of Protoplasm* (1928); and in W. SEIFRIZ, *Protoplasm* (1936). A critique of the protoplasm concept (asserting its downfall) is found in G. HARDIN, "Meaninglessness of the Word Protoplasm," *Scient. Mon.*, 182:112–120 (1956).

Cell classification: A collection of papers on "Prokaryotic and Eukaryotic Cells" was published in 1970 as number 20 of the *Symposia of the Society for General Microbiology*. In this volume, an essay by R.Y. STANIER on "Some Aspects of the Biology of Cells and Their Possible Evolutionary Significance" summarizes the problems of the designs of cells in an incisive way. The divergence of cells from a common type for particular functions is dealt with in *The General Physiology of Cell Specialization*, ed. by D. MAZIA and A. TYLER (1963). Books on microbial anatomy, protozoology, animal histology, and plant histology are easily accessible sources of information on the varieties of cells. Unfortunately, no work compares all the cell types in all the varieties of organisms in a comprehensive way. In the present article, the classes of animal cells have been drawn largely from A.B. NOVIKOFF and E. HOLTZMANN, *Cells and Organelles* (1970), which is outstanding with regard to clarity, concision, and illustrations. The information on plant cells has been drawn from K. ESAU, *Plant Anatomy*, 2nd ed. (1965); E.M. GIFFORD, "Plant Anatomy," in PETER GRAY (ed.), *Encyclopedia of the Biological Sciences*, 2nd ed. (1970); and M.C. LEDBETTER and K.R. PORTER, *Introduction to the Fine Structure of Plant Cells* (1970).

Modern treatises on the cell: JEAN BRACHET and A.E. MIRSKY (eds.), *The Cell*, 6 vol. (1959–64); D.W. FAWCETT, *An Atlas of Fine Structure* (1966); A. LIMA-DE-FARCIA (ed.), *Handbook of Molecular Cytology* (1969); LAWRENCE PICKEN, *The Organization of Cells and Other Organisms* (1960); HERBERT STERN and D.L. NANNEY, *The Biology of Cells* (1965); S.L. WOLFE, *Biology of the Cell* (1972).

Celtic Languages

The Celtic languages form one branch of the Indo-European language family, having in common certain sound shifts and vocabulary items. On both geographical and chronological grounds, the languages fall into two divisions, usually known as Continental Celtic and Insular Celtic.

Continental Celtic. Continental Celtic is the generic name for the languages spoken by the people known to classical writers as Keltoi and Galatae; at various times during a period of roughly 1,000 years (approximately 500 BC–AD 500), they occupied an area that stretched from Gaul to Iberia in the south and Galatia in the east. The great bulk of evidence for Continental Celtic consists of the names of persons, tribes, and places recorded by Greek and Latin writers. Only in Gaul and in northern Italy are inscriptions found, and the interpretation of these is in most cases doubtful. Given the nature of the evidence, knowledge for these languages is confined largely to the sound system and a small part of the vocabulary, and no certain conclusions can be reached as to their historical development or the differences between them.

Evidence for Continental Celtic

Insular Celtic. Insular Celtic refers to the Celtic languages of the British Isles, together with Breton (spoken in Brittany, France). As the name Breton implies, it is an importation from Britain and is not a Continental Celtic dialect. Although there is some scanty evidence from classical sources—mainly place-names—and a small body of inscriptions in the Latin and ogham alphabets from the end of the 4th to the 8th centuries AD, the main source of information on the early stages of these languages is manuscripts written from the 7th century onward in Irish and somewhat later in the British languages.

The Insular languages fall into two groups—Irish and British. Irish (often called Goidelic, from Old Irish *Goídel* "Irishman," or Gaelic, from *Gael*, the modern form of the same word) was the only language spoken in Ireland in the 5th century, the time when historical knowledge of that island begins. The two other members of this group, Scottish Gaelic and Manx, arose from Irish colonizations that began about that time. There were also important Irish-speaking colonies in Wales, but no trace of their language survives apart from a few inscriptions.

British (often called Brythonic, from Welsh Brython "Briton") had almost the same degree of influence on the island of Britain and the Isle of Man. Inscriptions and personal names surviving from Scotland show clearly that there was a non-Indo-European language spoken there, usually called Pictish, which was later replaced by British. There were undoubtedly dialectal differences within the island, but the existing dialects arose from the fragmentation of British by the Irish invasions of Man and what is now Scotland and by the English invasions that began in what is now southern England and finally reached Scotland. Scotland has ever since been partitioned linguistically between English (or "Scots") and Irish (or "Erse"—the Scots form of "Irish" —or "Gaelic"). A British dialect, now labelled Cumbric, lingered on in the western borderlands between England and Scotland until perhaps the 10th century, but almost nothing is known about it. In what is now Wales, British survived as the dominant language until a century or so ago; it is now known as Welsh. Another pocket of British speech survived in Cornwall until the end of the 18th century. It was from this area that emigrants in the 5th and 6th centuries AD had brought Celtic once more to the European mainland by establishing a colony in northwestern France, still called Brittany. It is just possible that there were some traces of the Continental Celtic language (*i.e.*, Gaulish) at that time in this remote area, although Breton is too similar to Cornish (an Insular Celtic tongue) to suggest any serious influence from Gaulish.

Re-establishment of Celtic on the European mainland

HISTORICAL DEVELOPMENT

Common Celtic. The reconstruction of Common Celtic (or Proto-Celtic)—the parent language that yielded the various tongues of Continental Celtic and Insular Celtic—is of necessity very tentative. Whereas Continental Celtic offers plenty of evidence for phonology (the sound system), its records are too scanty to help much with the grammar (morphology or syntax), for which the best available evidence is Old Irish, the most archaic of the Insular languages. The records provide a picture of a language of the same type as Latin or Common Germanic; that is, one that still maintains a considerable part of the structure of the ancestral Indo-European language and has not lost final or medial syllables. Its vowel system differs only slightly from that reconstructed for Indo-European by the French linguist Antoine Meillet. Differences include the occurrence of Celtic **ī* for Indo-European **ē* (*e.g.*, Gaulish *rix* and Irish *rí*, "king"; compare Latin *rex*) and **ā* in place of **ō*. (An asterisk [*] before a letter or word indicates that the sound or word is not attested but is a hypothetical, reconstructed form.)

The consonantal system, too, is conservative, although there are some striking features. Among them are the loss of **p* (*e.g.*, Irish *athair* "father"; *cf.* Latin *pater*) and the falling together of the aspirated and unaspirated voiced stops assumed for Indo-European. (A stop is a consonant made with complete momentary stoppage of the breath stream some place in the vocal tract; voiced stops are those produced with the vocal cords vibrating, such as *b*, *d*, *g*. An aspirated sound is accompanied by a puff of breath, often written as an *h*, as in *bh*, *dh*, *gh;* an unaspirated consonant lacks this accompanying puff of breath.) Thus, Old Irish *dán* "what is given" corresponds to Latin *donum* "gift" (from Indo-European **d*), but Old Irish *de-naid* "sucks" corresponds to Latin *fe-* in *fe-mina*, *fe-llare* (from Indo-European **dh*). This loss of distinctive aspiration occurs with three out of the four voiced stops, a situation close to that of Slavic.

Other considerations, however, show that Celtic belongs to the so-called southern group of the European branch of Indo-European languages, or in another classification, to the same centum group as Latin, whereas Slavic belongs to the satem group. (The centum and satem divisions of Indo-European languages are made according to the treatment of certain sounds, called palatals, that existed in the ancestral Indo-European language.)

The loss of **p* in Celtic was very early; only the place-name Hercynia, preserved in Greek, shows that, in initial position, it became an *h* sound before disappearing. In most of the known Celtic languages, a new *p* sound has arisen as a reflex of the Indo-European **k*^{w} sound. Thus there is Gaulish *pempe*, Welsh *pimp* "five," compared to Old Irish *cóic* and Latin *quinque* "five." The Irish evidence shows that **k*^{w}*enk*^{w}*e* must be reconstructed as the form in Common Celtic. The terms P-Celtic and Q-Celtic are sometimes used to describe assumed divisions of Common Celtic; to use one sound shift to distinguish dialects is, however, hardly justified, and the classification will not be used in this article.

Correspondence of Celtic *p* and *q*

The morphology (structure) of nouns and adjectives shows no striking changes from Indo-European. The Irish verb, however, exhibits a remarkable archaism not found in any other recorded Indo-European language. It has recently been demonstrated that the so-called primary and secondary endings of the Indo-European verb, as in the 3rd person singular endings *-(e)t* and *-(e)ti*, both occurred in the same tense. The forms with *-i* were used when the verb had absolute initial position; those without it were used in the normal verbal position at the end of the sentence. This is reflected in the Old Irish forms *beirith* (from **bereti*) "he bears" and *ní beir* (from **beret*) "he does not bear." It cannot be stated with certainty that Continental Celtic had preserved such forms. The Continental Celtic dialects show a few cases of sentences—admittedly imperfectly understood—in which the verb appears to be placed after the subject and before the object, as in modern western European languages. The history of Insular Celtic, however, shows a gradual shift from the older final position of the verb to the initial position, a position that has now become regular in all of the languages.

Relationships and ancient contacts of Celtic. The question of the relationship of Common Celtic to the

other Indo-European languages remains open. For some time, it was held that Celtic stood in an especially close relation to the Italic branch; some scholars even spoke of a period when an Italo-Celtic "nation" existed, toward the end of the 2nd millennium BC. The existence of a *q–p* relationship (see above) inside Italic too (*e.g.*, Latin *quattuor* "four," but Oscan *petora*) was thought by some to support this view. Much of this argument is, however, based on accidental resemblances (*e.g.*, the Irish future tense in *f-* and the Latin future in *b-*) or on formations such as the deponent and passive verb forms ending in *-r*, which at one time were known mainly in Italic and Celtic but have since been found in the Hittite and Tocharian languages as well. The undeniable common features between Celtic and Italic, such as the superlative endings of adjectives (Latin *-issimus;* Celtic **-samos, *-isamos*), are hardly sufficient to justify the assumption of a special relationship, and the whole concept of an Italo-Celtic unity has been powerfully criticized by the linguists Carl J.S. Marstrander and Calvert Watkins.

The original home of the Celts cannot be located precisely, but, on the whole, the evidence points to the eastern part of central Europe. There is more evidence for their contacts with other Indo-European peoples. One group of Celts, at least, found themselves neighbours of the Germanic peoples and were often confused with them by classical writers. It can be inferred that the Celts had attained a higher standard of social organization than the Germanic peoples from the existence of words such as Gothic *reiki* and *andbahts* (modern German *Reich, Amt*), apparently borrowed from Celtic **rīgion* "kingdom" and **ambactos* "officer." To the Greeks and Romans, on the other hand, the Celts were inferior in culture; Celtic words in Greek are restricted to those describing Celtic institutions, such as *bardoi* "poets." The borrowings from Celtic into Latin, which derive mainly from the period before the expansion of Roman power, belong to a few restricted categories, such as war (*lancea* "lance"), transport (*carrus* "baggage wagon" and *carpentum* "light carriage"), and agricultural products (*cervesia* "beer"). When the Romans finally conquered Gaul and imposed their language, a number of Celtic words came into Latin, but the Celtic terms were mainly concerned with rural life. These are more common in French dialects than in standard French, which preserves a mere handful, such as *mouton* "sheep," *ruche* "beehive," and *arpent* "land measure."

Contacts with the Greeks and Romans

Early records of Celtic. *Continental Celtic.* Celtic died out very quickly in eastern Europe. In its farthest outpost in Asia Minor, it may be assumed that the *Letter of Paul to the Galatians* was addressed to a people whose culture was already Greek but whose Celtic origins are clear from names preserved by classical authors; *e.g.*, Drunemeton "the very sacred place," formed from two distinctively Celtic elements. When commenting on that Letter, St. Jerome (died AD 419/420) said that the Galatians still spoke a language almost the same as that of the people of Trier. As he had been in both places, his evidence cannot be dismissed offhand, and it may be that a few speakers of Celtic still existed in both areas. Since St. Jerome did not claim to know any Celtic dialect, however, his statement cannot be accepted with certainty. Speaking generally, the history of Continental Celtic comes to an end as that of Insular Celtic begins.

Insular Celtic. The earliest evidence for Insular Celtic consists, like that for Continental Celtic, mainly of names recorded by Greek and Latin authors. In the case of Ireland, these were entirely by hearsay, and many of the Irish place-names recorded by Ptolemy in the 2nd century AD have not yet been identified. From perhaps the 4th century, ogham inscriptions (see ALPHABETS) are found in Ireland, consisting almost entirely of personal names. From the 5th century onward, British names in Latin inscriptions are recorded in Wales, as well as Irish names in both Latin and ogham alphabets in areas of Irish settlement. These scanty records are of value above all in establishing that, up to very nearly the time at which written documents become available, British and Irish had remained similar in structure to Gaulish. Thus, in Britain is found the genitive (possessive form) Catotigirni, which in Old Welsh gives Cattegirn, and in Ireland the genitive Dovatuci exists, which in Old Irish gives Dubthaich. These changes—loss of final syllables and connecting vowels, weakening of consonants between vowels, and so on—are very similar to what was happening to Latin in France at the same time; *e.g.*, Latin *avicellus* and *aqua* finally became *oiseau* and *eau*. There is no satisfactory explanation of why these profound changes should have occurred at this time, nor can the period at which they occurred be fixed precisely, for the engravers of the inscriptions clearly went on using traditional forms long after the sound had changed.

LINGUISTIC CHARACTERISTICS OF THE INSULAR CELTIC TONGUES

The new languages, the only forms of Celtic that are known thoroughly, present a considerable number of unusual features, some of them unknown to other Indo-European languages. Some scholars have argued that these features may have resulted from the presence of a large non-Celtic substratum in the British Isles. Because it is hardly likely that the Celtic invasions of those islands began much before 500 BC or that the invaders exterminated the existing inhabitants, such a possibility cannot be denied. On the other hand, some features once thought to be exotic, such as the initial position of the verb in the sentence, have been convincingly demonstrated to be organic developments from Indo-European. Others, such as the system of counting by 20s, are clearly innovations, but this system is shared by English ("three score and ten"), French (*quatre-vingts* "80"), and Danish, in all of which it is also an innovation, as well as Basque, in which it appears to be old.

Possible influences of substratum languages

Phonological characteristics. The most remarkable phonological feature of Insular Celtic is the development of a double series of consonants in which strongly articulated consonants are distinguished from their weak counterparts. The two series were originally merely phonetic variants, with the strong variety occurring in absolute initial position and in certain consonant clusters and the weak elsewhere. Later, however, the two series became independent, or phonological. In the languages as they first appear in writing, considerable changes have taken place in the phonetic forms of the two series. Both in Irish and in Welsh, Cornish, and Breton, the opposition (contrast) of strong:weak in the voiced stops has been replaced by stop:spirant (*e.g., b:v*). (A spirant, such as *v, f, s,* is produced with local friction and without complete stoppage of the breath stream.) Irish has the same system for the unvoiced stops (*e.g., t:th*), but Welsh, Cornish, and Breton have voicing in this instance (*e.g.*, voiceless *t:*voiced *d*). These changes by themselves are not very different from the weakening of consonants between vowels that occurs in other western European languages (compare Welsh *pader* "prayer," a loanword from Latin *pater* "father," with Spanish *padre* "father," deriving from Latin *patrem*), but, in Insular Celtic, they occurred not only inside the word but also inside the phrase, so that the initial consonant of a word preceded by another word ending in a vowel was weakened. When the final syllables were lost in the evolution to the modern languages, these variations remained, and a system of initial mutations (changes) was thus set up. If, for example, a Goidelic nominative form **sindos kattos koilos* "the thin cat" is reconstructed, this will give Old Irish *in catt coel* after the loss of final syllables, but the genitive **sindī kattī koilī* "of the thin cat" will give *in chaitt choíl* with changed initial consonants. The same sort of change occurred in one Italian dialect: in Tuscan, there occur *porta* "door," *la forta* "the door," *tre pporte* "three doors," from Latin *porta, illa porta, tres portae*. In both cases, consonant weakening has spread from word to sentence; there is a common development, but it cannot be claimed that it is distinctively Celtic.

Grammatical characteristics. Another feature of Insular Celtic is its lack of the infinitive form of the verb found in most other Indo-European languages—*e.g.*, English "to do," "to call." The equivalent is the verbal

noun, which is a noun closely linked to the verb, though not necessarily derived from the same stem. Being a noun, it can have a following noun in the genitive case, which, in the older languages at least, is subjective or objective according to whether the verb with which it is linked is intransitive or transitive. Thus, from the Old Irish sentence *téit in ben* "the woman goes," the verbal noun phrase *techt inna mná* "the coming of the woman" can be derived, whereas from *marbaid in mnaí* "he kills the woman" can be formed *marbad inna mná* (*lais*) "the killing of the woman (by him)." Among many other functions of the verbal noun is its use, when preceded by the appropriate preposition, with the substantive verb to provide a tense with continuous meaning. Thus, to *téit in ben* there is a parallel *a-tá in ben oc techt* "the woman is at going" (= "the woman is going"), and to *marbaid in mnaí* corresponds *a-tá oc marbad inna mná* "he is killing the woman." The close resemblance of this system to that of modern English, in which it is a comparatively recent development, has been variously explained as the working of a substratum or, more recently, in terms of areal (regional) development.

Verbal nouns

MODERN LANGUAGES OF THE FAMILY

The discussion of the individual languages that follows divides them into the two main groups, beginning with Irish, which is the oldest attested.

Irish. The history of Irish may be divided into four periods: that of the ogham inscriptions, probably AD 300–500; Old Irish, 600–900; Middle Irish, 900–1200; and Modern Irish, 1200 to the present. This division is necessarily arbitrary, and archaizing tendencies confuse the situation, especially during the period 1200–1600, when a highly standardized literary norm was dominant. After 1600, the modern dialects, among them Scottish Gaelic and Manx, begin to appear in writing.

The Latin alphabet was introduced into Ireland by British missionaries in the 5th century and soon began to be used for writing Irish. By the middle of the 6th century, the process of putting into literary form the rich oral tradition of the native learned class was certainly well advanced. The problems of interpreting the early writings are complicated by the fact that the orthography was based on that of Latin, but with a British pronunciation; *e.g.*, Latin *pater* was read as *pader*, the form of the loanword in Modern Welsh, and Old Irish *Pátric* was read as *Pádraig* (as it is spelled in Modern Irish). No new letters were evolved; the weak (less forceful) consonants were distinguished only in instances in which there were Latin spellings that could be utilized (*e.g.*, strong *ll*:weak *l*, strong *rr*:weak *r*, *nn*:*n*, *c*:*ch*, *t*:*th*) or with the help of the *punctum delens* (*s*:*ṡ*, *f*:*ḟ*), a dot that shows that the sound is not pronounced. As a result, many ambiguities remain: *ní beir* can mean either "he does not carry" or "he does not carry it," according to whether the *b*- is read as a *b* sound or a *v* sound. Nor was the Latin alphabet capable of dealing with the new system of consonant quality that appears in Irish alone among the Celtic languages. Thus, from the Celtic nominative singular and plural forms *bardos*, *bardī* developed Welsh *bardd*, plural *beirdd*, with a vowel alternation like that of English "mouse, mice." In Irish, the forms are *bard*, *baird;* the *-i-* of *baird* is purely graphic, serving to indicate that the following consonants are both palatalized. (Palatalized consonants are those in which the pronunciation is modified by raising the tongue toward the hard palate.) This palatalization had been purely phonetic as long as the *-ī* that caused it survived, but in Old Irish the palatalization became independent, so that each consonant of Common Celtic evolved into four distinct consonants (*i.e.*, phonemes); for example, from original Common Celtic *b* are derived a *b* sound and a palatalized *b* sound, and a *v* sound and a palatalized *v* sound.

Development of palatalized consonants

Apart from these phonetic developments, Old Irish is striking chiefly for the extraordinary proliferation of particles that appear before the verb and are used in forming compound verbs. For example, the Latin word *suffio* "I fumigate" is translated as *fo-timmdiriut*, composed of *fo* "under," *to* "to," *imb-* "around," *di* "from," and the stem *reth-* "run," with vowel and consonant changes appropriate to the 1st person singular present tense. Such forms, combined with a system of infixed accusative and dative pronouns (*i.e.*, pronouns inserted within a word) and syntactical accent shifts, produced a verbal system almost as complicated as that of Basque, though transparently Indo-European in origin. This system began to break down during the Old Irish period; the process was no doubt accelerated by the Viking raids that began at the end of the 8th century and that disrupted the monastic system, the guardian of the literary norm of Old Irish. Popular forms broke through in the Middle Irish period, though always mixed with archaizing forms; the backward-looking Irish scribes were never content to write down their own vernacular. During the 12th century, many ecclesiastical synods were held with the object of bringing the organization of the Irish Church more closely into line with that of western Europe, and the Anglo-Norman invasion took place in the latter part of the same century. It may have been these far-reaching changes that inspired the Irish literati to undertake a new standardization of their language. From the beginning of the 13th century, there is a rigidly fixed norm, often called Classical Modern Irish, which, for over four centuries, was used as the exclusive literary medium in Ireland and in Gaelic-speaking Scotland (there is no evidence for the Isle of Man).

The Scandinavians were first contained and then absorbed; they contributed a small number of loanwords to Irish, mainly in the field of navigation but also in that of urban life, for they were the first to establish towns in Ireland, though only on the coast. The Anglo-Normans were a more serious problem. After almost complete success in the early period, however, they became largely Gaelicized in custom and language outside the towns they had founded. They contributed a large number of loanwords to Irish in the fields of warfare, architecture, and administration, though many of these were comparatively short-lived. When English took over from Anglo-Norman as the language of administration and English colonies began to be planted in Ireland, English loanwords began to come into Irish. Few of these, however, were recognized in the literary language, and only from the evidence of the modern dialects has it become clear that they were quite numerous.

It was not until the beginning of the 17th century that the English power was finally consolidated in Ireland, first by military conquest and later by the planting of English-speaking colonists on a much larger scale than before. From this time onward, the decline of Irish began, with Irish becoming the language of an oppressed people. With no schools to teach the literary language nor any native nobility to support the literati who used it, the dialects appeared for the first time and began to be written in the paper manuscripts that constituted almost the only form of publishing available to those using Irish. By the beginning of the 19th century, it is probable that the population was almost equally divided between Irish speakers, mainly in the western half, and English speakers, mainly in the eastern half. The real imbalance lay in the fact that many of the Irish speakers were bilingual, whereas few of the English speakers were. The first census to record language use was taken in 1851, after the great famine that had struck the western areas with exceptional severity. By this time, the total number of Irish speakers was 1,524,286 (23 percent of the population), but only 319,602 spoke Irish exclusively. The decline of Irish has continued to the present day, in spite of a revival campaign initiated by the Gaelic League in 1893 and made part of official policy after the establishment of the Irish Free State in 1921.

The decline of Irish

Since then, Irish has been recognized as the first official language of the state; it is a compulsory subject in all of the schools and is a requirement for civil service and some other posts. There are probably more people able to read Irish—perhaps 300,000—than there ever were before. From 1945 onward, a standard written language has evolved, and there is a small but flourishing literary movement. Nearly all of the readers of Irish are English

speakers by upbringing, however, and not many of them would claim that Irish had become their main language. In the western areas in which Irish was the traditional speech, there are now fewer than 50,000 people to whom it is a mother tongue, and all but a handful of these have a more or less adequate command of English.

Scottish Gaelic. Some aspects of the modern Scottish Gaelic dialects show that they preserve features lost in the language of Ireland during the Old Irish period; such archaism is characteristic of "colonial" languages. The innovations are, however, more striking than the archaisms. Most remarkable is the loss of the voicing feature (*i.e.*, the vibration of the vocal cords) in the stops. All of the stopped consonants are unvoiced, and the original voiceless stops have become strongly aspirated; for example, the equivalent of Irish *bog* "soft" is [pok], *p* being the voiceless counterpart of *b*, and that of *cat* "cat" is [k^{h}aht], the superscript ^{h} after *k* indicating the aspirated quality. (The brackets indicate that the symbols printed within them are phonetic rather than orthographic.)

Scottish Gaelic was planted on British soil, and the verbal system has been remolded on the lines of the British language, which originally had no future tense. As in Modern Welsh, the inherited present tense has largely future meaning, and present time is mainly expressed by the present-tense form of the substantive verb and the preposition *a(ig)* with the verbal noun. (In Insular Celtic, there are two verbs for "to be," a substantive verb with the meaning, roughly, "to exist," and a linking verb such as "is" in "John is a boy" or "sky is blue.") Thus, from Old Irish *téit in ben* "the woman goes" is derived Scottish Gaelic *théid a' bhean* "the woman will go," and from Old Irish *a-tá in ben oc techt* "the woman is going" results the Scottish Gaelic form *thà an bhean a' dol* "the woman goes" or "the woman is going."

It is only from the 17th century onward that the development of Scottish Gaelic can be studied, for, up until then, Classical Modern Irish was the literary norm. Indeed, the first book to be printed in Irish was a translation of the Calvinist *Book of Common Order*, published in Edinburgh in 1567, and the Scottish Reformers used the Irish Bible for some time, until it became clear that it was too foreign for the people to understand. A native Scottish standard emerged gradually during the 17th century, as poets ignorant of the Irish norm began to compose in their native dialects. It was not until the 18th century that the orthography became more or less fixed, and, until recent reforms in Ireland, the divergencies between the written languages were comparatively small.

Scottish Gaelic as a separate language from Irish

It is clear, however, that Scottish Gaelic must now be regarded as a separate language, though the differences between it and Irish are no greater than those between standard German and the Swiss dialects.

Scottish Gaelic was confronted by northern dialects of English (Scots) from the very beginning; these rapidly penetrated into the east of the country, especially in the area centred on Edinburgh, the capital. The so-called Highland Line, marking the boundary between the two languages, has been steadily receding to the west since medieval times. By 1901, there were 230,806 speakers of the language, including 28,106 who spoke Scottish Gaelic exclusively; 106,466 persons, including nearly all of the monolingual Scottish Gaelic people, lived in the two counties of Inverness and Ross. The decline has continued steadily, and, even in those two counties, Gaelic is rapidly disappearing from the mainland, though it is holding its ground well in the Hebrides. Scottish Gaelic speakers in the 1961 census numbered 80,978, which shows that the state of Scottish Gaelic survival is in many ways less serious than that of Irish. Because the majority of Gaelic speakers are Protestants who are accustomed to reading the Bible and using the vernacular in their religious services, literacy in Gaelic has been widespread. Furthermore, however low the census figures may be, they give an accurate picture of the number of those to whom Gaelic is a mother tongue because the number of English speakers who have acquired it is negligible. It must be admitted, however, that the recent literary revival finds its audience among the displaced Gaelic speakers of Edinburgh and Glasgow rather than in the Hebrides, where Gaelic is still confined to the home and English is the language of culture. In addition, the Canadian census of 1961 recorded 3,702 Gaelic speakers in Nova Scotia.

Manx. The history of the Isle of Man is imperfectly known. It was first inhabited by British speakers, then colonized from Ireland, and later became part of the Scandinavian Lordship of the Isles until 1266, when the King of Norway ceded both Man and the Hebrides to Scotland. From then on, it became involved in the wars between England and Scotland until 1346, when it passed finally to England. Though an Irish dialect survived as the speech of the majority of the people, these circumstances were not propitious for literary contacts with Ireland, and Manx was apparently not written until the Welsh bishop John Phillips translated the Anglican *Book of Common Prayer* in 1610, using an orthography based on that of English. This orthography makes Manx difficult to understand for readers of Irish and Scottish Gaelic, to whom it is of considerable interest because it represents a dialect entirely free of literary influences. The orthography soon became fixed, and a far-reaching series of later phonetic changes made the written form a highly inaccurate representation of the final stages of the language. Phonologically, it has more in common with the eastern dialects of Irish than with Scottish Gaelic, but its morphology and syntax are much more like those of Scottish Gaelic, probably because of the common British substratum. Its tense system is similar to that of Scottish Gaelic and Welsh, and its use of periphrastic verb forms (*i.e.*, longer forms with several elements) with the auxiliary meaning "to do" goes further than either of these, especially in its final stages.

Extinction of Manx in the early 20th century

In the beginning of the 18th century, English was still not understood by most of the people, but during the 19th century the decline of Manx was rapid, and the census of 1901 showed only 4,419 speakers of the language, all bilingual. Twenty years later, the language had ceased to be used as a normal means of communication, but, until recently, investigators have been able to find old people capable of giving useful information.

British languages. Britain was thoroughly romanized, and it is clear that the British language itself had been much affected by Latin; on the level of vocabulary, such an everyday word as Welsh *pysg* "fish," for example, derives from Latin *piscis*. The vowel system lost independent vowel quantity, the length of vowels becoming determined by the structure of the syllable, a situation that also occurred when the later Latin developed into Romance. Even after the collapse of Roman rule, Latin retained the same prestige among British Christians that it had in the rest of the Western Empire. The Irish monks introduced to the British speakers the custom of writing down the vernacular language at about the end of the 8th century; they adapted the clumsy Irish orthography for that purpose. At this period, the British dialects were very close to one another and can hardly be classed as separate languages, though they soon began to diverge. Like Old Irish, they had lost their final syllables and had undergone many other changes from the state shown by the inscriptions. Notably, the languages show only the merest traces of the declension of the noun, although the verb preserves a full inflectional system (that is, it has a full series of endings). It is clear that no future tense existed in early British, though the separate languages were later to fill this gap by various means.

Welsh. Welsh is the earliest and best attested of the British languages. Although the material is fragmentary until the 12th century, the course of the language can be traced from the end of the 8th century. The earliest evidence may represent the spoken language fairly accurately, but a poetic tradition was soon established, and by the 12th century there was a clear divergence between the archaizing verse and a modernizing prose. The latter was characterized by a predominance of periphrastic verbal-noun constructions at the expense of forms of the finite verb. By this time, too, the forms corresponding to other Celtic and Indo-European present-tense forms had large-

ly acquired future meaning; *e.g.*, Welsh *nid â* "he will not go" (future) contrasts with Irish *ní aig* "he does not drive" (present). The gap thus left was filled, as in Scottish Gaelic and Manx, by a construction involving the substantive verb and the verbal noun; *e.g.*, *y mae'r wraig yn myned* "the woman goes" or "the woman is going" is composed of the verb *mae* "is" and the verbal noun *myned* "going."

By the 14th century, prose and verse styles became more similar, the prose being less colloquial and the verse less archaic. This marks the beginning of modern literary Welsh, which was finally fixed by the Bible translation of 1588. Modern literary Welsh developed at a time when Welsh national identity was beginning to be seriously threatened by the close relations with England that followed on the accession of the Welshman Henry Tudor (Henry VII) to the English throne in 1485. Welsh was being written less and less, and the spoken language was being penetrated by English words. In 1536, the Act of Union deprived Welsh of its official status. By the beginning of the 18th century, the position of the Welsh language had fallen very low, though it was still the vernacular of the vast majority of the people. It was saved by the Methodist revival of the 18th century, which established schools everywhere to teach the people how to read the Welsh Bible and which brought the Bible itself, together with Welsh religious books, into almost every home. The literary language rejected most of the English loanwords that had come into the popular speech, and, by the 19th century, a highly literate Wales was equipped with reading material of every kind in the Welsh language. Meanwhile, however, the popular speech diverged further from the fixed literary norm, which was never spoken except in the pulpit or on the platform. Modern Wales has a literary language that no mother speaks to her child and widely differing dialects that appear in print only to represent dialogue in stories and novels.

Effect of the 18th-century Methodist revival on Welsh

The Industrial Revolution of the 19th century first undermined the dominance of Welsh in Wales: English-speaking workers were brought into the mines and factories in such numbers that they could not be absorbed linguistically. By 1901 English speakers outnumbered Welsh speakers for the first time. Out of a population of 2,012,876, only 929,824 were reported as Welsh-speaking, though 280,985 people spoke Welsh alone. By 1961 the number of Welsh speakers had dropped to 656,002, representing just under 25 percent of an increased population. Most of rural Wales, however, is still Welsh speaking, and recent years have seen a great improvement in the official status of Welsh and a considerable increase in its use in the schools; it is certainly the most firmly rooted of the modern languages of Celtic origin.

In addition, there are still about 8,000 Welsh speakers in parts of Patagonia, Argentina, which was colonized by Welsh settlers in 1865. These people maintain cultural contacts with the homeland but are all bilingual in Welsh and Spanish and seem fated to final assimilation.

Breton. Breton disappeared from sight after the early period, and no literary texts are available until the 15th century. These, mainly mystery plays and similar religious material, are written in a standardized language that is by now completely differentiated from Welsh and, to a lesser degree, from Cornish. The divergence between Breton and Cornish is largely a matter of the English loanwords in Cornish and the French loanwords in Breton. The present tense was retained in its original function, whereas a future and conditional were formed from the present and past subjunctive, respectively. Later, the Breton dialects became written and showed considerable divergencies in this form. Not until the 1920s was an attempt at standardization made, and even then it was necessary to adopt two norms. One was called KLT, from the initials of the Breton names of the dioceses of Cornouaille, Léon, and Tréguier, the dialects of which agree with Welsh and Cornish in having the stress accent on the next to the last syllable. The other norm was the dialect of Vannes in the south, which has the stress accent on the final syllable and many other distinctive features, at least some of which can be explained by its close contacts with French. More recently, two norms have been evolved to cover all four dialects; one of these is used by most writers, whereas the other is officially recognized by the universities of Brest and Rennes, in both of which Breton is taught.

Breton dialect norms

Up until recently, Breton was the common language of the people in Cornouaille, Léon, Tréguier, and Vannes, within the boundaries of the *départements* of Côtes-du-Nord, Finistère, and Morbihan. Breton may still have more speakers than Welsh, but this is quite uncertain because no language statistics exist for France. There is, however, general agreement that very few children today are being brought up speaking Breton. This is at least partly the result of French official policy, which in effect excludes the language from primary and secondary schools, though the poor economic opportunities in Brittany also play a part. The literary movement is, therefore, confined to an intelligentsia of perhaps not much more than 10,000 people, many of whom live outside Brittany. The overwhelming mass of the remainder of Breton speakers are literate only in French, and chances for the survival of Breton seem very poor.

Cornish. Like Breton, Cornish had no literary texts before the 15th century. Those that exist are mainly mystery plays, some of which are almost literal translations from English. Cornish is much closer in structure to Breton than to Welsh, but it has also been heavily influenced by English. At the beginning of the 18th century, there were still a number of areas in which Cornish was spoken, but it died out as a means of communication by the end of the century.

BIBLIOGRAPHY. H. LEWIS and H. PEDERSEN, *A Concise Comparative Celtic Grammar* (1937), is the most recent survey of the entire field. The early history of the British group is discussed in detail by K.H. JACKSON, *Language and History in Early Britain* (1953); for the later history of Welsh and Breton, J. MORRIS JONES, *A Welsh Grammar* (1913), and F. GOURVIL, *Langue et littérature bretonnes* (1952), give useful information. R. THURNEYSEN, *Grammar of Old Irish*, rev. ed. (1946), is a classic among linguistic handbooks; for the later development of Irish, T.F. O'RAHILLY, *Irish Dialects Past and Present* (1932), is full of information and contains chapters on Scottish Gaelic and Manx. B.O CUIV (ed.), *A View of the Irish Language* (1969), containing 12 essays by various hands, maps, and illustrations; and D. GREENE, *The Irish Language* (1966), are directed to the general reader rather than to the linguist. The relevant sections of GLANVILLE PRICE, *The Present Position of Minority Languages in Western Europe* (1969), give full bibliographies of works dealing with the political and social status of the surviving Celtic languages.

(D.Gr.)

Celtic Religion

The Celts, an Indo-European people who were at the height of their power numerically and geographically in 4th-century-BC Europe, have left no literature on the Continent. The literature of the insular Celts (Irish and Welsh), however, though late in time, imparts valuable information about their religion in the myths that have been preserved. Celtic religion, presided over by the Druids (the priestly order), presents beliefs in various nature deities and certain ceremonies and practices that are similar to those in Indian religion. The insular Celts and the people of India also shared certain similarities of language and culture, thus indicating an ancient common heritage.

SOURCES

Greek, Roman and Celtic sources

For information about the Celts of the Continent scholars depended upon what Greek and Roman historians have reported, often at second hand. Another important source of information is found in Celtic sculpture and inscriptions. The Greek and Latin historians seem to have derived their information from a single source, namely, the historical works of Poseidonius, a Stoic philosopher of the late Roman Republican period. The most important witnesses dependent upon Poseidonius are Strabo, Diodorus Siculus, and Julius Caesar. The sculpture dates almost entirely from the Gallo-Roman period.

Julius Caesar stated in *The Gallic War* that in Gaul Mercury was the most honoured of all the gods and that many images of him were to be found. Mercury was regarded as the inventor of all the arts, the patron of travellers and of merchants, and the most powerful god in matters of commerce and gain. After him the Gauls honoured Apollo, Mars, Jupiter, and Minerva. Of these gods they held almost the same opinions as other peoples did: Apollo drives away diseases, Minerva promotes handicrafts, Jupiter rules the heavens, and Mars controls wars. Caesar distinguished five separate gods among the Gauls, but he cited them only by their Roman names; however, his statement may well have been based upon deliberate inquiry.

As for the inscriptions, they are in a few instances associated with effigies of a god, such as on the famous Paris "altar" and the altar at Sarrebourg, and from them the Celtic gods Cernunnos, Esus, Sucellus, and Taruos Trigaranus can be recognized. Esus and Sucellus, and the god with the wheel, Taranis, can be identified elsewhere, but the images of most of the sculptures are not positively identifiable. The 1st century AD Latin poet Lucan, in a passage of his *Pharsalia* describing various Gaulish tribes, named three of the Celtic gods—Teutates, Esus, and Taranis—and stated that they were appeased by human sacrifice. An early commentator on Lucan's work identified Teutates with Mars, Esus with Mercury, and Taranis with Jupiter, and thus later scholars have a working hypothesis from which to start their inquiries.

MYTHOLOGY

The Celtic pantheon

Pre-Roman gods. The Celtic pantheon is difficult to construct, since some 400 names of Celtic gods are known and of these more than 300 occur only once and are apparently names of minor local deities. Caesar distinguished five gods, and names of three more gods were supplied later by Lucan. Besides these there are the names of two gods that occur more often than any others, Belenus (20 times) and Grannus (19 times), both later identified with Apollo. Moreover, three others have been mentioned already, as well-known from sculpture: Cernunnos, the god with the horns of a stag; Sucellus, the god with the mallet; and Taruos Trigaranus, the bull with three cranes. One god, perhaps the greatest of all, survived in Irish mythology as Lug Lámfota, Lug of the Long Hand. On the Continent he is known directly from three dedications, two of them in plural form; but his name is widespread in the place name Lug(u)dunum, which has given the modern Lyon, Loudun, and Laon in France, Leiden in The Netherlands, and Legnica in Poland. Most of the goddesses appear only in association with one or other of the gods. Sucellus has for consort Nantosuelta; Luxovius, a god of healing and patron of the baths at Luxeuil, has Brixia; Borvo, another god of healing, has Damona. Rosmerta, a goddess of plenty, appears with Mercury and chiefly in eastern Gaul. The most interesting goddess is Epona, the mare goddess, whose name occurs 26 times and whose cult seems to have been known all over the Celtic world. Epona is often represented as mounted on a mare, and she was the patroness of the cavalry and of travellers on horseback, and of mares and foals. Her image was often used to adorn the stables.

Most notable, however, among female deities are the mother goddesses, of whom there are many effigies. In Gaul the mother goddess was worshipped in triple form under the title Matres or Matronae. The dedicatory texts that survive are in Latin, and the figures are either represented with baskets of fruit, or with horns of plenty, or with children in their laps. (Matrona was the name of the River Marne, which was also thought to be a goddess.)

Gallo-Roman gods. The 20th-century French scholar Paul-Marie Duval distinguished two periods in the history of the worship of the Gaulish gods: the early period ending in the middle of the 1st century AD and the later period of Roman Gaul, when much syncretism (accretion and coalescence) between Celtic and Roman gods had taken place and the effigies of old Gaulish gods appeared under Roman names.

The great god of the Celts was the one Caesar called Mercury, the god of all the arts, but his Gaulish name is not given. In the later period, under the name Mercury, he appeared in 440 inscriptions and 350 sculptures, which are still extant, and thus he is the most richly documented of all the gods. In Ireland he was called Lug of the Long Hand, and the name Lugus appears in three dedicatory texts on the Continent: one in Switzerland at Avenches, where the form is Lugoues; one at Asma (Tarragona), where the form is Lugouibus, in a dedication by the guild of cobblers; and one at Peñalba de Villestar, where the form is Luguei. He was apparently sometimes thought of as a triple god. In Ireland Lug was called *samildánach* ("possessed of many talents"), which is in agreement with Caesar's account of Mercury, and his regular epithet was *lámfota*. A very ancient cult of the God with the Long Hand, who appears in rock-carvings in Sweden, was also known in the Caucasus, and one of the Swedish effigies is known to this day as "the Cobbler," echoing the dedication of Asma. In the Welsh tale *Math fab Mathonwy* the hero is called Lleu Llaw Gyffes ("Lug of the Dexterous Hand"), and in one episode he appears disguised as a shoemaker. Plainly there was a myth about Lugus as patron of cobblers, and he was also known as the dexterous god, patron of the arts. His Irish epithet connects him with the ancient God of the Long Hand, and a similar epithet *pṛthu-pāṇi* ("of the large hand") is applied in India to the Vedic Savitṛ, god of the sun. The web of tradition is difficult to disentangle, but Lugus emerges as a great god, whose name was for some reason rare on the Continent as the name of a god but familiar in Ireland. In Ireland his feast, Lugnasad, was on August 1, the date of the harvest festival, and it has survived to the present as "Garland Sunday." The identification of Esus with Mercury is probably not exclusive; the god to whom Caesar referred as Mercury probably was Lugus.

Lug of the Long Hand

Taranis, whose name was noted by Lucan, was later identified with Jupiter; *taran* means "thunder" in Welsh. He may be identified as the god of the sky and of thunder, and his symbol was the wheel. Though some have identified Sucellus with him, this is doubtful. The symbol of Sucellus is the mallet, depicted in more than 20 effigies. Henri Hubert has suggested that Sucellus might be the patron of brewers.

Teutates, later identified with Mars (Mars Toutatis), bears a name that is derived from the reconstructed word *teuta* ("tribe, people") and could mean "(god) of the tribe," and that may have been in origin a common noun. In Irish sagas the common form of oath is: "I swear by the god by whom my tribe swears," suggesting that each tribe had its own tutelary god whose proper name was subject to a tabu. Lucan stated that victims sacrificed to these gods were killed by being plunged headfirst into a vat. Such a scene is presented on the Cauldron of Gundestrup, now in the National Museum at Copenhagen. Teutates was probably the tribal god and also the god of war.

Esus, the third of Lucan's triad, is a mysterious figure. His name is on the Paris "altar," where he is depicted in the act of cutting a tree and in the company of a bull with three cranes on his back under the legend Taruos Trigaranos. A similar scene is presented on the altar at Trier, and it probably portrays a lost myth. The bull figures in Irish mythology, too, but no Irish tradition helps to explain the character of Esus. Because of the lack of a written literature the myth involving Esus is not known.

The horned god Cernunnos

Another mysterious deity is the horned god Cernunnos, who appears on the Gundestrup Cauldron in the yoga posture, with the horns of a stag, and surrounded by animals, including the Serpent with a Ram's Head, who is elsewhere associated with Teutates. Here Cernunnos strongly resembles the Indian god Śiva Paśupati ("lord of animals") on a seal from Mohenjo-daro now in the Delhi

Museum. He is also portrayed and named on the Paris "altar," again in the yoga posture, and with the horns of a stag. Cernunnos and Taruos Trigaranus are animal deities, the Stag and the Bull, and there was probably a serpent god as well. In Britain the Horned God is widely attested. In Ireland the bull god survives in shadowy form in the great *Táin Bó Cuailnge*, and Donn, the Brown Bull of Cooley, and the White-Horned Bull seem to be supernatural beings. They appear at the end of a series of transmigrations in which two fairy swineherds change themselves into stags, champions, spectres, dragons, and worms; and as worms they are taken from sacred springs by two cows at their drink and are reborn as the two great bulls of Ireland.

Belenus and Grannus were both later identified with Apollo. Belenus may have been a god of the sun. His name echoes the Irish Beltine ("fire of Bel"), name of the summer festival, May 1. Grannus was a god of healing. Borvo was another healing deity, and several thermal springs had local patrons. The cult of a god of healing under various names could lie behind Caesar's mention of Apollo. Another god that is worthy of mention is Ogmios, the god of eloquence, who was described by Lucian as the god who was represented as Hercules, because the Celts believed that eloquence was more powerful than strength.

British and Irish Celtic gods. Insular tradition provides the names of other gods common to Ireland and Wales, but their Gaulish names are not known. Goibniu is the smith among the Irish gods, and his Welsh name is Gofannon. Manannán (Welsh Manawydan) is the god of the sea, and Nuadu of the Silver Arm (Welsh Lludd of the Silver Arm) is a god who is portrayed in a dedication that occurs on a monument in Gloucestershire and shows him equipped as a fisherman. He is probably the ancestor of the Fisher King in the Quest of the Holy Grail in Arthurian romance. In Ireland Nuadu preceded Lug as king of the gods, and Lug was succeeded by the Dagda, "the Good God."

Triple deities

Lugus was sometimes thought of in the plural, and the Matres were adored in triple form. There are as many as 32 images of a three-headed god extant on the Continent, and some have been found in Britain and in Ireland. On a stela at Reims, Mercury has three faces, but the Three-Headed God is more often anonymous. In Ireland several deities appear in threes, notably the Three Gods of Danann, from whom Lug received his weapons. There are three Brigits: a goddess of poetry, a goddess of healing, and a goddess of smithcraft. There are three Machas and three goddesses of battle: Morrígan, Badb, and Nemain. The trio Mac Cuill, Mac Cécht, and Mac Gréine are husbands of three goddesses of Ireland, Banba, Fótla, and Ériu. Brigit ("the exalted one") appears in Britain as Brigantia and was perhaps the tutelary goddess of Brigantes, although her name does not occur in Gaul. She has been identified with Caesar's "Minerva" and would then be an important Gaulish and Insular Celtic goddess.

Wells, rivers, and sacred trees were objects of devotion and had patron gods or goddesses. There was a sanctuary of the Dea Sequana at the source of the Seine and one of the Dea Matrona near the source of the Marne. The Yonne (Icaunis) and the Saône (Souconna) rivers were also viewed as divine. In Ireland the Boyne (derived from *bōuvindā*, "cow finder") and the Shannon rivers also were regarded as goddesses. Of the trees of the forest, the beech, the oak, and the yew were revered in Gaul, and in Ireland there were many sacred trees. There is a word *bile* ("sacred tree") that occurs in the place name Moville (*Mag Bile*, "plain of sacred trees") in Ireland, and the place name Billom (from the reconstructed word *Biliomagus*) in France.

BELIEFS, PRACTICES, AND INSTITUTIONS

Beliefs. Little is known about the religious beliefs of the Celts of Gaul. They believed in a life after death, for they buried food, weapons, and ornaments with the dead. The Druids, the early Celtic priesthood, taught the doctrine of transmigration of souls and discussed the nature and power of the gods. The Irish believed in an Otherworld, imagined sometimes as underground and sometimes as in islands beyond the sea. These two notions, it has been suggested, arose from the cult of a sun god, who arose at dawn out of sea or earth and returned there at night. The Otherworld was variously called "the Land of the Living," "Delightful Plain," "Land of the Young" and was believed to be a country where there was no sickness, old age, or death, where happiness lasted forever, and a hundred years was as one day. It was similar to the Elysium of the Greeks and may have belonged to ancient Indo-European tradition. In Celtic eschatology (pertaining to the end of history), as noted in Irish vision or voyage tales, a beautiful girl approaches the hero and sings to him of this happy land. He follows her, and they sail away in a boat of glass and are seen no more; or else he returns after a short time to find that all his companions are dead, for he has really been away for hundreds of years. Sometimes the hero sets out on a quest, and a magic mist descends upon him. He finds himself before a palace and enters to find a warrior and a beautiful girl who make him welcome. The warrior may be Manannán, or Lug himself may be the one who receives him, and after strange adventures the hero returns successfully. These Irish tales, some of which date from the 8th century, are infused with the magic quality that is found 400 years later in the Arthurian romances. Something of this quality is preserved, too, in the Welsh story of Branwen, daughter of Llyr, which ends with the survivors of the great battle feasting in the presence of the severed head of Bran the Blessed, having forgotten all their suffering and sorrow. But this "delightful plain" was not accessible to all. Donn, god of the dead and ancestor of all the Irish, reigned over Tech Duinn, which was imagined as on or under Bull Island off the Beare Peninsula, and to him all men returned except the happy few.

Life after death

Practices and institutions. Though there was a full pantheon of gods and probably a rich mythology among

the Celts, many local deities, and some whose cult was widespread, no detailed account of individual gods is possible. Even the Irish gods have little personality, and of Irish pagan rites practically nothing is known. Human sacrifice was practiced in Gaul: Cicero, Caesar, Suetonius, and Lucan all refer to it, and the elder Pliny says that it occurred in Britain too. It was forbidden under Tiberius and Claudius. There is some evidence that human sacrifice was known in Ireland and was forbidden by St. Patrick, who apparently also reproached the Irish for worshipping the sun; and if the God with the Long Hand was a sun god, then Lug may have been originally the god of the sun. There is no clear evidence, however, of sun worship in Ireland.

Sacrifice

Druids. The priests who served the Celtic gods and presided over the sacrifice were the Druids. The name means "knowing the oaktree" (*dru-vid-*) and may derive from Druidic ritual, which seems in the early period to have been performed in the forest. Caesar stated that the Druids avoided manual labour and paid no taxes, so that many were attracted by these privileges to join the order. They learned great numbers of verses by heart, and some studied for as much as 20 years: they thought it wrong to commit their learning to writing but used the Greek alphabet for other purposes.

Shrines. As far as is known, the Celts had no temples before the Gallo-Roman period, and their ceremonies were performed in forest sanctuaries. In the Gallo-Roman period pagan temples were erected, and many of them have been discovered by archaeologists in Britain as well as in Gaul.

Divination. There were also seers (*vates,* Greek *manteis*) who had various means of divination and could foretell the future by watching the flight of birds or observing the animals slain in sacrifice. On important occasions a human victim was stabbed in the midriff, and from the manner of his fall, the twitching of his limbs, and the flow of blood they could foresee events. The Irish word for seer is *fáith* and both men and women practiced divination. One of the rites was called "bull-sleep" (*tarb-feis*) and involved the slaughter of a bull. Its flesh was boiled, and the seer bathed in the broth and ate the meat and then slept, and in his sleep he saw the future king of Tara.

Festivals. Irish sources provide important information about Celtic religious festivals. The year was divided into two periods of six months by the feasts of Beltine (May 1) and Samain (November 1), and each of these periods was equally divided by the feasts of Imbolc (February 1), and Lugnasad (August 1). Samain was, in Ireland at least, the great feast of the year. The word was thought to mean "end of summer" (*sam,* "summer," *fuin,* "end"), but it may mean "assembly," for Beltine is also called *Cetśamain* ("First Samain"). Imbolc has been compared by the French scholar J. Vendryes to the Roman lustrations and apparently was a feast of purification for the farmers. It was sometimes called *oímelc* ("sheep milk") with reference to the lambing season. Beltine ("Fire of Bel") was the summer festival, and there is a tradition that on that day the Druids drove cattle between two fires as a protection against disease. Lugnasad was the feast of the great god Lug Lámfota, presumably a harvest festival when the Fair of Tailtiu was held.

Beltine and Samain

One rite practiced in Ireland down to the Middle Ages deserves mention because it closely resembles the Hindu ritual of the horse sacrifice (*aśvamedha*) and is therefore probably of Indo-European date. The Welsh ecclesiastical writer Giraldus Cambrensis (died *c.* 1223) described a ritual practiced in one of the northern kingdoms of Ireland that involved the sacrifice of a mare at the inauguration of the king. The king went through a symbolic union with the victim and then bathed in the broth of its flesh and drank thereof. Through this ritual the king sought fertility for himself and his kingdom. A just king brought prosperity to the kingdom. If he was unjust, a curse fell upon the land.

Sovereignty was regarded in Ireland as a goddess whom the king must wed in order to ensure the welfare of his people. The notion may have been a development from the primitive idea of marriage of a tribal god to a goddess of the earth, or of water, as a source of fertility.

Art and iconography. Two of the most interesting examples of the religious art of the Celts are the mysterious Cauldron of Gundestrup and the Paris "altar" now preserved at the Musée de Cluny (France). The cauldron is the most curious object of all. Its date and provenance are unknown. Though it was found at Gundestrup in Jutland, it is believed to have been brought there as plunder and to have come originally from the territory of the Scordisci on the middle Danube. It may belong to the 1st century BC, but another opinion is that it came from eastern Gaul and is as late as the 4th century AD. Another strange monument, apparently of religious significance, is the Monster of Noves, which perhaps portrays a bear god. The human form must at least sometimes have been represented in sculpture in Gaul before the Roman conquest, for there are a few headless figures from Roquepertuse that may be as early as the 3rd century BC. Most of the religious sculpture of the Celts, however, is Gallo-Roman. The highest achievement of Celtic art lies in the purely imaginative decoration of metalwork on helmets and shields, on mirrors and collars and coins, or of stone monuments such as the pillar at St. Goar.

The Gundestrup Cauldron

CONCLUSION

At the present stage of scholarship, the picture of Celtic religion is necessarily vague and confused. It is possible to suggest probable functions for some of the many gods and goddesses and to sense a rich mythology that, so far, is only dimly visible. Esus and the horned god Cernunnos remain enigmas. There was a cult of wells and rivers and a cult of trees with marked specialization of the oak. The king was sacred and was closely concerned with fertility and with the prosperity of his people. This much is known, and there remains the hope that more may be learned about the religion of the Celts from a closer study of insular Celtic sources.

Celts, Ancient

The Celts were the first prehistoric people to rise from anonymity in the European territories north of the Alps. Until the middle of the first millennium BC nothing was known of them by the civilized Mediterranean world. For the Greeks they were *Keltoi;* the Romans called them Gauls. At the time when these Celts had become the predominant people in the barbarian world they were settled throughout a great part of Europe, extending from Ireland and Britain to the Balkans, and even as far as Anatolia. They were a numerous people of considerable political and military significance. Their creative activity completed the prehistoric development of Europe; by the 4th century BC Greek writers ranked the Celts, together with the Scythians and the Persians, among the most numerous "barbarian" peoples of the then known world. Although they never formed a unified ethnic group or a great empire and were split into many tribes with differ-

ent dialects, they became an important factor in the development of a specifically European civilization.

HISTORY

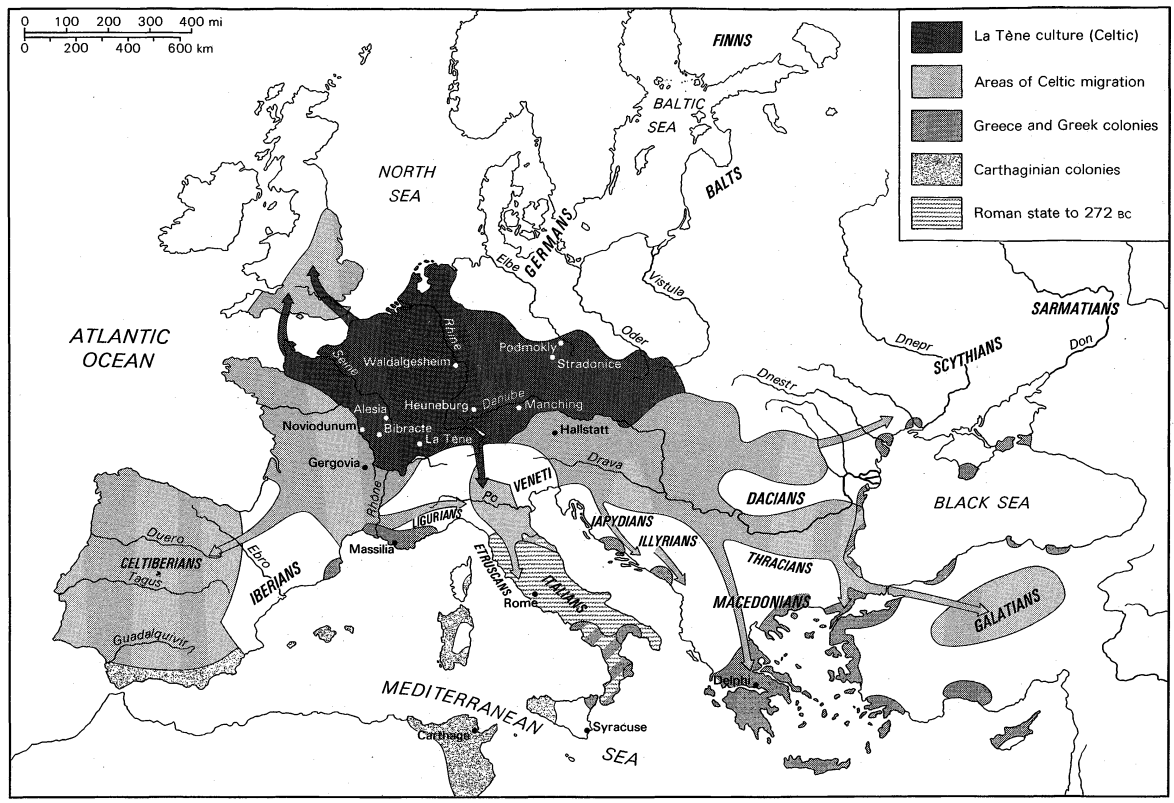
From the 5th century BC on, the Celts became well known throughout the contemporary world, and their culture at the time of the zenith of their power (5th–1st centuries BC) has been exhaustively studied by archaeologists. Called the La Tène culture after a Swiss archaeological site on Lake Neuchâtel, it represented the second Early Iron Age and followed chronologically upon the Hallstatt Age (see below). But the history of the Celts before the 5th century remains very uncertain.

Early Celtic settlements. Archaeological investigation strongly suggests that the area in which the historical Celtic tribes developed comprised part of present-day France, southern Germany, and adjacent territory reaching as far as southern and central Bohemia. It is possible to trace their origins as far back as the Bronze Age Tumulus culture, which reached its high point about 1200 BC. Various cultural components were unified in the succeeding Urnfield culture (12th–8th centuries BC; "tumulus" and "urnfield" refer to the burial customs of these cultures). This was followed by the Hallstatt Period (7th–6th centuries; named after the burial ground near Hallstatt in the Salzkammergut in upper Austria). During that time other peoples known to history made their appearance in Europe: the Illyrians in the southeast and the Germans in the north.

From the Urnfield period on, archaeological evidence of the Celtic confederation northwest of the Alps is increasingly noteworthy, producing, in the later Urnfield stage, a fresh phase of Tumulus burials, some of these being located in areas where Celtic power later became predominant.

Burial finds

Burial grounds of the Hallstatt period comprise chamber graves containing four-wheeled wagons, splendidly decorative yokes and harness fittings, and a large amount of pottery and other artifacts, which indicate a complex burial ceremony. Such elaborate burials, found in Bohemia, throughout southern Germany, and in northeastern France, would appear to be those of chieftains or members of a leading oligarchy. To this period there may also be ascribed the first known fortified castles of western central Europe. The fortified hill residence at Heuneburg on the Danube, dating from the late Hallstatt period, was rebuilt at least five times. One phase shows a mature building technique including the use of brick



The Celtic migrations.

From Grossen Historischen Weltatlas, vol. I, *Vorgeschichte und Altertum* (1963); Bayerischer Schulbuch-Verlag, Munich

masonry in towerlike bastions, a Mediterranean characteristic quite alien to the region. Adjacent to Heuneburg is a group of chieftains' barrows, one of which, Hohmichele, has wood-lined chambers and wall draperies and contains a four-wheeled wagon, gold decorations, and jewelry. It is clear that imports from the south, such as amphorae of wine or Greek Black Figure pottery, were common. A fortified hill site on Mt. Lassois near Châtillon-sur-Seine, France, in which Greek pottery was found, was built at the junction of long-distance trade routes. A bronze vessel, also of Greek manufacture, was found in the neighbouring grave of a Celtic princess.

The wealth of the Celtic princes seems to have been very great, some of the barrows (mound graves) being particularly richly furnished for their size. That at Apremont (Haute-Saône), with an average diameter of 70 metres, contained a wagon, gold objects, a crown, brooches, and a vessel. The grave at Pflugfelden near Ludwigsburg (Württemberg) was the burial of a man in a splendid robe and a golden crown; the hilt of his dagger was inlaid with amber. By the 6th century the wealth of the ruling Celtic groups was well established and they were able to import Etruscan wares, the merchants of Massilia (Marseille) acting as distributing agents.

The unusual concentration of early Hallstatt chieftains' burials on the upper Danube and on the upper Rhine as far north as the Neckar River lasts only to the beginning of the 5th century. At that time the Celts were preparing armed raids into the remaining parts of Europe. Thereafter, rich burials are found farther northwest, on the middle Rhine or on the Saar and Moselle rivers. The number and the richness of the burials steadily increased, including two graves at Schwarzenbach that contain two beaked flagons, a vessel in a gold openwork casing, and various gold ornaments showing mask motifs. Other sumptuous burials were at Bad Dürkheim in the Rhineland-Palatinate (including a complete set of table dishes), at Reinheim near Saarbrücken (including a bronze mirror), and a celebrated double grave at Waldalgesheim (Hunsrück), where the jewelry shows the maturation of a new art style (La Tène).

The La Tène culture. Artifacts from this culture, which developed in the 5th century BC, are found in the barrows of the middle Rhine and of Champagne in France. From the second half of the century at the latest native Celtic craftsmen were adapting southern models and developing their own style with increasing confidence. The geometric patterns found in ornament of the Hallstatt period give place to zoomorphic and floral designs, supplemented by human-head motifs or masks.

A remarkable genre of the style are the bronze-mask brooches, adorned with human and animal masks varying from lifelike to fantastic portrayal. Such brooches have been found at Panenský Týnec near Louny (animal mask) and near Manětín-Hrádek in the Plzeň region (imaginative human likeness) in Czechoslovakia and at Parsberg and Oberwittighausen in Germany.

These early La Tène pieces, typical of the second half of the 5th century BC, are still much influenced by southern models. The mature La Tène style, also called the Waldalgesheim style, dates from the second half of the 4th century, and its products are found in chieftains' graves throughout Europe. In the 3rd century the use of jewelry extended to all social classes, and craftsmen became more numerous, no longer working exclusively in the entourage of the rulers. While elaborately linked bracelets and brooches became common ornaments, the skill of leading craftsmen was adapted to ornamenting swords, scabbards, and helmets for the aristocracy.

The development of Celtic art in Britain was quite individual in character. Local workshops and "schools" were established, in which the native craftsmen combined technical skill with a freshness of conception. When the Celtic art of the Continent had passed its zenith, that of Britain continued to flourish, producing a variety of beautiful artifacts, such as gold and silver jewelry, swords and scabbards, shields inlaid with enamel, and bronze mirrors.

Literary Sources. The archaeological evidence for the close relationship of the Celts with the south is borne out by contemporary literature, which shows that the Celts were known to the Greeks as early as the 5th century.

Hecataeus of Miletus (6th–5th century BC) places the land of the Celts (Keltikē) near that of the Ligurians, while Herodotus (5th century BC) says that the Danube rises in the land of the Celts. Later authors, such as Polybius, Poseidonius, and Pompeius Trogus, give additional information. The main Roman source, however, is Julius Caesar. During his war in Gaul (58–51 BC), described in *De bello Gallico*, he acquired considerable knowledge of some Gallic tribes, which is now confirmed by archaeological findings. Strabo, the geographer, Velleius Paterculus, and Tacitus give later indirect evidence about the Celtic world.

Caesar and the Celts

Celtic expansion. During the Hallstatt period, the Celts expanded through France to the Iberian Peninsula, to the British Isles, and also to some extent eastward into central Europe. Military expansion, probably due to overpopulation and social tensions, is more easily traced in literary sources than through archaeological and linguistic evidence. Celtic bands also entered Italy, groups such as the Boii, the Insubres, the Lingones, and the Senones first attacking Etruria, while later groups reached the Adriatic coast and about the year 387 BC (the conventional date is 390) raided and plundered Rome, also penetrating into southern Italy. The Romans later recovered and drove the Celts back to the Alpine foothills, whence some of them withdrew, probably into central Europe.

In the second stream of expansion their raids reached central Europe, the Carpathians, and the Balkans. This expansion was later described by the Roman historian Livy, who recounts how two branches of the Bituriges settled near the Hercynian Forest, a range of mountains of southern and central Germany (under their ruler Sigovesus) and in Italy (under Bellovesus). Literary sources suggest that the Celts reached the Carpathians in the 4th century, later moving into present-day Bulgaria, Romania, Thrace, and Macedonia; they raided the shrine at Delphi, Greece, in 279. One group reached Anatolia, where they settled and gave their name to Galatia. In the 3rd century Celts were serving as mercenaries in Greece, Anatolia, and Egypt.

Military cemeteries

The archaeological remains of the Celtic military occupation of central Europe are their so-called flat (*i.e.*, imperceptible) cemeteries, containing mainly inhumation burials, although cremation burials became more common later. They have been dated between the 4th and the early 1st centuries BC. A striking concentration of these burial grounds extends from the Krušné Mountains, through Bohemia, Moravia, and Austria, to the Carpathian region, including also part of Slovakia and Transylvania. To the north it covered part of Polish Silesia, in the vicinity of Wrocław. These burials show many features common to the La Tène culture and also to the more Western Celtic art forms. Some of the cemeteries are military, containing burials of men with their weapons, the condition of some of the skeletons showing that death occurred in battle. The counterparts of these military graves were elaborate graves of women furnished with jewelry and bronze and glass ornaments. There are also simple graves containing no artifacts at all.

Invasions by the Cimbri and Teutones. An important dividing line in the history of the Celts was the incursion of the Germanic Cimbri. Their assault was repulsed by the Boii about 113 BC, somewhere in the neighbourhood of Bohemia. They then attacked the Scordisci near Belgrade, and later, in association with the Teutones, they attacked several Celtic tribes in the west, penetrating as far as Aquitania in Gaul. Although the Cimbri were defeated by the Romans in the Po Valley at the end of the 2nd century, their incursion into Celtic territory foreshadowed later invasions.

Gaul and Britain. In the 1st century BC Gaius Julius Caesar described Gaul as having three regions, inhabited respectively by the Galli (Gauls, present central France), the Aquitani (southwestern France), and the Belgae in the north. The Gauls comprised many tribes: the Helvetii in present-day Switzerland, the Sequani and Lingones farther west, the Arverni in Auvergne, the powerful Aedui between the Saône and Loire rivers, and the Bituriges along the Loire Valley. The Celts reached the shores of the Mediterranean later than other parts of Gaul; the Carthaginian commander Hannibal made contact with them there late in the 3rd century BC. In the 1st century, Caesar subdued the Helvetii and other tribes, pressed the Germans back beyond the Rhine, and made two expeditions to Britain. Finally, he suppressed a revolt of Gallic tribes under Vercingetorix. From that time, Gaul was subject to Rome and increasingly open to Romanization. Britain was subjugated in the 1st century AD (see GAUL and BRITAIN, ANCIENT).

In the 2nd century BC the Romans reached southern Gaul and founded their province Gallia Narbonensis (Provence).

The names of many tribes in the British Isles are known: the Dumnonii in Cornwall, the Dobuni on the upper Thames, and the Ordovices in Wales. About the middle of the 3rd century BC a new wave of immigrants from Gaul introduced the La Tène culture into Britain. Some Belgic tribes (the Cantae, Catuvellauni, Atrebates, Durotriges) settled in Britain in the 1st century BC.

The final phases. From the middle of the 1st century BC the Celtic world was caught in the press of two dangerous forces: the Roman Empire was extending its frontiers to the Rhine and the Danube, while the Germanic tribes were thrusting southward. Even before this time a strong settlement of the Celtic Boii existed in Pannonia, where they had apparently taken refuge after being driven out of Bohemia. After Burebistas, king of Dacia, destroyed the Boii (*c.* 50 BC), the Celts withdrew across modern Switzerland into Gaul. By the end of the century the Celts on the Continent had lost their commanding position and the Rhine and the Danube and were confined to the frontier between the Roman and Germanic worlds.

The Celtic tradition survived most strongly in Britain and Ireland, where its art was still flourishing at the beginning of the Christian Era. Several of its elements were revived in the neo-Celtic art forms of the 7th to 9th centuries AD (see BRITAIN AND IRELAND, HISTORY OF).

CELTIC SOCIETY

In the eyes of Greeks and Romans, the Celts were remarkable for their height, muscularity, and fair colouring. These were characteristics of the warrior class rather than of the whole population, and skeletal remains point to considerable variations in stature and head form. Strabo describes them as a people who love war and adventure, pleasure and feasts. Information on Celtic institutions is available from various classical authors and from ancient Irish literature. A striking feature, even as early as the La Tène period, is the large number of tribes competing for dominance. Kingship was common among some tribes in the La Tène period. Some kings, however, were elected, and the power of the aristocracy tended to increase, their rule predominating in Gaul in Caesar's time. In Ireland, by customary law, the social system was threefold; king, warrior aristocracy, and freemen farmers. In the later period in the western Celtic world, the strength of the aristocracy was increased and the freedom of common people was diminished by the widespread introduction of clientism, a system by which lesser men placed themselves under obligation to a powerful lord from whom they received protection. As in other Indo-European systems, the family was patriarchal and kinship was recognized by agnatic descent (from a common male ancestor). Landownership was vested in the family, which was also responsible for many social obligations. The household was of the "archaic-joint" type, consisting of a man with his wives, children, and grandchildren. The status of women seems to have varied considerably according to rank and the prosperity of the community.

Druids

The Druids, who were occupied with magico-religious duties, were recruited from families of the warrior class but ranked higher. They offered sacrifices and were responsible for the education of the young nobles, and the sacred oak groves were under their protection. Druidism,

still flourishing at the beginning of the Roman occupation of Celtic areas, strongly resisted Romanization and was thus particularly marked out for deliberate suppression. It survived longest in Ireland, where the Romans did not penetrate. Caesar describes the Celtic sacred sites, woods with sacred trees and groves (*loci consecrati*). There is no evidence that they had temples in his time, but these were built later, in the Gallo-Roman period. Cult sites have been found, however, in several places in central and western Europe. An example is at Libenice near Kolín in Bohemia, excavated in 1959, which had a stone slab for sacrifices. In the centre of the cult area a woman was found buried, with typical La Tène ornaments. Cauldrons connected with the cults spread as far as northern Europe, and splendid examples have been found in silver at Gundestrup and at Brå in East Jutland. It is difficult to generalize about Celtic religion and mythology, because each tribe seems to have had its own cults and local deities. There is no firm distinction between gods and heroes; the names of some deities (*e.g.*, Taranis, Teutates, Esus, Lug) antedate the Romanization of Gaul, but later they sometimes became associated with Roman gods. Divine or semidivine pairs and trinities also occurred.

The basic economy of the Celts was mixed farming, and, except in times of unrest, single farmsteads were usual. All kinds of grain were cultivated, also flax, hemp, beetroot, and several other kinds of vegetables. The grain was stored in special pits or silos deep in the ground or in large jars. Owing to the wide variations in terrain and climate, cattle raising was more important than cereal cultivation in some regions. The prevalence of oak forests encouraged the breeding of pigs, and boar hunts were a popular sport. The wool of Celtic sheep was well known in Rome. Later, Gaul supplied the Roman armies on the Rhine with horses.

Trousers, perhaps an Eastern innovation, were worn by men of the Cisalpine Gaulish tribes from at least the 3rd century BC and are attested in the 1st century BC in Transalpine Gaul, but a belted tunic, or shirt, with a cloak seems to have been the most widespread form of male dress. Women wore a single long garment with a cloak. Coarse linen as well as wool was employed, and bright colours were popular. According to Poseidonius the food of the Celts consisted of bread and meat, either boiled or roasted. Beer, home brewed from barley, was the most common drink; the upper classes also used wine imported from the south. The Celts were hospitable, fond of feasting, drinking, and quarrelling, and incapable of prolonged concerted action. At feasts bards sang the praises of those present, accompanying the song with a lyrelike instrument. The Celts greatly prized music and many forms of oral literary composition.

Hill forts. The earliest Celts had fortified strongholds or chieftains' residences; hill forts (*oppida*), with a considerable concentration of population and production, were constructed from the second half of the 2nd century BC, partly as a result of Germanic pressures. A belt of flourishing hill forts existed in Caesar's time, but his victory led to their decline in Gaul, although many in central Europe were occupied until the end of the last century BC.

The hill forts varied in construction and size. Bibracte, the centre of the Aedui, about 2,625 feet (800 metres) above sea level and covering an area of about 333 acres, is the most thoroughly excavated hill fort in France. Alesia covered an area of 240 acres, Gergovia (Clermont) 185 acres, Noviodunum about 99 acres. The *oppidum* of the Vindelici tribe at Manching near Ingolstadt, Bavaria, is in the process of excavation. It covers an area of 939 acres and is the easternmost known hill fort with walls built in the Gallic style described by Caesar. The hill fort at Kelheim, Bavaria, is still larger, while Heidengraben, north of Urach in Württemberg, comprises a whole series of fortified sites on an area of more than six square miles. Six *oppida* are known in Bohemia, the most notable, in Stradonice near Beroun, having the richest finds and covering an area of about 203 acres.

Coinage. Celtic prosperity and widespread trade necessitated the minting of coins, the first that were produced by barbarians in Gaul and central Europe. The Celtic coinage is of gold and silver, coins of other metals being much rarer. Ultimately derived from Macedonian-Greek exemplars, they first appear in the second half of the 2nd century BC. Later the Celts minted a coinage of their own design (horse and rider, human figure, etc.). In central Europe at the turn of the 2nd and 1st centuries gold coins appeared bearing the picture of a boar or coiled dragon, and in the first half of the 1st century two kinds of sunk-panel gold coins appeared: the so-called rainbow drops (*guttae iridis*), attributed to the Vindelici tribe, and shell staters marked with crescent signs. Coarse forms with indistinct pictures were a part of the celebrated hoards, each of about 5,000 coins, found in Podmokly near Zbiroh in the Rokycany region of southwest Bohemia. Later on, silver coins came increasingly into circulation. One of them, the latest Celtic coin found in central Europe, dating from the second half of the 1st century BC and strongly influenced by the Roman denarius, is commonly called a Biatec, after one of the issuing chieftains. Most of the hoards of this coin were discovered in the Bratislava region of Slovakia.

Cement

The word cement is used to define adhesive substances. It is derived from the Latin *caementum*, which meant stone chippings such as were used in Roman mortar, not the binding material itself. In its general sense it covers a wide variety of binding materials used for many different purposes, but more commonly it implies the binding materials used in building and civil engineering construction. These constructional cements, which will set and harden under water, are often called hydraulic cements. The most important of these is portland cement. Others are the slag-containing cements and high alumina cement. This article covers constructional cements. Adhesive cements are covered under ADHESIVES.

Cements are finely ground powders that, when mixed with water, set to a hard mass. Setting and hardening result from the hydration of the cement compounds, giving submicroscopic crystals or a gel-like material with a high surface area. Cements may be used alone (*i.e.*, "neat," as grouting materials), but the normal use is in mortar and concrete in which the cement is mixed with inert material known as aggregate. Mortar is cement mixed with sand or crushed stone less than $\frac{3}{16}$ inch (4.8 millimetres) in

size. Concrete is a mixture of cement, sand or other fine aggregate, and a coarse aggregate that for most purposes is up to ¾ or 1 inch (1.9–2.5 centimetres) in size but that may also be as large as 6 inches (15 centimetres) for concrete placed in large masses, as in dams. Mortars are used for binding bricks, blocks, and stone in walls or as surface renderings. Concrete is used for a large variety of constructional purposes (see CONCRETE). Mixtures of soil and portland cement are used as a base for roads. Portland cement also is used in the manufacture of asbestos cement sheets, pipes, tanks, and other goods. The products are made in a factory and supplied ready for installation in a building.

Because concrete is the most widely used of all construction materials today, the manufacture of cement is widespread. The consumption of cement per capita ranges from several hundred kilograms in industrialized countries to 20 kilograms or less in developing countries (see Table 1).

Table 1: Cement Production and Consumption

	production (1970) (000 metric tons)	consumption (1966) (kg per capita)

HISTORY OF CEMENT

The origin of hydraulic cements goes back to classical Greece and Rome. The materials used were lime and a volcanic ash that slowly reacted with it in the presence of water to form a hard mass. This formed the cementing material of the Roman mortars and concretes of 2,000 years ago and of subsequent construction work in western Europe. Portland cement is a successor to hydraulic lime first developed by John Smeaton in 1756 when he was called in to erect the Eddystone Lighthouse off the coast of Devon, England. The next development, about 1800 in England and France, was a material obtained by burning nodules of clayey limestone and later in the U.S. of what was called "cement rock." These materials belong to a class known as natural cement, allied to portland cement but more lightly burned and not of controlled composition. The invention of portland cement usually is attributed to Joseph Aspdin of Leeds, Yorkshire, who in 1824 took out a patent for a material produced from a synthetic mixture of limestone and clay. He called the product portland cement because of a fancied resemblance of the material, when set, to portland stone, a limestone used for building in England. Aspdin's product may well have been too lightly burned to be a true portland cement, and the real prototype was perhaps that produced by Isaac Charles Johnson in southeast England about 1850. The manufacture of portland cement rapidly spread to other European countries and, about 1870, to the U.S.

Portland cement

RAW MATERIALS

Portland cement consists of compounds of lime mixed with silica, alumina, and iron oxide. The lime is obtained from a calcareous raw material and the other oxides from an argillaceous (clayey) material, the two mixed in the required proportions. Additional raw materials such as sand, iron oxide, and bauxite may be used in smaller quantities to get the desired composition. The commonest calcareous raw materials are limestone and chalk; but others, such as coral or shell deposits, are also used. Clays, shales, slates, and estuarine muds are the common argillaceous raw materials. Marl, a compact calcareous clay, and cement rock contain both the calcareous and argillaceous components in proportions that sometimes approximate cement compositions. Another raw material is blast-furnace slag, which consists mainly of lime, silica, and alumina and is mixed with a calcareous material of high lime content. Kaolin, which contains little iron oxide, is used as the argillaceous component for white portland cement. Industrial wastes, such as fly ash and calcium carbonate from chemical manufacture, are other possible raw materials; but their use is small compared with that of the natural materials. The magnesia content of raw materials must be low because the permissible limit in portland cement is 4 to 5 percent. Other impurities in raw materials that must be strictly limited are fluorine compounds, phosphates, metal oxides and sulfides, and excessive alkalies.

Blast-furnace slag

Another essential raw material is gypsum, some 5 percent of which is added to the burned cement clinker during grinding to control the setting time of the cement. Portland cement also can be made in a combined process with sulfuric acid using calcium sulfate or anhydrite in place of calcium carbonate. The sulfur dioxide produced in the flue gases on burning is converted to sulfuric acid by normal processes.

The percentage compositions of some typical raw materials used for the manufacture of portland cement are shown in Table 2. Raw materials are extracted by quarrying in the case of hard rocks such as limestones, slates, and some shales, with the aid of blasting when necessary. Some deposits are mined. Softer rocks such as chalk and clay can be dug directly by excavators. The excavated materials are transported to the crushing plant by trucks, railway freight cars, conveyor belts, or ropeways, or in a wet state or slurry by pipeline. In regions where limestones of sufficiently high lime content are not available, some process of beneficiation can be used. Froth flotation will remove excess silica or alumina and so upgrade the limestone, but it is costly and used only when unavoidable.

Table 2: Raw Materials Used in the Manufacture of Portland Cement
(percentage composition)

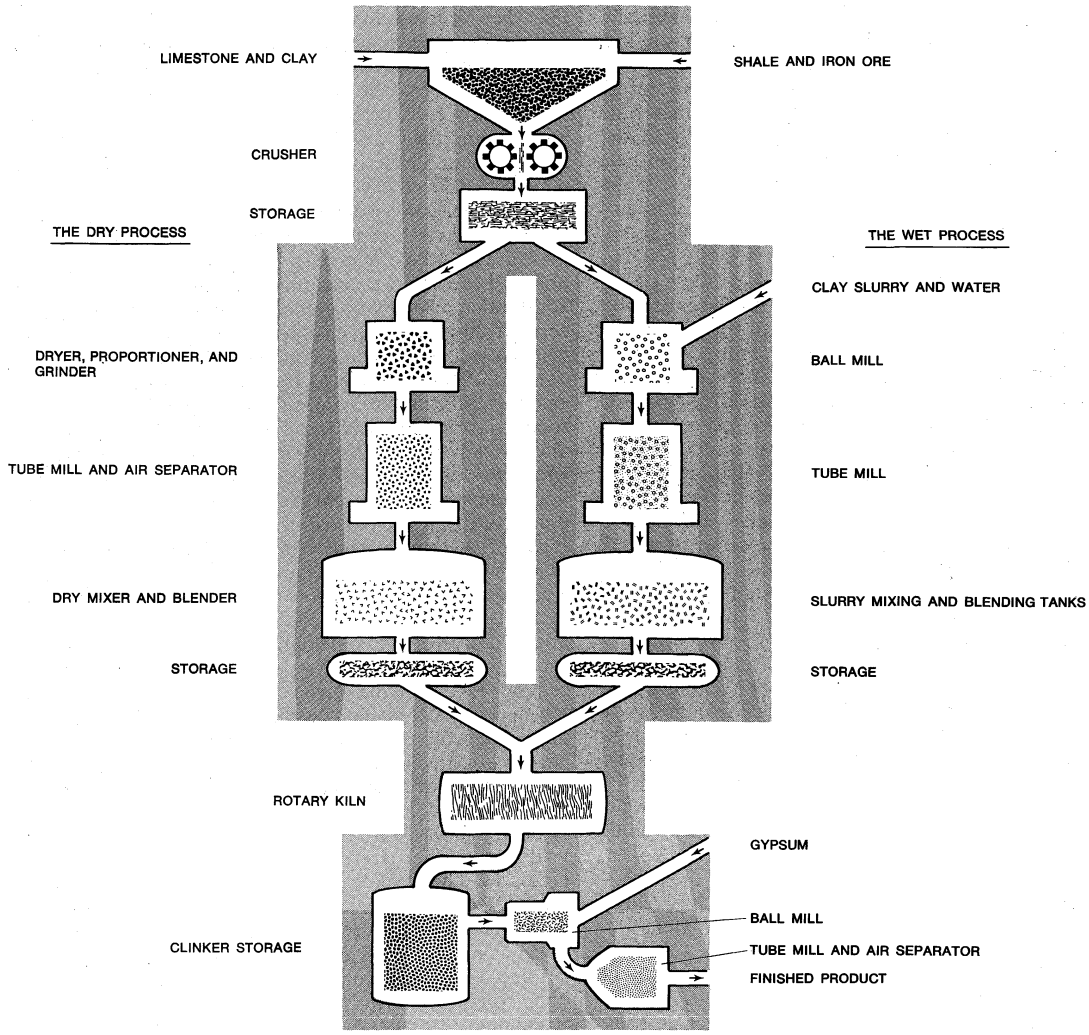
raw material	lime	silica	alumina	iron oxide	magnesia	loss on ignition
Limestone	52	3	1	0.5	0.5	42
Chalk	54	1	0.5	0.2	0.3	43
Cement rock	43	11	3	1	2	36
Clay	1	57	16	7	1	14
Slag	42	34	15	1	4	0

Froth flotation

MANUFACTURE

There are four stages in the manufacture of portland cement: (1) crushing and grinding the raw materials; (2) blending the materials in the correct proportions; (3) burning the prepared mix in a kiln; and (4) grinding the burned product known as cement clinker together with some 5 percent of gypsum (to control the time of set of the cement). The three processes of manufacture are known as the wet, dry, and semidry processes and are so termed when the raw materials are ground wet and fed to the kiln as a slurry, ground dry and fed as a dry powder, or ground dry and then moistened to form nodules that are fed to the kiln.

Crushing and grinding of raw materials. All except soft materials are first crushed, often in two stages, and then ground, usually in rotating, cylindrical ball, or tube



Cement-making process, dry and wet methods.
Drawing by D. Meighan

mills containing a charge of steel grinding balls. This grinding is done wet or dry according to the process in use, but for dry grinding the raw materials may need first to be dried in cylindrical, rotary dryers. Soft materials are broken down by vigorous stirring with water in wash-mills, producing a fine slurry, which is passed through screens to remove oversize particles.

Blending. A first approximation of the required chemical composition is obtained by selective quarrying and control of the raw material fed to the crushing and grinding plant. The finer control is obtained by drawing ground material from two or more silos containing raw mixes differing slightly in composition in the dry process and from slurry tanks in the wet process. Thorough mixing of the raw materials in the silos in the dry process is ensured by agitation and vigorous circulation induced by compressed air. In the wet process, the slurry tanks are stirred by mechanical means and/or compressed air. The slurry, which contains 35 to 45 percent water, is sometimes filtered, reducing the water content to 20 to 30 percent; and the filter cake is then fed to the kiln. This reduces the fuel consumption for burning.

Burning. The earliest kilns in which cement was burned in batches were bottle kilns, followed by chamber kilns and then continuous shaft kilns. The shaft kiln in a modernized form is still used in some countries, but the dominant means of burning is the rotary kiln. These kilns —up to 200 metres (660 feet) long and 7 metres (23 feet) in diameter in wet process plants but shorter for the dry process—consist of a steel, cylindrical shell lined with refractory materials. They rotate slowly on an axis that is inclined a few degrees to the horizontal. The raw material feed, introduced at the upper end, moves slowly down the kiln to the lower or firing end. The fuel for firing may be pulverized coal, oil, or natural gas injected through a pipe. The temperature at the burning end ranges from 1,300° to 1,500° C (about 2,400° to 2,700° F), according to the raw materials being burned. Some form of heat exchanger is commonly incorporated at the back end of the kiln to increase heat transfer to the incoming raw materials and so reduce the heat lost in the waste gases. The burned product emerges from the kiln as small nodules of clinker that pass into coolers where incoming air is heated and the product cooled. In the semidry process, the raw materials in the form of nodules, containing 10 to 15 percent water, are fed onto a travelling chain grate before passing to a shorter rotary kiln. Hot gases coming from the kiln are sucked through the raw nodules on the grate, preheating the nodules.

Rotary kilns

Dust emission from cement kilns can be a serious nuisance; and in populated areas it is usual and often compulsory to fit cyclone arrestors, bag-filter systems, or electrostatic dust precipitators between the kiln exit and the chimney stack.

Modern cement plants are equipped with elaborate instrumentation for the control of the burning process. Raw materials in some plants are sampled automatically, and a computer calculates and controls the raw mix composition. The largest rotary kilns have outputs up to 3,000 tons per day. The clinker may be immediately ground to cement or stored in stockpiles for later use.

Grinding. The clinker and the required amount of gypsum are ground to a fine powder in horizontal mills similar to those used for grinding the raw materials. The

material may pass straight through the mill (open-circuit grinding), or coarser material may be separated from the ground product and returned to the mill for further grinding (closed-circuit grinding). Sometimes a small amount of a grinding aid is added to the feed material. For air-entraining cements (discussed below) the addition of an air-entraining agent is similarly made. Finished cement is pumped pneumatically to storage silos from which it is drawn for packing in paper bags or for dispatch in bulk containers.

Closed-circuit grinding

COMPOSITION AND PROPERTIES

Portland cement. Portland cement is made up of four main compounds: tricalcium silicate ($3CaO \cdot SiO_2$), dicalcium silicate ($2CaO \cdot SiO_2$), tricalcium aluminate ($3CaO \cdot Al_2O_3$), and a tetra-calcium aluminoferrite ($4CaO \cdot Al_2O_3Fe_2O_3$). In an abbreviated notation differing from the normal atomic symbols, these compounds are designated as C_3S, C_2S, C_3A and C_4AF, where C stands for calcium oxide (lime), S for silica, A for alumina, and F for iron oxide. Small amounts of uncombined lime and magnesia also are present, along with alkalies and minor amounts of other elements. The composition of portland cements falls within the range of 60 to 67 percent lime, 19 to 25 percent silica, 3 to 8 percent alumina, and 0.3 to 6 percent iron oxide together with 1 to 3 percent sulfur trioxide, derived mainly from the added gypsum, 0.5 to 5 percent magnesia, and 0.3 to 1.3 percent alkalies. Titanium oxide is usually present to the extent of 0.1 to 0.4 percent. Manganese oxide is usually present only in small amounts except when blast-furnace slag is used as a raw material; then it may rise to 1 percent, giving the cement a brownish tinge rather than the normal gray colour.

The strength developed by portland cement depends on its composition and the fineness to which it is ground. The C_3S is mainly responsible for the strength developed in the first week of hardening, and the C_2S for the subsequent increase in strength. The alumina and iron compounds that are present only in lesser amounts make little direct contribution to strength. Set cement and concrete can suffer deterioration from attack by some natural or artificial chemical agents. The alumina compound (C_3A) is the most vulnerable to chemical attack in soils containing sulfate salts or in seawater, while the iron compound (C_4AF) and the two calcium silicates are more resistant. Calcium hydroxide is released during the hydration of the calcium silicates, and this is also vulnerable to attack. Cement liberates heat when it hydrates; and consequently concrete placed in large masses, as in dams, can cause the temperature inside the mass to rise up to 40° C (72° F) above the outside temperature. Subsequent cooling can be a cause of cracking. The highest heat of hydration is shown by C_3A, followed in descending order by C_3S, C_4AF, and C_2S.

Resistance to chemical attack

Five types of portland cement are standardized in the U.S.: ordinary (Type I), modified (Type II), high-early-strength (Type III), low-heat (Type IV), and sulfate-resisting (Type V). In other countries Type II is omitted, and Type III is called rapid-hardening. Type V is known in some European countries as Ferrari cement. Typical compositions are shown in Table 3. These various types are differentiated both by requirements as to their composition and by various tests. Thus in Type V, the content of C_3A is limited to 3.5 to 5 percent in different countries, and in Type IV to a slightly higher value. The content of C_3S ranges from about 40 to 65 percent except for Type IV, where it is usually below 30 percent. The content of C_2S varies more or less inversely to that of C_3S, falling as low as 10 percent in rapid-hardening cement and rising as high as 60 percent in low-heat cement. The C_3A content usually falls between 6 and 15 percent in Types I and III, and that of C_4AF between 5 and 10 percent. In types IV and V, the C_4AF content is usually higher and may exceed 15 percent.

Table 3: Typical Percentage Compositions of Portland Cement

type of portland cement	lime	silica	alumina	iron oxide	magnesia	alkalies	sulfur trioxide
Ordinary	64	21	6	3	2	1	2
Modified	63	22	4	3	2	1	2
High-early-strength	65	20	6	3	2	1	2.5
Low heat	61	25	4	3	2	1	2
Sulfate-resisting	64	23	3	4	2	1	2

There also are various other special types of portland cement. Coloured cements are made by grinding 5 to 10 percent of suitable pigments with white or ordinary gray portland cement. Air-entraining cements are made by the addition on grinding of a small amount, around 0.05 percent, of an organic agent that causes the entrainment of very fine air bubbles in a concrete. This increases the resistance of the concrete to freezing and to the action of calcium chloride or common salt spread on concrete roads to melt snow and ice. The air-entraining agent can alternatively be added as a separate ingredient to the mix when making the concrete. Low-alkali cements are portland cements with a total content of alkalies not above 0.6 percent. These are used in concrete made with certain types of aggregates that contain a form of silica that reacts with alkalies causing an expansion that can disrupt a concrete. Masonry cements are used primarily for mortar. They consist of a mixture of portland cement and ground limestone or other filler together with an air-entraining agent or a water-repellent additive. Waterproof cement is the name given to a portland cement to which a water-repellent agent has been added. Hydrophobic cement is obtained by grinding portland cement clinker with a film-forming substance such as oleic acid in order to reduce the rate of deterioration when the cement is stored under unfavourable conditions. Oil-well cements are used for cementing work in the drilling of oil wells where they are subject to high temperatures and pressures. They usually consist of portland or pozzolanic cement (see below) with special organic retarders to prevent the cement from setting too quickly.

Slag cements. The granulated slag made by the rapid chilling of suitable molten slags from blast furnaces producing pig iron, forms the basis of another group of constructional cements. A mixture of portland cement and granulated slag, containing up to 65 percent slag, is known in the English-speaking countries as portland blast-furnace (slag) cement. The German *Eisenportlandzement* and *Hochofenzement* contain up to 40 and 85 percent slag, respectively. Mixtures in other proportions are found in French-speaking countries under such names as *Ciment Portland de Fer*, *Ciment métallurgique mixte*, *Ciment de haut fourneau*, and *Ciment de liatier au clinker*. Properties of these slag cements are broadly similar to those of portland cement, but they have a lower lime content and a higher silica and alumina content. Those with the higher slag content have an increased resistance to chemical attack.

Slag mixtures

Another type of slag-containing cement is a supersulfated cement consisting of granulated slag mixed with 10 to 15 percent hard burned gypsum or anhydrite (natural anhydrous calcium sulfate) and a few percent of portland cement. The strength properties of supersulfated cement are similar to those of portland cement, but it has an increased resistance to many forms of chemical attack. Pozzolanic cements are mixtures of portland cement and a pozzolanic material that may be either natural or artificial. The natural pozzolanas are mainly materials of volcanic origin but include some diatomaceous earths. Artificial materials include fly ash, burned clays, and shales. Pozzolanas are materials that, though not cementitious in themselves, contain silica (and alumina) in a reactive form able to combine with lime in the presence of water to form compounds with cementitious properties. Mixtures of lime and pozzolana were used by Roman engineers 2,000 years ago and still find some application but largely have been superseded by the modern pozzolanic cement. Hydration of the portland cement fraction releases the lime required to combine with the pozzolana.

High alumina cement. High alumina cement is a rapid-hardening cement made by fusing at 1,500° to 1,600° C a mixture of bauxite and limestone in a reverberatory or electric furnace or in a rotary kiln. It also can be made by sintering at about 1,250° C. Suitable bauxites contain 50 to 60 percent alumina, up to 25 percent iron oxide, not more than 5 percent silica, and 10 to 30 percent water of hydration. The limestone must contain only small amounts of silica and magnesia. The cement contains 35 to 40 percent lime, 40 to 50 percent alumina, up to 15 percent iron oxides, and preferably not more than about 6 percent silica. The principal cementing compound is calcium aluminate ($CaO \cdot Al_2O_3$). This cement gains a high proportion of its ultimate strength in 24 hours and has a high resistance to chemical attack. It also is used in refractory concretes for furnaces. A white form of the cement, containing minimal proportions of iron oxide and silica, has outstanding refractory properties.

Refractory properties

Expanding and nonshrinking cements. Expanding and nonshrinking cements expand slightly on hydration, thus offsetting the small contraction that occurs when freshly made concrete dries for the first time. Expanding cements were first produced in France about 1945, but their present manufacture is confined to the U.S. and the U.S.S.R. The U.S. type is a mixture of portland cement and an expansive agent made by clinkering a mix of chalk, bauxite, and gypsum.

Other cements. Gypsum plasters are used for plastering, the manufacture of plaster boards and slabs, and in one form of floor-surfacing material. These gypsum cements are mainly produced by heating natural gypsum ($CaSO_4 \cdot 2H_2O$) and dehydrating it to give calcium sulfate hemihydrate ($CaSO_4 \cdot \frac{1}{2}H_2O$) or anhydrous calcium sulfate. Gypsum and anhydrite obtained as by-products in chemical manufacture also are used as raw materials. The hemihydrate (plaster of paris) sets within a few minutes on mixing with water; for building purposes a retarding agent, normally keratin, a protein, is added. The anhydrous calcium sulfate plasters are slower setting, and often another sulfate salt is added in small amount as an accelerator. Flooring plaster, originally known by its German title of *Estrich Gips*, is of the anhydrous type.

Magnesium oxychloride (Sorel cement) is the cementing agent in magnesite flooring. This is made from a mixture of lightly burned magnesia, magnesium chloride solution, and an inert filler. Magnesium oxysulfate is similarly used as a binder in some wood-wool slabs.

Plastics cements find a use in construction as binding materials. Epoxy resin cements are used as a jointing material between structural units, as binders for the repair of concrete, and in protective surface coatings. Polyester and some other resins are similarly used. Synthetic polymer emulsions such as polyvinyl acetate and acrylic resins, natural rubber latex, and bituminous emulsions find use as additives to concrete mixes for flooring, jointing, and lining where special properties are required.

Epoxy resin cements

There are many other materials—protein glues, vegetable gums, rubber solutions and emulsions, and synthetic resins solutions and emulsions—that are used as adhesives in thin films; but these are not classed as constructional cements.

Cement testing. Various tests to which cements must conform are laid down in national cement specifications to control the fineness, soundness, setting time, strength, and chemical composition. Fineness was long controlled by sieve tests, but more sophisticated methods are now largely used. The most common method, used both for control of the grinding process and for testing the finished cement, measures the surface area per unit weight of the cement by a determination of the rate of passage of air through a bed of the cement. Other methods depend on measuring the particle size distribution by the rate of sedimentation of the cement in kerosene or by elutriation (separation) in an air stream. After it has set, a cement must not undergo any appreciable expansion, which could disrupt a mortar or concrete. This property of soundness is tested by subjecting the set cement to boiling in water or to high-pressure steam. Unsoundness can arise from the presence in the cement of too much free magnesia or hard-burned free lime. The setting and hardening of a cement is a continuous process, but two points are distinguished for test purposes. The initial setting time is the interval between the mixing of the cement with water and the time when the mix has lost plasticity, stiffening to a certain degree. It marks roughly the end of the period when the wet mix can be molded into shape. The final setting time is the point at which the set cement has acquired a sufficient firmness to resist a certain defined pressure. Most specifications require an initial minimum setting time at ordinary temperatures of about 45 minutes and a final setting time no more than 10 to 12 hours.

The tests that measure the rate at which a cement develops strength are usually made on a mortar commonly composed of one part cement to three parts sand, by weight, mixed with a defined quantity of water. Tensile tests on briquettes, shaped like a figure eight thickened at the centre, were formerly used but have been replaced or supplemented by compressive tests on cubical specimens or transverse tests on prisms. The American Society for Testing and Materials (ASTM), Philadelphia, specification requires tensile tests on a 1:3 cement-sand mortar and compressive tests on a 1:2.75 mortar. The British Standards Institution (BSI), London, gives as alternatives a compressive test on a 1:3 mortar or on a concrete specimen. An international method issued by the International Standards Organization (ISO) requires a transverse test on a 1:3 cement-sand mortar prism, followed by a compressive test on the two halves of the prism that remain after it has been broken in bending. Many European countries have adopted this method. In all these tests the size grading of the sand, and usually its source, is specified.

Tensile and compressive strength

In the testing of most cements a minimum strength at 3 and 7 days and sometimes 28 days is specified, but for rapid-hardening portland cement a test at one day also is sometimes required. For high alumina cement, tests are required at one and three days. Strength requirements laid down in different countries are not directly comparable because of the differences in test methods. In actual construction, to check the strength of a concrete, compressive tests are made on cylinders or cubes made from the concrete being placed.

Cenozoic Era

The history of the earth is divided into three parts in accord with the fossil evidence of organic evolution: the Paleozoic Era (225,000,000 to 570,000,000 years ago) is the "ancient age" of animals, the Mesozoic Era (65,000,000 to 225,000,000 years ago) is the "middle age," and the Cenozoic Era (the last 65,000,000 years) is the "new age" of animals; the latter is subdivided into the Tertiary and Quaternary (the last 2,500,000 years) periods.

The Cenozoic Era is distinguished by mammals and angiosperm plants, and because Cenozoic sediments tend to be unconsolidated and only slightly altered, they frequently are richly fossiliferous. The modern characteristics of continents and seas, and of life as it exists today, became evident during Cenozoic time. Evidence favouring continental drift indicates that present continental positions and climatic zones were established during the Cenozoic. The rise and evolution of mammals (including

Characteristics of Cenozoic time

man) as the dominant terrestrial animal group is, however, one of the most fascinating aspects of Cenozoic history.

The Mesozoic/Cenozoic time boundary (about 65,000,000 years ago) is characterized by the reduction or extermination of many groups of organisms that were prominent in Upper Cretaceous faunas. Most impressive is the disappearance of many orders of reptiles and invertebrates. Complete stratigraphic sections show the evolution of planktonic (floating and swimming) foraminifers during Cenozoic time; the highly evolved globotruncanas of the Upper Cretaceous disappear and are succeeded by a zone of primitive globigerinas at the base of the Tertiary. At the end of the Tertiary Period (about 2,500,000 years ago), climatic deterioration affected the distribution of organisms and vital, robust life forms spread widely, as more delicate organisms either died out or retreated to equatorial regions.

This article presents an overview of earth history during Cenozoic time. For greater detail on the relevant time intervals, see TERTIARY PERIOD; PLEISTOCENE EPOCH; HOLOCENE EPOCH. See also FOSSIL RECORD and MAMMALIA for further information on the principal animal groups of Cenozoic time and STRATIGRAPHIC BOUNDARIES for discussion of the Mesozoic-Cenozoic and wholly Cenozoic boundaries.

CENOZOIC STRATIGRAPHY

Tertiary and Quaternary periods

Subdivision of Cenozoic time. By international agreement the Cenozoic is divided into the Tertiary and Quaternary periods. The Tertiary is subdivided as follows:

subdivision	epoch	duration (000,000 years)
Younger Tertiary or Neogene	Pliocene	4.5
	Miocene	19.0
Older Tertiary or Paleogene	Oligocene	12.0
	Eocene	16.0
	Paleocene	11.0

The epochs of the Tertiary are further subdivided into stages, although this subdivision has always been open to much discussion. Subdivision into biozones, based upon the evolution of planktonic Foraminifera, is preferable to the classical subdivision. Similarly, subdivision of the Quaternary can be based upon the glacial record; the preglacial, glacial, and postglacial (Holocene) stages generally can be distinguished within the Quaternary record. Correlation of the preglacial in northwestern Europe, the Mediterranean region, and North America is as follows:

Northwestern Europe	Mediterranean	North America
Waal warm period Eburon cold period	Siciliano	Rexroad
Tegelen warm period Bruggen cold period	Calabriano	Blanco

The Quaternary also is subdivided into the Holocene Epoch (also termed Recent, Alluvium, or Postglacial), which comprises approximately the last 10,000 years, and the Pleistocene Epoch (Diluvium, or Glacial Age, are sometimes used synonymously), which comprises approximately the last 2,500,000 years.

Alternation between periods of glacial advance and retreat permits subdivision of the Pleistocene Epoch. Classical regions are the southern limit of glaciated areas in Europe and North America and the Alpine region of central Europe. The subdivisions that are generally used in the respective regions and their assumed correlations are as follows:

Subdivisions and Assumed Correlations of the Pleistocene Epoch

North Germany	Alps	North America
Weichsel Ice Age	Würm Ice Age	Wisconsin Ice Age
Ehm Warm Period	Riss/Würm Interglacial	Sangamon Interglacial
Saale Ice Age	Riss Ice Age	Illinoian Ice Age
Holstein Warm Period	Mindel/Riss Interglacial	Yarmouth Interglacial
Elster Ice Age	Mindel Ice Age	Kansan Ice Age
Cromer Warm Period	Günz/Mindel Interglacial	Aftonian Interglacial
Weybourne Ice Age	Günz Ice Age	Nebraskan Ice Age

Tectonic-volcanic phases

The Tertiary Period was a time of major crustal movements (tectonic changes), the most important of which was the Alpine mountain building that began in Mesozoic time. The Tertiary tectonic phases gave rise to the big mountain chains of today (*e.g.*, Cordilleran, Andes, Alps, Caucasus, Himalayas) and are largely responsible for the present form and appearance of these chains. Worldwide volcanic activity was associated with this tectonism and created the present volcanic regions of the world. Intrusions of Pacific-type granites, basaltic eruptions on a gigantic scale, and regional deposition of volcanic rocks occurred. The volcanic belt from Greenland across Iceland to Scotland, the basalts of the Columbia and Colorado plateaus in North America, and the Deccan Trap of India, which cover areas as large as 100,000 square kilometres (40,000 square miles) in great thickness, are especially remarkable. Volcanic activity and crustal movement continued in the Quaternary, and although much of this movement was truly tectonic in origin, isostatic movements (adjustment toward equilibrium) also occurred, caused by the melting of large ice sheets; thicknesses of several kilometres of Pleistocene ice depressed entire continental blocks, and slow glacial rebound of the land followed its removal during the Holocene Epoch.

Tectonic phases during the Cenozoic Era and their relation to subdivisions of Cenozoic time are as follows:

Cretaceous/Tertiary boundary	Laramic phase
Upper Eocene/Lower Oligocene boundary	Pyrenean phase
Oligocene/Miocene boundary	Savic phase
Middle to Upper Miocene	Styrian phase
Pliocene	Rhodanic phase
Tertiary/Quaternary boundary	Wallachian phase

General characteristics of sediments. Marine sediments of Paleogene age are widely distributed in regions that were tectonically stable; marginal deposits (marine and nonmarine) also cover considerable areas. Highly fossiliferous limestones or calcareous sandstones predominate and these marine sediments are interbedded with river and lake deposits.

The subdivision of epicontinental strata (sediments deposited in stable areas in relatively shallow water) can be based upon changes of facies (lateral gradations of sediment type), cyclic repetition of marine transgressions, and freshwater influences. Many classical localities for Paleogene stages are within the epicontinental strata of western Europe, where they are best developed in the Paris Basin and in Belgium. Paleogene sediments of geosynclinal facies are characterized by flysch deposits consisting of a repeated succession of turbidites (sandstones deposited by density currents) and marly layers at great depths; tracks and burrows of animals are characteristic fossils.

Due to mountain building, the advance of nappes (great overturned folds), and the narrowing of the geosynclines, the original area of deposition of flyschlike rocks is not preserved, and paleogeographical reconstruction of Paleogene environments is rather difficult.

Neogene sediments generally are less consolidated and disturbed than those of the Paleogene; marls, clays, and gravels predominate and *Lithothamnium*-limestones characterize the marginal facies. These unconsolidated rocks are termed molasse, and molasse zones follow geosynclinal axes that form the foreland of the Alps and Carpathians. Continental (nonmarine) sediments are widely distributed over the surface of the old continental shields in North and South America, Siberia, and Central Asia, and sands, gravels, and clays attain considerable thickness in areas of downfaulting or warping. Vertebrates are the most important fossils in these deposits of lacustrine and fluvial origin, and important mammal discoveries have been made in the interior continental basins of North America.

Deposition of continental sediments

During the Cenozoic, sea level attained its present altitude, and the area of the continents covered by marine strata progressively diminished. During Quaternary time the deposition of continental sediments predominated. The low-lying parts of the continents are almost completely covered by Pleistocene or Holocene deposits and, following the change of climatic conditions, sediments in

northern regions were characterized by loess (wind derived sediments) and glacial deposits. In the south, in the region of present savannas and deserts, the sediments suggest that the climate was wetter than at present; clastic sediments of fluvial origin (river sands and gravels) represent the Pleistocene over wide areas of the earth.

Other characteristics of sedimentation include the increased rate of deposition in deep-sea areas during the Pleistocene because of an increased supply of materials of glacial, fluviatile, or eolian origin. In addition, the circumpolar belts of glacial-marine deposits and of diatom ooze advanced toward lower latitudes, especially during glacial ages, thus narrowing the equatorial zone of Globigerina-ooze.

Distribution of Tertiary rocks. *Europe.* In western Europe, Paleogene epicontinental facies with rich and typical faunas are present in the Paris Basin, in Belgium, and in Great Britain. They also are present in northern Germany and Denmark. In central and southern Europe flysch-type deposits of Paleogene age exist within the young mountain chains (Pyrenees, Alps, Carpathians, Dinarids, and others). A richly fossiliferous calcareous facies extends across southeastern Europe (Crimea) to the Caucasus.

The Neogene of Europe exhibits a differentiation of faunal provinces (regions characterized by distinctive plant or animal assemblages), and in the north the Neogene sequence of the northwestern European region can be clearly defined. Northern faunal elements distinguish it from the Atlantic-Mediterranean region, and it is possible that a land bridge between Great Britain and Iceland existed at this time. Continental deposits with considerable soft coal were formed in central Europe, and marine sequences of the Atlantic region were developed in Brittany and Aquitaine. In southern Spain a connection between the Atlantic and Mediterranean Region temporarily existed.

The Mediterranean sequence includes richly fossiliferous strata, especially in the Po region, where the Pliocene begins with a transgressive fauna and connections existed from the eastern Mediterranean to the Indo-Pacific regions.

The molasse zone accompanying the Alpine Arc is mostly Neogene in age, whereas the area east of the Alps to the Aral Sea is covered by Neogene sediments that contain characteristic faunas.

Asia. Epicontinental facies of Paleogene age extend east of the Urals in a northerly direction, separating Siberia from Europe and, farther south, Paleogene rocks exist in the Tarim Basin. Continental Neogene deposits cover large areas in Siberia and Mongolia.

Following the axial direction of young mountain chains, the Paleogene (mainly Eocene) occurs in Anatolia and Iran. Through Baluchistan and the Punjab it extends into the Himalayas, where it may underlie alpine type nappes; across the Middle East—in Syria, Iraq, and the Arabian Peninsula—calcareous facies of Paleogene age are distributed; Neogene rocks are limited to regions near the coast. Tertiary sediments also exist in Assam and Burma, Indonesia, the Philippines, Taiwan, and on Honshu and West Hokkaido in Japan. West of Kamchatka, a marine embayment from the Pacific region extends far into eastern Siberia.

Australia, New Guinea, and the islands of the southwestern Pacific. Tertiary rocks occur in Western Australia only within a narrow zone along the coast. In the south they are present in the Eucla, Adelaide, Murray-Southwest-Victoria, and Gippsland embayments, and marine Tertiary surrounds Mesozoic cores in several basins on New Zealand.

In western and central New Guinea, the Tertiary is represented by foraminiferal-calcareous Eocene facies, and in the east a geosynclinal-abyssal (deepwater) facies is present. In the southwest Pacific region, the outer Melanesian Zone comprises the Solomon Islands, New Hebrides, Fiji, and Tonga, each of which contains Tertiary rocks; the interior Melanesian Zone comprises southeastern New Guinea and New Caledonia.

North America. Marine sediments of Tertiary age in North America exist only along continental margins. They are developed along the Pacific coast in western Washington, western Oregon, California, and the southern region of Vancouver. On the Atlantic coast, Tertiary rocks extend from New Jersey in the north, across Maryland, Virginia, the Carolinas, and Georgia, south to Florida. Tertiary sediments are perhaps best represented along the Gulf Coast, however, where they extend from Florida to the east coast of Mexico and down to Yucatan; the Mississippi embayment extends far into the continent. Sediments of the Gulf Coast are, of course, closely related to the Caribbean faunal province. Tertiary faunas of the West Coast are rather distinctive and are known as the Californian faunal province, being quite different from the West-Atlantic Province along the East Coast. The deposits in the interior of the continent contain mammalian faunas and are of great importance because they show that Central North America was a mammalian evolutionary centre during the entire Tertiary.

The Central America land bridge

Central and South America. Central America is important as a land bridge that made possible the migration of mammals during Cretaceous-Tertiary time, although North and South America were separated during most of the Tertiary, and only certain faunal elements could enter South America. It was not until the close of the Pliocene Epoch that the Panama land bridge became passable for mammals, although marine connections permitted exchange of faunal elements between the Atlantic and the Pacific. Eocene and Miocene sediments exist at several localities in Central America and the West Indies, whereas marine sediments of Neogene age in South America are limited to coastal regions despite their relatively great extent in comparison to the size of the subcontinent. In the north (Trinidad, Venezuela, Colombia), they are closely connected with the Caribbean faunal province. Separated by large continental areas, marine Tertiary occurs again in the south, in the La Plata Basin, Patagonia, and Tierra del Fuego; but in central South America only lacustrine and other nonmarine sediments are known.

A seaway across the Sahara

Africa. During Upper Cretaceous time (Maastrichtian) a great marine transgression occurred and the Mediterranean was connected with the Gulf of Guinea across the Sahara. Eocene sediments also reflect a time of transgression, and an incomplete sequence in the east and flysch facies in the west characterize the Upper Eocene. Neogene deposits are transgressive upon the margins of the continent. In South Africa, the Tertiary is represented primarily by the continental series of the Kalahari System. Richly fossiliferous sediments of the Eocene in Egypt are of great interest because they contain large nummulites (distinctive, shallow-water Foraminifera that occur in calcareous facies) and because materials for the construction of the pyramids were obtained from these rocks.

CENOZOIC LIFE

Flora. The cenophytic flora appeared in the Middle Cretaceous and became dominant in the Tertiary. It largely replaced the gymnosperms, the dominant forms of the Mesozoic, although during the warm epoch of the Eocene the floral distribution on earth was similar to that of the Upper Cretaceous. The Tertiary-Holocene flora of angiosperms originated in the Arctic region and spread steadily southward; Eocene floras from Greenland and Alaska reached the middle latitudes of North America and Eurasia during the Miocene.

With the retreat of floral belts southward, the trends of mountain ranges became an important ecological factor. In most of Eurasia the ranges trend east–west, and most of the Tertiary plants therefore died out and could not return after Pleistocene time. In America and southeast Asia, however, mountain ranges extend north-south and in warmer periods the floras could return to the north. The similarity of European Tertiary floras to those now existing in Mexico, California, or South China is explained by this fact.

Calcareous algae belonging to the Dasycladaceae were predominant in Mesozoic seas and persisted into the Tertiary, but they are unimportant compared to the Corallinaceae or Nullipora (*Lithothamnium, Melobesia*), whereas Characeae are widely distributed in freshwaters. The nannoplankton (very small, floating marine organisms) of the Tertiary are distinguished from that of the Cretaceous by the appearance of discoasterids.

The decrease of temperatures during the Quaternary established the modern zones of vegetation. Tundra, characteristic of Arctic latitudes, and mosses and polar willows covered much of central Europe at the southern limit of glaciation, and the limit of forests also retreated toward the south. Interglacial periods show conditions similar to former ones (see CLIMATIC CHANGE).

Evolution of the Foraminifera

Lower animals. In the Tertiary, as in older strata, fossils come from marine sediments. Many genera and species of Mesozoic Foraminifera persisted into Tertiary time, although the majority of benthonic Foraminifera showed a tendency to evolve new forms that accelerated in the younger Paleocene, especially among the Rotaliacea, which evolved large forms with a complicated structure. The trend reached its maximum in the Middle Eocene, although contrary to the peak of foraminiferal evolution in the Upper Paleozoic, large and complicated Foraminifera appeared in several phylogenetic groups in the Tertiary. The most widely known are the nummulites, which are paralleled only by the vertebrates with respect to their intensive evolution.

In the older Paleocene "pillar-bearing rotalids" are widely distributed and the discocyclines appear, reaching their peak in the Eocene and disappearing in the Upper Eocene. Several genera of the Nummulitidae evolved giant forms. Nummulites in the restricted sense appeared as small forms in the Upper Paleocene and reached their optimum size in the Middle Eocene, with tests (shells) as large as 200 millimetres in diameter or more. In the Upper Eocene small or very small forms with a diameter of two to five millimetres again predominate, and in Europe they disappear in the Upper Oligocene. Evolutionary sequences of larger Foraminifera also appear in the Neogene; the most important of these for stratigraphic purposes are miogypsins and lepidocyclines.

Benthonic foraminifers evolved numerous new forms during the Cenozoic. Most important for stratigraphic correlation is the evolution of the plankton, because their worldwide distribution provides a base for intercontinental correlation. The *Globigerina*-range in the oldest Paleocene (Danian) is followed by the evolution of the Paleogene plankton with *Globorotalia* and *Truncorotalia.* During the Oligocene the variety of forms is much reduced, and only primitive globigerinas persist. The characteristic genus *Globigerinoides* appeared in the Miocene; *Praeorbulina* and *Orbulina* appeared in the Middle Miocene. The Miocene-Pliocene boundary is based upon species of *Globorotalia.*

Evolution of other invertebrate groups

Corals did not evolve to any great extent in the Tertiary, but their distribution changed because of a decrease of water temperatures. Mollusks, especially gastropods and bivalves, are among the most important fossils of the Cenozoic; many genera and species evolved among the Cenogastropods, among which siphonostomous forms are especially noteworthy.

Evolution of landsnails also was marked. Only a few species are known from the Cretaceous, but during the Tertiary several groups evolved distinctive genera and species, especially the *Pupillacea, Clausiliacea,* and *Heliacea.* During the Quaternary, heat-loving species disappeared from the northern continents, and robust forms spread over Eurasia and North America.

The rising of young mountain chains in Neogene time separated the northern part of the Tethys Geosyncline from the oceans in central Europe, southeastern Europe, and central Asia. During the Miocene and Pliocene, this led to the evolution of molluscan faunas with some extremely specialized types. This is an excellent example of the results of isolation of which few parallels can be provided within the history of life.

At the end of the Pliocene, temperature lowering caused species of the northwest European province to migrate into the Mediterranean province and this "advance of northern guests," together with a retreat of more delicate species, is taken as a criterion for the beginning of the Pleistocene and the onset of glacial conditions.

The evolution of the arthropods in the Tertiary appears to show a trend toward their present importance, and although terrestrial invertebrates can be fossilized only under very favourable conditions (for example, in amber), it appears that during the younger Paleogene many species were similar to those living today.

Ostracodes occupy a special place among the arthropods because they are abundant in the fossil record and show a strong trend toward evolution of different and distinctive forms in the Tertiary.

Among Bryozoa, cheilostomate forms dominate in the Tertiary. The number of brachiopod species is strongly reduced compared with the Cretaceous; some groups were forced down to lower bathymetric levels, and banks of *Terebratula* are relatively frequent. Remains of echinoderms are not rare in the Tertiary and echinoids occur frequently, especially irregular and burrowing forms. Most of the groups dominant during the Paleozoic and Mesozoic lose their importance, however.

Vertebrates. At the Cretaceous/Tertiary boundary the highly specialized reptiles of the Mesozoic disappeared, although turtles, crocodiles, snakes, and lizards continued. Several Mesozoic groups of fishes died out, whereas others existed as rare relics (crossopterygians); teleost diversity increased. Among amphibians, frogs and toads showed progressive evolution. Bird fossils are rare, but it seems that in the Paleogene most of the living groups already had evolved.

Evolution of mammalian faunas

The evolution of the mammals is the most important biologic phenomenon of the Tertiary. During the Mesozoic, small, primitive mammals spread all over the earth, and most of them became extinct during the Mesozoic, although a few relics persist in Australia. Generally speaking, only the stem groups of marsupials (pouched mammals) and placental mammals survived the end of the Mesozoic.

The isolation of Australia throughout the Tertiary led to a separate evolution of marsupials, with many forms adapting to different conditions; however, autochthonous (originating within) placental mammals do not exist in Australia. During the Paleocene, specialized groups evolved out of the primitive placentals, and, together with marsupials, they reached South America, which then lost its direct connection with the other continents until the Pliocene. Contrary to the Australian example, the marsupials did not evolve to the same extent, although the primitive placentals evolved many specialized forms, some of which still exist.

In the Old World and in North America, the mammalian fauna of the Paleocene was replaced in the Lower Eocene by increasingly progressive and differentiated forms; such forms as rodents, carnivores, hoofed animals, and primates became predominant. Some evolutionary branches returned to the sea; seals and whales are prominent examples.

During the Paleogene, the carnivores are represented by creodonts (*Arctocyon, Hyaenodon,* and others) whose dentition is not as specialized as is that of the more modern carnivores of the Oligo-Miocene (*Amphicyon, Hemicyon, Felis*).

Herbivorous ungulates evolved multicusped molars, broad and high-crowned, with their dentine and enamel folded into narrow ridges that enabled the tooth to deal with tough grasses. Swift-running ungulates reduced their number of toes, and the evolutionary line of horses leads from four-toed forms (*Hyracotherium*) to three-toed ones (*Miohippus, Merychippus*). *Hipparion* of the Lower Pliocene ran only on the middle toe, a trend continued by the Pleistocene genus *Equus.*

At the beginning of the Neogene, mastodonts migrated from Africa to Europe and later to Asia and America. They also showed specialization of their dentition, par-

ticularly with respect to size of tusks. In the Middle Miocene the cervids had primitive antlers (single-ended), which became more and more complicated as evolution progressed. The largest mammals that ever lived on land (Baluchitherium) existed in the Paleogene.

At the beginning of the Pleistocene, modern mammalian faunas consisting of *Equus*, *Elephas*, *Ursus*, and others spread over the Eurasian continent, and these faunas are useful for defining the boundary between Tertiary and Quaternary. During the Quaternary, the modern mammalian species appeared, probably as a result of adaptation to swiftly changing climatic conditions. Robust forms inhabited the polar regions, more delicate forms retreated into warmer regions, and glacial relics remained in high mountains and other isolated territories.

Evolution of Hominids. Manlike forms appeared at the beginning of the Quaternary, and even the oldest remains show that upright posture and modern limb proportions had been developed. The earliest remains are known from East Africa, South Africa, and Indonesia, together with associated implements. The brain increased in size, dentition became weaker, face profiles became steeper. *Homo erectus* in Europe and Asia developed the "hand-ax cultures" of the older Paleolithic, and *Homo neanderthalensis* perfected these stone tools. In the Würm glacial time, *Homo sapiens* appeared; cave paintings in France and Spain show his artistic achievements. Mesolithic and Neolithic man devised settlement and agriculture, and civilization commenced.

Censorship

To censor is to judge and criticize, to count and calculate, and to prohibit and suppress. The function or office of censorship in a political, religious, or social community is to proclaim common ends and values for the community, draw up programs of action, adherence, and ideology to achieve them, establish devices and agencies to enforce them, and enumerate crimes and sins, errors and obscenities, heresies and treasons by which they are endangered. The history of censorship is therefore part of the history of learning (the construction of encyclopaedias of true knowledge and factual information to supplant ignorance, misinformation, and superstition), of education (the development of liberal arts to correct distorted or bad education), of political institutions (the establishment of democracy to replace despotism and imperialism), of religious beliefs (the adjustment of old doctrines to new prophecies, the propagation of beliefs to new believers, the reformation of practices to new circumstances), and of the arts (the renaissances, revolutions, or changes of style in opposition to academic, imitative, and sterile art).

Some form of censorship has appeared in all communities, small and large, in all parts of the world, at all stages of history. The operation of censorship, like the operation of civil law, religious commandments, and social customs, is by sanction, negation, prohibition, and restriction. The problems of censorship today reflect changes in communication (and misrepresentation and secrecy), in community (and prejudice and tension), in belief (and skepticism and commitment), and in knowledge (and ignorance and misconception). New extensions of rights and of freedom of thought and expression have been achieved, and unprecedented devices of intimidation, repression, and suppression have been constructed. A review of what has been censored in the past and of the methods of censorship and the reasons advanced in its defense and promotion may clarify present problems.

ANCIENT CENSORSHIP

Dynasties, learning, and history in China. In ancient China, Tao (the Way or the Law) was the way of ordering one's life and the world; it was the moral and political law expounded in philosophy and institutionalized in the state. Philosophers studied the ways of past dynasties to find guidance in the great Tao or great Community; rulers protected the law of their dynasties from criticism and opposition by destroying the records of the dynasties they supplanted. The teachings of Confucius (*c.* 551–479 BC) were one of the "100 schools" that flourished in his time. He lamented the lack of documents by which to study the learned men of earlier dynasties, since such study was the only source of wisdom. The philosophy of Confucianists was a philosophy of humanity—love of men and understanding of men. Among their opponents were the Legalists, who advocated power and control as the goals of life. On the command of the first Chinese emperor, Shih Huang Ti, the Legalists prepared the first of the long line of Chinese encyclopaedias about 220 BC. This encyclopaedia, "The Mirror for the Emperor," provided an authoritative ideological foundation for the Ch'in dynasty (221–206 BC). Shih Huang Ti built the Great Wall and burned books to protect his realm from opposition. In 213 he ordered the destruction of all books except those in medicine, pharmacy, divination, agriculture, and arboriculture. Five hundred scholars were executed and thousands were banished. The *Analects* of Confucius was among the books burned. The punishment for failure to burn proscribed books within 30 days was branding and condemnation to forced labour.

Destruction of opposition in China

Empires, religions, and ways of life in India. In ancient India, Dharma (the Law) was found in the sacred literature of the Hindus and was expounded by philosophical and religious commentators as universal law—divine and moral, transcendental and human. Dharma was the basis for distinguishing classes or functions in society and stages or ways of life. There were four classes, or *varṇas* (colours): Brahmins (priests and thinkers), Kṣatriyas (rulers and warriors), Vaiśyas (farmers, artisans, and merchants), and Śūdras (laborers, unskilled workers, and slaves). There were four stages of life: austere life as a student, married life as a householder, a life of meditation and penance as a hermit, and a life of homeless wandering as an old man. Two unorthodox sects, Jainism and Buddhism, departed from the Veda and from gods, priests, and rites to interpret Dharma in terms of the actions of saintly men.

The Aryan invasions, which began about 1500 BC, subjugated the earlier inhabitants of India and introduced Indo-Iranian religious and cultural ideas in the Vedas. The unification of India reached its widest extent in the Mauryan Empire under Aśoka, a Buddhist, who, in the 3rd century BC, after a bloody war, abandoned conquest by war for conquest by Dharma. Aśoka proclaimed that Dharma applied to all sects in his empire—Brahmins, Ājīvikas, Jains, and "other sects as well as Buddhists"—and to all peoples of the world—such as the kings of Syria, Egypt, and Macedonia. But he also drew up a canon of texts for Buddhists, and to eliminate sectarianism he called the third Council of Buddhists about 247–246 BC, which made the Theravāda school orthodox and expelled many heretics. Missionaries were sent to Ceylon, Burma, Thailand, and Cambodia to preach the orthodox version, where it continues to this day, while the Buddhist sects of China and Japan grew out of the Mahayana tradition. The fate of religion and philosophy in India and China illustrate two kinds of censorship: one a cultural, sectarian censorship resulting in the disappearance of books and studies; the other a dynastic, official censorship resulting in their destruction and outlawing.

Imposition of conformity in India

The people and the Law of God in Israel. In ancient Israel, Moses had led his people from bondage to a God-promised land, where they were to live under a law received from God. The Torah (the Law) was considered unchanging, and in times of crisis "the book of the law of Moses which the Lord had given to Israel" was consulted. Since at each consultation a prophet is needed to explain the Law's meaning, the formulation and interpretation of the Law varied with circumstances and with prophets. The development and preservation of Israel depended on a double censorship, one by which the written book of the Law was preserved intact and uncontaminated, and another by which the secret art of interpretation was transmitted orally. The interpretation of the Law guided the people and helped Israel in its wars against its enemies. After the fall of Jerusalem (586 BC), however, the problems of the preservation of the canon and the continuity of the oral tradition took a new turn during the Babylonian Captivity. A hierarchical government prepared the way for the Sanhedrin (the supreme rabbinic court), and priestly legislation laid the foundations of rabbinic interpretation. Judaism was Hellenized under the Hellenistic kings of Egypt and Syria, and in 168 BC the Seleucid king Antiochus IV Epiphanes established the worship of Olympian Zeus (merged with the Syrian god Baal), burned the Torah, and condemned those who possessed the book, or followed the Law, to death.

Preservation of a people in Israel

The interpretation of the divine Law transmitted in the Torah provided the means both of distinguishing the Jews from other peoples and of adjusting Judaism to other cultures. The methods of interpretation evolved in controversies which, in the Hellenistic period, resulted in the formation of sects—*e.g.*, the Pharisees, the Sadducees, and the Essenes. In Hellenized Alexandria, a Greek translation of the Old Testament, the Septuagint, was prepared for Jews who knew no Hebrew or Aramaic. The canon of the Old Testament was extended in the Septuagint to include the Law, the Prophets, the Hagiographa, and the Apocrypha; and Philo of Alexandria (died after AD 40) used the analogical methods of Greek literary criticism and Neoplatonic dialectic to interpret the books of the Old Testament. Christians later learned the method from Philo and applied it to the New Testament. As Tao had been used to establish the rule of a dynasty and Dharma to relate peoples, Torah was used to preserve the uniqueness of a people.

War, politics, and education in Greece. The Greeks came into existence by the assimilation of a succession of invading peoples and achieved unity by resisting invasion by the Persian Empire in the early part of the 5th century BC. Victory over the Persians did not lay the ground for a continuing unity of the Greeks: Themistocles, the Athenian, and Pausanias, the Spartan, who had been outstanding in contributing to the victory, were judged guilty of treason, un-Hellenic activities, and Persian sympathies; and Athens and Sparta signed a treaty under which they carried on a cold war that developed into the Peloponnesian War (431–404 BC). The avowed purpose of both sides in that war was to free the Greeks. Censorship appeared in education and in politics. According to Plutarch in *The Ancient Customs of the Spartans*, the Spartans learned to read and write for purely practical reasons, and all other educational influences—books and treatises as well as learned men—were banned. The arts and philosophy flourished in democratic Athens, but many artists and philosophers, among them Aeschylus, Euripides, Phidias, Socrates, and Aristotle, were exiled, imprisoned, executed, or took flight. Aeschylus was accused of violating the secrecy of the Eleusinian Mysteries.

Greek dimensions of censorship

Greek philosophers framed the theoretic arguments that have been used for centuries in support of freedom and of censorship, and Greek lawgivers distinguished the practical reasons that have become standard grounds for censorship. Plato would have banished poets because, he claimed, they lied about gods, heroes, and men and thus impeded the formation of virtue in the individual citizen and justice in the state; and he opposed rhetoricians and naturalistic scientists because, he charged, they deceived in communication or erred in inquiry. Later censors have been able to think of no reasons for banning books or other forms of expression other than the four accusations levelled against Socrates: (1) impiety; (2) corrupting the morals of the young; (3) popularizing science that might lead to skepticism or disbelief; and (4) deceiving by trickery and making the weaker argument stronger. The Greeks condemned such discourse and teaching because they endangered the state, and Socrates himself justified the judgment against him, in the *Crito*, as essential to the preservation of the laws of Athens.

The Hellenistic kingdoms, after 323 BC, established libraries, two of which—those at Alexandria and Pergamum—laid the foundation of Western culture and censorship. The Hellenistic libraries were not formed by collecting books but by making them. The texts of the books had to be established, frequently from scattered fragments, as in the case of Homer; the authors had to be identified and distinguished from other authors of the same name or of similar works, and their works had to be verified; sequences, synchronisms, and classifications had to be established, and empirical sciences had to be developed for these purposes. The Hellenistic libraries marked the beginning of two forms of censorship. The work of editors and the classification of great books influenced the content as well as the interpretation of the books, for the choice and the compilation of the editor fixed the texts of the classics that have survived. The works of other authors not chosen and edited did not survive, sometimes to the regret of later scholars. The concentration of books in large numbers encouraged and facilitated a second form of censorship—the burning and pillaging of books. There are many accounts (which are significant as accounts even when they are inaccurate factually) of the burning, in several stages, of part or all of the library at Alexandria, from the siege of Julius Caesar in 47 BC to its destruction by Christians in AD 391 and by Muslims in 642. In the latter two instances, it was alleged that pagan literature presented a danger to the Old and New Testaments or the Qur'ān.

Law, morals, and monotheism in Rome. The office of censor was established in Rome in 443 BC. Taking the census, *i.e.*, counting and classifying the inhabitants of Rome, included regulation of their morals, violations of which might result in a citizen being deprived of status and functions. The mechanism of censorship in Greece was judicial trial; in Rome it was executive judgment in which the informer or delator played an important part in protecting the native virtue of Rome from treason and immorality. After the accession of Augustus, imperial censorship was directed to extirpating treason and curbing immorality. Treason included allusion, statement, and criticism. A drama that attacked Agamemnon, the semimythical commander of the Greeks against Troy, and a history that presented as the last of the Romans Brutus and Cassius, the assassins of Julius Caesar, uncle of Augustus, were condemned, as well as statements interpreted as being critical of the government. Philosophers and rhetoricians were twice banished by law, and the political rights of actors were curtailed by edicts of the censors. Immorality often took the form of adultery, which provided lucrative opportunities for informing. Even during the republic, when Rome came into contact with the culture of Greece, Cato the Elder, also known as Cato the Censor, a statesman and ardent advocate of the Third Punic War, remembered for his reiterated proclamation, "Carthage must be destroyed," opposed the spread in the 2nd century BC of Greek arts and pedantry as dangers to the ancient virtues of Rome, whereas Scipio Aemilianus, who also served as censor later in the same century, formed a group of philosophers, historians, poets, and statesmen (the Scipionic Circle) who looked to Greece as a source of Roman culture. When Rome abandoned its policy of maintaining the freedom and independence of the Hellenistic kingdoms, the admission of citizens into the new provinces was made a censorial act. The emperor Augustus purged the Senate in the 1st century BC as an exercise of censorial powers.

The Roman censor

The persecution of the Jews and the Christians during

the first three centuries of the Roman Empire arose from a conflict of laws and of books. The laws of Rome tolerated all gods, but the Jews and the Christians refused to place their one God in a pantheon and they refused to perform civic duties (including service in the army or attendance at civic functions, games, and the theatre) that required sacrifice to idols. Christians, Jews, and later Muslims (who recognized their affinity in opposition to heathens as three peoples of the Books) developed different patterns of censorship to interpret divine law. They interpreted their three Books—the Old Testament, the New Testament, and the Qu'rān—as formulations of the law of Moses, but each tradition included in its censorship interpretations made in the other two traditions; and in all three traditions the controversy concerning whether pagan arts and sciences, Greek philosophy and Roman law, should be prohibited or should be used to interpret sacred writings continued unabated and unresolved. Despite prohibitions, pagan philosophy, science, and literature were preserved to the present only by the labour and erudition of medieval scribes, translators, and commentators. Each tradition faced the problem of drawing up a canon of authentic sacred books and lists of heretical schismatic, and erroneous books.

Law and tradition in Judaism. The destruction of Jerusalem and of the Temple by the Romans in AD 70 raised grave problems in the interpretation of the Torah, since much of the Law centred on the Temple and its ritual. The Torah was reinterpreted and reformulated in the Palestinian Talmud by rabbis who fled to Babylonia. The Talmud consists of two parts, the Mishna or "Repetition," a codification begun before the destruction of the Temple, and the Gemara or "Completion," a commentary on the Mishna. The Torah is not limited to the Ten Commandments, or to the laws of Deuteronomy; the Talmud itself is Torah. The law is formulated in dialectical exposition and defense in the *Halakha;* its moral implications and precepts are presented narratively and are made accessible to all in the stories of the *Haggada.* It is universal law, but it separates Jews from other peoples, including the Romans. One book of the Talmud is devoted to idolatry and to the problems Jews faced in an empire of idolators. Jews were persecuted with Christians, and Roman officials sometimes did not distinguish between them. In the 4th century, Christianity became the religion of the empire, and Christian officials persecuted Jews.

Law, doctrines, and institutions in Christianity. During the period of persecution, the Christian Apologists argued that Christian law was not a danger to the law of Rome; in AD 313 the Edict of Milan gave Christians equality with other religious groups in the empire. According to the Christians, the New Testament was a continuation of the Old Testament, a fulfillment of the prophecies of the Old Testament in the teaching of Jesus. The creed was the statement of the facts that established that continuity. The Nicene Creed was formulated at the first ecumenical Council at Nicaea, called by the Roman emperor Constantine in AD 325, and the decisions of councils and of the Church Fathers were put on a level of authority only after the Old and New Testaments for the interpretation of law and doctrine. The ecumenical councils did not succeed in unifying the empire or the church. The empire was divided into two empires in 363, and the last ecumenical council recognized by the Greek Church was the second Council of Nicaea in 787. The church was divided by the schism of East and West in 1054. From the first, Latin Christians constructed ecclesiastical institutions, like the councils and the curia, for the statement and interpretation of laws and doctrines, while the Greek Christians formed theological systems and adapted the dialectical, analogical method of Philo of Alexandria in the interpretation of Christian and pagan doctrines. The canon of Holy Scripture proclaimed officially by Pope Damasus I in 382, by Pope Gelasius I in 496, and by Pope Hormisdas in 520 was based on earlier compilations, and later compilations were sometimes ascribed to an earlier author. Thus, the *Apostolic Constitutions,* probably written in the 4th century but ascribed to a companion of the Apostles, contains a list of falsely ascribed and apocryphal books of Scripture and also a prohibition of all gentile books on the ground that the "law of God" (the Bible) includes all genres of literature—history, sophistry, poesy, and law. The *Gelasian Decretal* contains five lists, of which the second is a canon of Holy Scripture and the fifth a Decretal of "Books to be Accepted and Books not to be Accepted." The rejected books were branded apocryphal or heretical. The Roman canon of the Old Testament differs from the Jewish by including the works classified by the Jews as Apocrypha; the Greek canon contains some but not all of those works. The Protestants later returned to the Jewish Canon, but the longer canon was then reaffirmed by the Council of Trent for the Roman Catholics.

The development of a church canon

Law and learning in Islām. The Qu'rān is a revelation of eternal law by returning to the law of Abraham undistorted by human prophecies, institutions, or speculations. The interpretation of the law is a science and is to be expounded in the context of other sciences. Three sciences were of particular importance for the interpretation of law in Muslim encyclopaedias: political science, which treats law under ideal conditions following Plato; legal science, which treats actual laws in existing states; and the *kalām,* which is a speculative science of religion and government. The great rift in Muslim interpretations of the science of law was over the possibility of the science of *kalām.*

The *kalām* of Islām

All three monotheistic religious traditions made use of pagan arts and sciences in interpreting the law, but a kind of unconscious cultural censorship determined their selection of what to use and what to omit. The Jews used Neoplatonic dialectic and Hellenistic literary criticism; the Latin Christians used Roman law and Ciceronian rhetoric and philosophy; the Greek Christians used Greek speculative philosophy and literature; the Muslims used the whole body of Greek sciences. Contact with Muslim speculation on the *kalām* turned Jewish theologians to the consideration of philosophical questions, and translations of arabic medical works into Latin in the 11th century and of arabic works on mathematics, astronomy, the organization of the sciences, and Aristotle in the 12th century were the beginning of scientific inquiry in western Europe. Many of the new translations from Arabic, Greek, and Hebrew and many of the works in philosophy and science stimulated by them were prohibited by ecclesiastic, academic, and political authorities, but they slowly became the basis of education, inquiry, and culture.

MEDIEVAL AND RENAISSANCE CENSORSHIP

Doctrinal and academic censorship in the Middle Ages. Translations brought Jewish, Christian, and Muslim monotheistic cultures into contact. Paradoxically, Christian theologians and philosophers of the 13th century knew and discussed Jewish and Muslim positions more fully and soundly than philosophers have communicated across cultures at any time since, but Christian inquisitors burned the Talmud in the 13th century, and the 12th-century Latin translation of the Qur'ān made by Peter the Venerable (abbot of Cluny) was later prohibited.

The liberal 12th and restrictive 13th centuries

The 12th century was a period of the cultivation and development of the liberal arts in an atmosphere of tolerance and curiosity. John of Salisbury castigated the arrogance of the illiterate masses and set forth maxims to guide reading of the potentially harmful as well as the potentially helpful books. He argued that all writings should be read, but although the wise man "does not shun fables, stories, or spectacles in general," the Fathers condemned the evil careers of actors and mimes. Theodoric of Chartres, who made an enormous collection of the liberal arts in the *Heptateuchon* and encouraged his students to study Arabic and to translate Arabic science, was summoned before a council to answer for the theological consequences of his cosmological system.

The introduction of the new sciences into programs of education encountered problems of censorship, as is often the case in framing a new program for a public institution. The Council of Paris in 1210 prohibited the teach-

ing, publicly or privately, of Aristotle's works on natural philosophy and of commentaries on them. The statutes of the newly founded University of Paris in 1215 authorized the teaching of Aristotle's logic but prohibited his books on metaphysics, physics, and natural science, as well as expositions of them, together with the books of three heretics. The prohibitions were repeated during the course of the century, but the statutes also set requirements for degrees which included knowledge of Aristotle's scientific and metaphysical doctrines. The medieval European universities, in the same paradoxical fashion, laid the foundations of academic freedom and freedom of thought and expression, but the faculties of the universities met periodically to condemn or expurgate the writings of their colleagues. The record of this censorship, or judgment, fills the three large volumes of the *Collection of Judgments Which Have Been Proscribed and Noted in the Church from the Beginning of the Twelfth Century After the Incarnation of the Word to the Year 1632 as well as the Censorial Judgments of the Outstanding Academies, Among Others Paris and Oxford and Louvain and Douai in Belgium and Other Colleges of Theology Among the Germans, Italians, Spaniards, Poles, Hungarians, and Lorrainians.* After the proscriptions against the works of Aristotle had been lifted, controversies continued concerning doctrines derived from or attributed to Aristotle. In 1277 the Bishop of Paris condemned 219 errors and was echoed in less than two weeks by the Archbishop of Canterbury. The errors included positions set forth by the Arabic and Persian philosophers Averroës and Avicenna and also some of Thomas Aquinas. Teaching was controlled, not only by prohibition of errors, but also by regulations placed on booksellers or "stationers" (stationarii) who were authorized under oath by the university.

Effects of Humanism

Corrective and preventive censorship in the Renaissance and Reformation: the Index. The rebirth of letters, the reformation of religion, and the development of printing brought about changes in the methods of censorship. Censorship of books before publication was differentiated from prohibition of uncensored books after publication. Ecclesiastical and secular censorships were separated by the establishment of official bodies of clerical and governmental censors. Prohibition of distribution, possession, and reading of books was guided by the publication of catalogs and indexes.

The humanists of the Renaissance transformed the liberal arts by applying them to the study of ancient literature, art, and oratory. They ended the medieval cultural censorship of ancient literature and imposed a censorship on medieval letters of their own, which continued to be effective until the 19th century. During the Renaissance, programs of study arranged according to the subject matters that were treated in the new learning and handbooks of factual information concerning those subject matters were both called encyclopaedias.

The theologians of the Reformation transformed theology by returning to the study of the Bible and the Church Fathers. Medieval theological theses were refuted as heresies by Protestant theologians, and Protestant innovations were in turn refuted as new heresies. The word controversy became a technical term, and new lists of banned books and new rules for judging books and statements were produced by the controversies. Pope Innocent VIII late in the 15th century decreed that all books be submitted for examination and permission before being issued for general reading. The regulation was repeated at the Lateran Council in 1515 and was formulated as one of the rules for judging books drawn up at the Council of Trent in 1563. In the condemnation of the heresies of Luther by the faculties of theology of Cologne and Louvain in 1519 and of Paris in 1521, the propositions enumerated for censure were often accompanied by detailed lists of books that affirmed the error. In 1520 Pope Leo X anathematized the doctrines and books of Luther; and Luther, in response, burned the bull of the pope. In 1543 the University of Paris published a list of 65 books condemned or accepted with qualification, which included unauthorized translations of the Bible and works by Luther, Calvin, Rabelais, and Erasmus. Four "catalogs" of books, in Latin and in French, censored by the faculty from 1544 to 1551, fill 23 folio columns. In 1559 Pope Paul IV used the word "index" in the title of his Index of Forbidden Books; and in 1564 the Index of the Council of Trent appeared, prefaced by ten general rules for the control of literature elaborated at the council.

The Index

The first rule provided that all books condemned prior to 1515 and not mentioned in the Index were still condemned. The second was concerned with the judgment of heresiarchs, including the Protestant reformers; and the third and fourth with editions and translations of Scripture. The fifth set down conditions by which books edited by heretics may be permitted or emended, and the sixth stated regulations concerning books of controversy between Roman Catholics and heretics. The seventh treated lascivious or obscene subjects that might corrupt morals. The eighth provided that books of which the principal argument is good but which occasionally tend to heresy or impiety, divination, or superstition may be allowed after they have been corrected by Roman Catholic theologians under the authority of the General Inquisition. The ninth prohibited books of magic and superstition, and the tenth set up conditions for the examination and licensing of books before publication and for the inspection of printing houses and bookshops.

The Congregation of the Index was established in 1571 to publish new editions of the Index and to pronounce on works referred to it. The governments of various nations promulgated laws and appointed officials to regulate the printing and distribution of books. In France the number of printing houses and bookshops permitted in each city was established by law. Like regulations were extended to newspapers and theatres.

Dynastic patterns of censorship in India and China. In India and China, as in Europe and the Near East, periods of imperial unification alternated with periods of dynastic rivalry and foreign subjugation, and a diversity of sects and philosophies alternately interpreted a common eternal law in tolerant coexistence or fought for dominance to the exclusion of other interpretations of the law and the truth. Two forms of censorship evolved, one in India, one in China, both distinct from the forms of censorship developed in the Western monotheistic religions based on tradition, creed, or science.

Censorship in imperial China and India

Missionaries took the Theravāda or Pāli canon of Buddhism from India to Ceylon, Burma, and Thailand during the empire of Aśoka. Beginning in AD 67, Indian and Chinese scholars took the Mahayana or Sanskrit canon to China and Tibet, and eventually to Japan. Buddhism was still flourishing in India in the 4th century. In the 11th century, monks fled with manuscripts to Tibet. From the 8th to the 15th century, India suffered three successive invasions from Arabia. The Mughal Empire reached its widest extent in the 16th century under Akbar, who returned to the ideal of a united, pluralistic India. In the 18th century, Akbar's grandson, Aurangzeb, reversed Akbar's policy of tolerance.

The Chinese empire was unified in the Sung period, during the 10th century. Confucianism had triumphed, and the "Emperor's Mirror from the Era of Greatest Peace," completed in 983, was compiled as a collection of the whole scientific and literary knowledge available at the time. At the beginning of the 15th century, a vast encyclopaedia, the "Great Handbook of the Era of Eternal Joy," in 11,000 volumes, was assembled. Like the "Emperor's Mirror," it was a collection of all Chinese writings, but it included unorthodox Buddhist and Taoist as well as Confucian works. In the 18th century the Manchu emperor Ch'ien-lung undertook to reduce the "Great Handbook" to manageable size by purging it of unorthodox and seditious books. The results included a new encyclopaedia, an imperial catalog—now indispensable in scholarly work—and two indexes, one of meritorious books, the other of banned books.

The three great empires that unified India without ideological censorship or subjugation of minorities under a Buddhist, a Hindu, and a Muslim emperor were followed

by imperial, censorial, and social suppression; and the modern introduction of Western forms of censorship under the British rule led to an independence that separated India into two parts that practiced two forms of censorship, one Muslim scientific, the other Hindu legal. The succession of dynasties that unified China prepared larger and more inclusive, or smaller and more orthodox, encyclopaedias, and China achieved independence of the Manchu emperors and Western powers, first with a Western form of freedom of thought and expression, modulated by administrative and judicial censorship, and then with a Western form of Marxist censorship that reiterates the Legalist ideology of the first encyclopaedia and the first empire: the ideas of force and control, a bamboo curtain rather than a Great Wall, and the hundred flowers rather than the hundred schools.

MODERN CENSORSHIP

Controversies and interpretations in the West in the 17th and 18th centuries. Since the Roman Catholic Indexes denounced the doctrines of the Protestant Reformation as heresies, Protestants for their part analyzed the Indexes as instruments of repression of truth and faith and as promulgations of error and superstition. The Indexes were recommended and used as lists of books to be acquired and studied. Indexes appeared in great numbers, periodically, and in all parts of Europe. They encountered opposition not only because of religious differences, but also because of jurisdictional rivalry. Paolo Sarpi, whose *History of the Council of Trent*, published in 1619, is a chief source of information concerning deliverations and debates in the preparation of the Tridentine Index, advocated in his controversy with Pope Paul V regulation by the state of the temporal powers of the church. He advised his countrymen in Venice not to yield to Roman authorities but to preserve their own right to ban pernicious books, and he argued that the Expurgatorial Index made it impossible to ascertain whether a book presented the author's views or those of the Curia.

It is difficult to reconstruct the early stages of the controversy concerning the Index since arguments against the Index were themselves prohibited and destroyed, and the Index Expurgatorius was at first secret and not given general circulation. The nature, methods, and subjects of controversy were, however, given classical statement by Cardinal Robert Bellarmine, who worked on the Clementine edition of the Vulgate to reduce the inaccuracies of the previous edition of the official translation of the Bible and a friend and adviser of Galileo and one of the examiners of Galileo's works prior to his trial and condemnation, in his *Disputations on Controversies of Faith against the Heretics of the Time* in three volumes from 1586 to 1593 during the early disputes concerning the Tridentine Index of 1584. During the 17th century many replies to Protestant critics of the Index appeared. Jakob Gretser, a Jesuit, wrote *On the Law and Morality of Prohibiting, Expurging, and Abolishing Heretical and Harmful Books* in 1603. Another Jesuit, Théophile Raynaud, differentiated four kinds of books in his *Erotemata on Bad and Good Books and on the Justice and Injustice of Incapacitating Them* in 1653. Some books, he said, are bad and harmful—books of heretics and atheists, books of magic and superstition, and obscene books. Some books are bad but not harmful—polytheistic, Islāmic, rabbinic, and Talmudic books, and some heretical books. Some are not bad but are harmful—some because of the fragility of the reader, some, like books on alchemy, because the practice is dubious, and some because the argument is inane. Some are neither bad nor harmful—books that might stir up disorders, anonymous and pseudonymous books, and books that present new doctrines.

Patterns of censorship established in the West in the Renaissance were modified with the development of new methods of publication, new organizations of religious doctrine, new institutions of nation states, new encyclopaedias of arts and learning, and new modes of communication. The reasons that were advanced to justify censorship were similar to those given by the Greeks: impiety, treason, immorality, and heretical or treasonable science. In the 16th century the emphasis was on heresy and subversion; in the 19th century it shifted to morality and science. Philosophical speculations in the 17th century concerning freedom prepared the way for the formulation of the French and American bills of rights in the 18th century, both of which included provisions for freedom of speech and of the press. The 17th-century Dutch philosopher Spinoza argued, in the *Tractatus Theologico-Politicus*, that the bases of morals, religion, and politics are distinct, and that not only may freedom of thought and speech be granted without prejudice to piety and public peace but they may not be withheld without endangering piety and public peace. The English political philosopher John Locke argued, in his first *Letter Concerning Toleration* (1689), that the commonwealth is constituted for civil interests which do not include the salvation of souls and that toleration of differences is an essential part of Christianity.

Movements for toleration

During the Middle Ages, the universities had assumed the function of judging books. Their judgments had been enforced by ecclesiastical decreta and governmental proclamations. With the introduction of printing, prepublication censorship assumed a new importance. It could be used to control an edition rather than single manuscripts, and agencies of ecclesiastical approbation and governmental registry were formed to authorize the issue of books marked with imprimaturs and licenses. Secular was separated from ecclesiastical censorship in different ways in different countries as the Reformation proceeded. The universities continued to supply experts to serve as members of boards of censors, but the faculties lost their function of preparing corporate judgments of books and doctrines. The task of censoring was broken into parts by the separation of kinds of errors—such as heresy, treason, and obscenity—and kinds of subject matter—such as drama, literature, and science.

The mode of licensing

Licensing was applied in the control of the theatre before it was applied to books. In the Middle Ages, authorization was needed to play in the cathedral or in adjacent courtyards or streets. In France players were prohibited by act of Parlement or were required to secure permits from civil authorities in the 14th and 15th centuries. In 1609, authorization was required for comedies and farces, but the absence of designated licensing agencies left the possibility of conflicts of judgments—as in the case of Molière's *Tartuffe*, which was authorized by the king, prohibited by the Parlement, and placed on the Index by the archbishop. In 1706 special censors were appointed for the theatre, 35 years before the institution of censors for printed works.

In England the official who had authorized the production of spectacles in the Middle Ages had been the Master of Revels or the Lord of Misrule. In 1559 Queen Elizabeth I established a licensing system designed to prohibit plays that presented matters of religion or government not suited for treatment before general audiences. The revenue derived from licensing fees provided a motive for extending the functions of the Master of the Revels after 1623, until all stage plays were prohibited under the Puritan Commonwealth in 1647 and theatres were demolished. With the restoration of the Stuart dynasty in 1660, the licensing of plays was re-established with an emphasis on the control of plays dangerous to religion and morality. In 1698 Jeremy Collier, a nonjuring clergyman and conversationalist, published *Short View of the Immorality and Profaneness of the English Stage*. Many dramatists acknowledge the truth of his allegations, and criticisms, including John Dryden, from whom they elicited a confession of fault and a declaration of repentance. The function of restraining or preventing immorality on the stage reverted to the Lord Chancellor of his majesty's household, and in 1737 the Playhouse Bill conferred the statutory power of licensing plays on that official. In the history of English censorship, the original permissive rule of holiday revelry or misrule was successively modified by the misrule of graft, of puritanical suppression, and of fear of the masses, who might be corrupted and roused to sedition against religious or political authority.

Printing began in France in 1470 when three German printers set up their presses in the Sorbonne on the invitation of the university under the medieval provision of sworn bookdealers (*libraires jurées*). The number of bookdealers and publishers was limited by law, first in Paris, then in all the cities of France. In 1470 the number of printing houses for Paris was four; by 1704 it was 36. Though bookshops and printing houses were searched, and clandestine presses were prohibited, such clandestine organizations for the distribution of manuscripts and books continued to flourish. Books were published with false names of publishers and false places and dates of publication, and prohibited books were smuggled across borders. In 1530 Francis I set up a board of censors, consisting of magistrates selected by Parlement and divines selected by the Sorbonne, and the list of prohibited and permitted books was published by the authority of Parlement and the guild of bookdealer-publishers. In 1563 Charles IX prohibited the publication of books without the permission of the king. In the 18th century, censors were appointed for their competence in different fields: of the 79 censors in 1742, 35 were for belles lettres, ten for theology, ten for jurisprudence, ten for medicine, natural history, and chemistry, and eight for mathematics.

Printing was introduced into England in 1476. Patents were issued by the King's Stationer under Henry VII after 1485, and Henry VIII issued catalogs in 1526 and 1529 prohibiting the publication of works of the Protestant heretics. The Privy Council administered censorship from 1538 until it was transferred to the Company of Stationers, which was incorporated in 1556. Prepublication censorship came to an end in 1695 when the Licensing Act was not renewed, in part because of corrupt practices of the Company of Stationers in licensing. The abolition of prepublication censorship was later described by the English historian Thomas Macaulay as a greater contribution to liberty and civilization than either the Magna Carta or the Bill of Rights.

During the 18th century, fear of disorder "across the waters" (first the agitations of the Jacobite rivals to the English throne and later the turmoil of the French Revolution) and of the enemy within (first the religious dissenters, then the seditious critics such as John Wilkes) led Samuel Johnson and David Hume to view the problem of censorship as one of achieving a balance between the danger of unbounded liberty and the danger of bounding it. Morality, obscenity, and libel changed their effective meanings as the audiences affected by the press increased in size, age, and diversity. Restraints on libel were designed to protect reputations. Even after the lapse of the Licensing Act in 1695, seditious, blasphemous, obscene, and defamatory publications were still punishable at common law, but defamation led primarily to actions for *scandalum magnatum* ("scandal directed at the great"). With the spread of communication and democracy, all men acquired reputations; the crime of "obscene libel" took its place beside "seditious libel."

In France, prepublication censorship continued in the 18th century under a code, promulgated for Paris in 1723 and extended to all France by decree in 1744, administered by the chancellor of France. The character of censorship and of resistance to it varied with the policy of the administration of the publishing industry. Writers of prominence and authority presented numerous and well-reasoned arguments against censorship. Important works by Montesquieu, Voltaire, Rousseau, and many of their contemporaries were published in Switzerland, Holland, or England and circulated clandestinely in France; and the small city of Trévoux, north of Lyons, became a publishing centre for works like the *Journal de Trévoux* and the *Dictionnaire de Trévoux*, published by the Jesuits there because they could not publish in Paris. The prospectus and the first two volumes of the French *Encyclopédie* were attacked for plagarism and irreligion, both in the *Journal* and the new edition of the *Dictionnaire*. On the other hand, during the administration of Chrétien de Malesherbes as director of the *librairie* (that is, head of press censorship) from 1750 to 1763, quarrels of authors, theologians, and booksellers and enforcement of judgments of competent censors proceeded so judiciously that Voltaire called Malesherbes the "minister of literature." Malesherbes was succeeded in 1763, however, by the lieutenant general of the police in Paris.

"Positive" censorship: developing culture

Censorship may be the enforcement of judgments based on power, passion, corruption, or prejudice—political, popular, elite, or sectarian. It may also be based on scholarship and the use of critical methods in the interest of advancing a taste for literature, art, learning, and science. Adrien Baillet, librarian of the advocate general of Lamoignon, found time during the labours of preparing an index of that excellent library to write *Judgments of Scholars Concerning the Principal Works of Authors*. In the first volume, *On Books in General*, he argued for the liberty of authors to write and the liberty of readers to judge. But the art of judging is difficult, and one needs a knowledge of how to judge in order to gain access to the knowledge in books. After examining 14 prejudices, such as the prejudice for the ancients, which influence the judgment of books, information is presented concerning publishers and critiques. The successive volumes provide the reader with further information concerning fields and authors in which he can make his own judgments.

Judgments and regulations in the West in the 19th and 20th centuries. In Revolutionary France, the "free communication of thoughts and opinions" was exercised within the repressive limits imposed by the Reign of Terror and the guillotine. The theatre was never freed from the requirements of licensing. Prepublication censorship was established, and censors were appointed in 1822. Each subsequent change of regime and republic made provision for the licensing of books and plays—within the formula of freedom of writing and printing and in conformity with laws guarding against abuse of the freedom. These regulations were extended to motion pictures after 1912 and later to radio and television.

The evolution of censorship followed a different pattern in 19th-century England. Political censorship was coloured from 1792 to 1832 by the fearful example of what was happening in France and the mounting tension in Ireland. Publication of seditious writings ("seditious libel") or utterance of seditious speech ("seditious words") was a crime at common law. Libel law was liberalized in the Libel Act of 1792 by referring decision concerning whether or not a publication or a statement is seditious to juries. Tom Paine's *Rights of Man* was condemned in 1792. Treason trials against members of the early workers' education and trade-union movement took place in 1794. Membership in societies which take mutinous oaths or engage in seditious activities was prohibited in a series of acts culminating in the Seditious Meeting Act of 1817. Efforts were made to control the radical press as well as radical organizations and meetings. The Reform Bill of 1832 removed many of the causes of complaint and attenuated restrictions on the freedom of the press.

A Society for the Suppression of Vice was established in England in 1802, and Thomas Bowdler issued his "bowdlerized" version of Shakespeare in 1818. Control of the circulation of obscene books extended to bookdealers and lending libraries who found it prudent to refuse to stock a book questioned by clientele, except on demand. The question of freedom and control was a subject of philosophic differences among writers. The philosopher Herbert Spencer argued against governmental restraint of freedom of speech in his *Social Statics* (1851), and the philosopher John Stuart Mill sought to establish the case for absolute freedom of expression in *On Liberty* (1859).

The Obscene Publications Bill was passed in England in 1857. Few prosecutions were brought against serious works of literature in the 20th century, in part because publishers guided themselves prudently by earlier conceptions of obscenity; although D.H. Lawrence's *The Rainbow* was banned in 1915, publication of his *Lady Chatterley's Lover* was not even attempted in England until after passage of the more liberal Obscene Publications Act of 1959. This act differed from the Obscene

Liberalization of censorship

Publications Act of 1857 by making statutory provision for the acquittal of works whose publication would be in the interest of literature, science, or learning. A bill to amend the blasphemy laws, which would have removed blasphemous libel from the calendar of crimes, was introduced in the House of Commons in 1930 but dropped. A succession of laws clarified the legal meanings of libel, obscenity, pornography, blasphemy, sedition, and malicious misrepresentation, reducing the incidence of legal repression and removing the danger of a return to censorship. But extralegal pressures and indirect governmental actions continued to restrain the circulation of newspapers, magazines, and books; and censorship continued in drama, motion pictures, radio, and television, and in the self-censorship of publishers and writers.

The history of censorship in the United States has reflected the diverse censorships of the countries from which the colonists came and the diverse injustices and intolerances from which they fled. The fugitives from repression did not establish freedom of speech and communication in their new communities. The Massachusetts Bay Colony was a censorial theocracy. By law, every Quaker book was burned by the public executioner and its possessor fined ten pounds per book, half of the fine to be paid to the informer. A president of Harvard University said, "I look upon unbounded Toleration as the first born of all abominations." Roger Williams fled into the wilderness to found Rhode Island and to establish freedom of religion and speech. The middle colonies were more humane, and Quakers in Pennsylvania and Delaware tolerated other religions but not infidels and non-Christians. Maryland, and later Louisiana, gave evidence of French respect for and deviation from the Index. Sir William Berkeley, colonial governor of Virginia, thanked God in 1671 that Virginia did not have free schools or printing, "for learning has brought Disobedience and Heresy and Sects into the world and Printing has divulged them and libels against government." The publisher John Peter Zenger was charged in 1734 with "scandalous, virulent, false and seditious reflections" in articles published in the *New York Weekly-Journal*. The jury decided in Zenger's favour on the basis of the truth of the alleged libellous statements, contrary to English procedures, and made a step in advancing the freedom of the press from judicial censorship.

In common law, the publication of such writings or pictures as are of a blasphemous, treasonable, seditious, or obscene character constitutes libel. A libel upon a person is a tort, and the truth of the libel, or the fact that it is a privileged communication, or a fair comment on public acts of public men, is a defense in civil action. A libel on the government or the state is a crime, and in criminal prosecutions the truth of libel is not a defense at common law.

The first amendment to the U.S. Constitution in 1791, by which Congress can make no law abridging freedom of speech or press, has been interpreted as prohibiting prepublication censorship. The control of newspapers and books has taken the form of administrative acts of banning or impeding the distribution of books and printed matter, or nongovermental pressures (such as might be exerted by a local parent–teacher association or chamber of commerce, for example) on booksellers and libraries, and judicial reviews of such actions.

Classified information in government

All four age-old grounds for censorship have been used in those governmental and nongovernmental acts of censorship and in their defense in court when their legality has been questioned. (1) Sedition has occupied a prominent place in such actions from the Alien and Sedition Act of 1798 against "false, scandalous, and malicious writing or writings against the government of the United States," through the restrictions put on the press during wars and immediately after their cessation, to the limitation of access to "classified" information, on the ground that its publication might endanger national safety or diplomatic negotiations or military policy, and to the "credibility gap" caused by the difference between statements of policy released for publication and actions undertaken in the administration of policy. Philosophers such as Francis Bacon have distinguished two methods of communication, the method of disclosure and the enigmatical method, the method of teaching and the method of concealment, which are applied to the secrets and mysteries of religion, policy, and philosophy. The controversy concerning the publication of the *Pentagon Papers* is one more stage in the struggle between censorship and the right to information. Freedom of speech and the press was an issue in the advancement of labour organizations, and free-speech fights were prominent in radical organizations and activities such as those of the Industrial Workers of the World (IWW) in the early 20th century. (2) Impiety and blasphemy functioned as motivations in organized movements for decency in literature, the theatre, and the motion pictures. (3) Obscenity continued to be the subject of legislation to define and prohibit pornography or to regulate its flow through action to be undertaken by the customs or postal services. The importation of obscene literature was prohibited under the Tariff Act of 1842 and its distribution by the mails prohibited by the Comstock Law of 1873. (4) Censorship of science was effected primarily in education, as, for example, in the banning in certain states of the teaching of Darwin's evolutionary theory. The choice of textbooks for public schools has profound effects on the content and orientation of education.

Throughout the world the fundamental force and the basic processes of censorship are being modified, as they have been in the past, by changes in communication, knowledge, and law. As in the past, censorship reflects the movements of peoples and their oppositions, the interplay and the suppressions of cultures, and the cultural perspectives, which have transformed what has been accepted and which have been modified by what has been rejected. Today, two fundamentally opposed frameworks of censorship still operate, but under profoundly altered conditions. In Russia prepublication censorship modelled on the French system was abolished in 1905. Under Communism, the Soviet Union provides no freedom of speech or of the press to enemies of Socialism. The government press has made selected classics widely available, but in the name of protecting Socialism, a great deal of literature and science has been prohibited. A flourishing clandestine circulation of literature has developed, along with sources of publication abroad. In Great Britain and the United States in the absence of prepublication censorship, the struggle against censorship has pressed for a series of judicial decisions that have removed some restrictions and prohibitions. In the wake of these decisions and in response to reactions against established values, all four of the ancient and perennial arguments for censorship—immorality, sedition, treasonable science, and impiety—have undergone paradoxical reversals, moderated only by vestigial limitations defended in the name of the young or of the public good. Obscene words have appeared in print and have been used on the stage and in motion pictures without restraint for the protection of morality, and erotic acts have been portrayed in all three media, though with some lingering concern to repress "hard-core pornography." But such material has not been permitted on radio and television. There is no reliable or scientific knowledge of the psychological or moral effects of the portrayal of violence or sexual acts, but it is unlikely that such lack of knowledge will weaken the conviction of many that it corrupts the young. The control of sedition and treason by banning radical literature, which was in process of attenuation, is rendered even more difficult by the "new radicalism" which the youth evoke against established institutions in general and against established law and order for the advancement of human rights and the removal of newly recognized injustices, the establishment of peace, and the protection of the environment. Large scale science depends on the "establishment" and comes under attack as an instrument for prolonging warfare and extending inequality; and a warfare has been detected between two or three cultures, science and the humanities with the social sciences mediating or enlarging the oppositions. Heresies are no longer proscribed because impiety and blasphemy are as much

Censorship under Communist and Western governments

matters of indifference as obscenity, and ecumenical cooperation of religions is in part an effort to revive a recognition of the "relevance" of religion.

Future of censorship

Censorship in its preventive and prohibitive forms continues, but there is hope that the positive side of censorship will assume a new importance. Statements of opposed ideologies are more easily available and an increased interest in understanding them would contribute to peace and cooperation among diverse political and economic systems. The availability of great books in paperback editions could lay the foundations of a world culture in which the arts and sciences contribute to the appreciation of values across cultural and subject-matter lines. The eternal law governing the movements of things, thoughts, aspirations, and arts reappears from time to time, despite the obscurities which have been thrown over it by the dogmatisms and skepticisms of religion, politics, science, and culture. The positive form of censorship depends on the availability of information, art, and ideas; on an alert and well-grounded interest in considering, appreciating, and understanding them; on circumstances that stimulate their expression and production; and on confidence in the possibility of sympathy and understanding as restraints on prejudice and discrimination, so making the pursuit of common interests and values possible. The old censorships will continue and will provide stimulation for the new censorship, if it emerges, for it will not be a new imposition but a new actualization of equality of opportunity for self-realization and for education in common values.

BIBLIOGRAPHY. In antiquity, censorship was advocated by philosophers, debated by orators, institutionalized by statesmen and jurists, and practiced by conquerors of cities and upholders of traditions; see EDWARD A. PARSONS, *The Alexandrian Library, Glory of the Hellenic World: Its Rise, Antiquities, and Destructions* (1952).

The ancient monotheistic religions, the religions of the "books," like the ancient libraries, prepared lists, or canons, or indexes of genuine and spurious books; or, in the case of religious indexes, authentic, apocryphal, and banned books. For the development of the canons and indexes, see HEINRICH DENZINGER and ADOLFUS SCHONMETZER, *Enchiridion Symbolorum, Definitionum et Declarationum de Rebus Fidei et Morum*, 33rd ed. (1965; Eng. trans. of 30th ed., *The Sources of Catholic Dogma*, 1957), and, for an interpretation of the effect of ecclesiastical censorship, GEORGE H. PUTNAM, *The Censorship of the Church of Rome and Its Influence upon the Production and Distribution of Literature*, 2 vol. (1906). After the 16th century, science joined philosophy and theology as sources of error to inquisition and censorship: ANDREW D. WHITE, *A History of the Warfare of Science with Theology in Christendom* (1896); GEORGE G. COULTON, *Inquisition and Liberty* (1938); JOSEPH M. PERNICONE, *The Ecclesiastical Prohibition of Books* (1932).

In the West, censorship was applied to literature and the stage from the time of the Greeks. See JOHN MCCORMICK and MAIRI MACINNES (eds.), *Versions of Censorship* (1962); ALEC CRAIG, *The Banned Books of England and Other Countries: A Study of the Conception of Literary Obscenity* (1962); ANNE L. HAIGHT, *Banned Books*, 2nd ed. (1955); W.M. DANIELS (ed.), *The Censorship of Books* (1954); EDWARD DE GRAZIA, *Censorship Landmarks* (1969); H. MONTGOMERY HYDE, *A History of Pornography* (1964); ELMER E. SMEAD, *Freedom of Speech by Radio and Television* (1959); and also IRA H. CARMEN, *Movies, Censorship and the Law* (1966).

Political censorship, likewise, has taken different forms in different times and cultures: LEONARD W. LEVY, *Legacy of Suppression: Freedom of Speech and Press in Early American History* (1960); ROBERT B. DOWNS (ed.), *The First Freedom: Liberty and Justice in the World of Books and Reading* (1960); HAROLD L. CROSS, *The People's Right to Know* (1953); JAMES R. WIGGINS, *Freedom or Secrecy*, rev. ed., (1964); RALPH E. MCCOY, *Freedom of the Press: An Annotated Bibliography* (1968); JACK NELSON and GENE ROBERTS, JR., *The Censors and the Schools* (1963); HAROLD SWAYZE, *Political Control of Literature in the USSR, 1946–1959* (1962); PETER COLEMAN, *Obscenity, Blasphemy, Sedition: Censorship in Australia* (1962); LIN YU-T'ANG, *A History of the Press and Public Opinion in China* (1936).

Problems of censorship—of repression, suppression, and control—are treated, more and more, as problems of human rights and freedoms: MILTON R. KONVITZ, *Fundamental Liberties of a Free People* (1957); HARRY STREET, *Freedom, the Individual and the Law* (1963); DERRICK SINGTON, *Freedom of Communication* (1963); RICHARD MCKEON, ROBERT K. MERTON, and WALTER GELLHORN, *The Freedom to Read* (1957).

Central Africa, History of

In this article, Central Africa includes what is now the Central African Republic, Gabon, Congo (Brazzaville), and Zaire (former Democratic Republic of the Congo).

The article is divided into the following sections:

I. Developments to the 19th century
- Early inhabitants
- Central Africa, 14th–19th centuries
  - The Bantu states
  - Portuguese contacts
  - Unifying influences

II. From the 19th century to the present
- European penetration in the 19th century
  - European exploration
  - The African enterprises of Leopold II
- The Central African colonies
  - The Belgian Congo and its northern periphery
  - The French colonies
- The republics
  - Republic of Zaire
  - The Central African Republic
  - The People's Republic of the Congo (Congo [Brazzaville])
  - The Gabon Republic

I. Developments to the 19th century

EARLY INHABITANTS

Development of toolmaking

The evolution of man in Central Africa is closely associated with the development of the skill of toolmaking and with climatic factors. Most of Central Africa consists of woodland and grass savanna, and it would seem that the reasons this environment gave rise to stone and pebble toolmaking are cradled in economic and social necessity.

The long dry season of the savanna combined with climatic deterioration to induce the small and very defenseless hominids to develop ways of supplementing their sources of vegetable foods; this, it is thought, is the reason for the resort to eating the flesh of such small animals as could be caught, and this demanded the development of some sharp cutting tool. Such a tool was necessary in order, for example, to open the skin of an antelope and could at the same time be used to point sticks for digging and even for attack and defense. The most detailed knowledge of the development of prehistoric cultural patterns depends heavily on the unique evolutionary sequence laid bare by the British archaeologists L.S.B. Leakey and his wife in the Olduvai Gorge in northern Tanganyika, outside Central Africa; but inductive reasoning provides substantial evidence that toolmaking spread through most of Central Africa (and, indeed, through western Europe and certain other parts of the world) to form the so-called Chelles-Acheul, or hand-ax, culture. The latter term is derived from the most common type of tool, which was shaped rather like a hand seen in silhouette.

In the second half of the hand-ax culture (the Acheulean) there took place a population movement into hitherto uninhabited areas, while Acheulian man developed larger and more varied stone tools. At the very end of Acheulian times, perhaps between 50,000 and 60,000 years ago, man in Central Africa first became a regular user of fire, probably as a response to the climate becoming cooler and wetter. This, in turn, made possible further expansion into areas hitherto unpeopled, and the resulting more sophisticated culture, the Sangoan, became dominant throughout most of Central Africa. In the words of the British archaeologist J. Desmond Clark,

> For the first time Man now began to occupy caves and rock shelters as regular homes, for, with his control of fire, these provided safe and more comfortable living-quarters. Furthermore, because of the regulation of the seasonal movements of the bands and the use of efficient carrying devices [both of which can be deduced from African Early Stone Age sites], he could now afford to stay in one place for much

longer. . . . Increase in the size of the band, more permanent residence, and ability to live in a greater variety of habitats, previously unfavourable, must have been the inevitable concomitant of increasing technical skill and mental ability.

Evolution of *Homo sapiens*

From about 35,000 BC, Middle Stone Age cultures began to evolve from the Sangoan; and in the Congo forests, which comprise much of Central Africa, its local variant is known as the Lupemban culture, a culture characterized by many types of ax and magnificent lanceolate knives. It is in this period that *Homo sapiens* evolved by natural selection from earlier hominoid types with an accompanying appearance of religious beliefs, manifested in careful burial of the dead, and of an aesthetic sense, shown by the use of paint and ornamentation.

The Middle Stone Age lasted until 10,000–8000 BC; and during its last period (as during the so-called Makalian period—*c.* 5500–2500 BC) a wetter and cooler climate, which improved water supplies and made possible a southward extension of Mediterranean flora, led to north–south contacts between Mediterranean and Negroid peoples. These contacts resulted, for example, in the appearance of tanged projectile heads in the Congo, while the later of the two wet phases gave a new significance to waterside habitats, and rivers and lakes were exploited for their food resources as never before.

This later Stone Age also witnessed such further technical advances as the bow and arrow, the discovery and use of poison, and barbed fish spears, and probably the beginnings in some areas of primitive cultivation. Also evident is the emergence of distinctive culture variants, with those on plateaus differing from those in the forests. Around the beginning of the Christian Era a development of critical importance took place—stone tools began to be replaced by metal, possibly accompanied by the introduction of Asian food plants. This, in turn, made possible the spread of Negroid and Bantu culture in Central Africa and beyond, a theme that dominates the study of Central Africa during the next 1,000–1,500 years.

In the study of the early stages of Bantu expansion the linguistic evidence predominates. From a lexical comparison of about 50 common words in Western Sudanic and Bantu languages, the American scholar Joseph H. Greenberg concluded that Bantu languages belonged to the Western Sudanic family but that they did not even form a distinctive subgroup within this family; rather, they formed part of a subgroup that also included most of the languages spoken in east central Nigeria and the Cameroons. From this, Greenberg concluded that, when the speakers of the Western Sudanic languages began to move southward from the savanna into the forest belt, those at the eastern end of the line of advance, not being stopped by the sea, continued southward and eastward into the Congo Basin and thence fanned out to occupy what is now Bantu Africa. To this theory another U.S. anthropologist, G.P. Murdock, added an important condition of this expansion—that these Western Sudanic peoples had received Southeast Asian food plants, which had made their way to the far-western coast after entering Africa through the lowlands of Ethiopia. A linguistic contribution of equal or greater importance with Greenberg's was that of Malcolm Guthrie of Great Britain, whose thorough and wide-ranging approach was through the study of cognates in different Bantu languages; he was able to construct some 2,300 sets of cognates with items from some 200 Bantu languages. From this, Guthrie inferred that all the cognates in a given set evolved from a "general root" in some ancestor language; of such general roots he discovered more than 500 distributed over the Bantu area as a whole. The important historical application of this linguistic research was that it could easily be used to plot the movements of peoples from an original core by simply counting the number of general roots present in each language, expressing them as a percentage of all general roots, and plotting the percentages on a map. The percentages range from about 15 to about 55, with the cluster at the higher end taken as the location of the Proto-Bantu language. That location was "in the bush country to the south of the equatorial forest midway between the two coasts."

Guthrie's study of Bantu languages

In more recent work, the British historian Roland Oliver built on the research of Guthrie and found no necessary contradiction between Guthrie and Greenberg. Greenberg's thesis is a perfectly possible explanation of the movement southward and eastward, while Guthrie's accounts for the first main population increase and the directions and intensity of its expansion. Oliver also did more. He plotted the percentages of general roots on a map and showed that

> the highest percentages form a cluster on the map, in the shape of a long, flat ellipse, with its main axis running east and west, roughly from the mouth of the Congo to the mouth of the Rovuma, with its centre in the Luba country of northern Katanga. . . . On present evidence the explosive nucleus at the heart of the whole system would seem to have been, again and again, the Luba-speaking peoples of the Katanga.

Oliver drew attention to the fact that Guthrie's "long, flat ellipse," with its average rainfall and intersecting rivers, is comparable with what the new arrivals would have known in their original habitat north of the forest barrier. He suggested, on limited evidence, that the important means of their ability to thrust southward was their mastery of iron making, with all the improvement in tools, woodwork, and weapons that this implies, and pointed to the significance of the practice of iron smelting in the Nok culture north of the Benue by about 250 BC. Oliver reasoned that the likely significance of Southeast Asian food plants is in connection with a third stage of the expansion (tentatively dated as during the second half of the 1st millennium AD), not all of which was in Central Africa, for this northward and southward expansion was in the areas of higher rainfall where the Southeast Asian food plants, especially the banana, are known to have played a vital role.

The evidence thus far is linguistic, but Oliver rightly invoked archaeological evidence from the important burial ground of the 8th and 9th centuries AD on the shores of Lake Kisale in the heart of the Luba country. This as yet scarcely worked site, in its sheer size and in the quality and quantity of its grave goods, bespeaks a society of considerable wealth and technical skill.

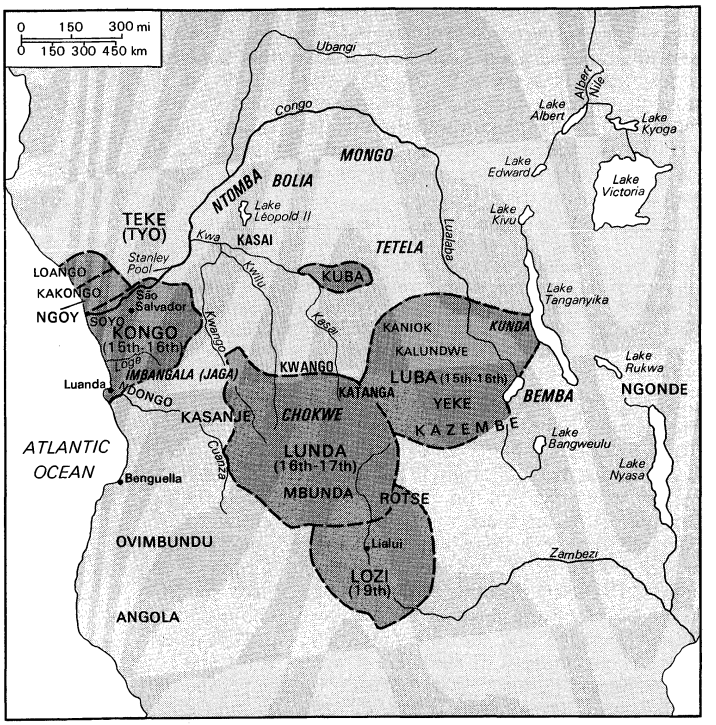
Traditional and archaeological evidence may help to establish the chronology; much archaeological research remains to be done in Central Africa, but there is substantial agreement that the most promising hypothesis for the Bantu expansion, the dominant movement in Central African history in the first millennium and a half of the present era, is on the lines set out by Greenberg, Guthrie, and Oliver.

CENTRAL AFRICA, 14TH–19TH CENTURIES

The Bantu states. As noted above, the Luba country of North Katanga constituted the heartland of the Bantu expansion. It is therefore appropriate to begin a study of this 400- to 500-year period of Central African history with the emergence of Luba culture and Luba states and then to follow the emergence of the various Lunda states that themselves owed so much to Luba culture, noting also such cultures—only less important, though their territorial sway was more restricted—as those of the Lower Kasai and as the Bolia to the north of Lake Léopold II. Of comparable importance to the Luba and Lunda cultures was the Congo kingdom of the Atlantic coast; because the Congo was the scene of an important early European attempt to disseminate Western culture in Africa, a good deal of attention is devoted to this experiment. The section concludes with some study of the impact on the rest of Central Africa of European influences.

The Luba kingdom. According to tradition, the first Luba state made its appearance during the 16th century. At that time, the whole country between Lake Tanganyika and the Kasai was largely divided into small chiefdoms, and Luba history began with the appearance in central northern Katanga of a powerful warrior, Kongolo, who, after subjecting a number of small chiefdoms, set up his capital near Lake Boya. There he was joined by a hunter, Ilunga Mbili, and his following; but after a

The beginning of Luba history



Bantu states of Central Africa from the 15th to the 19th century.
From J. Fage, *An Atlas of African History;* Edward Arnold (Publishers) Ltd.

period of amity Ilunga returned whence he came as a result of a quarrel. Shortly afterward a son, Ilunga Kalala, was born to Kongolo's half sister (Ilunga Mbili's wife); when he grew up, Ilunga Kalala showed great prowess at war and helped Kongolo to extend the area of his kingdom to the west. Jealous of Ilunga Kalala's success, Kongolo sought to kill him, whereupon Ilunga Kalala returned to his father's homeland, where he recruited an army with which he defeated Kongolo, brought the first Luba empire to an end, and established the second. Organized in patrilineal lines, with one or several of such lines forming a village and several villages a chiefdom and with each chief in the line of either Ilunga Kalala or Kongolo, the Luba state pyramid culminated in the king. In an important sense the king was the motive force of the state, because he drew his authority not merely from the fact of belonging to one of the two original lineage lines but also from the divine right to rule, which direct descent from the previous king conferred. Three other states—Kaniok, Kalundwe, and Kikonja—became established as Luba kingdoms during the same period.

The Lunda kingdoms. The Luba kingdoms proper never attained really large dimensions, but Luba influence was paramount in the transformation of the original Lunda kingdom, situated southwest of Luba territory. According to Lunda tradition, a member of the Luba royal house, Cibinda Ilunga, married a princess of the Lunda country and became its king. In the third generation the name of the king gave birth to what was thenceforth the dynastic title of the Lunda monarch, the Mwata Yamvo; and by the close of the 17th century the Lunda state had so far grown as to be bounded, approximately, by the Kasai in the north and south and by the Kwilu River in the west. The political structure of the Lunda kingdom is the key both to its rapid expansion and to the ability of Lunda bands, using the same methods, to set up their own loosely associated satellites in a wide arc from west to east of their homeland. The administrative structure was hierarchical and lineage based, as with the Luba, but in addition, in the words of the Belgian-American scholar Jan Vansina (*Kingdoms of the Savanna;* University of Wisconsin Press, 1966),

Lunda political structure

> the whole political structure rested on the twin mechanisms of positional succession and perpetual kinship. A successor inherited not only an office but also the personal status of the deceased, including his name and kinship relationships.

This meant that the political structure was not bound to the real descent structure and, no less importantly, that Lunda political institutions could be adopted by peoples subjected by Lunda bands without the necessity of great changes in their social structure. Because the Lunda expansion was primarily an affair of small groups gaining recognition by force of arms where the formidable reputation of the Lunda did not suffice, it is evident that there could not have been tight political control, quite apart from the centrifugal tendency implicit in the departure of Lunda bands from the homeland. The Lunda's success was due, at one level of explanation, to their acceptance of the need to secure the assent of the subjected; at another it was due to their technique of government. To quote Vansina again:

> The crucial event in the earlier history of Central Africa has been not the creation of a Luba kingdom by Kongolo and Kalala Ilunga, but the introduction of Luba principles of government into Lunda land under Cibinda Ilunga and their transformation by the Lunda. The new political pattern, which evolved around 1600 in the Lunda capital, could be taken over by any culture. Its diffusion was to condition until 1850 the history and the general cultural evolution of a huge area. . . . It was not the military might of the Lunda which was responsible for the upheavals: it was the superiority and the adaptability of their pattern of government, and the adventurous spirit of the *conquistadores*, who spread it wide and far. And this diffusion was facilitated by the simple fact that this was an open savanna where no natural boundaries could stem the flow.

Lunda influence thus spread in a wide arc from the Kwango in the west to southeastern Katanga. Lunda adventurers brought about the submission of the formidable Imbangala (Jaga) state in Angola, to the west of the Kwango, in the early 17th century. In that same century the Lunda expanded into the more northerly part of the Kwango Basin, and by the end of that century they had established themselves on the plateau of Northern Rhodesia and in southeastern Katanga. In the 18th century the Lunda kingdom, the heartland, expanded southward so that it took in the sources of the Zambezi; between 1750 and 1850, as the outcome of an expansion begun in the early 18th century, the Lunda kingdom of Kazembe, in south central Katanga, was the most extensive and the strongest of all the Lunda states. In the same period the Lozi kingdom in the valley of the Upper Zambezi, although less powerful, also bore its tribute, in both the literal and metaphorical senses, to the Lunda genius.

The Mongo people. But Lunda influence did not permeate everywhere in Central Africa. To the north and west of the Luba, pressing up to the inside of the vast inverted U described by the Congo River, were the Mongo, an ethnic group characterized by the possession of a segmentary political structure based on a grouping, the *etuka*, comprising some half dozen lineages. Only in certain parts of the Mongo cluster—notably in the west and among the Tetela of the east—did the political structure include an area larger than the village or small group of villages.

An important development among the western Mongo was the concept of divine kingship, which was brought westward to the region of Lake Léopold II by the Bolia, perhaps in the 14th century, and diffused by them among other western Mongo, namely the Ntomba group and the Sengele. The western Mongo bordered on the Lower Kasai group of peoples to their west and south. In the 14th century this Kasai group—apart from the Teke (Tyo), who had possibly also developed a form of kingship similar to that of the Congo kingdom (see below, *The Congo kingdom*)—had an unsophisticated two-level chieftaincy system. The village headman was the eldest male member of the senior patrilineal line, while the district chief was the senior member of a single patrilineage. The Teke constituted the largest of these Lower Kasai states: their territory was bounded, downstream and upstream of Stanley Pool, by the Congo River until their border cut across to Mushie on the Kwa, back to

Bolobo on the Congo River, and then described a wide arc in Congo (Brazzaville) to rejoin the Congo west of Stanley Pool. It appears that the most striking developments in the centuries after the 14th are a limited diffusion among the Lower Kasai group of the Bolia concept of divine kingship and the appearance of a variety of political systems, most notably the Kuba, with a sophisticated system of checks and counterbalances of royal authority. Developments of a different kind resulted from the European intrusion into the Congo kingdom and Angola (see below).

Concept of divine kingship

The Congo kingdom. Other than that their earlier history was a part of the Bantu expansion, nothing certain is known about the pre-14th-century history of the Congo people. Sometime in the 14th century, however, the son of a petty chief in the region of Boma, on the north bank of the Congo River, crossed south of the river with a small following, conquered the Kimbundu (Ambundu) people living there, and made himself master of that whole plateau, which included the site of the future São Salvador do Congo. The invaders intermarried with the local people and rapidly either subdued the surrounding area or incorporated existing kingdoms. By some time in the 15th century the core of the Congo (Kongo) kingdom thus included the provinces of Nsundi, Mpangu, Mbata, Mpemba, Soyo, and Mbamba; additionally, territories between the Loge and Cuanza rivers on the southern marches, because they sent intermittent tribute to the Congo king, or *mani* Kongo, can more equivocally be included within the kingdom.

In the kingdom of the Congo the basic political unit was the village, presided over by a chief whose office was hereditary in a core matrilineage. Above the village was the district and above the district, the province, the governor of which, together with many of the district heads, was usually appointed by the king. All these officials were titleholders and constituted a self-aware aristocracy. The kingship itself was not hereditary, the monarch being chosen, by a kind of electoral college, from the male members of every line of descent from the founder of the kingdom or, after 1540, from Affonso I. Such a state structure could command an income from taxation and labour service. Tribute was in raffia cloth, ivory, hides, and slaves, and there was also a shell currency, over which the king had absolute control.

An important weakness in this sophisticated political structure was the lack of clear rules for the succession to the throne, and its effects became ever more serious as the number of eligible candidates increased with time. Factions developed years before the likely death of a reigning monarch, while the very existence of separate provinces was potentially divisive. The Congo kingdom, though with increasing difficulty, survived nearly two centuries of considerable Portuguese influence, an influence that brought it some benefits as well as much harm; but interaction of outside intervention with the two above-mentioned institutional weaknesses were important reasons for the decline and fall of the Congo kingdom.

Weakness in the Congo political structure

Portuguese contacts. In 1483 the Portuguese navigator Diogo Cam (Cão), in quest of a passage linking the Atlantic to the Indian Ocean, stumbled upon the Congo Estuary and so first brought that great river within the ken of Europe. Cam sent an embassy to the King of the Congo; but, believing its members to have been forcibly detained and wanting to return to Portugal himself, Cam took with him some Congolese hostages against the return of his own men when he should make a second voyage to the Congo. The Congolese hostages were evidently well treated in Portugal and returned full of praise for Christianity and things European; powerful though their testimony was, the appeal of the newly revealed European culture to the Congolese generally was enhanced because it was borne to them in ships issuing out of the sea, which was traditionally the domain of the sacred. Entirely credible was the Congolese king's request to John II of Portugal, spelled out by a contemporary Portuguese chronicler:

> he asked him in his grace and required him in the name of God to accord him without delay that which with so much love and devotion he had invited him to receive, the Holy Water of Baptism.

To this was joined a request for Portuguese artisans to instruct the Congolese, while other Congolese youths were sent to Portugal to learn to read and write and to become Christians.

Portuguese missionaries. A considerable Portuguese missionary effort resulted. The King of Portugal responded to the original request with an expedition despatched in 1491. The missionaries were Portuguese secular clergy and found early triumphs in the baptism of the Governor of Soyo and subsequently of the King of Congo himself, who took the European name of John I, and of most of the nobility. John's successor, Affonso I (ruled 1506–43), was a completely serious and devoted convert who worked hard to further the conversion of his kingdom. According to a tradition recorded by J. Cuvelier, Belgian missionary and historian in 1946, Affonso called all his nobles together and told them:

> Cease to honour fetishes, to believe in amulets, now that we have seen the Cross of the Son of God. . . . Whoever honours them will be condemned to death.

But even Affonso's considerable efforts were vitiated by the inability of Portugal to supply enough priests, and too many of those who came were either unsuited or succumbed to the climate. After the triumphs of the initial period, which ended with Affonso's death, the most fruitful missionary work was probably that of the Italian and Spanish Capuchins, who, for two centuries after 1645, bore their witness of poverty, austerity, and devotion, though from the beginning of the 18th century in declining numbers and with declining effect.

Interestingly, at the very beginning of the 18th century the Congo witnessed a prophet movement—Antonianism, the name of a politico-religious sect centring on a young Congolese woman, Kimpa Vita, who took the name Saint Anthony. This movement, though it attested the tension between old beliefs and the new faith, no less showed that Christianity had significantly entered into the life of the Congo. (It was also a most interesting forerunner of a not dissimilar movement in 20th-century Congo land, see Kimbanguism under *Belgium's Congo policies* below.) All in all, there is credibility in a Capuchin missionary's assessment of 1710:

> It is true that the Congolese, and much more those who were at San Salvador, embraced the holy faith completely and lovingly. They had a true knowledge of it and became true Christians. However, in the provinces, the peasants were subsequently baptised always in too great numbers, but never had the true knowledge of the faith. They never abandoned their pagan customs. . . . That being said, I would say that Christianity in the Congo is at present a true Christianity, catholic and Roman, but much weakened by ignorance, war and superstition.

But, by the end of the 18th century and certainly in the 19th century, the missionary presence was slight, and corruptions of Christianity were widespread.

The original hopes, shared by Portuguese and Congolese alike, of a rapid and authentic Christianization of the Congo kingdom were only very partially realized. But the reasons for this are only partly noted above. Portuguese political involvement and, above all, economic exploitation of the kingdom combined with the interplay of African politics to cause the breakup of the Congo kingdom and in so doing to confirm the verdict of failure on this experiment in acculturation.

Failure of acculturation

Portuguese involvement. A quarter of a century after Affonso's death the warlike Jaga of Angola fell upon the Congo kingdom with such effect that the Congolese king had to take refuge on an island in the Congo Estuary. In this extremity he appealed to Portugal for help, and in 1571 an army appeared from the Portuguese Atlantic colony of São Tomé and, after arduous campaigning and profiting from the moral effect rather than the destructive power of the harquebus (a portable firearm), drove the Jaga from the land. This was the most striking intervention in support of the Congo kingdom that Portugal ever made, and it helped the Congo to endure for another

century. But long before this intervention the main weight of the Portuguese presence, other than the missionary, had been harmful. It was not so much that, at least as early as 1512, the Portuguese crown made it abundantly clear that it expected payment for its services to the Congo (although these payments were to include slaves, as well as ivory and copper, a limited and controlled development of this slave trade would not necessarily have done widespread harm); it was rather that the Portuguese crown proved unable to control the Portuguese who went to the Congo, and what the king of Portugal was unable to do the king of the Congo had little hope of achieving. Coinciding as the period of Portuguese involvement did with the rise of the slave trade to São Tomé and across the Atlantic, the great hope of the resident Portuguese was to grow rich on the profits of slave trading, an activity in which a faction of them were commonly abetted by the governor of São Tomé. The most that the Congolese authorities could do, and that not always successfully, was to prevent the enslavement of their own subjects; but a continuing slave trade was possible only if there was continual skirmishing on the frontiers. The problem was compounded by all the possibilities of intrigue that the political structure of the kingdom presented. The autonomous tendencies of the provinces and the bitter rivalries that attended the succession gave abundant opportunity to the slave traders, thus eroding the power of the king, while provincial governors often became virtually independent and the common people periodically suffered greatly from oppression.

Rise of the slave trade

Specifically, by 1556 the Portuguese in São Tomé had opened a direct trade with the loosely attached Ndongo peoples on the southern borders of the kingdom, and in 1560 Portugal ceased to defend the Congo king's monopoly rights in that area (indeed, Portugal soon established its own colony of Angola). Before this, in 1550, the governor of São Tomé and some newly arrived Jesuits backed a rival claimant to the throne, though the plot was defeated. In the 17th century, matters became worse. From at least 1600, Soyo became virtually independent, using its maritime position and the resulting wealth to conclude its own agreements with both Portuguese and Dutch. Soyo openly proclaimed its independence in 1641, by which time there was also frequent trouble in and with the other provinces. The substantial end of the original kingdom came with the Portuguese defeat at the Battle of Ambuíla in 1665, over whether the allegiance of the duke of Wandu was to be to the Congo or the Portuguese colony of Angola, and over the possession of the mines in the area. The enforced abandonment of São Salvador between 1678 and 1703 made the decline of the Congo kingdom clear. By 1795 only about 100 people lived in 22 huts scattered among the imposing ruins of São Salvador's churches.

After Ambuíla the peoples of the Congo still recognized the king but accorded him no significant authority. Effective power was now in a series of chiefdoms, but it was not simply that the top levels of the pyramid of government had been removed, leaving the lower levels functioning in the same way as before. Rather, the whole basis of political power in the Congo region had changed, and it had changed because of the slave trade. The men who gained effective power in Soyo, south of the Congo River, or in Kakongo, Ngoy, and Vili (Loango)—kingdoms north of the Congo River—were those who built up their own bands of domestic slaves and used their strength to supply slaves from the interior to the Europeans on the coast. The political offices that counted were those that dealt with the European slave traders (*e.g.*, the harbour governor, or *mafuk*). Just as the slave trade had been an important cause of the decline of the unitary Congo kingdom, so it both determined the political structure of the chiefdoms that remained and led to such further fragmentation that by the end of the 19th century there was usually no political unit larger than the village.

Changes in the basis of political power

But the effects of the European demand for slaves and of the introduction of guns—which were among the most coveted of the goods the Europeans gave in exchange and the means by which those possessing them raided ever more widely for slaves—were not restricted to the Atlantic coast. The Teke, in the Stanley Pool region, received slaves from up the river and passed them on by a variety of routes to points along the coast from Luanda in the south to Loango in the north. So important was this monopoly that in the 19th century the upriver Bangi (Bobangi) frequently challenged it. Similarly, the Imbangala of the kingdom of Kasanje raided in the Kwango, but most of their trade was probably with the Portuguese in Angola. Nor was this the limit of the effect of the European demand for slaves and the complementary introduction of European goods into Central Africa. From the late 17th century onward, trade routes extended even farther inland, with the Lunda states of the interior sometimes directly participating in long-distance trade but in any event consciously profiting from it. For example, from the late 17th century the Imbangala organized an important trade route back to the capital of the Lunda kingdom, whence, after 1740, the route was extended to Kazembe, where it connected with trade routes from the east coast. The rise of the Lunda states is integrally connected with their use of the guns that reached them along the trade routes from the mid-17th century onward and with the profit they drew from slave raiding and slave trading (as well as with the political structure noted above).

In the mid-19th century, changes came in the Lunda-dominated interior. This was not because of a decline in the importance of the slave trade—when the Atlantic trade ended in the 1860s, slaves were still bought by the coastal peoples and used to produce wealth in exchange for European manufactures, and from about 1840 the Arab slave trade from the east coast became ever more important—but as a result of internal convulsions in the Lunda states. The Chokwe, whose homeland was some 50 miles southeast of Kasanje, were a Lunda people almost unheard of before 1850, but in the next half century they overthrew existing authorities in the Kasai and as far eastward as western Katanga; the Lozi kingdom fell to Rotse invaders from the south; the Yeke, originating in the Nyamwezi country far to the northeast, conquered most of Kazembe and dominated southern Katanga up to the right bank of the Lualaba; by the early 1890s the Arabs from the east coast dominated the country from the upper Lomami almost to Lisala on the Congo River and raided beyond it. But, before this new pattern could settle down, a new and yet more powerful force appeared—the Europeans who were now engaged in establishing formal colonial rule.

Changes in the Lunda-dominated interior

Unifying influences. It would be wrong to exaggerate the extent to which Central Africa between the 14th and 19th centuries was a unity. But a number of factors of different kinds did impose their own unities. This was the first great area of the Bantu expansion; some degree of political unity or, at any rate, association was given by the Lunda expansion, while kingship was widespread. There was much similarity in religion, material culture, economic life, and social organization, and matrilinearity was common; trade routes made possible the spread of maize (corn) and manioc throughout virtually the whole area from their Congo and Angola points of introduction in the late 16th and 17th centuries, respectively. Above all, the slave trade gave its own sombre unity to the area. Indeed, Vansina, who has made a uniquely valuable contribution to the history of Central Africa, concludes his own study of the kingdoms of the savanna with the judgment that

> the interaction between the growing slave trade and the normal evolution of the political systems explains most of the history of the kingdoms in Central Africa from 1500 to 1900.

II. From the 19th century to the present

EUROPEAN PENETRATION IN THE 19TH CENTURY

The previous sections have demonstrated that Central Africa had a history of its own in the precolonial era, albeit a history profoundly influenced by the export slave

trade, by firearms, and by trade goods. In the 19th century, however, actual European penetration of the region became more important. Up until the last quarter of the century, that penetration was almost exclusively the work of European explorers, and it is their work that marked the transition between the period when Central Africa, though profoundly influenced by Europe, was autonomous and the era of colonial rule.

European exploration. The 19th-century British explorer-missionary David Livingstone was not the first to explore Central Africa, and indeed he was only peripherally concerned with that part of the continent; but his achievements inspired other explorers, who made more direct contribution to the knowledge of the region, and the felt need to carry relief to him led directly to the major journeys of exploration in Central Africa.

Livingstone's explorations. Livingstone's first journey, begun from his South African mission-station base, was designed to blaze a path northward for the Christianity that it was his passion to propagate. "It appeared very plain," he said,

> that no mission could succeed unless we could get a well-watered country having a passage to the sea either to the East or the West coast. This is a project I am almost afraid to meet but nothing else will do.

Meet the project he did, and his most significant discovery was the course of the Upper Zambezi. This he followed northward until he crossed the divide into the Congo Basin and, after many hardships and much danger, came to the Atlantic Ocean at Luanda.

Significance of Livingstone's explorations

There was a twofold significance in these early explorations of Livingstone, spanning the years 1851–56. In geographical terms he confirmed the hypothesis of Sir Roderick Murchison, president of the Royal Geographical Society, that, in Livingstone's own words,

> the peculiar form of the continent was then ascertained to be an elevated plateau, somewhat depressed in the centre, and with fissures in the sides by which the rivers escaped to the sea.

Moreover, he revealed the border areas of south central Africa to be often fertile, well watered, and well forested. Additionally, the devastation by slave raiders of parts of the Zambezi and southern Congo Basin that he witnessed attested that here was no possibility of simple missionary advance but rather a need for commerce to join with the Christian missionary to extirpate the slave trade. Linked to this and stemming also from the simple fascination of the geographer for search and discovery was a growing conviction of the importance of navigable waterways for the extension of civilization. Only with the beginning of his last journey, in 1866, was Livingstone's work again directly significant for the exploration of Central Africa —in the intervening decade his work had centred on the Middle and Lower Zambezi and on Lake Nyasa. Now his major concern, the quest for the source of the Nile involved him in much exploration in the Lake Tanganyika–Lake Bangweulu–Lualaba River area in order to prove his theory that the Lualaba was the Nile's ultimate source.

Livingstone died in May 1873, 18 months after his famed meeting with the explorer-journalist Henry Morton Stanley, probably uncertain whether in the Lualaba he had discovered the true source of the Congo or of the Nile. But the very impression that his missionary zeal, his devotion to Africa, and his geographical discoveries had made in Britain inspired others to carry on his work. Although one of the two expeditions sent to carry succour to Livingstone itself got no farther than São Salvador when its leader, Lieut. W.J. Grandy, died, the expedition under Lieut. V.L. Cameron, which approached from the east coast, had considerably greater success. Cameron concluded that "the Lualaba had nothing whatever to do with the Nile, but was, in very truth, the main stream of the mysterious Congo." But beyond Nyangwe, in the Manyema country some 200 miles west of Lake Tanganyika, Cameron felt unable to take the obvious course of navigating down the mighty Congo to the Atlantic. This was because he could have obtained the necessary canoes only by seizing slaves with which to pay for them, a refusal entirely consonant with the general conduct of an explorer who was in this respect in the Livingstone tradition. Instead, availing himself of an offer by Tippu Tib, the Arab potentate of the interior, to escort him southward through rich and unexplored country, Cameron entered upon a march to the Atlantic well to the south of the Congo River, which took him through such rich territory as Katanga; he finally reached the sea at Benguella in November 1875. An interesting portent of Cameron's journey was his signing of numerous treaties with African chiefs along his route aimed at securing for his country a species of colonial authority. But the old tradition of noninvolvement in so unpromising an area, as tropical Africa was still thought to be in official circles, was strong enough to secure the rejection of Cameron's treaties by the British government.

Stanley's expedition of 1874–77. Stanley's great transcontinental expedition of 1874–77, financed by the London *Daily Telegraph* and the *New York Herald* and designed to complete Livingstone's work, began with exploration in the Lakes region and an attempt to resolve most outstanding problems concerning the sources of the Nile. But his ultimate objective was to follow the course of the Lualaba and prove conclusively that it emptied into the Atlantic. Equipped with a sectional boat, the "Lady Alice," Stanley took to the water somewhat below Nyangwe and added canoes to his fleet. Soon afterward, when the local people refused to sell the expedition food, Stanley allowed his men to seize it. In addition to major attacks on his expedition, stemming possibly from the unrest into which the country had been cast by the ravages of Arab slave traders, Stanley had to manhandle the boats around the cataracts above present-day Kisangani. Only with the rounding of the greatest of these, which he proudly called Stanley Falls, at the site of the future city long called Stanleyville, did the expedition enter upon what proved to be more than 1,000 miles of navigable waterway. Only below Stanley Pool, the site of what are now Kinshasa and Brazzaville, was the river's course again broken by cataracts. These imposed an overland haul on Stanley until he reached the Congo Estuary at Boma, after a coast to coast journey lasting two years and nine months.

Stanley's attempt to follow the course of the Lualaba

Exploration of the interior. The same series of cataracts that constituted Stanley's last great obstacle had also caused the failure of the first attempt to penetrate up the Congo from the Atlantic. This was the British government's expedition of 1816, led by Capt. J.H. Tuckey. It was then widely believed that the Congo, whose massive outlet was known, was in fact the Niger, which was, from knowledge of its upper reaches, already known to be a major river. Tuckey bestowed on the Congo the highest compliment an Englishman can bestow, namely that "the scenery was beautiful, and not inferior to any on the banks of the Thames," but his own death and the decimation of his expedition by fever shed no light on the course of the river. Nor did a later explorer, Adolf Bastian, penetrate beyond the lower-river region in his expedition of 1858. In the period 1850–65, however, a number of explorers began to penetrate inland from the coast of the French colony of Gabon. The most important contributions were those of Lieutenant Commander Aymes, who led a naval expedition in 1867, and Paul du Chaillu, who reached one of the headstreams of the Ogowe, travelled through southern Gabon, and explored some of the shorter rivers to the north and south of the Ogowe.

Exploration farther into the interior of Gabon was the work of P.S. de Brazza of France in the later 1870s and the 1880s, but by that epoch exploration was positively associated with the founding of colonies, a process that, in Central Africa, had begun in the aftermath of Stanley's transcontinental journey. Stanley himself had developed the hope that the vast lands rendered accessible by the great river he had followed could be opened up to the beneficient operation, as he saw it, of European commerce and humanity. "I had hoped," he wrote in his journal,

> to have inspired Englishmen with something of my own belief in the future of the Congo. I delivered addresses after

dinner speeches, and in private have spoken earnestly to try and rouse them to adopt early means to secure the Congo basin for England.

But, just as Cameron's words had fallen on stony ground in official circles, so did Stanley's in the commercial world to which he primarily addressed them. Disappointed, he was receptive to the invitation of Leopold II of Belgium to undertake a great work for him in Africa, and with Stanley's acceptance began the new stage in African exploration—the closer association of exploration with the foundation and consolidation of colonies.

Colonization

The African enterprises of Leopold II. As sovereign of a small European state that scarcely provided him with sufficient outlet for his energies and enthusiasms, Leopold turned to overseas enterprise as a field for his drive and ambition. Impelled by the conviction that colonial rule, if carried out on the model of the Dutch East Indies, could be both profitable to Belgium and advantageous to the colonized, he also saw colonial achievements as likely to redound to the credit of the dynasty. Leopold realized early on that inward-looking Belgium was unready for colonial expansion; he therefore made numerous bids on his own account to acquire territory in parts of the world ranging from Sarawak to Argentina. All were unsuccessful, but he lit on a different approach in 1876, when, taking advantage of the prevalent enthusiasm for African exploration, he convened a geographical conference at Brussels and saw it accept his proposal for the opening up of Central Africa by the establishment of a chain of rest houses and scientific stations spanning the continent. Little had come of this when Leopold, alone among kings and statesmen, saw the opportunity given by Stanley's revelation of the Congo as a superb route into the interior, subject only to the rounding of the cataracts on the lower river. For the opening up of the Congo, Leopold formed the Association Internationale du Congo and selected as his chief agent Stanley, whose task included further exploration, the establishment of stations, and the blazing of a permanent portage route around the cataracts and the preliminary reconnaissance for the constitution of a railway to link Stanley Pool with the estuary. In the five years 1879–84 Stanley kept up the searing pace of his earlier expeditions and, in addition to making such discoveries as Lake Tumba and Lake Léopold II, established a chain of stations on the river itself. During this period and in the years immediately following, other explorers—often with Leopold's backing and sometimes, indeed, employees of the association—made further significant discoveries. Most notable were the German explorer Hermann von Wissman's three journeys, with the Kasai River system as his main focus and achievement; the penetration up the Ubangi of Alphonse Van Gele, an agent of the Congo State; and the varied work on a number of the Congo's tributaries of the English Baptist missionary George Grenfell. The conclusion of the heroic age of exploration in Central Africa came with Stanley's forcing of a passage over the Congo–Nile divide in 1887–88 and with a mission of exclusively political inspiration, namely the Frenchman Col. J.B. Marchand's great march from Libreville to the Upper Nile at Fashoda in 1897–98.

In the Stanley Pool region, Stanley entered into serious rivalry with the Frenchman de Brazza. This naval lieutenant had reached the pool from the Gabon coast and in this and other journeys undertaken after 1875 laid the basis of the French colony of Moyen-Congo. This rivalry was but a major instance of the political dimension that exploration now possessed and also pointed up the fragility, in terms of international law, of Leopold's Association Internationale. Leopold was aware of the vulnerability of his work now that the powers of Europe were beginning to display some interest in tropical Africa. To meet this and by masterly diplomacy, Leopold played a major part in defeating an Anglo-Portuguese attempt to establish Portuguese sovereignty (with important safeguards for free trade) over the Congo mouth, his lifeline, and obtained both French and United States recognition of his association—all in 1884. He completed the task of acquiring recognition by a series of bilateral agreements with the powers, conducted on the sidelines of the Berlin West Africa Conference of 1884–85, and thereby emerged as sovereign in his own right (*i.e.*, not as king of Belgium) of the Etat Indépendant du Congo (Congo Free State).

An important key to understanding Leopold's creation in the quarter century of its life is its sheer size—the Congo state was some 80 times the size of Belgium—and this combined with Leopold's undisciplined imagination, passion for further expansion, and lack of interest in good administration to give the state its special characteristics. Leopold was fascinated by the Nile, and from the first days of the Congo state's life he began to plan for expansion toward Egypt. Despite these immense African commitments, Leopold maintained his quest for rule or concessions in other parts of the world. From Mongolia to the Canary Islands, from Eritrea to Siberia, he sought lodgments. Well might Stanley complain, as early as 1885, of the "enormous voracity to swallow a million of square miles with a gullet that will not take a herring."

The resources for these large enterprises in Africa were inadequate. The Berlin Act, a product of the Berlin West Africa Conference, in creating a Free Trade Zone straddling Central Africa and including the Congo state, had stipulated that there should be no import duties. And, though he was a wealthy man in his own right, Leopold could not sustain the expense of adequately financing his African estate. He was saved by a burgeoning demand for wild rubber following on the development of rubber tires. From 1891 onward, by unusually rigorous application of the principle that all vacant lands belong to the state, by decreeing that taxes could be levied in labour or in kind, by premiums to administrative officers, and sometimes by the making over of whole areas to concessionaire companies, an ever larger tribute of the precious rubber was exacted. Abuses were numerous. In 1899, for instance, a state official told a British consular officer of his method of rubber collection in the Ubangi region. He would arrive at a village, whereupon the inhabitants invariably bolted; his soldiers then started looting and after this attacked the inhabitants and seized some of their women as hostages. The ransom demanded was a couple of goats apiece and the required amount of wild rubber. In this way the official went from village to village until he had obtained his quota of rubber. Nor was this the worst, for on numerous occasions brutality passed over into atrocity. From 1904 onward the earlier, isolated voices of protest were gathered into a chorus of denunciation, a chorus that questioned Leopold's right to continue as ruler of by far the largest colony in Central Africa.

THE CENTRAL AFRICAN COLONIES

The Belgian Congo and its northern periphery. The rubber atrocities were the beginning of the end for Leopold and the Congo Free State; they engendered a public clamour for reform that could not be withstood. The report of the British consul Roger Casement on a journey of investigation through certain of the rubber areas, published in 1904, inspired the Congo Reform Campaign, and such was its pressure that the British government, with the support of the United States government and against the background of mounting protest in Belgium itself, eventually demanded that Belgium take over the Congo. In international law the Congo Free State had no standing; Belgium, however, had its due place in the comity of nations and could be held accountable by the larger European powers in a way that was impossible with the Congo state. Belgians, too, came to see that it was almost a matter of national honour to remedy the evils for which its king was responsible, with the result that a vote to annex the Congo followed Leopold's reluctant yielding to the diplomatic pressure that demanded he give up his private colony and at a time not of his choosing.

Belgian acquisition of the Congo

In an important sense, therefore, Belgium was a reluctant colonial power, a nation that had assumed charge of an empire out of a sense of national obligation and that had no habits of imperial rule to draw upon. But Belgium was also a nation that owed its sure, if modest, stature in

the world to the commercial and industrial achievements of its people. It thus naturally hoped that the development of the Congo's resources might yield a profit. Alongside these considerations and assumptions was the belief that Europe had a civilizing and Christianizing mission in Africa, a task that, in the Congo, should as far as possible be entrusted to Catholic missions (Belgium was predominantly a Catholic country). Also influencing Belgium's conduct in the Congo was the extreme pragmatism and distrust of theorizing that seems to be a characteristic of Belgians. These then, rather than any defined national purpose, were the determinants of Belgian policy in the Congo.

Belgium's Congo policies. In the early years of Belgian rule, attention was primarily given to preventing the recurrence of the kind of abuses that had marred the Free State and to fulfilling the various demands of World War I (1914–18). During the interwar years (1918–39), however, the Belgians developed the ad hoc responses of their first decade of rule into more considered policies. World War II (1939–45) had important repercussions in the Belgian Congo, but it was not actually a turning point, because most of the policies of the 1920s lasted into the 1950s and some even to independence, 1960. The new minister of the colonies, Louis Franck (appointed 1918), quickly realized the disarray into which native administration had fallen. He saw a fragmentation of both the administration and Congolese society because of the recognition of a large number of *chefferies*, or chiefdoms, and it was especially clear that many of these *chefferies*, numbering more than 6,000 in 1917, either differed from traditional groupings or were groupings under a chief who possessed no traditional authority. Franck stated that

> the *chefferies* are too small, many chiefs lack all authority. The means of obtaining obedience formerly possessed by the chief have disappeared. The time is not far distant when, if we are not careful, in many regions, the collapse of indigenous authority will be complete.

Franck's solution was to restructure the native administration. The legislative basis was two decrees, of 1926 on Tribunaux Indigènes, and of 1933 on Circonscriptions Indigènes, but the reform process actually preceded the decrees in several areas. In essence the reforms amalgamated *chefferies* that had been wrongly constituted or that were too small to be viable into new administrative entities called *secteurs*. The chiefs of the dissolved *chefferies* would become members of the *secteur* council, and the most suitable one would be made chief of the *secteur*. The administrative authority of this chief would be increased, while the *secteur*'s viability would be built up by the location at its headquarters of a school and a dispensary and of a native tribunal that would administer customary law in civil and criminal matters and that, by express authorization, might also try statutory offenses.

The creation of *secteurs*

The new *secteurs* were to be launched carefully and tactfully so that the chiefs and people would not see them as just imposed groupings. This sometimes happened, but many busy administrators had neither the time nor the insight to carry out such a delicate and difficult task. Africans with experience of European ways—*e.g.*, former clerks or noncommissioned officers—were all too often appointed chiefs; their understanding of European ways made them valuable to the administrators, but their lack of position in traditional society gave such appointments a clear balance of disadvantage. The native policies beginning in the 1920s seemed, in their application, more concerned about regulating traditional life than about restructuring local government to satisfy the people. The world depression forced the accentuation of this tendency by administrative economies of 1933. A reduction in the number of administrative officers left those remaining without enough time for the thorough investigation that was to precede the creation of *secteurs* and put them under greater pressure to find chiefs who would serve as mouthpieces of the administration.

Implicit in the too frequent nomination of acquiescent chiefs was a positive concern to intervene in traditional life. This was an important characteristic of the Belgian presence in the Congo, and its effects were particularly important because the population was relatively small—perhaps 9,000,000 at the beginning of Belgian rule and about 13,000,000 in 1960. An even more overt type of intervention in traditional life, however, was that of large European companies—especially mining and plantation firms. The Congo's rich mineral deposits, especially in Katanga, had been a lure since the early 1900s, and with the mining of copper and other minerals, mining townships developed involving great demands for labour. By the 1920s this created a serious population imbalance in a number of districts, and the administration tried to restrict recruitment. Real change, however, began in 1925 when the Union Minière du Haut Katanga (an extensive Belgian mining company in Katanga) initiated the stabilized-labour policy, whose aim was to form a permanent work force that would necessarily be more efficient. To obtain workers for a minimum of three years, conditions and amenities were improved, and, above all, the workmen were encouraged to bring along their wives and families. This new policy was so successful that by the 1950s enough workers were voluntarily renewing contracts to allow the Union Minière to recruit new workmen almost entirely from the families of older ones. Other large companies followed suit, and pleasant communities adjoining mines or plantations became common features.

Stabilized-labour policy

The motives for the stabilized-labour policy were economic, but it resulted in a significant achievement in controlled acculturation. Considerable evidence, not least in increasing readiness to re-engage, indicates that it met a real need of the African confronted with a new work situation and with new and more complex relationships resulting from the departure from tribal life. Other Congolese, too, were subject to European influences. The peasants remaining in villages were increasingly subject to European intervention. There was a conviction imbued by the depression and voiced by Leopold III, on a tour of the Congo as heir apparent, that there was too much emphasis on mineral extraction and too little on peasant agriculture. As a result a policy of compulsory crop production to encourage peasant agriculture was taken seriously beginning in 1933. During World War II the need to increase the supply of primary agricultural produce by every possible means made compulsion even more onerous. Even after the war, a scheme (the *paysannat indigène*) to resettle peasants under conditions in which production for market could yield them a good living, though its intentions were beneficial, involved major intervention. Pressures in the bush were an important reason for drift to the towns.

Administration and economic enterprise by Europeans were two overt agencies of change. Less obvious but more fundamental change came because of the Christian missions and their schools. Assessment of their impact is difficult because of a wide variation in the degree and mode of acceptance of Christianity and Western education; many Africans who did not seriously accept the new became dissatisfied with the old. There were natural tensions between Western, Christian individualism and the more corporate African life; between a culture that distinguished between the natural and supernatural and one that did not; between a culture with technological sophistication and one with inferior technology. An indication of the cultural stress was the emergence in the 1920s of prophet movements—especially of Kimbanguism, named for Simon Kimbangu, its founder—which protested what were felt to be the inadequacies of both traditional religion and Christianity and which developed some kind of synthesis of them.

Cultural stress during the colonial period

The changes stemming from the Belgian presence were most apparent and least controlled in the towns. There, Africans were involved in a variety of different relationships—with Europeans and with other Africans. An African man was more likely to marry a woman from another tribe so that the marriage became much more an individual compact than a traditional alliance between two groups. A town dweller's friendships, especially if he became educated, were no longer confined to mem-

bers of his own tribe. He was more aware of European political, technological, and cultural dominance and, if he progressed up the educational ladder, would himself enter the colonizer's culture. And the number of town dwellers was growing. By the end of 1958 nearly a quarter of the Congolese population, a relatively high proportion, lived away from the bush.

Congolese nationalism. It was in the towns, too, that Congolese nationalism was born in the years following World War II. This was because it was in the towns that a Congolese usually entered the colonizer's culture, but, as Bronislaw Malinowski pointed out 30 years ago, the entry itself was usually partial and frustrating; the colonial situation denied an African adopting European ways full admission into European culture. In commerce, in politics, in the drawing room, in the police or army, there was eventually a barrier that could not be crossed without the colonizer yielding up power. Naturally, the better educated Congolese became more aware of this barrier, and it was this class—called *évolués*, in French-speaking Africa—that formed the vanguard of the nationalist movement.

After the war the Belgians tried to satisfy this class by giving it a special status. Originally a small but growing number of *évolués* was, by a process termed immatriculation, to achieve the same legal status as Europeans. But the *évolués* themselves apparently expected the new status to apply to nearly all their number, while the actual scope of immatriculation was greatly whittled down, making it hardly worth coveting. The *évolués*, therefore, felt a double disappointment. Although there are substantial indications of a continuing *évolué* attachment to Belgian culture and rule, from the mid-1950s there was a transition to political activity in order to obtain personal and national emancipation.

Political activity of the 1950s

External influences and forces were important in the nationalist movement's launching and development and, indeed, in determining Belgium's response to it. In 1955 a Belgian academic, A.J. van Bilsen, called for Congolese independence in 30 years. He apparently named such a period in order to be heard by a nation whose pragmatism and whose distrust of the long view had kept it from realizing that African nationalism had become a fact of life. The nationalist movement grew rapidly during the next five years. Some parties evolved out of ethnic cultural associations, most notably the Abako (Alliance des Ba-Kongo) Party. Many others made implicit or explicit ethnic appeals; with the lack of developed national feeling, and with the pillars of the colonial universe shaking and a need for an alternative seat of authority, the natural recourse was to the ethnic group. Some regional parties emerged, however, either because they had only partly reached their professed goal of becoming national parties or because several tribes united in resistance to other tribes they believed were dominating them. An example of the latter was Conakat (Confédération des Associations Tribales du Katanga).

Against all odds, two serious national parties developed. The most significant was the Mouvement National Congolais, led by Patrice Lumumba, which gained meaningful support in four of the six Congo provinces. Its success was apparently a result of Lumumba's charisma and his flair for forming profitable tactical alliances with smaller ethnic parties.

Party rivalries

Serious party rivalries began in 1957–58 and quickly increased as parties felt the need to outbid their rivals. An economic recession in the late 1950s brought unemployment and gave the parties new opportunities. External events, such as Charles de Gaulle's visit to nearby Brazzaville in 1958 and his offer to the French Congo of either complete independence or autonomy within the French Community, had a considerable influence. Meanwhile, nationalist movements elsewhere in Africa were gathering pace, and the Brussels government must have seen that Britain and France, the two major colonial powers, were not resisting them seriously. Moreover, the United States, the major power in the North Atlantic Treaty Organization, could still allow itself the luxury of anticolonial statements. By mid-1959 Belgium's colonial administration had begun to lose control in a few regions, and at the Brussels Round Table Conference in January 1960 Belgium agreed to Congolese independence beginning that June 30.

Belgium did in 1960 only what the major colonial powers had earlier decided to do. It undoubtedly reasoned that the Belgian companies' economic interests, the Belgian planters' livelihood, and the missionaries' and teachers' labours would be assured after independence because the Congolese could not manage without them. It must be said, however, that Belgium left the Congo ill-prepared for independence. Because Belgium failed to think ahead it also failed to prepare Congolese to take over authority by neglecting to give them a significant growing share in it under Belgian rule. Nevertheless, Belgium did give the Congo a number of valuable things, especially in the fields of economic development and welfare, in extensive missionary work, and in a massive program of primary education. Although too many Belgian nationals continued to exhibit a racial arrogance, by 1960 even the virtuous actions of a colonial power could gain no credit.

The French colonies. To the north of the Belgian Congo lay three French colonies—Gabon, Moyen-Congo, and Oubangui-Chari—which, with Chad, constituted Afrique Équatoriale Française (AEF). The three territories together were little more than half the size of the Belgian Congo, and their combined populations probably never amounted to as much as one-half of the Congo's. AEF is commonly compared with the larger French colonial federation of Afrique Occidentale Française (AOF; comprised of Senegal, Mauritania, the French Sudan, Upper Volta, Niger, French Guinea, the Ivory Coast, and Dahomey), which inspired it. In both there was centralization on the *gouvernement-général* at Brazzaville and Dakar, respectively; both were fields for working out the same colonial policies, and both witnessed marked fluctuations in policy aims and methods. The decisive difference was that AEF was always the poor relation.

France had come to possess the AEF area with little positive purpose, and various administrative arrangements were followed in the early years of French rule. The AEF federation was set up in 1908—the same year that the Belgian Congo proper was established. But there had been further similarities. From 1898 onward most of what was then termed French Congo had been parcelled out to concessionaries on the model, seemingly, of the Congo Free State. Similar abuses resulted from the methods used to acquire rubber and ivory, and eventually this led in 1905 to de Brazza's recall from retirement so that he might report on the problem. Significantly, local officials obstructed de Brazza's investigation, but enough of his strongly critical report was published to bring improvement in the so-called Clementel reforms of 1906 (de Brazza himself died at Dakar on the way home). Steadily, the area leased out to concessionaries was cut down to a fraction of its former size, and tighter control was enforced on fewer companies—again, the parallel with Belgian policy after 1908 is striking. But abuses continued and were again brought before French public opinion by writers such as René Maran in *Batouala* (1921) and André Gide in *Voyage au Congo* (1927). Clearly, abuses by concessionaire companies were still being condoned or echoed by administrators. The resulting outcry led to the colonial ministry refusing to extend or renew existing leases.

Parallels with the Belgian Congo

Underlying these abuses was the poverty of the whole area, accentuated by an absence of communications, apart from rivers. French national pride refused to accept the permanent use of the Belgian Congo railway between the Lower Congo and Stanley Pool, but work on the alternative, a new railway from Pointe Noire to Brazzaville, commenced in 1924, only made abuses worse for a time. This was because the absence of sufficient local labour forced the use of conscripted labour from the interior parts of the federation, and insufficient attention to diet and housing led to probably 15,000–20,000 deaths in the construction camps. In the long run, however, the Congo–Ocean Railway brought major benefits by giving

the federation a good link, joined as it was by the river route up to Bangui, with the outside world.

The touchstone of the style of French administrators in the area was the role accorded to the chiefs. Full assimilation never took place, but in parts of AEF, such as the forest regions of Gabon and Moyen-Congo, a centralized administrative control, which is one dimension of assimilation, was introduced. A hierarchy of village and cantonal chiefs was set up there, having no correspondence with recognized traditional authorities; the clear lack of influence of such chiefs led to modification of the system. Meanwhile, in other parts of the federation, such as eastern Oubangui, "indirect rule" through powerful traditional rulers was for a long time left to continue for lack of any alternative. Compounding these administrative problems was a near-constant pull among the three territories (plus Chad) and the *gouvernement-général* and probably a too-often lower calibre and numerical insufficiency of administrators in what was generally regarded as a little-favoured group of colonies.

AEF prominence and prosperity

If the AEF was little regarded by Frenchmen, as by others, before World War II, it leapt into prominence in 1940, when, under the leadership of Felix Eboué, a West Indian and the governor of Chad, and others, it became the main centre of Free French support in Africa. The consequential involvement of AEF in the Allied war effort brought prosperity; and Eboué, who became governor general in 1941, was also concerned about strengthening traditional institutions and bringing forward *évolués* for a role in the institutions of self-government that, he foresaw, were to come. Eboué died in 1944, and the end of the war was the end of wartime prosperity. Nevertheless, the postwar years saw notable economic and political advance. In 1946 the foundation by France of FIDES (Fonds d'Investissement et de Développement Économique et Social) introduced an era of substantial metropolitan capital investment and of increased economic activity, which resulted in turn in considerable expansion of health services and education. At the political level, the constitution of the Fourth Republic and the French Union, promulgated in the same year, created federal and territorial assemblies in AEF whose members included elected Africans. The war was an important watershed for the AEF. As the U.S. scholars Virginia McLean Thompson and Richard Adloff write in *The Emerging States of French Equatorial Africa*,

> After the war, AEF was for the first time provided with an adequate number of qualified administrators and technicians, investment funds on a large scale, and elective political institutions. To be sure, this same constructive policy was applied to other parts of the French Union, but it had an exceptionally great impact on AEF because of that federation's comparatively undeveloped status.

An important effect of the constitutional changes of 1946 was not only that they gave political experience to Africans but also that they tended to stress the importance of the territories at the expense of the federation. This tendency went further with the *loi cadre* of 1956, which gave a large measure of self-government with emphasis on the territorial rather than the federal level. Two years later, all of the three territories (and Chad) voted in referendum to accept the constitution of the new French community. Gabon entered it as the Republic of Gabon, Moyen-Congo as the Congo Republic (soon to be better known as Congo [Brazzaville]), and Oubangui-Chari as the Central African Republic (Chad also entered, as the Republic of Chad). By then, a lively political life had developed in each of the territories.

THE REPUBLICS

Following the attainment of independence, all four Central African republics moved sharply away from the democratic constitutions with which they were endowed. Two of them—the Central African Republic (CAR) and Congo (Brazzaville)—acquired military regimes. Meanwhile, Congo (Kinshasa), the former Belgian Congo, gained a presidential regime, the actual president having originally seized power in an army coup d'état. All became members of the Organisation Commune Africaine, Malgache et Mauricienne (OCAM). For a time, Congo (Kinshasa) was linked with the CAR and Chad in the Union des États de l'Afrique Centrale (UEAC), but the more strongly based and permanent links were those joining the CAR, Congo (Brazzaville), and Gabon—especially in the economic alliance L'Union Douanière Économique de l'Afrique Centrale (UDEAC)—thus perpetuating an important degree of the interdependence established among the component territories of the old AEF.

Republic of Zaire. The road to autocracy, however, saw certain differences. Congo (Kinshasa) enjoyed an even moderately tranquil independence for less than a week. Starting on July 5, 1960, there was a mutiny of the Force Publique, the combined army and gendarmerie. This was caused not by the political aspirations of some of its officers but by the fact that the force had been under strain over several months of political unrest, by the rapid promotion to wealth and affluence of politicians and civil servants, by the strict maintenance of the status quo in the army, and possibly by the disruptive impact of some politicians, who sought to create followings in the Force Publique of men of their own tribe. Exaggerated reports of counteraction by Belgian metropolitan troops at Matadi led to escalation and to a panic in the country that was even more serious than affairs warranted. Most Belgians and many other Europeans fled as reports of the killing of Europeans flooded in, and the inexperienced government of Prime Minister Lumumba was, understandably, unequal to the occasion.

Mutiny of the Force Publique

United Nations intervention. United Nations intervention began in mid-July, desired by the Congolese government as a means of getting Belgian troops out and by member states as a means of preventing both anarchy and the escalation of the situation into a Cold War confrontation. Because its military contingents remained in the Congo for four years, the United Nations necessarily became a force in Congolese politics. Because there were no real precedents for the role it must fulfill, once it departed from a posture of nonintervention in the affairs of a member state—which attitude, if rigorously adhered to, would have made its presence a nonsense—its actions were controversial in the view of some member nations and for this or that faction in the Congo. Agreement in the United Nations on policy could be obtained only by refuge in ambiguities, which it was left to the secretary generals, Dag Hammersjköld and his successor, U Thant, to resolve. Particularly controversial was its action or, as some thought, inaction over Katanga (now Shaba), which had seceeded from the Congo (Kinshasa) on July 11, 1960. The secession, aided by Belgian officers and civilians, of the wealthiest of the Congo's provinces was a major problem for the Léopoldville (Kinshasa) government; the apparent role of Katanga's prime minister, Moise Tshombe, as a puppet of Belgian mining interests gave the secession a broader significance. In fact, however, the Katanga government, though dependent for its survival on Belgian aid, was no one's puppet. This did not, however, prevent its collapse when, after two outbreaks of fighting in southern Katanga, the United Nations took the offensive at the end of 1962.

Meanwhile, secessionist attempts, accompanied by intertribal bloodlettings, in northeastern Congo and in South Kasai, had also been ended; but the dismissal of Lumumba by Pres. Joseph Kasavubu in September 1960, a military coup presided over by Col. Joseph Mobutu (now Mobutu Sese Seko), followed by five months' rule by a college of commissioners set up by Mobutu, indicated a fundamental political instability that was only apparently ended by Prime Minister Cyrille Adoula, whose three-year government began in August 1961. More dramatically, Patrice Lumumba, who after his dismissal had fallen into the hands of the college of commissioners (the United Nations authorities controversially did not feel it their duty to prevent his capture), was murdered in Katanga. The facts about his death are unclear, and, on the dismal extenuation that torture is not necessarily intended to involve death, his actual death may not have been willed by anyone. But various figures in the Léopoldville government, who were responsible for sending him to

The death of Lumumba

Katanga, and individual members of the Katanga government must, it seems, share the basic responsibility for his death, when he was rapidly becoming the symbol of African nationalism. A further tragedy was the death of UN secretary general Hammarskjöld, when his aircraft crashed at Ndola (now in Zambia) in September 1961 while on his way to negotiations with Tshombe at the height of the Katanga crisis. (R.T.An.)

Rebellion. After a period of increasing difficulty in financing the UN Congo peacekeeping operation, it came to an end in mid-1964. No sooner had the last UN troops gone, however, than the Congo erupted into rebellion, especially in the Kwilu region and the eastern and northeastern parts of the country. Enjoying some external aid, the rebels for a time carried all before them and at one time denied to the central government control of about half the country. In a reversal that has never been fully explained, Tshombe was recalled to power in July 1964 as prime minister of the central government. Rebel power in Stanleyville (now Kisangani) was ended by the combined attack of a force of European mercenaries, raised by Tshombe, and of a force of Belgian paratroopers dropped over the city in November 1964. The presence of a few good units of the Congolese army and the bravery of its commander, Gen. Joseph-Désiré Mobutu, combined with the mercenaries' sophisticated weapons and ruthlessness and with Belgian and U.S. logistical support, were enough to drive into forest fastnesses a rebellion whose leadership became increasingly divided.

Tshombe in power again

Mobutu's regime. Division among the leadership was not, however, a prerogative of the rebels. In the autumn of 1965 General Mobutu overthrew Tshombe. As president of the republic he steered a relatively successful course between the radicalism of the educated young and a moderation necessary to attract overseas capital.

Major features of Mobutu's rule were the establishment of internal political stability, the expansion of the economy, and an active program to foster nationalism. The rebellion in Katanga was ended in 1967. In that year a new constitution establishing a strong federal government was accepted by a referendum in which women voted for the first time. In the national elections of 1970, Mobutu was re-elected to a seven-year term as president. All members of the legislature ran unopposed as members of the one political party, the Mouvement Populaire de la Révolution (MPR), which held its first congress in 1972.

In foreign affairs Mobutu worked to improve international investment and to increase trade with his country's African neighbours. Economic ties with the West were strengthened, and in 1972 full diplomatic relations with China were established. As president of one of the states bordering white-controlled southern Africa, Mobutu allowed guerrillas fighting the Portuguese regime in Angola during the early 1970s to take refuge in his nation.

The economy continued to depend upon mining, especially of copper. In 1967 the Union Minière, the largest of all Congo companies, was nationalized amid charges of mismanagement; terms of compensation were agreed upon in 1969. The mines are managed by the state agency Générale des Carrières et des Mines du Zaire (Gécamines). A major hydroelectric project was begun on the Congo River at Inga in 1969, the first stage inaugurated in 1972. Rising unemployment and low copper prices led in 1973 to nationalization of foreign-owned agricultural land and of controlling interest in foreign-owned mining companies. A second wave of nationalization two years later included all industry, the building trades, and distribution services. In 1976, however, more than half of the companies were restored to the private sector.

Nationalized mines

Nationalization was paralleled by a political campaign to promote nationalism. It began when the country's name was changed to the Republic of Zaire on October 27, 1971. Place-names throughout the country were also changed. A nationality law of 1972 required the taking of Zairian names by all citizens, including President Mobutu, who changed his name to Mobutu Sese Seko. Nationalism was threatened by the invasion of Shaba (formerly Katanga) province by former Katangese rebels from Angola in March 1977. Mobutu appealed to the U.S., France, and Morocco for aid and the invasion was ended in May.

The Central African Republic. In the years before independence, Barthélémy Boganda dominated the politics of Oubangui-Chari. His party was the Mouvement d'Évolution Sociale de l'Afrique Noire (MESAN), and by 1957 it controlled the territorial assembly. Boganda himself became president of the grand council of Afrique Équatoriale Française (AEF) in June 1957 and sought to create and lead into independence a united Central African state as the heir to the old AEF. This proposal foundered because of the opposition of the principal politician in Moyen-Congo, Fulbert Youlou, and because premature death in an air crash in 1959 prevented Boganda from taking any further initiatives. More immediately, his death left no successor of comparable stamp. David Dacko, the man chosen by MESAN to lead, believed in an organic conception of the state with the party becoming a mass movement, but he never succeeded in ending corruption in the civil service or even keeping it within bounds. His problems were compounded by a near-stagnant and extremely poor economy, and a move to make all civil servants refund 10 percent of their salaries in 1965 created a situation in which the army, led by Col. Jean-Bédel Bokassa, took power. The constitution of 1959 was abrogated in 1967 and replaced by an act that gave full powers to Bokassa, the new president.

Bokassa's regime was characterized by a continued concentration of power in the person of the president. In 1972 a MESAN party congress declared Bokassa president for life. On September 5, 1976, Bokassa dissolved the government and replaced it with a Council of the Revolution, and on December 4 he declared the country to be a parliamentary monarchy, the Central African Empire, with himself as emperor. In a fantastic ceremony on December 4, 1977, the ruler crowned himself Bokassa I.

The People's Republic of the Congo. The former French colony Moyen-Congo also came under military rule, but it was by a more complex route in which ethnic rivalries played a more evident role. At the time of independence there were two main parties—the Mouvement Socialist Africain (MSA) and the Union Démocratique de Défense des Intérêts Africains (UDDIA). Formally, the former, led by Jacques Opangault, was in the Socialist tradition, and the latter, led by Fulbert Youlou, was in that of the Christian Democrats. The Mboshi and other peoples of the north constituted the main strength of MSA, and the Kongo (Bakongo) of the south, with their Vili allies of the coast, formed the backbone of UDDIA. A crisis developed at the territorial assembly in November 1958, when a vote switch between the finely balanced parties gave Youlou the right to form a government. But there was immediate rioting and deaths in Pointe-Noire, a coastal enclave of MSA strength, followed by much more serious intertribal rioting at Brazzaville in February 1959. Youlou, however, was elected premier and president in November 1959. In August 1963 an attempt to curb the opposition and trade unions led to arrests of union leaders, a general strike in Brazzaville, Pointe-Noire, and Dolisie, the forcible liberation of the arrested leaders, and the resignation of Youlou.

Ethnic rivalries

For the next five years the Congo (Brazzaville) was ruled under a partly presidential, partly parliamentary constitution; and, although Pres. Alphonse Massamba-Débat was a moderate politician, there was a marked shift toward Marxist radicalism, seen notably in the formation of the Mouvement National de la Révolution (MNR) and of its militant youth wing. The President's dismissal of a conspicuously pro-Chinese prime minister in January 1968 and his own apparent ineffectiveness led to a disturbed year until the army commander in chief, Maj. Marien Ngouabi, seized power in August, becoming head of state in 1969. That year the new regime adopted the name of People's Republic of the Congo and the form and trappings of a Communist state, combined with presidential–one-party rule, but political groupings within the country remained obscure.

Despite general elections and a referendum accepting the new constitution in 1973, domestic politics continued

to be unstable, and unsuccessful plots against the state were frequently reported. In a government reorganization of 1975–76, a nine-member Council of State was established with Ngouabi as chairman. On March 18, 1977, Ngouabi was assassinated; among those executed the following week was the former president Massamba-Débat. In April Col. Joachim Yombi Opango was named president, the constitution of 1973 was suspended, and an 11-member military committee headed by Opango replaced the government.

The Gabon Republic. Of all the former AEF territories, Gabon was the least enamoured of interterritorial collaboration. It felt itself the loser from the construction of the Congo–Ocean Railway and the paymaster, from its own buoyant economy, of other members of the federation. Of its close relations with France, on the other hand, stemming from a contact more than a century old, there was never much doubt. Three further important features of Gabon were its considerable economic resources, its relatively small population (estimated at 1,150,000 in 1975), and its ethnic (Fang) homogeneity. The considerable and ever-growing prosperity of a state well-endowed with natural resources evidently eased its emergence as an independent nation. Until his death in 1967, the dominant figure in Gabon politics was Léon M'ba; elected mayor of Libreville, the capital, in 1956 and to the highest office open to an African in the government council in the same year and leader of the Bloc Démocratique Gabonais, he was the natural leader for independent Gabon, being elected president in February 1961. Friction with his main rival, Jean-Hilaire Aubame, and opposition to M'ba's moves toward a one-party state led to a rising in February 1964 in which the army and Aubame seized power. Within three days, however, M'ba was restored, as a result of intervention by French troops in response to a plea by the Vice President. In April, however, the opposition did well in the election for the national assembly. In March 1967 the opposition was forbidden to participate in elections, and in March 1968 the Bloc Démocratique Gabonais was declared the sole political party, a move that Aubame supported.

Relations with France

Upon the death of M'ba, the presidency passed to Albert-Bernard Bongo (forename changed to Omar in 1973). Re-elected in 1973, he successfully administered the country's prospering economy and its apparently stable political structure. Gabon became an important producer of petroleum; unaffected by the international oil crisis of 1974, it acquired full membership in the Organization of Petroleum Exporting Countries (OPEC) the following year. In 1976 relations with France were temporarily strained, and Gabon announced its withdrawal from the Organisation Commune Africaine, Malgache et Mauricienne (OCAM). Construction of a trans-Gabon railway was begun in 1977; the country's only railway, it will provide access to interior mineral deposits and aid in the development of the lumber industry. (Ed.)

The first inhabitants: J.D. FAGE and ROLAND A. OLIVER (eds.), *Papers in African Prehistory* (1970), reprints invaluable articles by Clark, Guthrie, Oliver, and Nenquin; J.H. GREENBERG, *Studies in African Linguistic Classification* (1955); G.P. MURDOCK, *Africa: Its Peoples and Their Culture History* (1959).

The Bantu states: G. BALANDIER, *La Vie quotidienne au royaume de Kongo du XVI^e^ au XVIII^e^ siècle* (1965; Eng. trans., *Daily Life in the Kingdom of the Kongo from the Sixteenth to the Eighteenth Century,* 1968); W.G.L. RANDLES, *L'Ancien Royaume du Congo, des origines à la fin du XIX^e^ siècle* (1968); J. VANSINA, "Long Distance Trade-Routes in Central Africa," *Journal of African History,* 3:375–390 (1962), a seminal article; *Kingdoms of the Savanna* (1966), an outstanding work on the history and political and social organization of this region in the precolonial era.

Nineteenth-century explorers: ROBERT BROWN, *The Story of Africa and Its Explorers,* 4 vol. (1892–95, reprinted 1896–98), still valuable as a good and comprehensive summary; PIERRE DAYE, *Léopold II* (1934), perhaps the most perceptive biography of Leopold (in French); DAVID LIVINGSTONE, *Missionary Travels and Researches in South Africa* (1857, many reprints); RUTH M. SLADE, *King Leopold's Congo* (1962), a good, recent study of the Congo Independent State; H.M. STANLEY, *Through the Dark Continent,* 2 vol. (1878, many reprints).

The Belgian Congo: ROGER ANSTEY, *King Leopold's Legacy: The Congo Under Belgian Rule, 1908–1960* (1966), a history of the Belgian Congo, particularly concerned with the study of the impact of European culture; S.J.S. COOKEY, *Britain and the Congo Question, 1885–1913* (1968), a good study of the Congo reform campaign; RENE LEMARCHAND, *Political Awakening in the Belgian Congo* (1964), a study by a political scientist containing much historical information; CRAWFORD YOUNG, *Politics in the Congo: Decolonization and Independence* (1965); W. ROGER LOUIS and JEAN STENGERS (eds.), *E.D. Morel's History of the Congo Reform Movement* (1968), Morel's unpublished history edited by a leading Belgian historian of the Congo and by a leading American historian of the region (with chapters of their own added); HENRI ZIEGLE, *Afrique équatoriale française* (1952).

The republics: J. GERARD-LIBOIS, *Sécession au Katanga* (1963; Eng. trans., *Katanga Secession,* 1966), the most balanced study of this issue; CATHERINE HOSKYNS, *The Congo Since Independence, January 1960–December, 1961* (1965), very detailed and judicious; PATRICE LUMUMBA, *Le Congo* (1961; Eng. trans., *Congo, My Country,* 1962), written before Lumumba had achieved political fame; CONOR CRUISE O'BRIEN, *To Katanga and Back: A UN Case History* (1963), a readable, if sometimes disputable, account by one involved in the events that he describes and interprets; VIRGINIA THOMPSON and RICHARD ADLOFF, *The Emerging States of French Equatorial Africa* (1960), a good and very detailed study; B. VERHAEGEN, *Rébellions au Congo,* 2 vol. (1966–69), an invaluable document-based study.

(R.T.An.)

Central African Republic

The Central African Republic (République Centrafricaine) is an independent state located in the centre of the African continent. It has an area of more than 240,000 square miles (620,000 square kilometres) and is bordered by Chad to the north, The Sudan to the east, Congo and Zaire to the south, and Cameroon to the west. It is thinly populated; no official figures were released after 1968, when its population was estimated by the government to be about 2,256,000, but later UN estimates were about 600,000 persons lower. The capital, Bangui, is situated on the southern boundary, which is formed by the Ubangi (Oubangui) River, a tributary of the Congo.

The country has long suffered from isolation and lack of economic development. Upon independence from France in 1960, agriculture was at a subsistence level; there was a chronic trade deficit and a grave lack of funds and trained personnel, so that the country remained almost wholly dependent upon France. By the mid-1970s, production of cotton and peanuts (groundnuts) had grown substantially, though coffee had fallen off somewhat; educational and health facilities had been expanded; important mineral deposits had been located; and the republic was relying less and less on the original cornerstone of its foreign policy—close allegiance to France. These changes, however, often had been made at the expense of political freedom.

Central African Empire

On December 4, 1976, the nation's military ruler, Jean-Bédel Bokassa, declared the country a parliamentary monarchy, the Central African Empire, and one year later crowned himself Emperor Bokassa I.

For an associated physical feature, see CONGO RIVER; for historical aspects, see CENTRAL AFRICA, HISTORY OF.

The landscape. *The natural environment.* The republic occupies a vast rolling plateau that rises to between 2,000 and 2,500 feet above sea level and forms the watershed between the Lake Chad and Congo River basins. In the north, the rivers flow into the Bahr (river) Aouk, a tributary of the Chari River. In the south, the rivers join the Ubangi River.

Topography

The vast central plains rise gradually to the Chaîne des Mongos (4,593 feet [1,400 metres]) to the northeast and to the Massif du Tondou in the east and southeast. In the west, the Monts Karre (4,000 feet) form a high granite range that declines eastward into sandstone plateaus, dissected by the Lobaye and Nana rivers. Spurs run into the area of Bouar and Baboua, where great round boulders give a chaotic aspect to the landscape.

In the east, gneisses (coarse-grained rocks in which bands containing granular minerals alternate with bands containing schistose minerals) and quartzites predominate. Surfaced with sandstone and occasional granitic knolls, a vast plain gradually climbs from the valley of the Mbomou River to the crest of the Congo–Nile watershed. The rock formations that interrupt the monotony of the landscape reach a height of 3,900 feet (1,200 metres) at Djebel Abourassein.

In the north, in the region of Ndélé and Ouanda Djallé, rock formations caused by the erosion of sandstone cover a metamorphic and quartzite base. The most important mountains are those of the Dar Challa range, which rise to 4,423 feet (1,348 metres) at Mt. Tinga.

In the southeast, an ancient layer of quartzites is covered by horizontal layers of sandstone. This territory forms a plain that gradually climbs toward the crest of the Congo Basin; rivers often cut deep into its landscape. The granite massif (mountainous mass) of ranges surrounding M'Poko and Libby, north of Bangui, forms a zone of hills that traverses the surrounding plain.

The climate is tropical. The Central African Republic lies in a transitional climatic zone between those of the sub-Saharan to the north and the equatorial to the south. In the southern region, the climate is hot and humid; the highlands are cooler and experience more frequent thunderstorms.

During the wet season (from March to October or November) heavy rainstorms occur almost daily and are frequently accompanied by thunderstorms. Early morning fog is also typical. Maximum annual rainfall occurs during August and September, especially in the upper Ubangi region (71 inches) and in the Karre highlands (59 inches). During this season of southwest monsoon (rain-bearing) winds, the temperature ranges between 66° and 86° F (19 and 30° C).

The dry season—brought by the northeast trade winds, or harmattan—generally begins in October and ends in February or March. The air is dry, and temperatures range between 64 and 104° F (18° and 40° C); it is warm during the day and considerably cooler at night. The skies are clear and seldom cloudy, although some dry fog can be observed. Sand or dust storms also occur in the extreme north.

The country lies largely in the savanna (grassy parkland) zone of Africa. While the north is treeless, dense rain forests follow the southern rivers and stretch far into the savanna country. Bush fires in the dry season are a constant threat to the republic's 7,500,000 acres of timberland, which is densest in the Lobaye and Upper Sangha regions.

Animal life

There is a great variety of wild animals. In the dense forests are gorillas, chimpanzees, monkeys, and giant squirrels, while the savanna regions are inhabited by a variety of deer and antelope, buffalo, elephants, and hyenas. Along the rivers, abundant with fish such as Tilapia (an African freshwater food fish), hippopotamuses, crocodiles, and rhinoceroses are to be found. A rich and varied birdlife—in addition to many varieties of snakes, bats. and insects, including many butterflies and moths—

CENTRAL AFRICAN REPUBLIC

makes the territory zoologically one of the most interesting in Africa.

The landscape under human settlement. About 75 per cent of the total population is rural. The main purpose of the country's agrarian reform program (known as "Operation Bokassa") is to alter the organizational structure of the peasant communities so as to raise production and the standard of living. This is to be achieved partly by the creation of large state farms in the form of cooperative-type agricultural centres (one now exists). This policy, however, has met with opposition from the traditional village farmer, whose land and hunting rights are threatened.

Tribal traditions in the savanna country assign men to the tasks of fighting, hunting, and fishing, and it is often considered dishonourable for a male from the age of 15 years upward to till the land. Cultivation is the work of women, who grow a little manioc and a few banana trees around their huts; in the savanna lands peanuts are grown for family consumption.

In the early 1970s the largest urban area was the capital city of Bangui (population 238,000) on the Ubangi River. Other towns were Berbérati (40,000), Bossangoa (36,000) and Bouar (29,000), in the west; Bambari (31,000) and Bria (25,000), in the central plains; and Bangassou (28,000) and Mbaïki (18,000), on the Ubangi.

People and population. The national language, Sango, is a lingua franca, although it has many dialects. A written form is used in mission publications and schools. The official written language is French, which is taught in the schools. Other tribal languages, such as Zande, are also spoken. There is no written history nor does a strong oral tradition prevail.

The east and northeast are thinly populated. Only along limited zones of the Ubangi River and along the Chad border are rural population concentrations found.

Origin of the population

Almost all of the inhabitants of the country trace their origin to settlements established in the 19th century. These came into existence when populations fled from Arab and European slave traders operating between the Nile and the Atlantic: the Baya, for example, arrived between 1805 and 1830 from the north and the Banda between 1830 and 1890 from the Anglo-Egyptian Sudan. These people found asylum in an almost desert-like country, which, since the end of the 18th century, had been depopulated by the slave trade. Therefore, they did not have to fight against an indigenous population. Despite ethnic differences in the population, there was a considerable degree of unity, and tribalism constituted no problem. Since independence, however, a different situation has emerged. In the role of traders and fishermen, the Mbaka, Yakoma, Banziri, and Buraka tribes had served other groups as middlemen, thus providing the colonial administration with an indigenous infrastructure. In the early 1970s, with few exceptions, most leading political figures belonged to these Ubangi region tribes, and other tribes, far more numerous, were beginning to resent this situation.

The Ubangi (a general name for the riverine peoples, numbering about 150,000) live along the shores of the Ubangi River and in Mbomou prefecture; they include the Buraka, the Azande (who number almost 20,000 in the republic but who have 1,000,000 kinsmen in Zaire and The Sudan; they are related linguistically to the 30,000 members of the Ubangi group called Nzakara), the Yakoma, the Sango, the Banziri, and the Mbaka. The Banda (336,000) live in the highlands in the centrally located triangle between Bria, Bambari, and Fort-Sibut; some of their settlements also stretch into Zaire and The Sudan. The Mandja (260,000), who live mainly around Fort-Sibut, are mixed with the Baya (300,000), especially in the southwestern square between the towns of Bouar, Bossangoa, Boda, and Berbérati. The Sara (85,000) are spread along the northern border; their settlements stretch into Chad as far as Fort-Archambault. The Fertit (30,000) live in the northeast. The Mbum (73,000) reach as far as Chad and Cameroon; the majority live a poor and isolated existence in the northeast. The Pygmies (10,000), a remnant of the original population, inhabit the southwestern rain forest. In the 1920s some 15,000 nomadic Bororo-Fulani (Bororo-Peul) settled around Bouar and Bambari; in the early 1970s they were still basically a nomadic people, about 90 percent of whom were cattle herders. The European minority, largely French, numbers about 9,000, and most live in Bangui.

Central African Republic, Area and Population

Animism is practiced by 60 percent of the population. Of about 145,000 Christians, the majority are Roman Catholics and the remainder Protestants. There is a small Muslim community in the north.

Since 1955 and especially since 1965, political refugees from the southern Sudan have entered the republic. Numbering about 24,000 in 1971, most were resettled in Haut-Mbomou prefecture with the aid of the United Nations and other international organizations. Some 3,700 refugees from Zaire were considered as being permanent settlers.

The population is unevenly and generally thinly distributed. The annual birth rate was 46 per 1,000 population, the death rate 25 per 1,000, and the infant mortality rate 190 per 1,000 births. About 42 percent of the population was under 15 years of age, and the annual rate of population growth was 2.1 percent.

The national economy. The Central African Republic is a member of the Communauté Financière Africaine (CFA; African Financial Community); the currency is the CFA franc. The country is an active member of the Union Douanière Économique de l'Afrique Centrale (UDEAC; Central African Customs and Economic Union), the Organisation Commune Africaine, Malgache, et Mauricienne (OCAMM; Afro-Malagasy and Mauritius Joint Organization), and other African and international organizations. It is also an associate member of the European Economic Community (EEC).

Mineral deposits

Natural resources. Diamond deposits are located north of Bria, west of Bangui, and near Berbérati. About 8,000 tons of uranium deposits were discovered near Bakouma in 1969; there are also reserves of lignite (brown coal) and peat and coal in the same area, and about 700,000 tons of iron ore have been located near Bogoin. Other known mineral reserves include mercury at Baboua, limestone at Fatuma and Bangui, chalk at Bobossa, manganese at Bour-N'Gam, and copper at N'Gade.

The country's forests represent substantial wealth in such hardwoods as mahogany, obeche (with soft white to pale yellow wood), and limba (a straight-grained wood from a tall whitish-trunked tree). The coal deposits are a potential source of thermal power, and the country's waterfalls, especially Kotto Falls on the Kotto River, a tributary of the Ubangi in the eastern part of the country, constitute a source of hydroelectric power.

Sources of national income. Most agricultural activity is on the subsistence level. Crops grown for domestic

consumption include corn, rice, manioc, sorghum, plantain, and sweet potatoes. About one-tenth of the peanuts and one-sixth of the sesame grown are for commercial use. The main cash crops are cotton, grown in the Karre highlands and around Bambari, and coffee, raised particularly in the southwest.

Livestock includes 470,000 head of cattle and 580,000 sheep and goats. Sleeping sickness, caused by the deadly tsetse fly, is a serious threat to cattle throughout the country, and most meat for Bangui is imported from Chad or The Sudan.

Agricultural production has been increased through the development program known as "Operation Bokassa." The agronomical institute (Institut d'Études Agronomiques d'Afrique Centrale) in Wakombo assists in crop diversification; new crops include oil palms, cacao, pepper, rubber, tobacco, and jute. The purchase, processing, and sale of all cotton is a monopoly of the Central African Cotton Union, in which the government owns a controlling interest, in Bangui.

Forestry was little developed in the early 1970s. Commercial rights over 889,000 acres of forests were granted to 12 French and other European companies in 1969.

Diamonds are the most important export product. They represented over 40 percent of the total value of exports in 1970; the diamond industry is the largest in the country, employing about 45,000 people. Uranium mining was expected to begin in 1972 or 1973, with an anticipated yield of 500 to 700 tons of ore annually, which is to be refined at Bakouma. Mining is to be carried out under the auspices of the Compagnie des Mines d'Uranium de Bakouma (Bakouma Uranium Mines Company) in which the government has an interest of 20 percent, the United States Atomic Energy Commission 40 percent, and the French Uranium Corporation 40 percent.

Manufacturing, concentrated in Bangui, was still in the infant stage in the early 1970s and employed 20,000 Africans and 1,500 expatriates. Small factories produce cotton textiles, processed food, soap, and beer; there are also assembly plants for motor bicycles and radios. There is a dairy products plant at Sarki, and a refrigerated slaughterhouse is to be built at Bangui.

Electric power is produced by hydroelectric power stations at Boali, Bouar, Mbaïki, and by a thermal station at Bangui. Total production in 1970 was 45,727,000 kilowatt-hours. Construction was scheduled to begin in 1972 on a diesel power station in Bangui and a hydroelectric station at Kotto Falls. The Banque Centrale des États de l'Afrique Équatorial et du Cameroun (Central Bank of the Equatorial States and Cameroon) is the main bank. Others include the Banque Nationale de Développement de la République Centrafricaine (National Development Bank of the Central African Republic), the Union Bancaire en Afrique Centrale (Banking Union of Central Africa), and the Banque Internationale pour l'Afrique Occidentale (International Bank for West Africa).

Tourism is based on big-game hunting and fishing. The scenery and waterfalls are also attractions, as are the two national parks—Saint-Floris and André Félix. There are also several nature reserves. Safaris are expensive, however, and few tourist accommodations are available, except for luxury hotels in Bangui.

Balance of trade

There is an unfavourable balance of trade. The main export commodities are diamonds, coffee, cotton, wood, and tobacco, which are sold to France, Israel, Italy, and the United Kingdom. The chief imports are automobiles, petroleum products, cotton textiles, and machinery, which are bought mainly from France, West Germany, the United States, The Netherlands, and Italy.

Management of the economy. While the government's economic emphasis is on Socialism, the economy is primarily dependent upon foreign investments and foreign aid. Private investment is negligible, and public government funding has difficulty in finding its priorities. The principal sources of foreign loans and aid are the United Nations, the EEC, the International Development Association (IDA), France, the United States, West Germany, China, and the Soviet Union.

Taxes are levied on property and income. The rural population tends to be taxed more heavily than the urban. All imports, except those from other UDEAC countries (Cameroon, Chad, the Congo, and Gabon), are taxed. Since many items of daily use must be imported, the country has one of the highest cost of living indexes in Africa.

The General Union of Central African Workers (UGTC) is the only labour union. Created in 1964, it had some 55,000 members in the early 1970s; its president is also president of the republic. A central office of social security administers the labour laws and regulations.

Transport and communications. The transport system is controlled by the fact that the Central African Republic is a landlocked country 900 miles from the Atlantic Ocean. The road network was once said to be the best of all the French colonial territories, but the construction and upkeep of the much deteriorated internal road system now consume vast amounts of foreign aid. About one-third of the road system consists of all-weather roads, of which fewer than 50 miles are paved. The main roads run from Bangui through Bossangoa to Fort-Lamy (capital of Chad) and from Bangui, via Bambari, to Tambura in The Sudan.

Inland waterways

There are no railroads in the republic, and waterways are the main means of communication and commerce. The most used is the 370-mile stretch of the Ubangi River between Ouango and Ouadda, which is navigable for ten months of the year (*i.e.*, except in the dry season). The usefulness of this stretch is greatly diminished by its being cut off north of Bangui by 31 miles of rocks and rapids. The Ubangi is again navigable the year round from Bangui to Brazzaville, Congo; from there, goods are shipped by rail through the Congo to the Atlantic port of Pointe-Noire. A number of the Ubangi's tributaries, such as the Lobaye and Sangha rivers are seasonally navigable, but many of them flow through sparsely inhabited regions that are untouched by external trade.

Bangui is the chief port. It has been gradually improved since the mid-1950s and has about 1,000 feet of quays, which handle about 264,000 tons of cargo annually. The port of Salo on the Sangha River is also important, and a port for the evacuation of timber is being constructed upstream from Salo at Nola.

There is an international jet airport at M'Poko, near Bangui. Nine other all-weather airports are capable of taking DC-4 aircraft; 15 are open to DC-3s and 13 to light planes depending on weather conditions. The two local air companies are the privately owned Air Centrafrique and Air Bangui, which both operate regular internal services. Outside Bangui there is no telephone service, but radio contact is maintained with population centres.

Administration and social conditions. *The government.* Since the coup d'etat of 1966, the constitution has been abrogated and the National Assembly dissolved. The president rules by decree, and frequent changes in ministers and ministries have taken place. The president is also prime minister and heads a number of the ministries, including the Ministry of National Defense. Under presidential command, power is held by the National Gendarmerie, the Republican Guard, the river navy, the army (3,000 men, scheduled to be doubled), and the small air force, which consists of about 20 planes. All government officials must take a four-month military training course.

Administratively, the country is divided into 14 prefectures, 46 subprefectures, and four administrative control ports, established within subprefectures. Beneath the subprefecture level are mayors or burgomasters, who are also chairmen of local representative councils.

There is no expression of political opposition in the capital and no focus for concerted action for whatever discontent there may be in the provinces. The execution of the minister of health in 1969 effectively silenced any expression of independent action. In the early 1970s the only political party, the Mouvement d'Évolution Sociale de l'Afrique Noir (MESAN), was headed by the president.

Judiciary

Besides the Supreme Court, a court of appeals, and a criminal court, there are several lower tribunals and a

military tribunal. Judges are appointed by the president. The judicial system is loosely based on that of the French. There are traditional courts on the local (subprefecture) level. Disorders sometimes bring prison sentences of between five and ten years.

Social conditions. In the early 1970s between 70 and 80 percent of the population was illiterate. Over 170,000 children were receiving primary education in 2,700 primary schools; 7,200 students obtained a secondary education at 25 secondary schools and two teacher-training institutes; and some 800 attended a secondary technical school. There is also a school of administration, a technical college, the Agricultural College (École Territoriale d'Agriculture) in Grimari, and the agronomical institute in Wakombo. Higher education is available at the Jean-Bédel Bokassa Université de Bangui, which offers courses in law, science, and medicine. Of the university students who study abroad, a high proportion go to France. A trade school is to be established in Bangui for use of the members of the UDEAC.

Health and welfare

In the early 1970s the Bangui hospital was the main health facility, but there were also 36 hospitals on the prefecture level, 36 maternity clinics, about 100 dispensaries, and 200 first-aid posts. All but two of the country's 40 to 50 doctors were expatriates. Sleeping sickness, leprosy, and tuberculosis were rampant. A national institute for the training of public health personnel was established in 1968. Welfare benefits include maternity and child-care allowances.

Cultural life and institutions. Traditional tribal life in the countryside persists, and the stress on tourism is likely to increase the government's attention to the preservation of this cultural heritage. The Musée Ethnologique in Bangui contains exhibits of traditional musical instruments, implements of warfare, and village architecture, hunting tools, pottery, and religious objects. Written histories of the various tribes do not, however, exist.

The press is centred in Bangui. *Bangui La So*, published in French, is one of the two daily newspapers. Government publications include a weekly information bulletin and the *Journal Officiel de la République Centrafricaine* (published twice a month). Newspapers from France and Zaire are available in the capital, but all foreign news publications are censored by the government.

Radio Bangui (Radiodiffusion Nationale Centrafricaine) is owned and operated by the government. It broadcasts programs in French, English, and Sango to most population centres. A television station was being constructed in Bangui in the early 1970s.

Prospects for the future. In the early 1970s the lack of cash in the treasury seriously threatened the republic's economic and political stability. General Bokassa was making a determined effort to maintain good diplomatic relations with a large number of countries in order to overcome this handicap—for example, by possibly obtaining substantial support for the five-year development plan announced in 1971. This plan stressed agriculture, tourism, and forestry. The officially sponsored policy of "Centrafricanization" (replacing expatriate personnel with nationals) had shown few results in the private sector because of the lack of capital and trained manpower. Thus, most development projects were still in the hands of foreign companies that repatriated their earnings rather than investing them in the republic. Under the tense political atmosphere, economic recovery appeared uncertain. Meanwhile, the absence of a parliament prevented the airing of subjects of potential dispute between the political haves and have-nots.

BIBLIOGRAPHY. A good historical survey of the country's development is VIRGINIA THOMPSON and RICHARD ADLOFF, *The Emerging States of French Equatorial Africa* (1960). JOACHIM DE DREUX-BREGE, *Le Problème du regroupement en Afrique Équatoriale* (1968), treats historical development in the wider context of Equatorial Africa as a whole. For reliable and accurate information on current political, social, and economic developments, see the *Africa Research Bulletin: Political, Social and Cultural Series*, and *Economic, Financial and Technical Series*. The German journal *International Afrika Forum* performs a similar critical function. *Jeune Afrique*, supplement no. 423 (1970), provides a somewhat popularized but rather complete survey and description of industry, agriculture, and tourism. Statistical sources vary in their reliability because no official statistics have been released since *Annuaire Statistique de la République Centrafricaine* (1962). "L'Afrique d'expression française et Madagascar," *Europe/France Outremer* (June 1970) is, however, a relatively trustworthy source, although the figures may be somewhat inflated in an attempt to justify European and U.S. economic aid. Projected aid is described in *Development Plans for the CAR* published by the UNITED NATIONS DEVELOPMENT PROGRAM. There is a relatively large literature available on the refugee situation, including reports from the *United Nations High Commissioner for Refugees* (Geneva) and the *Commission on Interchurch Aid, Refugees and World Service* (World Council of Churches, Geneva); while more specifically, the CHURCH WORLD SERVICE, *M'Boki: A Style of Diakonia* (1969); and UNHCR, *The Promise of M'Boki* (March 1969), outline program aims and objectives of voluntary agencies. On cultural life and institutions there are few scholarly or other works.

(J.v.H.)

Central American and Northern Andean Cultures

The Central American and Northern Andean culture area comprises most of Central America (south from Guatemala) and the northern coast of South America (including the northern drainage of the Orinoco River); the West Indies are also customarily included. Although the area has meaning in terms of the distribution of indigenous cultures and languages, it does not coincide with any named region in a geographic sense, nor does it coincide with contemporary national political boundaries.

The area is situated entirely within the tropics, and the seasons are marked more by differences in precipitation than in temperature. Lowlands tend to be hot, but elevation tempers the climate on some of the islands and along the mountain ranges that run through Central America, Colombia, and Venezuela. Areas of heavy rainfall support dense forest, whereas a few dry regions support little more than sparse grass.

NATIVE PEOPLES

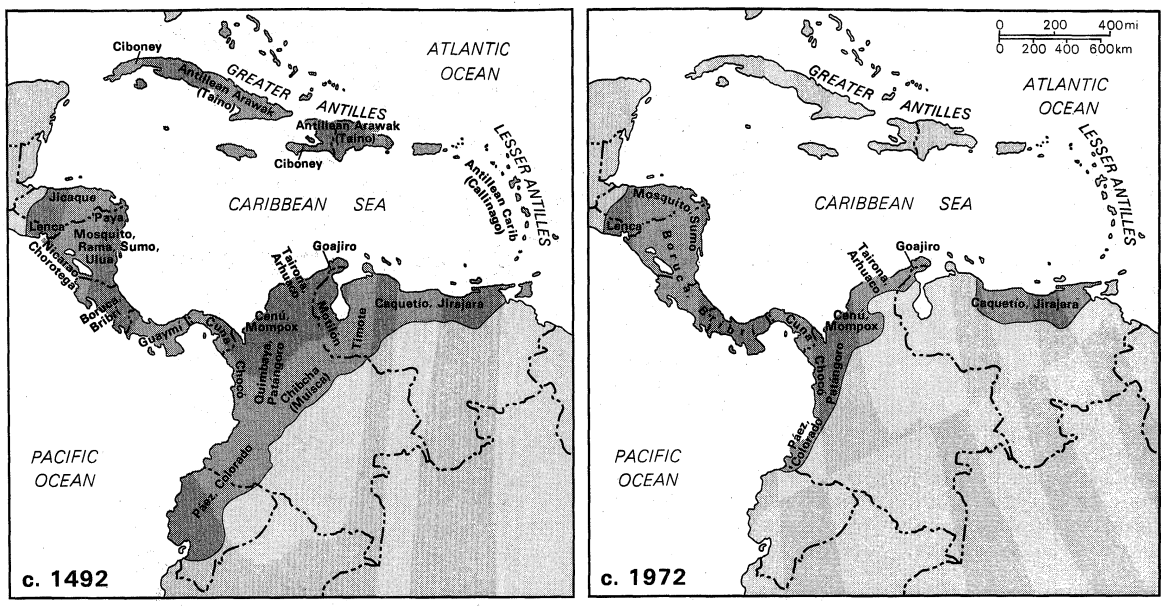
In archaeological terms, this area is of strategic significance for various reasons. First, as the relatively narrow corridor between the northern and southern continental land masses, Central America is a promising area in the search for remains of the ancient culture of the palaeo-Indians, of a generalized Mongoloid stock, who moved into South America at least 10,000 years ago. Second, an exceptionally rich and diverse variety of local cultures had evolved in the area by 500 BC. Third, between AD 1000 and 1500 the area was intermediate between the major centres of high civilization in Mexico and Peru.

In this region, unlike much of Latin America, most native cultures did not long survive the arrival of the Europeans, and there is controversy among anthropologists over whether many of the indigenous groups may, by reference to such criteria as language, patterns of beliefs and behaviour, or political affiliation, be justifiably designated tribes. Map 1 illustrates the approximate distribution of about 30 of the best known "tribes" in 1492; nearly 200 "tribes" were reported in early Spanish documents, but descriptions of most are sporadic and imprecise.

Native languages spoken in the area at the time of European conquest were many and varied. Although some historical and structural linkages can be traced with other groups in North and South America, individual languages reflect millennia of relative isolation (see SOUTH AMERICAN INDIAN LANGUAGES; MESO-AMERICAN INDIAN LANGUAGES).

PRE-COLUMBIAN CULTURE PATTERNS

Accounts of the indigenous cultures are fragmentary and based largely on occasional reports by missionaries, explorers, and soldiers. In some instances, widespread and apparently important cultures are represented by little more than archaeological evidence, but it is possible to



Distribution of Central American and Northern Andean cultures.

note a series of characteristic patterns and variations on those patterns that recur in the area.

Economic practices

With respect to basic subsistence, for example, intensive horticulture by the slash-and-burn (swidden) method was general. A variety of crops, including manioc, maize, sweet potato, bean, and others, were staples in various regions. Numerous other vegetables, as well as tropical fruits and sometimes cotton, were also grown in some areas. This form of horticulture is far more efficient than is popularly believed and produces abundant food without enormous or constant effort. In the cultures of this region, unlike many of those in the Amazon Basin, such intensive farming was usually done by the men. Improvements on the basic slash-and-burn pattern are rare throughout the world, but in this area they included irrigation, and even occasional terracing, by the Antillean Arawak, Arhuaco, Chibcha, Jirajara, Páez, and Timote, all of whom evidenced other cultural elaborations as well. In contrast with such highly developed groups, a few cultures in the area were based more on hunting or fishing than on even simple farming; among those were the Antillean Carib, Chocó, Ciboney, and Motilón.

The form and scale of communities tended to be closely linked to economic activities. Those groups, for example, whose subsistence base was fishing or gathering had the smallest houses and most dispersed settlement patterns in the area. Similarly, the largest and most permanent buildings, as well as the most densely populated villages, occurred among those tribes that had the most intensive and varied food production, including some with highly developed agriculture. The warring expansionist groups, such as the Chibcha and Guaymí, even built palisades around their larger towns, many of which included palaces and temples. Ball courts and large ceremonial plazas were constructed only among the Antillean Arawak, who were unusual in having communities with as many as 3,000 people.

Arts and crafts

The high degree of regional variation in crafts is probably related to the small scale of political organization, in which regional chiefdoms predominated. The hammock apparently originated in this area and was widespread; little other furniture was used. Houses varied considerably in size and shape, although virtually all had palm-thatched roofs and walls of thatch or adobe. A wide variety of baskets was made, usually by women; bark cloth was made in those few regions where loom weaving was unknown. Clothing was simple, usually comprising no more than a breechclout for men and a short skirt for women, and few remains of textiles have survived. Most of the Indians adorned their bodies richly, however, with painted designs, tattooing, and a wide variety of jewelry and feathered ornaments.

Nearly all of the peoples in the area made at least some pottery, and a few of the mainland groups produced exceptionally abundant, fine, and varied ceramics. Excellent in their own right, some of these wares reflect styles, media, and techniques from both the Andean and the Mexican centres of high civilization. The same few groups—notably the Chibcha, Chorotega, Guaymí, and Nicarao—carved jade and other stones and worked copper, gold, and several alloys with an unusual combination of technical skill, imagination, and aesthetic sensitivity. Abundant ornaments were made of metal and of precious and semiprecious stones, both for adornment and for interment in the graves of distinguished men, but few utilitarian tools are known.

Overland transportation was by foot, and widespread trade was carried on throughout much of the area without the benefit of either draft or pack animals. Dugout canoes, often of considerable size, provided transportation from island to island and along rivers.

Outposts of the sophisticated and warlike Aztec Empire extended as far south as the region inhabited by the Nicarao, where military and commercial operations linked what is now Costa Rica with Mexico. In the south, the Colorado and Páez peoples of the northern Andes similarly faced the frontier of an empire—that of the Incas—and carried on trade with the centre of high civilization in what is now Peru. The Chibcha proper (also called Muisca) comprised several feudal states, among whom war and tribute were commonplace, and their fine manufactures of gold, copper, and pottery became widespread through extensive trade. Not only were there regular markets but in some regions even a standard of exchange (namely cacao) was recognized.

The majority of the cultures of this region, however, were small chiefdoms, in which a single village or a small group of nearby communities was led by a chief whose semidivine position was inherited through the maternal line of descent. Such men were powerful within limited regions, but widespread confederations of such chiefdoms were rare, and warfare among them was typical in some areas. The Antillean Caribs, for example, had been encroaching on the peaceful Antillean Arawaks just prior to the arrival of the Europeans, taking both territory and captives. In general, it was the cultures with more highly developed agriculture that had the greatest degree of political integration, whereas those with the simplest subsistence economies rarely had any organization beyond the local community.

Religious practices

Shamanism for curing and sorcery, as well as popular worship of natural phenomena, was widespread. In areas of relatively dense population there were full-time religious practitioners who maintained temples dedicated to

idols at ceremonial centres. The elaborate and bloody state religion of the Aztec Empire extended as far south as the Nicarao region; the Chibcha practiced large-scale human sacrifice; and the cannibalism of the Antillean Caribs also apparently had some religious significance. A trait distinctive of the Antillean Arawaks was the *zemi*, a triangular carved stone that represented the hierarchically ranked individual guardian deities of each household in the society.

Social stratification varied in much the same way as political organization. It ranged from virtually absent among the nonagricultural Ciboney to fairly complex among the warring tribes that had highly developed agriculture. At most, four classes were differentiated: semidivine chiefs whose Arawakan name, *cacique*, has come through Spanish into English, who usually enjoyed considerable power and luxury; nobles (usually by descent but sometimes on the basis of wealth or military exploits), whose prestige and perquisites included little political authority; commoners; and often slaves. The meaning of slavery in this context is somewhat different from the Western tradition of using human beings as chattel. In many instances, women taken in warfare were kept as low status wives or concubines, their children not being slaves. Captive men were usually slain in religious sacrifice, as human trophies, or for cannibalism.

The idea that a man should have many wives was widespread, especially among chiefs and nobles, and descent was often reckoned through the maternal line, but there is no firm basis for popular accounts of female-dominated societies that were given by some early writers. An unusual outcome of the pattern of marriage with prisoners was the use of Arawak as "the language of women" in Carib society, illustrating how a vanquished people can change the customs of their conquerors.

Cuna Indian woman, Archipiélago de las Mulatas, Panama.
Dan Slaby

EUROPEAN CONTACT AND ITS AFTERMATH

The coming of Europeans resulted in the downfall of most of the cultures of the Central American and Northern Andean region. Few of the chiefdoms survived beyond the 17th century, and none exists in similar form today. Many of the cultures summarily described above are now extinct, including all of those in the West Indies and most of those in Central America. Vestiges of some cultures remain, significantly transformed, in a few areas remote from cities and roads.

Although this was the area first explored by the Spaniards, it was soon surpassed in importance by Mexico and Peru, both of which were rich in minerals and had large native populations accustomed to paying tribute in wealth and labour. Shallow sources of gold in the Antilles were quickly exhausted, and neither Central America nor the northern coast of South America offered much of interest to the conquistadors. None of the peoples of the region worked effectively under the Spaniards.

Disintegration of indigenous cultures

One striking feature that characterizes the history of contact with European culture in virtually every one of these instances is the disintegration or impoverishment of the indigenous culture. Whereas many observers might have expected new and increasing elaborations in those cultures that survived, the opposite has occurred. Agriculture is less varied and less productive; pottery and weaving are practiced less and are less sophisticated, and metallurgy has disappeared. Communities are generally smaller now than they were four centuries ago, and even regional political integration is lacking. The temples, warfare, and class stratification characteristic of many chiefdoms are gone, and, with few exceptions, the contemporary peoples try to avoid contact with others.

Although there had been warfare, trade, and other kinds of intercultural contact in pre-Columbian times, the impact of the Spanish conquest was different in kind as well as in scale, involving as it did not only unprecedented military power but also a wholly new economic system and a deliberate policy of reshaping Indian life to conform to European ideals.

One need not believe literally in the "black legend" about Spanish cruelty toward the Indians to understand the rapid depopulation of the West Indies. Newly introduced diseases took a heavy toll among the natives during the early years of contact, as did forced labour at unaccustomed tasks. Survivors often fled to the forested mainland coasts that were scorned as useless by the Europeans. Others quickly lost their cultural and racial identity as a result of mixture with Negroes who had been imported from Africa as slaves. Some of the mixed populations remained in the islands while others sought refuge from the Europeans on the coasts. Noteworthy among this latter group are the Black Caribs (descendants of Carib Indians and Africans, also called Bush Negroes), who went to British Honduras and Guyana.

There are, however, a few exceptions to the general pattern of extinction or isolation. The Cuna of Panama, for example, have become largely Hispanicized, but their colourful dress makes them an asset in terms of the tourist trade, unlike the similarly acculturated Lenca of Honduras. As early as 1550, the Goajiro of northeastern Colombia had virtually abandoned their pre-Columbian slash-and-burn horticulture in favour of an economic pattern previously unknown in the New World—the herding of goats and cattle. Small nomadic bands, based on ties of kinship, travel constantly to find pasturage within their limited and arid territories, which are the subject of frequent feuds. The hot, humid Mosquito Coast of eastern Honduras and Nicaragua was long used as a base by English loggers, buccaneers, and others who sought to undercut Spain's commercial and political dominance throughout the Caribbean, and the Jicaque, Mosquito, Paya, and Sumo Indians, as well as many free and runaway Negroes, collaborated with them. However, these peoples have again been relegated to a position that is economically and politically marginal.

During the 20th century the remaining cultures have resisted modernization to a degree unusual among Indians of the Americas. As pressures on their refuge areas mount, however, it is not clear whether they will adapt or become extinct.

BIBLIOGRAPHY. The most comprehensive work is still JULIAN H. STEWARD (ed.), *Handbook of South American Indians*, vol. 4, *The Circum-Caribbean Tribes* (1948). JULIAN H. STEWARD and LOUIS C. FARON, *Native Peoples of South America* (1959), provides a convenient summary and relates the peoples of the area to their neighbours. On the prehistoric and early historic periods, useful articles appear in GORDON F. EKHOLM and GORDON R. WILLEY (eds.), *Handbook of Middle American Indians*, vol. 4, *Archaeological Frontiers and External Connections* (1966).

(D.B.H.)

Central American States, History of

The independent states of Central America include Guatemala, Honduras, El Salvador, Nicaragua, Costa Rica, and Panama. British Honduras, also located in Central America, is a crown colony of Great Britain. The states enjoyed a brief period of federation in the 1820s and 1830s, after they gained independence from Spain and separated from Mexico. Since the 1840s, however, except for a few unsuccessful attempts at unification, their histories have been separate. Because of its location between the Atlantic and Pacific oceans, Central America has been important since the 16th century as a potential link between the two oceans. Indeed, both Panama and Nicaragua were considered for the interoceanic canal that was finally built across the Isthmus of Panama early in the 20th century.

The Maya Indians developed a flourishing civilization in Honduras, Guatemala, and at Chiapas and the Yucatán Peninsula of Mexico before the Spanish conquest in the early 16th century (see MESO-AMERICAN CIVILIZATION, HISTORY OF). Today, descendants of the Maya still live in parts of Central America and Mexico.

Spain ruled the Central American region for about 300 years, contending with English, French, and Dutch interests in the Caribbean. The danger of Caribbean invasion forced most Spanish settlements to develop away from the Caribbean coasts. Among the important Spanish cities were León and Granada in Nicaragua, Guatemala City, and San Salvador and San Miguel in El Salvador. The British attempted to settle several regions in Central America; successful settlements include those at Belize (British Honduras) and along the Mosquito Coast, but only British Honduras still remains in British hands.

British and United States commercial interests in Central America conflicted in the mid-19th century and were settled by the Clayton–Bulwer Treaty of 1850, which prevented either nation from controlling any region in Central America and guaranteed the neutrality of any route that might be built. The United States built railroads in Panama, Costa Rica, El Salvador, and Guatemala, which aided the development of banana plantations and the production of coffee and also brought large profits to U.S. businessmen. In 1901 the United States and Great Britain signed the Hay–Pauncefote Treaty, which allowed the United States to build the Panama Canal.

THE UNITED PROVINCES OF CENTRAL AMERICA, 1821–38

Independence from Spain. Central American political, military, religious, and university leaders proclaimed independence at Guatemala City in 1821, and the cities in El Salvador, Honduras, Nicaragua, and Costa Rica agreed with the decision. On September 15, 1821, the Spanish captain general of the *Audiencia* of Guatemala became the head of a new independent Central America. The Central American conservatives, however, preferred annexation to the new Mexican empire of Agustin Iturbide. Despite liberal opposition, conservative leaders in Guatemala City decided on the annexation to Mexico on January 5, 1822, believing that the new nation needed the protection of Mexico in order to survive. Salvadoreans, under Manuel José Arce and the priest José Matías Delgado, resisted the annexation and found sympathizers among Central American republican liberals, including those of Guatemala City. A Mexican army led by Gen. Vicente Filisola reached Guatemala City, where it reorganized the government and then invaded San Salvador, which resisted for several months before its defenses were finally broken.

Under attack from republicans in Mexico, Iturbide's empire fell in 1823, a triumph for Mexican and Central American liberals. Filisola then convoked a congress in Guatemala City, according to a provision of the 1821 declaration of independence.

The Central American congress

Federation. The congress prepared a decree of absolute independence from Mexico, Spain, or any other nation (July 1). It adopted a republican form of government, appointed an executive triumvirate, and demanded Filisola's departure. Filisola persuaded Chiapas to remain with Mexico, although its southern part, Soconusco, continued under Guatemalan jurisdiction until 1842. The congress designated itself the National Constituent Assembly of the United Provinces of Central America and formed a federal system, with the states of Guatemala, El Salvador, Honduras, Nicaragua, and Costa Rica as its members.

During the next year, the assembly made a series of institutional changes and revisions of public finance and suppressed monopoly and privilege. Indians were freed of tributes. Slavery was abolished (April 24, 1824), and many slaves fled to the new republic from British Honduras. A constitution was drawn up, and general elections were held in 1825. The Liberals gained enough strength in the federal congress to elect their candidate, Manuel José Arce, as the federation's first president. The Conservative candidate was José Cecilio del Valle.

Arce had problems finding qualified people to fill the executive offices of the government and in asserting his authority. Another problem developed because the central government was located in Guatemala City, which had not been placed under federal jurisdiction, and Juan Barrundia, the governor of the state of Guatemala, also remained in the city. Meanwhile, the congress appointed a French officer, Nicolás Raoul, as an adviser to its commission of defense. Raoul, however, refused to recognize Arce as the general in chief. Repeated differences forced Arce to order the capture of Raoul and the arrest of Barrundia. The vice governor of Guatemala, Dr. Cirilo Flores, left the city and moved to Quezaltenango, where he decided to make armed resistance against Arce. But local opinion in Quezaltenango, led by conservatives, turned against Flores, who was murdered by a mob.

Great ideological differences had developed between Arce and his own Liberal Party. The federal congress now refused to approve any more of the President's decrees, whereupon Arce assumed dictatorial powers and ordered that an extraordinary congress be elected to meet at Cojutepeque, in El Salvador. Meanwhile, he prepared to fight the Liberals of San Salvador, who were the leaders of the opposition. He won a victory over Salvadorean forces at the Battle of Arrazola, near Guatemala City, but the Liberals continued in open rebellion.

Conservatives now controlled Guatemala City and supported the federation, identified with Arce. While San Salvador resisted a federal siege, Francisco Morazán led an army from Honduras to rescue the city (1829). When part of the federal army left San Salvador to meet Morazán's forces, Salvadoreans broke the siege. Morazán defeated the federal forces at the Battle of Chalco and arrived in San Salvador as a liberator. Then, reinforced by Salvadorean troops and officers, he marched toward Guatemala City. Arce resigned his office. The Guatemalan Liberals welcomed Morazán, and the Conservatives signed a capitulation, giving up all resistance. When Morazán's followers allegedly found a secret cache of military supplies at the cathedral of Archbishop Casaus y Torres, the conditions of the capitulation were disregarded. Arce and the leading Conservatives were arrested and forced to leave the country, as was the archbishop. José F. Barrundia, brother of the former Guatemalan governor, became provisional president of the federation.

Morazán's liberation of San Salvador

The leadership of Francisco Morazán. Morazán gained the presidency in the 1830 elections and tried to restore peace to the republic. But he faced a Conservative uprising in Honduras and political unrest and economic difficulties in El Salvador, which was still the leader among the provinces. Morazán tried, with little success, to bring all the factions together. Meanwhile, Arce led a two-pronged invasion of Central America—one force from Cuba, the other from Mexico. Because these forces were weak, Morazán and Raoul overcame the invasion.

In the 1834 elections the Conservatives chose Valle to oppose Morazán. Valle won the election, but he died of natural causes a few days before congress could confirm the results. Thus, Morazán remained in office and set out to institute a radical program—a balance between

the states and the federal government. He moved the government to San Salvador. The congress issued constitutional reforms—accepted only by Nicaragua and Costa Rica—that strengthened the federal executive at the expense of the states. Changes in representative districts were planned: about half of the republic's population lived in Guatemala, and the eventual creation of one or two new states was proposed, to be taken from Guatemala. A federal district was also planned, possibly at Cojutepeque or Sonsonate.

In 1837 Guatemala, under the leadership of Gov. Mariano Gálvez, instituted a new penal code, based on that of Louisiana, which included jury trials and other reforms. But the new code faced strong opposition among the state's illiterate peasants and Indians. Gálvez finally ordered its suspension for political reasons.

An embittered public debate developed between Barrundia and Gálvez. The Liberal Party in Guatemala, already split, lost prestige. At the same time, a cholera epidemic had killed hundreds of Guatemalan peasants, particularly in the eastern provinces, which were the centre of unrest. The government tried to isolate the region and impose an effective quarantine. But the peasants were afraid of outsiders and doctors and were led to believe that the government had caused the epidemic by poisoning the water.

The rise of Rafael Carrera

A powerful popular movement took shape, led by a barely literate but charismatic mestizo, Rafael Carrera, who gained the help of the lower clergy, the support of the Conservatives, and the sympathy of Barrundia's followers, who saw a peasant rebellion as a useful tool to fight Gálvez.

Gálvez assumed dictatorial powers and imposed martial law. But Carrera, aided by the popular discontent and by the Conservatives and the church, both fighting for their survival, defeated Gálvez' forces in January 1838 and captured Guatemala City. Gálvez resigned, and Carrera was acclaimed a hero by Liberals and Conservatives.

End of the federation. Western Guatemala now demanded recognition from Guatemala City as a separate state—Los Altos, with its capital at Quezaltenango. The state legislature referred the matter to the federal Congress, which accepted Los Altos as the federation's sixth state.

The Congress passed a resolution in May 1838 that permitted each state to leave the federation. By April 1839 only El Salvador remained loyal; meanwhile, Morazán's term had expired in February, but no elections had been held to name a successor, and Carrera seized control of the state of Guatemala and assumed dictatorial powers. Early in 1840 Morazán invaded Guatemala, hoping to restore the Liberal government. On March 18 his army assaulted Guatemala City; Carrera had purposely abandoned the city, and Morazán captured it easily. Carrera then surrounded Morazán's army and inflicted a disastrous defeat. Morazán returned to San Salvador. He resigned his office and left for Panama and, later, Peru. Two years later he gained control of the Costa Rican government, but he was executed during an insurrection there (September 15, 1842). (Ed.)

NATIONAL HISTORIES OF THE CENTRAL AMERICAN STATES

Guatemala. The origin of the name Guatemala is certainly Indian, but its derivation and meaning are undetermined. Some hold that the original form was Quauhtemallan (which indicates an Aztec rather than a Mayan origin), meaning land of trees, and others hold that its origin was Guhatezmalha, meaning mountain of vomiting water, referring no doubt to the so-called volcano of water that destroyed Ciudad Vieja (Santiago), the first permanent Spanish capital of the captaincy general.

Under the Spaniards the capital was eventually established at Antigua, Guatemala; it achieved a certain magnificence, and the major towns acquired some aspects of Spanish culture, but the outlying areas were only lightly affected. When Antigua was razed by an earthquake in 1773, the capital was moved by royal order to the site of modern Guatemala City.

The colony developed no great degree of economic prosperity. The cultivation for export of agricultural staples, principally cacao and indigo, by Indian or Negro labour was the major economic activity, exclusive of production for subsistence. Commerce, however, was never extensive; a satisfactory port was never developed, internal transportation was difficult, and pirates harassed the coasts and preyed on shipping.

Early history. Following independence, Guatemala was the political centre of the Central American federation. The principal factor in the collapse of the federation was the backcountry uprising in Guatemala led by Rafael Carrera, who established himself as the military arbiter of the state (1838) and, from the executive's chair or from behind it, controlled policy until his death in 1865. Elections were dispensed with in 1854, when the presidency was conferred upon him for life.

Carrera, with Conservative support, returned Guatemala to a regime similar to that of the colonial period. He restored the Church to its position of privilege and power and catered to the aristocracy. He followed a nationalistic policy, and in March 1847 he formally declared Guatemala an independent and sovereign nation. In 1859 he made a treaty with Great Britain defining the status and boundaries of British Honduras, the interpretation of which is still an issue between the two governments.

Nationalistic policy

In 1871 a revolution headed by Miguel García Granados and Justo Rufino Barrios overthrew Gen. Vicente Gerna, Carrera's Conservative successor in office, and inaugurated a period of Liberal ascendancy that extended almost unbroken to 1944. After a brief period in the presidency, García Granados ceded to Barrios (1873), who became known as the Reformer because of the sweeping changes he introduced.

With the approval of the assembly, Barrios broke the power of the local aristocracy; brought the church under civil control and confiscated its properties; instituted lay education; promulgated a new constitution (1876); fostered the construction of roads, railways, and telegraph lines; encouraged development by private initiative of Guatemala's resources; and opened the country to foreign capital. He stimulated the cultivation of coffee to replace the declining trade in cochineal and enacted legislation designed to assure producers of a ready supply of labour. He was an ardent exponent of the idea of Central American union, and, when persuasion failed to produce the ends he desired, he invaded El Salvador and lost his life at the Battle of Chalchuapa (1885) in an attempt to accomplish them by force.

After the death of Barrios, Manuel Lisandro Barillas occupied the presidency. He was succeeded by José María Reina Barrios, a nephew of the Reformer, who was elected in 1892 and assassinated in 1898. Manuel Estrada Cabrera then became provisional president, regularized his status by an election, and by repeated reelections maintained himself in power until leaders of the opposition Unionist Party, with the cooperation of some of his former adherents, forced him from office by having the assembly declare him insane (1920).

Economic development and progress

During his long tenure in power, Estrada Cabrera fostered economic development and progress along the lines established by Barrios. He encouraged improvements in agriculture, made concessions to the United Fruit Co. (1906), owned by United States businessmen, continued to build roads, supported railroad construction, and had the satisfaction of seeing the railroad to the Atlantic completed. Health conditions were improved, and education, especially in practical fields, was stimulated. Estrada Cabrera's political policies were less admirable, however. He persecuted political opponents, disregarded individual rights and liberties, muzzled the press, and summarily disposed of his enemies.

After the fall of Estrada Cabrera the presidency was held by Carlos Herrara, Gen. José M. Orellana, Lázaro Chacón, Baudilio Palma, Gen. Manuel Orellana, and José María Reina Andrade, for periods ranging from a few days to nearly a full six-year term. In 1931 Jorge Ubico was elected president and began the fourth of Guatemala's extended dictatorships.

Contemporary period. Ubico stressed economic development and, in particular, the improvement and diversification of agriculture and the construction of roads. He balanced the national budget and transformed a deficit into a surplus. His financial achievement was due in part to economies, in part to the efficiency and honesty of his administration. Ubico's paternalistic policies toward the natives established him as their patron, although his vagrancy law (1934) made workers, especially Indians, liable to periods of forced labour at critical seasons. During his motorcycle tours of the country or in his office, he listened to their complaints and dispensed immediate "justice." This relationship deluded Ubico (called Tata, "father") into stating that Guatemala no longer had an Indian problem.

Education, which had received considerable emphasis under preceding Liberal regimes, was of but slight interest to Ubico. He closed several institutions of secondary level outside the capital, allowed teachers' salaries to remain at low levels, and, as a final disparagement, militarized the schools and required teachers and students to march in his parades and festivals.

Ubico's administration dramatized the degree to which Liberal thought had lost its idealism and was concerned principally with material progress. The new socio-economic groups that had been brought into existence by such innovations as lay education, mechanized transportation, and industrial development found no stimulation and no hope in the dreary materialism and military repression that had come to characterize Liberal regimes. These potential sources of opposition were solidified and focussed by the increasing disregard shown by the dictator for individual rights and liberties. The trappings of military dictatorship became increasingly evident, and the reorganized national police came to be regarded as an espionage force. Protests were answered by sterner restrictions and even by violence. The discontent was increased by economic dislocation during World War II and by the unfavourable contrast between the idealistic pronouncements of Allied war leaders and conditions in Guatemala. Ubico was thought to admire the totalitarian dictators, but in December 1941 his government declared war on Japan, Germany, and Italy.

Rise of opposition groups

In June 1944 a general strike forced Ubico to resign. Labour was allowed to organize, political parties were formed, and a presidential electoral campaign was begun, in which Juan José Arévalo soon emerged as the most popular candidate. Gen. Federico Ponce Vaides, head of the interim government, was ousted on October 20, 1944, by an uprising headed by students and teachers, workers, and younger elements of the military. A revolutionary junta presided over the drafting of a new constitution, the electoral campaign, and, in March 1945, the inauguration of Arévalo.

The Arévalo administration attempted to consolidate the social revolution implicit in the October uprising. A favourable labour code was enacted, and a social security system that promised progressive extension of benefits was inaugurated. Urban labour increased in strength, and the organization of agricultural workers began. Public school education was expanded and improved, teachers' salaries were increased, and the university was granted autonomy. Arévalo also pressed the Belize issue with Great Britain, subjected foreign enterprises to regulation that he conceived to be in the national interest, and attempted to guarantee Guatemalan labourers a larger share of the benefits produced by their toil and an improved status vis-à-vis foreign employees of foreign corporations operating in the country. Thus, the revolution and the Arévalo regime accomplished the transfer of political power in Guatemala from the military to a popular group, of which organized labour was the most important single element.

The transfer of political power during the Arévalo regime

Guatemalan Communists turned this development to their advantage. Lack of leadership from the labour rank and file allowed Communists to organize the labour movement and use it for their own ends. Arévalo was not friendly to their activities, but his nationalistic bent gave them opportunity to establish themselves as his most enthusiastic and reliable backers on issues for which he badly needed support. In this fashion they secured a degree of toleration that permitted them to operate.

The most likely candidates to succeed Arévalo were Francisco Arana and Jacobo Arbenz Guzmán. Arana was assassinated in 1949. Arbenz Guzmán became the official candidate, was elected—with Communist support—over Gen. Miguel Ydígoras Fuentes, and assumed office in March 1951. Arbenz Guzmán made agrarian reform the central project of his administration. With strong Communist support, the assembly passed a measure providing for the expropriation of unused portions of landholdings in excess of a specified acreage and for the distribution of the land, title to which remained with the government, among landless peasants.

The growth of Communist influence in Guatemala became the most controversial issue of the Arbenz Guzmán regime. The President's toleration allowed the Communist Party to operate openly and individual Communists to hold key posts in government, official agencies, and organized labour. Internal opposition to the trend was eventually stifled by increasingly terroristic means, but exiles and foreign recruits, headed by Col. Carlos Castillo Armas, planned outside the country to overthrow the government. When the invasion began, military officers informed Arbenz Guzmán that the army would not fight in his defense and forced him to resign (June 1954).

The rise of Castillo Armas

Castillo Armas emerged from a military junta as provisional president, and a plebiscite subsequently regularized his status. He attempted to extirpate Communist influence, moderate the social reforms inaugurated by his predecessors, and restore the confidence of foreign investment capital, but he was assassinated in July 1957. After two temporary governments and an election nullified by the Congress, Gen. Miguel Ydígoras Fuentes of the National Democratic Reconciliation Party was declared elected to the presidency and took office March 2, 1958. In March 1963 a coup led by the defense minister, Enrique Peralta Azurdia, ousted Ydígoras on grounds that his failure to prevent the return of Arévalo to the country heightened the possibility of an extremist victory in the election scheduled for November 1963. As provisional president, Peralta Azurdia cancelled the election, promising to hold one later. The frustration, during these regimes, of the social reforms promised by the revolution of 1944 made restive elements of the population increasingly receptive to counsels of resistance and even of resort to violence.

On March 6, 1966, Guatemalans elected a new president and a new Congress. Violence was feared, but orderly ballotting gave a law professor, Julio César Méndez Montenegro, candidate of the moderately left-wing Revolutionary Party, an unexpectedly large plurality over Col. Juan de Diós Aguilar de León, candidate of the military regime, and Col. Miguel Ángel Ponciano Samayoa. Méndez Montenegro did not obtain the majority of votes required for election, but the new Congress, in which the Revolutionary Party had gained a majority, declared him elected. The government was thus returned to a civilian head, but its hopes of reform were largely frustrated, and its attention was absorbed by increasing acts of violence and terrorism, including the assassination of the United States ambassador and two members of the United States military mission in 1968.

The presidential election of March 1, 1970, also was orderly, although violence and the kidnapping of the Guatemalan foreign minister, Alberto Fuentes Mohr, marked the pre-election period. None of the three candidates—Col. Carlos Arana Osorio, backed by the right-wing, anti-Communist coalition; Mario Fuentes Pieruccini of the Revolutionary Party; Jorge Lucas Caballeros of the Christian Democratic Party—received a majority of the vote. On March 21 the Congress named Colonel Arana Osorio president. (W.J.Gr.)

Honduras. Early in the colonial period a silver strike in the highlands brought a rush of prospectors to Honduras (1570s), resulting in the rise of an important population centre at Tegucigalpa. The coastal area along the

Caribbean became a rendezvous for the pirates and buccaneers who preyed on the Spanish treasure ships and attacked the colonial ports. Later, the region, with its fine logwood forests, attracted the English, who by the end of the 18th century controlled the Mosquito Coast from the Río San Juan, in Nicaragua, to Belize, and also the Islas de la Bahía offshore.

Early history. Francisco Morazán, elected to head the Central American federation in 1830, was a Liberal whose impact on his native Honduras and on the confederation was in terms of liberalism, a principal goal of which was the curtailment of the power and age-old privileges of the church and the clergy. Honduras declared its absolute independence on November 5, 1838. The Conservatives in Honduras took control under Francisco Ferrera, who was inaugurated as the first constitutional president January 1, 1841.

Conservative domination in the late 19th century

The domination of the Conservatives, in Honduras and generally throughout Central America, lasted until the 1870s. The church was restored to its former commanding position. In 1861 the Honduran government signed a concordat with the Holy See, as Guatemala had done a few years before. The ascendancy of Justo Rufino Barrios in Guatemala influenced a return to liberalism in Honduras, where Marco Aurelio Soto, a Liberal, assumed the presidency (1876). A new constitution (1880) sought to undo the work of the Conservatives. Five years later, when Barrios attempted to revive the old Central American union by resorting to force, Liberals in Honduras and elsewhere proved to be nationalists first and blocked this attempt at domination by Guatemala. This resulted in a return to power by the Conservatives almost everywhere.

Twentieth century. During the second half of the 19th century, Honduras was often disturbed by interference from Guatemala. In the first decade of the 20th century, interference came from another quarter—the current strong man in Nicaragua, José Santos Zelaya, who put Miguel Dávila into the Honduran presidency. This led in 1911 and 1912 to something more serious than periodic revolutions. The United States president William Howard Taft was pressured to send marines to protect United States banana investments in Honduras, which by this time had grown considerably and included the Cuyamel Co., the Standard Fruit and Steamship Co., and the United Fruit Co., all exploiting this Honduran product. All three companies had made large capital outlays in the form of improved port facilities, railroads, workers' settlements, and similar developments in the plantation area, the lowland region along the Caribbean coast.

In 1918, during World War I, Honduras declared war on Germany but took no active part in the conflict. Political upheavals continued after the war. In 1932, after years of unrest, a strong man, Gen. Tiburcio Carías Andino, was elected president and remained in office until 1949. Carías dealt with several abortive revolutions during his virtual dictatorship. During World War II Honduras declared war on Japan on December 8, 1941, and on Germany and Italy on December 13. Lack of shipping occasioned much economic distress during the war. Export surpluses of bananas, coconuts, and copra piled up, leading to widespread unemployment and consequent unrest. But the government was able to maintain itself, and it promulgated some beneficial reforms. The United Fruit Co. increased wages for its employees and inaugurated several new enterprises, such as the planting of improved Hevea rubber trees and the raising of the tropical fibre-yielding plant abaca. Carías survived a revolution in 1947, but two years later the combination of two rival parties proved his undoing.

Wartime economic problems

Juan Manuel Gálvez assumed control and sought to restore constitutional guarantees. In 1954–56 there was a short-lived dictatorship by Julio Lozano Díaz. During this regime a ten-week strike of United Fruit Co. workers, fomented quite openly by Communist elements, led to a new labour code that gave the workers the right to organize and to bargain collectively.

Despite impressive gains on the labour front, Hondurans were restive under the Lozano Díaz regime. He was unseated by a bloodless coup in October 1956, and a three-man junta took control of the country. The junta, headed by Col. Héctor Caraccioli, quickly won the confidence and support of the people and took steps for the election of a constituent assembly, set for September 1957. Earlier in 1957 Honduras had a border dispute with Nicaragua over rival territorial claims to an area north of the Río Coco, which flows eastward to the Atlantic. Prompt action by the Organization of American States (OAS) prevented hostilities. (The International Court of Justice awarded the area to Honduras in 1960.)

The constituent assembly, elected in September 1957, met in October, drafted a constitution, and availed itself of the power, written into the constitution, to choose the president. The Liberal leader, Ramón Villeda Morales, was elected and took office on December 21. His first official act was to proclaim the new constitution in force; this replaced the 1936 constitution, which had been suspended in 1954.

On October 3, 1963, ten days before the scheduled presidential elections, Villeda Morales was deposed by a military coup led by Col. Osvaldo López Arellano, who declared himself head of state, dissolved the legislature, and cancelled the elections. A nationwide election of delegates to form a constituent assembly, early in 1965, resulted in victory for López Arellano. The assembly convened in March 1965, elected him president, and approved a new constitution, which differed little from that of 1957.

Summer 1969 brought a war with El Salvador, called the Soccer War. The conflict, triggered by a soccer game, resulted actually from severe economic and demographic problems (see below *El Salvador*). Though quickly ended by the OAS, the war dampened hopes for economic and political integration of Central America.

In March 1971 Ramón Ernest Cruz was elected president of Honduras for a six-year term. Cruz, the National Party candidate, narrowly defeated Jorge Bueso Arias, the Liberal nominee. (W.M.Cl.)

El Salvador. The provinces of Sonsonate and San Salvador developed separately under the Spaniards. Sonsonate was the smaller of the two but remained wealthier until the cacao trade declined under competition from Ecuador. San Salvador grew more slowly, with dependence upon stock raising, general agriculture, and the manufacture of indigo, but it eventually became more important. The city of San Miguel was included in San Salvador's territory as was the Spanish town of San Vicente and Cihuatehuacán (Santa Ana), an Indian centre, which grew second in size to the city of San Salvador. By the late 18th century both provinces had large mestizo populations with some mixture of Negro blood as well. Most of the important "Indian" villages, including Ahuachapán, Chalchuapa, Zacatecoluca, Cojutepeque, Suchitoto, and Usulatán, were becoming progressively non-Indian in their customs.

Role in early-19th-century affairs

Independence. San Salvador played an active role in the rapid evolution of Central American affairs from 1811 to 1840. The first Central American defiance of Spain occurred there in November 1811, inspired by the deeds of Miguel Hidalgo y Costilla in Mexico and led by another priest, José Matías Delgado (who aspired to become San Salvador's first bishop), and his nephew, Manuel José Arce. Both this attempt and another in 1814 failed. When the government in Guatemala declared independence from Spain, on September 15, 1821, subject to the approval of a Central American congress, the authorities in San Salvador went one step further (September 22) and declared absolute independence. Although San Salvador, which became a state in the Central American federation, tried unsuccessfully to secede in 1832 and 1833, the federal capital was transferred there in 1834. After the union ended in 1839, Francisco Morazán, its second and last president, was forced to leave San Salvador in 1840.

The Republic of El Salvador (The Saviour) was named on January 30, 1841, but only provisionally so until 1856. It then underwent 45 years of checkered history,

in which Conservatives (heirs of the opposition to Francisco Morazán) battled with Liberals (the Morazán party, generally the more interested in a renewal of the Central American union) for control of the country. Both groups found support from and lent assistance to similar parties in the neighbouring countries. In the midst of the turmoil, El Salvador organized its first university and was finally established as a bishopric. Agitation quieted somewhat during the longer administrations of Francisco Dueñas (served 1863–71), who was backed by Conservative elements in Guatemala, and Rafael Zaldívar (served 1876–85), a protégé of Dueñas who nevertheless maintained friendly relations for some time with Liberal administrations in all the bordering republics. Coffee, introduced as a crop in 1840, was exported in sizable quantities by the 1870s. Zaldívar successfully opposed the move of President Barrios of Guatemala to reunify Central America by force (1885), but he was pushed out of office soon after Barrios was killed.

Coffee became all-important to the country's economy in the period from 1885 to 1931, while international conflicts became less frequent and the presidential succession more regular. Violence upset only one of the eight four-year terms that followed each other starting in 1899. But the relative absence of turmoil did not bring democracy. Each president was succeeded by a friend or close relative, and all power remained in the hands of the wealthy. But the coffee plantations flourished; companies from Britain and the United States built a national network of railroads; the port of La Unión was developed; the population more than doubled (passing the 1,000,000 mark); and El Salvador enjoyed some of the blessings of peace.

Military dictatorships. An attempted step toward democracy in 1931 led to a military dictatorship instead. Pío Romero Bosque, president in 1927–31, decided not to control the election of his successor. When no candidate won a majority of the popular vote, Arturo Araujo was chosen by congress, but he was overthrown by force before the year was out. Gen. Maximiliano Hernández Martínez, who came to power through that coup d'etat, maintained authoritarian rule until 1944. Hernández Martínez established a new coinage system, organized a national bank, completed the Inter-American Highway across the country, and extended state control over the coffee industry. But he also followed a ruthless policy toward his critics, not hesitating to use mass executions when he felt them necessary. Although considered sympathetic to the Axis powers at the beginning of World War II, he declared war on the Axis and received benefits from the Allies.

Hernández Martínez' resignation came after a fierce revolt, which brought bombings and fire to the capital as well as a general strike. Salvador Castaneda Castro took office March 1, 1945, after elections, and lasted until December 14, 1948, when a military junta took control. Maj. Oscar Osorio, prominent in this junta, was the popular choice in new elections of March 1950. His political group, the Partido Revolucionario de Unificación Democrática (PRUD) dominated the political life of the country until 1960. Material progress during Osorio's term (1950–56) was considerable. Significant sales of cotton were added to El Salvador's coffee exports, and a few modern industrial plants were constructed. The development of a hydroelectric power project on the Río Lempa, the asphalting of the Inter-American Highway, and the construction of a new east–west highway closer to the Pacific all gave the country new potential. Low standards of living continued to prevail for the masses of underpaid workers, but various measures, including government construction of low-cost homes, held some hope for their future.

Dominance of PRUD

Lieut. Col. José Maria Lemus of PRUD was elected president in 1956, when all the opposition parties either were barred from the ballot or withdrew from the race. PRUD also held all the seats in the national legislative assembly after elections of 1956 and 1958. Lemus continued the policies of his predecessor; he carried out public works projects, undertook a variety of measures to buoy sagging price levels for coffee, and arranged a treaty with Guatemala for mutual hydroelectric developments utilizing the waters of international Lago de Güija. Continued one-party rule in the face of mass discontent with low standards of living, however, led to the ousting of the government by force on October 26, 1960.

Plans for a democratic election were sponsored by the six-man junta that ruled El Salvador for the following three months. Those efforts were foiled, however, when another junta seized control on January 25, 1961, and arranged a constitutional convention with the sole participation of its own new Partido de Conciliación Nacional (PCN). Lieut. Col. Julio Adalberto Rivera, that party's candidate, was elected without opposition as president for five years beginning July 1, 1962. Rivera reformed the income tax, set a minimum wage for agricultural labour, and allowed fairer elections for municipal offices and the national assembly in 1964 and 1966. Business prospered, and many new industries were founded, in large part a response to El Salvador's participation in the Central American Common Market.

Minority parties that gained much attention during the Rivera tenure in office were the Christian Democrats, of the democratic left, and the Partido Acción Renovadora (PAR), which dropped a conservative leadership and took on a strong Marxist flavour. Lawyer Abraham Rodríguez for the Christian Democrats and university rector Fabio Castillo for the PAR contended in the 1967 presidential election, which was won by Col. Fidel Sánchez Hernández of the PCN, who gained 54 percent of the vote. Sánchez' moderate stand on a border dispute with Honduras in the election year enabled his opposition to play on Salvadoran nationalist feelings; in 1968 PCN retained only a one-vote majority in the National Assembly.

War with Honduras. The continued strength of the military was evidenced once again in El Salvador in 1969 in a crisis that Sánchez did not initiate but in which he consented to play a prominent role. The occasion came in response to a new bad feeling between Honduras and El Salvador. A Honduran agrarian reform, passed in 1962 but not executed until May 1969, made it impossible for persons born outside Honduras to participate in distributions of public land. Individuals who left crowded El Salvador to seek a better living in Honduras were affected by this legislation, and it revived memories of the border dispute of 1967 and of the unresolved national frontier line.

Causes of the Honduran war

Emotions were already running high when El Salvador and Honduras became engaged in a three-game soccer series to determine the Central American representative to a world soccer event. The games led to disruptive violence, with each nation's communication media carrying atrocity stories. Salvadoran charges seemed to take on substance when some 15,000 of the 300,000 Salvadorans who lived in Honduras fled that country.

Both sides complained to the OAS, which investigated the alleged terror. Before those investigations had been completed, however, El Salvador opened hostilities July 14, dropping bombs on Honduran airports and driving into Honduran territory. Honduran planes reciprocated with bombs, but Honduran ground troops did not invade El Salvador. After a few days the main contention became whether or not the Salvadoran troops would withdraw before guarantees were made concerning persons of Salvadoran birth living in Honduras. The OAS demanded and finally received (July 29) an agreement from El Salvador to withdraw unconditionally, and the Salvadoran delegation was promised that the OAS would intervene to protect the rights El Salvador believed had been abridged. Ill feeling between El Salvador and Honduras remained as they ceased buying one another's products while carrying on protracted negotiations for peace.

OAS settlement

President Sánchez, widely thought to have been pushed into this war by elements in his army, nevertheless chose to support another colonel, Arturo Armando Molina, for the presidential term beginning July 1, 1972. The chief opposition in the elections held in February 1972 was the Christian Democratic candidate, the mayor of the capital city, José Napoleón Duarte. Also running for the

office were José Alberto Medrano, head of the army during the war, and José Antonio Rodriquez Porth. Molina, the PCN candidate, won a plurality in the voting and was elected president by the National Assembly.

Nicaragua. Nicaragua's name is said to have been derived from that of Nicarao, an Indian chief whose people lived on the shores of Lago de Nicaragua. Under Spanish rule the cities of Granada and León developed strong political and commercial rivalries. Granada became a centre of conservatism and of trade: León, of liberalism and agriculture. The country to the east and north, called the district of Tologalpa by the Spaniards, had a separate history because of the lack of Spanish settlement. Negroes from the West Indies gave parts of the coast a new racial complexion. By the mid-17th century a few permanent settlements were formed, including that at Bluefields. Later in the same century Great Britain formed an "alliance" with the chief of the Miskito tribe (of mixed Indians and Negroes), and from 1740 to 1786 the Mosquito Coast, containing many English residents, was counted as a British dependency.

Independence. In December 1811 the governing intendant of Nicaragua was deposed in a revolution inspired by the struggles in Mexico and El Salvador. Ill feeling between León and Granada was intensified when León returned early to the royalist cause and Granada bore the brunt of the punishment for disobedience. León declared independence from Guatemala on September 28, 1821 (following Guatemala's act of independence from Spain, September 15), but Granada chose to stay with Guatemala. Both accepted union with Mexico (1822–23) but fought one another until 1826, when Nicaragua was organized as a state in the Central American federation. Dissension remained the order of the day until 1838, when Nicaragua left the federation and continued as part of the general isthmian struggle between Liberals and Conservatives.

Foreign intervention. Meantime, in the east, relations between the "king" of the Miskito peoples and the British government were strengthened to the point where English officials were again living in Bluefields. San Juan del Norte was seized by the British in 1848.

The discovery of gold in California brought attention to Nicaragua's strategic position between the oceans. The Accessory Transit Co. of the American Cornelius Vanderbilt, which carried passengers by steamship and carriage from San Juan del Norte to the Pacific, began operations in 1852. An adventurer, William Walker from Tennessee, invited to assist the Liberals in warfare in 1855, brought new excitement to Nicaragua. By 1856 Walker had made himself president of the country. In 1857 he was routed through the joint efforts of the five Central American republics and the Accessory Transit Co.

William Walker's invasion

Tomás Martínez, who assumed the Nicaraguan presidency in 1857 and held it for ten years, was the first of a line of Conservative chiefs of state who ruled until 1893. Under them Nicaragua enjoyed relative peace, though with little democracy. The capital was placed in Managua as a compromise between Granada and León. The first railroads were built, agriculture was revived to some extent, and a treaty with Great Britain (1860) provided for the nominal reincorporation of the eastern coast with the nation under the form of an autonomous reservation. José Santos Zelaya, Liberal president from 1893 to 1909, established real Nicaraguan jurisdiction over the Miskito peoples and increased his power to the point where he could interfere in the affairs of Honduras and El Salvador. Two great writers sprang from Nicaragua during this quieter half century—Rubén Darío became recognized as one of Latin America's greatest poets; Salvador Mendieta was a distinguished diagnostician of his own region's ills, who dedicated his life to the rebuilding of a Central American union. Both men were critical of the new interest taken in isthmian affairs by the United States once the decision was made to build the Panama Canal.

A new era in Nicaraguan history involved intervention by forces of the United States government. Philander Chase Knox, secretary of state under U.S. president William Howard Taft, became angered at the 1909 execution of two U.S. citizens who had participated in an anti-Zelaya revolution. When Zelaya resigned late in 1909, the United States refused to recognize his successor, José Madriz. In 1910, U.S. naval forces prevented government occupation of Bluefields, the revolutionary headquarters, an act leading directly to the success of the revolution. When new civil war broke out in 1912, U.S. forces took a direct hand in support of Adolfo Díaz, president from 1911 to 1917. The 100 marines stationed at the United States Embassy also helped to maintain the peace under Pres. Emiliano Chamorro Vargas (served 1916–21) and his nephew successor, Diego Manuel Chamorro (served 1921–23). United States bankers meanwhile managed the Nicaraguan customs collections, the national bank, and the railway. The Bryan–Chamorro Treaty of 1916, between the U.S. and Nicaragua, gave the U.S. the right to build and operate an interoceanic canal across Nicaragua and to establish naval bases on the Gulf of Fonseca and the Corn Islands. The treaty was terminated, however, in 1970.

Withdrawal of the marine guard (1925) led to new complications. Rebellion by Chamorro against a new administration brought Díaz back as a compromise president (1926–28), reinforced by 2,000 United States Marines. Díaz was opposed in a civil war (1927) led by Juan Bautista Sacasa, Gen. José María Moncada, Gen. César Augusto Sandino, and others. Though elections in 1928 under U.S. auspices brought Moncada to the presidency, followed in 1933 by Sacasa, Sandino fought on against both his old friends and the marines and came to typify for many Latin Americans the cause of resistance against *yanqui* imperialism.

Recent developments. Sacasa's inauguration (January 1, 1933) terminated the stay of the U.S. Marines. Within a year Sandino made peace with his government. Prominent on the scene by then were the Nicaraguan National Guard, carefully trained by the U.S. Marines before their withdrawal, and its commander, Gen. Anastasio Somoza García, nephew of the President. In February 1934, just after he had dined with Sacasa, Sandino was assassinated by members of the National Guard with Somoza's approval. Against Sacasa's wishes Somoza decided he would next have the presidency, though both his position and his family relationship made him ineligible. Constitutional problems were "solved" by the deposition of Sacasa (June 1936) and Somoza's temporary relinquishment of the guard command. Somoza became president on January 1, 1937, backed by a coalition of segments of the old parties. Leonardo Argüello, his defeated opponent, had received support from the traditional parties.

The rise of Somoza

Somoza controlled Nicaragua for the next 20 years. A new eight-year term commenced March 30, 1939, under a revised constitution, which increased the power of both the President and the National Guard. In 1945, after caudillos (military strongmen) had been removed from office in El Salvador and Guatemala, Somoza announced that the guard would remain loyal to the winner of the next elections. When Argüello won those elections and took office May 1, 1947, Somoza (still at the head of the guard) had him ousted within a month. Somoza's uncle, Víctor Manuel Román y Reyes, who was chosen to succeed by the party organization of Somoza's National Liberal Party, was president until he died May 6, 1950. Somoza subsequently reassumed the position of president and was elected to another six-year term beginning May 1, 1951. A pre-election agreement with Emiliano Chamorro guaranteed the opposition a minority voice in the new congress.

The development of a small gold mining industry by foreign capital in the 1930s gave the nation its first sizable export commodity. Strict economic dictatorship was coupled, after 1941, with wartime cooperation with the United States, which brought material benefits to Nicaragua. After the war an aura of prosperity developed, with new large plantings of coffee and cotton for export (subsistence crops suffered badly for a time), establishment

of textile and food-processing industries, and the organization in 1953 of a private shipping line—Marina Mercante Nicaragüense (Mamenic). But observers noted the extent to which Somoza family holdings bound the economy together, while the people at large benefited little from the rise in national income.

A constitution in 1950, written by agreement between Somoza and Chamorro, provided that no president of Nicaragua might be re-elected and that no person might be elected to the office who had exercised the presidency temporarily during the last six months of the term or who was a relative of the president. Despite these provisions, it became clear as Somoza's term progressed that he intended to succeed himself. A serious attempt to assassinate Somoza failed in 1954. On September 21, 1956, a few hours after he was nominated by his National Liberal Party for six more years in office, he was shot by Rigoberto López Pérez; he died eight days later. But the death of Anastasio Somoza García did not end the rule of his family.

Continuing dominance by the Somoza family

The National Liberal majority in congress gave 34-year-old Luis Somoza-Debayle his father's position at once. A younger son, Anastasio Somoza-Debayle, remained head of the National Guard. Luis was then nominated as the National Liberal candidate for the presidency in his father's stead and was duly elected for the term 1957–63. The son ruled somewhat more gently than his father had, even seeing that the constitutional provisions concerning the presidential succession were reinstituted in 1959. The opposition Traditionalist Conservatives and Independent Liberals nevertheless backed an unsuccessful attempt by Enrique Lacayo Farfán to unseat the regime by force in that same year and refused to participate in the 1963 elections when the President would not ask supervision by foreign and neutral observers.

René Schick Gutiérrez, a close friend of the Somozas, thus easily won the presidency for a four-year term beginning May 1, 1963. Nicaragua's economy prospered during the Schick years, in part because of its participation in the Central American Common Market, but the basic financial plight of the great majority of the people remained unchanged. Schick died in office on August 3, 1966, and was succeeded by Lorenzo Guerrero Gutiérrez, selected by Congress to fill out the term. In January 1967, Fernando Agüero Rocha, the Traditionalist Conservative opponent, tried unsuccessfully to promote a general strike in favour of electoral guarantees. Anastasio Somoza Debayle then won the election for the presidency for a five-year term, 1967–72. In 1971, it was announced that a junta would rule from 1972 to 1974, while the Congress engaged in constitutional reform. After two years, Somoza would be constitutionally eligible to enter the presidency again. The so-called "Somoza dynasty" would thus continue. (F.D.P.)

Costa Rica. The name Costa Rica, or "rich coast," was possibly the result of Columbus' discovery of gold there. Another explanation is that the name is a corruption of *costa de oreja* (earring coast). Under Spain most of the people of Costa Rica were poor farmers whose only income came from the illegal sale of tobacco to Panama or to British smugglers. Costa Ricans viewed Guatemala as the source of their poverty because taxes were levied from that city and officials were sent from there to enforce the Spanish mercantilist laws.

Early history. Along with the rest of Central America, Costa Rica became independent on September 15, 1821, when word was received that Mexico had successfully revolted against Spain. Although its poverty and lack of population caused Costa Rica briefly to join Mexico and, in 1824, to join the Central American federation, many citizens favoured a policy of complete separation from isthmian politics. The Ticos, as they called themselves, felt unique among Central Americans. Because the Indian population of the country was slight, there were few mestizos, and a large percentage of the people were pure white. There was little mineral wealth and no landed aristocracy. While the general cultural and economic level during the early 19th century was low, there were no sharp class distinctions. Few Costa Ricans could be considered wealthy, and there was no vast labour supply awaiting exploitation as in the Indian lands of Spanish America. These differences from the rest of Central America, coupled with distrust of Guatemalan power and size stemming from colonial times, brought about a policy of isolationism. With the dissolution of the Central American federation, the last official ties were soon broken, and in 1838 Costa Rica went its own way. Subsequent attempts among the five nations to revive the federation met least response in Costa Rica.

Development of isolationism

Poor communication and distrust by peasants brought about serious provincial rivalries and also reflected a desire of opposing groups to possess the capital city. In colonial times the capital city was Cartago; a brief civil war in 1823 brought the capital to San José. Rivalry between Cartago, San José, and other towns led to the "Ley de Ambulancia" of 1834, which provided that the government of Costa Rica be rotated every four years among the four largest towns. Much of this competition declined in later years as San José grew much more rapidly than the others.

Foreign demand for coffee brought Costa Rica a steady income. Beginning in the 1840s a constant train of oxcarts carried coffee from the *meseta central* to Pacific ports and European-bound ships. British investment in Costa Rica was large. Small farmers could derive a simple, comfortable existence, and the groundwork was laid for a rural society that demanded schools and roads from its government and found political participation necessary to achieve these goals.

Costa Rica shared the Río San Juan with Nicaragua and suffered from some of the canal fever and filibustering that nearly destroyed its northern neighbour. The two nations were often on bad terms because of disputes over boundaries (settled by treaty in 1896) and because the large province of Guanacaste seceded from Nicaragua and joined Costa Rica in 1825. British interest in Costa Rica and North American activity agitated this rivalry in the mid-19th century. But when William Walker invaded Nicaragua in 1855, Costa Rica came to its assistance and, under the leadership of Pres. Juan Rafael Mora, defeated Walker at Rivas, in Nicaragua.

Material progress during the Guardia administration

Costa Rica was not without some of the political partisanship found elsewhere in Central America, but it was less bitter. Material progress came about rapidly under the administration of Gen. Tomás Guardia, who dominated Costa Rica by dictatorial methods from 1870 to 1882. The government curtailed liberty and enlarged the national debt but brought substantial increases in sugar and coffee exports and began widespread school construction. A new constitution was adopted in 1871 and continued in effect until 1949. The railroad building program during the 1870s and 1880s ended Costa Rica's isolation from the world. With funds borrowed mainly from Great Britain, Costa Rica began to link the *meseta central* with the seaports. The chief promoter was an American, Minor C. Keith, who made a fortune with the opening of a rail line between Cartago and Limón. Keith entered the banana business, as did others, on the basis of vast land grants from Costa Rica for building the railway. Thereafter, bananas regularly rivalled coffee as the chief source of income for Costa Rica. In 1899 the United Fruit Co. took over Keith's investments.

The last decades of the 19th century were marked by a gradual relaxation of Roman Catholic Church activity in secular affairs. The Jesuits were expelled for a few years, cemeteries were secularized, and public education was expanded. The constitution of 1871 provided religious toleration, although the government continued to support the Roman Catholic Church. A law of 1886 provided free and compulsory public education. A normal school, a museum, and a national library were founded.

In spite of great bitterness, a truly democratic election in 1890 resulted in victory for José Joaquín Rodríguez—some scholars consider this the first entirely free and honest election in Central America. It helped dramatize and strengthen the tradition of democracy for which Costa Rica is famed among Latin American nations.

Twentieth century. When Nicaragua, in the Bryan–Chamorro Treaty of 1916, gave the United States permission to use the Río San Juan, between Nicaragua and Costa Rica, as a portion of an interoceanic canal route, Costa Rica protested that its rights in the river were being ignored. The claim, based on a treaty of 1858 and reaffirmed in an award of Pres. Grover Cleveland, was brought before the Central American Court of Justice. The court ruled that Nicaragua had violated Costa Rican rights, but both Nicaragua and the United States refused to accept the decision. This case was a significant factor in the destruction of the court.

Dispute with Panama

Costa Rica's boundary with Panama (originally with Colombia) was not delimited until 1941. An arbitration award by the president of France in 1900, confirmed by the Chief Justice of the United States in 1914, was generally favourable to Costa Rica but was rejected by Panama, which continued to hold part of the disputed area. Finally, in 1921, Costa Rica attempted forcible occupation of the Coto region (on the Pacific coast), which had been adjudicated to it. Large-scale hostilities were averted only by the intervention of the United States in support of Costa Rica's claim. Panama thereupon evacuated the Coto area, but relations between the two countries were broken until 1928, and the dispute continued. A treaty of settlement was made in 1938, but opposition in Costa Rica was so strong that the treaty was withdrawn from Congressional consideration unratified. Finally, in 1941, the government of Rafael Ángel Calderón Guardia reached an agreement with Panama delimiting the common boundary.

When Costa Rica held an election under a system of direct suffrage for the first time in 1913, no candidate won a majority; the congress then chose Alfredo González Flores as president. One of González' supporters, Gen. Federico Tinoco Granados, became disgruntled with a tax revision and other reforms proposed by the González government and staged a successful revolution in January 1917. Tinoco failed to take advantage of his popularity, however, and behaved despotically at times. His administration was hindered by the refusal of the U.S. government to recognize regimes brought into office by force. During World War I, under Tinoco, Costa Rica declared war on Germany, but the president of the United States, Woodrow Wilson, succeeded in keeping Costa Ricans from participating in the Treaty of Versailles discussions. Numerous revolts and the danger of intervention caused Tinoco to resign, and he went into exile in 1919.

Julio Acosta García was then elected president and was promptly recognized by the United States. Under Acosta and succeeding presidents, Costa Rica acquired the reputation of being the most democratic and orderly republic in the Americas. It continued its tradition of democratic elections and nonmilitary rulers. President Acosta was followed in orderly succession by Ricardo Jiménez Oreamuno (1924–28), who had served earlier, Cleto González Víquez (1928–32), Jiménez for a third term (1932–36), León Cortés Castro (1936–40), Rafael Ángel Calderón Guardia (1940–44), and Teodoro Picado Michalski (1944–48). A literacy test for voters was adopted in 1920 and a secret ballot in 1925. The country participated for a few years in the activities of the League of Nations but withdrew in 1924. On December 8, 1941, the day after Japan attacked Pearl Harbor, the Costa Rican congress declared war on Japan even before the United States did, and on December 11, 1941, it declared war on Germany and Italy.

Political crisis in 1948

Costa Rica's only serious political crisis after 1917 came in 1948. A faction containing some alleged Communists tried to prevent the seating of president-elect Otilio Ulate. José Figueres, a Socialist landowner, put down the rebellion and turned the government over to Ulate. A new constitution was adopted in 1949. Figueres soon turned against Ulate and was legally elected president in 1953. He nationalized the banks and threatened the United Fruit Co. and power company holdings. Aided by the OAS, Costa Rica in 1955 repelled an invasion by exiles in Nicaragua. In 1958 Mario Echandi Jiménez was elected president to succeed Figueres. Echandi was succeeded in 1962 by Figueres-backed Francisco J. Orlich Bolmarcich. Orlich in turn supported Daniel Oduber in the 1966 election, but Oduber was defeated by José Trejos Fernández. In 1970 José Figueres again won the presidency.

After 1950 Costa Rica changed dramatically. It still relied heavily on agricultural exports for income but assumed many aspects of an industrialized society. The number of commercial and industrial establishments expanded greatly, and urban growth increased about 50 percent faster than did the nation as a whole.

In March 1963 the presidents of Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua, and Panama met with U.S. Pres. John F. Kennedy in San José. Kennedy emphasized contributions in financial aid under the Alliance for Progress to bolster the region's economy.

In March 1963 Mt. Irazú erupted and poured sulfurous ash over much of the Meseta Central. Crops and animals were poisoned, and many persons in Cartago and San José became ill. The volcanic ashfall continued into 1964 and brought serious dislocation to Costa Rica's economy. By the mid-1960s the eruptions had ceased, and the economy began to recover. The annual increase in population as well as gross national product exceeded 4 percent, very high figures for Latin America. (T.L.K.)

Panama. Panama was an important part of Spain's commercial system, and Portobelo was the centre of Spain's commerce in the New World until the British admiral Edward Vernon stormed Portobelo in 1739. Nine years later the port's great annual fair was discontinued. Political subordination paralleled economic decline, and in 1751 the isthmus was demoted to a dependency of Santa Fe de Bogotá, Colombia.

Union with greater Columbia. Panama proclaimed its independence from Spain in 1821, but after a few months it voluntarily joined the Colombian union. In 1826 representatives of the Latin American states met in Panama, where they passed resolutions for union and confederation. For a time Panama enjoyed considerable local autonomy under New Granada, but in 1843, under a new constitution, the executive power at Bogotá was greatly strengthened, including the appointment of provincial governors. Tomás Cipriano de Mosquera, elected president of Colombia in 1845, negotiated the building of the Panama Railroad and concluded a convention with the United States by which that country guaranteed the neutrality of and free transit across the isthmus. During the late 19th century Panama was beset by chronic civil strife up to 1903, the year of its independence.

Canal plans and construction attempts. The gold discoveries in California in 1849 provided the impetus for building the railroad, which upon completion in 1855 encouraged the canal builders. The Universal Interoceanic Canal Co., headed by the builder of the Suez Canal, Ferdinand de Lesseps, began construction, but legal entanglements, fraudulent financial arrangements, and, particularly, disease precipitated the collapse of the company in 1889.

United States interest in a canal

The possibility of the completion and the control of a canal under foreign auspices and the journey of the United States warship "Oregon" around Cape Horn during the Spanish–American War prompted a considerable agitation in the United States for a U.S.-controlled canal. Pres. William McKinley sent a commission to consider a canal built by the United States. In 1901 the United States signed the Hay–Pauncefote Treaty with Great Britain, gaining the right to build and operate a canal on the isthmus (guarantees were later added to keep the canal open to merchant and war vessels of all nations); the United States made a separate agreement with France regarding construction rights in 1902. The Hay–Herrán Treaty was signed in 1903, by which Colombia authorized the United States to build a canal across Panama; but the Colombian Senate rejected the treaty.

Panamanians, fearing that the canal would be built across Nicaragua instead, planned a revolt against the Colombian government and requested United States support. The United States promised no aid; but on November 2, 1903, a U.S. warship, the "Nashville," arrived at

Colón. Colombian troops were thus prevented from crossing the isthmus, and on November 3 Panama proclaimed its independence from Colombia. On November 6 the United States recognized the new republic.

According to the terms of the Hay–Bunau Varilla Treaty of November 18, 1903, the United States gained from Panama, in perpetuity, the exclusive use, occupation, and control of the Panama Canal Zone. Formal U.S. acquisition took place on May 4, 1904. Construction on the canal was completed on August 15, 1914.

The Republic of Panama. On February 13, 1904, a constitution was adopted, which contained a provision authorizing U.S. intervention and which provided for a centralized government headed by a president, with four provincial governors appointed and dismissed by will of the president. This arrangement was altered in 1917 and 1919 to allow popular election of president, vice president, and governors. The constitutional convention of 1904 unanimously elected Manuel Amador Guerrero as the first president. Subsequent elections were tumultuous, and in 1908, 1912, and 1918, United States military forces intervened to preserve order.

The political history of the republic remained stormy, and there were many internal upheavals. At the outbreak of World War II, American ministers of foreign affairs met at Panama City and in the Declaration of Panama announced, in October 1939, a 300-mile-(500-kilometre-) wide neutral zone around the Americas. Panama declared war on Japan on December 8, 1941, and on Germany and Italy on December 12. To strengthen defenses, the United States requested that Panama provide sites outside the Canal Zone for landing fields, roads, and warning stations. The election of the pro-Fascist Arnulfo Arias to the presidency in June 1940 led to protracted negotiation in which the Panamanian government demanded conditions and compensations. Among these were a monetary compensation for the sites, cancellation of a road construction debt, the transfer to Panama of certain properties of the Panama Railroad Co., water and sewer systems of Panama and Colón, the assignment of surplus power from Alhajuela Dam, and the building of a bridge over the canal. In addition, Panama requested a short-term lease for the sites, Panamanian use of the airfields, and partial criminal jurisdiction in the sites. In domestic matters Arias prompted a change in the constitutional base of government so as to extend the length of his term and to expand the sphere of his power.

U.S. military sites in Panama during World War II

Recent developments. Although U.S. army units were authorized to begin operations on one of the sites on March 6, 1941, the negotiations were not terminated until May 18, 1942. This conclusion was facilitated when Arias was deposed in October 1941 and succeeded by Ricardo Adolfo de la Guardia. Insofar as war circumstances permitted, the Panamanian conditions were met, and the U.S. Congress approved legislation providing the necessary funds in April 1943.

During and after the war the United States returned 98 defense sites to Panama, and the two countries engaged in long negotiations on the remaining 36. Agreement was reached, but the Panamanian assembly, influenced by public pressure, rejected the proposals, and the sites were abandoned in 1947.

The political pressures that led to the refusal by Panama to permit willingly the continued U.S. occupation of the military bases played a part in the return to the presidency of Arnulfo Arias in 1949. In 1951 opposition to him was stimulated by his closing of the privately owned Federal Trust Co. Political and financial opponents called a general strike, and a run on a government-supported savings bank brought swift changes. The arrest of the former president Ricardo de la Guardia, for inciting trouble, was followed by the suspension of the constitution and the reimposition of the 1941 authoritarian constitution. The balance of power lay with the national police force and its leader, José Remón. The Arias regime was overthrown in 1951, and the vice president, Alcibiades Arosemena, succeeded to the presidency.

In the elections of May 11, 1952, Remón won a decisive victory, but his tenure was cut short by assassination on January 2, 1955. His successor, José Ramón Guizado, held office only a few days because he was convicted of conspiring to kill the President. Ricardo Arias Espinosa presided over the government in 1955, a year notable for the flow of capital into Panama. Work on the Inter-American Highway and on local roads was promoted by a loan of $9,650,000 from the International Bank for Reconstruction and Development. In 1957 the Panama Refining and the Panama Refining and Petrochemical companies began investments that eventually were to total an estimated $93,000,000 in two oil refinery establishments. New synthetic rubber and plastics industries were also announced.

Industrial expansion in the 1950s

Ernesto de la Guardia, Jr. was inaugurated president on October 1, 1956. His administration, auspiciously begun, did not run smoothly. In the spring of 1958, student riots led to the imposing of a state of siege and the threat of a general strike. The settlement of May 31 pointed to the nature of the antagonism that had been generated; the tenure of guardsmen was thenceforth limited, and their control of the jails ended. The finding of caches of arms, the quelling of riots, and charges of subversive plotting marked the late summer days of that year. The new year provided little respite, for disorders occurred in each of the first four months, and Independence Day produced an ominous march into the Canal Zone to raise the Panamanian flag there; the march was turned back.

Roberto Francisco Chiari was the successful contender for the presidency in 1960. With a national debt of about $83,000,000 and a budget deficit of approximately $10,000,000, he announced plans for a vast program of slum clearance, housing, health services, and hospital construction. By comparison with the debt, the loans from the Inter-American Development Bank and the Development Loan Fund for housing and road construction, and the grant under the Alliance for Progress program, appeared small. Serious differences of opinion developed in 1963 over the type of development plans to be favoured. Gravel-surface feeder roads and housing for low income groups competed with more permanent highways and housing and schools for middle income groups. The plans for aiding the poor found a champion in former president Arnulfo Arias. He was defeated in a close contest for the presidency in May 1964 by Marco A. Robles, supported by President Chiari.

Under the Robles administration the economy of Panama was uneven. The riots of January 1964 reduced the income from the Canal Zone and frightened away foreign capital. Unemployment in Colón and Panama City totalled 10 percent of the nation's work force, and agricultural development continued to be much retarded. Gradually, however, loans from abroad became more plentiful, and income from the Canal Zone rose, due in part to the war in Vietnam and the closing of the Suez Canal. Tax reforms were instituted, bringing the government more income and distributing the burden more equitably. Restlessness among the populace occasionally broke into open rioting, which Robles suppressed through the use of the National Guard. Particularly severe were disorders in March–May 1968, when Arnulfo Arias, again a candidate for the presidency and in control of the national assembly, unsuccessfully attempted to bring about the impeachment of the President.

Arias won the election of May 12, 1968. He took office as president on October 1, only to be removed 11 days later through a coup of the national guard, led by Col. Omar Torrijos. The new government promised economic and administrative reforms and elections by mid-1970 under a new constitution and electoral law. The junta named Col. José M. Pinilla president.

Negotiations to change the treaty structure between Panama and the United States began in 1954. The agreement of August 23, 1955, provided for an increase in the canal annuity from $430,000 to $1,930,000 and for the transfer to Panama of certain lands and improvements, including Punta Paitilla. The United States agreed to the imposition by Panama of taxes on those working in the

U.S.–Panamanian treaty negotiation

Canal Zone, except for citizens of the United States and certain others. It yielded its monopoly over communication systems, any rights to build roads, and its obligations concerning sanitation in Panama City and Colón. In 1958 President Guardia expressed the desire for equal status for the Panamanian language and flag in the Canal Zone. That year the United States Congress appropriated $19,000,000 for a bridge across the canal, and an instrument of transfer was signed that conveyed to Panama real estate valued at about $25,000,000. The disorders in 1958–59, with the demands to fly the Panamanian flag in the Canal Zone, led to recognition by U.S. president Dwight D. Eisenhower that titular sovereignty over the zone resided with Panama and to the display of the flags of both nations at a specified place in the zone.

President Chiari, soon after his inauguration, announced his intent to seek a revision of the treaty structure between his country and the United States; and in 1962 he conferred with U.S. president John F. Kennedy. In July 1963 the two presidents issued a communiqué announcing various benefits for the Panamanian employees in the Canal Zone: a binational labour commission was to be created; health and life insurance equal to that enjoyed by United States citizens were to be made available; and the minimum hourly wage was to be raised.

Violence in 1964 precipitated a severe deterioration of relations between Panama and the United States. American students in Balboa, contrary to rule, displayed a U.S. flag at their school. About 200 Panamanian demonstrators then marched peacefully into the Canal Zone, but they triggered widespread violence upon their return to Panama. Mobs engaged first the police and then the military forces, resulting in more than 20 dead and many injured and in severe property damage. Panama severed diplomatic relations with the United States and accused it of aggression. Spokesmen for the United States denied the accusation and accused the Panamanian government through a directed press and radio of inciting people to violence and of delay in restoring order. Panama brought its charge before the United Nations Security Council but without a request for specific action. Its complaint was referred to the Inter-American Peace Committee and, after that body's efforts failed, to the OAS. The discussions were protracted because Panama insisted upon agreement to a revision of the treaties between the two disputants as a precondition to re-establishing relations, while the United States refused to proceed under precommitments.

Negotiations between the United States and Panama during the first part of the Robles administration led to three new treaties in June 1967. The first abrogated the 1903 accord, reduced the size of the Canal Zone, and provided for the joint operation of the canal. The second continued the responsibility of the United States for the zone's defense, and the third provided for a possible sea level canal, built by and at the cost of the United States but jointly administered. These proposals aroused objections from many affected quarters, and they remained unratified through the tumultous period of the election and deposition of Arias in 1968. The junta that succeeded Arias was recognized by the United States on November 13, 1968. From the junta, Col. Omar Torrijas emerged as the controlling power. He rejected the draft treaties concerning the Canal Zone, but new talks with the United States began in 1971. Following a 1972 election, the junta was confirmed in power with a six-year term; Torrijas remained in control, as chief executive. (A.R.W.)

British Honduras (Belize). British Honduras is known to most Central Americans as Belice. It was formerly called Belize or Balize. The earlier name may be a corruption of the name of the Scotsman Peter Wallace, a pirate who came to the region in the 1630s.

After the collapse of the great Maya civilization in about the 9th century AD, the population receded from what is now British Honduras. This inhospitable and deserted coast was not invaded by the Spaniards until English logwood cutters settled on it in about 1638 and began to break Spain's valuable logwood monopoly. The Spaniards made periodic attempts by force and diplomacy to expel these competitors, culminating in a major naval attack in 1798 that was routed by the British settlers and their African slaves. Living conditions created good relations between masters and slaves, and abolition was readily accepted.

When, in 1847, the Indians in Yucatán rose in revolt against their white Mexican overlords, thousands of refugees sought sanctuary in the northern part of British Honduras. The territory was formally proclaimed a British colony in 1862 and was subordinated to the governor of Jamaica until 1884, when it became a separate colony.

Disagreements over the extent of British holdings in Central America led Great Britain to disputes with the Central American federation and later with separate Central American states. Great Britain signed separate treaties with Honduras, Nicaragua, and Guatemala in 1859–60. In 1859 Guatemala and Great Britain signed a trade convention that provided for a cooperative effort to build a road to benefit the trade of both countries. The proposed route ran from the Lago de Izabal (Guatemala) to Guatemala City, and the cost was not expected to exceed £100,000. But when the joint engineers surveyed the route, their estimate came to £145,465, and Guatemala undertook to seek a less costly route. Before this could be found, trade conditions changed and rendered the proposed road of little value to either party. Guatemala repeatedly rejected Great Britain's offer to settle the dispute over British Honduras before the International Court of Justice, preferring to present the matter to the UN or the OAS. The claim was submitted to United States mediation in 1965, but no solution was obtained. It remained unresolved into the 1970s. (Ed.)

Central Asian Cultures

Central Asia comprises the inland part of Asia, furthest removed from the world oceans, in the midst of the greatest land mass on earth. Because of its geographic location, prevailing winds, and drainage, it is a zone of great aridity, extending from the Caspian Sea in the west to northwestern China and Mongolia in the east, and from southern Siberia in the north to northern Iran and Afghanistan in the south. Throughout the region rainfall never exceeds 12 inches (300 millimetres) in an average year, far too little to grow grain; parts of Central Asia receive less than 4 inches (100 millimetres) of rain per year. The exception is near mountain ranges, where there is higher rainfall and a more rapid change from one climatic and ecological zone to the next. The prevailing winds blow from west to east, losing their moisture before reaching the inland parts of Asia. Consequently all agriculture requires artificial irrigation.

Natural zones

There are four major natural, or ecological, zones of Central Asia: steppe, steppe-desert, desert, and mountain. All are vast arenas for the interaction of such natural forces as wind and water, land forms, mountain building, vegetation, and animal life. Only recently and in a minor way has man disturbed the ecological processes in the area. These ecological zones run in broad stripes from east to west across Eurasia. The northernmost zone is the steppe, covering Mongolia and northern Kazakhstan, extending into southern Siberia and eastern Europe. The steppe is a belt of grassland covered in the spring and summer with a tall, feathery grass. The terrain is flat, almost featureless, with few rivers and mountains. The grass cover is denser toward and within the European parts; there the steppe is somewhat wetter and more lush; in eastern Kazakhstan the grass cover thins out, becoming the dry steppe. Central Asia is tilted downward from the east. Mongolia is a high-altitude steppe, averaging about a mile above sea level; Kazakhstan is low-altitude steppe, lying at sea level. Steppe-desert (semidesert), too, is grassland, drier than the steppe, lying at low altitude and not extending into Europe or Siberia. There the grass cover is thinner than in the steppe, although of the same types, with greater aridity and patches bare of plant cover increasing in size and number toward the south. It is likewise flat terrain with few water courses and no mountains. The desert has the greatest aridity of the region, grasses yielding to dry vegetation (called xerophytes) and supporting desert fauna. There lie the innermost parts of Asia, south of the steppe and steppe-desert, furthest from the moisture-bearing winds and the seas, with most intensive water evaporation. The Central Asian deserts are vast, spreading from the Red Sands (Kysylkum) of Turkmenia to the Black Sands (Karakum) of southern Kazakhstan, to Sinkiang, and to the Gobi, a system of separated arid places scattered in southern Mongolia. The regime of aridity in Turkmenia extends to southwest Asia in Iran and Baluchistan because of the same forces of wind, land forms, and water courses. The mountain zone lies in the southeast of Soviet Central Asia, the Pamir Ranges rising to nearly five miles as part of the highest mountain systems in the world, connecting with the Himalayan range to the south.

The cereal grasses, including various forms of wheat, are native to the region, being found wild even at present. They were domesticated by the early farmers and have been continuously bred since. Other crops, such as rice and cotton, are historically recent imports. The grasses of the steppe and steppe-desert are a favourable livestock fodder. Animals native to the steppe include the wild horse still found in modern times and cattle in prehistoric times; the wild yak is native to the mountains of Tibet and Mongolia; mountain fauna include wild sheep and goats; desert fauna include the camel and still other goat species. All these animals, when domesticated, play the central role in the herding economy. They are raised for food, trade, and transport.

The few rivers are water-poor and do not link the urban centres; their channels are shallow, narrow, and shifting. They flow only inland, some into the Caspian, Aral, Balkhash, and lesser lakes of the region; others lose themselves in the sands of the desert. Many are seasonal rivers, dry in summer. They are of limited usefulness for transport and navigation. Most importantly, however, they irrigate bands of fields along the rivers.

Transportation is chiefly overland; hence the importance of the domesticated animals: the world historical significance of Central Asia was that it served in the manner of a great inland sea, connecting China, India, Iran, and Europe by means of camel, ass, and horse caravans that moved goods and peoples, permitted military invasions, and spread technology, religions, cults, ideas, and science through and across its breadth.

The vegetation and fauna of the arid zone made possible two great indigenous economic specializations: first, irrigation agriculture developed near the valleys of the Amu Darya, the Syr Darya, the Ili, and the Zeravshan rivers, and in such mountain valleys as the Fergana; second, and equally important, specialization in pastoralism occurred. The pastoralists occupy the steppe and steppe-desert belts, where grasses and water provide sustenance for their livestock. Those herding communities living in the vicinity of the deserts bring their flocks there in the spring when the desert briefly flowers.

The two economic branches, agricultural and pastoral, were mutually supportive, each being dependent on the products of the other. Each had a characteristic habitat to which their economies were adapted—the cultivators along the river valleys, the herdsmen out on the steppe—hence, they were great ecological specializations as well.

The peasants lived in permanent settled villages, in houses of sun-dried brick. Their villages were apart from the fields. The herding families lived in tents of felt stretched over lattice frames that they collapsed and packed into carts, moving from pasture to pasture. Their communities were always mobile, each family having a camel or two to pull the family cart, its tent, and possessions; horses to transport goods and carry the herdsmen to, from, and around the pastures; mares and cows for breeding and milking; sheep and goats for milk and wool. They owned many sheep and goats but small numbers of the other stock. The herdsman camped upon the pastures.

Languages of the area

The traditional languages of the region are members of the Altaic and the Indo-European families of languages. The Altaic family comprises three major divisions: Turkic, Mongolian, and Manchu-Tungus; the first two are represented in Central Asia and neighbouring parts of Siberia and China; the third division, found in Siberia and China, is not significantly spoken in Central Asia. The Turkic speakers in Central Asia are Kazakhs, Kirgiz, Uzbeks, Kara-Kalpaks, and Turkmens. The Mongolian speakers include the Khalkhas of Mongolia, Buryats of southern Siberia, Kalmyks of the Volga, and several groups in the neighbouring provinces of China (Ordos, Chahar, Monguor). The traditional Indo-European speakers of Central Asia are the Tadzhiks, speaking an Iranian language and thus related to the Indic, Slavic, Greek, Romance, Celtic, and Germanic speakers. In ancient times Central Asia was inhabited by a number of other Iranian-speaking groups (Scythians, Massagetae, Parthians). Central Asia has in recent centuries received new migrants from Russia and the Ukraine.

The Turkic, Mongolian, and Iranian speakers of Central Asia were encountered in antiquity, and modern peoples in the region are their descendants, mixed together with the later immigrants, invaders, settlers, and resettlers. None are pure races.

TRADITIONAL CULTURE PATTERNS

Continental setting. The historical period in Central Asia began about 500 BC with the rise of the traditional

cultures. These cultures flourished about AD 500 down to the 20th century, when the region was absorbed in the great revolutionary movements emanating from Russia and China.

Pastoral culture patterns

The cultural pattern of the herdsmen grew rapidly, and, according to Chinese reports, these peoples by the 3rd century BC had already formed the herding communities that they now have. The Chinese reported that their country "is the back of a horse," meaning that the communities were nomadic.

The herding village community moved as a single unit across pastoral tracks that they owned and defended, for if others used their tracks their own herds would die for lack of grass or water on the way from pasture to pasture. Herds and men spread out in the summer pasture, gathering in closely during the winter encampment. The herdsmen defended the herds from predacious beasts, such as wolves and snow leopards, and helped the herds to forage beneath the snow. They helped the mares to foal, the cows to calve, and the lambs and kids to find the teats of their mothers beneath the woolly undercoats. The herds provided food (mainly milk, rarely meat) and materials for clothing and housing. The pastoralists were traditionally nomadic; that is, they moved about in small communities together with their herds in fixed annual round, from winter camp to spring and summer pastures, and back to the winter camp. The Kazakhs, Kirgiz, Turkmens, Uzbeks, and Karakalpaks raised herds of horses, cattle, sheep, goats, camels, and asses; the Mongols raised all of these except the ass; in the east, the Mongols of Mongolia also raised the yak.

The cultural pattern of the Central Asian irrigation-cultivators differed little from that of the great agricultural civilizations neighbouring them in China, Iran, India, and the Near East. Water was scarce, and thus life depended on careful maintenance of the soil and water systems by village communities that collectively coordinated their labour and managed their resources. The result was an ability to support great populations in dense concentrations, ranging up to hundreds of persons per square mile. Harnessed to the needs of their livestock, the pastoral peoples stood in sharp contrast: they spread out thinly over the landscape, their average density being no more than two or three people per square mile.

Irrigation required a collective and planned effort and a peaceful inner regime so that the peasants could work together. War disturbed these efforts both by preventing peaceful labours and by drawing the peasants away to military defense and attack. When wars came, the irrigation channels deteriorated, and civilizations raised upon them disappeared rapidly.

The Tadzhiks had an old tradition of agriculture in Central Asia; the Turks, their neighbours, originally herdsmen, gradually developed an agricultural wing to their village economies. Over centuries agriculture became increasingly important among the Uzbeks, somewhat less so among the Turkmens, Kazakhs, and Kirgiz. The agricultural peoples grew grain (rice and wheat), cotton, and vegetables and raised fowl. Central Asia, together with Iran and Sinkiang, is still a world centre of melon growing; many fruits and nuts such as the peach, pistachio, and almond originated there.

Exchange systems

Mongols and Turks became highly specialized herders and undertook little or no agriculture. They traded for most of their agricultural needs with farmers who were likewise specialized. The Mongols traded with the northern Chinese, who spared no land for pasture; and the Turks traded with the neighbouring cultivators, some of whom were Turks, some Chinese, and some Iranian (Tadzhiks, Persians). Neighbouring Chinese, Iranians, and the farmers of Central Asia similarly depended on the herders for pastoral products, being bound together in great institutional networks of economic exchange, their products distributed in the bazaars and caravan trade and collected and offered as political tribute—actions of great economic significance. Marriage ceremonies also were occasions for ritual presentations and gifts in localized exchanges. The great institutional networks embraced the entire Asian continent, as well as parts of Europe and North Africa during the period of the nomadic empires in the Middle Ages. The most highly specialized relation was that of the Mongols and the Chinese; the former monopolized the herding, the latter the farming of east Asia. Their symbiotic system was not a smoothly working mechanism; it broke down frequently, accompanied by wars and unrest among the great economic wings and civilizations.

Social organization. The Central Asian Turks and Mongols had the same kinship system, founded upon the principle of common descent reckoned patrilineally, from father to son. The founding father and his son or sons formed a kin-village community, together with their wives, children, more distant collateral kin, dependents, and clients. The villages were maintained by the direct male descendants over a number of generations, forming new ones as the population grew and the need for land increased. Families related by descent and marriage lived in a common household, raised the crops or herds together, and maintained a common economy. Several such great families, whose founders were related as brothers or close cousins, formed a village. Each family owned stock and land in common; the agricultural village was the unit of management of the cultivated land and the irrigation channels; the nomads' village was the unit of range (pasture, camp, and track) management.

Marriage rules

A son brought his wife to the paternal household; the daughter joined that of her husband and his father. Marriage with several wives was practiced, but it was costly and rare. In arranging marriages, elders would trace ancestry back to the sixth generation and even further. In theory, a marriage was permitted only if a common male ancestor existed beyond the sixth generation. This restriction meant that a marriage partner could be found not only out of the village, but out of the neighbouring villages or districts, because these villages were generally composed of kinsmen descended from a common male ancestor only four or five generations removed. The kin-community clusters formed a local district and had a number of economic functions, managing the pastoral range land, maintaining local resources and pasture tracks, and fending off incursions. They also provided troops of horse to the imperial armies when levies of men were made.

The village of the sedentary agricultural peoples of Central Asia was likewise composed of patrilineal extended families, but the long lineage organization of the herdsmen was not found there. Marriage outside the peasant village community was nevertheless required; the husband took his wife to the father's household; and the daughter left the family into which she was born to join that of the husband, under the patriarch, his father. The peasant villages were bound to the political system of the Oriental empires, which centred on the great cities.

Political organization. At the base of the Mongol empire of Genghis Khan, which flourished in the 13th and 14th centuries, stood the nomadic kin communities that were clustered in groups, tracing descent through the male line from a common male ancestor and living on a common territory. These descent groups formed a clan ruled by a chief. The clan chief was a relative in the father's line of every member of the clan. He was a minor nobleman and the senior member of the highest line traced back according to the principle of primogeniture to the founding ancestor. The differentiation into aristocracy and commoners began at this point. The clans were grouped into clan confederations, and these in turn into principalities, with the nobility becoming ever grander. At the peak stood the emperor, who was related in theory to every Mongol in the first to twentieth degree or even higher. He was, however, also surrounded by courtiers and retainers, warriors who respected neither kinship nor grandeur in carrying out the imperial commands. The Mongol empire ruled briefly over most of Asia and eastern Europe when the strength of the herding peoples prevailed over the agricultural empires whose leadership was broken down. Life in the villages below went on as before.

The peasant villages were linked in local exchange sys-

tems with the herding communities; the empires of herdsmen and agriculturists were linked in great, continent-wide exchange institutions. When these institutions of trade, tribute collection, and exchange broke down, one side would sweep in and conquer the other. Thus Genghis Khan and his dynasty prevailed during the 13th century. China then was using its soldiers to maintain internal order and could not keep the nomads out. The horsemen came to trade, but instead they took the agricultural produce they wanted and retained the stock they had intended to exchange. The nomad chief returned from the encounter doubly enriched, and this attracted further braves to his standard. The increased wealth and armed might enabled him to extend his conquests further. The pattern on different scales and with some variations in products is encountered again in the west of Asia, between Kazakhs, Uzbeks, Tadzhiks, Turkmens, and Iranians.

Relationship between the city and peasantry. The agricultural principalities centred on the great cities of Central Asia, such as Samarkand, Bukhara, and Khiva, all known for their magnificence. Their wealth was based on the labour of the peasantry. At times their hegemony embraced the surrounding pastoral peoples; at times the pastoral dynasties swept in and conquered the city-based empires. The cities usually tempered and civilized the nomad conquerors, so that after a few years their dynasties were no different from any other.

City centres

The cities were the centres of rulership over the agricultural domains, at times over those of the pastoralists as well, alternating between dynasts of one or the other provenience. The cities served as the centres of trade and exchange between the products of the herdsmen and the soil cultivators; also, they served as the centres for the great transcontinental exchange between China, India, and the West; hence their wealth. They were also local manufacturing centres, particularly of the sumptuary ware of the courts: the jewels, silks, brocades, rugs, tiles, and metalwork that were the wonder of the world. The separation between town and countryside was not so pronounced as in the modern day, and the opposition between peasants and townsmen was not so deep as that found, for instance, in European history. The peasants engaged in manufacture and in cottage industries such as spinning and weaving. The nomads worked in leather, felt, and other pastoral products. All brought their goods to the bazaars and caravanseries of the cities for trade. The cities were also international trade centres, typically for the medieval Silk Road linking China and the Mediterranean across Central Asia. Gardens and orchards were cultivated by the urban populations within and immediately without the city walls. During the 14th to 16th centuries there were no greater centres for astronomy, mathematics, medicine, history, theological doctrine, metaphysical speculation, and poetry.

The great Oriental monarchies were built around the urban centres. Land was cultivated by the peasantry living in the village communities. The monarchs taxed the peasants heavily, but solely to maintain themselves, their court, and their army. Nothing was spent on the health, education, or welfare of the subjects. The only other enterprise in which the monarchic power and the peasantry interacted occurred when the central power mobilized the peasantry to clean the irrigation canals.

Religions of Central Asia. The religious leaders of the Turks and Mongols were shamans. The shaman is a figure who induces a state of trance in himself, wherein he believes that he communicates with the spirits of the supernatural world. He then performs rites of divination and makes oracular pronouncements about the outcome of a hunt or of battles; and he dispels the evil spirits that cause disease and bring misfortune to men and beasts. As the Turks and Mongols came into increasing contact with the great civilizations of Asia, their shamanist practices and beliefs became intermingled with those of the great world religions, particularly Buddhism and Islām. Buddhism, originating in India, became implanted in Tibet and then in Mongolia. It gained influence among the Mongols as their relations to the Chinese and Tibetans were intensified and diminished when the contacts faded. The Mongols were converted in some degree to Buddhism in the 13th and 14th centuries; its role among them retreated in the 15th and 16th centuries; but they were converted again in the 1590s, and its influence remains among them today.

Buddhism and Islām

The forms of Buddhism are many. The Mongolian form is that of Tibet, founded on the existence on earth of the perpetual reincarnation of the Buddha. The Dalai Lama is the "Living Buddha," the head of the cult. His chief officers are manifestations on earth of the lesser members of the Buddhist pantheon, who intercede on behalf of the salvation of the devout. The entire cult centres on a system of monasteries governed by abbots and staffed by monks who perform the rituals of the faith and in turn are supported by its followers. It is now a state church in the Mongolian People's Republic.

Islām came to western and Central Asia within a few decades of the Hegira or Flight of Muḥammed (supposedly in AD 622). It has been the traditional religion of the Turks and Tadzhiks for more than 1,200 years. Most of the Muslims are Sunnī, as opposed to the Shīʿites of Iran and to the Ismāʿīlīs, a sect represented by a few small tribes in the mountains of Tadzhikistan, but more importantly in Afghanistan and Pakistan. The tradition of Islām was rigidly followed in the cities and sedentary villages of central Asia and more liberally or freely observed in the nomadic communities. Women went veiled in the cities, less so in the villages, and not at all in pastoral encampments. The doctrine was fully debated in the cities, but superficially, if at all, among the peasants and herdsmen; there were many mullahs, or clerics, in the cities, but few in the villages, and fewer still among the nomads. The great urban mosques and *ʿulamāʾ*s (religious colleges) were centres not only of prayer but also of learning—primarily theology and, to some extent, philosophy and of the sciences.

The religious systems of Buddhism and Islām involved Central Asia in a great set of institutions and institutional relations that bound the area to similar institutions of east and south Asia (in the case of Buddhism) and to the Near East (in the case of Islām). These institutional networks of the Buddhist monasteries and of the Islāmic mosques and religious foundations (*waqf*) and orders (brotherhoods of monks and preachers) traced out paths across the entire continent similar to the economic and political networks of institutions. In addition to religious conversions of entire countries and transfer of cults and belief systems from one part of the world to another, the widespread movement of people, ideas, world views, science, and technology resulted. Whole populations were brought from the Middle East to Central Asia in the wake of the Islāmic conquest and conversion. Primitive peoples in the refuge areas of the mountains and the Arctic were brought into contact with the literate civilizations to the south, east, and west. And the great literate civilizations were brought into contact with one another, Central Asia serving as the zone of contact. The means for bringing this active contact was not any vague process of diffusion; instead, it was the network of trade routes, the institutions of political rulership, and those of the world religious systems.

THE CULTURES TODAY

The Turks and Mongols of Central Asia are all parts of the Soviet Union and of the Peoples' Republics of China and Mongolia. The traditional ways of life have been radically changed by the revolutionary processes of the 20th century. Since the 1920s, millions of Russians and other peoples from different parts of the U.S.S.R. have been settled in Central Asia, continuing a process begun in the 19th century. The surviving remnants of older regimes, such as the emirate of Bukhara and the Khanate of Khiva, have been replaced by the Soviet political system. As a consequence, the profound divergencies and symbiosis between cultivators and pastoralists have been virtually eradicated. The two great cultural wings have been caught in a single institutional system emanating from the Soviet regime.

Modern agriculture

Central Asian agriculture continues to require artificial irrigation, and the same crops are raised: the cereal grains (wheat, rice), cotton (of improved sorts), vegetables, hemp and other fibres, fruits and melons. The agricultural production of Soviet Central Asia today, however, is carried on not by the family or the village but by a system of state and collective farms. Tractors and trucks have advanced the mechanization of agriculture. The agricultural population still lives in villages of sun-dried brick, but electric power is everywhere. The pastoral practices of Central Asia and Mongolia have been rationalized. The herds now consist of great flocks or herds of one type of animal, instead of mixed combinations as of old, because the family no longer maintains the old pastoral practices; teams of herders are now employed. The family used to need animals in a definite proportion; now the herding family lives in a settled village and the herders go off to ranges with the animals for pasturing (transhumance). They no longer live in tents but in the same kinds of houses and villages as the tillers of the soil.

The Islāmic faith is much restricted, the number of colleges and mosques reduced, and the brotherhoods and foundations absolutely banned. The Buddhist monastic system is sharply reduced in Mongolia: at one time, it is guessed, the monasteries included one-third of all the males of the country; today there are only two major monasteries, numbering together but a few score monks. Religious proselytization is restricted throughout the region.

Soviet Central Asia is organized into the union republics of Uzbekistan, Tadzhikistan, Kirgizia, and Turkmenia; Karakalpakskaya is a part of Uzbekistan, each republic bearing the name of one of the major peoples of the region. Kazakhstan is included with these republics in the ethnographic accounts. Russians form the majority of the population of Kazakhstan, and they are second in number to the native people in each of the other republics. The Russian migration into the area has accompanied a vast effort, begun in the 1930s, to collectivize the agriculture and the herding according to the Soviet pattern, and to nationalize all the land for farming and herding and all the manufacturing and mining industry. The cities have been built up along modern lines, and transportation has been modernized. The Russian population has been closely associated with the new developments, as well as with the Soviet administration. The capitals and other cities of the region are at once administrative centres of the Soviet system and centres of industry, trade, education, the arts, and public entertainment. The natural resources of Central Asia are intensively exploited, including oil, iron ore, coal, and nonferrous metals. Railroads and airfields have replaced the caravans of old.

Mongolia has been developed on the pattern of the Soviet system; the Mongolian People's Republic is a member of several economic and political blocs of nations in which the U.S.S.R. is the dominant power. There are 1,200,000 people in Mongolia, whose capital, Ulaanbaatar, the administrative, industrial, and cultural centre of the country, includes one quarter of the total population of the country.

The ancient lineage and clan systems have been entirely forgotten. The genealogies are no longer kept up because their function in social organization, marriage, and military and economic activities is no longer applicable in modern Central Asia. The great extended families, under a patriarch's dominion, have been replaced by the new forms of the family, small in size and composed of parents and their children. The father of the family is typically a wage earner in a factory or state farm. The children now go to school in the Soviet educational system, rather than, as before, in the schools run by the Islāmic or Buddhist clergy. Modern technology is being introduced throughout the region, and modern medical, educational and welfare practices have been instituted. The desire of parents to have many children in order to have someone to take care of them in old age is no longer a deeply felt social incentive; medical practices have reduced infant mortality so that the need to have many children in the hopes that a few would survive to care for the parents has likewise been reduced as a social force in child breeding. These trends hold equally for pastoralists and cultivators, for the old differences in institutional organization between them have been eradicated by the broad trends of modernization and collectivization.

BIBLIOGRAPHY. General surveys of the peoples and culture of Soviet Central Asia may be found in LAWRENCE KRADER, *Peoples of Central Asia*, 3rd ed. (1971); and in GEOFFREY WHEELER, *The Peoples of Soviet Central Asia* (1966). General histories of Mongolia and of Soviet Central Asia have been prepared by CHARLES R. BAWDEN, *The Modern History of Mongolia* (1968), and GEOFFREY WHEELER, *The Modern History of Soviet Central Asia* (1964). The cultural background of the Turks and Mongol pastoralists are given in LAWRENCE KRADER, "The Cultural and Historical Position of the Mongols," *Asia Major*, 3:169–183 (1952); "Feudalism and the Tatar Polity of the Middle Ages," *Comparative Studies in Society and History*, 1:76–99 (1958); and "Pastoralism," *International Encyclopedia of the Social Sciences*, vol. 11, pp. 453–461 (1968). Central Asian Peoples, Arts of

The term Central Asia has no specific boundaries in a geographical context, but cultural historians generally apply it to the territory bordered on the north by Siberia in the Soviet Union and on the south by Iran, Pakistan, Bangladesh (formerly East Pakistan), and India. This area comprises the present Soviet republics of Kazakstan, Turkmenistan, Uzbekistan, Kirgiziya, and Tadzhikistan and portions of the Sinkiang Uighur Autonomous Region of China—the populations of which are largely of Turkic stock—and the kingdom of Afghanistan. For the purposes of this article, the term is further extended to include as well Siberia and the Soviet Arctic lands and, in the south and east, the Altaic regions of Mongolia, Manchuria (Northeast Provinces), and Tibet and the Himalayan kingdoms of Nepal, Bhutan, and Sikkim.

This immense tract of land—with its highly varied topography and climate and its diversity of ethnic and linguistic backgrounds—encouraged the development of greatly varied artistic styles and traditions among the inhabitants of widely separated regions. These differences were magnified by the emergence of dissimilar religions, which in turn encouraged the formation of distinctive schools or traditions of art. Further artistic variances can be attributed to cultural time lag, for comparable stages of artistic development were not reached simultaneously throughout the area.

The arts that developed across Central Asia often fed or were fed by those of adjoining cultural regions or by such supraregional influences as Islām. Although reference will be made to such cross-cultural interactions wherever appropriate, more detailed information on these other areas may be found in such articles as ISLAMIC PEOPLES, ARTS OF; and SOUTH ASIAN PEOPLES, ARTS OF and in separate articles on the specific arts of East Asia, especially the sections on China. (T.T.R.)

This article is divided into the following major sections:

I. Literature

Of the relatively few Central Asian languages that have developed written literatures, the most important are Turkic, Tibetan, and Mongol. (For a treatment of the Central Asian languages, see ALTAIC LANGUAGES; PALEOSIBERIAN LANGUAGES; SINO-TIBETAN LANGUAGES.) This article will deal with Tibetan and Mongolian literatures from their inception to the 20th century and with Turkic literature from its inception to the 11th century, when the Muslim invasion introduced a period of Islāmic culture. Subsequent Turkic literature is treated in the Turkish literature section of ISLAMIC PEOPLES, ARTS OF, which also treats Central Asian literatures written in Arabic and Persian. (For literature in Chinese, written in Central Asia, see the article LITERATURE, EAST ASIAN.)

TURKISH LITERATURE

The purely Turkish period in the history of Turkish literatures came before the conversion of the Turks to Islām and covers approximately the 8th century to the 11th AD. The oldest literary legacy of the pre-Islāmic period is to be found in the Orhon inscriptions, discovered in the valley of the Orhon, northern Mongolia, in 1889 and deciphered in 1893 by the Danish philologist Vilhelm Thomsen. The inscriptions are on two large monuments, erected in 732 and 735 in honour of the Turkish prince Kül and his brother Bilge Kagan and are carved in a script used also for inscriptions found in Mongolia, Siberia, and western Turkistan and called by Thomsen "Turkish runes." They relate in epic and forceful language the origins of the Turks, the golden age of their history, their subjugation by the Chinese, and their liberation by Bilge Kagan. The polished style suggests considerable earlier development of the language. Excavations in Chinese Turkistan have brought to light important specimens of writings of the Uighur Turks from the 9th century to the 11th. Maḥmūd Kāshgarī's comprehensive dictionary (1071?) contains specimens of old Turkish poetry in the typical form of quatrains (*dörtlük*), representing all the principal genres: epic, pastoral, didactic, lyric, and elegiac. (F.I.)

"Turkish runes"

TIBETAN LITERATURE

Tibetan was developed as a literary language from the 7th century onward as a result of earlier cultural contacts with neighbouring Buddhist countries, namely, the small states of the Takla Makan, especially Khotan (Ho-t'ien) and the ancient kingdoms of northwestern India (modern Gilgit, Kashmir, and Kulu) and Nepal. Scripts of Indian origin were in use in these countries, so the Tibetans also adapted an Indian script to suit their own very different language. By far the greater number of the works produced between the 7th century and the 13th are skillfully methodical translations of Buddhist works, largely from Sanskrit, on which Indian scholars and Tibetan translators worked side by side. In order to translate them, the Tibetans had to create an entirely new (and therefore artificial) vocabulary of religious and philosophical terms, mainly by ingenious compounding of simple terms available in their own language. Apart from some religious terms in daily use, this vocabulary remains a specialized scholarly language. An indigenous literature was also produced: annals and chronicles, sets of spells and prognostications, legendary and liturgical works, all representing the remains of ancient oral traditions. Large collections of such manuscript fragments, all earlier than the 11th century, were discovered early in the 20th century in the Cave of the Thousand Buddhas near Tunhuang (at the eastern side of the Takla Makan).

Indigenous literature of Tibet

The quasi-official work of translating authorized Indian Buddhist texts, which continued for six centuries, gave incentive to the Bon-pos (the followers of the pre-Buddhist religion of Tibet) to collect and write down their own early traditions; but in so doing they adopted many Buddhist ideas and, inevitably, used the new vocabulary. The followers of the earliest Buddhist traditions to enter Tibet (the rNying-ma-pa, or "The Old Order") also committed their teachings to writing; and, conversely, these are interspersed with pre-Buddhist traditions.

The official Tibetan Buddhist canon was closed in the 13th century; it consisted of two parts, the *Kanjur* ("translated word," teachings or reputed teachings of the Buddhas themselves) and the *Tanjur* ("translated treatises," mainly commentaries by Indian teachers). By this time, however, there already existed some orthodox Buddhist works of Tibetan origin (for example, *Mi-la ras-pa* and *sGam-po-pa*); and from the 13th century onward, under the impetus given by the prolixity of religious houses and orders, there were produced such lengthy and numerous collections of historical and biographical works, treatises and commentaries, liturgy and religious drama that Tibetan literature must be one of the most extensive in the world. Just as in the European Middle Ages there was little secular literature worth the name, so there is none in Tibetan except for a great epic (*Rgal-po Ge-sar dgra-'dul gyi rtogs-pa brjod-pa*, "The Great Deeds of King Gesar, Destroyer of Enemies") that recounts the exploits of the king and magic hero Gesar. This work grew through the centuries, assimilating whatever material pleased the fancy of the bards.

Secular literature

After the craft of printing from incised wood blocks was introduced from China, possibly in the 14th century, certain monasteries became famous printing houses. This form of printing continued until the Chinese invasion in 1959. Manuscripts and block-printed books are always of elongated shape, thus imitating the form of ancient Indian palm-leaf manuscripts. There are considerable collections in some European libraries—London, Paris, and Rome—but few translations are available because of the small number of scholars of Tibet.

Despite the phonetic changes in the spoken dialects since the script was fixed, the Tibetans have never changed their system of writing. Thus, once the literary language and the various types of script have been mastered, the reader has immediate access to all literature of the 7th to the 20th century, though changes in style and vocabulary have left many obscurities in the earliest works. Since there is no modern style of writing, the 20th-century colloquial language can be written only in the traditional medium (as though, for example, one had to write modern Italian with Latin spellings and grammatical forms); the Tibetans themselves compose even personal letters in a conventional literary style. (D.L.S.)

MONGOLIAN LITERATURE

Mongolian literature begins with the *Secret History of the Mongols*, an Imperial chronicle dealing with the life and times of Genghis Khan and his successors, written about 1240. *Üligers*, orally transmitted epic stories in verse, form the bulk of native literary expression. Highly stylized, they relate adventures of legendary heroes and villains. In spite of their great length (sometimes more than 20,000 lines), they are recited from memory by bards. Like the other epics, such as the Greek *Iliad* and the Roman *Aeneid*, they are genuine artistic creations. The verses alliterate in couplets or quatrains, are seven or eight syllables long, and are characterized by parallelism. Besides Genghis Khan, the epic stories tell of heroes such as Erintsen Mergen, Engke Bolod Khan, and Geser Khan (the last of Tibetan origin). The villain of the epics is the many-headed monster, the *manggus*, whom the hero always defeats.

Historical chronicles represent another important form of indigenous literature. Usually beginning with the crea-

tion of the world from primordial elements, they attempt to link the Indian and Tibetan rulers with the house of Genghis Khan. Such are the *Altan tobchi* ("The Golden Button"), composed about 1655 and giving a world history down to Ligdan Khan (1604–34); another *Altan tobchi* (written about 100 years later); and the *Erdeni-yin tobchi* ("The Jeweled Button"), written in 1662 by Saghang Sechen.

Mongolian historical chronicles

Mongolian written literature was profoundly influenced by the introduction of Buddhism around the end of the 1500s. Earlier surviving written works (on stone or paper) are mostly official documents; and no oral epics were written down until the late 1880s. The advent of Buddhism evoked translations of its sacred writings and related works. A Buddhist canonical collection, the *Kanjur* (comprising the *sūtras* and *vinaya* of the *Tripiṭaka*), was translated and printed in 1635 in 108 volumes; the *Tanjur*, containing canonical commentary and non-canonical works in its 225 volumes, followed in 1741. Two especially well-known sermons (*sūtras*) of Buddha are the *Altan gerel* ("Golden Beam") and the *Chagan lingqua* ("White Lotus"), or, as they are known in Sanskrit, *Suvarṇaprabhāsa* and *Saddharmapuṇḍarīka*. None of these works, however, is indigenous.

Religious but nondogmatic birth stories (called in Sanskrit *Jātaka*) deal with Buddha's meritorious deeds, and, like the parables of Christianity, illustrate religious truths. Best known is the *Üliger-ün dalai* ("The Sea of Stories"). Translations of other Indian fables are the *Siddhi Kür* ("Tales of the Vampire") and the *Bigarmijid* ("Saga of King Vikramāditya").

In the 18th and 19th centuries Chinese traders brought from China many Mongolian translations of Chinese novels of enchantment and romance, including the *San Kuo chih yen-i* (*Romance of the Three Kingdoms*) and others.

20th-century literature

In the early 20th century T. Zhamtsarano, a Russian-educated Buriat writer and intellectual, founded the short-lived Mongolian newspaper *Shine toli* ("The New Mirror"). He also translated the works of some Western authors, such as Edgar Allan Poe, Jules Verne, and H.G. Wells.

After a Soviet state was established in Mongolia in the early 1920s, the power and influence of the Tibetan Buddhist church declined, and with it the literature it sponsored. There began to arise a revolutionary and Socialist literature serving the people according to the current beliefs of the Communist Party. Popular themes were social criticism of the feudal past, with its exploitation of the people, and exemplary tales that showed new Socialist values and educated readers to overcome the resistance of reactionary forces. Mongolian reliance on and gratitude for the fraternal Soviet Union and its assistance is an ever-present undercurrent. The rise of a system of schooling, extending to the university level, has enabled many young Mongolian writers, poets, artists, and actors to achieve, within limits, a self-expression never before available to them. Leading 20th-century modern writers are Dashdorjiyn Natsagorj, Ts. Damdinsürün, D. Sengee, S. Erdene, and others. (J.R.Kr.)

II. Music

Music in Central Asia flowered along centuries-old caravan routes linking the Near East with China and India via Turkistan, the vast region extending from the Caspian Sea to Sinkiang province in China. Musical instruments diffused from one region to another, and many of the musical styles still display foreign influence. The variety of musical styles ranges from the systematically organized classical music of Turkistan, to the notated religious chants of Tibet, to the highly varied folk music styles of the region's numerous ethnic groups. The main thrust of this examination of Central Asian music will be on the traditions and styles first of Afghanistan and the sedentary population of Turkistan, then of the Turkic nomads, the Mongols, and the Siberian peoples, and, finally, of the Himalayan peoples in Tibet, Bhutan, Nepal, and Sikkim.

AFGHANISTAN AND THE SEDENTARY POPULATION OF TURKISTAN

This region of Central Asia includes Afghanistan, present-day Uzbek Soviet Socialist Republic (Uzbekistan) and Tadzhik S.S.R. (Tadzhikistan), and the oases of eastern (Chinese) Turkistan. The region lies within the Persian cultural area, and in the arts and in language the Persian imprint has endured over many centuries. In music the links with Persia appear most clearly in terminology and instruments. Islām, another Near Eastern heritage, predominates in this region and results in a generally low social status of musicians and musical performance—a situation generally not found in other regions of Central Asia.

The area includes two main streams of musical practice: folk music in a broad range of styles, often closely linked to specific ethnic groups; and the more exclusive, cosmopolitan, classical music, derived from the medieval court music of Bukhara, Samarkand, and other urban centres of Transoxania (modern Uzbek S.S.R., Tadzhik S.S.R., and Turkmen S.S.R). A third stream is now in the process of formation: popular music disseminated through the mass media.

Folk music. Generally characterized by a scarcity of musicians and musical instruments, folk music of this region is predominantly a matter of solo playing and singing, small ensembles, and a complete lack of musical notation or codified musical theory. In their general types, the musical instruments are closely related to those of Persia and the Near East, but specific forms and playing styles are purely local. Thus, there are numerous variants of the Persian long-necked lute, with names derived from the Persian *tanbūr* or *dūtār;* small spike fiddles, in which the neck skewers the body, forming a spike at the base; various block or fipple flutes, with air ducts like that of the Western recorder; transverse (horizontally held) flutes; oboes; metal jew's harps; and two basic drum types, a single-headed vase-shaped drum of pottery or wood and a large single-headed frame drum, or tambourine—all instrumental types widely diffused in the Near East.

Musical instruments

Stylistically, the music relates to that of both the Near East and the surrounding nomadic Turkic peoples of Central Asia. Songs are completely monophonic (*i.e.*, consisting only of a line of melody), but instrumental music often includes two-part polyphony (music in more than one voice, or part). The polyphony may take the form of a drone (sustained note) with a melody played above it. Or it may be organum style; *i.e.*, the second part playing the same melody as the first but at a higher or lower pitch. Most common are parallel fourths or fifths (a fourth encompasses four notes of a Western major or minor scale; a fifth, five). In structure, much of the music is based on small forms, frequently binary, or two-section, and ternary, or three-section. Small musical units may be repeated many times and varied slightly at each appearance. The recurrence of melodic phrases and an emphasis on marked rhythms is common and is related to the frequent role of music as dance accompaniment. Thus in the following example, a dance tune from Afghan Turkistan, sections A and B are similar in their overall melodic structure, and also in the small units of three or four notes on which they are built. The se-

quence ABAB, etc. is repeated throughout the dance. Vocal music may have greater rhythmic flexibility and melodic range, but in form it is almost always subordinated to the structure of the song text. Quatrains such as the *rubai* and *charbaitai* are the most prominent village verse forms, with the exception of the *lundai*, a couplet used by the nomadic Pashtuns of Afghanistan. In the urban oases, couplet forms based on the classical Persian *ghazal*, a lyric poem of 6 to 15 couplets, are more common.

Attitudes toward music

The generally negative attitude of Islām toward music has led in Afghanistan to strictures against musical performance and to extremely low social status for musicians. Music is heard mainly in male-dominated public teahouses or at private celebrations such as weddings and circumcisions. Women may have their own musical genres within their enclosures; in this context the strong tradition of women's music in the Fergana Valley of the Uzbek S.S.R. is noteworthy.

Within this general picture there is enormous diversity. The Uzbeks (a Turkic people) and Tadzhiks (an Iranian group), who live side by side across northern Afghanistan and southern Turkistan, tend to share many musical traits and instruments. In contrast, most groups, such as the Pashtuns, Ḥazāra, and Baluchi of Afghanistan and Pakistan or, in the extreme, the isolated mountain peoples of Nūrestān in Afghanistan and of the Pamirs in the Tadzhik S.S.R. and Afghanistan, have maintained distinctive musical styles and, in some cases, unique musical instruments. The Nūrestāni *vaji*, an arched harp (having a bow-shaped body with no forepillar), is a striking case of the possible survival of an instrument type on the margins of a now disintegrated culture area; there are no other harp traditions today between the Caucasus and Burma, although iconographic evidence indicates that in ancient times harps were widespread in Central Asia, the Near East, and India. The music of the Ḥazāra includes vocal effects produced by striking the throat while singing, causing a break in the sound, and Baluchi music also features a broken-voice style.

Classical music. In contrast to the folk music styles just described, the court-derived classical style of Bukhara and Samarkand represents a highly systematic, theoretically grounded, cosmopolitan musical tradition. Lying along the medieval silk route, the Turkistani oases were open to musical cross-currents. Today's musical roots may reach back to the period in which urban Central Asian music was in vogue at T'ang dynasty courts in China (618–907). The movement of musical instruments across the caravan trail from the Near East to China via Central Asia is well documented since early times. Over the centuries, town musicians evolved an urban style patronized by the local courts, notably under Timur (Tamerlane) and his descendants (*c.* 1350–1500) in Herāt (now in Afghanistan) and Samarkand. The degree of musical eclecticism characteristic of the era is illustrated by a court historian's description of the festivities of Timur's son:

Medieval court music

> Golden-tongued singers and sweet-sounding musicians played and sang to motives [melodic figures] in Persian style, to Arab melodies according to Turkish practice and with Mongol voices, following Chinese laws of singing and Altai meters.

By the 17th century the court style had been codified into sets of nonimprovised suites of instrumental and vocal pieces using poetic texts in classical Persian and local court Turkish (Chaghatai). In Bukhara this collection of suites was known as the *Shashmaqām*, or six *maqāms* (suites), with each *maqām* (an Arabic term, but changed in meaning) set in one of the classical Persian musical modes. (The Persian modes are melodic frameworks, each with a given scale, typical melodic figures, and accepted emotional content.) Regional courts and large towns developed their own sets of *maqāms*, performed in unison by an orchestra and a male chorus.

Areas of Turkistan under Soviet rule since about 1920 have undergone far-reaching modification of traditional music practice, although the older styles such as the *Shashmaqām* are also maintained. Changes include the reconstruction of local instruments to fit the Western musical scale of 12 equally spaced half steps, establishment of music schools and conservatories, creation of orchestras of folk instruments, introduction of vocal polyphony and the writing of works in Western forms (symphonies, operas, chamber music) by native and European Soviet composers. In Afghanistan, musical change has begun on a national basis since the 1950s under the influence of Radio Afghanistan, which broadcasts principally popular styles based on Pashtun folk music and songs of the Indian film industry.

20th-century changes in music practice

TURKIC NOMADS, MONGOLS, AND SIBERIAN PEOPLES

This region includes primarily the great open spaces of Central Asia, from the Turkmen desert in the southwest to the Kazakh steppes, Mongol plains, and from the Gobi to the vast Sub-Arctic Siberian evergreen forests, or taiga, and tundra, or Arctic plains, stretching to the Pacific. The considerable mobility and often close linguistic affinity of the peoples in the area led to substantial interchange of musical terms and instruments, and to common social functions of music relating to the traditional tribal social structure of most of the groups of this region.

Social role of music. Three basic functions of music are common throughout most of the region: music as ritual, with magical connotations (shamanism), music as tribal record, aiding group solidarity (epic recitation), and music as entertainment (itinerant performers, festivals). Music is the medium of the shaman, or priest-medicine man, as he performs his role as mediator between the seen, or men, and the unseen, the spirits that inhabit the spheres above and below the earth. Traditional shamanistic séances were creative, impassioned musico-dramatic scenes produced by a single performer, the shaman. Not only is music the shaman's aid in inducing the trance that enables him to contact spirits, but in Siberia his drum (a very large tambourine) may be considered a steed for the trip to other worlds. Thus great attention is given to each stage of drum construction, from selecting the wood of certain trees to the painting of symbolically charged designs on the drumhead. The metal hangings, sometimes including bells, on the shaman's costume also play a musical role. Among the Kirgiz and Kazakhs and until recently among the Turkmens, a fiddle with horsehair strings and bow performs the same function as the Siberian drum. Metal ringlets are attached to the head of the fiddle, and a niche is hollowed there for a mirror to catch the reflections of spirits. Shamans' horsehair fiddles can even be found among townspeople of northern Afghanistan. The occurrence of shamanism has sharply declined in Soviet portions of Central Asia.

The shaman's music

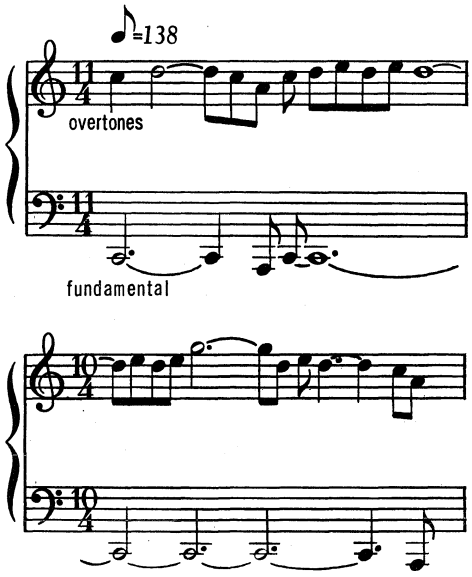
Epic recitation, which may serve as tribal history, also has magical overtones. Among Turks, the same term (*bakhshi*) may be used for both shamans and bards, and both may be called to their trade by spirits to undergo a difficult period of initiation. Storytellers use a fiddle or lute as accompaniment, and tales may run through several nights of exhaustive performance; one Kirgiz bard is known to recite 300,000 verses of the *Manas*, the major Kirgiz epic. Such marathon performances are facilitated by the use of stereotyped melodic motives—standard short melodic figures—often invented by the individual performer. Local epic traditions vary widely in dramatization; *i.e.*, the proportion of dialogue, monologue, and narrative.

The third area-wide musical function, entertainment, takes many forms. One common diversion is the singing contest, in which rival minstrels compete in wit and virtuosity. Such trials of skill are most notable among the Kirgiz, Kazakhs, and Mongols. The contests follow strict rules of versification, musicality, and procedure. Often the loser must pay a forfeit to the victor, who receives acclaim from the audience and gifts from wealthy patrons; a singer's reputation may be made or broken in a single afternoon. Frequently a contestant will vilify the clan championed by the opposing singer and laud his own faction. In Siberia another type of entertainment

The singing contest

is the widespread practice of bear festivals at specific times of the year, during which a bear is killed and his head displayed, to the accompaniment of music, dance, and games.

Instrumental and vocal styles. Across the region the principal instrument types are lutes, with two or three strings, the necks either fretted or fretless; fiddles, largely horsehair fiddles; flutes, mostly open at both ends and either end-blown or side-blown; and jews' harps, either metal or, often in Siberia, wooden. Few percussion instruments are found, except for the shaman's magic drum. Considerable instrumental polyphony is played on lutes and fiddles, particularly among the Turkic peoples. Vocal polyphony may occur in special ways: singers among the Mongols and Tuvins (a Siberian people northwest of Mongolia) can produce two parts while singing solo, as in the example below, by strongly reinforcing



upper partials (overtones) while singing a very deep fundamental pitch. West of the Urals, Bashkirs may hum a basic pitch while playing solo flute pieces, and certain Siberian peoples may sing choral overlapping responsorial songs (in which group and soloist alternate, one beginning slightly before the other finishes).

The vast geographic stretch of the region produces musical links to neighbouring areas as well as highly distinctive local styles. The Turkmens live in Afghanistan and Iran as well as Turkistan and manifest some Persian influence in musical terms and instruments, yet they possess unique vocal and instrumental styles. Particularly striking is their series of guttural sounds serving as vocal ornaments. The Kirgiz and Kazakhs, closely related musically, maintain ties to Mongol and northern styles (*e.g.*, of the Bashkir and Tatar peoples, west of the Urals) as well as to Turkistan. Nevertheless, their relaxed voice quality, musical scales, and distinctive instrumental polyphony set them off. Noteworthy here is the versatile polyphonic style of the three-stringed Kirgiz *komuz* lute, based on extensive development of short melodies called kernel tunes. In the *komuz* piece shown below, the kernel tune is stated in the first two measures and is varied and developed as the piece progresses. An-

other Kirgiz-Kazakh specialty is programmatic music, in which instrumentalists tell specific stories without words, through musical images alone.

Mongolian and Siberian music

The Mongols display links to both Chinese and Tibetan music. Chinese influence is apparent in the use of certain instruments (*e.g.*, some flutes and fiddles) and perhaps in the structure of melodies; Tibetan impact occurs in the religious music and musical instruments of Tibetan Buddhism, introduced in the 16th century. Mongolian music also has its own distinctive profile, sporadically documented since the 13th-century *Secret History of the Mongols*, the first written Mongolian chronicle. Of interest is the fact that Arghūn Khān, Mongol ruler of Persia, sent a musician as emissary to Philip IV the Fair of France in 1289. Because of the focal position of Mongolia at the heart of Central Asia, some Mongol epic melodies have spread westward as far as the Kalmuks on the Volga River, and eastward to the Ainu of Sakhalin Island, north of Japan. Mongol songs may be either quick and marked rhythmically or drawn-out in free rhythm, with extensive melodic ornamentation. The Mongol horsehair fiddle accompanies a singer with simultaneous variations on the melody, a technique called heterophony.

Siberian music includes a broad spectrum of styles over a huge geographic expanse. Many unique traditions occur, such as the bridgeless, often rectangular zithers of the Khants and Mansi, Ugrian peoples along the Ob River; farther east, the solo flute-and-voice polyphony of the Tuvins and Bashkirs; and the rapid, compact songs with nonsense syllables of the Gilyaks, Chukots, and other peoples of the Far Eastern Amur River region and Pacific coast. At that northeastern shore of Siberia there is a carryover of musical style to the Ainu of northeastern Japan and possible musical ties between the Eskimos of Asia and of North America. Other links beyond Central Asia may exist at the far western end of Siberia, for example, to the music of Lapland in the Scandinavian Arctic; or the relation of tunes of certain peoples of the Volga River region, such as the Mari or Cheremis, with old Hungarian folk songs.

Outside the few written Mongol references to music, the only approach to discovery of the stylistic history of this region of Central Asia is through fragmentary information about musical instrument types. Perhaps the most remarkable instrument finds were made at Pazyryk in south central Siberia, where Soviet archaeologists found wooden objects which possibly form pieces of a harp and an artifact resembling a vase-shaped drum, both dating from the 5th century BC.

THE HIMALAYAN PEOPLES

This region, including Tibet, Sikkim, Bhutan, and Nepal, occupies an important middle ground between India and China, and its central position is reflected in the local music cultures. Of utmost importance for musical life was the introduction of Buddhism from India via Turkistan, beginning in the 7th century AD. Music became an integral part of the official creed of Tibetan Buddhism, and the considerable cultural influence of Tibet spread Tibetan religious music to the nearby areas of Nepal, Sikkim, and Bhutan and, much later, to Mongolia.

Tibetan music. Tibetan religious music is the only Central Asian repertoire that has a long history of written notation. This notation, for liturgical chant, consists of neumes; *i.e.*, symbols representing melodic contour rather than precise pitch, similar to the earliest music writing of medieval Europe. Also distinctive is the metaphysical aspect of Tibetan Buddhist music, related to Indian philosophy. Each instrument of the monastery orchestra, as well as the drawn-out tones of chant, is believed to represent an externalized form of the *mantras*, or sounds inherent in the human body, accessible otherwise only through steadfast meditation. For the monks, such music is a basic aid to devotion and prayer. Musical styles vary somewhat among the sects of Tibetan Buddhism, but the basic approach and instruments are the same.

The monastery instruments typify the crossroads posi-

tion of Tibet. Some, such as the large cymbals, stem from China, while others (the majority), such as the conch-shell trumpet and handbells, can be traced to Indian influence and are found as instruments of Buddhist worship as far away as Japan. Still other instruments, such as the large oboe and the ten-foot metal trumpet, are perhaps Near Eastern in origin. One wind instrument, the short trumpet made from a human leg bone, seems to be of purely local invention. Similarly, the structure of the music seems basically Tibetan. It is founded on a principle of greatly prolonged dense, deep sounds, such as unison long and short trumpets with oboe, or the seemingly endless bass chant of groups of monks, whose long, drawn-out notes are punctuated by sharp, extended bursts of percussion. Each monk is said to be able to sing two or even three notes simultaneously.

Festival dramas

Much of this music emerges from monasteries only at festival time, when the great *cham* dramas, which may last several days, are performed for the public's entertainment and edification. These plays, which generally show the triumph of Buddhism over Bon, the earlier shamanistic religion of Tibet, may involve hundreds of musicians in the guise of masked dancers with drums, backed by a large temple orchestra. Other types of public music also abound, such as secular, perhaps Chinese-related historical plays with an alternation of dialogue and songs with orchestral accompaniment. There is also a strong tradition of folk dance, which may include songs sung by mixed antiphonal choirs (*i.e.*, two alternating groups of singers). Minstrels ply their trade along the caravan routes and play instruments perhaps more related to general Central Asian traditions than to the Indian and Chinese background of religious music.

The music of Nepal, Bhutan, and Sikkim. Little is presently known about the music of Nepal, Bhutan, and Sikkim. Minstrels play a major role in the musical life of Nepal, where under Indian influence musicians are classified according to caste, and each group features specific instruments and repertoire. There appears to be a great deal of both Indian-related and indigenous folk music in the three Himalayan kingdoms. Varieties of lute, such as the long-necked *damyan* of Nepal and its Sikkimese relative, may be linked to a similar instrument of the Pamir Mountains; while a Sikkimese flute having an outside air duct (in contrast to the inside duct of a Western recorder) seems to be a unique instrument. The Sherpas of Nepal and other Tibetan-related populations of the Himalayas, along with the thousands of Tibetan refugees now living in the area, maintain the traditions of Tibetan Buddhist religious music. The *mani-rimdu* dance-drama of the Sherpas, a variant of *cham*, is a good case in point.

THE STUDY OF CENTRAL ASIAN MUSIC

In the West, the study of Central Asian music has until recently been restricted largely to travellers' accounts and analyses of small samples of music. By far the bulk of collection and study of Central Asian music of Turkistan and Siberia lies in the domain of Soviet scholars, who instituted systematic fieldwork as early as the 1920s; this literature remains largely inaccessible to the non-Russian reader. Mongol music was the subject of sporadic but intensive fieldwork by Scandinavian researchers in the 1920s and early 1930s, so that some of the traditional music culture was documented before Mongol society underwent the changes brought by war and the advent of socialism. Tibetan music has attracted increasing attention since the late 1950s, when large numbers of Tibetan refugees poured into the Himalayan kingdoms and northern sectors of India, thus making Tibetan music more accessible to outside observation. Afghanistan has been the object of intensive musical investigation only since the mid-1960s. Thus, outside Soviet contributions, Central Asia remains a lightly researched although quite fertile area of musical investigation. (M.S.S.)

III. Performing arts: dance and theatre

The performing arts have played an important role in the spiritual and social life of Central Asia, where they evolved as didactic art forms within a religious context. Performance, therefore, occurs in conjunction with some religious or special event. There are two main types of performance which predominate throughout Tibet, Nepal, Sikkim, Bhutan, Mongolia, and parts of Asian U.S.S.R.: those related to shamanism and those derived from Buddhism. The performing arts of the Turkic peoples of Afghanistan and Turkistan are different from these because of the influence of the Islāmic religion and are discussed in the article ISLAMIC PEOPLES, ARTS OF. The Hindu influence found in Nepalese theatre and dance is treated in the article SOUTH ASIAN PEOPLES, ARTS OF.

Although primarily intended to serve the overt purposes of religion, dance and theatre in Central Asia are performing arts with covert aesthetic values. Vocal and physical expressions of appreciation by an audience attending a performance depend on the graceful and rhythmic execution of hand gestures, body movements, and footwork. Aesthetic values are best expressed in the elaborate and artistic costumes, masks, and makeup, coupled with effective though crude stage effects and props.

Use of music in dance and theatre

Musical instruments play an important role in the performance of Central Asian dance and theatre. Usually a drum, but in some cases a string instrument, is used by the shaman to induce the ecstatic trance during which he symbolically journeys to the heavens or to the netherworld when playing the role of a psychopomp, or conductor of souls. Performances of the Buddhist monastic dance, known as 'Cham (dance), and the Buddhist morality plays, called *a-che-lha-mo* (Older Sister Goddess), were accompanied by a variety of instruments, especially drums and horns. The word is, like *'cham*, Tibetan. There were large and small drums, short horns with fingering holes, and long horns, particularly the *dung-chen* (great conch shell) made of brass and extending many feet. The *dung-chen* with a deep haunting wail accentuates the macabre that is so much a part of *'cham*. The Tibetan guitar *sgra-synan* (pleasant sound) is a stringed instrument used almost exclusively by Himalayan peoples for folk song and dance.

Perhaps because of the subjectivism of their religions, it was not the custom among the peoples of Central Asia to carry out objective studies of elements in their cultures, and, therefore, no indigenous evaluation of their dance and theatre is available. Although a few manuals for the performance of shamanic rituals, music, and the *'cham* do exist, as do scripts for the *a-che-lha-mo*, much of the history and traditional staging of these forms of theatre and dance was handed down by oral tradition.

SHAMANIC RITUAL

Teachings that spirits are responsible for unexplainable phenomena, such as disease and death, and that these spirits can be controlled by an individual with special powers, such as a shaman, evolved in many primitive societies throughout the world, including those of the nomadic peoples of Central Asia. The roles of the shaman include oracle, healer, sacrificer, and psychopomp, and each role calls for the performance of specific rituals. The earliest form of theatre and dance in Central Asia, these rituals developed into an often complex genre of the performing arts. The horse-sacrifice ceremony among the Altaic peoples of east Central Asia, for example, embraces a full range of dramatic elements despite the fact that like all shamanic ritual it is essentially a one-man performance. The ceremony, which lasts two to three days, is one in which the shaman undertakes a journey to the heavens. After having set the stage, the shaman symbolically releases the soul of a real horse and then, astride a goose-shaped device, he chases the soul of the horse, all the while imitating the noises of the goose and the horse. Capturing the soul of the horse, the shaman, with help from the audience, then kills the real horse, and the flesh is prepared. The next evening, the shaman offers pieces of the horse meat to the spirits, and, amid loud drumming and chanting, symbolically goes to the heavens on the soul of the horse while ascending a notched pole. As he ascends through the higher and higher heavenly

Altaic horse-sacrifice ceremony

planes, the shaman communicates to the audience important information, such as predictions about the success of the coming harvest and about epidemics and misfortunes that threaten and how to avoid them through sacrifices. The ceremony is followed by merrymaking and drinking.

Shamanism maintains that the soul of one who dies a heroic or violent death ascends to the heavens, but that the soul of one who dies from disease, which is caused by an evil spirit, must go to the underworld. The part of a psychopomp, or conductor of souls to the netherworld, was, therefore, another role commonly played by the shaman. The shaman guides the soul to its destination while narrating details of its journey to his audience. In some cultures, such as that of the Lolo, or Yi, in the mountains of southwestern China, the souls of all the dead are led in this manner to the underworld; while in others, such as that of the Tungus, a subarctic forest people of eastern Siberia, the shaman is only called upon to act as psychopomp if the soul of the deceased continues to haunt his residence.

The shaman also serves as the repository of tribal folklore and beliefs. Through dance and dialogue, he instructs the audience in the traditional teachings of their ancestors, and by passing his knowledge and techniques down to his successor, those teachings remain intact for future generations.

Rituals for curing the sick, guiding the soul of the dead to the netherworld, invoking a deity, or visiting the heavens are performed by the shaman in a state of trance induced by frenetic dancing to the music of a drum or a string instrument. Elaborate, symbolic costumes and ritual objects used in the ceremony provide a dramatic and mystic spectacle. The expectations of the audience are directly connected with the purpose of the shamanic performance; but whether it is the hope that the patient would be cured or that the oracular communication be auspicious, those attending the shamanic performance do so with the expectation that it will be an entertaining religious experience.

Before the introduction of Buddhism in shamanic Central Asia, there were no centres for the performing arts in the usual sense of the word. Each shaman performed his dramatic arts at his own residence or environs as the occasion demanded. He had his own ritual costumes and paraphernalia, which displayed regional variations, particularly in ornamentation. The representation of animals and birds is common, and metallic objects, which are thought to possess a soul and do not rust, are also important. For example, the costume of a Siberian Yakut shaman must have from 30 to 50 pounds (15 to 25 kilograms) of iron to be efficacious, while a Siberian Buryat shaman, except for an iron casque, or helmet, wears mostly furs. The metal ornaments represent such diverse things as the internal organs, bones, a woman's breasts, the sun or the moon; but the object common to all shamans is a metal mirror, in which the shaman can see the souls of the dead. Regardless of the variations in dress, the purpose and performance of the rituals remain essentially the same, whether carried out by a Buddhist monk among the Sherpas of Nepal, or by a true shaman among the Siberian Yakut.

Regional variations in costumes

Tungus shaman, detail of an engraving from Witsen's *Noord en Oost Tartarye*, 1785.

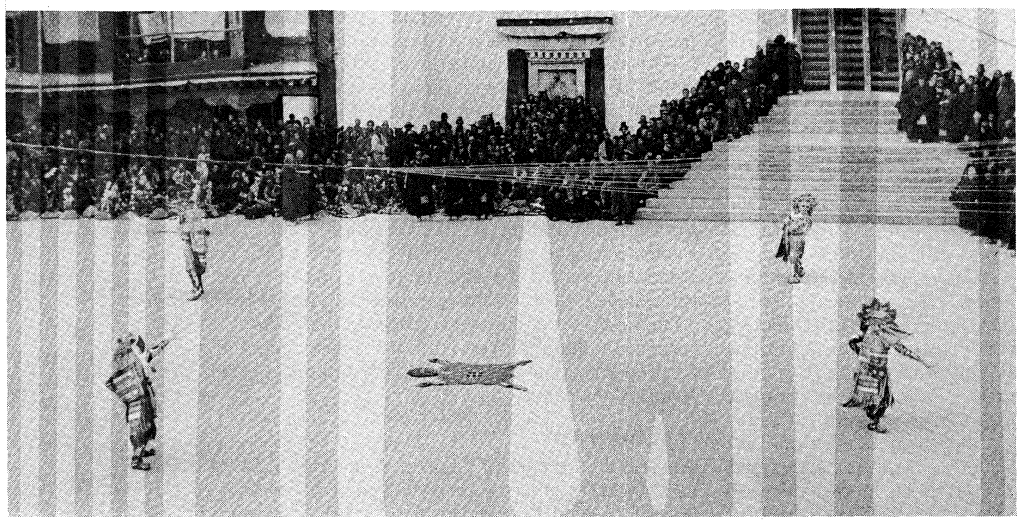
The shamanic rituals of the steppe and desert peoples have analogies among the dramatic arts of the Himalayan kingdoms, where, because of the tolerance of local beliefs and rituals, many shamanic practices were adopted into Tibetan Buddhism. For example, the State Oracle of Tibet, a monk whose oracular powers were exercised on behalf of the government and the monastic system, was regarded as a high ranking ecclesiastic, yet his ritualistic performances were no different than those of shamanic mediums throughout Central Asia. The adaptation of the psychopompic role of the shaman into Tibetan Buddhism resulted in the recitation of the *Tibetan Book of the Dead* to an effigy of the corpse. This book describes in detail the frightening apparitions the deceased encounters day after day while in the forty-nine-day interval between death and rebirth, and its reading is analagous to the shaman's narration of his journey to the underworld.

BUDDHIST RITUAL

Buddhist Monastic Dance. The second major genre of the performing arts to develop in Central Asia was 'Cham, the ritualistic dance performed in Buddhist monasteries. The origins of *'cham* may well be an older form of shamanic ceremonial dance in Tibet, but centuries of evolution within a Buddhist dominated society led to the recasting of the roles and theme of the dance in keeping with Buddhist dogma. *'Cham*, which was introduced along with Tibetan Buddhism into Mongolia and parts of the southern Asian U.S.S.R. in the 16th century, became the main form of religious entertainment in eastern Central Asia.

Origins of *'cham*

The origins of *'cham* lie in Tibet's dim past, long before the introduction of Buddhism. Initially, it was performed as a ritual to drive out evil spirits and to appease the guardian spirits by means of human and animal sacrifices, thus assuring an auspicious and prosperous new



(Left) *'Cham* performance during the New Year celebrations at the Potala, Lhasa, Tibet.

year. According to Tibetan tradition, the ancient shamanic dance was adapted as a Buddhist one by Padmasambhava, the Indian tantric teacher who introduced Buddhism into Tibet in the 8th century AD. He is said to have interpreted the dance as symbolizing the victory of Buddhism over the shamanism of Tibet, and, since blood sacrifices are abhorrent to a Buddhist, these were simulated by clever techniques using effigies and red-coloured substances.

Sectarianism developed in Tibetan Buddhism in the 11th century, primarily as a reaction to the unreformed teachings of Padmasambhava and his followers; nevertheless, each of the sects retained the monastic dance as part of their religious repertoire. The reformed Yellow Hat sect changed the time for its performance from the birthday of Padmasambhava to the end of the official year, which would coincide with the lunar month from the middle of January to the middle of February.

The acceptance and spread of Buddhism led to the eventual establishment of monastic communities throughout eastern Central Asia. These monasteries became fixed centres for the performance of 'Cham. Every monastery of adequate size and monastic population maintained its own masks, costumes, props, and musical instruments. In spite of regional and sectarian variations, the performance of *'cham* remains basically the same. The stage is set outdoors in the courtyard of the monastery called the *'cham-ra* (dance enclosure). With the exception of high lamas and members of the nobility who sat on special seats, the audience stood or sat around on the edge of the dance floor or ground. The musicans with horns and drums take their places, usually under a cloth canopy. Then, accompanied by music, the various dancers emerge from a building or from behind a stage curtain and perform. The first to appear are dancers wearing wide-brimmed black hats, topped with a simulated human skull. The costume of these dancers has led to the performance being referred to in some Western works as the Black-hat devil dance. Although of shamanic origin, the costume of the black-hat dancers is said by the Buddhists to represent the black disguise worn by Dpal-gyi-rdo-rje, a 9th-century Tibetan monk who assassinated the fanatic anti-Buddhist king, Glang-dar-ma.

Black-hat dancers

The black-hat dancers are followed by a variety of performers, including those wearing monstrous masks representing a host of evil spirits that harass mankind, those costumed as skeletons and wearing skull masks, and those representing Indian teachers of Buddhism. There are also masked dancers representing the tutelary deities of Buddhism, and the most impressive of all is the Chos-kyi-rgyal-po (King of the Religion), who wears a mask fashioned after the head of a bull, which is emblematic of the aspect of the deity that vanquishes the Lord of the Dead. It is this dancer who dismembers an effigy of a corpse and scatters the parts in a simulation of the sacrificial and expulsional elements of the ancient shamanic dance rituals.

The dance is not all macabre. Comic relief is provided by a dancer wearing a mask with an expression of stupidity. This buffoon represents Ho-shang, the Chinese monk, who was defeated in an 8th-century debate on the merits of Indian versus Chinese Buddhism. Ho-shang is represented in the 'Cham of the Sherpas of Nepal by a dancer wearing a mask portraying a balding, bearded old man, called Mi-tshe-ring (Long-life Man), who delights the audience by his farcical antics and pratfalls.

The whole of the 'Cham performance, which takes two or three days, is a visual presentation of the fear of demons and monstrous creatures and the way in which Buddhism serves to alleviate that fear. The audience is reassured that the good forces of religion have neutralized the evil powers of demonic spirits, and so the new year will be a prosperous one. This religious dance is performed on varying scales of grandeur in monasteries throughout the Buddhist cultures of Central Asia, but the most magnificent of all is its performance in Lhasa for the Dalai Lama, the ruler of Tibet.

Buddhist morality plays. The last performing-arts genre to develop in Central Asia was the Buddhist morality play, called *a-che-lha-mo*. The plays are based on the lives of legendary and historical figures, and through costume and masks the ethnic origin and ethical character of the players are revealed. Folktales, as well as historical and Buddhist canonical literature, are sources for the stories presented in *a-che-lha-mo*. Most plays are about mythical heroes who prove that Buddhism and its virtues conquer all evil in the end; but there are those that tell the story of historical personages.

Origins of *a-che-lha-mo*

Although traditions among the Central Asian peoples are vague about the development of shamanic rituals and *'cham*, they are clear about the origin of *a-che-lha-mo* and even point out the historical creators of the art. Some scholars regard the plays as derivatives of Indian theatre, but Tibetan tradition claims that the first performance of a morality play was produced by Thang-stong rgyal-po, a famous bridge builder of the 15th century.

One story is of some Tibetans who were building a bridge and found that what they assembled during the day, demons dismantled at night. Thang-stong rgyal-po, a holy man well versed in the capricious ways of demons, advised the Tibetans to stage a play to divert the attention of the evil spirits. Thus, they were able to complete the bridge. This story would seem to indicate that the primary purpose of the play was to entertain, but another story states that Thang-stong rgyal-po realized that religious teachings would have a greater influence on the people if they were dramatized, so he developed the morality play to serve this purpose. Regardless of his in-

tent, *a-che-lha-mo* evolved as didactic entertainment, and Thang-stong rgyal-po is regarded by the Tibetans as its patron saint.

From primitive beginnings, the morality plays developed into a popular performing art, complete with stylized costumes and masks, complex scenarios and effective staging. The scripts are written in a dialogue song style called *rnam-thar*. There are at least nine traditional plays in the Tibetan repertoire.

Mythical and historical plays

The most common type of *a-che-lha-mo* is the drama based on legend and mythology which often reflects a strong influence of Indian theatrical tradition. An example is the play *'Das-log Snang-sa*. *'Das-log* means to return (*log*) from the beyond (*'das*) and is used in Tibetan to refer to anyone who was believed to be dead and then returns to life and relates all that was witnessed in the netherworld. The story, *'Das-log Snang-sa*, is about a virtuous woman named Snang-sa who was unjustly accused of adultery and beaten to death by her jealous sister-in-law. When Snang-sa was led before the fierce Lord of the Dead (*gshin-rje*), he found that she was pure of heart and mind, and he allowed her to return to life. Once home again, her husband and relatives began to mistreat her, so she became a nun. The play ends with Snang-sa flying away from the convent roof and disappearing like a rainbow in the sky.

Another type of *a-che-lha-mo* is the plays based on the lives of Tibetan holy men or pious kings. *Rgya-bza' Bal-bza'* ("Chinese-wife, Nepalese-wife"), for example, tells the story of king Srong-btsan sgam-po (died AD 649) and his two Buddhist wives: Wen-ch'eng, a Chinese princess, and Bhrikuti, a princess from Nepal. These three historical figures are believed by faithful Tibetans to have been incarnations of Buddhist deities, and their story is very popular with the audience.

The performance of a play may take more than a day. Narrative recitation is used to set scenes, delineate character, and give continuity to the songs that tell the main story. Comic sketches or dances are performed between the acts. Each character in a play has a distinctive costume or mask. Usually Tibetan male characters and the heroes wear no mask, while virtuous female characters wear flat, teardrop-shaped masks, particularly the serpentine deities. Three-dimensional masks are worn by evil foreigners, demons, and witches, and masks that cover the entire head are used to portray animals. Like the *'cham*, the morality play is performed outdoors, with the audience, except for the specially seated lamas and nobles, standing or sitting on the ground around the performing area.

The morality plays are performed for profit by groups consisting of lay men and women, and some have Buddhist monks or nuns as members. These troupes are generally associated with a given locale, such as a village or a monastery; however, they often travel to give performances on special occasions, transporting their wardrobe and stage props with them. In time, four of the most popular troupes were required by the Tibetan government to perform plays at the summer palace of the Dalai Lama. These performances were obligatory as a kind of taxation. There are still several of the *a-che-lha-mo* troupes to be found among the Tibetan refugees in Nepal and India, where their performances are in popular demand.

Mongolian plays of Noyan Hutuqtu

The *a-che-lha-mo* did not spread from Tibet into other parts of Central Asia until the 19th century. According to tradition, the Monoglian lama Noyan Hutuqtu (1803–56) studied *a-che-lha-mo* as performed in the Kokonor (Tsinghai) region of northeastern Tibet and then introduced his own adaptations of it at Tulgatu-yin keyid, his own monastery near the village of Saynshand, in Mongolia. For the first time, in 1832, he produced a repertoire of four plays, and their performance required 17 full days. The four plays were based on the textual biographies of the historical Buddha, the Indian Buddhist Teacher Atīśa, the revered Tibetan hermit-poet Mi-la Ras-pa, and the fabulous "Moon-cuckoo" (*Saran-u Kökügen-ü Namtar*), a mystical story of a pious prince who became a cuckoo bird living in the forest.

Noyan Hutuqtu's productions differed from the usual performance of *a-che-lha-mo* in certain respects. His repertoire did not include any of the plays traditional in Tibet. His actors, unlike those of *a-che-lha-mo*, wore no masks; instead they painted their faces, a makeup technique associated with Chinese opera. Whereas *a-che-lha-mo* is usually performed outdoors in the Himalayan regions, Noyan Hutuqtu had a special theatre constructed near his monastery. It was a three-sided, two-storied, mud-brick building with two stage floors; thus, two scenes could be performed at the same time. The upper stage represented the sky, the lower one the earth. There were stage exits on both sides and trap doors in the floor.

The first Mongolian actors were called *schabi*, or disciples, of the lama Noyan Hutuqtu. These men and women formed a regular troupe and were invited all over Mongolia to perform.

FOLK DANCE

Among the peoples of Central Asia, folk dancing occurs as a form of entertainment at social occasions, such as festivals, weddings, and other celebrations, and private parties. Often impromptu, folk dances are sometimes performed without the accompaniment of musical instruments, and the performers rely on singing and footwork to maintain the rhythm.

Formalized folk dance does not appear to have evolved among nomadic peoples of the steppe and desert regions, but such dances did develop among the sedentary agriculturists, particularly in the Himalayan regions, where troupes of amateur performers were formed for local entertainment. Some dances were performed by a group of men and women forming a circle; in others, facing each other in lines. The dance steps and body movement were done according to a stylized routine, and the rhythmic beat was accented by a measured stamp of the foot.

(T.V.W.)

IV. Visual arts

The immense tract of Central Asia, with its varied topography and climate, encouraged the development of different artistic styles and traditions among the inhabitants of its widely separated sections. These differences were increased by the growth of dissimilar religions, which encouraged the formation of distinct schools of art. Further artistic variance can be attributed to cultural time lag, for comparable stages of artistic development were not reached simultaneously throughout this vast territory. In this article, the diverse and complicated subject of Central Asian art is divided into the following sections: prehistoric; nomadic cultures; Parthian kingdoms of western Turkistan and Afghanistan; Kushan; eastern Turkistan; Arctic regions; and the Himalayan cultures of Nepal and Tibet.

PREHISTORIC CULTURES

Paleolithic cultures. The earliest artifacts discovered in the Central Asian region were found in Siberia and western Turkistan and are from around the 13th millennium BC. During the millennia that followed, migrants entered the region from various directions, regardless of the geographical obstacles they encountered. As a result, some of their artifacts correspond with those produced at a similar stage of development in more western areas; some finds from the northeastern part of Soviet Turkistan, for example, are related to certain objects made in Iran and Mesopotamia, and those from northwestern Central Asia are linked to eastern and central Europe by means of the Volga River and of Kazakhstan.

The Paleolithic (Old Stone Age) sites of western Turkistan are mainly concentrated in the Lake Baikal area. A cave in the Baysuntau Range containing the body of a Neanderthal boy aged about nine had been so carefully prepared that it is evident that the people who made his grave believed in an afterlife. The site of Malta, 50 miles (80 kilometres) to the southeast of Irkutsk, and that of Buret, 80 miles (130 kilometres) to the north, are noted for their mammoth-tusk figurines of nude women. They resemble Paleolithic statuettes of Europe and the Near

Fertility images and rock painting

East and probably served as fertility symbols or as representations of the great goddess, whose cult was widespread. Some of these figurines depict elegant, slender women, others heavy, corpulent ones. Of five found at Buret, one is unusual in that it is of a clothed woman wearing a one-piece trouser suit with a hood attached to it comparable to those still worn by present-day Eskimos. In recent years Paleolithic sites have been discovered south of Samarkand, and rock paintings have been found at Zaraut Say (Zaraut Stream) in the Babatag Range, 50 miles east of Termez, and in the Shakty Caves in the Pamirs. Executed in red ochre, they depict hunting scenes. Those in the Shakty Cave are the older and include a man disguised as a bird and other men wearing skins and shooting at wild oxen with bows and arrows.

The invention of the bow is ascribed to the 10th millennium BC, the Mesolithic Period. Man's artistic development during this period is attested by a pottery fragment of a most expressive woman's face dating from the 3rd millennium BC and recovered from the site of Vosnesenovka in western Siberia.

Neolithic and Metal Age cultures. Numerous Neolithic sites have been discovered in Asiatic U.S.S.R., and the number of Bronze Age sites is even higher. The majority have been found on the middle reaches of the Yenisey River, especially in the Minusinsk Basin, where metallurgy developed early. They testify to the existence of three main, basically successive, yet often overlapping cultures: the Afanasevskaya, Andronovo, and Karasuk, so-called after the three villages near which each culture was identified.

Afanasevskaya burials

A cemetery to the southwest of Krasnoyarsk, on the slopes of the Afanasevskaya Mountains, contained 80 burials dating from the 2nd millennium BC. The earlier ones were flat and marked by stone circles symbolizing the sun god; the later ones took the form of barrows, or large mounds of earth, but were also encircled by similar stone slabs. The earlier graves contained elongated, spherical pottery vessels with pointed bases decorated with herringbone patterns. In the later graves this type of ware was superseded by flat-bottomed pots usually associated with sedentary pastoralist cultures. The graves also contained numerous stone and bone objects. Although copper objects were rare, they heralded the dawn of a new cultural period, the Metal Age.

The Andronovo culture succeeded the Afanasevskaya in the 2nd and 1st millennia BC. Although found to the southwest of Krasnoyarsk, it is more frequently encountered in western Siberia and Kazakhstan. The settlement and cemetery of Alekseevskoe (present Tenlyk), some 400 miles (600 kilometres) south of Sverdlovsk, is especially important, because its earth houses were designed for permanent habitation. Their roofs rested on logs, and each dwelling had a central hearth used for heating purposes with side hearths intended for cooking. Bronze objects were numerous, and workshops existed for working copper. The metal probably came from mines in the Minusinsk Basin, Kazakhstan, and the western Altai Mountains, the latter having been worked as early as the 14th century BC.

Houses of Andronovo culture

Dating from about 1200 to about 70 BC—the dawn of the Iron and historical age—the Karasuk culture was located in the Minusinsk Basin, on the Yenisey River and on the upper reaches of the Ob River. Its creators must have been in touch with East Asia, for certain bronze objects, notably elbow-shaped knives, are related to those used between the 14th and 11th centuries BC in China during the Shang period. Stone pillars topped either with ram's heads, stylized animal forms, or human figures have also been discovered. Dzheytun, northwest of Ashkhabad, in what is called the Kyzylkum desert, is the oldest known agricultural settlement in Central Asia. It possessed a thriving Neolithic flint industry.

Annau, six miles (ten kilometres) southeast of Ashkhabad, and Namazga-Tepe, situated in the same region and occupying an area of some 145 acres (60 hectares), are important Bronze Age sites. The pottery vessels recovered from Namazga-Tepe are decorated with painted plant and animal motifs showing affinities with contemporary pottery wares from the Near East. Figurines of dogs and sheep were numerous, and a model of a house has also been found. At Karatepe, also near Ashkhabad, an agricultural society produced fine pottery from the 3rd millennium BC, but it reached its fullest development in the 2nd millenium BC in a series of vessels decorated with particularly spirited animal designs.

Pottery in the Ashkhabad region

The main Neolithic and Bronze Age cultures produced several distinctive offshoots, which began to emerge by the early Iron Age. In Chorasmia, the Neolithic culture discovered at Dzhan-Bas-Kala is known as the Kelteminar and that of the Bronze Age, as represented by the Chorasmian level of Kokcha III, as the Tazabagyab. The Neolithic Hissar culture of southern Tadzhikistan spread across northeastern Central Asia into the Semirechiye, or foothills of the Tien Shan, while in Siberia the Bronze Age Karasuk culture was replaced in the 8th century BC by the Tagar culture. The latter endured until the 2nd century BC, producing an art of animal motifs related to that of the Scythians of southern European Russia.

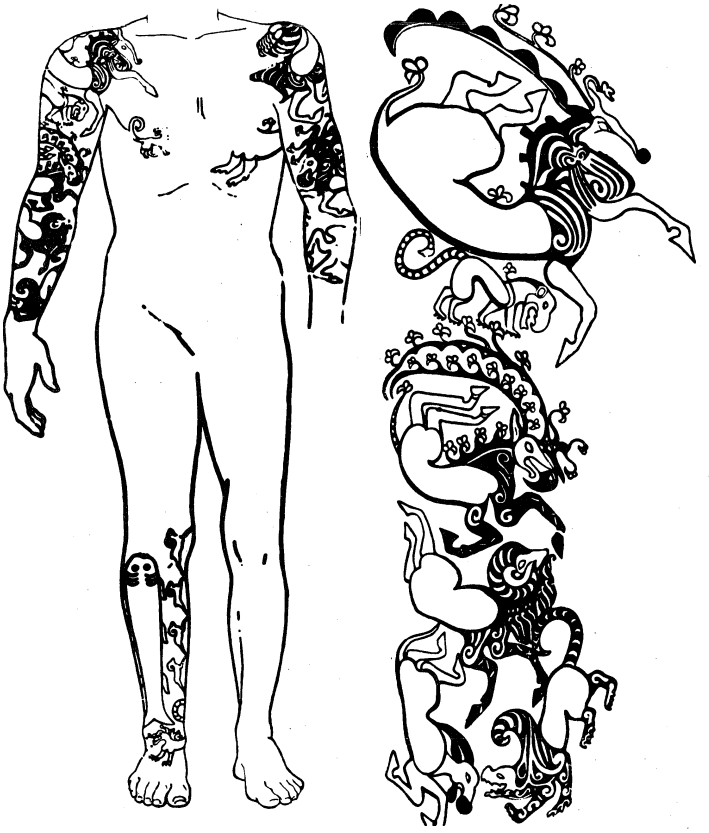
The Bronze Age culture on Fergana's western border is associated with settlers living in large houses grouped to form settlements of considerable size. Some of the inhabitants worked in copper mines at the time when potters of the Chust Bronze Age culture of the Fergana Valley were producing fine-quality tableware, as well as cruder pottery articles. The best Chust pottery was very thin, covered with a red slip (liquid clay) and decorated after glazing with black triangular and scroll designs.

NOMADIC CULTURES

During the 1st millennium BC and the 1st centuries of the Christian Era, certain nomadic tribes affected the course of Central Asia's artistic history. Cyrus II the Great, the ancient Persian king who founded the Achaemenid Empire, was killed by the nomadic Massagetae when campaigning in eastern Iran in 530 BC. At the time, the Śaka tribe was pasturing its herds in the Pamirs, central Tien Shan, and in the Amu Darya Delta. Their gold belt buckles, jewelry, and harness decorations display sheep, griffins, and other animal designs that are similar in style to those used by the Scythians, a nomadic people living in the Kuban Basin of the Caucasus region and the western section of the Eurasian plain during the greater part of the 1st millennium BC. When considered together with objects of a like nature recovered from the frozen burial sites of the western Altai Mountains, it becomes evident that many of the Central Asian tribesmen commonly shared the traditions and culture that were once associated only with the Scythians.

Altaic tribes. Because of a freak climatic freeze, some of the Altaic burials, notably those of the 5th century BC at Pazyryk and neighbouring sites, such as Katanda, Shibe, and Tuekt, were isolated from external climatic variations by a protective layer of ice that conserved the organic substances buried in them. At Pazyryk these included the bodies of horses and an embalmed man whose

By courtesy of the State Hermitage Museum, Leningrad



Tattooed designs on the male body found in Kurgan II, Pazyryk, 4th century BC. (Right) Detail from the right shoulder and right arm. In the Hermitage, Leningrad.

The Pazyryk burial site

body was covered with tattoos of Scythian animal motifs. The remarkable textiles recovered from the Pazyryk burials include the oldest woollen knotted-pile carpet known, the oldest embroidered Chinese silk, and two pieces of woven Persian fabric (Hermitage Museum, Leningrad). Red and ochre predominate in the carpet, the main design of which is of riders, stags, and griffins. Many of the Pazyryk felt hangings, saddlecloths, and cushions were covered with elaborate designs executed in appliqué feltwork, dyed furs, and embroidery. Of exceptional interest are those with animal and human figural compositions, the most notable of which are the repeat design of an investiture scene on a felt hanging and that of a semihuman, semibird creature on another (both in the Hermitage Museum, Leningrad). Clothing, whether of felt, leather, or fur, was also lavishly ornamented. Horse reins either had animal designs cut out on them or were studded with wooden ones covered in gold foil. Their tail sheaths were ornamented, as were their headpieces and breastpieces. Some horses were provided with leather or felt masks made to resemble animals, with stag antlers or rams' horns often incorporated in them. Many of the trappings took the form of iron, bronze, and gilt wood animal motifs either applied or suspended from them; and bits had animal-shaped terminal ornaments. Altaic animals frequently display muscles delineated with dot and comma markings, a formal convention that may have derived from appliqué needlework. Although such markings are sometimes included in Assyrian, Achaemenid, and even Urartian animal representations of the ancient Near East, they seldom appear on those of purely Scythian origin. Roundels containing a dot serve the same purpose on the stag and other animal renderings executed by contemporary Śaka metalworkers. Animal processions of the Assyro-Achaemenid type also appealed to many Central Asian tribesmen and are featured in their arts.

Altaic decorative motifs

Certain geometric designs and sun symbols, such as the circle and rosette, recur at Pazyryk but are completely outnumbered by animal motifs. Such specifically Scythian features as zoomorphic junctures—*i.e.*, the addition of a part of one animal to the body of another—are rarer in the Altaic region than in southern Russia. The stag and its relatives, however, figure as prominently in Altaic as in Scythian art. Combat scenes between carnivores and herbivores that occur quite often in Scythian art are exceedingly numerous in Pazyryk work; but, whereas the Scythians show the victim passively accepting its fate, as on 5th-century BC gold triangular plaques from the so-called Seven Brothers burial in the Kuban, the Pazyryk beasts are locked in such bitter fights that the victim's hindquarters become inverted.

Siberian tribes. In the virtually contemporary metalwork of Siberian nomads, single animals of the cat family, such as panthers, carry the Altaic tendency of exaggeration further by twisting their bodies into a circle. In slightly later Siberian plaques, subtle openwork is used, a feature rarely present in Altaic or Scythian objects but frequently encountered in the more rounded versions of the animal style produced in the Ordos region of China, perhaps by Hunnish craftsmen, between the 4th century BC and the 2nd century AD. In the latter part of the 1st millennium BC, Siberian metalworkers adorned many of their gold and bronze plaques with artificial gems made of glass, as well as with jewelled inlays. They produced belt buckles shaped like the letter *B*. Two such gold buckles (Hermitage Museum, Leningrad) are of particular interest because of their figural content. It has been suggested that they illustrate some ancient Central Asian epics, for one depicts a hunting scene and the other a warrior lying under a tree with his head resting on a woman's lap, while a servant holds their two horses. These subjects, possible forerunners of certain episodes in the *Shāh-nāmeh* ("Book of Kings," a work by the 10th century Persian poet Firdausi giving an account of ancient Iranian history), are thought to complement those on a series of openwork plaques, some of them of Ordos origin, on which either two dismounted riders are shown fighting while their horses stand passively on either side or two horses are seen locked in battle, pursuing their masters' quarrel (Hermitage Museum, Leningrad).

Mongolian Huns. In the 4th century BC the Huns started to migrate westward from the Ordos region. By the 3rd century BC, they had reached the Transbaikalia and had begun to enter Mongolia, which soon became the centre of their empire. Numerous mounds mark their progress. Those in the Zidzha Valley lie in the same latitude as the Pazyryk mounds and were subjected to similar conditions of freezing temperatures, which helped to preserve their contents. The richest of the excavated burial sites, however, are those of Noin Ula, to the north of Ulaanbaatar, on the Selenge River. Like those at Pazyryk, they included horse burials. The furnishings of one tomb were especially lavish. The prince for whom it was made must have been in contact with China, for his coffin was apparently made for him there, as were certain of his possessions buried with him (among them, a lacquer cup inscribed with the name of its Chinese maker and dated September 5, AD 13, now in the Hermitage Museum, Leningrad). His horse trappings (Hermitage Museum, Leningrad) are as elaborately decorated as many of those discovered at Pazyryk. His saddle was covered with leather threaded with black and red wool clipped to resemble velvet. The magnificent textiles in his tomb included a woven wool rug lined with thin leather (Hermitage Museum, Leningrad); the centre of the rug depicts a combat, of Scytho-Altaic character, between a griffin and an elk, executed in purple, brown, and white felt appliqué work. The animals' bodies are outlined in cord and embroidered. The design on another textile is embroidered in the form of a tiger skin with a head at each end. The animal's splayed-out body is formed of

series of masks, some of them modelled; others, casts taken from the dead. They were painted with the features rendered in blue, red, and green against a yellow ground. Spirals disposed on the foreheads, temples, and cheeks of many of these masks probably represent tattoos. In many cases pearl necklaces worn by the women are also included. Although the animal motifs of the Tashtyks remained strongly Scytho-Altaic in style, the community was so much influenced by China that even its architecture was affected. Just south of Abakan, a large house made of beaten clay in the Chinese style has been discovered. Its roof had been covered with Chinese tiles, some of which carry inscriptions of the Han dynasty.

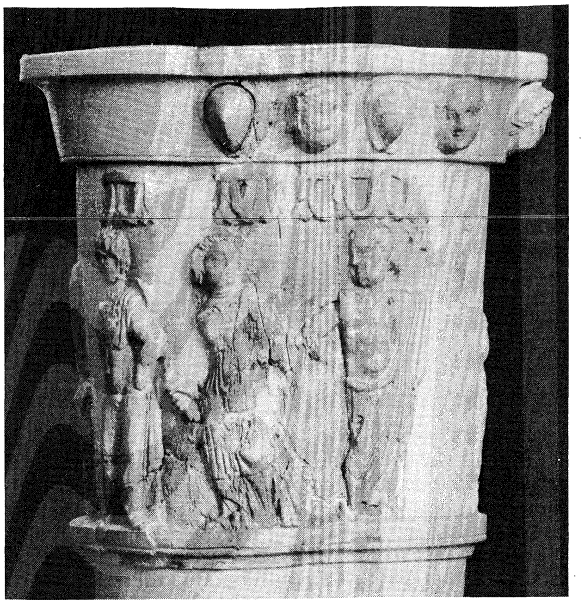
Painted masks

PARTHIA

The Parthian Empire came into being in Khorāsān during the reign of Seleucus I, 358–281 BC, following the absorption by the Parthians of Parni (Dahae) tribesmen. The caravans traversing their territory brought them wealth and ideas from abroad. The figural art of the Hellenistic world made an especially strong impression on them. The finest Parthian objects come from Old Nisa, a town situated on the edge of the Karakoram Range, some 11 miles (18 kilometres) south of Ashkhabad in Tadzhikistan, close to the later town of New Nisa. Old Nisa was founded around 171 BC by Mithradates I to serve as a royal Parthian residence and necropolis, as well as the kingdom's capital. It contained several fine temples and an impressive palace built around a vast central hall, the roof of which was upheld by wooden supports set in stone bases—a practice followed in the town's larger houses. Lifesize clay statues of men and women stood between these supports. The royal treasuries contained many valuables, including silver and silver gilt statuettes of local Parthian deities and of Greek gods, bronze and iron weapons, burnished and painted pottery, glass, and cast bronze animals, such as griffins. The most significant of these treasures, however, is a series of ivory horn-shaped drinking vessels, or rhytons. Some are embellished with paste inlays and precious stones, other have a carved frieze or band encircling their open ends. One rhyton (Hermitage Museum, Leningrad) has a frieze of a procession that includes a Greek god. Conceived in the purest Hellenistic style, the frieze contrasts sharply with the rhyton's horned, lion–griffin-shaped terminal ornamentation, which is admirably modelled in the round, in accordance with the Scytho-Altaic tradition.

THE KINGDOMS OF WESTERN TURKISTAN AND AFGHANISTAN

Skill in irrigation, with the resulting expansion in agriculture, encouraged urbanism and the growth of states, changes that coincided with the rise of nomadism. While the nomadic cattle and horse breeders took over the steppelands, the culturally distinct states of Sogdiana (part of Uzbekistan and much of Tadzhikistan), Fergana (the greater part of Uzbekistan), Chorasmia (the Tashkent region), and Bactria (mainly Afghanistan) were established. At times independent, at other times reduced to vassaldom, the first three states were centred on rivers —Sogdiana around the Zeravshan and Kashkadarya, Fergana on the lower Syrdarya, and Chorasmia on the Amu



Detail of an ivory rhyton from Nisa, 2nd century. The frieze shows a procession that includes a Greek god. In the Hermitage, Leningrad.

Darya's basin. (The earliest references to these states are to be found in the Avesta, the principal scriptural work of the Zoroastrian religion, and in the inscription cut by order of the Persian king Darius I (reigned 522–486 BC) on the face of the rock of Bīsitūn in the Kermanshah province of Iran.) Bactria extended from the Syrdarya to the Hindu Kush (southern Tadzhikistan and Afghanistan) and is rich in unexplored mounds. Excavations at Balkh show that its first inhabitants settled there when others were doing so at Afrasiab (Samarkand) and Merv.

The political and economic changes that developed in the 4th century BC, following the Macedonian Greek king Alexander the Great's conquest of these states and their incorporation in the Seleucid Empire, and the conquests made, in turn, by the Parthians, Arabs, Turks, and Mongols are reflected in the regions' arts. The city of Alexandria-Kapisu (Begrām), founded by Alexander the Great, became the clearing house for India's western trade. India's religious beliefs, especially Buddhism, and the scriptural style that evolved in Gandhāra (an area situated between the Qondūz and Indus rivers in the Lower Kābul Valley of northwestern Pakistan) and Mathurā (in the Punjab [Pañjāb] region of northwestern India) followed along the trade routes and reached not only Bactria but, at times, also Kashmir, Tibet, China, and even the remote oasis towns of the Tarim Basin in Sinkiang. At the same time, Seleucid support resulted in the introduction of Greco-Roman art forms into Bactria, Kapisu, Taxila (Rāwalpindi), Gandhāra, Mathurā, and, after thirty years, even into Seistan.

Sogdiana. Sogdiana, with its capital of Afrasiab, was already noted for the sophistication and number of its towns when Alexander the Great conquered it in 328 BC and opened it up to Greek soldiers and administrators, and eventually to Roman traders. The Sogdians resented being governed by Alexander's successors, the Greek kings of the Seleucid dynasty. It is difficult to establish their relationship with their Seleucid suzerains and still more so with the later Kushans, but there is ample evidence to show that neither group of conquerors hindered the rise in both Sogdiana and Chorasmia of a local feudal nobility and class of rich farmers.

Pottery sculpture

A considerable amount of secular and religious pottery sculpture dating from the early Christian Era to the Arab invasion of the 8th century has been found at Afrasiab. The more interesting examples consist of statuettes of clothed women, some of them representing Zoroastrian deities such as Anahita. They have foreshortened bodies and large heads with a withdrawn expression on their faces and wear tiaras, hats, or hoods sewn to their cloaks. When the cloaks are sleeveless, they are worn over straight, long-sleeved robes instead of draped garments. All of the figures hold a piece of fruit, a symbol of fertility. Third-to-fourth-century statuettes from the fortified town of Tali Barsu, to the south of Samarkand, depict Syavush, the god of annual death and spring rebirth, as a musician. Statuettes of women flutists, riders, animals, and the Iranian semihuman-semianimal demi-god Shah Gopat have also been discovered there. In the 7th and 8th centuries, sculpture, whether in clay or alabaster, was highly developed at Pyanjikent, a site some 40 miles (60 kilometres) east of Samarkand, where Indian influence was often felt.

The earliest of Turkistan's mural paintings have been found in its eastern section. Those at Niy date from the 2nd century AD; those at Miran, from the 3rd. The inspiration in both stemmed from Rome, whereas Buddhism provided the impulses for the slightly later murals at Bāmiān and Kizil. In the eastern zone the paintings were designed as backgrounds to sculpture, and, as in western Turkistan, they were executed in tempera. Some very high quality murals recently discovered in western Turkistan are dated slightly later. The oldest ones, which are extremely fragmentary, are from the Varakhsha, a princely residence to the northeast of Bukhara, now lying in the desert; they date from the 3rd to the 4th century AD. Murals discovered at the beginning of the 20th century at Samarkand, which are almost contemporary with those at Varakhsha, have been lost. The importance of these murals is wholly eclipsed by the slightly later works discovered recently in Sogdiana, such as the 7th-century works at Varakhsha. Some of the rooms in the main apartments of the Varakhsha Palace (which consisted of several detached buildings) are decorated with high-relief alabaster stucco panels and carved woodwork, as well as with paintings. Benches are inserted into the walls of one room, the area above them divided into two registers, or horizontal rows, both painted red. In the upper register was a procession of animals, little of which survives, and, in the lower, splendidly attired hunters seated on elephants pursued spirited leopards and creatures of the griffin family.

Mural paintings at Varakhsha

Some 200 miles (300 kilometres) east of Samarkand, in a once fertile, now desert tract of land, the ruins of the great feudal castle of Mug survive. Among the objects excavated there was part of a wooden shield with the painted figure of a rider (Hermitage Museum, Leningrad), which foreshadows a type commonly found in Islāmic Persian book illumination. Mounted on a splendidly caparisoned horse, he wears a tunic of local cut and is equipped with a long sword, two daggers, two bows, and a quiver full of arrows. He is wasp waisted in the manner of figures depicted in murals of Varakhsha and Pyanjikent.

At Pyanjikent, a site close to Mug, and some 40 miles (60 kilometres) east of Samarkand, Sogdian architecture can be seen to advantage. The desert-engulfed city contained several large temples built of rectangular adobe bricks and blocks of beaten clay. The bricks were used for vaults and domes, while the flat sections of the roofs were made of rafters supported by wooden pillars or piers, some of which had been set in stone bases. Many of the more important houses were two storied. A square room measuring 26 by 26 feet (eight metres by eight metres) had served as a temple sanctuary. Although, in a series of rooms connected to it, some fragmentary religious paintings survived, the paintings in another temple are better preserved. They depict the death, the Sogdian burial rite, and the rebirth of a youthful Syavush. Over 50 figures of this vast composition survive, some representing Sogdian noblemen, some a group of Turks. A number of the Sogdians are seated crosslegged in the oriental manner and hold gold and silver vessels of Sāsānian shape in three fingers of one hand. The men's single, close fitting Sogdian tunics—elegant versions of the nomadic dress—resemble garments depicted in paintings of the Buddhist temples of Bāmiān and eastern Turkistan, notably at Kizil and Kuca. The style and, in some cases, the

Temple architecture and decoration at Pyanjikent

subject matter of these Sogdian scenes must have influenced the illuminators of such Islāmic Persian works as the Shāh-nāmeh. Another set of murals is unusual in that it is executed in high relief and then coloured. It shows human beings, sea monsters, and fish, with the waves of the sea rendered in lower relief than the figures. Yet another mural depicts a feast against a black background; a king and several priests sit crosslegged under a canopy; a woman harpist, some musicians and dice players, and a procession of elephants complete the scene. By placing light figures against dark or vivid backgrounds, Sogdian artists evolved a distinct form of perspective.

A study of the religious paintings shows that Central Asian Zoroastrianism retained elements from the earlier indigenous cult of the sun and moon. Some of the scenes in the secular works are linked in their subject matter (but not their style) to a small group of older Siberian gold and bronze *B*-shaped buckles and to the Siberian and Ordos plaques that are thought to illustrate local epics. Other secular scenes give full expression to Sogdian interest in the splendour of contemporary court life and prowess in hunting and warfare. The love of overall decoration and of animal motifs is as prevalent as in nomadic art. Details incorporated in Sogdian paintings proclaim the eclecticism of the society they depict and for which they were created. Sāsānian influence from Persia is seen in crowns trimmed with ribbons, veils, and bells; in the styling and trimming of hair and beards; and in many of their vessel shapes. The helmets worn by the warriors in the Pyanjikent libation scene resemble those depicted in the murals of eastern Turkistan. The clothes follow local fashions, and certain horse trappings display disks the shapes of which recall nomadic types.

Sāsānian motifs in Sogdian textiles

Sogdian textiles are known to have been in great demand among their neighbours. Sāsānian motifs must have reached Sogdian weavers by way of imports from Persia, indirectly routed through Parthia, and also from Zoroastrians seeking protection in Sogdiana from Persian persecution. These motifs often figure both on surviving textiles and on those recorded in the paintings. The murals at Varakhsha, for example, include motifs taken from textiles; and a 5th-century mural from Balalyk Tepe displays the head of a tusked, boarlike animal set in a roundel that is almost identical to that on a Sāsānian fabric found at Astana in eastern Turkistan.

Between the 5th and 7th centuries, the Sogdians made dried-brick caskets shaped like rectangular rooms to contain ossuaries, or urns for the bones of the dead. The sides and lids of the ossuaries were decorated. The ornamentation on an ossuary from Bia Naiman (Hermitage Museum, Leningrad) has so many points in common with the decorations on a series of silver vessels that were, until recently, assigned to Bactria that the latter have come to be accepted as Sogdian. Several ewers have niches containing nude women rendered in a markedly Indian style, thereby recalling many a carved ivory plaque from Begrām. Very similar niches adorn the Bia Naiman ossuary, but these contain crowned figures. In both cases the niches owe their form to Western influence, but those on the ossuary are formed of columns surmounted by capitals upholding pearl-studded arches, while on the ewers the Central Asian rosette replaces the capitals and the pearls.

Sculpture, both in relief and in the round, was widely produced in Sogdiana. Much of the earlier work takes the form of panels or friezes made of alabaster, stucco, and, occasionally, wood. Rosettes, roundels, disks, and vegetation provide the chief motifs. Audience chambers and large reception rooms often contained statues in the round. Even the statues attached to the wall had the appearance of being worked in the round. The earliest wooden caryatids, or columns in human form, are found in western Turkistan at Pyanjikent. The caryatids in the form of women have their hair elaborately dressed, and, although nude at the waist, they wear boleros, as well as close fitting, heavily trimmed skirts and splendid necklaces of Indian appearance. Once again, these figures recall those on Begrām's ivory plaques and Buddhist statuettes of the 1st to 5th centuries.

Fergana and Chorasmia. Fergana produced much pottery of quality, but, as yet, there have been no finds of comparable importance to those in Sogdiana. Its arts appear to have paralleled the developments in the more prosperous, more heavily populated, and more highly urbanized state of Chorasmia. Chorasmia's defensive architecture was particularly notable. Its great citadels and palaces were enclosed by two lines of walls strengthened by massive towers that were fitted with lookout posts and firing slits and topped by archers' galleries. Chorasmian entrance gates were labyrinthine in plan. Many of these splendid buildings have disappeared be-

neath the desert's encroaching sands. Recently excavated, Toprak kala, near Termez, is thought to have served not only as a citadel but perhaps as Chorasmia's capital until about the 7th century. Defended by stout walls, the palace of sun-dried bricks was equipped with three lookout towers. The ground floor of this two storied building acted as a foundation for the living rooms and storerooms above. Many of the rooms were adorned with sculpture: its most impressive room, the Hall of Kings, had niches fitted with grills ranged along the tops of its walls to hold statues of Chorasmia's rulers and notables; the Alabaster Hall contained many sculptures executed both in the round and in relief; a Hall of Victories contained statues of kings seated in the presence of a goddess of victory; statues of warriors carrying shields adorned the Warriors' Hall. All of the Chorasmian figural works are so lifelike that it is evident that portraiture had reached a high state of development by the 3rd and 4th centuries AD. Surviving decorations in the fortified manorhouse of Teshik Kala display the palmette, rosette, lotus, and ace-of-spade motifs that the Seljuqs later carried westward to Anatolia and beyond in the 11th and 12th centuries.

Bactria. The most Hellenized of these states in western Turkistan and Afghanistan was Bactria. Its fine coinage, for example, was distinctly Hellenistic in style, and Bactrian silversmiths were often influenced as much by Roman as Greek Hellenistic metalwork. Alexander the Great annexed Kābul to Bactria and founded Alexandra-Kapisu, a city astride the Indian caravan route, to serve as the province's capital. The multiracialism of Kapisu's population is reflected in the origins of the objects found there. Imports included articles from India, China, and the Greco-Roman world, especially from Syria. Artistic conventions characteristic of all these countries blended with the local Central Asian ones, with the Indian conventions predominating, to create Bactria's own distinctive style in sculpture, whether in alabaster, stone, ivory, or wood. Its mural paintings are wholly Buddhist in content, but they often contain features that link them to Fundukistan in India and the Sāsānian Persian world.

Importance of the decorative arts in Bactria

The decorative arts were highly developed in Bactria. Many of their sun-dried-brick houses were large enough to include several reception rooms, which contained many luxurious decorative objects. Potters remained attached to animal forms derived from nomadic art. The large production of votive statuettes, especially representations of Anahita and Syavush, may be partly attributed to the belief that Zoroaster was born in Balkh. This tradition was also evident at Merv until the Arab Invasion of Central Asia. The Bactrians mastered the technique of working metals at an early date. A 4th-century-BC lion-griffin (British Museum) in cast bronze is descended from a Scytho-Altaic prototype and so, too, is a pair of slightly earlier gold armlets (British Museum, London), originally embellished with inlay, from the Oxus Treasure. A series of silver dishes (Hermitage, Leningrad) from the end of the 1st millenium BC are, on the other hand, decorated with scenes drawn from the tragedies of the Greek dramatist Euripides and Greco-Roman mythology rendered in a markedly Hellenized style. Other silver dishes employ Indian motifs such as elephants. By the 8th century, these diverse ornamental motifs had fused, as on a silver-gilt bowl (Hermitage, Leningrad), dated between the 5th and 8th centuries AD, into a Kushan style that may well have provided the basis for Persia's later Rey figural pottery style.

KUSHAN

The Kushans replaced the Greeks in Bactria around 130 BC. They are thought to have been of Yüeh-chih stock with a strong admixture of Hephtalites, Asiani, Śaka, and Tokharian. One branch of this group migrated to the Tarim Basin and founded a short-lived empire, while the other, under the name of Kushan, gained control of Central Asia. Capturing a section of the great trade route leading from India and China to the west, the Kushans derived much of their revenue from the transit dues they exacted from the caravans crossing their territory, which often were carrying supplies of Chinese gold, silver, and nickel from the Tarim oasis towns to the Seleucid Persians. Around 106 BC, the first caravan to carry silk from China direct to Persia passed through territory that had belonged to the Seleucids but was now divided between the Kushans and Parthians.

Kushan art reached its fullest development in the 2nd century AD, when the great king Kaniṣka is believed to have reigned. A magnificent, almost lifesize, now headless sculpture of Kaniṣka (Archaeological Museum, Mathurā) shows him wearing an elegant version of nomadic dress. His kingdom extended from Central Asia to include Gandhāra and Mathurā, where the Seleucids had so firmly established Hellenistic art that Western influence continued to maintain its hold even in the reign of the first members of India's Gupta dynasty. When Mahāyāna Buddhism reached Gandhāra during the 4th and 5th centuries AD, its sculptors turned to the Hellenistic world as a matter of course for a visual conception of Buddha and quickly evolved several Hellenistic versions. In the popular Apollo version Budda is long faced, long nosed and has wavy hair. This type survived into the 5th century and penetrated as far as Kashmir and Turkistan.

The Gandhāra and Mathurā styles of Buddhist sculpture

A school of religious sculpture equal in importance to that of Gandhāra developed almost simultaneously at Mathurā. Its earliest Buddhist images are virtually contemporary with the earliest ones produced in Gandhāra but, in Mathurā, Indian influences predominate. The portrayal of Buddha in the Mathurān style is softer yet more direct. The features are more Eastern; eyebrows extend in a continuous, sinous line; hair is straight; the earlobes are elongated; and an enigmatic smile replaces the withdrawn expression of the Hellenized Buddhas of Gandhāra. While the sculptors of Mathurā used a red sandstone, the Gandhārans worked in limestone or a local gray schist. They generally chose the latter for the small, uniform-sized panels with which they faced their *stūpas* and *vishanas*, carving them with scenes of Buddha's life. On the panels, the story unfolds from left to right, each scene being framed either within trees, leaves, or Corinthian columns sometimes linked by arches. These religious narratives often include furniture and details drawn from contemporary life. The figures, which use gestures of Indian origin to convey emotion, display racial characteristics that range from Indo-European to Mongolian. Many figures are presented in the frontal position favoured by Parthian artists, while others appear three-quarter face, as in Hellenistic art. Some wear Hellenistic robes and headdresses such as those worn in Palmyra, an ancient city in Syria. The Gandhāran style of sculpture was no longer produced after this area was invaded by the White Huns, in the 6th century.

Central Afghanistan is rich in Kushan sites. Āteshkadeh-ye Sorkh Kowtal, situated in the Qondūz Valley, close to the Kābul-Mazār-e Sharīf road, is dated by an inscription to the time of Kaniṣka's reign. Architecture was highly developed there. The town was protected by a double row of walls that ascended the hill on which it stood. The most impressive site within the wall was occupied by a dynastic fire temple, built to an Achaemenid plan in large blocks of well-dressed stone and approached by an imposing staircase. Within, columns topped by Corinthian capitals supported the roof. Numerous sculptures had originally adorned the interior, those worked with floral and animal motifs conforming to the Gandhāran tradition, while figural works followed Scytho-Parthian and, to some extent, Hellenistic traditions.

Buddhist art at Bāmiān

The Buddhist art of central Afghanistan is admirably represented at Bāmiān, where Mani, the Iranian founder of the Manichaean religion, probably lived and encouraged the growth of a religious pictorial art in the 3rd century AD. At both the eastern and western approaches to Bāmiān, a huge statue of Buddha as ruler of the world was cut into the face of the rock. The smaller statue measures 120 feet (about 40 metres) and dates from soon after the town's foundation in the 4th century AD; the other measures 170 feet (50 metres) and dates from the 5th century. In their commanding monumentality, both statues reflect the influence of the Mathurān image of King Kaniṣka and the portrait sculpture of Sāsānian kings and Parthian notables. Traces of painting showing Sāsānian and Indian influences survive in the rock-hewn niche behind the earlier Buddha.

Regardless of Manichaean influence, Sāsānian elements prevailed at Bāmiān between the 4th and 6th centuries. At Dūktar-e Nowshirvān, near Bāmiān, a 4th-century painting of a Sāsānian king flanked by attendants survives. The murals in Bāmiān's 5th-century temple of Kakrak include one of a deified king of Sāsānian appearance, while others display the figure of Buddha set within a circle and wearing a costume of the Sāsānian type. Sāsānian motifs of paired birds and griffins placed in medalions or pearl circlets are common. In the murals at Imgur-Enlil, Buddha wears a close-fitting tunic resembling that worn by the Sāsānian king depicted on the rock carvings of Ṭāq-e Bostān. The traces of Hellenism, which are also evident in these wall paintings, began to disappear by the 5th century, when Sāsānian influence gradually gave way to the Gupta style of India.

Stemming from Gupta art is the practice adopted at Bāmiān between the 5th and 6th centuries of painting in the dome of a sanctuary a Buddha within a circle or hexagon. Gradually, these circles and hexagons became symbols of the heavenly Buddha. Many developed into rosettes and eight pointed stars—motifs that were retained in the 10th and 11th centuries by the Islāmic Seljuqs, who carried them to Persia and Asia Minor. As Gupta influence increased, sculpture gained in importance. A new style had evolved by the 8th to 9th centuries, but it did not penetrate into western Turkistan,

where the Arab conquerors religiously opposed figural art. In the 9th century many Buddhists left Kashgaria, and Islām gained ground. Figural sculpture was forced underground and was primarily produced by secret shamanistic cults of an indigenous Central Asian origin. Although figural art was never to flourish in western Turkistan as gloriously as it had prior to the Arab invasion, there was a revival under the Mongols in the form of book illuminations.

EASTERN TURKISTAN

Uighurs. The figural arts found new patrons in eastern Turkistan among the Turkic Uighurs, who while living in T'ang dynasty China had been influenced by Manichaean figurative art. The overthrow in China in 846 AD of Buddhism by Confucianism forced the Buddhist Uighurs to migrate to eastern Turkistan. Gradually, they gained control over the Tien Shan region, Turfan, and the northeastern section of the Tarim Basin. The Turkic Uighurs especially favoured portraiture. In the 7th and 8th centuries Uighur artists already had acquired great proficiency in rendering likenesses in a style heavily influenced by Chinese portraiture of the T'ang period. These portraits were painted on silk and often inscribed with the sitter's name.

Portraiture of the Turkic Uighurs

Khitans. The figural style is believed to have been transmitted to the Mongols by the Khitans when the latter were living on the middle reaches of the Yenisey. The wealth of the Khitan princes is reflected in the furnishings of burial mounds discovered at Kopeni, some 200 miles (300 kilometres) to the south of Krasnoyarsk. Dating from the 7th to 8th centuries, these mounds were similar in type to those constructed by the nomads of the 1st millennium BC. One of the richest graves contained four gold jugs set on a silver dish and a number of gold, silver, and bronze ornaments (Hermitage Museum, Leningrad). Two of the jugs, although undecorated, carry Orkhon inscriptions on their bases. Two others are covered with delicate relief representations of birds and fish surrounded by flowers and vegetation, executed in a style influenced by Islāmic art. A Scytho-Altaic hunting motif of riders pursuing a tiger, a deer, and a panther appears on a bronze ornamental object.

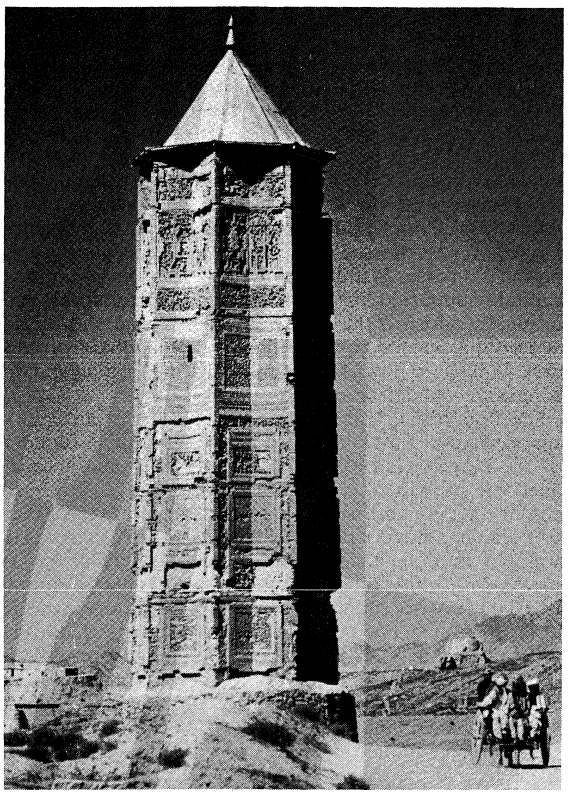
Turkic tribes had been massing in Central Asia from about the 5th century AD. In the 6th century the Kul Tepe and Bilge Khan tribes established a state of their own in the Orkhon Valley. The inscriptions that they carved on the valley's rocks are of considerable historical importance. In the 7th century the Turkic Oğuz people were so numerous that they constituted 24 tribes. The Sāmānids, Ghaznavids, Ghūrids, and Seljuqs were of Oğuz extraction.

Sāmānids. The Sāmānids centred their kingdom in Khorāsān. In the 9th century, under the leadership of Esmā'il, they ruled over Transoxiana and eastern Persia from their capital of Bukhara. Esmā'il's *türbe*, or mausoleum, the oldest Islāmic monument surviving in Bukhara, reproduces the form of the Zoroastrian *chanar taq*, or fire temple. In Sāmānid and Seljuqid hands, the *türbe* generally took the form of a small circular or octagonal building, roofed with a turret shaped like the point of a pencil. Mounted on a solid or single vaulted substructure, its single chamber had a domed ceiling and a mihrab, or niche indicating the direction of Mecca. In the more elaborate *türbes*, the single door was framed with bands of geometric decoration, and the turret was sometimes ribbed.

Türbe construction

Ghaznavids and Ghūrids. Alptegin, a slave of Turkic origin at the Sāmānid court, escaped in 962 AD to Kābul, where he rapidly gained control of the town. He transferred his headquarters to Ghazna in central Afghanistan and established his dynasty there. Few Ghaznavid works of art have survived, but the admirably proportioned and

Josephine Powell, Rome



One of the two mortuary towers at Ghazni, Afghanistan, 10th–11th century.

decorated mortuary towers at Ghazna are architectural achievements of great splendour. Still finer is the minaret of Jām, a Ghūrid structure of the 11th century. Standing alone in a desolate region, it escaped discovery until 1957. It is conjectured that the minaret may mark the position of the lost Ghūrid capital of Fīrūzkūh.

Seljuqs. The art of the Seljuqs, who founded kingdoms in Persia, eastern Byzantium, Syria, and Iraq, eclipsed that of the Sāmānids, Ghūrids, and Ghaznavids. They were great architectural patrons and constructed numerous mosques, madrasah (Islāmic religious schools), hospitals, orphanages, baths, caravanserais, bridges, and *türbes* notable for their decorative masonry, elaborately ornamented portals, and use of Kūfic script as an architectural decorative device. The Seljuqs also attained a high standard in their decorative arts, especially metalwork, wood carving, and pottery. The Mongols, who terminated the Seljuq period, adopted certain Seljuqid

artistic conventions, particularly the use of ornamented portals and glazed-tile paneling.

Mongols. Genghis Khan (died 1227), the renowned Mongol conqueror, sacked and destroyed Bukhara in 1224, sparing only the 12th-century Kalyan tower, which was used for throwing criminals to their death. The 14th-century Turkic conqueror Timur, however, endowed Samarkand with new glory by building a series of religious monuments widely renowned for their splendour and decorative use of glazed tiles. In the 16th century, Bābur, prince of Fergana, coveted Samarkand. Failing to capture it, he chose Kābul as his headquarters for his conquest of India. His tomb there (he died in 1540) is the only visible testimony to the years he spent in the city.

Emirate of Bukhara. Although fine-quality pottery decorated with animal, bird, and figural designs was being made in New Nisa in the 15th century, the artistic revival of the Mongol period that Timur had launched in western Turkistan had died out by the 16th century, when the emirate of Bukhara, incorporating much of Sogdiana, was established. Except for gold-thread embroidery and carpet making, in most of Central Asia the visual arts largely stagnated. In Mongolia the conversion of the Buryats to Lamaism in the 18th century brought into their tradition of ornamentation such Tibetan motifs as the lotus, dragon, and lion.

Russian-Soviet period. In 1882 the emirate of Bukhara was incorporated as a Russian state. This political act had little cultural effect, and European art remained unknown to Central Asians. Traditional indigenous architecture of baked or unbaked brick construction was revived in the 18th century. Carved doors and screens were again produced. Old styles of Islāmic script were combined with arabesques to adorn metalwork. Zoomorphic junctures persisted in the animal designs created by metalworkers and potters alike, although the ornaments worn by nomadic women had become so stylized as to have lost all resemblance to the ancient animal motifs from which they were descended. Openwork remained a feature of much of the jewelry, notably of the necklaces formed of small openwork plaques linked by rings or chains.

Revival of traditional architecture and decoration

Following the Russian Revolution, a new phase of art began in the Soviet-controlled regions of Central Asia. Although the Soviet authorities took steps to maintain the existing carpet and textile industries, they encouraged the inclusion of genre scenes and native animals and vegetation. They also founded schools to train artists in the traditions of European art. Pictorial arts are naturalistic in style, conforming with the principles of social realism as defined by the Soviet authorities. The first Buryat-Mongolian Turkmen painter to achieve distinction in this style was Tsyrenzhap Sampilov.

ARCTIC REGIONS

In the arctic zone of Central Asia, the prehistoric age extends from the 3rd millennium BC to the arrival of Europeans around AD 1800. Knowledge of the region's arts is still very limited, for it is wholly dependent upon the sculptures produced by Eskimos living on the shores and in the hinterland of Siberia and the Bering Strait. These sculptures are mostly in walrus tusk, though wood and reindeer horn examples also exist. The majority are small in size and worked in the round to form terminal ornaments for utilitarian or ceremonial objects or statuettes. The latter are not provided with bases and thus must have been designed to be carried about. Many of the implements are decorated with incised patterns formed chiefly of lines and dots. As in all early arts, the statuettes and terminal ornaments are largely concerned with hunting or the magical practices of shamanism. The earliest and finest statuettes are assigned to the Okvik culture, which some scholars date to the pre-Christian era, others to its early centuries. Okvik art is concerned primarily with the representation of the human figure, differing in that respect from the contemporary or slightly later Old Bering Sea culture, where interest largely centres on animals, such as reindeer, elks, bears, and seals.

Okvik sculpture

Works of the Okvik and later Arctic schools often depict women, sometimes in the nude, sometimes clothed. The nude figures seldom include more of the arms than shoulder stumps. Their bodies are short and flat, their heads large, pear-shaped, and carefully worked, as are hands when included. The faces are carved and are sometimes incised with lines, probably denoting tattooing. The so-called Okvik Madonna (University of Alaska Museum, College) is perhaps the most expressive of these statuettes.

Walrus ivory carvings from the Arctic. (Left) Ipiutak rake or comb showing the head of a bear (or seal), found near Spencer Point, near the western tip of the Seward Peninsula in northeastern Alaska, 1st–6th century AD. Length 26 cm. (Right) The Okvik Madonna, found on an island off the southeastern coast of St. Lawrence Island in the Bering Sea, 1st–5th century AD. Height 17.1 cm. In the University of Alaska Museum, College.

Some Okvik animal designs are particularly interesting because of certain stylistic details that point to a relationship with works of the Scytho-Siberian school. Reindeer are so frequently depicted that the discovery at Pazyryk of a horse's mask in the form of a reindeer's head led to the suggestion that the mask was a survival from a reindeer cult acquired by the Altaians from a northern people such as the Eskimo. That theory has been discounted, yet some Okvik works are undoubtedly related to certain slightly older examples of Siberian metalwork. Thus, the heads of some terminal ornaments bear a close resemblance to those of certain Siberian works. The lozenge-shaped muscles that appear on Eskimo carvings amid lines intended to portray the animal's skeleton are very similar to those of the Pazyryk dot and comma markings. In late- or post-Okvik times certain specifically Eskimo objects, such as masks, were decorated with stylized animal heads executed in relief and accompanied by bosses that recall the Altaic, especially those that reflect Chinese influence. Compositions such as that on an unidentifiable object (possibly a rake or comb) in the University of Alaska Museum, which includes as its central motif the head of a bear resting on its forepaws and flanked by griffins, display a marked affinity with west Siberian ones.

In the 17th century, climatic changes led, in the 19th century, to contacts with the outer world and brought the traditional Eskimo school of sculpture to an abrupt end. When, toward the end of the century, art started to revive, it did so under European influence, eventually de-

veloping a greater concern for aesthetic than religious considerations. The new style retained much of the directness of approach and formal conventions of the traditional style, but, in addition, there was a greater emphasis on naturalism. Group scenes, too, became popular, as did animal and bird compositions. There has been an extensive production of small sculptures, chiefly of fish, bird, or animal forms, in the 20th century. (T.T.R.)

HIMALAYAN CULTURES OF NEPAL AND TIBET

Nepal. The art of Nepal is centred in the Kāthmāndu Valley, in an area of less than 250 square miles (650 square kilometres). The artists are Newars, or Mongoloids, different ethnically from, though partly intermingled with, the peoples of India, whose art they made their own—whether its themes were Hindu or Buddhist.

Architecture. There is only one Nepalese architectural style, varied according to its function as private dwelling, palace, Buddhist monastery, or Buddhist or Hindu temple. The style is the protracted local flowering of an Indian architectural tradition—of brick and wood architecture with tiered, sloping roofs—other varieties of which are found in the western Himalayas and in Kerala in the southwest.

Essentially, there are two kinds of Nepalese Buddhist shrine, or *stūpa* (also called *caitya*): the large *stūpa* and the small, monolithic *stūpa*. Characteristic of the large *stūpa* like the one at Bodnath is the low base from which it rises and its crowning dome-shape. The small *stūpa* was generally set in the courtyard of a Buddhist monastery. The extant monasteries, none of which date earlier than the 14th century, are consistent in their plans and structures. A central courtyard flanked by residential buildings is entered through a gate with a richly carved tympanum (torana) and porch. Opposite the gate and in the centre of the courtyard is the main building, the *stūpa;* with its one- to three-tiered roof, it rises higher than the buildings that surround it and forms the square of the courtyard. Most Hindu temples are freestanding. The more ancient temples have two superimposed roofs; the later ones are five-roofed temples, given further height by tiered brick socles, or bases. On each story of the towerlike structure, wooden beams and struts (a structural piece designed to resist pressure in the direction of its length) support a widely projected slanting roof, the struts ascending diagonally from the central structure to the edge of the tiled roof. The majestically tapered, ascending profile of the structure, with its strong contrast of light playing on the roofs and masses of shade looming below, is peculiar to Nepal. Rich in textures and colours, the temples are embellished with carved and painted struts, carved doorframes and window frames, and embossed, gilded copper sheets. Like the pantheon on the stone temples of India, the pantheon of Nepal is laid out mainly on the exterior of the temple—in contrast to Tibet, where it is displayed on the interior of the temple.

Buddhist monasteries

Sculpture and painting. Combinations of Hindu and Buddhist iconography came about easily, though there is something facile about them, a smoothness found also in the form of the Nepalese images, which lack the surging dynamism of Indian form. Characteristic of the Nepalese transformation of Indian styles is a loss of depth but a gain in grace. Suavity of line, temperance of modelling, tonal clarity of vivid, contrasting colours raise Nepalese works far above the merely derivative. An indigenous physiognomy, too, modifies the physical formulas for sculpture laid down in India.

While Nepalese sculpture is known to exist from the 2nd century BC (terra-cotta plaques, a stone *bodhisattva,* and a Buddha image), it was in the 5th to the 7th centuries BC that stone sculpture in Nepal came into its own. Viṣṇu Vikrānta (the three strides of Viṣṇu), dated AD 467, and 6th-century panels illustrating the Kumārasambhava ("Birth of the War-God," an epic by the 5th-century Indian poet and dramatist Kālidāsa) are masterworks of narrative relief and dramatic mythical composition. On the more intimate level of daily life, sculpture takes the form of the many fountains that adorn watering places (*pranali*) of Nepal. Water spouts forth from *makara* (Hindu water monster with the body of a crocodile and the head of an elephant) snouts sheathed in gilt copper into reservoirs laid out with architectural dignity. As far as present knowledge goes, Newari sculpture was dominated from the 8th century into the 18th by gilt-copper images. In their glowing splendour, the gilt, sometimes jewel-encrusted images embody the Buddhist quality of compassion that leads to enlightenment.

Painting. Painting in Nepal is known from the 11th century on palm leaves and wooden bookcovers of manuscripts, some of them hardly distinguishable, at first, from the Bengali prototypes. The Nepalese style, less nervous, more conscious of the beautiful line and clear, compartmental order of the surface, is fully developed in scrolls, or *prabhas* (most of them, vertical), on cotton known from the 13th century. These scrolls are of two kinds: one consists of arrays of religious images with a large figure of the main deity in their midst; the other consists of a *maṇḍala,* the Hindu and Buddhist symbol of the universe—a circle enclosing a square with the deities disposed within. Narrative panels or sections in the margins of both types of scroll soften the rigour of the composition. While this Nepalese hieratic, or sacerdotal, style was at its peak, a narrative style developed in manuscript illuminations such as the

Hitopadeśa (1594; Kāthmāndu) and horizontal scroll paintings such as the Rathayātrā Scroll (1617; Cambridge). Its planar intricacies reveal a new and vital aspect of Nepalese painting, an immediacy of emotion and action of its protagonists, the figures of which are placed on an opaque, velvety ground. The colours of these book illustrations and scrolls retain the strength and depth of those of the hieratic scrolls, which continued to be painted into the 17th century. The influence of the more realistic Indian, Rajasthani paintings, from the latter part of the 17th century, finally overwhelmed the hieratic style. Its disappearance was further hastened by a wave of Chinese-influenced Tibetan painting. (S.Kh.)

Tibet. Tibetan art comprises ancient pre-Buddhist decorative and domestic crafts and the all-prevading religious art that was gradually introduced from the 8th century onward from surrounding Buddhist countries and developed subsequently as recognizably distinct Tibetan imagery, sculpture, and decorative architectural motifs. In all its forms Tibetan art has remained subservient to special lay or religious intentions and has never become an art pursued for aesthetic ends alone. The religious art is primarily didactic and symbolic; the lay art, decorative. Therefore, while lay art may be easily appreciated, to understand the significance of the religious art requires knowledge of Tibetan religion and religious symbolism. Since the destruction of Tibetan cultural traditions by Chinese-trained Communists from 1959 onward, a greater interest has arisen in the West in the surviving Tibetan *objets d'art* preserved in museums and private collections.

Up to the 9th century AD, Tibet was open to cultural influence from Central Asia, especially Khotān, and from China. For two centuries, up to the collapse of the old Tibetan kingdom in 842, the Tibetans controlled the whole Takla Makan and the important trade routes from the Middle East to China. Stone carving and metalwork were certainly practiced in the pre-Buddhist period, and Persian, Indian, and Chinese influences, all received through Central Asia, have been noted.

The introduction of Buddhism from the 8th century onward led to the arrival in Tibet of Buddhist craftsmen from Central Asia and later from Nepal and northwest India, all of which were then Buddhist lands. Some cast images from this first Buddhist period may survive in Lhasa. After 842, central Tibet dissolved into political chaos for over 100 years, and from the 10th century onward the cultural initiative passed to a line of kings in western Tibet. For temple decorations, such as wood carving of doorways and posts, decorative painting on ceilings and woodwork, temple frescoes, and terra-cotta and stucco images, they drew heavily on the cultural resources of pre-Islāmic Kashmir. Surviving monasteries and temples, with their magnificent contents, were made known to the Western world in the 1930s. With the establishment of religious hegemonies in central Tibet from the 11th century onward, cultural contacts with Nepal and the Buddhist centres in the main Ganges Valley flourished as never before. Conversely, cultural contacts with China dwindled for several centuries, at least in central and southern Tibet. From this time until the 20th century, Tibetan religious art and Nepalese Buddhist art remained a single unified tradition. Meanwhile, eastern Tibet, where the ancient pre-Buddhist crafts of metalwork had never died out, began to develop religious styles under the influence of craftsmen from central Tibet. From that time, the spread of Tibetan culture and art became coterminous with the spread of Tibetan religion; and, thus, from the 13th century onward, when Tibetan lamas began to convert the Mongols, Mongolian religious art developed as a branch of Tibetan art. Through the Mongols, China began to extend its political influence over Tibet, and this led to a steady increase in Chinese cultural influence, especially in the east. From 1721, when the Chinese emperors became the suzerains of Tibet, Chinese influence was felt much more strongly throughout central as well as eastern Tibet, and Tibetan religious paintings and especially domestic decoration reveal distinct Chinese features.

Chinese cultural influence

Decorative arts. In the main temple (*fo-khang*) of Lhasa there is a pre-Buddhist silver jug with a long neck surmounted by a horse's head; and there are textual references to all kinds of articles made of gold: a large golden goose holding seven gallons of wine, a wine vase, a miniature city decorated with gold lions, and golden bowls. Gold animals are mentioned as decorating the camp of King Ral-pa-can when a Chinese envoy visited him in 821. These early Tibetan skills lived on through the Buddhist period. Tibetan metalworkers have excelled in producing fine things for ritual and domestic use: ritual lamps, vases, bowls, bells, prayer wheels, decorated trumpets and horns, for the temples, and, for home use, ornamented teapots, jars, bowls, ladles, and especially

beautiful stands, often in silver or gold, to hold porcelain teacups, capped by finely worked lids of precious metals. Hand-woven rugs of magnificent Central Asian and Chinese designs, always adapted to Tibetan preferences, cover low seats, and tables and cabinets of carved and painted wood were commonplace in prosperous homes.

Sculpture. From the 7th to 9th centuries there survive pre-Buddhist carved-stone pillars decorated with Chinese, Central Asian, and Indian motifs and also a stone lion showing traces of Persian influence.

Metal casting

The art of casting images in bronze and other metals entered Tibet from Nepal and India. Having first followed foreign models, the Tibetans gradually developed their own styles and began to depict their own lamas and teachers as well as the vast pantheon of buddhas, gods, and goddesses inherited from India, each distinguished iconographically by posture, hand gestures, and accoutrements. (Of lesser divinities and especially of lamas, the identification is often difficult. It is rare that an image is named in an inscription and even rarer to find a date. Because of the extremely conservative nature of Tibetan art, correct dating within several centuries is often impossible.) Images of vast size, rising up through two or three stories, are quite often seen in Tibetan temples, and their construction and dedication is considered a work of vast religious merit.

Since images are mainly cast or molded, carving is restricted to decorative motifs, especially on wooden pillars and roof beams. Wood carving and terra-cotta, particularly in western and southern Tibet, were common. Papier-mâché, elaborately painted, was also used for the masks of divinities, especially for those worn in monastic dances. This use presumably originated in Kashmir.

Painting: frescoes and temple banners. Temple interiors are usually covered with frescoes and often hung with painted banners (*thang-ka*). For the preparation of the latter, a taut cotton cloth is impregnated with a mixture of chalk and glue, rubbed smooth by some suitable object; for example, a flat polished stone. A religious painter trained in the tradition draws in the outline, often using printed designs for the main figures. There is no scope for originality so far as the iconographic details of divinities are concerned, and, thus, such painting is a highly skilled craft. For decorative details—for example, flowers, cloud effects, rocks, and groups of devotees—there is wider scope. The tradition of fresco painting and temple banners certainly goes back to that of the great Buddhist monasteries of northwest India and the Ganges Valley, but these Indian origins of the 9th to 12th centuries are now entirely lost. The Indian Buddhist paintings of Ajanta are of a much earlier period (up to the 6th century AD), thus predating the great increase in the Buddhist pantheon and in occult symbolism typical of the later Indian Buddhism received by the Tibetans. Central Asian styles certainly reached central Tibet well before the 9th century, but, after that date, it was India and Nepal that

Influence of Indian Buddhist painting

were to have lasting influences on the development of Tibetan art. In more recent times, especially from the 18th century onward, Chinese influence became noticeable in the details of paintings, particularly in the freer but still balanced arrangement of the main figures and the use of Chinese-style landscapes as subsidiary decoration. With the disappearance of Buddhism from Central Asia and India from the 12th century onward, Tibetan art developed as a style exclusive to the Tibetans, the Newari Buddhists of the Nepal Valley, and the Tibetan converts of Mongolia.

Decorative architectural motifs. For temples, monasteries, and official residences such as the Potala Palace

The Potala Palace, Lhasa, Tibet, 17th century.

of the Dali Lama in Lhasa, the Tibetans used their own solid indigenous styles but embellished these with Indian, Nepalese, and (very much later) Chinese motifs. Tiered, ornamented temple roofs are originally of Indian origin, as received through Nepal and later through China. The magnificent interior carving is of Indian and Nepalese inspiration. (D.L.S.)

Centrifuge

A centrifuge is any device that applies a sustained centrifugal force; that is, a force due to rotation. Effectively, it substitutes a similar, stronger, force for that of gravity. Every centrifuge contains a spinning vessel; there are many configurations, depending on use. A perforated rotating drum in a laundry that throws off excess water from clothes is a type of centrifuge. A similar type is used in industry to separate fluids from solid matter after crushing. Another application is separating fine suspensions of solid or liquid material; *e.g.*, a cream separator.

GENERAL PRINCIPLES OF CENTRIFUGATION

The fact that a force tending in an exterior direction occurred whenever a mass changed its direction was certainly known to primitive man, but the exact nature and significance of the force were only formulated by Sir Isaac Newton in the 17th century.

As Newton showed in his laws of motion, a freely moving body tends to travel in a straight line and if directed along a curved path by some restraining force (for example, a string) exerts a force of its own against the string. Further, the strength of this latter force can be increased by increasing either (1) the speed of rotation (2) the mass of the body, or (3) the radius, or distance of the body from the centre of the curve. Increasing either the mass or the radius increases the centrifugal force proportionally, but increasing the speed of rotation increases it in proportion to the square of the speed; that is, an increase in speed of ten times, say from 10 to 100 revolutions per minute, increases the centrifugal force by a factor of 100. Centrifugal force is expressed by the basic relation $F = mv^2/R = 4\pi^2 mn^2 R$; F is the centrifugal force, m the mass, R the radius, v the speed, and n the number of revolutions per second.

Centrifugal force is expressed as a multiple of g, the symbol for normal gravitational force (strictly speaking, the acceleration due to gravity). Centrifugal fields of over 1,000,000,000 g have been produced in the laboratory.

The widest use of centrifuges at the present time is for the concentration and purification of materials in suspension or dissolved in fluids.

Suspended particles more dense than the suspending liquid tend to migrate toward the periphery, while those less dense move toward the centre. The rapidity with which the migration proceeds is dependent on the intensity of the centrifugal field, the difference between the density of the particle and that of the suspending liquid, the viscosity of the liquid, the size and shape of the particle, and to some extent the concentration of the particles and the degree to which they are electrically charged. The net motivating force exerted on the particle is the difference between the centrifugal field acting on it and the opposing buoyancy of the liquid. All other things being equal for two particles, one with a diameter ten times that of the other will require only one one-hundredth as much average centrifugal field to move a given distance in a given time as the smaller.

Speed of migration

From the foregoing discussion, it is clear that a practically complete separation of the suspending medium and the suspended particles can be produced if the centrifugation is allowed to continue until all particles have collected against the outer wall of the spinning vessel or centrifuge. It should also be noted that a partial separation of two groups of suspended particles of different size can be effected by allowing centrifugation to continue only long enough for all of the larger particles to be completely packed into the sediment, since then many of the small particles will still be suspended in the fluid. If separation of the larger as well as the smaller particles is desired, the surface fluid can be drawn off and the sediment resuspended in some suitable liquid and subsequently centrifuged again to effect further separation.

TYPES OF CENTRIFUGES AND THEIR APPLICATIONS

Centrifuges may be classified in three general categories depending upon whether the spinning centrifuge bowl that contains the material to be separated has a solid wall, a perforated wall, or some combination of the two. Also, they may be characterized according to whether the material is treated in a continuous flow process, a batch process, or a combination of the above processes. The common notation used for centrifuges employed in industry has not been standardized, and often essentially the same type of centrifuge, when used in different industries, is known by different names, which sometimes leads to confusion. In this article, a few clear-cut individual types will be described in order to illustrate the wide application of the centrifuge in research and industry.

Bottle centrifuges. A bottle centrifuge is a batch-type separator primarily used for research, testing, or control. The separation takes place in test tube or "bottle-type" containers, which are symmetrically mounted on a vertical shaft. The shaft is usually driven by an electric motor, gas turbine, or a hand-driven gear train located above or below the rotor. The rotating parts are mounted on resilient supports so that they can partially seek their own axis of rotation and so that excessive vibrations are damped. Usually, the bottles are supported by high strength metal containers in such a way that their axis is perpendicular to the axis of rotation. The machine is designed so that a breakage of a bottle will not cause the rotating parts to become sufficiently unbalanced to damage the centrifuge or injure the operator. The sedimentation takes place in a radial direction and in some bottle centrifuges the test tubes or bottles are inclined at an angle of about 37° to the axis of rotation in order to reduce the distance that the material must settle. In such cases, when the material reaches the inclined wall of the test tube it slides down and collects on the bottom and hence is not forced to settle the whole length of the bottle. The bottles are usually sealed to prevent evaporation and the rotating parts are surrounded by a chamber strong enough to contain the rotor in case of an explosion. Radial temperature variations, if large enough, will produce convection, which in turn produces remixing.

Bottle centrifuges are standard equipment for most biological, chemical, or medical laboratories. They are used to separate solid materials in suspension or to clarify liquids when precipitation will not take place in a reasonable time in the gravitational field g. In most commercial bottle centrifuges the centrifugal field may be varied from a few g's up to tens of thousands. Commercial uses of the bottle centrifuge include tests for the butter-fat content of milk, determination of the sediment in crude mineral and vegetable oils, and clinical tests of various kinds.

Uses of bottle centrifuges

Tubular centrifuges. The tubular centrifuge is used primarily for the continuous separation of liquids from liquids, or of very fine particles from liquids, although in some cases it is used as a batch-type centrifuge. In general, it is used when higher centrifugal fields are required for separation. The rotating bowl consists of a long hollow tube (length many times its diameter) mounted at one or both ends in damper bearings as shown schematically in Figure 1. These damper bearings are necessary because such a long tubular body, if given a large disturbance, will tend to turn over. Furthermore, a long tube spun at high speeds may pass through speeds at which it vibrates. These are known as critical speeds. At speeds removed from the critical, the rotor spins comparatively smoothly. Except in special cases, tubular centrifuges are designed to spin below the first critical speed of the tube. For continuous separation the feed or material to be centrifuged enters at one end near the axis and is removed in two streams containing the separated material. In many cases the separation is not complete and the separated

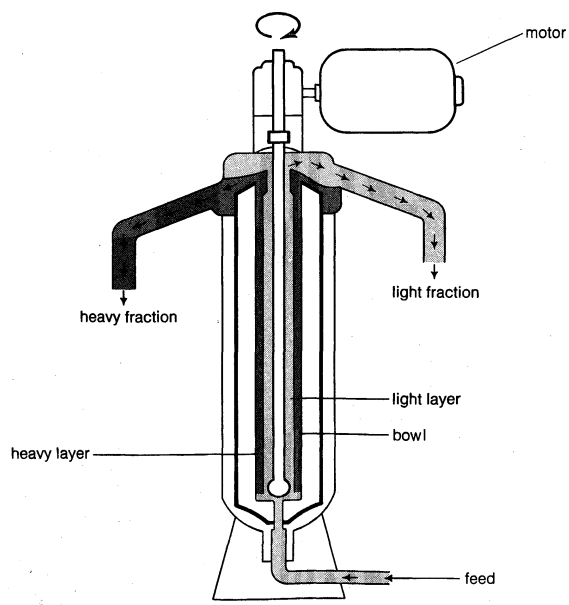

Figure 1: Tubular centrifuge

fractions must be passed through the machine several times. Many different designs for the internal structure of the tube are employed, but in general radial vanes are used to bring the feed material up to speed and to slow down the separated streams before they are discharged. Great care must be taken to prevent the internal structure of the tubular rotor from producing imbalance or from developing its own critical vibrations. The centrifuge is driven by a high-speed motor or an air or steam turbine. The sedimentation takes place as the fluid flows from one end of the tube to the other. When the heavy material consists of very fine particles or molecules and the concentration is very low, the solid material is usually allowed to deposit on the wall. In this case the machine is operated as a batch centrifuge.

The tubular centrifuge is finding an increasing number of applications because of the high centrifugal fields that may be used (10^5 g near the periphery in some cases). A few typical uses are as follows: (1) the purification of vaccines (uncentrifuged vaccines contain a large amount of nonessential and harmful material); (2) purification of lubricating and industrial oils; (3) clarification and purification of food products such as essential oils, extracts, and fruit juices; (4) separation of immiscible liquids that cannot be separated by gravity.

Disk-type centrifuge. The disk-type centrifuge consists of a stack of thin disks in the shape of cones. The sedimentation takes place in the radial direction in the space between adjacent cones. This greatly reduces the settling distance and hence increases the rate at which the material is separated. The angle of the cones is designed so that upon reaching the inside surface of the cone the heavier material slides down along its surface in a manner that is similar to that of the 37° fixed-angle bottle centrifuge.

The disk-type centrifuge usually operates continuously. The material to be processed enters in one stream and is separated into two purified streams. These centrifuges are used primarily for the separation of liquids in which the solid or immiscible components occur in relatively low concentrations. The familiar cream separator, widely used in the dairy industry and on farms for separating cream from milk, is a typical example of this type of centrifuge. They also are used for the purification of fuel oil, the reclamation of used motor oil, and the removal of soap stock in the refining of vegetable oils.

Basket centrifuges. Basket centrifuges are often called centrifugal filters or clarifiers. They have a perforated wall and cylindrical tubular rotor. In many cases the outer wall consists of a fine mesh screen or a series of screens with the finer mesh screens supported by the heavier coarse screen, which in turn is supported by the bowl. The liquid passes through the screen, and the particles too large to pass through the screens are deposited. Though in most cases the centrifuge must be stopped for discharge, in some types it may be discharged at full or reduced speed. The size and design of the basket centrifuge are dictated by its intended use, but usually the bowl is shorter than its diameter. The basket centrifuge is employed in the manufacture of cane sugar, in the home and in laundries for the rapid drying of clothes, and in the washing and drying of many kinds of crystals and fibrous materials, etc.

Continuous and batch operation

In the case of tubular-, disk-, and basket-type centrifuges that are employed in manufacturing processes, operation with high efficiency and low cost is critical. This usually requires the continuous operation of the centrifuge since the batch process requires extra labour, increased power, and is time-consuming. As a result, many ingenious methods have been devised for unloading the sediment collected in the bowl while the machine is operating at full speed and without disturbing the sedimentation continuously taking place in the centrifuge.

Vacuum-type centrifuges. In the centrifuges described above, the rotor spins in air or some other gas at atmospheric pressure. The gaseous friction on a spinning rotor increases at a relatively high rate so that the power required to drive the rotor also increases rapidly. As a result, the temperature of the rotor rises until heat convection and conduction to the walls balances the heat generated. For high-speed rotors in air at atmospheric pressure this temperature may exceed the boiling point of water. Since the rotor surface near the periphery moves faster than near the axis a thermal gradient or variation in temperature through the rotor wall is established along the radius with the periphery at a higher temperature than the axis. This arises not only from gaseous friction but from the direction of the air or gas circulation around the rotor. As shown previously, small radial temperature gradients are effective in producing convection within the centrifuge. These convection currents cause remixing and disturb sedimentation. Convection-free sedimentation has been obtained in a high-speed oil-driven centrifuge by surrounding the rotor with hydrogen at about 10 torr (1 torr = 1 millimetre of mercury). At 660 revolutions per second the temperature of the rotor was only 1.5° C above that of the walls. Convection-free centrifuges have been called ultracentrifuges.

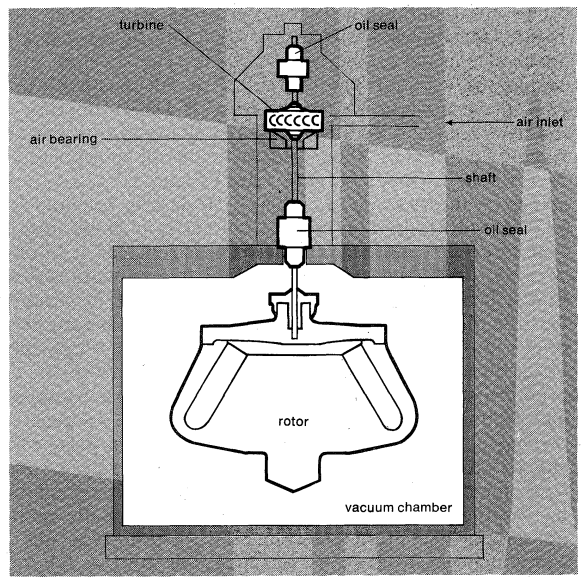

Figure 2: Air-driven, vacuum-type ultracentrifuge.

The gaseous friction on a rotor decreases with decreasing pressure and becomes negligible at pressures routinely produced by mechanical and diffusion pumps. Consequently, a centrifuge rotor spinning in a vacuum should be convection free and, therefore, ultracentrifuge at any speed, provided a negligible amount of heat is conducted to the rotor by the shaft on which it spins. This was accomplished in 1934. Figure 2 shows a schematic diagram of one of the early vacuum-type ultracentrifuges. The centrifuge rotor located inside the vacuum chamber is connected to the air-supported, air-driven turbine by a vertical, small-diameter, flexible steel shaft. The rotating members are supported by an air bearing and are spun by air impinging upon the turbine. The air pressure surrounding the rotor is very small (less than 10^{-6} torr) so that the air friction on the rotor is negligible even at the highest peripheral speeds possible. Also, the diameter of the shaft is small (0.1 inch), which reduces friction in the lower oil seal and heat conduction to the rotor. Constant temperature of the lower oil seal is maintained by circulating oil at the same temperature as the thermostated metal vacuum chamber. This chamber is heavy enough to contain the rotor should it explode. Consequently, the temperature of the rotor is held constant at the known value of the surrounding chamber and hence is free of thermal gradients. The comparatively long flexible shaft allows the rotor to seek its own preferred axis of rotation and consequently to spin smoothly without the need of precise dynamic balancing. It is, however, always desirable to have a good dynamic balance even with a flexible shaft. In practice the maximum rotational speed is set only by the mechanical strength of the rotor.

The combination of high-centrifugal field, large-size rotor, lack of need for tedious dynamic balancing, absence of thermal gradients, low power requirements, etc., makes the vacuum-type centrifuge an ideal convection-free ultracentrifuge. A typical rotor is 18 centimetres in diameter and carries 300 millilitres of liquid in a centrifugal field of over 300,000 g. Practically all substances of importance in medicine and biology and all other substances with molecular weights of 50 daltons (one dalton is 1.66×10^{-24} grams) or more are easily purified in this type of bottle centrifuge. If the rotor is replaced with one with sector-shaped cells and crystal quartz windows so that sedimentation can be optically measured, it is found that the theoretically predicted sedimentation is routinely obtained. Consequently, the vacuum-type centrifuge may be used for the determination of the molecular weights of practically all substances in solution. Modern commercial vacuum-type centrifuges employ many of the general principles used in the early design, but the air drive and support have been replaced by the more efficient and convenient electric motor drive and the entire machine has been redesigned and made almost automatic in its operation. The present commercial vacuum-type ultracentrifuge has become an indispensable tool in laboratories where it is necessary to purify substances of importance in biochemistry, biophysics, biology, and medicine. The ultracentrifuge can be used in two principal ways for determining the molecular weights of various proteins. The first consists in carrying out the sedimentation in a centrifugal field high enough to produce a relatively sharp sedimentation boundary; *i.e.*, the boundary between the sedimenting molecules and the pure solvent. The rate at which this boundary moves out along the radius toward the periphery is then measured and the value of the molecular weight is calculated. This is called the rate of sedimentation method. The second method consists in centrifuging the material until equilibrium is established in the centrifuge cell; *i.e.*, until the rate at which the material settles out is balanced by back diffusion. If the concentration in the centrifuge cell is then determined (usually through optical observation) at various radial distances, the value of the molecular weight (M) can be calculated.

Molecular weight

Although the equilibrium method of measuring M is much more reliable than the rate of sedimentation method, the latter has a wider use because of the comparatively long time (days) required for the equilibrium measurements and the stringent requirements of speed and temperature controls.

Vacuum-type tubular centrifuges are finding a most important use in the purification of many biological materials that cannot easily be separated in other ways. They have been used both as continuous-flow and as density-gradient centrifuges. The density-gradient centrifuge consists in setting up a radial density variation or gradient in the tubular centrifuge with slowly sedimenting nonreactive smaller molecules such as sucrose or calcium chloride. If then the density of the substance to be purified falls within the range of the artificial density gradient, it will collect in a thin cylindrical surface at a definite radius. If more than one substance is in the solution, each of the substances will collect at a radius determined by its particle density. Various devices have been used to harvest the separated material after it has collected on the cylindrical surfaces. A density-gradient centrifuge method of purifying vaccines has recently been used on a commercial scale. This timely and important development will probably be used to purify most vaccines and many other biomedical materials.

The ideal centrifuge

An ideal centrifuge would be one in which the rotor is free to spin about "its own axis" and hence would not require accurate balancing. Also, the rotor should not be limited in size or weight. It should spin in a vacuum on a friction-free bearing and when desired, attain speeds limited only by the strength of the material. It should not have a shaft that will conduct heat to the rotor during operation. It should be free of speed fluctuations and it should be readily accessible so that the sedimentation taking place in the centrifuge can be observed optically or otherwise. Starting in 1937, workers at the University of Virginia developed a magnetically supported ultracentrifuge, which essentially meets these specifications. Figure 3 is a schematic diagram of a method of mag-

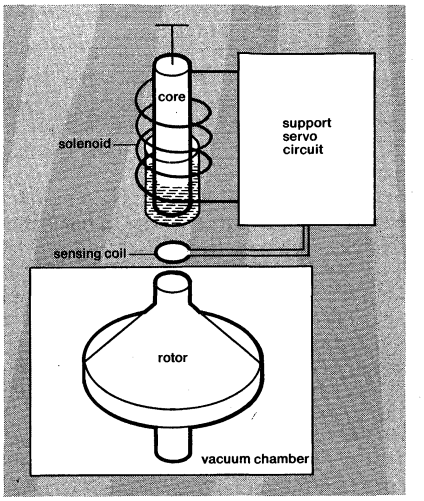

Figure 3: Magnetically suspended rotor.

netically supporting a rotor inside a vacuum chamber. The axial core of the rotor is made of steel or other ferromagnetic material. When sufficient electrical current is passed through the solenoid, the rotor is pulled upward by the solenoid and would strike the top of the vacuum chamber if it were not for the operation of the support servo circuit. As the rotor rises the impedance of the small sensing coil is changed in such a way that the servo circuit reduces the current through the solenoid. When the rotor starts falling, the current through the solenoid is increased, and effective damping in the servo circuit prevents vertical oscillations. In this way the rotor is held very precisely at the desired vertical position in the vacuum chamber. The only measurable friction on the rotor is that due to the residual air in the vacuum chamber. When this pressure is reduced to 10^{-7} torr, which is not difficult with a diffusion pump, a 30-pound ultracentrifuge rotor will lose less than one revolution per second per day when spinning at 800 revolutions per second, or roughly 10^{-8} of its speed per second.

The rotor may be driven to operating speed in a number of ways but usually it is spun up to speed with a motor outside and below the vacuum chamber. The thin flexible drive shaft passes through a vacuum oil gland in the bottom of the chamber. When the desired operating speed is attained the shaft is pulled downward and disconnected from the rotor and the rotor is allowed to coast freely during the sedimentation process. When the measurements have been completed the shaft is reconnected to the rotor and the rotor decelerated to rest. Since the rotor coasts during the measurements, troublesome speed fluctuations are eliminated. Also, the very slow deceleration of the rotor allows the sedimentation to reach equilibrium faster than if the rotor speed was absolutely constant. A second method of driving the rotor consists in mounting nonelectrical conducting permanent magnets on the bottom of the rotor in such a way that they can be driven by a rotating synchronous magnetic field surrounding the rotor. With care in design, negligible heating is produced in the rotor during the period of acceleration and deceleration. Much less heat is, of course, produced during the long sedimentation period when the speed is automatically held at the desired value to one part in 10^5.

The size of the rotor in Figure 3 may be varied over large ranges. Their weights have been varied from 10^{-9} to over 10^2 pounds. Rotor speeds of 1.5×10^6 revolutions per second and centrifugal fields of over $10^9 g$ have been obtained. The method has been used accu-

rately to measure the tensile strength of materials both in bulk and in thin sheets. It has also been used to determine the absolute value of adhesion of one substance to another, and for spinning rapidly rotating, constant-speed mirrors.

Gas separation by centrifuge

When a gas is subjected to a centrifugal field a radial pressure gradient is immediately established. Consequently, a mixture of any two gases with different molecular weights may be separated in a centrifuge with the lighter gas being concentrated on the axis. In 1919 after it was pointed out that it should be possible to separate the isotopes of an element by centrifuging, a number of attempts were made to obtain separation but were all unsuccessful, probably due to convection and remixing in the centrifuge. In 1937 the isotopes of chlorine were separated with a vacuum-type ultracentrifuge. An evaporative centrifuge method was used in which the material to be separated is admitted to the rotor and condensed on the periphery with the rotor stationary. The rotor is then driven to operating speed and the lighter material pumped out through the hollow shaft while the heavier material remains in the centrifuge to be collected later. While the separation obtained was in excellent agreement with the theory, the method is a batch operation and not efficient except for small-scale separations. The centrifuge should be spun as rapidly as possible and should be as long as possible. Also, the centrifuge method is suited to the separation of the heavier isotopes as well as the lighter ones, since it depends upon the differences in the masses rather than on their absolute values.

It will be surmised from the above discussion that the tubular vacuum-type centrifuge is perhaps the best-suited type for the isotope or gas separation problem. As a result, the need for the purification of the isotope of uranium-235 in considerable quantity has stimulated the development of long high-speed centrifuges. During World War II centrifuge tubes of various lengths were used with uranium hexafluoride gas to test the method both in the U.S. and in Germany. In the U.S. a centrifuge tube 11.33 feet (345.5 centimetres) long and 7.35 inches (18.66 centimetres) inside diameter was used in some of the experiments. A number of different flow patterns inside the tubular centrifuge were tested. It has been shown both experimentally and theoretically that a countercurrent flow method produces the largest amount of separative work when properly used. In the countercurrent method the gas or vapour flows in two continuous cylindrical concentric streams along the length of the spinning tube. One stream flows from top to bottom along the periphery, and the other from bottom to top near the axis. The centrifugal and diffusive action between the two flowing streams concentrates the lighter isotope in the axial stream and the heavier one in the peripheral stream. This produces a buildup of material with the lighter isotope enriched at the top and the heavier isotope at the bottom of the spinning tube. The materials are drawn off at any desired rate, one from the top, the other from the bottom. The two axial concentric streams are found to be stable over considerable distances along the tube so that long tubes may be used. It is easy to see roughly why this is true in a hollow tubular centrifuge. If, for example, a small quantity of the gas in the peripheral stream moves inward along the radius, its angular velocity is increased like a figure skater going into a spin, since angular momentum is conserved. This in turn increases the centrifugal effect and the gas moves back outward. Furthermore, the pressure gradient is large so that the element of gas moving inward expands and cools, which also tends to move it back toward its original radial position.

Since World War II the technique of gaseous centrifuging has been further developed and extended. Workers in Germany and in The Netherlands have reported considerable success with the method. A remarkably simple vacuum-type gas centrifuge that is especially adapted to uranium isotope separation has been devised. According to reports in 1970 a centrifuge plant was being planned in Europe for the purpose of commercially producing reactor grade uranium-235 for use in nuclear power plants.

Uranium-235 for power plants

It is clear that current improvements in the ratio of strength to density of rotor materials and in machine design and control should greatly increase the potential of the centrifuge for isotope separation and the general purification of gases.

Cephalochordata

The Cephalochordata, a subphylum of the phylum Chordata, are small, eel-like animals (*e.g.*, amphioxus, or lancelet) up to eight centimetres (about three inches) long. About 23 species—all living—are known. Exclusively marine, cephalochordates usually live in an area of the seabed consisting of fairly coarse shell gravel.

Cephalochordates are distributed throughout tropical and subtropical shallow seas where suitable bottom conditions exist. They also occur in the waters of many temperate areas, and some have been observed as far north as the coastal waters of Norway. Although they are known to occur at depths of 100 fathoms (600 feet [about 180 metres]), cephalochordates are usually found at depths of less than 50 fathoms. Some species are very widespread; others are restricted in distribution. The group apparently originated in the Indo-West Pacific, the majority of species being found there. The presence of cephalochordates usually indicates clean water with a minimum rate of flow. The filtering activity of large numbers of the organisms actually helps to maintain cleaner conditions. *Branchiostoma caribaeum* occurs in concentrations as great as 5,000 per square metre (500 per square foot).

Biological significance

Cephalochordates are of particular interest because they exhibit chordate features in a most primitive form. The biological significance of amphioxus arises from its structure, which is clearly related to that of vertebrates, despite the fact that it lacks a true head and backbone. Any theory concerning the origin of the entire class Vertebrata—and thus man's own origin—rests heavily on the nature of amphioxus, even though this animal, as a living form, may or may not have changed since its origin. Amphioxus is particularly abundant in certain coastal waters of China. The animal is so abundant that a commercial amphioxus fishery has long been established there.

Natural history. *Reproduction and life cycle.* Cephalochordates are dioecious; *i.e.*, the sexes are normally separate but with no external differences. The development of both male and female gonads in the same individual (apparent hermaphroditism) has occasionally been observed. In temperate waters, there is one breeding season per year, in the tropics two or more. No special mating behaviour is known. The gonads develop singly or in pairs in successive body regions corresponding with separate myotomes, or sections of muscle, in the region between the mouth and the atriopore, an opening about two-thirds of the way back on the ventral (lower) side. In the genus *Branchiostoma* a row of gonads develops on both sides of the body; in the genus *Asymmetron* gonads develop only along the right side. Each gonad is a separate sac projecting into the atrial cavity, a chamber surrounding the pharynx. Eggs or sperm, released by rup-

ture of the gonad wall, pass out through the atriopore into the water, where fertilization occurs.

The rate of growth and development is related to the temperature. About 48 hours after fertilization, the egg develops into a larval stage with a single gill slit. As the larva grows, additional gill slits develop, the number varying from about 12 to 35, according to the species. The larval form, similar in general appearance to the adult, is planktonic, or drifting, in habit. Larvae eventually assume the vertical migration pattern well-known in planktonic animals. When the larva is between three and 11 millimetres (0.1 and 0.4 inch) in size, depending on the species, a change in body form (metamorphosis) occurs. The larva becomes more symmetrical—for example, the mouth, in most cases, opens on the ventral midline instead of on the left side. Secondary gill bars develop, the gut grows, and the endostyle, a ventral groove, develops. After metamorphosis, the larva settles to the bottom and adopts the life of the adult.

If, during the normal vertical migrations, a larva drifts into water so deep that it cannot reach the bottom, growth probably continues, thus giving the larva more time in which to find a suitable area in which to live. In such circumstances the larva grows to a larger than normal size.

Behaviour and ecology. Normally, the adult lives buried, usually in rather coarse shell gravel but sometimes in sand or sandy mud. Burrowing is very rapid, either forward or backward; both the shape of the body, which is pointed at both ends, and the tough cuticle (rough body covering) facilitate the burrowing movements. The feeding position is nearly vertical, with the anterior end up and about a quarter of the body length projecting above the bottom. A water current drawn into the buccal cavity passes out through the gill slits into the atrium. Food particles are filtered off in the process. When not feeding, the animal is usually withdrawn completely into the substrate, but at night it is not uncommon for the animals to rise and swim near the bottom. Cephalochordates are not normally very reactive to changes in the intensity of light, but a sudden change of light immediately provokes swimming, burrowing, or both. They are very sensitive to touch, particularly anteriorly, and the lightest touch induces withdrawal into the gravel or rapid swimming. Swimming is not continuous but consists of short bursts of activity at intervals. There is no buoyancy mechanism, and in water of normal salinity the animal sinks rapidly to the bottom after activity ceases.

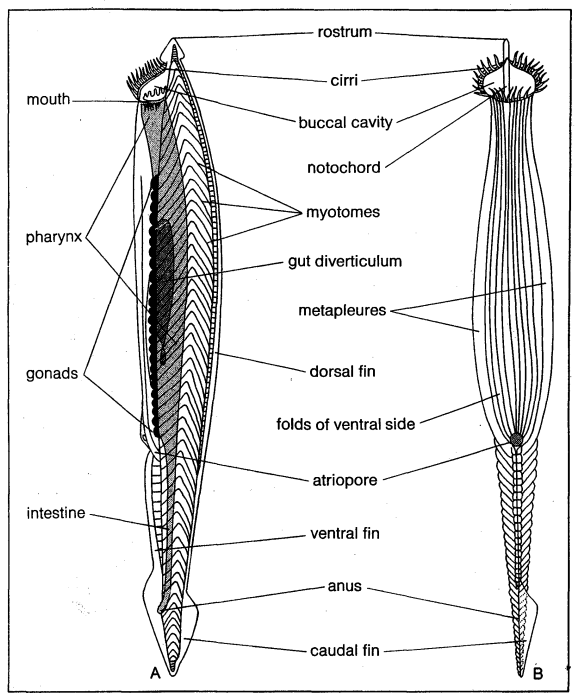
Burrowing

Form and function. *Structural features.* All species of cephalochordates are generally similar in body structure. Maximum length is about 80 millimetres (three inches), but tropical species are usually much shorter. The name of the best known species, *Branchiostoma lanceolatum*, refers to its lanceolate, or spearlike, shape. The body, somewhat flattened sideways, is covered by a tough, iridescent cuticle. The muscles of the body wall are divided into myotomes, which usually number between 50 and 85, depending on the species. The myotomes of the two sides do not develop in parallel but are staggered. When the animal swims forward, contractions begin at the anterior myotome; the myotome immediately posterior then contracts, and so on down the body. Bending of the body is effected by myotome contractions to provide forward motion.

The notochord is a hydrostatic (*i.e.*, supported by internal fluid pressure) structure; its rigidity is variable and controlled by the nervous system and by contraction of notochordal muscle. A dorsal fin along the back continues around the tail and becomes a ventral fin. In some species this continuous median fin is expanded at the tail to form a distinct caudal fin. Dorsal and ventral fins are supported by fin chambers. No paired fins are present, but folds along the edge of the ventral side, the metapleures, could be the homologues of the lateral, or side, fin folds of ancestral fish.

The notochord

There is no true differentiation of a head in cephalochordates, but a slight swelling at the anterior end of the dorsal hollow nerve cord forms a cerebral vesicle. A pigment spot is prominent at its anterior end. There are segmental dorsal and ventral nerve roots, but these do not join to form mixed nerves as in higher chordates.



Amphioxus (*Branchiostoma lanceolatum*). (A) left lateral and (B) ventral views.
From P. Grasse, *Traite de Zoologie*, vol. 11 (1948); Masson & Cie, Paris

The circulatory system is typically chordate, with forward blood flow along the ventral side and backward flow along the dorsal side. There is no differentiated heart. The colourless blood contains no respiratory pigment but includes cells known as lymphocytes.

Feeding and digestion. Cephalochordates are filter feeders and require a large surface area for the extraction of particles. The mouth is covered by an oral hood, the edges of which form the buccal cirri. When feeding, the cirri overlap to form a primary coarse filter to keep out large particles. The inflowing current originates from the beating of cilia on the gill bars. The gill bars form the so-called branchial basket, which has a cartilaginous support but can be contracted by muscles. The feeding current passes in through the buccal cirri and through the tentacles of the velum, a structure surrounding the actual mouth. After following a rather complicated path, the water enters the pharynx, passes out through the gill basket into the atrium, and out of the body through the atriopore. Particulate matter is trapped by a mucus lining of the gill basket. Part of this mucus originates from the endostyle, which is located along the floor of the pharynx. The path followed by the mucus-enmeshed food particles is quite involved; basically, however, the particles move up the sides of the pharynx, are collected in the epipharyngeal groove, and then pass into the gut and into its diverticulum.

Digestion appears to occur mainly in an area of the gut whose walls are more opaque than are those of the rest of the gut. Digestive enzymes include protease, lipase, and amylase. In larval forms a part of this area known as the iliocolonic ring contains a bright-green fluorescent pigment. Phagocytosis (*i.e.*, the engulfing of food particles by cells) and digestion within cells occur, both of which features are nonchordate in character.

Enzymes and phagocytosis

Excretory and biochemical features. Perhaps the feature most atypical of chordates is the excretory system, the basic unit of which is a nephridium. Each primary gill bar has a corresponding nephridium; thus, there are about 200 nephridia in one individual. All of these structures are situated above the pharynx, and the main excretory canal from them opens into the atrium.

The endostyle, an important structure of the Cephalochordata, is also found in the Hemichordata, Tunicata,

and, in modified form, in lamprey larvae. It is the homologue of the vertebrate thyroid gland, and, although it is not certain that iodinated tyrosine molecules (an active product of the vertebrate thyroid secretion) function as regulatory substances (hormones) in cephalochordates, such molecules are produced in the cephalochordate pharynx, almost certainly in the endostyle. It is significant that the endostyle develops at the time of larval metamorphosis and that the metamorphosis of axolotls, a type of salamander, is accelerated by implants of cephalochordate endostyle.

Classification. *Distinguishing taxonomic features.* No positively identified fossil cephalochordate has yet been found. The classification of the group, then, is based entirely on the characters of living species. The dorsal hollow nerve cord, the branchial apertures, and the well developed notochord extending almost to the anterior tip are all present in both larva and adult, clearly indicating that they are chordates. Affinities between the Cephalochordata and the subphylum Vertebrata can be shown with the Cyclostomata; for example, the so-called ammocoete larva of the lamprey, a cyclostome, is similar to the cephalochordates in its endostyle and thyroid gland.

Annotated classification.

SUBPHYLUM CEPHALOCHORDATA

Small, fish-like, and free-swimming; all chordate and many vertebrate features; complex system of blood vessels; excretion by means of nephridia; sexes separate (dioecious); about 23 species; occur throughout tropical and subtropical shallow seas, some temperate regions.

Family Branchiostomidae

One genus, *Branchiostoma*, and about 15 species; double row of gonads along body wall; metapleural folds (located laterally along ventral side) symmetrical.

Family Asymmetrontidae

One genus, *Asymmetron*, and about 8 species; 1 row of gonads along the right side only; metapleural folds asymmetrical; right fold merges with the ventral fin.

Critical appraisal. The general taxonomy of the Cephalochordata is simple and accepted by modern workers, but specific identification is not always positive, especially with immature animals. Various families and genera have been erected in the past, but are not now generally accepted, as are the two families given above. A small point for debate is that there is some justification for the inclusion of a second genus, *Epigonichthys*, within the Asymmetrontidae specifically for the New Zealand lancelet *E. hectori*. This species retains the larval sinistral (*i.e.*, on the left side) mouth at maturity.

Cephalopoda

Cephalopoda is a small class of highly organized exclusively marine mollusks with about 130 known living genera and 650 species, of which the octopus, squid, and cuttlefish are familiar representatives. The extinct forms outnumber the living, the class having attained great diversity in late Paleozoic and Mesozoic times. Of the extinct cephalopods, the ammonites and belemnites are the best-known examples.

GENERAL FEATURES AND IMPORTANCE TO MAN

The cephalopods agree with the rest of the Mollusca in general structure and appear to have the closest affinity with the Gastropoda. The best-known feature of the Cephalopoda is the possession of tentacles, 8 or 10 in most forms, but about 90 in *Nautilus*. Except for the nautilus, all extant members of the class show great reduction of the characteristic molluscan shell.

Cephalopods range greatly in size. The giant squids (*Architeuthis* species) are the largest living invertebrates, *A. dux* attaining a length of more than 20 metres (60 feet), including the extended tentacles. The smallest cephalopod is the squid *Idiosepius*, rarely an inch in length. The average octopus usually has arms no longer than 30 centimetres (12 inches) and rarely longer than a metre (39 inches). Specimens with arm spans of up to nine metres (30 feet) have been reported. The shell of the fossil ammonite *Pachydiscus seppenradensis* from the Cretaceous measures 205 centimetres (6 feet 8 inches) in diameter; it is considered to have been the largest shelled mollusk. Though not as abundant as in earlier times, the Cephalopoda are still a major group of marine animals.

Cephalopods occur in large numbers and form one of the greatest potential food resources of the oceans. They are eaten in many parts of the world but have never been accepted as part of the general diet in North America or northern Europe. They also are indirectly important to man since they furnish a large part of the diet of the sperm whale and smaller whales and seals.

Commercial landings of cephalopods

Japan leads in the cephalopod production, landing about 600,000 tons of squid annually. Korea is second, with 117,000 tons of squid; China produces 80,000 tons of cuttlefish alone, but accurate statistics are unavailable. The United States produces about 10,000 tons, while Newfoundland alone produces about 11,000 tons in good years. Nearly 2,000,000 tons are produced annually throughout the world.

Cephalopods are taken in many ways, the squids usually by trawls, purse nets, jigs, or traps. Octopuses are taken in fish traps, in earthen pots strung together, or else by hooking or spearing them and by trawling. They may be eaten fresh, sun-dried, or canned in olive oil.

NATURAL HISTORY

Life cycle. The eggs of most cephalopods are enclosed within a capsule that may be gelatinous and transparent (*Octopus* and squids of the genus *Loligo*) or opaque and leathery (cuttlefish). Little is known about the eggs of oceanic species. The eggs of most coastal species are laid inshore and are attached singly or in clusters, primarily to bottom objects. Parental care is exhibited only by octopuses, in which the female broods over the eggs, and in the paper nautilus (*Argonauta*), in which the eggs are carried in a special shell secreted by the female. In most others the eggs are left uncared for. Squids that attach their eggs to the bottom engulf them in a gelatinous mass that protects them from fungus and deters predators. Cuttlefish squirt their eggs with ink to hide the otherwise white egg case.

All cephalopod eggs are provided with a remarkable amount of yolk, unlike that in the rest of the Mollusca, so that segmentation is incomplete and restricted to one end of the egg. The embryo is localized at this end. The mouth in early development is not surrounded by the arm rudiments; these arise as outgrowths of the lateral and posterior edges of the primordial embryonic area. They pass forward during latter development until they reach and encircle the mouth. The funnel arises as a paired outgrowth of the same area, a condition that is retained in *Nautilus;* in all others the two portions fuse together in the median line.

The embryo of cuttlefish (*Sepia*), squid (*Loligo*), and octopus (*Octopus*) is provided with a yolk sac. In certain presumably archaic Teuthoidea there is less yolk, and the yolk sac is practically absent. There is, nevertheless, no certain indication in the development of any known cephalopod of those larval phases that characterize the development of other mollusks.

Incubation is variable, but in *Octopus* young hatch in

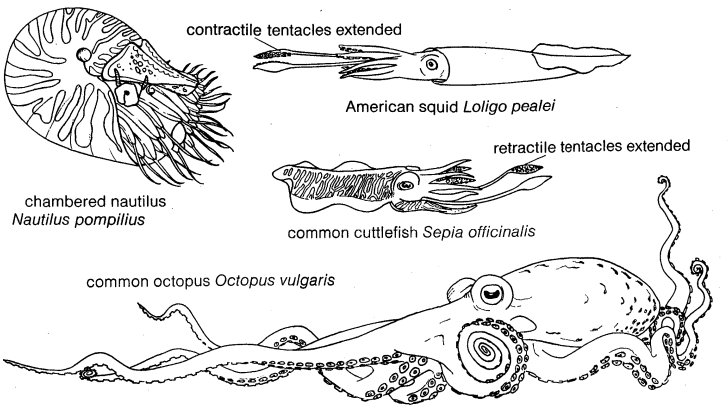

Figure 1: Body plans of typical Cephalopoda.

about 50 days and in *Loligo* in about 40 days. At hatching, the animal may closely resemble the adult or may go through a larval stage, differing widely from the adult, and spend a considerable time in the plankton as part of the drifting life. The larvae of many cephalopods were described as distinct genera before their larval status was discovered, and the generic names are still used for certain distinctive larval forms. In octopods with small eggs (*e.g.*, *Octopus vulgaris*) the larvae are planktonic, spending several weeks in the plankton; the "*Macrotritopus*" stage of *Scaeurgus* may greatly prolong its larval life until a favourable bottom is found. In octopods with large eggs (*Octopus briareus*) the young resemble the adult and immediately assume a bottom life.

In the order Sepioidea (cuttlefish and bottle-tailed squid) the young closely resemble the adults and are only briefly planktonic. In the Teuthoidea (squids), especially the Oegopsida, the larvae differ widely from the adult and the larval period is quite long.

Life span

Little is known about the life span of cephalopods. Studies have shown that in *Octopus joubini* raised from the egg in aquariums, sexual maturity and spawning were reached in five months; in a loliginid squid (*Sepioteuthis sepioidea*), likewise raised from the egg, sexual maturity and full growth were also attained in five months. It thus appears that the smaller inshore species may have a life span of no more than one year, or exceptionally, two or three. Nothing is known of the life span of the large oceanic squid, but it is presumed that giants like *Architeuthis* attain their bulk only after a period of years. In the smaller octopus and squid observational data indicate that many of the males die after mating and females after the first major spawning.

Behaviour. Cephalopods are unique among the invertebrates in the degree of cephalization and cerebralization exhibited. The uniting of the major ganglionic centres of the central nervous system constitutes a brain of considerable complexity. Studies undertaken at the Zoological Station in Naples by J.Z. Young, M.J. Wells, and others have demonstrated that *Octopus* is capable of learning and considerable intelligence. Most of the research has been concentrated on octopuses because they can be maintained in aquariums. A few investigations have been conducted on cuttlefish, but squids have not been investigated, largely because of the inability of experimenters to maintain them in confinement. It is expected that the behaviour of these two groups (squid and octopus) would be considerably different because of their different modes of life.

Laboratory behavioural studies have dealt mainly with learning processes and have centred around food acceptance, reward and punishment, maze work, and shape discrimination. By means of surgical techniques it has been possible to determine the various locomotor centres of the brain of *Octopus* and transmission and receiving pathways.

Less research of a detailed nature has been concerned with colour change. A wide range of colours may be exhibited. Most cephalopods possess colour pigment cells (chromatophores) and reflecting cells (iridocytes) in the skin. The chromatophores are expanded by nerves controlled by the brain and the colours exposed (brown, black, red, yellow, or orange red), each species usually possessing three pigments. Colours and colour patterns are exhibited according to specific behavioural conditions; *e.g.*, attack on prey, camouflage, rest, and alarm or defense. Alarm patterns are the most readily recognized, consisting of strong contrasting light and dark areas, bars and peripheral dark outlines, or sudden displays of spots.

Other behavioural patterns are found in changes in skin sculpture: the erection of branched or straplike papillae and curling of the arms. These often are attempts at concealment or camouflage imitating bottom type (sand, seaweed, etc.).

Discharge of ink

The ink of cephalopods is used as both defense and escape mechanisms. In *Octopus* under attack by a moray eel the cloud of ink seems to paralyze for some time the eel's senses of sight and smell. The ink cloud may also be used as a screen behind which the octopus escapes. In squids the ink is ejected as a cigar-shaped object about the size of the squid itself, the ink coagulating in the water. With this "dummy" left behind, the squid contracts its chromatophores, becomes nearly transparent, and speeds away.

Many cephalopods (but not *Nautilus* and *Octopus*) possess special light organs (photophores), which emit cold light or bioluminescence. Light is produced by the enzymatic reaction of luciferin and luciferase or, in bottle-tailed squids (sepiolids), indirectly, through cultures of luminescent bacteria. Photophores distributed over the body are employed at night or in the mid-depths in mating play, recognition of the sexes, aid in schooling, attracting prey, defense, and camouflage. The light organs of the squid *Histioteuthis* are highly complicated, consisting of reflector, light source, directive muscles, lens, diaphragm, window and colour screens.

Octopus, squid, and cuttlefish display considerable skill and cunning in hunting, stalking patiently, or luring prey within reach of their arms or tentacles. Both cuttlefish and octopus use the tips of their arms as wormlike lures to attract small fishes, and octopus has been reported to thrust stones between the valves of clams to prevent their closing. This has not been verified by later observers, but such intelligence is not beyond belief.

Locomotion. Cephalopods move by crawling, swimming, or jet propulsion, mainly the latter. The mantle, which has a passive role in the majority of mollusks, in cephalopods has become involved in locomotion, having almost entirely lost its rigid shell and become highly muscular. Its expansion and contraction produce a locomotory water current by drawing water into the mantle cavity and expelling it through the funnel. The rapid ejection of this jet of water enables the animal to execute quick backward and forward movements.

Jet propulsion

Water is drawn into the mantle cavity by the relaxation of the circular muscles and resultant expansion of the mantle. It enters around the neck region or aperture of the mantle and through the funnel in some species. In the oceanic squid the system is more efficient, with a valve that prevents water from entering through the

funnel. When the mantle is contracted the aperture is closed by locking mechanisms and contraction of the anterior ring muscle, and the water is forced out through the funnel. This mobile organ is constructed similarly to a jet nozzle and may be turned in any direction, giving great flexibility of motion to the animal.

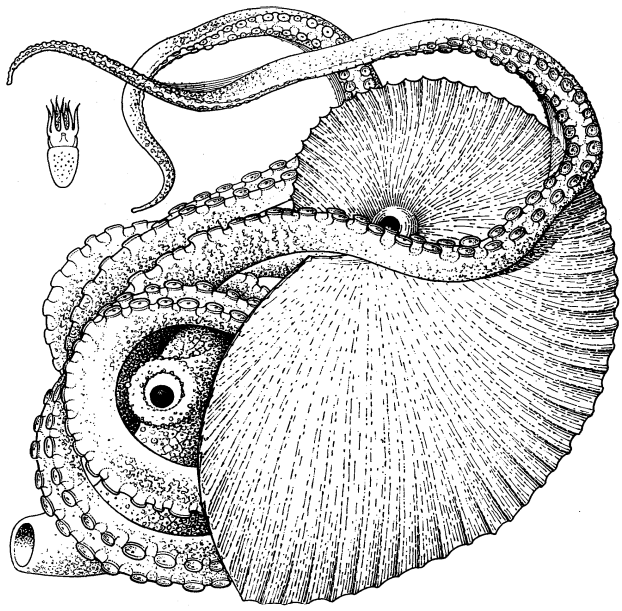

Figure 2: *Paper nautilus (Argonauta).*
(Upper left) Male about 16 millimetres (⅝ inch) in longest dimension; female about 150 millimetres (6 inches) from tip of siphon to outer curve of shell.

Squids also possess terminal or lateral fins used in slow movement or hovering. Locomotion is by the rapid undulation of the outer edges of the fins. Movement downward or upward is aided by lateral expansions (swimming keels) on the outer surface of the third pair of arms. Some squids (*Onychoteuthis, Thysanoteuthis*) are able to "fly" for several hundred feet, driven into the air by powerful thrusts from their jets and gliding on their expanded fins and arm keels. When the squid jets rapidly through the water, the fins are often curled tightly around the mantle. Cuttlefish, because of the large cuttlebone, are less active animals and spend most of their life lying on or hovering slightly above the bottom. Both jet and fins are used, the latter more frequently.

The benthic octopods are bottom crawlers, gliding about the bottom and in and out of crannies with amazing agility through the use of their eight arms and suckers. Because of the extraordinary flexibility of the body, they are able to pass through openings hardly larger than the diameter of one eye. When disturbed, octopods swim rapidly by jet propulsion. Mass swimming migrations have been reported.

The finned octopods and the bottle-tailed squids have paddle-shaped fins that are probably most useful for balancing and slow hovering movements. The female paper nautilus (*Argonauta*) propels herself by jet propulsion while encased in her paper-thin shell. The true *Nautilus* is a less active swimmer, partly due to the funnel, which is composed of two flaps instead of a single fused tube.

The active swimmers and most bottom dwellers apparently possess no hydrostatic organ. The cuttlefish, however, which swims or hovers above the bottom or rests on the bottom, adjusts its buoyancy through the amount of gases contained in the porous cuttlebone. *Nautilus*, which swims slowly above the bottom or in midwater, accomplishes this similarly, adjusting the gases in the chambered shell. Inactive oceanic squid such as some cranchiids concentrate light ions in their body chamber, while others, such as *Bathyteuthis*, concentrate light oils in the fatty cells at the posterior end of the mantle.

Reproduction. The sexes are usually separate in the Cephalopoda. Sexual dimorphism is common but is usually expressed in slight differences of size and in the proportions of various parts. In the paper nautilus (Figure 2) and the blanket octopus (*Tremoctopus*), the males are not only different in appearance but are much smaller than the females; they exhibit one of the greatest size discrepancies in the animal kingdom.

The female reproductive system is simple, consisting of posterior gonads and paired oviducts. Nidamental glands exist in species that lay eggs encased in heavy capsules.

In males, the reproductive system contains a series of chambers or sacs along the course of the vas deferens, which produce long tubes (spermatophores) to contain the spermatozoa. The final sac (Needham's organ) is also used for storage of spermatophores. The spermatophores are complicated, containing sperm reservoir, mid-part, horn, cap, and a delicate triggering mechanism for bursting the tube. Since spermatophores vary from species to species, they are important taxonomic characters.

During courtship, the male deposits spermatophores in the female, either within the mantle cavity or on a pad below the mouth, by means of a specially modified arm, the hectocotylus. The hectocotylized arm of *Octopus* bears a deep groove on one side, ending in a spoonlike terminal organ. In *Argonauta* and *Tremoctopus* the arm is highly modified and in mating is autotomized and left within the mantle cavity of the female. In the squids a much larger section of the arm may be modified; often the suckers are degenerate and the distal half of the arm bears rows of slender papillae, although special pouches and flaps may often be found. The modified arm of *Nautilus* is termed the spadix.

Little is known about the mating habits of most cephalopods. In the common octopus the male and female remain some distance apart while the male caresses the female with the tip of the hectocotylized arm. The male then inserts the tip of the arm into the mantle cavity of the female, where it remains for over an hour, during which time the sperm bundles travel down the spermatophoral groove of the arm. In the cuttlefish (*Sepia*) according to L. Tinbergen, the pair swims side by side, the male indulging in some "love play" with its arms. Eventually, mating takes place by the pair intertwining their arms and remaining together while the spermatophores are placed on the inner side of the female's mouth membrane. In loliginid squids a somewhat similar type of mating occurs except that it takes place en masse in schools of thousands of individuals.

Eggs are laid shortly after mating. In loliginids they are fertilized as they are ejected and before being fixed in the egg capsule. In the octopods, they may be fertilized as they pass through oviductal glands near the end of the oviduct. In cuttlefish, the eggs are fertilized before the heavy capsule is formed. Egg laying in octopods is accomplished by the female individually fixing the eggs singly or in festoons by a short stalk or thread (see Figure 3). In loliginids the eggs often form immense mops, the result of the communal spawning of perhaps hundreds of individuals. Spawning of oceanic squids has not been observed. The number of eggs laid during a spawning period varies greatly; it may range from only a few dozen in octopuses with large eggs to over 100,000 in the common octopus, laid over a period of about two weeks. In cuttlefish the number of eggs is smaller, about 200 to 300 being laid in a season. In loliginids several thousand eggs may be laid by a single female, and the egg mop of the European common squid, resulting from the efforts of many individuals, may contain more than 40,000 eggs.

Numbers of eggs produced

Ecology. The Cephalopoda are exclusively marine animals. There are numerous littoral species, but few have been reported from even slightly brackish water except for the squid *Lolliguncula brevis*, which occurs along the Florida coast in several areas having a salinity of 15–17 parts per thousand (about half that of the open ocean). Cephalopods are excluded from the Baltic Sea by lower salinities but have been found in areas of the Suez Canal where salinities are higher than in the oceans. There is some evidence that in parts of the open sea that differ

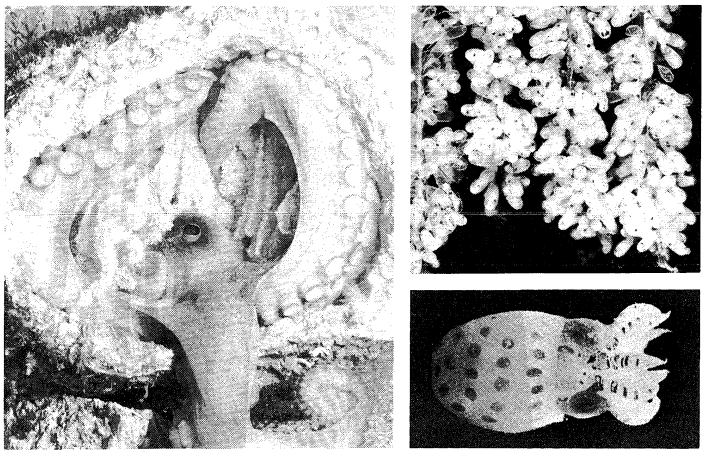

Figure 3: *Common octopus (Octopus vulgaris).* (Left) The female remains in her lair guarding her eggs until they hatch. She continually washes the eggs in a fresh stream of water to increase aeration and keep them free of parasites. (Top right) Actual size of egg cluster. Fifty thousand eggs may be produced in a two-week period. (Bottom right) Underside of larva (magnified 5 ×) showing pigment spots. At this stage the arms are relatively undeveloped; the young swim freely with the current rather than "walk" on the ocean floor. (Left, top right) Marineland of Florida, (bottom right) Douglas P. Wilson

only slightly in salinity there may be a varying cephalopod fauna. G.E. Pickford has found that the vertical distribution of young in *Vampyromorpha* is governed by water density, and according to C.F.E. Roper a similar situation exists in the squid *Bathyteuthis.*

The majority of Coleoidea are carnivorous and live principally on crustaceans and small fishes. An interesting food cycle has been shown for the squid *Illex*, in which the adults feed upon young mackerel and the adult mackerel feed upon young squid. Squid also are cannibalistic. *Octopus* feeds upon bivalve mollusks and on decapod crustaceans, sometimes causing severe losses to the lobster industry. The smaller oceanic squid probably feed primarily upon small fish, copepods, heteropods and caridean shrimp. The Cirrata, which have reduced musculature and radula, indicating a loss of activity and of masticatory power, probably feed on bottom debris or minute plankton.

The Cephalopoda are fed upon by many marine mammals, large fish, and sea birds. The stomachs of sperm whales often contain whole and fragmentary squids, from small to giant species.

The nineteenth-century French naturalist Alcide d'Orbigny asserted that the Cephalopoda are in general sociable, and this statement is certainly true of *Nautilus*, which are found together in droves. Some authorities, studying the Mediterranean forms, have concluded that only certain pelagic cephalopods are gregarious (*Todarodes, Ocythoe*). Schools of the large oceanic squid *Thysanoteuthis rhombis* have been reported at Madeira. Although there is no proof that numbers constitute gregariousness, octopus colonies have been reported.

The breeding season has a marked effect on the local distribution of certain Cephalopoda. The common cuttlefish comes into shallow water in the spring and summer to breed, and similar migrations have been observed in some squids (*Loligo, Alloteuthis*).

The geographical distribution of cephalopods is incompletely known. In general, the open ocean pelagic and bathypelagic forms are cosmopolitan in warm and temperate waters (*Onychoteuthis banksi, Cranchia scabra*). Others may be limited by genera to particular oceans or to continental waters. Even some species of bathypelagic habitat are limited to one ocean. The Octopoda, as a result of their bottom-dwelling habits, show stronger restrictions in their distribution, but *Octopus vulgaris* and *O. macropus*, both species with planktonic larvae, have gained worldwide distribution. In general, the pelagic and planktonic cephalopods conform in their distribution to other pelagic animals.

The vertical distribution is also incompletely known. *Nautilus* moves vertically through the water, living near the bottom, and has been obtained at a depth of about 550 metres (1,800 feet). It is fished in the Philippines, however, when it comes into shallow water. Of the cuttlefishes, the Sepiidae are littoral, whereas the Sepiolidae dwell on or near the bottom, down to considerable depths. Among the squids, the Myopsida are coastal forms, whereas the Oegopsida are oceanic, living from the surface to depths in excess of 5,000 metres (16,400 feet).

The Octopoda occur from the surface of the open ocean (*Tremoctopus*) to the ocean floor (*Pareledone, Bentheledone*) in excess of 4,500 metres (14,700 feet); most are bottom-dwelling forms restricted to the continental shelf and its slope. One group, the Cirrata, are deep-sea in habitat, showing many adaptations for this mode of life.

FORM AND FUNCTION

Cephalopods vary from elongate, streamlined oceanic organisms to saccular, slow-moving bottom and drifting forms. Their body plan is indicative in many ways of the habitat in which they dwell and their mode of life.

The viscera of a generalized cephalopod are covered by a dome-shaped or elongated sheath of muscle, the mantle, which is in close contact with the body anteriorly. Ventrally, the mantle is free and encloses the mantle cavity, the space into which the gills project and the excretory and reproductive systems open.

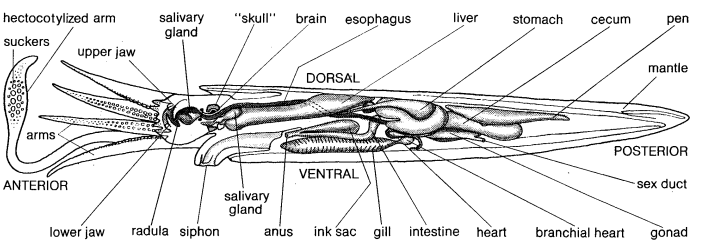

Figure 4: Internal structure of squid (*Loligo*); left side of body and five arms removed.

Number of arms and tentacles

Anterior to the mantle is the head-foot, which bears a ventral muscular tube, the funnel. Surrounding the mouth there are eight long, prehensile arms, provided with suckers in octopuses and argonauts (order Octopoda), or eight arms and two tentacles, equipped with horny ringed suckers bearing teeth or hooks in squids and cuttlefishes (orders Sepioidea and Teuthoidea). The primitive *Nautilus* has about 90 small suckerless tentacles.

The fossil nautiloids and ammonites (represented today only by *Nautilus*) were primitive, less-specialized forms, probably leading a rather inactive sluggish life. The modern octopuses, squids, and cuttlefishes have acquired an active, vigorous life that has led to marked departures in structure and function from the type represented by *Nautilus.* Modern forms are divided into three basic life styles: the ancestral sluggish life in the great depths of the sea, a floating life in the midwaters; and a more active, aggressive existence near the surface. The nautiloids and ammonites were probably shallow-water animals living near the bottom and, like the slow-moving *Nautilus*, relied for protection on a calcareous external shell.

All cephalopods have an internal cartilaginous covering of the main ganglia of the nervous system. In all except ammonites and nautiloids it constitutes a cranium. Various other skeletal supports are found at the base of the fins, and in the "neck," gills, and arms.

The alimentary system consists of a buccal mass with a pair of jaws (mandibles) and a rasping tongue (radula), esophagus, salivary glands, stomach, cecum, liver, and intestine. In the Octopoda the esophagus may be expanded to form a crop, while in the deep-sea Cirrata the radula may be degenerate or lacking. Except in *Nautilus* and certain deep-sea Octopoda there is an intestinal pouch or ink sac located near the anus. This secretes a dark fluid, the sepia or ink, which can be forcibly ejected.

All members of the Coleoidea (octopuses, squids, and

cuttlefishes) possess a closed circulatory system of blood vessels; in *Nautilus* it is partly lacunar (*i.e.*, made up of minute spaces). The blood contains a blue respiratory pigment, hemocyanin (a copper compound), dissolved in the plasma. There are three hearts, one systemic and two branchial, one at the base of each gill. The rhythmical contractions and expansions of the mantle cause a circulation of water over the gills where gas exchange takes place between the sea water and blood. The feather-like gills, consisting of a central axis with a row of lamellae on either side, are suspended freely in the mantle cavity.

The excretion of nitrogenous wastes is carried out exclusively by the kidneys. There are four kidneys in *Nautilus* and two in the coleoids.

Nervous system and sense organs

The central nervous system is highly developed, the major ganglionic centres being concentrated in the head. In some of the cuttlefishes (Sepioidea) the cerebral centres are subdivided for specialization, with the pedal ganglia divided into brachial and epipodal elements that innervate the arms and funnel respectively. In certain squids the mantle is innervated by giant paired dorsal axons, the largest nerve fibres known. Much of the present knowledge of mechanisms of nerve impulse conduction has come from the study of these giant axons. The sense organs of the cephalopods are eyes, rhinophores (olfactory organs), statocysts (organs of equilibrium), and tactile organs. In *Nautilus* the eyes are open pits without lenses. In the Coleoidea the eyes are complex and approach those of vertebrates in efficiency.

EVOLUTION AND PALEONTOLOGY

The first cephalopods were probably provided with a simple, caplike shell. With elongation of the shell and the formation of septa or partitions, the nautiloid shell could be formed (Early Cambrian). The primitive elongate shell of *Orthoceras* would become unmanageable and coiling would result, as in the Gastropoda.

The Ammonoidea are usually considered to have evolved from Devonian straight-shelled forms (*Bactrites*) with certain nautiloid traits. Coiled ammonites appeared in the Late Devonian (*Goniatites*).The subclass became extinct in the Cretaceous.

From *Guide to Fossil Invertebrates;* by permission of the trustees of the British Museum (Natural History)

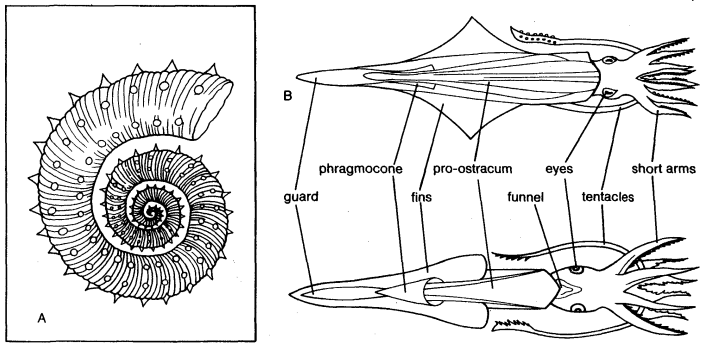

Figure 5: *Examples of fossil cephalopods.*
(A) Partially coiled Cretaceous ammonites. (B) Restoration of two belemnites.

Modern cephalopods possess an internal and partly degenerate shell, straight except in *Spirula*. The state of the shell in modern forms is due to the progressive overgrowth of it by the mantle, probably accompanying the acquirement of an active swimming life. The first evidence of the modification of the shell is in *Aulococeras* in the Triassic. The belemnites, with their modified, internal shell gave rise to *Spirula* (coiled shell), to cuttlefish (calcified phragmoconal septa, forming a thick shell), and to the squids (only the pro-ostracum as a horny "pen"). These forms appeared in the Jurassic and were probably derived from belemnite-like ancestors.

In the Octopoda the shell persists as cartilaginous stylets or fin supports. *Palaeoctopus newboldi*, from the Cretaceous of Syria, the oldest known octopod, was already too advanced to provide a clue to the derivation of the Octopoda. The Vampyromorpha are considered to be a possible connecting link between the Teuthoidea and the Octopoda.

CLASSIFICATION

Distinguishing taxonomic features. In fossil cephalopods reliance is placed upon shell details (general shape, type of coiling, external sculpture, and sutures). In living forms, except for the Sepioidea, the shell is strongly degenerate or missing and the characters used consist of details of the soft parts: presence or absence of an eyelid, tentacles retractile or contractile or both, shape and size of fins, number of arms, number of sucker rows, presence or absence of teeth and hooks on arm and tentacular suckers, radular dentition, structure of funnel organ, and spermatophores.

Annotated classification. The following classification has gained considerable acceptance among modern specialists.

CLASS CEPHALOPODA
Mollusks in which typical molluscan foot surrounds head and forms arms and tentacles. Mantle surrounds mantle cavity and is part of locomotory system; central nervous system highly developed, forming true brain encased in cartilaginous cranium; mouth contains pair of parrot-like jaws (or beak); body usually somewhat streamlined. Eyes highly developed, most closely resemble those of vertebrates. About 650 living species.

Subclass Nautiloidea (Nautiloids)
Cambrian to present; now living only in the Indo-Pacific region, particularly East Indies. External coiled or straight chambered shell present, chambers connected by median siphuncle; smooth septa; sutures simple, little or no external sculpture; tentacles suckerless, adhesive; living and supposedly fossil forms with 4 gills; funnel formed of 2 nonfused flaps. About 6 living species, in genus *Nautilus*.

†**Subclass Ammonoidea** (Ammonites)
Devonian to Cretaceous; fossils only. External, coiled or straight chambered shell with marginal siphuncle, last chamber protected by single horny plate or 2 calcareous plates; septa wrinkled; complex sutures; external sculpture.

Subclass Coleoidea (octopuses, squids, belemnites, cuttlefishes)
Triassic to present. Shell internal, reduced, vestigial or lacking; 2 sets of gills; 8 or 10 arms, having suckers or hooks.

†*Order Belemnoidea* (belemnites)
Triassic to Tertiary; fossils only. Shell consisting of solid rostrum, small chambered phragmocone and anterior, broad pro-ostracum; 6 to 10 arms bearing hooks in 1 or 2 rows. Total length 5–210 cm.

Order Sepioidea (cuttlefishes and bottle-tailed squid)
Tertiary to present. Worldwide with family exceptions. Shell coiled and chambered (Spirulidae), straight with vestigial chambering (Sepiidae), vestigial, or lacking; eyes covered; 8 sucker-bearing arms and 2 retractile tentacles. Total length 2.5–90 cm.

Order Teuthoidea (squids)
Tertiary to present. Worldwide. Shell thin, horny gladius; 8 arms, 2 tentacles, which are contractile only. Total length 1.5 to at least 1800 cm. (0.75 in to 60+ ft).

Suborder Myopsida. Eye covered by skin; neritic, inshore animals.

Suborder Oegopsida. Eye open to water, completely surrounded by free eyelid; open ocean animals living from the surface down to at least 3,000 metres.

Order Vampyromorpha
Present. Worldwide. Purplish-black gelatinous animals with 1 or 2 pairs of paddle-shaped fins at various stages of growth; 8 arms and 2 small retractile filaments not homologous with tentacles; deep web between the arms. One species.

Order Octopoda (octopuses)
Cretaceous to present. Worldwide. Shell lacking or vestigial, secondary shell or egg case in female argonautids, fins absent or present, body generally saccular, with 8 mobile, highly contractile sucker bearing arms. Total length 5–540 cm (2 in–18 ft); arm spread to about 900 cm (30 ft).

Suborder Palaeoctopoda (finned octopod). Cretaceous, some living.

Suborder Cirrata. Recent. Soft-bodied, deep-webbed forms with cirrate arms, and small to large paddle-shaped fins. Primarily deep sea. Sometimes called Cirromorpha.

Suborder Incirrata. Present. Compact, saccular to round bodied, finless forms with muscular, contractile arms. Pelagic to deep-sea and shallow waters. Somewhat secretive.

Critical appraisal. The elucidation of higher classification of the cephalopods is fraught with difficulties. Early specialists divided the living cephalopods into Octopoda and Decapoda without relation to their internal structure; these were both placed in the Dibranchia, in contrast to all fossil forms, which were considered as Tetrabranchia because *Nautilus* has four gills rather than two. This unnatural classification, accepted by d'Orbigny in 1838, was gradually modified through the efforts of A. Naef and G. Grimpe and later workers to the form given above. Phylogenetic linkages are still highly theoretical, but with X-ray techniques that reveal soft parts in fossils, and with new paleontological finds the unfolding of the evolutionary history is in sight.

Ceramics, Industrial

Industrial ceramics comprise all industrially used solid materials that are neither metallic nor organic. This definition expands the scope of ceramics far beyond the clay-based bodies of the potter and traditional industrial ceramics, as well as beyond the sand-dominated formulas of the glassmaker. In physical structure ceramics may be polycrystalline, glass, combinations of multicrystals with glassy phases, or single crystals. The universal properties of ceramics that account for their enduring utility include: mechanical strength in spite of brittleness; chemical durability (at both normal and elevated temperatures) against deteriorating effects of oxygen, water liquid or vapour, acids, bases, and salts at all concentrations, and organic solvents; hardness, contributing to resistance against erosion; and the ability to be decorated in a wide range of colours, textures, and designs.

Universal properties of ceramics

This article deals primarily with the raw-materials, manufacturing processes, and glazing techniques for industrial ceramics. Industrial ceramics products include glass; cement; structural clay products; refractories (high-temperature materials); abrasives; whitewares; porcelain enamels or ceramic-metal systems; ceramic mineral preparations; and newer technical products such as electronic and nuclear ceramics, carbon, graphite, diamonds, and ceramic composites. For information on glass, see GLASS PRODUCTS AND PRODUCTION. Cement is covered in the articles CEMENT and CONCRETE. The article BRICK AND TILE PRODUCTION describes structural clay products. For information on abrasives, see ABRASIVES.

In addition to the primary producers of glasses, cements, and multicrystalline ceramics, there are numerous industries that rework the primary materials into subassemblies, components, or systems that have strategic and economic importance. Often these products, such as computers, electric lamps, or television picture tubes, could not exist were it not for their ceramic constituents, yet the cost of the ceramic materials is small compared to the component and system values.

Functionally, ceramics technology draws upon the knowledge and skills of the pertinent sciences (physics, chemistry, rheology) and the design arts and the process capabilities of engineering to convert starting materials into new chemical and mineral compositions, with controlled microstructures (or, more broadly, character), dimensions, properties, and behaviour.

Separation of the ceramics and glass industries

Though the glass and the ceramics industries share in common most raw materials, many unit operations and processes and the same underlying sciences, they have throughout the world generally developed as two separate industries. This division has arisen because of competition for some markets, as well as because of differences in the technologies. The same is true of the industries based on cement. In the following text, then, industrial ceramics derived by compacting particulates and subsequent heat treatment will be differentiated from the products of the glass and cement industries, in which the materials are first heated and then formed.

A new class of ceramic materials has been developed by first forming the material as a glass and then reheating to precipitate crystal phases with 50 percent or less residual glassy phase. These "glass ceramics" (known by a variety of other names in each country) can be made to approximate many traditional particulate-formed and sintered (heated but not melted to give coherence) ceramics in chemical and mineral composition; because there are fewer inherent restrictions on control over microstructure, these materials can have superior properties, such as improved resistance to heat shock.

History. Industrial ceramics may be said to have begun with the first barter of the potter's ware. Through ancient times and the Middle Ages, the techniques for making clayware continued to advance, and, with the coming of the industrial and scientific revolutions, the industries were ready to supply the scientist with porcelain for chemical experimentation and manufacturing and also to supply an increased demand for containers, tableware, sanitary ware, and construction materials.

Makers of industrial ceramics were thus prepared for the extraordinary demands brought by the 20th-century growth of the chemical, electrical, electronic, nuclear, automotive, and aerospace industries. For the electrical industry the first products were insulators, such as the familiar porcelain suspensions of transmission lines. For electronics the first new products were insulators for even higher frequencies, with the steatites (a class of magnesium silicate minerals) as the first novel materials. With the science explosion during and after World War II, the applications of ceramics in the electronic field grew to include compact capacitors, piezoelectric transducers, resistor and semiconductor compositions, magnetic materials (hard, soft, memory core, and microwave; see also FERRITES), and other energy converters. Improved compositions for automotive and aviation spark plugs led to high alumina (aluminum oxide) ceramics that have been applied to many mechanical, wear, and electronic uses, including even lamps. Nuclear reactors use ceramics for moderators and controls and the ceramic forms of nuclear fuels (uranium and plutonium) in fuel rods. Strong, hermetic seals of alumina and other ceramics to metals are vital in many applications.

Particle bonding and packing. The forming of ceramics involves particle technology, including size reduction (comminution), measurement, and separation; blending and packing of particles; surface chemistry and physics; rheology, or the flow of more or less plastic materials under pressure; and bonding of particles. Other sciences contribute to the understanding and control of heat treatment.

Ceramics came into being because of the useful rheological properties of the clay–water system, with its capability of being shaped, whether as a paste or as a fluid suspension or as a damp, crumbly powder. Modern industrial ceramics often replace clay with organic or in-

organic additives to make the raw material easier to form and to provide strength before firing (final heating). Clay-based ceramics undergo both chemical–mineralogical and physical changes during heat treatment to form new phases, including a glassy phase that often constitutes the bond between the grains in the new microstructure. Such heat treatment involves sintering in the presence of a liquid phase. The complex series of occurrences accompanying heat treatments include gas evolution, oxidation, valence changes, chemical reactions, phase transformations, melting, shrinkage, and still other chemical and physical changes. The trend with modern ceramics technology is to simplify such changes by establishing the chemical and mineral changes before forming. Maximum density is sought in the forming batch, and compaction is achieved by applying the principles of particle packing. Then heat treatment brings about sintering in the solid state with a minimum of shrinkage; gas evolution; and attendant flaws, such as warping, cracking, or the formation of unwanted pores.

Changes induced by heat treatment

Many significant ceramic products, such as thermal insulation and filters for liquids and gases, require controlled porosity, both in terms of percent by volume and in pore diameters and distributions. In fact, texture comprises the prime distinction between refractories, whitewares, and electronic and glass-ceramics that may otherwise be identical in chemical and mineral compositions.

Processing of raw materials. Raw materials for industrial ceramics were originally derived from specific locations around the world where geological processes had prepared ore bodies of sufficient chemical purity and appropriate particle sizes and rheological characteristics for each specific product. Examples of this include the English china and ball clays for better grades of porcelain, the Grossalmerode clay that for centuries was considered essential for pots for melting glass, the Vallendar clay of the porcelain enameller, and the Manchurian talcs deemed superior for the early steatites.

Only with the increasing knowledge about the chemical and physical characterization of these materials and their transformations during processing was it possible to replace these geologically prepared, strategic materials, first with beneficiated minerals (minerals that have been concentrated by removing unwanted materials) and then with chemically prepared compounds. Economically, the natural minerals, more or less beneficiated, still are lowest in cost and remain the largest tonnage used in most established ceramic products. Even with the more specialized technical ceramic products, the ceramist at first tended to retain a pinch of his favourite clay in the formula. Completely synthesized ceramics are still a relatively small proportion of total output, though significant in strategic and monetary value.

With the depletion of the geologically prepared resources and with the possible savings in processing costs through faster firing rates and higher yields, synthesized raw materials are becoming acceptable substitutes for natural minerals. Many of the newer ceramics demand raw materials that either never existed in natural minerals or did not exist in useful ore concentrations. One example of the latter kind is silicon carbide. A current classification of materials used in the manufacture of ceramic products includes over 500 items.

Ceramic raw materials are classified functionally as aggregates, plasticizers, binders, fluxes, and modifiers (chemical, thermal, physical, electrical, colour). Traditional ceramic materials were largely derived from the elements most common in the earth's crust: oxygen, silicon, aluminum, iron, and so forth, but modern ceramics draw upon nearly every element. Although oxides remain most common, other useful compounds include carbides, nitrides, borides, sulfides, and fluorides.

Mining, crushing, grinding, milling, beneficiation, and mixing of the standard materials for ceramics are similar to the operations in other chemical and engineering industries. Clays going into common bricks, sewer pipe, or stoneware may be processed directly as dug out of the ground, though even here blending, aging, and tempering for uniform distribution of water are practiced. Such impure clays are workable because they contain fillers and fluxes associated with the clay minerals. For whitewares, the clays are washed and purified by settling out some impurities and floating off others. Silicas are purified by washing and separating unwanted minerals by gravity and by magnetic and electrostatic means. Feldspars are increasingly beneficiated by froth flotation, a process in which a frothing agent is added to separate the desired material from impurities. Blending from stockpiles is utilized to maintain constancy of chemical composition.

Use of impure clays

Raw materials for the newer ceramics are generally prepared by chemical reactions involving precipitation, filtering, calcination (firing at high temperature), solid-state reactions, melting, and even vapour formation, as well as other sophisticated methods. Freeze drying has been under intensive development as a means for providing a very fine-particled, free-flowing powder feed. Spray drying has become a widely used technique for removing process water at the raw material preparation plants and in mixed batches at the ceramic-processing factory.

Much of the art of the ceramic technologist has always lain in the compounding of raw materials into batches. The formulas, traditionally jealously guarded secrets, involve selection of the raw materials that confer the desired working characteristics and responses to heat treatment, yielding the sought-for character and properties. The clays must be selected and apportioned among the kaolins and ball clays for workability, fusibility, fired colour, and other requirements. The silicas, likewise, must meet criteria of chemical purity and particle size distribution. The fluxing ingredient is selected from one or more feldspars, nepheline syenites, Cornwall stone, bone ash, fritted (finely divided) glasses, and other candidates. The considerations include balance between sodium and potassium oxides, content of iron oxides and other unwanted impurities, and particle size distribution and behaviour during heat treatment. With the burgeoning of technical ceramics no longer requiring or permitting clays and traditional fluxes, the skill of the batch formulator has become dependent on his awareness of the functions and behaviour of organic aids.

Forming processes. Clay-based bodies utilize the plasticity of clay–water mixtures to permit easy shaping of the ware, in most cases accompanied by expulsion of air and densification. Forming processes are adapted to the dimensional requirements. The four principal processes are plastic forming, slip casting, pressing, and fusion casting.

Plastic forming. This is the oldest technique and can be visualized from offhand molding, coiling, and throwing on a wheel. In jiggering, the topside of the piece (dinner plate or bowl) is shaped by throwing a wad of body (forming batch of suitable consistency) on a gypsum plaster mold mounted on a rotating spindle; the bottom surface is formed by pressing a contoured pattern against the exposed face of the body. In plastic extrusion a stiff paste is forced through a die of the desired shape and cross section in a continuous column, which can then be cut to length. The body may be prepared separately or may be processed in a continuous apparatus that mixes the raw materials and water (pug mill), passes the mix through a vacuum chamber to remove air and thereby improve plasticity, and then forces it through the die. Structural clay products, such as brick and sewer pipe, are normally formed by this technique. Plastic formed bodies generally contain 15 to 25 percent of water by weight.

Slip casting. This process utilizes a fluid suspension of the body with controlled pH (acidity or alkalinity), specific gravity, water content, and additives for deflocculation (prevention of the small particles from combining into larger aggregates) called the slip. The deflocculants (for example, a few tenths of a percent each of sodium carbonate and a sodium silicate) confer the same fluidity at about 25 percent water as would require 100 percent water in their absence. Lower water means lower drying shrinkage and consequently lessened tendency to warp and crack and better dimensional control. The slip is poured into a plaster of paris mold that withdraws

enough water from the adjacent suspension to build a layer of solid body. After the desired wall thickness has been attained, excess slip is poured off. Vacuum, pressure, or centrifugal forces are sometimes used in conjunction with slip casting.

Slip casting applications

The slip casting technique is applied to many clay-free, nonplastic particulate materials. By deflocculation of the finer particles, a high-solids-content suspension can be prepared. Either alkaline or acid slips can be prepared at a pH where like electrical charges transferred to the particles cause them to repel each other. Similarly, nonclay bodies can be extruded or die pressed by using organic additives as plasticizers, binders, and lubricants. Like water, these additives are transient constituents, being expelled during the firing operation.

Pressing. Pressing forms a shape or a blank by compacting a free-flowing powder mixture in a die until the particles are bonded strongly enough to permit removal from the die and handling before heat treatment. Water content varies from 5 to 15 percent for clay down to as low as zero for bodies utilizing organic binders. In addition to the complexity of shapes (including holes) that can be formed, dry pressing has the advantage that the low water content results in less drying shrinkage. Pressing is carried out in rigid steel or carbide dies with equipment of increasing sophistication for controlling the rate and uniformity of load application, air expulsion, and ejection from the die. Flexible dies of rubbery polymers are also used for isostatic (uniform pressure) pressing, permitting more uniform density throughout a piece. Plastic bodies are being pressed by procedures that permit simultaneous forming and water removal, thus lessening shrinkage and increasing strength. The steam evolved in warm pressing acts as a parting agent to facilitate removal from the mold. Hot pressing is carried out in molds, usually made of graphite, that can be sufficiently heated by induction or radiation to bring about simultaneous shaping, densification, and in some cases chemical reactions. The resultant body can be of full density (pore free), of the same dimensions as the mold (no drying or firing shrinkage), and completely matured (fired). The chief barrier to wider use of this process has been the short life and high cost of the molds.

Fusion casting. In this process the batch is heated all the way up to melting temperatures and then shaped by casting into a mold, usually made from sand, corresponding to the casting of metals in foundries. So far, it has been largely limited to making large blocks of refractories for glass and metal melting furnaces. Other kinds of forming from melts and from vapours are being used for making ceramics, both in single crystal and in multicrystalline structures.

Heat treatment. Formed ware is generally passed through a drying oven to remove the liquid water carefully without introducing cracking or warping. The basis for the operation is to maintain initially a high humidity, so that the movement of water through the cross section is uniform. Dryers are usually based on heated air, but infrared and dielectric (radio-frequency) heating are being applied.

The goal of subsequent heating (firing) is to obtain cycles of time–temperature–atmosphere that are accurately reproducible. Again the rate of temperature increase must be carefully controlled to avoid spalling (chipping), cracking, warping, nonuniformity within a piece, and nonreproducibility from piece to piece and from day to day. Not only must dimensions be kept within tolerances, but colour and other pertinent physical properties must be maintained within acceptable limits.

Heat treating equipment

Equipment for heat treatment has undergone a considerable advance; the intermittent kilns of the potteries have been superseded by continuous tunnel kilns, and the means for transporting the ware through the cycle is undergoing active innovation.

Regardless of kiln design, there are four basic elements common to all heat treatments: (1) the source of the heat, (2) the containment of the heat, (3) the containment of the ware, and (4) the instrumentation for control of temperature and atmosphere.

Heat sources include combustion of fossil fuels and the passage of electrical current through metallic alloys or ceramics, such as silicon carbide. Induction and arc heating are not common in the ceramics industries, but very-high-frequency induction (radio frequencies in the megahertz range) finds special uses, as have other new sources of heat, such as electron beam, ion beam, and solar and arc imaging.

Containment of heat involves furnace design, including choice of refractories (furnace linings). The availability of refractory materials useful to ever-higher temperatures has been paralleled by advances in insulating refractories, cement-bonded materials that can be cast into the desired shapes, and high-temperature fibres. Lighter weight materials have made faster heating and cooling cycles possible and have contributed to lower fuel or power consumption.

Containment of ware has also moved in the direction of better heat economy and faster cycles with materials of higher thermal conductivity, higher service temperatures, less creep and deformation, and less reaction with the ware.

The use of instrumentation has also advanced rapidly with the innovations in program controllers and analysis of atmospheres. Computer-controlled firing is being evaluated.

Glazes and enamels. Glazes and porcelain enamels provide a meeting ground for glass technology and particulate ceramic technology. Glazes are generally used for reasons of appearance but can be designed to improve other properties, such as strength and imperviousness, and to improve smoothness, thus making cleaning easier and improving resistance to electrical tracking (development of paths over the surface along which electrical current can flow).

Glaze formulation

Traditionally, glazes were the province of the ceramic technologist and were frequently synthesized from raw materials at the site on the matured ware during a special gloss firing. Now formulation of glazes has become a specialty of supplier companies that melt glaze, enamel, and bonding formulas and quench them to glassy frits (finely divided material) by rapid cooling in water or passing through steel rollers. Coating slips (suspensions) comprised of milled frits, opacifiers, bonding clays, and various modifiers are applied to the ceramic or metal base by spraying, dipping, or flowing. With ceramic bodies the maturing of the glaze may take place in a single firing with the maturing of the body. With porcelain enamels a carefully cleaned metal surface is coated from a slip (or more rarely by dry dusting), and the glass coating is matured by a rapid heating and cooling requiring only about five minutes at peak temperature.

BIBLIOGRAPHY. ERNST ROSENTHAL, *Pottery and Ceramics* (1949), is a good introduction to the manufacture, properties, and uses of clay-based wares; M. CHANDLER, *Ceramics in the Modern World* (1968), extends the treatment, while F. and S.S. SINGER, *Industrial Ceramics* (1963), goes into more technical detail. For the individual product categories, selected references include F.H. NORTON, *Fine Ceramics* (1970), for a well-illustrated coverage of whitewares, and the same author's *Refractories*, 4th ed. (1968), remains the outstanding text for high-temperature materials. V.V. VARGIN, *Technology of Enamels* (1968; orig. pub. in Russian, 1965), is the most current treatment of porcelain enamelling, though A.I. ANDREWS, *Porcelain Enamels*, 2nd ed. (1961), is still authoritative. B.E. WAYE, *Introduction to Technical Ceramics* (1967); and E.C. HENRY, *Electronic Ceramics* (1969), are brief, informative treatments on newer ceramic products. To supplement a basic text such as W.E. WORRALL, *Raw Materials* (1964), current data on raw materials and processing appear each year in special issues of the trade journals *Ceramic Industry* for January (also see the annual *Ceramic Data Book*) and *Ceramic Age* for July. W.D. KINGERY'S misleadingly named *Introduction to Ceramics* (1960), marked the transition from teaching of ceramics by separate industries to consideration of the principles underlying the full scope of ceramics as a broad class of materials. Symposia such as R.M. FULRATH and J.A. PASK (eds.), *Ceramic Microstructures* (1968), have brought together the producers of ceramics and those who are using them in specific, often extreme environments.

(A.G.P.)

Cereals and Other Starch Products

Starch, a carbohydrate stored in most plants, is a major constituent of the average human diet, providing a low-cost energy source with good keeping qualities. Cereals are high in starch, which may be used in pure or flour form. Starches are also obtained from such root sources as potatoes and from the pith of tropical palm trees. Various starches are used commercially in food processing and in the manufacture of laundering preparations, paper, textiles, adhesives, explosives, and cosmetics.

Cereals, or grains, are members of the grass family cultivated primarily for their starchy seeds (technically, dry fruits), which are used for human food, livestock feed, and as a source of industrial starch. Wheat, rice, maize (called corn in the U.S.), rye, oats, barley, sorghum, and some of the millets are common cereals.

This article is divided into the following sections:

I. Origin and development of cereals
  Nomenclature and classification
  Cereals and cereal products in the human diet
II. Cereal production
  Cultivation
  Processing and utilization
  Marketing and trade
III. Products
  Wheat flour
  Nonwheat cereal products
  Products from other starch-yielding plants
  Other cereal and starch products

I. Origin and development of cereals

Cereals were among the first plants to be domesticated, having been grown long before the beginning of recorded history. Each of the world's great civilizations has depended upon cereals as a major food source. When ancient man learned to grow cereals, he was able to produce more than enough food for his own immediate needs, thus making possible settled communities.

Early man lived precariously by hunting and fishing and by eating edible roots, wild fruits, and wild grains. The early hunter required 10 to 15 square miles of land to feed himself, an area that when cultivated can provide food for 5,000 people. Thus a major turning point occurred when man learned that certain parts of food plants, saved from one season to another and put into the ground at appropriate times, produced many new plants similar to the original. Archaeological evidence indicates that early ancestors of cultivated wheat existed in the very early Stone Age (Early Paleolithic); crude milling implements have been found dating back 75,000 years. The earliest actual remains of grain date from about 5000 BC, toward the close of the Neolithic Period. Basic crops of Neolithic agriculture in the Near East were primitive husked wheats, wild einkorn (*Triticum boeotichum*) and wild emmer wheat (*T. dicoccides*), the latter regarded as the ancestor of cultivated emmer (*T. dicoccum*). Einkorn probably appeared earlier than emmer wheat, but the cultivated variety of emmer was widely distributed. Production of both einkorn and emmer decreased in the Bronze Age, with the greater use of barley (*Hordeum vulgare*). The main centres of cultivated barley were probably the northeast portion of Africa, including the mountainous districts of Ethiopia, and Southeast Asia. Barleys originated from *Hordeum spontaneum*. Rice is another primary crop, domesticated from a wild type. Secondary crops, originating as weeds in the primary crops, include oats and rye.

Einkorn and emmer

Maize, or corn (*Zea mays*), was cultivated in America before the first Europeans arrived, and little is known of its early history. Rice, now comprising some 25 species, was cultivated in Southeast Asia as early as 3000 BC. Rice growing (paddy cultivation) normally requires either irrigation or swamp conditions. There is no evidence of rice cultivation in the ancient Near East; it is not represented on Egyptian tombs and is not mentioned in the Bible.

Cereal grains were originally crushed between two stones and made into crude cakes. Remains of a kind of cake made from coarsely ground grain have been found in explorations of the Swiss lake dwellings (*c.* 3500 BC). Cereals were probably used primarily as human food by early communities but may also have been used as feed for wild cattle caught and kept as a reserve food supply.

By about 3000 BC all of the major cereals had been brought under cultivation; not a single new major crop has been introduced since.

NOMENCLATURE AND CLASSIFICATION

This article treats the major cereals, wheat, rice, barley, rye, oats, maize, sorghum, millet, and buckwheat; important starchy foods consumed in certain countries instead of cereals, including potatoes and cassava; and soybeans, legumes widely used in the bakery industry. Wheat species will be treated in detail, other cereals in a more general way throughout the article.

Wheat: varieties and characteristics. The three principal types of wheat used in modern food production are *Triticum vulgare* (or *aestivum*), *T. durum*, and *T. compactum*. *Triticum vulgare* provides the bulk of the wheat used to produce flour for bread making and for cakes and biscuits (cookies). It can be grown under a wide range of climatic conditions and soils. Although the yield varies with climate and other factors, it is cultivated from the southernmost regions of America almost to the Arctic and at elevations from sea level to over 10,000 feet. *T. durum*, longer and narrower in shape than *T. vulgare*, is mainly ground into semolina (purified middlings) instead of flour. Durum semolina is generally the best type for the production of pasta foods. *T. compactum* is more suitable for confectionery and biscuits than for other purposes and is decreasing in importance.

The wheat grain, the raw material of flour production and the seed planted to produce new plants, consists of three major portions: (1) the embryo or germ (including its sheaf, the scutellum) that produces the new plant; (2) the starchy endosperm, which serves as food for the germinating seed and forms the raw material of flour manufacture; and (3) various covering layers protecting the grain. Although proportions vary, other cereal grains follow the same general pattern. Average wheat grain composition is approximately 85 percent endosperm, 13 percent husk, 2 percent embryo.

Wheat grain composition

Characteristic variations of the different types of wheat are important agricultural considerations. Hard wheats include the strong wheats of Canada (Manitoba) and the similar hard red spring (HRS) wheats of the United States. They yield excellent bread-making flour because of their high quantity of protein (approximately 12–15 percent), mainly in the form of gluten. Soft wheats, the major wheats grown in the United Kingdom, most of Europe, and Australia, result in flour producing less attractive bread than that achieved from strong wheats. The loaves are generally smaller, and the crumb has a less pleasing structure. Soft wheats, however, possess excellent characteristics for the production of flour used in cake and biscuit manufacture.

Wheats intermediate in character include the hard red winters (HRW) of the central U.S. and wheat from Argentina. There are important differences between spring and winter varieties. Spring wheats, planted in the early spring, grow quickly and are normally harvested in late summer or early autumn. Winter wheats are planted in the autumn and harvested in late spring or early summer. Both spring and winter wheats are grown in different regions of the U.S. and the Soviet Union. Winter varieties can be grown only where the winters are sufficiently mild. Where winters are severe, as in Canada, spring types are usually cultivated, and the preferred varieties mature early, allowing harvesting before frost.

In baking and confectionery manufacture the terms strong and weak indicate flour from hard and soft wheats. The term strength is used to describe the type of flour, strong flours being preferred for bread manufacture and weak flours for cakes and biscuits. Strong flours are high in protein content, and their gluten has a pleasing elasticity; weak flours are low in protein, and their weak, flowy gluten produces a soft, flowy dough.

Wheat breeders regularly produce new varieties, not

only to combat disease but also to satisfy changing market demands. Many varieties of wheat do not retain their popularity, and often those popular in one decade are replaced in the next. New varieties of barley have also been developed, but there have been few varieties of rice.

Distribution and production: acreage and yield. There are considerable differences in yield per acre between the soft wheat grown in the U.K. and many parts of Europe and the hard wheats grown in the U.S. and Canada. A yield of as much as 50–60 bushels per acre is not uncommon in the U.K., but the strong wheats of North America yield only around 25 bushels per acre (an average bushel of wheat is about 60 pounds, or 27 kilograms). Table 1 illustrates wheat yield differences. The figures for individual countries show interesting variations. For example, in the U.K., during the period 1949–53, the average yield in bushels per acre was 41.7, but in later years it rose to well over 50. The highest figure recorded was 73.9 bushels in 1971 for The Netherlands (not included in table because year was odd-numbered). The yields in Canada and the U.S. from 1950 to 1970 varied around 17 to 31, but the tendency was toward an increase. In the Soviet Union the yield per acre has increased but is still on the low side; the yields in Asia, including China, remain poor.

Table 2 gives statistics on world wheat production. These figures show how much the harvest can vary from year to year and also the trend for the total wheat yield and production to increase.

CEREALS AND CEREAL PRODUCTS IN THE HUMAN DIET

Cereals and population

The world population is increasing at the rate of 75,000,000 persons a year. Of the present world population (around 3,850,000,000), half lives in Asia and three-quarters in developing countries. In these areas cereals play the leading dietary role. Thus it is of major significance that world production of wheat and some other cereals (see Table 3) has risen considerably owing to improved varieties, better resistance to disease, and higher yields per acre due to scientific application of fertilizers; but the demand for a sufficient supply of food, and for a more nutritious food, continues.

Nutrients. Foodstuffs consist of many types of nutrients, including carbohydrate, protein, fat, mineral matter, and vitamins. Carbohydrates (starches and sugars), proteins, and fats all provide energy. Their values are measured in calories, the heat unit required to raise the temperature of one gram of water from 15° to 16° C.

The heat-producing values, in calories, of the main food constituents (per gram) are carbohydrates 3.7, proteins 4.1, fat 9.3, and alcohol 7. Based on the percentage of the various food constituents contained, the values of some common foods, expressed as calories per pound, show the following comparison between cereals and non-cereals: white bread 1,037; wholemeal bread 1,012; rump steak 2,006; bacon (back) 2,696; chicken 360; hen eggs (in shell) 659; apples 196; butter 3,503; and cheese (full cream) 2,011.

Table 3: World Cereal Acreage, Production, and Yield
(1972, including China)

Oats	4.5	4.0	24.4
Other	18.5	10.0	14.6

*Percent of world total, by weight.

On the whole, the carbohydrate-rich cereals compare favourably with the protein-rich foods in energy value; in addition they are significantly less expensive to produce. Therefore most of the world's diets are arranged to meet main calorie requirements from the cheaper carbohydrate foods, and the proteins are used primarily to provide essential amino acids. Individual calorie requirements depend upon age, sex, and the amount of physical work being carried out. A man performing heavy work may require as many as 4,500 calories daily, while 2,400 will suffice for sedentary workers. Children require from 800 to 2,250 calories. The average figure often taken for the population as a whole is 2,400.

Protein consumption is of major importance in diets; insufficient protein intake ranks second to general insufficiency of food as a cause of malnutrition. Proteins are

made up of combinations of 26 amino acids, of which 8 are essential to the human diet: valine, leucine, isoleucine, threonine, methionine, phenylalanine, lysine, and trytophan. Protein from vegetable sources, with the exception of soybean, normally does not provide sufficient essential amino acids and is especially deficient in lysine. Such protein is described as having limited biological value. Although ideally only about half of the protein in the diet should come from vegetable sources, this is not possible in the developing countries, where animal protein sources are limited. Cereal products generally contribute a large proportion of the vegetable protein, in addition to their carbohydrate content. The soybean is an important source of protein in many countries.

Nutritional significance of cereals. Cereals are largely consumed as bread and to a lesser extent as cakes, biscuits, and breakfast foods. They are also consumed in other forms in some countries. There has been controversy as to the relative merits of white bread and bread made from flour of much longer extraction, which is darker in colour. Whiter flour consists of about 72 percent of the grain but contains little of the germ, or embryo, and of the outer coverings (bran). Since the B vitamins are concentrated mainly in the scutellum (covering of the germ), and to a lesser extent in the bran, the vitamin B content of white flour, unless artificially enriched, is much less than that of brown flour, particularly in vitamin B_1. Because the whole meal normally has a higher vitamin content than white flour, arguments have been advanced against excluding the vitamin-rich portions of the grain in flour produced for bread making. In most developed countries, the public prefers white flour and bread. It may be argued that there is no serious disadvantage if humans consume white flour, as opposed to darker flour, since the discarded portion is fed to animals, producing animal food for the human diet. Man does not digest brown flour and bread as easily and as fully as he does the white variety.

Role of the B vitamins

The relative value of the two types of bread became less important when vitamin B_1 was synthesized and could be manufactured and added to white flour. The chemically synthesized vitamins are identical with those occurring naturally and have the same biological activity. White flour is often routinely fortified with vitamins so that the vitamin content is similar to that of the darker flours.

Treatment by chemicals to improve baking quality is distinct from flour enrichment (see *Composition and Grade*). Table 4 gives the Joint Food and Agriculture Organization/World Health Organization Expert Committees' recommendations on flour treatment.

In the U.K. the law requires enrichment of each 100 grams of flour to reach minimum standards of 0.24 milligram B_1, 1.60 mg nicotinic acid or nicotinamide, and 1.65 mg iron. Bread-making flours are also fortified by the addition of calcium in the form of calcium carbonate, so that each 100 grams of white flour contains not less than 235 mg, or more than 390 mg of "chalk." Table 5 compares the composition of flour of various extractions.

In the U.K., where an attempt was made at one time to standardize flour on an 80 percent extraction, a committee studied the relative merits of the darker 80 percent extraction flour (milled to contain as much germ rich in B vitamins as possible) and fortified (or enriched) white flour (around 72 percent extraction) and concluded that the differences between low-extraction flour enriched as specified and 80% extraction flour would not significantly affect the health of the population.

Many of the important nutrients in the diet are contributed by bread, the main form in which cereals are consumed. Besides providing close to 17% of the calories required, fortified bread provides 17%–18% of the total protein in the diet, 16% of the calcium, 20% of the vitamin B_1, and 19% of the nicotinic acid. Taking all cereal products, these percentages are much higher. Although the protein is not ideal in biological quality because of its rather low lysine content, it is possible (now that pure synthetic lysine is available) that this situation could be remedied. In developed countries with good mixed diets, this may not be necessary. In developing countries, where the population lives largely on cereals, compulsory lysine enrichment may be of value. Where maize (exceptionally low in lysine) is a staple flour, another method has become practical: the cultivation of maize with a higher than usual lysine content.

Nutrients in bread

Table 6 illustrates the value of bread in the diet compared with other principal foodstuffs.

Based on cost, enriched bread in some countries is a comparatively inexpensive source of calories, protein, iron, vitamin B_1, nicotinic acid, and calcium in the diet. Cereal consumption varies enormously in different countries, and the more developed a country becomes, the lower is the amount consumed, because more of the attractive and expensive foods become available. In less developed countries, however, the bulk of the diet consists of cereals, and such diets are frequently insufficient in protein and carbohydrates. In the U.S.S.R. the diet is adequate in calories, but over half of the calorific value is supplied by flour and other cereals. In contrast, in the U.S., less than 25 percent of the calories in the diet come from flour, cereal products, and potatoes. Most western European countries fall somewhere between.

Other cereals are similar to wheat in nutritive value, containing mainly carbohydrates and some protein of

Fish	0.9	4.7	1.7	2.0	0.9	3.7

rather limited biological value. The nature of a protein is largely determined by its amino acids. Table 7 indicates the chief amino acids in various cereals. Although the distribution of the amino acids in these cereals is somewhat similar, the total amount of protein varies, with wheat usually containing 11 to 14 percent protein, and other cereals around 8 to 10 percent.

Wheat protein

The output of cereals is steadily growing. Overall, about 70 percent of the total crop goes for human consumption in the form of flour products, about 10 percent is returned to the soil as seed, and the remainder is divided among livestock feed, industrial uses, and waste. These proportions vary greatly among different countries; in the U.K., for example, half of the tonnage produced may go for livestock feed. Despite steadily increasing production, which has resulted in large stocks, or "carryovers," in the wheat-exporting countries, there remains a shortage. A critical problem is the loss resulting from insect damage to crops and from the various forms of spoilage occurring during storage.

II. Cereal production

CULTIVATION

The cultivation of cereals varies widely in different countries and depends partly upon the degree of development existing. The condition and purity of the seed is receiving increasing attention. Other factors include the nature of the soil, the amount of rainfall, and the techniques applied to promote growth. In illustrating production problems, this article will use wheat as the example; the procedures for other cereals are similar. Exceptions for rice and other cereals will be treated later.

Wheat can be cultivated over a wide range of soils and can be successfully grown over large portions of the world, ranging in altitude from sea level to over 10,000 feet. Annual rainfall of 10 inches (254 millimetres) is generally considered the minimum, and the soil should be sufficiently fertile. (Barley can be grown in soil less fertile than that required for wheat.) Soil benefits from a good humus content (partially decayed organic matter), and chemical fertilizers are also helpful.

Table 7: Amino Acid Content of Cereal Grains
(g amino acid/16g nitrogen)

amino acid	wheat	barley	rye	oats	rice	maize	sorghum

Serine	4.8	3.7	3.8	3.4	5.2	4.2	—

Purity of the seed is important. The seed wheat (or other cereal seeds) must be true to its particular variety and as free as possible from foreign seeds. Seeds are frequently cleaned to avoid contamination by other seed crops. Modern cleaning methods employ such devices as oscillating sieves or revolving cylinders. Seed obtained with a combine harvester is often unsuited for use as seed wheat without preliminary treatment. Spring and winter varieties exist for both wheat and barley. Winter varieties generally produce better crops. Winter wheat should form a good root system, and the plant should begin to form new shoots before the cold weather sets in; winter wheat is likely to have more tillers than spring wheat.

Importance of seed purity

The rate of sowing varies from 20 pounds per acre upward. Depth of sowing, usually one to three inches (2.5 to 7.5 centimetres), can be less in certain areas.

Breeding. Wheat and other cereals are self-fertilized. The pollen carried by the stamen of a given flower impregnates the pistil (stigma and ovary) of the same flower, enabling the variety to breed true. Wheat flowers are grouped in spikelets, each bearing from two to nine flowers, or florets. To produce new varieties by cross-fertilization, the cereal breeder artificially transfers the stamen from one variety to the flower of another before self-fertilization takes place. The production of a sufficient supply of the new type of seeds for sowing is time-consuming and expensive, but it allows new varieties to be evolved, retaining the desirable characteristics from each parent. For example, especially in the U.K. and Australia, varieties of the wheat that yield well often produce flour of poor baking quality; proper selection of parent plants permits new varieties to be produced that yield well and still possess good baking qualities.

Other reasons for developing new varieties include resistance to rust (fungus; see below) and other diseases, resistance to drought, and development of stronger and shorter straw to make harvesting easier.

Seedbed preparation. Various types of plowing machinery and other implements are employed to render the soil more suitable for seed wheat planting. The equipment used depends upon such factors as the climate, the nature of the ground, and the rainfall. Tillage is the process of preparing soil for cultivation purposes. The practices used and the implements employed vary considerably. Serious soil erosion may require special procedures to maintain clods and plant residues in the soil.

Tillage

In North America it is normal practice to grow wheat on the same ground for as long as sufficiently clean crops are produced, but eventually the ground must rest fallow for a year. The moisture of the land at the time of sowing is an important factor. The ancient procedure of growing legumes occasionally to improve the soil is still common in Europe, though less so in North America. Fertilization of the ground is useful to increase the crop yield, but it does not generally increase the protein content of the crop. In the large collective state farms of the Soviet Union, huge harrows set with spikes or teeth are employed, as well as the disk cultivating plow set with disks that break up the soil; the scarifier, a machine that pulverizes the soil, is popular in Australia.

Practices also differ between the semi-arid and subhumid climates.

Plant protection. Winter crops are frequently disturbed by frost, and the ground must then be rolled in the spring to consolidate the soil around the roots. If soil has become crusted by heavy rains followed by surface drying, the crop is usually harrowed in the spring to aerate the soil and kill young weeds. Although all of the required mineral nutrients may be added to the soil at the time of sowing, sometimes only part of the nitrogenous fertilizers are added at that time, and the remainder is applied to the growing crop in the form of a top dressing. In the cultivation of spring wheat all of the fertilizer is usually added before or at sowing time, but sometimes a small portion is reserved for later.

Weeds. Weeds present difficulties, as they compete with cereal crops for water, light, and mineral nutrients. The infestation of annual seeds planted in a field may cause many weeds in that field for successive years. Charlock or wild mustard, wild oats, crouch grass, and other common weeds are disseminated by wind, water, and birds.

Insects. In addition to weeds, wheat and other cereals are seriously affected by insects.

Grasshoppers and locusts cause immense damage. Spraying from airplanes with chemicals such as gamma BHC, Dieldrin, Chlordane, or Toxaphene is effective; on small farms grasshopper control is often accomplished by weed killers such as MCPA (2-methyl-4-chlorophenoxyacetic acid) and 2,4-D (2,4-dichlorophenoxyacetic acid).

The eggs of wireworms are laid in the soil, and the larvae live underground for some years, feeding on the roots and stems of the young plants (particularly slow-growing plants). To combat such damage, chemical seed dressing is used together with nitrogenous fertilizers. Other measures use such chemicals as gamma BHC (Lindane) or Dieldrin.

Aphids attack many plants, and the wheat aphid, or "greenbug," causes damage throughout the world. Preventive action includes preparing a good seedbed, sufficient fertilization, and early sowing.

The wheat stem sawfly (*Cephus cinctus*) is found in many parts of the world. Infested wheat shows fallen straw filled with a fine sawdust material harbouring brown-headed larvae that pass the winter in the base of the wheat straw; the wasplike adult insect emerges around June. The females thrust their eggs into the upper plant tissues, and the larvae feed within the stem toward the base until the stem collapses. Varieties of Manitoba wheat such as Rescue and Chinook are reasonably resistant to the pest, and thorough plowing in of the infested stubble is generally effective. Certain crops, such as brome grass, attract this pest and may be grown on the borders of wheat crops to distract the pests away from the wheat. The hessian fly (*Mayetiola,* or *Phytophaga, destructor*), resembling the mosquito, attacks the stems of wheat, barley, and rye. Late wheat usually escapes damage from this pest.

Many wheats in central Europe and the Middle East have shown evidence of attacks from the wheat bug (*Weizen-wanze*, or *blé punaisé*). The two main varieties are the *Aelia* and the *Eurygaster*. The eggs are laid in the spring, and the new generation appears in the summer. When the wheat is harvested, the bugs leave the stubble field and migrate to nearby foliage for the winter. To thrive and multiply, wheat bugs require sun, warmth, and absence of pronounced dampness.

Gluten damage

The wheat bugs puncture the grain and introduce by means of their saliva an enzyme that profoundly modifies the nature of the gluten. The puncture mark can be seen on the grain, usually surrounded by a yellow patch, and sometimes the grain is shrivelled. The main damage comes from attacks on the grain just before maturity. Although the insects leave, the damaged grain remains normal in size and remains in the wheat mixture sent to the mill.

The gluten of flour produced from infected wheat rapidly loses its cohesion upon standing in water, eventually disintegrating completely. Strong wheats resist wheat-bug attack better than soft, weak wheats do. There is little change in strong baking flours if only 1 percent of the grains are affected; in flour from soft wheats, the damage with even 1 percent to 2 percent of the grains affected can make the baking quality unacceptable. Countries in which the crop is affected by this pest include the Soviet Union, Romania, Hungary, Greece, and Morocco.

Fungus diseases. In the fungus group known as rust, the chief damage is caused by black rust (*Puccinia graminis*). Because this fungus spends part of its life on cereals, and part on the barberry bush, these bushes are often eradicated near wheat fields as a preventive measure. Black rust causes cereal plants to lose their green colour and turn yellow. The grain produced is small, shrivelled, and has a low weight per bushel. New wheats, more resistant to rust, are being introduced.

In many countries wheat is attacked by smut. Stinking smut (or bunt) is fairly common in the United Kingdom. Malformed grains are produced, filled with black spores that spread over noninfected grain and give off a "fishy" smell.

Ergot (*Claviceps purpurea*) is a fungus more often attacking rye than wheat. It forms a dark purple mass, larger than the grain, containing 30 percent fatty material and the alkaloid ergotoxine, which has a profound pharmacological effect on the human and animal body and can produce abortion. Much of this fungus is likely to be removed in the mill screen room, and the clean grain sent on to the mill should contain not more than 0.04 percent of this fungus and preferably less.

Harvesting. In the developed countries, harvesting of wheat and often other cereals is done principally by the combine harvester, though in the developing countries the ancient scythe, sickle, and flail are still widely used.

The McCormick reaper

The mechanical ancestor of today's large combines was the McCormick reaper, introduced in 1831 and followed by self-raking reapers that delivered the cut grain in bunches on the ground to be bound by hand. In 1843 a "stripper" was brought out in Australia that removed the wheat heads from the plants and threshed them in a single operation. Threshing machines were powered first by men or animals, often using treadmills, later by steam and internal-combustion engines. The modern combine harvester, originally introduced in California about 1875, came into wide use in the U.S. in the 1920s and 1930s and in the U.K. in the 1940s. In 1940 the self-propelled combine was introduced. The combine cuts the standing grain, threshes out the grain from the straw and chaff, cleans the grain, and discharges it into bags or grain reservoirs. Other crops can also be worked by adaptations of the machine, and the reduction in harvesting time and labour is striking; in 1829 harvesting one acre of wheat required 14 man-hours, while the modern combine requires less than 30 minutes. In the early part of the 19th century harvesting a bushel of wheat required three man-hours' work; today it takes five minutes.

For satisfactory results, crops should not be too damp and should be reasonably ripe. If the grain contains over 14 percent moisture, as often happens in the U.K. and other European countries, it must be dried after harvesting under controlled conditions to avoid damage to the gluten. Rice can be combine-harvested, but because of its high moisture content (approaching 20 percent) it must be immediately dried.

Grading. Wheat is an important commodity in international commerce, and many attempts have been made to ensure reliability in grading. In North America excellent grading allows the buyer to ascertain the type and standard of wheat he acquires. Canada has statutory grades for most of its wheats. For wheat moving overseas from the terminal positions, standard export samples are used in grading.

Flour from an inferior grade is not automatically weaker than the top grade.

In the U.S. much of the wheat is officially graded, notably the hard spring and the hard winter wheats. Grading also takes place in Argentina and Australia, although it is not usually as precise as in North America. In many countries there is little commercial grading of wheat,

and the buyer relies on his own testing and assessments of wheat arrivals. In Australia, "fair average quality" (FAQ) indicates wheat not obviously unsatisfactory visually but takes no account of the baking strength and the character of the flour yielded. In recent years, however, considerable improvement in grading has taken place, especially when hard strong varieties are sold, as in the case of special high-protein Australian wheat from northwest New South Wales and from Queensland.

In the U.K., there is no official wheat or barley grading as in North America. Barley is bought on appearance or by named variety. This is largely true in much of Europe, although the U.S.S.R. has introduced a grading system for wheat covering red spring, durum, white spring, red winter, and white winter, with special subclasses based on factors such as vitreousness, colour, and weight.

Storage. Cereal storage has been of concern from the earliest times; references are made to it in the Bible. Harvest variations from season to season produced carryover requiring storage, a problem that grew with increasing populations and developing commerce. The diary of Samuel Pepys (1633–1703) records the destruction of the wheat storehouses in the Great Fire of London (1666) and mentions the existence of these storehouses from the reign of Henry VIII (1491–1547). With modern international cereal trade, huge silos are now found at the main points of export and at the docks of importing countries. In the major exporting countries silos at the country elevators feed the terminal silos; inefficient storage at any of these points makes the cereals highly vulnerable to insects and rodent attack. In certain regions, such as India, losses have amounted to 40 percent of the crop.

Grain respiration

A constant danger also lies in the respiration of the grain. If the moisture content of grain is low (10–12 percent), a rise in temperature resulting from respiration is unlikely; but if the bulk is large and the moisture content high (over 16 percent), the heat may not be dissipated, causing the temperature to rise and further increase the rate of respiration. Consequently, cereal stocks are turned over to ventilate the grain and to keep the temperature low. The problem also occurs in the holds of ships; much litigation has resulted from the arrival of hot and damaged cargoes.

Molds and fungi are other sources of spoilage that have received extensive study in recent years. Cleaning processes remove as much as possible of external molds before storage, but in hot countries, particularly, the problem remains serious. Under primitive conditions the habits and development of communities depended largely on their skill in storing grain.

Heat is also frequently a cause of loss of weight, loss in milling value, and loss in food value through its provision of a favourable environment for such insects as the grain weevil (*Sitophilus granarius*), the rice and maize weevils (*S. oryzae*), the lesser grain borer (*Rhyzopertha dominica*), and the angoumois grain moth (*Sitotroga cerealella*). These are all endosperm borers. Among the grain germ eaters are the rust-red grain beetle (*Cryptolestes ferrugineus*), the saw-toothed grain beetle (*Oryzaephilus surinamensis*), the khapra beetle (*Trogoderma granarium*), and the warehouse moth (*Ephestra elutella*).

Secondary pests include the mill pest known as the Mediterranean flour moth (*Anagasta kuehniella*), the confused flour beetle (*Tribolium confusum*), the rust-red flour beetle (*T. castaneum*), the flat grain beetle (*Cryptolestes pusillus*), the broad-horned flour beetle (*Gnathocerus cornutus*), the cadelle beetle (*Tenebroides mauritanicus*), and a number of miscellaneous insects, including the yellow mealworm (*Tenebrio molitor*), the Australian spider beetle, and the biscuit beetle. Of the mites that invade mills, storehouses and bakeries, the commonest is the flour mite (*Tyroglyphus farinae*).

Good housekeeping, with special attention to sacks and bags and their regular cleaning and disinfecting, contributes to insect control. Frequently used insecticides include inert dusts, Pyrethrum (and synergists), gamma BHC. Other contact insecticides or fumigation may be required. The common fumigator is hydrogen cyanide, but methyl bromide and ethylene oxide have been recommended.

In Canada most of the older elevators hold 20,000 to 30,000 bushels of grain, but some hold as much as 100,000 bushels. A new Canadian elevator system at Port Cartier on the St. Lawrence River is designed for the berthing of supertankers; licensed storage capacity of this installation is 10,500,000 bushels. Unloading of lake vessels can be carried out at 88,000 bushels an hour; the two shipping belts each have maximum capacities of 50,000 bushels an hour.

In the U.S. storage facilities are similar, though the proportion of wheat exported is not as great as in Canada. Many interior terminals in the U.S. handle large amounts of grain received directly from farmers.

Storage methods in Australia have improved considerably in recent years, with increasing attention given to country storing and the modernization of terminal elevators. There has been a change from bag to bulk handling; 95 percent of the grain was bulk handled by the end of the 1960s. Huge terminal elevators operate in Sydney and Newcastle.

In Argentina large terminal elevators deal with a major export trade, but grading is not as reliable as that in North America. Argentine ports receive the wheat grown in their respective areas, which gives buyers some guidance on grade and type. Considerable quantities of maize are also exported from Argentina, with precautions taken to ensure reasonably low moisture content to prevent deterioration of cargoes in shipment.

Tilbury Grain Terminal

Handling of grain received in Europe from overseas is a large operation. The Tilbury Grain Terminal in London is a good example of modern grain handling. Capable of servicing bulk carriers of up to 65,000 tons, at a maximum rate of 2,000 tons an hour, the terminal not only feeds adjacent mills but offers a deepwater outlet for transshipment to both rail and road. Two marine leg (dockside) elevators each have a discharge rate of 1,000 tons an hour. Normal silo capacity of 105,000 tons can be extended to 240,000 tons. The silos are 127 feet high and individual bin capacities range from 60 to 900 tons.

PROCESSING AND UTILIZATION

Milling. Cereal processing is complex. The principal procedure is milling; that is, the grinding of the grain so that it can be easily cooked and rendered into an attractive foodstuff. Cereals are not usually eaten raw, but different kinds of milling (dry and wet) are employed, depending on the cereal itself and on the eating customs of the consumer. Wheat may be crushed with grinding stones or similar devices or by modern automated systems employing steel cylinders, followed by air purification and numerous sievings to separate the endosperm from the outer coverings and the germ.

Maize is often milled by wet processes, but dry milling is also practiced, especially in the developing countries. Maize, with its high germ, or embryo, content is inclined to respire more during storage and, unless precautions are taken, may increase in temperature on incorrect storage. Most other cereals are ground in the dry state.

Some cereal grains are polished, removing most of the bran and germ and leaving the endosperm.

Uses. *Human food.* Cereals are used for both human and animal food and as an industrial raw material. Although milled white flour is largely used for bread production, especially in industrialized countries, the grain may be converted to food in other ways. In India the major part of the grain is not ground into flour in roller mills but is roughly ground in small crushing mills into a meal called *atta*. This meal is cooked into flat cakes known as *chapatis*.

Animal feed. Cereals are important components of animal feeds; the modern farmer either uses balanced rations or attempts to balance the animal diet himself. The cereals mainly used are wheat and such wheat byproducts as the outer coverings separated in the preparation of white flour (bran and the more floury middlings), maize, barley, sorghum, rye, and oats. These are supplemented by protein foods and green fodders.

Animal foods require proper balance between the cereals (carbohydrates) and the more proteinous foods, and they must also contain suitable amounts of necessary minerals, vitamins, and other nutrients. The compounded ration for a milking cow generally contains about 50–80 percent of cereals, consisting of wheat by-products, flaked or ground maize, barley, sorghum, wheat, and oats. Requirements for most balanced rations for pigs and poultry are similar. Maize is especially useful in high-energy feeds either as meal or as the flaked and partly gelatinized product; barley is desirable for fattening, and oats help provide a better balanced cereal for livestock.

Without cereals for use in farm animal foods, the available supply of the animal protein required in the human diet would be greatly reduced.

Industrial uses. The relatively minor use of cereals in nonfood products includes the cellulose in the straw of cereals by the paper industry, flour for manufacturing sticking pastes and industrial alcohol, and wheat gluten for core binders in the casting of metal. Rice chaff is often used as fuel in Asia, and oats have been used for the preparation of the chemical furfural.

MARKETING AND TRADE

Cereals account for over 70 percent of the world's harvested area, and they provide over 50 percent of the food energy supply. Approximately four-fifths of the total wheat produced is used where it is grown, but the remaining one-fifth, a considerable quantity, enters into international trade. Conditions vary widely from year to year, and it may occur that a normally exporting country will at times require importation of grain, especially of wheat.

Production cost varies in different countries, and it is sometimes necessary to provide protection for domestic cereal producers, especially to cover the possibility of a large world "carryover" in the exporting countries, causing prices to fall. Permanent protection, or financial assistance, is administered in various ways to growers in both the wheat-importing and wheat-exporting countries. The economics of cereal production is complicated by the occasional vast surpluses produced and exported by the large wheat-growing countries. This surplus wheat is usually in potential competition with the domestic producer, and governments must consider production costs, selling prices, and other factors.

Carryover

In the developed countries cereal production is increasingly concentrated in large farm operations and in specific areas. In the U.K., for example, the Minimum Import Price Scheme was instituted to reduce instability in the domestic cereal market, caused by low priced imports, and to reduce the need for large government subsidy payments to domestic producers to fulfill price guarantees. By mutual consent with the cereal-exporting countries, a minimum price was set, and levies were to be imposed on the imported consignments if their price on entry dropped below the agreed minimum. When the U.K. joined the European Economic Community (EEC) in 1973, complicated trade agreements had to be negotiated.

Prices may be largely guaranteed by a managed market, coupled with import controls, or there may be a relatively free market with guarantees to the grower effected by deficiency payments, a form of subsidy.

In the EEC, prices are maintained largely by official support, in the form of "intervention buying," when market prices approach or reach a predetermined level. Grain acquired by intervention is subsequently resold at subsidized prices on world markets or wheat may be denatured for animal feeding. The cost of subsidizing the sale of stocks on world markets or of denaturing for sale as animal feedstuff is met by EEC funds contributed by member states.

EEC price supports

Although cereal consumption tends to decrease in the developed countries, there is a continuous demand for more grain in the less developed countries, and international trade in cereals will probably continue to grow with the growing world population.

The main wheat-exporting countries are the U.S., Canada, Australia, U.S.S.R., Argentina, and France; the main importing countries are the U.K., China, West Germany, India, Japan, Brazil, and a number of smaller countries. The U.K., for example, may import as much as 4,500,000 tons of wheat a year, as well as large quantities of maize. The volume of exports and imports is influenced by the extent of the carryover, or unsold portion of the previous year's crop, but the international wheat trade often amounts to as much as 50,000,000 metric tons annually. China, although an importer, is the second largest producer of wheat (after the U.S.S.R.), illustrating the needs of an increasing population and improved food standards.

Most of the international trade in cereals follows the same pattern, mainly wheat for human consumption and secondarily maize and similar cereals for animal feedstuffs. Storage facilities and highly developed transportation systems have made wheat and other grains available for export throughout the year, with movement and trade no longer concentrated in immediate postharvest periods.

Soon after World War I, especially around the 1930s, some international coordination in the wheat trade was considered necessary to assure stability and fair treatment for both the exporting countries and the farmers in the importing countries. Although conferences were held, progress was delayed by World War II. In 1945 the United Nations, through its Food and Agriculture Organization (FAO) acted to increase coordination, an action that became the basis of the formation of the World Bank, with capital subscribed by member countries. The International Monetary Fund was established in 1946 with the objective of helping to stabilize exchange rates. The General Agreement on Tariffs and Trade (GATT) in 1948 was followed by the International Wheat Agreement accepted by bulk exporters and importers; similar agreements were made in 1953, 1956, 1959, and 1962. These agreements, specifying guaranteed purchases by importers, balancing lists of guaranteed sales by exporters, and maximum and minimum prices, contributed to stabilization of wheat prices.

III. Products

WHEAT FLOUR

The milling of wheat into flour for the production of bread, cakes, biscuits, and other edible products is a huge industry. Cereal grains are complex, consisting of many distinctive parts. The objective of milling is separation of the floury edible endosperm from the various branny outer coverings and elimination of the germ, or embryo. Because wheats vary in chemical composition, flour composition also varies. Table 8 shows the approximate composition of wheat and white flour.

Table 8: Composition of Wheat and White Flour
(percent)

	wheat	flour
Moisture	9–18	13.0–15.5
Starch	60–68	65–70
Protein	8–15	8–13
Cellulose (fibre)	2.0–2.5	trace–0.2
Fat	1.5–2.0	0.8–1.5
Sugars	2–3	1.5–2.0
Mineral matter	1.5–2.0	0.3–0.6

Although some important changes have occurred in flour milling, basic milling procedure during the past 100 years has employed the gradual reduction process as described below.

Milling. In modern milling considerable attention is given to preliminary screening and cleaning of the wheat or blend of wheats to exclude foreign seed and other impurities. The wheat is dampened and washed if it is too dry for subsequent efficient grinding, or if it is too damp it is gently dried to avoid damaging the physical state of the protein present, mainly in the form of the elastic substance gluten.

Gradual reduction process

The first step in grinding for the gradual reduction process is performed between steel cylinders, with grooved surfaces, working at differential speeds. The wheat is directed between the first "break" or set of rolls and is partially torn open. There is little actual grinding at this stage. The "chop," the resulting product leaving the rolls, is sieved, and three main separations are made: some of the endosperm, reduced to flour called "first break flour"; a fair amount of the coarse nodules of floury substances from the endosperm, called semolina; and relatively large pieces of the grain with much of the endosperm still adhering to the branny outsides. These largish portions of the wheat are fed to the second break roll. The broad objective of this gradual reduction process is the release, by means of the various sets of break rolls, of sufficient inner endosperm of the grain, in the form of semolina, so that the various semolinas from four or five break rolls can be separated by suitable sieving and the branny impurities can be removed by air purifiers and other devices. The cleaned semolinas are reduced to fine flour by grinding between smooth steel rolls, called reduction rolls. The flour produced in the reduction rolls is then sieved out. There are usually four or five more reduction rolls and some "scratch" rolls to scrape the last particles of flour from branny stocks. Since the various sieving and purification processes free more and more endosperm in the form of flour, flour is obtained from a whole series of processing operations. The flour is sieved out after each reduction roll, but no attempt is made to reduce to flour all of the semolina going to a particular reduction roll. Some of the endosperm remains in the form of finer semolina and is again fed to another reduction roll. Each reduction roll tends to reduce more of the semolina to flour and to flatten bran particles and thus facilitate the sieving out of the branny fractions. The sieving plant generally employs machines called plansifters, and the air purifiers also produce a whole series of floury stocks.

Modern flour processing consists of a complicated series of rolls, sieves, and purifiers. Approximately 72 percent of the grain finally enters the flour sack.

The sacked flour may consist of 20 or more streams of flour of various states of purity and freedom from branny specks. By selection of the various flour streams it is possible to make flour of various grades. Improvements in milling techniques, use of newer types of grinding machinery in the milling system, speeding up of rolls, and improved skills have all resulted in flour produced by employing the fundamentals of the gradual reduction process but with simplified and shorter milling systems. Much less roll surface is now required than was needed as recently as the 1940s.

Patent flour

The purest flour, selected from the purest flour streams released in the mill, is often called patent flour. It has very low mineral (or ash) content and is remarkably free from traces of branny specks and other impurities. The bulk of the approximately 72 percent released is suited to most bread-making purposes, but special varieties are needed for some confectionery purposes. These varieties may have to be especially fine for production of specialized cakes, called high-ratio cakes, that are especially light and have good keeping qualities.

In many countries the flour for bread production is submitted to chemical treatments to improve the baking quality.

In modern processing, regrinding of the flour, and subsequent separation into divisions by air treatment, has enabled the processors to manufacture flour of varying protein content from any one wheat or grist of wheats.

Composition and grade. As seen above in Table 8, flour consists of moisture, proteins (mainly in gluten form), a small proportion of fat or lipids, carbohydrates (mainly starch, with a small amount of sugar), a trace of fibre, mineral matter (higher amounts in whole meal), and various vitamins. Composition varies among the types of flour, semolinas, middlings, and bran.

For bread making it is usually advantageous to have the highest protein content possible (depending on the nature of the wheat used), but for most other baked products, such as biscuits (cookies) and cakes, high protein content is rarely required. Gluten can easily be washed out of flour by allowing a dough made of the flour and water to stand in water a short time, followed by careful washing of the dough in a gentle stream of water, removing the starch and leaving the gluten. For good bread-making characteristics, the gluten should be semi-elastic, not too stiff and unyielding but not soft and flowy, although a flowy quality is required for biscuit (cookie) manufacture.

Gluten

The gluten, always containing a small amount of adhering starch, is essentially hydrated protein. With careful drying it will retain its elasticity when again mixed with water and can be used to increase the protein content of specialized high-protein breads.

Sometimes locally grown wheat, often low in protein, may be the only type available for flour for bread making. This situation exists in parts of France, Australia, and South Africa. The use of modern procedures and adjustment of baking techniques, however, allow production of satisfactory bread. In the United Kingdom, millers prefer a blend of wheat, much of it imported, but modern baking procedures have allowed incorporation of a larger proportion of the weak English wheat than was previously feasible.

Treatment of flour. Use of "improvers," or oxidizing substances, enhances the baking quality of flour, allowing production of better and larger loaves. Relatively small amounts are required, generally a few parts per million. Although such improvers and the bleaching agents used to rectify excessive yellowness in flour are permitted in most countries, the processes are not universal. Improvers include bromates, chlorine dioxide (in gaseous form), and azodicarbonamide.

The most popular bleacher used is benzoyl peroxide (see Table 4).

Grade. The grade of flour is based on freedom from branny particles. Chemical testing methods are employed to check general quality and particularly grade and purity. Since the ash (mineral content) of the pure branny coverings of the wheat grain is much greater than that of the pure endosperm, considerable emphasis is placed upon use of the ash test to determine grade. Bakers will generally pay higher prices for pure flour of low ash content, as the flour is brighter and lighter in colour. Darker flours may have ash content of 0.7 percent to 0.8 percent or higher.

A widely employed modern method for testing flour colour is based on the reflectance of light from the flour in paste form. This method requires less than a minute; the indirect ash test requires approximately one to two hours (see also BAKING AND BAKERY PRODUCTS).

NONWHEAT CEREAL PRODUCTS

Barley. Most of the barley grown in the world is used for animal feed, but a special pure barley is the source of malt for beer production.

Barley can be cultivated on poorer soil and at lower temperatures than wheat, and world production has increased considerably in recent years. In the 1860s slightly over 1,000,000 acres were harvested in the U.S.; by the 1960s acreage had passed 10,000,000. Yield per acre in the 1860s was around 22 to 25 bushels, with total production of 23,000,000 to 30,000,000 bushels; in the late 1960s the yield reached 41 bushels per acre, with total production over 393,000,000 bushels. In the U.K. the 1935–39 barley crop was well under 1,000,000 metric tons; in 1964 it had reached nearly 8,000,000 metric tons, equalling the amount produced in France and in Argentina. World figures for the year 1971 suggest a world crop (excluding China but including the Soviet Union) of about 127,000,000 metric tons.

An important characteristic in barley is "winterhardiness," which involves the ability to modify or withstand many types of stresses and particularly that of frost.

Barley is subject to many of the diseases and pests that affect wheat. Although used principally in animal feed and malt production, barley is also used in the manufacture of vinegar, malt extract, some milk-type beverages,

and in certain breakfast foods. Barley is also used in flaked form in some sections of the brewing industry, and pearl barley (skins removed by emery friction) is used in various cooked foods.

The use of barley in animal feed is increasing; it has been a basic ingredient of pig foods for years and is increasingly used for cattle feed. Its use in poultry foods has decreased because of its lower starch equivalent when compared with wheat or maize, thus providing a lower energy ration, unsuitable in modern poultry production. Barley vitamin content is similar to that of wheat.

Maize (corn) and sorghum. These grains are sometimes called "coarse grains." Maize, or corn, a cereal cultivated in most warm areas of the world, has many varieties. The U.S., the principal producer of maize, cultivates two main commercial types, *Zea indurata* (flint corn) and *Zea indentata* (dent corn). The plant grows to a height of up to ten feet or more. The maize kernel is large for a cereal, with a high embryo content, and maize oil extracted from the germ is commercially valuable. The microscopic appearance of the starch is distinctive, and the principal protein in ordinary maize is the prolamin zein, constituting half of the total protein. On hydrolysis zein yields very little tryptophan or lysine, making it low in biological value. The proteins of maize, like those of most cereals other than wheat, do not provide an elastic gluten.

Flint and dent corn

World production of maize averages about 250,000,000 metric tons annually, with the U.S. providing almost 42 percent of the total.

Much of the maize is wet processed to produce corn flour, widely used in cooking. Maize, dry milled as grits or as meal or turned into flaked maize with some of its starch partially gelatinized, is a popular component in compounded animal feed stuffs. In dry milled form it is also the basis of human food throughout large areas of Africa and South America. Its nutritive value is limited by its low lysine content. Much recent research has involved development of a maize with higher lysine content. Mutants have been produced containing much less zein but possessing protein with higher than normal lysine and tryptophan contents, sometimes increased as high as 50 percent. These maizes, called Opaque-2 and Floury-2, possess certain drawbacks. They are generally lower in yield than dent hybrids, are subject to more kernel damage when combine harvested, and may be more difficult to process. Nevertheless, these new hybrid maizes are expected to become widely cultivated, and the principles involved in their production may also be applied to sorghum, wheat, and rice. Maize is popular for use in breakfast foods.

Sorghum, also called milo, is of smaller size than maize but is generally the same type of cereal, with similar appearance. Its numerous types are mainly used for animal feeding. It is grown extensively in the U.S., Pakistan, central India, Africa, and China. Annual world production averages around 44,000,000 metric tons. In the sorghum endosperm, the proteins soluble in hot 60 percent alcohol, called kafirin, constitute the major portion of the protein. Milo germ oil is similar to maize germ oil; its major fatty acids are palmitic, stearic, and particularly oleic, and linoleic. Milo is commercially graded in the U.S. In waxy varieties, the starch is principally in the form of amylopectin, with very little amylose. Such starches possess special viscosity characteristics.

The vitamin content of maize and sorghum generally approximates that of wheat, but these cereals have lower nicotinic acid contents.

Oats. Oats belong to the botanical genus *Avena*, including many types, the principal being *A. sativa*, *A. sterilis*, and *A. strigosa*. Oats are widely grown in most countries but are not suitable for Mediterranean climates. Annual world production is about 53,000,000 metric tons. Oats are often grown on farms as feed for the farm's livestock. They are well balanced chemically, with fairly high fat content, and are particularly suitable for feeding horses and sheep.

Although a large portion of the world's oat production is used for animal feed, oatmeal is a popular human food in many countries. Thin-skinned grains, fairly rich in protein and not too starchy, are selected. Preliminary cleaning is essential for human consumption. The oats are then kilned (roasted). Thin-husked oats yield 60 percent oatmeal; varieties with thick husks yield only 50 percent.

Rapid development of rancidity is a serious problem in oats and oat products. The free fatty acid content must be controlled because formation of these acids tends to produce a soapy taste resulting from the activity of the enzyme lipase. A few minutes of steam treatment normally destroys the lipase activity in the grain.

Rye. Rye, which has been known for some 2,000 years, ranks second to wheat as a bread flour. World production is around 30,000,000 to 35,000,000 metric tons, the main producers being Germany, Poland, the U.S.S.R., and other eastern European countries. The popularity of true rye bread is decreasing, and a similar bread, retaining some of the original characteristics, is now made from a rye and wheat blend. The protein of European rye tends to be low and does not yield gluten in the same way as does wheat. Rye bread, closer grained and heavier than wheat bread, is aerated by the use of a leaven (sour dough) rather than yeast. The grain is susceptible to attack by the parasitic fungus ergot (*Claviceps purpurea*).

Rice. Cultivated rice is known botanically as *Oryza sativa*, comprising some 25 species. The importance of this cereal to certain parts of the world may be seen from the fact that in Sanskrit there exists, besides the usual word for rice, another term signifying "Sustainer of the Human Race."

Rice is the staple food for millions in Southeast Asia, almost equal to wheat in importance among the world's cereal crops. The bulk of the crop is produced in relatively small quantities by large numbers of producers who are bound by customs and tradition but are shrewd, hardworking, and resistant to change. The term paddy is applied to both the land on which the plant is grown and to the unhusked seed. Over 90 percent of the world's rice is grown in Asia, principally in China, India, Pakistan, and Southeast Asia, with small amounts grown in Japan and the Philippines. The conversion of paddy to milled rice varies from about 62 percent to 72 percent. Rice is also cultivated in parts of Europe, North and South America, and in Australia.

As stated, most of the world's rice is produced in relatively small quantities by primitive methods. The bulk of the rice cultivated in Asia is grown under water in flooded fields. Successful production depends upon adequate irrigation, including construction of dams and waterwheels, and on the quality of the soil. Long periods of sunshine are essential. Although the bulk of the rice produced is consumed by the inhabitants of the areas in which it is grown, Burma, Thailand, Laos, Vietnam, and Cambodia are normally exporters.

Table 9 indicates the extent of world rice production.

Table 9: World Area and Production of Paddy

continents and countries	area (000 acres)		production (000 metric tons)			
	average 1948–52	1970	paddy		estimated rice equivalent	
			average 1948–52	1970	average 1948–52	1961–62
Asia (including India, Pakistan, Indonesia, Burma, Japan, Philippines, Thailand, etc.)	171,937	223,863	97,600	180,103	63,096	89,329

Measured against China, the largest producer, India's rice production is about 60 percent, Pakistan's 20, and that of Thailand and Burma together 10–15. Rice yields vary considerably, ranging from 600 to 3,500 pounds per acre. Adequate irrigation, which means inundation of the fields to a depth of several inches during the greater part of the growing season, is a basic requirement.

Dry land paddy production, with harvesting by modern mechanical means, is limited to a few areas, and it produces only a fraction of the total world crop.

As with other cereals, weeds, especially wild red rice, are a constant problem. The commonest pests include plant bugs, stem borers, worms, and grasshoppers. The crop, often harvested with a sickle, is frequently dried in earth or concrete pits. Threshing is often carried out by trampling or with crude implements. Only in a few rice-growing regions are more modern procedures used in harvesting.

Manpower requirements for crops vary enormously, but over 400 man-hours per acre are required in small holdings in Asia, where labour is cheap.

Rice paddy soils

In Asia the paddy is cultivated in three main types of soil, including clays with a firm bottom within a few inches of the surface; silts and soft clays with soft bottoms becoming hard on drying; and peats and "mucks" containing peat, provided the depth of the peat is not excessive. Fields must be drained and dried before harvesting. When combine harvesters or binder threshers are employed, the grain must be dried to about 14 percent moisture so that no deterioration takes place in storage. When reaper binders are used, the crop is "shocked" in certain ways so that grain is protected from rain. Artificial fertilizers have had little success in Asia.

Milling methods used in most of Asia are primitive, but large mills operate in Japan and some other areas. Hulling of the paddy is usually accomplished by pestle and mortar worked by hand, foot, or water power. Improvements are slowly taking place. The yield of milled rice is dependent on the size and shape of the grain, the degree of ripeness, and the extent of exposure to the sun. Some large mills, producing 500 to 1,000 tons of paddy daily, have specialized hulling plants with consequent smaller losses from broken grain. They generally employ modern milling techniques and rely upon controlled drying plants instead of on sun drying.

The weight of the husk is around 20 percent of the weight of the paddy, and there are losses of about 5 percent from dirt, dead grains, and other impurities. Approximately 74 percent of the paddy is available as rice and rice by-products. The yield from milling and subsequent emery polishings includes about 50 percent whole rice, 17 percent broken rice, 10 percent bran, and 3 percent meal. Rice grains have a series of thin coats that can be removed or partially removed in the process of pearling and whitening.

About 60 percent of the Indian rice is parboiled. In the parboiling process the paddy is steeped in hot water, subjected to low-pressure steam heating, then dried and milled as usual. Parboiling makes more rice available from the paddy, and more nutrients (largely vitamin B_1) are transferred from the outer coverings to the endosperm, improving the nutritive value of the finished product. Parboiled rice may contain two to four times as much thiamine (vitamin B_1) and niacin as milled raw rice, and losses in cooking may also be reduced.

Alcoholic drinks, such as sake in Japan and *wang-tsin* in China, are made from rice with the aid of fungi. The hull or husk of paddy, of little value as animal feed because of a high silicon content that is harmful to digestive and respiratory organs, is used mainly as fuel. Table 10 illustrates the composition of husked and milled rice and also indicates losses in milling and polishing.

Nutrition value

The lysine content of rice is low. As rice is not a complete food, and the majority of Asians live largely on rice, it is important that loss of nutrients in processing and cooking should be minimal. Lightly milled rice has about 0.7 milligram of vitamin B_1 per 1,000 nonfatty calories, and the more costly highly milled product has only 0.18 milligram of B_1 on the same basis. For adequate nutrition, vitamin B_1 in the daily diet on this basis should be 0.5–0.6 milligram. The amount of fat-soluble vitamins in rice is negligible.

In some countries rice is enriched by addition of synthetic vitamins. According to U.S. standards for enriched rice, each pound must contain 2–4 milligrams of thiamine (B_1), 1.2–2.4 milligrams of riboflavine, 16–32 milligrams of niacin, and 13–26 milligrams of iron. In enriched rice the loss of water-soluble vitamins in cooking is much reduced because enrichment is applied to about one grain in 200, and these enriched grains are protected by a collodion covering. In ordinary rice, especially when open cookers are employed or excessive water is used, nutrient losses can be high.

Millet. This term is applied to a variety of small seeds originally cultivated by the ancient Egyptians, Greeks, and Romans and still part of the human diet in China, Japan, and India, though in Western countries it is used mainly for birdseed. The genus is termed *Panicum*. The small seed is normally about two millimetres long and nearly two millimetres broad. The term *proso* is one of several alternative names. Japanese barnyard millet is a well-known variety. Millet is not a major cereal; around 21,000,000 short tons are grown annually.

PRODUCTS FROM OTHER STARCH-YIELDING PLANTS

Cassava. Cassava, often called manioc, is not a cereal but a tuber; however, it replaces cereals in certain countries, supplying the carbohydrate content of the diet. The botanical name is *Manihot esculenta*, and the plant is native to South America, especially Brazil. It is now grown in Indonesia, Malaysia, the Philippines, Thailand, and parts of Africa. A valuable source of starch, cassava is familiar in many developed countries in a granular form known as tapioca.

Tapioca

Easily cultivated and curiously immune to most food-crop pests, cassava is a staple crop in several areas of Latin America. The actual tubers may weigh up to 30 pounds. Some tubers may be bitter and contain dangerously large amounts of prussic acid.

Table 11 compares the nutrients in cassava roots with those in potatoes (also a tuber) and rice. Dry milling of cassava is rarely practiced because it yields a product inferior to wet-processed starch in which the tubers are crushed or rasped with water and the starch is permitted to settle. Wet starch is dried to a point where it can be crumbled by pressing it through metal plates (or sieves). This crumbled material is subjected to a rotary motion, sometimes carried out on canvas cloth fastened to cradle-shaped frames or tumbled in revolving steam-jacketed cylinders so that the particles assume a round pellet form and are partially gelatinized as they dry. Sun drying is employed in both homes and small mills.

Table 10: Composition of Rice—Husked and Polished
(percent)

	husked			milled			losses on milling and polishing		
	Platt	Kik and Williams	Rosedale	Platt	Kik and Williams	Rosedale	Platt	Kik and Williams	Rosedale
Fat	2.45	2.0	2.23	0.37	0.3	0.4	84.9	84.6	86.5

Potato flour	15	331	—	0.3	82	0.3	0.4
Husked rice	15	347	8.0	2.5	73	1.5	0.7–1.0

Many tapioca factories and mills are equipped with modern raspers, special shaking or rotating sieves, and settling tanks of various types; but some fermentation takes place, and small rural mills can often be identified by the smell of butyric acid. In larger mills, centrifuges are replacing the settling tanks.

For its various industrial uses, the tuber usually goes under its alternative name, manioc. It is used in the textile industries, explosives manufacture, leather tanning, and production of glues and dextrins and alcohol.

Fresh cassava leaves are rich in protein, calcium, and vitamins A and C. Their prussic acid level must be reduced to safe limits by boiling; the duration of boiling depends on the variety. Cassava leaves are a popular vegetable in Africa, and the tuber is also used in meal for animal feed.

Soybean. Soybean (*Glycine max*) is not a cereal but a legume; because of its widespread use in the baking industry, it may appropriately be dealt with here. Soybean provides protein of high biological value. Although Asia is its original source, the U.S. is currently the major producer, providing in the early 1970s over 1,000,000,000 bushels out of a total world production of 1,500,000,000 bushels.

U.S. annual production of soybean meal is about 17,600,000 long tons, with oil production of about 3,500,000 long tons. Total U.S. soybean production is over 30,000,000 long tons, and nearly 8,000,000 tons are exported.

The valuable oil of the soybean, widely used in industry, is extracted either by solvents or by expellers. The amino acid distribution of soy protein is more like that found in animal protein than the protein from most vegetable sources; for example, lysine comprises about 5.5 percent. The oil content includes useful amounts of phosphorus; the phosphatide content of soy flour is about 2 percent and is a mixture of lecithin and cephalin. The low carbohydrate content exists mainly as sugars. Table 12 shows the chemical composition of soybeans on a moisture-free basis; the amino acid composition of soy protein is given in Table 13.

Table 12: Chemical Composition of Soybeans on a Moisture-Free Basis
(percent)

component	based on 10 varieties in 5 crop years		
	lowest	highest	average
Ash	3.67	5.90	4.99
Oil crude	14.95	22.90	19.63
Crude fibre	4.34	7.60	5.52
Crude protein (N × 6.25)	36.62	53.19	42.78
Sugar (total as sucrose)	2.70	11.97	7.97
Phosphorus	0.42	0.82	0.66
Potassium	1.29	2.17	1.67
Calcium	0.16	0.47	0.275

Although soybeans are a good source of thiamine, much of this may be lost in processing. Average vitamin contents of soybean (as micrograms per gram) are as follows: thiamine 12; riboflavin 3.5; nicotinic acid 23; pyridoxine 8; pantothenic acid 15; and biotin 0.7.

The bulk of the soybean produced in the U.S. is used for animal feed; the Asian crop goes principally for human diet.

Soybean milk

Soybean milk is produced and used in the fresh state in China and as a condensed milk in Japan. In these preparations, certain anti-nutritive factors (antitrypsin and soyin) are largely removed. In the Western world most soy products are treated chemically or by heat to remove these anti-nutritive factors along with the unpopular beany taste. Such processing affects the enzymic activity.

Soybean is milled to produce soy flour. The flour is often used in a proportion of less than 1 percent in bakery operations. It stiffens doughs and helps to maintain crumb softness. Unprocessed soy flour, because of its lipoxidase enzyme system, is employed with high-speed mixing to bleach the flour in a dough.

In addition to their use in bread, soy products are used in confectionery, biscuits, macaroni, infant and invalid foods, ice cream, chocolate, sausages, sauces, lemon curd, mayonnaise, meat and fish pastes, certain diabetic foods, and in such nonfood products as paint, paper, textiles, and plastics.

A recent development is the isolation of the soybean proteins for use as emulsifiers and binders in meat products and substitutes. Enzyme-modified proteins provide useful egg-albumen supplement for whipped products.

Aspartic acid	8.8

Buckwheat. Botanically, buckwheat is not a cereal but the fruit of *Fagopyrum esculentum*. Its name is probably derived from its resemblance to beechnut. Believed to have originated in China, the plant grows to a height of two to three feet or more and thrives best in cool, moist climates, although it does not easily tolerate frost. It can be grown on a wide range of soils, and a crop can be obtained within 10–12 weeks of sowing. The seed is dark brown in colour and often triangular in shape. It contains about 60 percent carbohydrate, 10 percent protein, and 15 percent fibre. A white flour can be obtained from the seeds (buckwheat cakes and pancakes are popular in certain areas), and buckwheat meal is also used in animal feed. The whole seed may be fed to poultry and game birds. There is some medical interest in buckwheat as a source of rutin, possibly effective in treatment of increased capillary fragility associated with hypertension (high blood pressure) in man.

OTHER CEREAL AND STARCH PRODUCTS

Flour by-products. Flour by-products, derived from the outer coverings of the wheat grain separated in extraction of the flour from the grain, consist of bran (coarse or fine according to the state of subdivision and how much adhering endosperm is attached) and the finer, more floury outer coverings called "middlings." The composition of such products may vary considerably, depending on the wheats used and the amount of endosperm present. Table 14 gives the general composition

Table 14: Approximate Analyses of Wheat By-Products (Offal) on Dry Basis
(percent)

	protein	fat	carbo-hydrates	fibre	ash
Bran	15.5	4.5	61.5	12.25	6.25
Pollards	16.6	5.5	64.0	8.9	5.0
Coarse middlings	19.0	5.8	65.0	6.0	4.2
Fine middlings	18.0	3.9	73.1	2.2	2.8

of these by-products, mainly used in livestock feed.

Cereals in bakery products. The water-absorption power of the flour employed is a critical factor affecting bread yield. Strong proteinous flours absorb more water than weak flours in producing a dough of correct consistency. The percentage of "damaged" starch in the flour is also an important factor. In making a dough of correct consistency, the amount of water that can be used depends on that taken up by the flour constituents. Approximately one gram of protein will absorb one gram of water, but one gram of ordinary undamaged starch will absorb only about 0.4 gram of water. All flour contains some of its starch in a "damaged" form (resulting from the mechanical action during milling), and the percentage may vary from 5 to 12 percent of the flour. One gram of damaged starch will take up two grams of water, which makes damaged starch an asset in commercial bread-making operations. There is, of course, an upper limit to the useful amount of damaged starch, and if there is much sprouted grain (rich in α-amylase) in the grist too much damaged starch is particularly dangerous.

Role of damaged starch

Increasing attention is being given to the regulation and control of this flour characteristic.

Modern baking operations require knowledge of the various enzymes in the flour (such as the α- and β-amylase) that affect the starch portion and of other enzymes producing physical change in the protein (gluten) portion of the dough. The amount of α-amylase is an important factor acting on the damaged starch and producing more sugar for the yeast to ferment toward the end of the fermentation stage, after the yeast has used the small amount of sugar originally in the flour. Additional sugar is sometimes added at the dough-making stage to ensure an ample supply throughout the fermentation process. Some baking operations employ malts (containing α- and β-amylase and certain sugars). Much depends on the nature and soundness of the wheats from which the flour has been made. Fungal enzymes, products rich in α-amylase produced by growing certain mold strains, are useful in many circumstances. Such enzymes possess a lower "thermal-destruction point" than cereal α-amylase and are destroyed early in the baking process before the mass of starch is gelatinized and rendered attackable. Marked changes in bread making have taken place since it has ceased to be necessary to ferment for several hours to achieve the essential ripeness in the dough before baking.

In the manufacture of biscuits (cookies), many different types of flour are used. Most biscuits require soft, weak flours (see also BAKING AND BAKERY PRODUCTS).

Commercial starches. Starch has been used for many centuries. An Egyptian papyrus paper dating from 3500 BC was apparently treated with a starch adhesive. The major starch sources are tubers, such as potatoes and cassava, and cereals. Current starch production is considerable. Among the major producing areas, the European countries use both domestic wheat and potatoes and imported maize as the raw material; the U.S. uses maize and such similar cereals as sorghum; and in South America the cassava plant is the major raw material.

Separated from tubers and cereals, starch is used for conversion into various sugars, and half of the world's separated starch is processed into glucose. Starch is also processed for use in adhesives manufacture. In the food industry starch is used as a thickener in the preparation of cornstarch puddings, custards, sauces, cream soups, and gravies. Starch from tubers and cereals provides the carbohydrate of the human diet.

Large quantities of starch and its derivatives are used in the paper and textile industries.

In Germany, The Netherlands, Poland, and a number of other countries, the extraction of the starch from potatoes (sometimes called farina) is a major industry. Some factories produce over 300 tons daily. Processing involves continuous and automatic cleaning of the potatoes, thorough disintegration in raspers or hammer mills, and separation of the fibres from the pulp by centrifugal (rotary) sieves. The resulting starch "milk" contains starch in suspension and soluble potato solids in solution. The starch is separated and washed free from the solubles, the water is removed by centrifugal action, and the damp starch is dried. The flash type of dryer, using hot air, is widely employed for starches derived from both tubers and cereals. Sulfurous acid is generally introduced into the process to prevent the development of various micro-organisms.

Potato farina

Potato flour is also produced in Germany and other countries, slices of cleaned potatoes being dried, ground, and sieved.

Starch granules from various plants as seen under the microscope differ widely in type, size, and shape. Some exhibit a dark spot, or hilum, around which the granule has grown. The hilum is often useful in identifying a starch. The character of the granules influences the ease with which the particular starch can be separated. Maize has a granule of fairly regular shape, simplifying the extraction of the starch. Wheat and barley both have a number of large roundish granules, comprising the bulk of the starch, which can be separated easily in centrifuges, but they also have a proportion of very small granules that cannot easily be collected by such means and can cause serious effluent problems.

In Germany a "potato sago" is produced. The starch cake obtained from the potatoes is crumbled to produce reasonably uniform-sized particles that are rounded by tumbling or similar operations, heated to gelatinize the outside layers of the starch, and then dried.

Potatoes were employed in baking to make the barm, or leaven, before compressed distiller's yeast was available, and they have also been used to supplement limited supplies of wheat flour. The potatoes are cleaned, boiled until soft but not mushy, and mixed, in a proportion of 2 to 3 percent, in the dough.

Modern, ready-to-use, dried and powdered mashed potatoes are popular consumer products.

Cassava and tapioca starches are sometimes partially gelatinized by vacuum drying. Protein impurities are low in commercial starches of potato, sago, and tapioca but as high as 0.2 percent in wheat starch and higher in corn flour.

Maize is wet milled to produce corn flour, or cornstarch, desirable for cooking because it forms a paste that sets with a "short" texture and separates from molds more cleanly than do the gels produced by such starches as potato, tapioca, and arrowroot, which are "long," or elastic. In wet milling, the grains are first dry-cleaned so that other cereals and some of the impurities are removed, then steeped in warm water containing sulfur dioxide. This process softens the grains, and the outer skin and the germ are rendered removable. The maize is coarsely ground in "degerminating mills," and the slurry is further wet-ground and sieved to remove all the germ and complete the separation of the starch.

The germ, rich in oil, is eventually dried, and the oil is expelled by pressure, providing an excellent edible oil for culinary use, often replacing olive oil. Corn oil is used for salad oil, margarine, and shortening and for such nonfood items as soap.

The pure starch, held in suspension, was formerly collected by gravity as it flowed down tables, but in modern practice the starch suspension is thickened by the elimination of water by means of machines, and the starch is finally separated by the use of centrifuges. The starch is readily dried without gelatinization taking place.

There is a regular demand for a good grade of corn flour, or cornstarch. Roller-milled maize is still produced for human consumption in Africa and elsewhere.

Corn flour

In the U.S. some maize grits are used by brewers, but the bulk of the maize grown is used for animal feed as meal, grits, or in partially gelatinized flake form.

Starch forms. The bulk of the starch produced is in an air-dry state as a microgranular powder, but there are other important varieties, including pearl, crystal, and pregelatinized forms.

The pearl form of starch is illustrated by sago, starch derived from the pith of several kinds of palm trees in the West Indies. Sago palms include *Sagus rumphii* and *S. farinifera*, but *S. laevas* produces most of the export material. The pith obtained from the trees yields a milky starch suspension. After purification, the starch settles out. The moist starch is semidried and converted into pearl sago. The sieved pearls are roasted in shallow metal pans, which partially gelatinizes and dries them.

Rice starch, largely used in laundry work, is normally prepared from broken white rice. The broken grains are steeped for several hours in a caustic-soda solution, and the alkali is finally washed away with water. The softened grains are ground with more caustic-soda solution, and the resulting mass is settled or submitted to centrifugation in a drum. The starch layer is agitated with water (often with 0.25 percent formaldehyde solution added), and the resulting starch liquor is dewatered, washed on a continuous rotary vacuum filter, resuspended in water, and finally dewatered in a perforated basket centrifuge to around 35 percent moisture. In modern processing it is usual to roll out a thick layer of moist starch, which is then slowly dried and falls to pieces as crystals.

When a starch suspension in water is passed over hot rollers, the starch is gelatinized and dried simultaneously. This pregelatinized starch, unlike raw starch, swells in cold water but does not reconstitute to as thick a paste as starch boiled in water. The pregelatinized starch, ground to a powder, has a number of important industrial applications. Added to pulp in paper production it helps bind the fibres together; added to sand in the foundry it helps form molds; it is used in making wallpaper paste, to help cool drills, and for many other purposes. Industrial starches are derived from wheat in Australia, the U.K., and Germany; from potatoes in Germany; and from maize in the U.S. and southern Europe.

Industrial starches

The various cereals and tubers produce starches that vary in size, shape, and appearance and possess varying characteristics. Cornstarch is valuable in cooking, rice starch in laundering, and arrowroot tuber starch is popular in toiletries. Wheat starch, a by-product of gluten production, can be heated and moistened to form a paste used chiefly for industrial purposes.

Starch composition. Starch consists of two components: amylose and amylopectin. The relative proportion of these two components varies, and they react differently to enzymatic attack. The enzyme β-amylase (maltogenic) attacks the straight chain amylose but is unable to attack most of the branch chain amylopectin. If only β-amylase is present, maltose is produced, together with a residue of the amylopectin portion, or dextrin of high molecular weight. When α-amylase (dextrinogenic) attacks starch, gummy dextrins of low molecular weight are formed and can produce a sticky crumb in bread.

In bread making there is only limited time for such enzymic attacks on the starch, and only the "attackable" or "damaged" granules can produce the fermentable sugar for the dough. The β-amylase has little effect on viscosity. The viscosity of gelatinized starch is markedly reduced by α-amylase, however, and is therefore valuable in syrup and dextrose manufacture.

The gelatinization of starch that occurs in hot water is an important characteristic, and the viscous pastes formed are influenced by the treatment the starch has received in its preliminary separation from the cereal or tuber. Chemicals affect degree and speed of gelatinization and the nature and viscosity of the pastes formed.

In certain cereals, particularly in special maizes, the starch consists almost entirely of amylopectin, and the term waxy is applied to such cereals. They are useful for their unusual physical properties and viscosities. They possess outstanding paste clarity, high water-binding capacity, and resistance to gel formation and retrogradation; they are helpful in production of salad dressings, sauces, and pie fillings and in some canned goods; they are useful because of resistance to irreversible gel formation and syneresis on freezing and especially for many products stored in the frozen state.

Processing. The carbohydrate starch is rarely consumed in the raw state and in cooking is always gelatinized to some degree. For industrial purposes, starches are submitted to many processes. Starch is often partially or almost wholly gelatinized or may be converted by heat or chemical treatment into dextrins for use in adhesive pastes, with the starch assuming a completely new form. Other treatments increase solubility, and hydrolysis with acids produces completely new products, including a variety of sugars.

Starch may be converted into sugars by the use of acids, and the sugars may be marketed as starch syrup, glucose syrup, or corn syrup; as glucose; and as commercial dextrose. Such sugars are useful in confectionery production.

Starch hydroxyl groups can take up metal ions yielding starchates, highly reactive with organic acids, anhydrides, chlorides, epoxides, etc., that produce commercially valuable products. Ethylene and propylene oxides are used to produce ethoxy or propoxy derivatives possessing special characteristics that give clear gels, solutions, or films widely used in the paper and textile industries. With chloracetic acid, or similar acids, completely soluble methyl or other carboxy acids having high viscosity and clarity, useful in textile printing, are formed.

The viscosities of these derivatives can be controlled by oxidizing the original starch before making the derivative or by treatment with various chemical agents that crosslink adjacent starch chains via the hydroxyl groups in the glucose units. Only a low degree of substitution, oxidation, or hydrolysis is usually required to exert a marked change in the physical properties of starches.

Other uses of starch include production of ethyl alcohol by fermentation procedures and production of acetone and other products. Indeed, it is impossible to record all the hundreds of uses of starch in the science-based industries.

Alimentary pastes. Alimentary pastes include such products as macaroni, spaghetti, vermicelli, and noodles. Such products are often called pastas. Italy is regarded as the place of origin of macaroni products, and annual consumption in that country is as high as 30–35 kilograms per person. Annual consumption is about 6.3 kilograms in France, 3.7 in the U.S., and only 0.4 kilogram in the U.K. Pasta is manufactured in a wide variety of sizes and shapes, the commonest being long, narrow strands. The most slender type of strand, vermicelli, sometimes called *capelli d'angeli* ("angel's hair") in Italy, has a diameter ranging from 0.5 to 0.8 millimetre and is normally cut into lengths of about 250 millimetre and twisted into curls. Short-cut vermicelli (15–40 millimetres) is easy to manufacture and to dry. Spaghetti has a diameter of about 1.5–2.5 millimetres and is usually straight. Noodles are solid ribbons, about 0.8 millimetre thick, and in a variety of widths. Macaroni is the commonest type of alimentary paste; it is hollow and has a greater thickness than the others. It can be shaped in a variety of forms, such as long, short, large, small tubes, etc.

Annual consumption of pastas

Macaroni is now commercially produced in large factories in Italy, North and South America, and other regions. Drying of the extruded paste is an important process, previously accomplished in Italy by sun drying.

Semolina, not flour, is the form of cereal used, and various plain macaroni products are made by combining the correct form of semolina, from durum wheat, with water. Richer alimentary pastes are made with the addition of eggs in fresh, dried, or frozen form, and egg noodles are popular. In low-income families, alimentary pastes often provide the bulk of the calories in the diet. Macaroni products supply about 3,500 calories per kilogram and, although not themselves good sources of vitamins, are commonly cooked and consumed with butter, oil, cheese, and other items containing the needed vitamins.

The use of hard durum semolina contributes to good quality in macaroni and other alimentary-paste products. The special mills involved use many breaks, and only a few reduction rolls, to produce as much clean semolina as possible. An efficient mill employing appropriate purifiers can produce as much as 65 percent semolina (together with a little flour). Before continuous processes for pasta production were introduced, a coarse semolina was valued. In modern production, semolina is dusted and freed from flour, and regularity in size is considered important for water absorption. Very fine semolina is not popular, and the preferred semolina usually has a moisture content of around 13 percent with less than 0.8 percent ash. Freedom from bran is desired to avoid the appearance of specks. The gluten in the semolina should be reasonably strong but not as elastic as that required for bread making.

In the early factories, batch mixing of semolina and water was followed by extrusion of the resulting paste through presses containing dies. In modern practice, the bulk of alimentary pastes is made by continuous processes.

The basic procedure for most macaroni products consists of adding water to a semolina made from suitable wheat to produce, in a short time, a plastic homogeneous mass of about 30 percent moisture. This mixture is extruded through special dies, under pressure, producing the desired size and shape, and is then dried. There are many types of continuous paste processes adapted to the specific types of paste wanted and to the manufacturer's requirements. In the earlier days of the cottage industry, long-cut products such as spaghetti were spread evenly by hand on wooden dowels about an inch thick and over 50 inches long, and the filled sticks were then placed on racks for sun drying. "Short" cut products were often scattered on wire mesh trays.

Automatic processing

In modern automatic processing the objective is to dry the extruded product, containing 31 percent moisture, to a hard product of about 12 percent moisture, decreasing the possibility of the goods being affected by the growth of molds and yeast. If moisture is removed too rapidly, the dried product may tend to "check" or split. If moisture is removed too slowly, souring or mold growth may occur. Proper drying is therefore ensured by adjusting air circulation, temperature, and humidity. Drying procedures differ for long and short macaroni. In the continuous process, after a first hour in which a crust is formed to protect against mold infection, slow drying is practiced.

Cooking tests are used to ensure that the final product is satisfactory. Considerable research has been carried out to control factors tending to destroy the desirable yellow colour. Destruction of the colouring matter, a xanthophyll, can occur in mixing due to excessive lipoxidase. Certain types of durum wheat may possess a high degree of lipoxidase activity, and it is difficult to control or check this action. The addition of ascorbic acid has been suggested as a means to decrease the destruction of the semolina pigments in processing.

In the U.S., alimentary-paste goods, described as noodles, egg spaghetti, or egg macaroni, must contain 5.5 percent of the solids of egg in the final product. The eggs can be used in the form of frozen yolks, dried yolks, frozen whole eggs, dried whole eggs, or fresh whole eggs or yolks. Spray dried egg yolks of good quality are now available.

Alimentary pastes are also used in the production of soup, puddings and sweets, and a variety of other food products.

Malt. Beer is produced in many countries, and barley is the main cereal employed. Until recently brewers have been unable to utilize the carbohydrate of barley directly. Instead, malt was produced by allowing the grains to sprout, changing the starches and proteins into more soluble forms of sugars and amino acids.

Modern techniques offer the possibility of brewing beer direct from barley, employing industrial enzymes. Such methods are not yet established commercial practice, and their success will depend primarily on the acceptability of the resulting flavour and character to both the brewing industry and the public. Partial substitution of wheat flour for malted barley has also been introduced.

In countries with damp climates, the barley used in beer making is dried in kilns or rotating drums, but in modern practice these devices are being replaced by newer types of driers. In the vertical type, the grain falls through heated air, and in the horizontal type air is blown through a moving band of barley. Safe storage of barley in bulk requires drying to 14 percent, and preferably 12 percent, moisture. The dried barley is then screened to remove awns (slender bristles), half corns, very thin corns, and weeds. The grain is usually stored for at least four weeks to overcome its natural dormancy and render it suitable for uniform germination.

The basis of the malting process is modification of the grain (morphological and histological changes) and degradation of the proteins and starch in the barley into more soluble substances by formation and liberation of certain change-producing enzymes.

The basic process is simple, but problems arise from the fact that the maltster produces various kinds of malt, each uniform and consistent in character, from a highly variable natural raw material. Some barleys germinate unevenly because of sensitivity to excess water, and this condition can be overcome by allowing the grain to take up about 30 percent moisture, arranging for growth to commence in the absence of free water and then completing the steeping process to the 45 percent or so of moisture required for malting. Certain additives are sometimes used in malting to reduce production costs and allow better control of the quality of the finished product. Minute quantities of gibberellic acid can stimulate the barley enzymes, shortening germination time. Potassium bromate may be used to restrict respiration and rootlet formation and to increase the malt yield. All malting techniques require control of temperature, atmospheric humidity, and grain moisture during the germination phase of the process.

Considerable attention is given to evaluation of the finished malt for brewing purposes, but techniques vary in the different countries. The most important analytical measurement is that of "extract," which gives a measure of the brewing value of a malt since it controls the quantity of beer of a given strength that can be produced from a standard weight of malt. Malt colour must be measured accurately since it strongly influences the colour of beer. The nitrogen or protein content is also considered since this factor is associated with beer hazes.

Malt extract

The quality of malt is largely dependent on the quality of barley employed. Analytical studies are often made on the barley to determine protein content, germination capacity, and potential extract. Great care is exercised in the selection of barley for malting, certain barley varieties being considered more suitable for malting than others.

In major brewing countries, beer production requires hundreds of thousands of tons of ordinary malt annually. In addition, a whole series of special malts are also used in brewing. There is a demand for coloured malts produced by roasting, imparting special colours and flavours to beer. Enzymic malt is made by subjecting germinating barley to an anaerobic phase (absence of oxygen) just prior to kilning (drying), and this malt is used to adjust acidity.

Malt is used in substantial quantities in the distilled liquor (*q.v.*) industry, with some 150,000 tons of barley used annually for this purpose in Scotland. The type of malt required is somewhat different from that used by the brewer, as the distiller wants a malt in which as much as possible of the starch has been converted into simple sugars, providing a maximum amount of fermentation material.

Apart from beer and liquor production, malt is used in some breakfast cereals and for the production of vinegar and malt extract, the latter useful because of its enzymic properties. Malted milk beverages are made by adding milk preparations to malt extract powder. Malt extract is used in desizing textiles, in making dextrin adhesives, in

the baking industry, and in laundries for the removal of starch from woven fabrics, although industrial enzymes are replacing malt in some of these processes. Malt extracts normally have to meet pharmacopaeia specifications (see also BREWING).

Breakfast cereals and snack foods. The modern packaged breakfast-food industry owes its beginnings to an American religious sect, the Seventh-day Adventists, who wished to avoid consumption of animal foods. In the 1860s they organized the Western Health Reform Institute in Battle Creek, Michigan, later renamed the Battle Creek Sanitarium. James Jackson of Dansville, New York, produced a cereal food by baking wholemeal dough in thin sheets, breaking and regrinding into small chunks, rebaking and regrinding. J.H. Kellogg of Battle Creek made biscuits about one-half inch thick from a dough mixture of wheatmeal, oatmeal, and corn meal. The dough was baked until fairly dry and turning brown, and the product was ground and packed. A patient at the sanitarium, C.W. Post, saw the possibilities in such a product entirely apart from the original conception of healthfulness and started a business. Kellogg's brother, W.H. Kellogg, did likewise, and the breakfast-food industry was launched, soon achieving mass sales of cereal products in flake, granule, shred, and puffed forms, with flavour obtained by roasting and the addition of sugar.

Kellogg and Post

Some breakfast cereals require cooking; others are packaged ready-to-eat. Roasted and rolled oatmeal, eaten as porridge, requires brief boiling. Cooking time of these processed cereals has been greatly reduced, and various "instant" forms are available.

Although cooked oatmeal porridge was formerly a standard breakfast food, the ready-to-eat cereals of various types are now the favourite breakfast-cereal foods.

The middlings produced in flour milling, essentially small pieces of endosperm free from bran and germ, are sold as farina and often consumed as a breakfast food in the U.S. Farina is usually enriched with vitamins and minerals and may be flavoured. To reduce cooking time, 0.25 percent disodium phosphate may be added; some products require only one minute of boiling before serving.

Ready-to-eat-cereals. These cereals are available in a variety of forms and are normally consumed with milk and sometimes sugar. Flaked and toasted varieties are the most popular. During processing the starch is gelatinized, halting enzymic reactions and thus ensuring product stability and good shelf life. The sugar content is dextrinized and caramelized by a roasting process. Roasting also ensures attractive crispness resulting from moisture reduction.

Wheat and rice flakes are manufactured, but most flaked breakfast foods are made from maize (corn), usually of the yellow type, broken down into grits and cooked under pressure with flavouring syrup consisting of sugar, non-diastatic malt, and other ingredients. Cooking is often accomplished in slowly rotating retorts at around 18 pounds steam pressure.

After leaving the cooker, the lumps (containing about 33 percent water) are broken down by revolving reels and sent to driers. These are usually large tubes extending vertically, through several stories, with the wet product entering the top and encountering a current of hot air (150° F). Other types of driers consist of horizontal rotating cylinders with steam-heated pipes running horizontally. The drying process reduces moisture to about 20 percent, and the product is transferred to tempering bins for up to 24 hours, to even moisture distribution.

The product is next flaked by passing it between large steel cylinders (180–200 revolutions per minute), with the rolls cooled by internal water circulation. The cooked and rather soft flakes then proceed to rotating toasting ovens (normally gas fired), where the flakes tumble through perforated drums. This treatment requires two to three minutes at 550° F (228° C). The product is dehydrated, toasted, and slightly blistered. After toasting, it is cooled by circulating air, and at this stage enrichment by sprays may be carried out.

The manufacture of wheat flakes is similar to that of corn flakes. Special machinery separates the individual grains so that they can be flaked and finally toasted.

Shredded wheat, differing from other breakfast foods, is made from whole grains with the germ and bran retained and no flavour added. In its final form it is in tablets composed of shreds of cooked and toasted wheat. The wheat is cleaned and then boiled in water, often at atmospheric pressure. The grains reach a moisture content of 55 to 60 percent and require preliminary drying to around 50 percent. They are then placed in bins to condition them. The shredding process consists of passing the cooked and partially dried wheat to the shredding rolls (six to eight inches in diameter and as wide as the finished tablet). On one pair of the rolls is a series of about 20 shallow corrugations running around the periphery; the surface of the other roll is smooth. The soft wheat is forced into the rolls under pressure and is cut into long shreds falling to a conveyor in such a way as to obtain superimposed shreds. These layers are cut into tablets by knives, and the tablets are transferred to baking pans. The pans pass to a revolving oven, with a baking temperature of approximately 500° F. After 10–15 minutes, the outside of the product is dry and toasted, while the interior is still damp. The tablet is transferred either to another hot air oven or to a different section of the same oven, where it is dried at 250° F for an additional 30 minutes and then cooled and packed.

Granular types are made by very different processes from the others. The first step is production of a stiff dough from wheat, malted barley flour, salt, dry yeast, and water. After mixing, fermentation proceeds for about five hours. The dough is then formed into large loaves and transferred directly to the oven. Baking requires about two hours at 400° F (205° C). The baked loaves are fragmented and the product is thoroughly dried. Grinding by corrugated rolls follows, and the product is sieved to standard size. Very fine pieces are added to subsequent dough batches.

Early in the 20th century, an American patent was taken out for the preparation of puffed wheat and rice. Puffed oats and maize are now also produced. The principle of the puffing process is heating the cereal, and sometimes other vegetable products, in a pressure chamber to a pressure of 100 to 200 pounds per square inch, then instantaneously releasing this pressure by suddenly opening the chamber, or puffing gun. Expansion of the water vapour occurs when the pressure is suddenly released, blowing up the grains or cereal pellets to several times their original size (8-fold to 16-fold for wheat, 6-fold to 8-fold for rice). The final product is toasted to a moisture content of about 3 percent to achieve desired crispness. In processing wheat, a preliminary step may be applied to free the grain from much of its bran coatings.

The puffing gun

Rice is usually parboiled, pearled, and cooked with sugar syrup, dried to about 25 to 30 percent moisture in rotating louvre driers, binned, and toasted and puffed. In puffing of mixed cereal products it is necessary to start with a stiff dough containing sugar, salt, and sometimes oil, and this mixture is then cooked. The dough is pelleted by extrusion through dies and dried to attain a suitable condition for the final puffing process.

Enrichment of breakfast cereals with minerals, and especially with vitamins, is now common practice. In many of the manufacturing processes employed in breakfast-food production, considerable vitamin destruction occurs. The various heat treatments involved may destroy 90 percent of the original B_1 content of the cereal, especially in flaked and puffed products. On the other hand, a proportion of the somewhat harmful phytic acid in cereals, interfering with absorption by the body of calcium, is also destroyed; and enrichment of the products with vitamin B_1, and sometimes other components of the Vitamin B complex, is not difficult to perform after the various cooking operations have been completed.

Ready-to-eat snack foods. In addition to potato crisps, or chips, pretzels, and popcorn, new types have recently

been developed. Cereals are usually the base, and special attention is given to texture and flavour. Baked snacks can usually be produced in bakeries using special extrusion equipment. Crackers are produced especially for hors d'oeuvres, and potato crisps are flavoured with cheese, onions, and other ingredients. Partially puffed varieties are popular, but great care is required to ensure crispness and flavour; and the final process usually involves drying, frying, puffing, or toasting. Oil and seasoned oils are often ingredients, and packaging is an important factor in marketing successful snacks.

Bakery products can be cooked and frozen for fast reconstitution and have good shelf life. A variety of starch products is produced using milo starch. Attention has been given to the ratios of amylose and amylopectin; the waxy-type (amylopectin) starches promote puffing and produce attractive light, but fragile, products.

There is also some demand for especially prepared breadcrumbs.

Sweeteners. Various types of sweeteners are made directly from starch. Glucose products made by starch conversion differ in composition and in sweetness according to whether conversion is effected by acid or by enzymes. Enzyme-produced glucose is higher in dextrose and maltose content than acid-produced glucose, which normally is higher in dextrin. Sucrose is a more powerful sweetening agent than dextrose, but glucose syrup made by enzymic treatment usually has twice the sweetening power of that produced by acid action.

In the production of starch separated by the wet milling of maize, one stream is normally used to produce starch, and the other stream is converted into corn syrup by heating the starch slurry in pressure tanks with acid or enzymes and following with refining processes. If the process of hydrolyzing starch is completed, the resulting product is glucose. Often the treatment is not carried to completion, and a series of dextrins and reversion products is produced. If full conversion is required, the treatment usually employs acids to liquefy, followed by saccharifying enzymes to complete the change to dextrose. Modern syrups and crystalline dextrose are made by continuous processes. The degree of conversion of the starch into the sugar dextrose is expressed as D.E. (dextrose equivalents), and confectionery syrups have a D.E. of around 36 to 55, while the fuller conversion of products with D.E. of 96 to 99 can be made for the production of almost pure glucose or dextrose, used in many food products (see also SUGAR PRODUCTION).

Sweeteners in the form of syrups are largely used in cake and confectionery products and also, especially in the U.S., in bread manufacture. U.S. bread is distinctly sweeter than normal European bread because of the fats and sweeteners used, and the loaves are larger per unit of weight than in the U.K. and most European countries.

In the U.S. the baking industry uses more than one-half of the dextrose and 10 percent of the corn syrup produced. Cookies (biscuits) and breakfast foods are also large users of sweeteners. The U.S. baking industry currently uses some 1,600,000 tons of sweeteners, of which 13 percent is dextrose and 6 percent corn syrup. Confectioners in Europe also used syrups of many types but not as widely as in the U.S.

BIBLIOGRAPHY. The composition, technology, and uses of the various cereals are treated in: D.W. KENT-JONES and A.J. AMOS, *Modern Cereal Chemistry*, 6th ed. (1967), a comprehensive work covering the chemistry of cereals and of breakfast foods and compounded animal feeding stuffs, with chapters on nutrition and analysis of cereals; N.L. KENT, *Technology of Cereals, with Special Reference to Wheat* (1966), a short, concise survey of the technology of cereals including useful world crop statistics, chemical composition, milling, and baking; S. MATZ (ed.), *The Chemistry and Technology of Cereals as Food and Feed* (1959), a discussion of the uses of cereals in foodstuffs and the technology involved; various articles of interest appear in the periodical *Cereal Chemistry* (bimonthly).

Works treating specific cereals include: R.F. PETERSON, *Wheat: Botany, Cultivation, and Utilization* (1965), with chapters on morphology, physiology, cytology and genetics, origin and history, varieties, distribution, diseases, husbandry, storage, chemical composition of various wheat types, and surveys on utilization and trade; I. HLYNKA (ed.), *Wheat Chemistry and Technology* (1964), chapters by various experts on production and utilization of wheat, quality criteria, microscopic structures, principles of milling, chemical components of wheat and flour, dough proteins, end products, soft wheat flours, and bread production; UNITED STATES DEPARTMENT OF AGRICULTURE, "Barley," *U.S. Agriculture Handbook No. 338* (1968), covers the origin of barley, its culture and production in the U.S., insect pests and diseases, breeding new varieties, genetics, and winter hardiness; A.H. COOK, *Barley and Malt* (1962), surveys the use of barley malts in brewing; D.H. GRIST, *Rice*, 4th ed. (1965), discusses the origin of the plant, characteristics, varieties and classification, paddy production, mechanics of cultivation, weeds, diseases, milling, nutritional value, parboiling, and enrichment. A detailed treatment of starch is available in J.A. RADLEY, *Starch and Its Derivatives*, 3rd ed. rev., 2 vol. (1953–54; 4th ed., vol. 1, 1968), a widely accepted textbook, treating the structure of starch, the manufacturing of starch and starch products, industrial applications, and examination of starches. Flour production is treated by J.F. LOCKWOOD, *Flour Milling* (1945), a standard work on modern flour milling; and L. SMITH, *Flour Milling Technology*, 3rd rev. ed. (1945), a useful survey of the technology of flour milling and the problems facing flour millers throughout the world. E.M. WIDDOWSON and R.A. MCCANCE, "Studies on the Nutritive Value of Bread and on the Effect of Variations in the Extraction Rate of Flour on the Growth of Undernourished Children," *Medical Research Council Special Series Report No. 287* (1954), tells of a nutritional study based on tests carried out in 1947 and 1948 on children in German orphanages to determine the effects of diets using breads made from flours of varying extractions. C. HUMMEL, *Macaroni Products*, 2nd ed. (1966), covers the manufacture of macaroni products, including ingredients, batch and continuous processes, drying, quality, storing, and packaging.

Cerebrospinal Fluid

In the vertebrate embryo the central nervous system is formed as a hollow tube with a canal extending its entire length. In later life the canal remains open in the brain stem but narrows considerably in the spinal cord. In each of the two cerebral hemispheres of the brain (see NERVOUS SYSTEM, HUMAN) the canal widens into cavities called ventricles. The cerebrospinal fluid (CSF) fills these ventricles and the canal within the brainstem. It also surrounds and bathes the spinal cord and the brain, acting as a lubricant and a mechanical barrier against shock. The fluid flows slowly from the ventricles, the principal site of formation; down through the canal of the brainstem; and ultimately out into the tissue spaces surrounding the central nervous system.

It is a clear and colourless liquid of low specific gravity. Like the blood it is slightly alkaline in reaction, hav-

Table 1: Comparison of Normal Cerebrospinal Fluid and Blood Plasma Average Values

Sodium	142 mEq/l	137 mEq/l

ing a pH of 7.3–7.4. It is about 99 percent water and has an average freezing point of 0.57° C. The fluid normally has less than five leukocytes (mononuclears or possibly lymphocytes) per cubic millimetre and no red blood cells. The relationship of the various chemical constituents of the cerebrospinal fluid to that of blood plasma is shown (Table 1).

Functions of CSF. The cerebrospinal fluid's many functions are chiefly mechanical. It bathes brain and spinal cord and helps to bear the weight of the brain. It lubricates the surfaces between brain and spinal cord, on the one hand, and the bones that encase them, on the other. The fluid is a buffer that distributes the force of a blow on the head. It helps to keep intracranial pressures relatively constant; its volume decreases to compensate for increased arterial pulsations or greater volume of blood or brain tissue and increases to compensate for a decrease in these factors, as in degeneration or atrophy of the brain. By means of the cerebrospinal fluid, substances are removed from the tissues of brain and spinal cord and carried into the blood stream, and the fluid may possibly act also in the reverse direction. Materials carried away by the fluid include metabolic waste products, antibodies, abnormal chemical constituents, and pathologic products of disease. It helps to circulate drugs administered in therapy. It does not carry enough nutritional substances to be of much help in the normal metabolism of nervous tissue.

During certain diseases that affect the meninges or the central nervous system or both, the cerebrospinal fluid may change significantly in physical characteristics, cytological constituents, and chemical contents; and there may be microbiologic and serologic alterations in the fluid. Careful examination of the cerebrospinal fluid in such a situation may be very useful in differential diagnosis. Table 2 illustrates the changes in the profile of the cerebrospinal fluid in the differentiation of certain diseases of the meninges and the central nervous system.

Formation and re-absorption of CSF. Although there are still differing views concerning the mechanisms of the formation of cerebrospinal fluid, the general belief is that the fluid originates largely by filtration across the membranes that line the spaces containing the fluid (the ependyma of both the choroid plexuses and the ventricles, as well as the arachnoid) but also by active secretion of substances such as protein and sodium.

From the cerebrospinal spaces the fluid enters into the venous system. It was formerly held that the greater part of the fluid is absorbed through the arachnoid villi or pacchionian granulations and passes into the dural sinuses and thence into the venous blood. Probably, however, much of the fluid is absorbed into the veins from the spaces around the spinal roots and cranial nerves and from the perivenous spaces. Some may also be absorbed through the ventricular ependyma and, in a reverse direction, through the choroid plexus and some, by osmosis, directly into the pial veins on the brain surface and into the capillaries of the pia arachnoid.

"Circulation" of CSF. Unlike the blood, the cerebrospinal fluid is not given energy for circulation by an organ like the heart; but there is a definite movement of the fluid from the lateral ventricles down into the third and fourth ventricles, the basal cisterns, and the subarachnoid space; and there is constant circulation in the sense that

Table 2: Cerebrospinal Fluid in Differential Diagnosis

condition or disease	initial pressure (mm CSF)	spinal subarachnoid block	appearance	cells (per mm³)	protein (mg/100 ml)	glucose (mg/100 ml)	chlorides as NaCl (mg/100 ml)	colloidal gold curve	comments
Normal	70–150	absent	clear colourless	0–5 mononuclear	15–45	50–80	700–750	00000000	
Infections on the central nervous system and meninges									
Acute purulent meningitis	200–600	absent	cloudy to purulent	500–20,000 mainly polymorphonuclear	100–1,000	10–20 mg or less	575–700	variable	organisms may be found by direct stain or culture
Tuberculous meningitis	200–500	absent	opalescent to faint yellow	100–500 mainly lymphocytes	60–700	15 mg or less	525–675	variable	tubercle bacilli may be found by stain or guinea pig inoculation
Cryptococcus meningitis	200–400	absent	slightly opalescent	100–500 mainly lymphocytes	50–300	30–40 mg or less	normal or slightly decreased	variable	yeasts may be found with India ink stain or special culture
Syphilitic meningitis	150–300	absent	clear to slightly opalescent	300–2,000 mononuclear	50–400	normal or slightly decreased	normal or slightly decreased	first or midzone	serologic tests usually positive
Parenchymatous central nervous system syphilis	normal	absent	clear	10–50 mononuclear	50–100	normal	normal	first or midzone	serologic tests usually positive except in late treated tabes
Viral meningitis and encephalitis	100–250	absent	clear	25–250 polymorphonuclear early; later lymphocytes	40–80	normal (occasionally more)	normal	normal or nonspecific	occasionally virus may be found
Acute anterior poliomyelitis	normal	absent	clear	50–250 mainly mononuclear	40–100	normal	650–750	variable	polymorphonuclear cells may be found in preparalytic stage; gradual rise in protein
Brain abscess	200–800	absent	clear colourless	30–100 mainly mononuclear	40–200	normal	normal	variable	polymorphonuclear cells present early, before encapsulation
Miscellaneous meningeal and nervous system diseases									
Carcinomatous meningitis	150–400	absent	clear to opalescent	100–500 mainly mononuclear	40–200	moderately decreased	normal	variable	cancer cells may be found in stained sediment
Brain tumour	150–500	absent	clear to yellow	usually normal, may be up to 50–100	20–150	normal	normal	variable	pleocytosis usually indicates tumour near ventricles or meninges
Spinal cord tumour	normal or decreased	partial or complete	clear to yellow	usually normal	50–5,000	normal	normal	first or midzone	with complete block may be marked increase in protein
"Guillain-Barre syndrome"	normal	absent	clear to yellow	normal	50–1,000	normal	normal	variable	often marked increase in protein without associated pleocytosis
Subarachnoid or ventricular hemorrhage	150–400	absent	bloody yellow	crenated red blood cells	50–500	normal	normal	variable	fluid grossly bloody; supernatant yellow
Multiple sclerosis	normal	absent	clear colourless	5-50 mononuclear	40–70	normal	normal	first zone in 20%; variable in 40%	

the fluid is being continuously secreted and absorbed. There is clinical evidence that obstruction of one opening, the foramen of Monro, between one lateral ventricle and the third ventricle will cause hydrocephalus on one side, with enlargement of that ventricle, and that obstruction of the Sylvian aqueduct will cause hydrocephalus on both sides, involving the third and both lateral ventricles. The forces that bring about the flow of the cerebrospinal fluid and affect its rate include the arterial pulsations within the choroid plexus, respiration, the increase in venous pressure brought about by thoracic and abdominal movements, movements of the head and body and changes in their position, and filtration and secretion pressures.

The normal adult has from about 100 to 150 millilitres cerebrospinal fluid. This fluid is replaced every six to eight hours or three or four times a day. Abnormally large volume is caused either by excessive formation or deficient absorption.

Lumbar puncture. In lumbar puncture a needle is inserted into the subarachnoid space in the lumbar region, and a little cerebrospinal fluid is withdrawn for use in diagnosis. In most cases the cerebrospinal fluid pressure is also measured and the flow of the fluid investigated. The interspace between the third and fourth lumbar vertebrae is chosen for the site of the puncture because at this level the spinous processes are farthest apart and because, in the adult, this point is below the level of the lower end of the spinal cord.

After clear fluid has been obtained, the pressure is determined, ordinarily by means of the Ayer water manometer. Pressures from 70 to 150 millimetres (of cerebrospinal fluid) are normal. If the pressure is within the normal range and there is no other contra-indication, such as suspected intracranial disease, the Queckenstedt test is done. This is a test of the response of spinal fluid pressure to constriction of the jugular veins in the neck and release of the constriction. Normally the pressure rises rapidly and falls with equal rapidity. A slow, incomplete rise and fall or no response whatever is a positive Queckenstedt reaction and indicates a partial or complete spinal subarachnoid block. The Ayala index, computed by dividing the final pressure by the initial pressure and multiplying by the amount of fluid removed (at least ten millilitres must be removed if the test is to be reliable), helps in differentiating between an expanding intracranial lesion and other causes of pressure within the cranium. A quotient of 5.5 to 6.5 is normal. A swift drop in pressure and a quotient of less than 5 are indications of a small fluid reservoir and point to the possible presence of brain tumour or abscess, obstructive hydrocephalus, or a spinal subarachnoid block. A large reservoir is indicated by a value of more than 7, and nonobstructive hydrocephalus or cerebral atrophy is suspected. Lumbar puncture is contra-indicated by infections in or near the puncture site, by systemic infections (except when meningitis is suspected), and by symptoms or signs of increased intracranial pressure (unless diagnostic gains outweigh potential dangers). If the contra-indications mentioned are taken into account aftereffects of lumbar puncture are usually negligible. Postpuncture headache, the most frequent sequel, occurs in 15–30 percent of patients. It usually is mild and lasts only a day or two. The occasional severe headache may incapacitate for a week or longer; it is often accompanied by neck stiffness, is aggravated by movement, and is lessened or relieved by lying down. Current studies tend to indicate that postpuncture headache may occur less frequently if a needle of very narrow gauge is used.

Contra-indications against lumbar puncture

(1967), a textbook dealing with the anatomic and physiologic basis of the neurologic examination with separate chapters on cerebrospinal fluid circulation and syndromes, spinal puncture, examination of the cerebrospinal fluid, and related examinations and procedures; R.A. FISHMAN, "Cerebrospinal Fluid," in A.B. BAKER (ed.), *Clinical Neurology*, 2nd ed., vol. 1 (1962), an authoritative discussion on the physiology and composition of spinal fluid and various spinal fluid syndromes; S. LUPS and A.M.F.H. HAAN, *The Cerebrospinal Fluid* (1954), a well-recognized textbook by Dutch investigators on the functions and anatomy of cerebrospinal fluid; H.H. MERRITT and F. FREMONT-SMITH, *Cerebrospinal Fluid* (1937), although now somewhat out-of-date, remains the classic reference book; J.W. MILLEN and D.H.M. WOOLLAM, *The Anatomy of the Cerebrospinal Fluid* (1962), a comprehensive discussion of the morphologic aspects of cerebrospinal fluid by current British investigators; W.W. TOURTELLOTTE *et al.*, *Post-Lumbar Puncture Headaches* (1964), a detailed critical analysis of the various theories regarding post lumbar puncture headache and methods for their prevention and treatment.

(R.N.DeJ.)

Ceremonial and Ritualistic Objects

Throughout the history of religions and cultures, objects used in cults, rituals, and sacred ceremonies have almost always been of both utilitarian and symbolic nature. Ceremonial and ritualistic objects have been utilized as a means for establishing or maintaining communication between the sacred (the transcendent, or supernatural, realm) and the profane (the realm of time, space, and cause and effect). On occasion, such objects have been used to compel the sacred (or divine) realm to act or react in a way that is favourable to the participants of the ceremonies or to the persons or activities with which such rituals are concerned or to prevent the transcendent realm from harming or endangering them. These objects thus can be mediatory devices to contact the divine world, as, for example, the drums of shamans (religious personages with healing and psychic-transformation powers). Conversely, they can be mediatory devices used by a god or other supernatural being to relate to man in the profane realm. They may also be used to ensure that a chief or sovereign of a tribe or nation achieves, and is recognized to have, the status of divinity in cultic or community ceremonies. Of such a nature may be phallic cult statues bearing the name of a king associated with that of the Hindu god Śiva, in areas under Indian influence (such as in ancient Vietnam, Cambodia, and Indonesia, where the lingam was worshipped under a double name: Indrés vara [Indra king of the gods, plus Īśvara, Lord—a name of Śiva]), or the Buddhist "body of glory" statues in Cambodia dating from the end of the 7th century. The religious dance masks of many societies, including those used in ancient Tibet and in Buddhist sects of Japan, may, to some extent, also belong to this class.

VARIETIES OF CEREMONIAL AND RITUALISTIC OBJECTS

Because such objects vary as much in nature as they do in form and material, they are difficult to evaluate. If limited strictly to religious practices, an inventory of ceremonial and ritualistic objects remains incomplete, because these objects have played significant roles on solemn secular occasions, such as consecrations, enthronements, and coronations, which may be closely linked to the divine order, as in Hindu-, Buddhist-, and Christian-influenced cultures.

Icons and symbols. Constituting a most significant category of cult objects are representations of a deity. Though such representations are often depicted in the form of statues and images (icons) of divine or sacred beings, they may also be either figurative or symbolic, the meanings often being equivalent. In Tantrism (a Hindu and Buddhist esoteric, magical, and philosophical belief system centred on devotion to natural energy), for example, the sacred Sanskrit syllable Om—which is a transcendent word charged with cosmological (order-of-the-universe) symbolism—is identified with the feminine counterpart of the god. In its written form, particularly on Tibetan banners (*thang-ka*), the word Om (often corresponding with the feminine counterpart—Tārā—of the patron of Tibet) is considered to be eminently sacred,

even more so, in some instances, than an anthropomorphic (human-form) divine effigy.

Religious statues and images

Statues and painted images occur most frequently in religious iconography, as noted above. These are often viewed as the permanent embodiments of the deities they represent, whether they are located in sacred places of religious communities, such as temples, shrines, or chapels, or on domestic altars, which contain statues or icons of the divinities of prosperity and fertility, mother goddesses, household gods, saints, relics, the tablet of the ancestors in ancient China, and other similar domestic cult objects. Many household cult objects are made from clay or terra-cotta and are sometimes multicoloured. The material of which major cult objects are composed is often explicitly defined and assumes a certain importance. If the statue is fashioned in wood, the choice of the wood (acacia, sandal, or any other) is symbolically important because it is considered auspicious. By the same token, the choice of stone is likewise important, depending on the region. If metal is chosen, it is one that is deemed precious (*e.g.*, golden statues bring prosperity). In the case of bronze statues and other cult objects, the composition is carefully defined and often corresponds to alloys to which symbolic values are attached. In addition to a proper and distinct form and material, the technique of fabricating and the procedural patterns of composing such objects are controlled by traditional rules that have become established rituals in many religions—sophisticated, folk, and primitive. In the production of statues in human or animal form, the last procedure is often the "opening the eyes" (*i.e.*, the painting of the eyes of a statue of a deity or inserting gold in them by an officiating priest during the installation of the statue [*pratiṣṭhā*] in the sanctuary, along with the reciting of appropriate prayers that make the statue "living" and "real"), particularly in Brahmanic India and Chinese-influenced areas (see also SYMBOLISM AND ICONOGRAPHY, RELIGIOUS).

Religious dress and vestments. The practice of wearing special garments for conducting rites, participating in worship, or even witnessing such ceremonies is very unevenly distributed, and the conceptions associated with this practice are highly varied and complex. The shamans of the Buryats, Yakuts, Altaic Turks, and other Asian peoples wear a ritual costume with a cloak made to look like a bird, with fringes symbolizing plumes; according to their beliefs, this costume magically transforms the wearer into a real bird that will fly to the sacred realm and back to the profane world. In many cases, however, worship requires no special costume, and the monastic or sacerdotal vestment of the officiant or priest may be without adornment, as in Theravāda (Way of the Elders) Buddhism. Sometimes the garment used in religious rites is merely more sumptuous in material or colour than that used in everyday wear. Occasionally, additional objects of liturgical or ritual significance are added to the costumes normally used in religious ceremonies. Certain types of headgear (which are primarily symbols of dignity), such as papal and episcopal mitres of Christian ecclesiastical officials or the "helmets" of the Tibetan Mahāyāna Buddhist monastery dignitaries, are used only on solemn religious ceremonies. In the various Christian churches, especially the Orthodox, Roman Catholic, Anglican, and Lutheran, both the colours and the components of sacerdotal vestments for celebrating worship rites are specifically defined according to the holiday or liturgical season. Garments, under certain circumstances, are even used to clothe cult statues in lands under the influence of both Western and Eastern religions—*e.g.*, in Czechoslovakia, Poland, Spain, and France and in India (see also RELIGIOUS DRESS AND VESTMENTS).

Forms and symbolic conceptions of religious dress

Instruments for worship and religious ceremonies. The types and varieties of instruments used in worship and religious ceremonies are almost innumerable. The role they play in ritual occasions may be as containers and sacred furniture, as objects with properties necessary for worship, and as "mediatory" objects, through which a magical or mystical connection is believed to be made between the human and divine worlds. There are also the materials used in bloody or nonbloody sacrifices.

Amulets and talismans. Amulets (charms) have been used for protection in all ages and in all types of human societies; they persist even today in industrial societies, in which they are mass-produced by the most modern methods (*e.g.*, mustard seeds encased in plastic to be worn as necklaces reminding the wearer of Jesus' words about the growth of the Kingdom of Heaven). The purpose of most amulets is not so much religious as it is for protection against danger, sickness, and bad luck (*e.g.*, the "mystical eye" of the ancient Egyptians or the "Hand of Fatima" of Muslims). The same is true of talismans, which offer the additional advantage of conferring supernatural power on other people, even on the deity, from a distance. Dancers' masks and jewels, such as earrings, bracelets, necklaces, and belts, may be classified with amulets. Such objects are individually worshipped in order to gain their goodwill among some Hindus in India and among the Pueblo and Navajo Indians of North America (see also MAGIC).

TYPES OF SACRED SETTINGS FOR CEREMONIAL AND RITUALISTIC OBJECTS

Places of worship and sacrifice. Throughout man's history, there is evidence that he worshipped at natural sites as well as at sites constructed for ritualistic purposes. In the protohistory and perhaps the prehistory of most ancient civilizations, people venerated trees, stones, bodies of water, and other natural objects, which gradually became the objects of established cults and which often were included, in some form, as aspects of later official ritual. Initially, the objects of this frequently occurring process were sacred trees considered to be the habitats of spirits or gods, such as in Vedic, Brahmanic, and Buddhist India or pre-Islāmic Arabia; sacred stones, such as fragments of meteorites, menhirs (upright stones), and rocks—such as the celebrated Kaʿbah, the black stone of Mecca; flowing waters, natural lakes, and sacred and purifying rivers, such as the Ganges; crossroads and junctions, such as the *tīrtha* (river fords and, by extension, sacred spots) in India; and other such objects or places of nature. According to Hesiod, an 8th-century-BC Greek writer, such objects of nature were venerated in the popular piety of the rustic people of Greece in his times.

Importance of the natural elements

The association on the same site of four natural elements (mountain, tree, stone, and water) is supposed to constitute a sacred whole (a quarternity of perfection), a sacred landscape or "geography" similar to the world of the gods. Such sites, in many civilizations, were the initial points of departure for pilgrimages or for the establishment of places of worship. In some instances the natural sacred places were gradually adapted for religious use (*e.g.*, the oracle at Delphi, in Greece), but in others the earlier natural sites were artificially recreated by using man-made symbolic equivalents. An artificial or natural hill, such as a barrow, mound, or acropolis (elevated citadel), often served as a base for the temple, but in many instances the temple itself has been an architectural representation of the mountain, as were the *bamot* ("high places," usually constructed with stones) of the ancient Hebrews, the ziggurats (tower temples) of the ancient Babylonians, and the pyramidal temples of Cambodia, Java, and pre-Columbian Mexico. A branchless tree has often been transformed into a cultic object: a sacrificial post, such as the Vedic *yūpa;* the central pole of a nomadic tent in Siberia and Central Asia, the *yurt*, or initiation hut; or a parasol shaft (*chattrāvalī*) in the Buddhist *stūpa*s (reliquary buildings) and the Japanese and Chinese pagodas. If represented in stone, the tree evolved into a column gnomon (a perpendicular shaft), such as the Buddhist *lāṭ*, the sacred pillar (*matzeva*) of the ancient Hebrews, or the obelisk of pre-Hellenistic Egypt (before the 4th century BC, especially from the 3rd millennium to the early 1st millennium BC). Stone, transformed into an altar, has been used either to support or seat the image or symbol of the deity, or to receive sacrifices, burnt offerings, plant offerings, or aromatic perfumes. Water, because to it is generally ascribed a power that is purifying or even curative or miraculous,

almost always plays an important role in or near sacred places. The whole assemblage of actual or symbolic mountains, trees, stone, and water is usually arranged architecturally within an enclosed space. An example of this arrangement is the typical Christian church, with its raised chancel (the mountain), the cross or crucifix (the tree), the altar (usually stone, but sometimes wood), and the baptismal font or tank (water).

This widespread scheme is almost everywhere bound up with a cosmology (theory of the universe) that establishes a symbolic identity between the divine world and the temple. This identity holds true in all stages of culture; *e.g.*, the sacred sites of the Algonquin, Sioux, and Blackfoot North American Indian tribes; the *templum* (temple) of the Etruscans in ancient Italy; the temple of Bel at Palmyra (in Syria); the Mithraic crypts centring on devotion to the Iranian god Mithra throughout the Roman Empire; the *kiva* (a circular, partly underground ceremonial room) of the Pueblo villages; the Temple of Heaven at Peking and that at Hue (Vietnam); the Buddhist *stūpa;* and Brahmanic, Buddhist, and Mexican mountain temples. The cosmic character of the Israelite king Solomon's Temple, of the 10th century BC, constructed on Mt. Moriah in Jerusalem, was not given such an interpretation, however, until Hellenistic times (3rd century BC–3rd century AD), as in the writings of Philo of Alexandria and Josephus. That of the Muslim mosques is very subdued, although the Ka'bah of Mecca, which contains the black stone, is believed by Muslims to be the centre of the cosmos. The cosmological scheme has been applied to Christian basilicas and churches—with square floor plans, an overarching dome, and symbolic ornamentation—from as far back as the 6th and 7th centuries.

Sacred furniture and related objects. Whatever its size and form, a sacred area is usually delimited by an enclosure, such as a simple fence around sacred trees or Buddhist *stūpa*s or high walls with immense gates around temples. The sacred space may comprise multiple enclosures, such as that of huge sacred structures—such as the temple of Śrīraṅgam in southeastern India, which has seven concentric enclosures. The dominant idea in delimiting the holy place is to protect the sacred element and its mystery. Access to the sanctuary is often hidden by grills or screens: the veil of the Jewish Temple in ancient Jerusalem, which separated the holy area (or *hekhal*) from the Holy of Holies (or *devir*); or the Eastern Orthodox *ikonostasis* (image screen), which hides the chancel from the view of the faithful except on certain ritual occasions when it is opened to them. Hindu sanctuaries also are concealed by hangings. In Roman Catholic, Lutheran, and Anglican churches, the chancel has usually been separated from the nave by a railing, before which the faithful kneel to receive the eucharistic (communion) meal.

Objects hiding access to sanctuaries

In Indo-European civilizations the essential element of the sacred furniture is the altar, the site of which varies according to the cult and period under consideration. Tables for sacrifice, burnt offerings, and offerings of plants or perfume have sometimes been placed outside the temple, as at the Temple of Solomon in Jerusalem and in temples of ancient Egypt. In early Christian cults, a single altar was placed in the chancel. Later, about the 6th century, the number of altars was increased, with one in each chapel of the larger church building.

The most sacred furnishings of temples are those most closely related to altars, such as the Jewish ark of the Law, or *aron ha-qodesh*, in the synagogues, which is made in the image of Moses' ark of the Covenant, and the tabernacle (the receptacle containing the consecrated bread and wine) of Roman Catholic and Eastern Orthodox churches. The ark, which is portable, is a kind of chest (*aron*) with a cover (*kapporet*), and the tabernacle, made of wood, metal, or stone, is a locked chest. On the fire altars of Zoroastrianism (a religion founded by the Iranian prophet Zoroaster in the 7th century BC) is a sacred metal urn (*ātash-dān*), containing the eternal fire, ashes, and aromatic substances.

When temples or other major sanctuaries are also places for assembly and common prayer, as, for example, Muslim mosques and Catholic and Protestant churches, pulpits are provided. They may be integral parts of the masonry, of the anterior screen of the chancel—as are ambos (raised platforms), or wooden furnishings fixed to the walls, like the formerly mobile *minbar* (domed boxes in mosques). In Manichaeism (a dualistic religion founded by the Persian prophet Mani in the 3rd century AD), the Bēma Feast was centred on the exaltation of a reconstructed pulpit (Bēma), which symbolically represented the rostrum from which Mani spread his teachings. Another important element of sacred furniture is the lectern, on which is placed one or more sacred books (from which one of the officiants reads aloud) or a collection of hymns and religious chants intoned by a cantor in monasteries or other religious structures.

Use of pulpits and lecterns

Permanent lighting is also required in certain cults. This has encouraged the creation of supports or vessels for inflammable materials, the most characteristic of which are the seven-branched candelabrum of the Jerusalem Temple, the Easter candle holder of Roman Catholicism, the sanctuary lights of Roman Catholicism that signal the presence of the Eucharist in the tabernacle, lights suspended before icons in Orthodox rituals, glass or perforated-metal lamps in mosques, and spherical lanterns adorned with an eye, which represents the universal monad (one), of Vietnamese Cao Daism (a syncretistic religion combining Roman Catholicism and Buddhism).

Protective devices and markers of sacredness. Other objects, such as fans, flyswatters, parasols, and standards —analogous to the symbols of royalty—often complete the permanent furnishings of sacred places. In addition to their utilitarian role, they are endowed with a sacred character; fans used in Brahmanic and Buddhist cults may be compared to the *flabella* ("fans") in the Roman Catholic and Orthodox churches. They are waved before the iconostasis during the Eucharist in the divine liturgy of the Eastern Orthodox Church, and they also are placed on either side of the papal chair in solemn processions. The parasol, or umbrella, is generally a symbol of the vault of heaven, as in India and China; the domes of *stupa*s are often surmounted by parasols (*chattra*s). In its symbolic and protective role the umbrella can be compared to the *baldachin* (canopy) in many of its forms. Whether it covers the altar, the statue or symbol of a deity, or even the imperial throne—as in Zoroastrian Iran during the Sāsānian period (3rd–7th centuries) and Orthodox Byzantium (during the 4th–15th centuries)—the *baldachin*'s celestial symbolic ornamentation is generally explicit, and its cosmic character is apparent. The standard (*dhvaja*), in the Brahmanic cults, takes on the appearance of a high column (*dhvajastambha*) erected in front of temples; it is surmounted by a divine effigy, most often that of the sacred steed, or *vāhana*, of the god. Simultaneously a signal (because of its height) and a protective device, it first receives the homage of pilgrims. The poles adorned with flags erected before the pylons of the temples of ancient Egypt may also have had such a double character.

The symbolic character of parasols, canopies, and standards

FORMS OF CEREMONIAL AND RITUALISTIC OBJECTS ACCORDING TO THEIR FUNCTIONS

Summoning, mediating, and expelling devices. In the form of magic or sacred words, singing, and music, sound plays or has played an important role in the worship of most religions. The same is true of light and of aromatic substances, such as oils, perfumes, and incense. The importance of these elements has brought about the creation or adoption of specific objects with functions that often serve converging purposes in worship. In most cases they are used to draw the attention of the deity, to establish a connection with it, and to exorcise forces that are evil or harmful to the god and to men. Because of the need to attract the deity's attention, the sound-producing instruments are usually percussive or shrill, rather than melodic, and drums, gongs, cymbals, bells, conches, and sistra (timbrils, or rattles) are the most common forms.

Sound devices. Summoning devices are played either alone, as objects to accompany prayers or litanies, as

in Tantric Buddhism, or as instruments in a temple orchestra. Their size and form and the materials used to make them vary according to locale. Generally viewed as sacred, they are often worshipped, as in West Africa, Malaysia, and Burma, and partake of divine attributes, as in Brahmanism, Mahāyāna (Greater Vehicle, or northern) Buddhism, and Tantrism. Drums vary most greatly in both size and form. The two-skinned *ḍamaru* (drum) of Śivism (devotion to the Hindu god Śiva) and Tantrism, which is shaped like an hourglass, with striking balls, is believed to be effective in communicating with the divine world. Gongs usually are suspended metallic disks, with or without a central protuberance. The gongs of ancient and contemporary China, however, are of varied form, with cutout designs, and may be made of resonant stone or of jade. Cymbals are very widespread and were used in the Hellenistic mystery (salvatory) religions, such as those of Dionysus (a god of wine) and the Eleusinian mysteries (centred on devotion to Demeter, a seasonal-renewal goddess). They were the only instruments played in the Temple of Jerusalem, where they were known as *metziltayim* or *tzeltzelim*. The sistrum, used in pre-Hellenistic Egypt in the worship of the goddesses Isis and Hathor and in Rome and Phoenicia, as well as among the Hebrews, is composed of a handle and frame with transverse metal rods and mobile disks. Producing a sharp ringing sound, it was regarded as particularly sacred and was carried to the temple by women of high rank. There are countless types of bells; the Indian *ghaṇṭā*, or Tibetan *dril-bu*, a metal handbell with a handle shaken during prayers in order to attract beneficent spirits and to frighten away evil ones, is used particularly during Brahmanic and Mahāyāna Buddhist ceremonies.

In this category of objects, the shaman's drum of the Buryats, Yakuts, Altaic Turks, and Eskimos is composed of a skin stretched over a circular or oval frame provided with a handle; it is struck with a curved beater. It plays the same magical role as the *ghaṇṭā*, but it also serves as a mode of ascending to the realm of the sacred for the shaman. The bull-roarer—a flat, elongated piece of wood, ivory, reindeer antler, or other material—used in primitive religions of Australia, equatorial Africa, western North America, Colombia, Brazil, and Sumatra, and the similar rhombus of the Hellenistic mystery religions, was propelled and whirled by a thin strap. Its humming sound and trajectory gave it the dual character of a summons to the divine world and a link with the celestial regions.

Lighting devices. In comparison with sound, which in worship usually presents a coercive character, lighting and fire, whether permanent or occasional, generally signify a sacred or spiritual presence, an offering, prayer, intercession, or purification. They are often viewed as sacred or even of divine origin, if not directly identified with the deity, as in the Zoroastrian fire altars. Their supports and containers can be made of either durable or perishable materials, depending on the ritual or ceremonial requirements. Torches have been used throughout history: in ancient Assyria and Babylonia they were used to carry a newly consecrated fire from torch to torch throughout the city three times a month; in ancient Rome they were sometimes placed in a hollow clay or metal shaft; and in the ancient Hebraic religion a lamp (*ner*) filled with sacred oil was used in the worship of the god Yahweh. In the Roman Catholic Church, from about the 10th century on, wax candles have been used, with bronze or copper candle holders—the forms of which changed according to style. Two of them were placed on the altar for the mass, and two others were carried by acolytes (light bearers). The Easter (Paschal) candle, made of beeswax around a wood core, had a candle holder appropriate to its size. At Westminster, in England, during the 14th century, a *candela rotunda* ("round candle") was the centre of a "festival of lights" during the feast of the purification of the Virgin Mary (February 2), also called Candlemas Day.

The use of torches

Festivals of lights have been and still are common throughout the world, especially among the Jews, who celebrate Hanukka, the Feast of Dedication of the Temple. In India and in Indian-influenced countries (particularly Thailand), the festival of lights (Dīpāvālī or Dīvālī) is celebrated by the Vaiṣṇava Hindus (devotees of the god Viṣṇu) in October–November, at the end of the monsoon season. It is practiced on other religious occasions by the Jaina (followers of the Indian reformer Mahāvīra, of the 6th century BC), Thais, and Tibetans, who celebrate it in December. The lamps, which are lit everywhere (*e.g.*, in temples, in houses, and at crossroads), are also set afloat on streams, rivers, and lakes. Some lamps are made of glass—like the votive lights of Roman Catholicism—with a wick dipped in a vegetable oil, usually coconut; some are made of clay; and others are made of rice paste with a central hollow filled with ritual clarified butter, or ghee (*ghī*), or are cut out of a plant stalk in the shape of a bark or raft. The Jaina use earthen saucers containing either wicks immersed in coconut oil or pieces of lighted camphor. Another form of this festival was known in Thailand, where three earthen pots, containing rice, seeds, beans, and an oil-soaked wick, were placed at the top of three poles opposite the temple entrance, and the fire was kept burning for three days.

The "cordons of light" placed around the sacred places of Buddhism during great festivals, such as at Bodh Gayā, in India, for the Buddhajayantī (the commemoration of the Buddha's 2,500th birthday) in 1958, are composed of thousands of small brass lamps in the form of footed cups filled with ghee, in which a cotton wick is soaked.

Incense and other smoke devices. The use of incense or the fumes of aromatic substances is especially widespread in the great religions of the world and has many symbolic meanings. It may signify purification, symbolize prayer (as among the Hebrews), or be an offering that rises to the celestial or sacred realm. Bronze incense burners were cast very early, as exemplified by such objects from the Chou period (*c.* 1122–221 BC). Their forms were often inspired by cosmological themes. In early Taoist ritual the fumes and odours of incense burners of varying size produced a mystic exaltation and contributed to well-being. Under the T'ang dynasty (AD 618–907), perforated golden vessels with handles were carried in the hand to accompany a votive offering. In Japan the censer (*kōdan*)—a vessel with a perforated cover and carried by chains—was used in both Buddhist and Shintō rituals. In pre-Hellenistic Egypt and among ancient Jews, incense was burned in golden bowls, which sometimes had handles, and also in cauldrons placed on or beside the altar or outside the temple. In pre-Columbian Mexico and Peru, incense burners were made of terra-cotta and sometimes of gold. Censers of precious metal provided with chains for hanging have been used since the 4th century in Christian churches, and the rite of swinging the censer is practiced in many rituals, both Christian and others.

Symbolism of incense and other aromatic substances

Expelling and other protective devices. Several of the objects already described serve as protection against evil or demonic spirits. Of such a nature are the *ghaṇṭā* and *dril-bu*, the shaman's drum, the lamps of the Indian Dīpāvālī, and the burning of incense, which has also been practiced in ancient Greece, pre-Columbian America, Morocco, and many other regions. The possession of a large number of the same form of a protective object often is believed to be effective; this is the reason for the large number of bells (*ghaṇṭāmālā*) suspended on lattices on the handrail of the balustrade (*vedikā*) around the *stūpa*s of ancient India; even today, small bells are hung from the roofs of Buddhist pagodas in Sino-Japanese regions. Like the small bells seen on the roofs of Romanian country dwellings until the beginning of the 20th century, these bells have a clapper provided with a feather or plaquette that enables the wind to ring them continually. Perhaps the most effective protective object, however, is the "diamond thunderbolt" (Sanskrit *vajra;* Tibetan *phur-bu*, or *rdo-rje*) of Mahāyāna Buddhism, Tantrism, and Lamaism (a Tibetan form of Buddhism and folk religion). Well-known in early Buddhism as an instrument held in the hand, the *vajra* is handled in the

middle and has, at one or both ends, four curved points that meet at the tips. Of varying size, they are usually made of gilded or ungilded bronze. The Tantric *vajra* is also associated with the *ghaṇṭā* (*vajra-ghaṇṭā*), for which it forms a handle. A symbol of the indestructible force of religion, it is believed to be able to drive away all manifestations of evil. Although they are perishable, gunshots and firecrackers are viewed as protective and expelling devices, as in China and Cambodia (where soldiers, in the early 1970s, fired ammunition at a lunar eclipse to drive away the dragon they believed was devouring the moon).

Representational objects. In many religions, the god or divine order is represented among men by objects, which may be regarded simply as the god's material form on earth or may be totally identified with the god and endowed with his powers. In pre-Hellenistic Egypt the god was believed to be present in his statue, and elsewhere the statue frequently was believed to contain the god.

Statues of divine beings and sacred masks

Figures. Statues of human or animal figures are the most explicit of the objects representing the divine order. In most iconic (image-using) religions the gods are generally anthropomorphic, half man, half animal (as in Egypt and India) or often entirely animal. In most cases the statues conform to an ideal physical type that is symbolic and conventional. The formulation of the ideal is governed by precise aesthetic and iconometric (ritual image proportion) rules, as well as by iconographic (image-representation) requirements, as in Egypt, Greece, and India. All such standards and requirements guarantee conformity to the divine model and, therefore, the effective presence of the god in his statue. Typical in this regard are the sculptured animals of the Hindu pantheon, such as elephants, lions, horses, bulls, and birds, which—erected at sacred places in India and other Hindu-influenced countries—serve as ever-ready sacred mounts (*vāhana*) for the journeys of the corresponding gods.

The masks representing beneficent and maleficent sacred or holy forces in religious dances—particularly in Buddhist monasteries of Nepal, Tibet, and Japan and in the majority of primitive societies—constitute another category of sacred representational objects. They are usually worshipped just as statues are worshipped.

Certain customs incorporating representational figures have been widespread since prehistoric times and appear to be more related to magic than to religion. One example of this type of practice is a custom observed in primitive or prehistoric societies—the incorporation of a skull in an anthropomorphic statue in order to emphasize its divine, sacred, or magical character. To some extent, a similar use of a skull, human bones, a mummified corpse, or a skeleton appears in Christian churches in the veneration of relics.

Plants and plant representations. In all civilizations, plants and trees have been viewed as sacred. Generally, the tree is either a god's habitat or the god himself and is worshipped. Such was the case, for example, in early Indian Buddhism. Trees may also be associated with the divine order because of some incident and subsequently venerated, as was the bodhi tree, under which the Buddha received his Enlightenment. Fences or even open-air temples, the form adopted for the early Bodh Gayā Buddhist temples, are built around such trees. Innumerable cases of sacred or divine trees and their painted or sculptured representations are found throughout written religious tradition and in the ethnological data. The branches of trees such as the palm, olive, and laurel are often associated with the gods; such branches may crown the god or be included among his attributes. Many are used in worship, as are the branches of the *bilva* (wood-apple tree) among the adepts of Śiva, and the *tulasī* (basil), symbol of Lakṣmī (Hindu goddess of prosperity and Viṣṇu's wife) and sacred plant of the Vaiṣṇavites.

Plants as symbols of life and immortality

As symbols of life and immortality, plants such as the vine of the Greco-Roman and the Christian world and the *haoma* (a trance-inducing or intoxicating plant) of pre-Islāmic Iran are planted near tombs or represented on funerary steles, tombstones, and sarcophagi. Two similar and related rites involving plants, the *haoma*, noted in the Avesta (ancient Zoroastrian scriptures), and the *soma*, noted in the Vedas (ancient Hindu scriptures), pertain to the ritual production of exalted beverages presumed to confer immortality. The ritualistic objects for this ceremony included a stone-slab altar, a basin for water, a small pot and a larger one for pouring the water, a mortar and pestle for grinding the plants, a cup into which the juice drips and a filter or strainer for decanting it, and cups for consuming the beverage obtained. In many sacrifices, branches or leaves of sacred plants, such as the *kuśa* plant (a sacred grass used as fodder) of the Vedic sacrifice and the Brahmanic *pūjā* (ritual), are used in rituals such as the Zoroastrian sprinkling (*bareshnum*), or Great Purification, rite, in which the notion of fertility and prosperity is combined with their sacred characters (see also ANIMALS AND PLANTS IN MYTH AND LEGEND; PURIFICATION RITES).

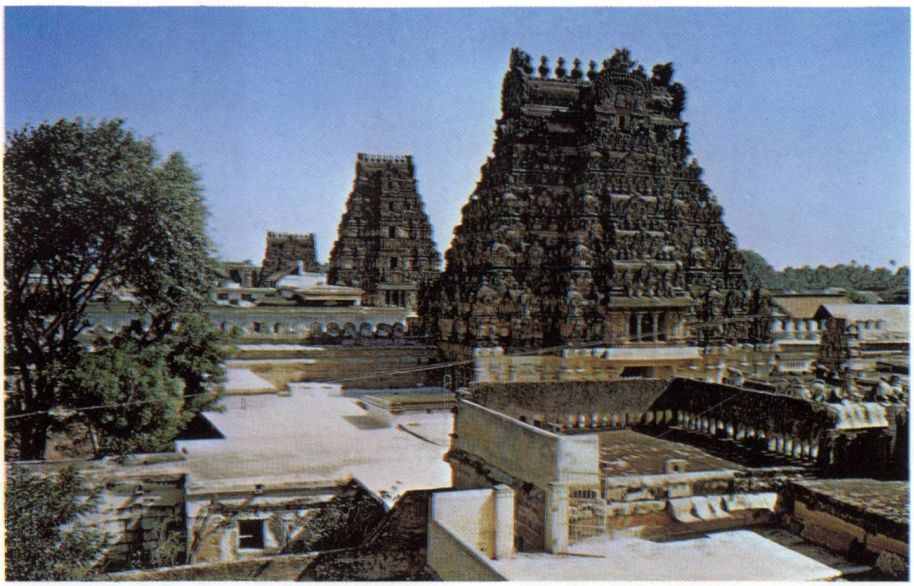
Use of banners and shields

Other representational objects. The staves of martial banners or standards are often surmounted by the figure of a god, which is frequently in its animal form. Such effigies, used by the Indo-Iranians, the Romans, the Germanic tribes, the Celts, and other ancient peoples, were probably meant to ensure the presence of the god among the armies. From the 4th century on, Byzantine armies placed the *labarum* (a cross bearing the Greek letters XP, signifying Christ) on their standards. Shields, such as the Greek *gorgonōtos* ("gorgon-headed"), were also often decorated with sacred figures, emblems, and symbolic themes, particularly in post-Gupta (4th-century) India, as seen in the 6th-century findings from the frescoes of Ajantā. In the Mycenaean civilization (15th–12th centuries BC) of ancient Greece, shields were worshipped in front of the temple, and at Knossos (in Crete) votive offerings were made of clay and ivory in the form of shields. The famous *ancilia* ("figure of eight" shields) of Rome were kept by the Fratres Arvales (a college of priests) and used by the Salii (Leapers), or warrior-priests, for their semiannual dances (in March and October) honouring the god Mars.

Relics. Relics of saints, founders of religions, and other religious personages, which are often objects of worship or veneration, generally consist of all or part of the skeleton (such as the skull, hand, finger, foot, or tooth), a piece or lock of hair, a fingernail, or garments or fragments of clothing. Such veneration is nearly universal, as is the production of reliquaries, or shrines that contain relics. The size, form, and materials of reliquaries vary greatly and often depend on the nature of the relic being exhibited. They may be fixed but are generally portable so that they can be carried in processions or on pilgrimages. Wood, bone, ivory, quartz, glass, semiprecious stones, and metals such as gold, silver, bronze, and copper are frequently used materials, and chasing (embossing), enamelwork, and precious stones often ornament reliquaries. They vary considerably in form; like the Tibetan reliquaries, or *ga'u*, they may be constructed on a small scale to look like churches, chapels, towers, *stūpa*s, or sarcophagi, but sometimes they assume the form of the relic, such as in the form of anthropomorphic statues, busts, hands, feet, and other forms. Occasionally, as in Tantrism and Tibetan Lamaism, the bones of holy persons are used to make ritual musical instruments—flutes, horns (*rkang-gling*), and drums (*ḍamaru*)—or objects such as the ritual scoop made of a skull cup (*thod-khrag*) and a long iron handle encrusted with silver.

In many Asiatic regions, however, human relics are replaced by copies of sacred texts introduced into statues of bronze, as in Tibet and Yunnan (China), or of stucco, as in Afghanistan (Haḍḍa, an archeological site near Jālālābād excavated since 1928) in about the 4th–6th centuries.

Other ritual objects. *Objects used in prayer and meditation.* In many religions the practice of prayer requires the use of certain objects, among which rosaries (strings of beads) and chaplets (circular strings of beads) occupy an important place in the popular piety of various religions. They are widespread in Hinduism, Buddhism,



Multiple gateways and enclosures delimit the sacred area of the temple of Srīrangam, India.

Protecting the mystery by creating a sacred space

Jewish ark of the Law, functioning as sacred furniture, encloses and protects the Torah. Wooden ark from Modena, Italy, 1505. In the Musée de Cluny, Paris.

Muslim prayer rug, protective object associated with prayer, symbolizes the sacred area of the mosque. Silk and wool rug from Turkey, 17th century. In the Staatsbibliothek, Berlin.

Torii marks the entry to the sacred space around a Shintō shrine, Hakone-yama, Japan.

Use of rosaries and chaplets

Islām, Roman Catholicism, Eastern Orthodoxy, and Judaism, although they are not found in Shintō. Brahmanic and Buddhist rosaries have 108 beads, made of *tulasī*, or basil (in Vaiṣṇavism), of lotus seeds or small bones (in Śaivism), or of small disks of human bone (in Lamaism). In China, rosaries are composed of coloured beads. Elsewhere, their number varies; the rosary of Japanese Buddhism has 112 wooden beads, that of Islām has 99 amber beads, and that of the Christian world—and of the well-to-do Jaina—has 150 beads made of various materials, such as wood, pearl, mother-of-pearl, precious or semiprecious stones, gold, and silver. The beads of Brahmanic and Buddhist rosaries are usually strung continuously, except in Japan, where cords—which may or may not have beads on them—are tied to the principal cord in several combinations. The Christian rosary is divided into "decades" (tens) with intercalations, and in many cases the rosary has a "head" composed of a larger bead, several other beads, and a Christian cross.

There are several other objects pertaining to prayer—in addition to the rosary, which is principally a mnemotechnic (memory-technique) device. One example is the Lamaist prayer wheel (*'khor-lo*), which varies widely in size. It is a cylinder, generally of chased metal, rotating on an axis and containing prayers inscribed on strips of paper, fabric, or parchment. Weighted by two balls suspended externally on small cords, the prayer wheels are set in motion when a hand rotates a handle extending from the axis or when the prayer wheels are aligned along a common axis. Some are driven by hydraulic power and others even by electrical power. There is some evidence of the use of prayer wheels among other peoples, such as the Japanese, the ancient Celts and Bretons, the ancient Greeks, and the ancient Egyptians. The idea of permanent prayer through the agency of objects is found in the candles lit in churches, in the perpetually burning lamps (*chōmyōtō*) of Buddhist Japan, and in Tibetan prayer flags, with sacred formulas painted on them, which wave in the wind around temples, houses, and villages. The phylacteries (*tefillin*) worn by traditional Jews during weekday morning prayers consist of two leather cases bound by leather straps to the forehead and left forearm; they contain parchment citations from the Pentateuch enjoining this as a reminder of God's commandments. An amuletic function has been attributed to them, but this is disputed. Among protective objects associated with prayer are Muslim prayer rugs, the rectangular shape of which symbolizes the sacred area of the mosque, and the fringe-trimmed prayer shawl (*ṭallit*) worn by devout Jews during synagogue services.

Permanent prayer by means of ritualistic objects

Related to prayer and meditation are sacred and magical diagrams. Typical examples are the *yantras* (two- or three-dimensional meditation apparatus, often geometrical or anthropomorphic in form) and *maṇḍalas* (symbols of the cosmos in the form of circles, squares, or rectangles) of Brahmanism, Tantric Buddhism, and Lamaism and found in India, Nepal, Tibet, China, Korea, and Japan. Derived from sacred syllables (*mantras*) or from geometric designs endowed with mystical and cosmological symbolism, they are executed on sand, on the ground with coloured powders, and on durable materials. They may be made on stones, engraved on plates of copper, silver, or some other metal, or drawn and painted on skins, linen, silk, or hempen cloth. Like statues, they are consecrated by the rite of "initiation of breath," *prāṇapratiṣṭhā* (see also PRAYER).

Objects used in purification rites. Large numbers of purification rites are performed universally on widely varying occasions, both in private life, from conception to death, and in religious ceremonies. Such rites employ materials that include water, dust, or dry sand (in Islām); water and henna, a reddish-brown dye (in Islām); oil, incense, balm, and natron, a salt (in ancient Egyptian religion); ale (*öl*) or wine (in post-15th-century Germanic religion); salt (in Shintō); bread, sugar, spices, and animal blood (in ancient Greek and Scandinavian religions); paper, used in the Shintō *gohei*, a white paper "whip" that is shaken; ashes, among the Brahmans; and other materials. Water, fire, and light play especially important roles in purification rites. Objects used in such rites include water vessels of various shapes and sizes used for ablutions; jugs and vats containing ale or wine; terra-cotta or glass containers used for balms and perfumes; incense burners, cauldrons, and censers for fumigation; containers used in Confucian rituals, which include a basin (*chin-lei*) for pure water, another small basin (*huan-po*), and seven goblets (*chio*) for the sacrificial wine; and ewers and basins of gold, silver, or copper used in purifying the hands and feet, as in pre-Hellenistic Egypt, or for ritual sprinklings.

Forms of objects in purification rites

The wearing of new clothes that have not yet been washed is also a purification rite, practiced, for example, in the spring of the year (October–November) in Brahmanic India, where it is associated with the festival of lights, the Dīpāvālī.

Purification may also be attained through mortification and penance, practices that were especially common in medieval Christianity and in Judaism. Methods included the wearing of hair shirts or sackcloth, wearing haircloth undergarments and belts bristling with spikes next to the skin, and flagellating oneself with a scourge made of leather straps or lashing oneself with a whip, such as the *sraoshō-karana* of Persia (see also PURIFICATION RITES).

Objects used in rites of passage. Most of the objects noted above have played or still play a role in rites of passage. Such objects play a secondary role in all such rites, which include rites of initiation, marriage, and death.

Objects of initiation and ordination rites

Circumcision in pre-Hellenistic Egypt and among the Hebrews, Muslims, Ethiopians, and certain primitive peoples was and is performed with a flint-blade knife, with some other kind of sharp knife, perhaps of metal, with a razor, or (as in Africa) with a pair of scissors. Among the Zulus and other African tribes, bull-roarers were launched on such an occasion of initiation. In the Brahmanism, Zoroastrianism, and Parsiism of the Indo-Iranian world, a sacred cord (Pahlavi *kuṣṭī;* Sanskrit *yajñopavīta*) is the mark of initiation; in Iran and among the Parsis (Zoroastrians in India), the *kuṣṭī* is wound around the torso, and in India the *yajñopavīta* is passed diagonally from shoulder to waist. Among the Parsis, including the women, the cord is made of strands of lamb's wool or of goat's or camel's hair, and in India the material varies according to caste and may be cotton, hemp, or wool. In addition, the Zoroastrians and Parsis wear a sacred shirt (*sudra*) made of two pieces of white cambric stitched together. For ordination, a shawl, a cotton veil (*padān*) to cover the nose and mouth, and a mace are added; the Brahmanic (Vedic) initiate also receives a tall staff and a black antelope skin. In Sikhism (an Indian religion combining Hindu and Muslim elements, founded by Gurū Nānak in the 16th century), initiations of novices formerly included drinking water into which sugar had been mixed with the blade of a dagger (*khaṇḍā*).

In the initiation of Buddhist monks, the tonsure (cutting the hair of the head) is performed with a razor with a handle, and each initiate receives three red or yellow garments, a belt, a bowl for alms (*pātra*), a filter or ewer (*kuṇḍikā*), an alms-collector's staff (*khakkara*), a needle, a toothpick, and a fan. Japanese Tantric monks are initiated when they are past 50 years of age, at which time they are baptized (*abhiṣeka*) by having water from five *kuṇḍikā* poured on their heads and receive, in addition to the objects listed above, a *vajra* ("thunderbolt"), a wheel (*cakra*), and a conch (*saṅkha*). The principal objects involved in the initiation of Christian priests and monks are the tonsure and sacerdotal vestments. The Buryat shaman receives, in addition to his magical cloak and drum, a four-legged chest (*shiré*) decorated with lunar and solar symbols.

Objects related to rites of marriage

The religious character of marriage is not universal. Objects involved in the ceremonies of betrothal and marriage include jars (*loutrophoroi*) for the water of the prenuptial bath of ancient Greece; metal rings placed on the ring finger of the betrothed or married couple among Hebrews, Zoroastrians and Parsis, and persons in classical Rome and in both Eastern and Western Christianity; the bridal veil, orange (*flammeum*) in Rome and

white in the Christian and Slavic worlds; the bride's crown, made first of marjoram and verbena and later of myrtle and orange blossoms in Rome and of various materials in the Christian and Slavic worlds; and the crown held above the heads of the bridal couple in Eastern Orthodox marriage ceremonies. In Roman and Slavic marriage rites a tunic or shirt was used, and in Hindu rites a yellow wool bracelet (*kautukasūtra*) is tied around the wrist of the betrothed girl by her mother.

The marriage ceremony sometimes takes place under a marriage pavilion or canopy, as among the ancient Etruscans of Italy. The Hebrews first used a closed tent (*ḥuppa*) and later a silk or tapestry canopy to symbolize the nuptial chamber. Hindus and Parsis use a tent or pavilion (*pandāl*), in which the bridal couple are initially separated by a curtain. Among the Sikhs, a paper parasol (*agast*) is rotated continually over the head of the bridegroom.

In some areas, particularly in contemporary Hindu India, a swing (*dolā*) is set up under the *pandāl*, on which the couple seat themselves after the official ceremony. The seesaw here symbolizes prosperity, love, and the union between earth and sky. The *aiōra* ("swing") used in the ancient Athenian Dionysiac festival, the swings of the spring festivals at Puri (Orissa) and in Thailand, also have similar symbolic connotations. During the winter solstice, a Vedic sacrifice (*hotṛ*) is performed on the swing (*preṅkha*).

Objects related to funeral rites

Except for Brahmanic and Buddhist ritual suicides by drowning, which require neither ceremony nor funeral apparatus, there are three methods of disposing of dead human bodies: cremation, stripping of the flesh, and inhumation, performed with or without embalming. These methods have coexisted and still coexist throughout the world. The preparation of the corpse often depends on the method adopted, which, in turn, governs the objects and instruments used. In Japanese sects, particularly in the Shingon and other Buddhist sects, a razor (made of gold in the Jōdo sects) is used for an actual or simulated tonsure of the head of the deceased. A mirror, used in magic to detect evil spirits, figured in the judgment of souls in ancient China. A copper mirror was placed under the head of the dead of pre-Hellenistic Egypt; one of bronze was placed near the head in Buddhist Japan. In Vedic and Brahmanic India, thin pieces of gold were used to close the facial and bodily orifices, and pieces of jade served the same purpose in ancient China. Mortuary masks made of gold, bronze, hard stone, many-coloured terra-cotta, and other materials were used at Mycenae, in pre-Hellenistic and later in Coptic (early Christian) Egypt, in Peru, and elsewhere to cover the face and sometimes the chest. Elsewhere, a cloth covering the face or a shroud, which often was red, was considered sufficient. Pieces of money to pay for the passage from this world to the next were placed in the mouth of corpses in ancient Mycenae, Greece, and Rome and in a pouch in Japan.

Corpses have been borne to funeral sites by various means. Among primitive peoples and in Tibet, they are carried on the back or in the arms, and among the Jews, Muslims, Parsis, Slavs, and Hindus they are carried on biers, which are sometimes richly decorated and are either put in a tomb or destroyed. In modern Western countries, the funeral chariots of Rome and elsewhere have been transformed into motor hearses, while the contemporary Chinese and Vietnamese use carts that have been specially fitted out. Funeral boats were used in pre-Hellenistic Egypt, in ancient Scandinavia, and in the Pacific islands; Venetians of Italy still use gondolas for funeral rites. The sledge was used in the Kurgans of southern Russia.

Cremation practices and objects

When cremated, the corpse is often burned with its bier. In the Buddhist world, as, for example, in Cambodia and Thailand, it is burned in a wood and paper coffin made in the form of a sacred animal, with a cloth canopy surmounting the pyre. If the ashes are dispersed after cremation, as in India, they are collected in a cinerary urn. The form and composition of such urns have varied considerably, being made of terra-cotta, stone, porphyry, alabaster, bronze, silver, gold, ceramic ware, and other materials. The urn is placed in the grave, as in ancient Assyria and elsewhere, on a bronze or terra-cotta support (usually an armchair) and lowered into a large jug, as among the Etruscans, or in the niches of the cineraria (places containing ashes of cremated bodies), columbaria (vaults containing urns of cremated bodies), or catacombs, as in Etruria (in Italy), Greece, and Rome. Among the Zapotec of Mexico, the ceramic urn was placed in the niches of cells, the *mogotes*, made beneath hills set aside for the purpose, a practice also observed by the Mosquito Indians of Nicaragua. In Buddhist countries the urn is often displayed on the domestic altar, and in Tibet the imperfectly calcined bones are ground up and mixed with clay and the mixture is molded into the form of a votive offering (*tsha-tsha*), which is placed in the niches of the funeral *stūpa* (*mchod-rten*). In ancient India the terra-cotta "feminine" urns had a pair of "breasts" formed by two bowls stuck onto the bulge of the urn.

Stripping the flesh of the corpse generally does not require the use of specific objects, since it is the work of vultures or sometimes of pigs, dogs, or other animals. The Parsis, however, build "towers of silence" (*dakhma*) for the purpose, to which they accompany the deceased with a pot containing fire.

Bodies have been and still are sometimes buried without coffins, as in Rome, where they were put into pit tombs. Among primitive and prehistoric peoples, ancient Egyptians, and the people of the Harappā civilization (*c.* 2500–1700 BC) of the Indus, the corpse was wrapped in a mat made of plant fibres. Coffins are sometimes carved or painted, and the crudest ones—such as those used by ancient Romans and primitive peoples—are made from hollowed-out tree trunks. Some coffins are modelled according to the human form, such as the colourful wooden coffins of pre-Hellenistic Egypt or the Chinese coffins covered with jade mosaic of the 2nd-century-BC Han dynasty. The majority, however, are oblong and made of wood; in ancient Greece, coffins were made of cypress. Tibetan coffins (*ro-sgam*) and Japanese Buddhist and Shintō coffins, however, are cubical, with the corpse placed in a sitting or crouching position. Among certain coastal peoples—*e.g.*, the Vikings—the deceased is either buried in his boat or put out to sea and cremated with it. Sarcophagi—used in many civilizations—were made of various materials; terra-cotta in Etruria, Greece, southern India prior to the 2nd century BC, and Japan; wood and stone in Japan; and marble in late Rome and in the Christian world. They are often richly decorated with symbolic or allegorical carvings and are frequently very colourful. In ancient Egypt the viscera were placed separately in canopic (burial) jars. The Etrurians also used such jars, the covers of which were decorated with the portrait of the deceased.

Use of coffins, burial boats, and sarcophagi

From prehistoric times, the deceased was accompanied by ordinary objects placed either in the coffin or in the grave itself, the most common of which were drinking cups, pitchers, cups or vessels for solid food, weapons, tools and ornaments, and jewelry. Ancient Chinese collections of funerary objects of high quality have been exhumed, but the most complete outfitting of the dead was that of the Egyptian tombs, which is completed by scenes painted or carved on the interior walls of the rooms of the tomb. Funeral models of houses, wells, farms, herds, and armies were used in the Han (206 BC–AD 220), T'ang (618–907), and Ming (1368–1644) periods of China as well as in ancient Egypt. Figurines representing the deceased were included among Egyptian funerary objects, along with figurines representing his retinue; in China the retinue figurines included dancers, musicians, and soldiers (*ming-ch'i*). The models were probably substitutes for the servants who formerly had been sacrificed in the royal tomb. For a long time the Chinese figurines were made of ceramic decorated in many colours, but in more recent periods (*i.e.*, after the revolution of 1911 and during the 19th century) they were straw effigies.

Some of the individual objects used in funeral rites include situlae, Roman and Egyptian bronze libation jars with a handle on the tops; Indian Brahmanic terra-cotta

jars with perforated bases, which are broken after their use in the aqueous purification of the pyre; and cages containing birds (Buddhist Japan), sometimes eagles (ancient Rome), released near the tomb after burial. There are also the objects used in postmortem rites, such as the tablet of the ancestors (Japanese *ihai*) in China, Japan, and Vietnam and the miniature straw boat, flat-bottomed and with a curved prow, which is set afloat with a bit of candle and food during the Japanese Shintō festival of lights (Bon Matsuri), returning the spirit of the ancestor to the land of souls after three days' visit (see also PASSAGE RITES).

Sacrificial sites

Objects used in sacrifices and in sacred meals. The most elementary type of site in which a sacrifice is performed is simply a massive rock or a hilltop, with no accoutrements. Menhirs (*e.g.*, the Hebrew *matzeva*, a conical stele rubbed with oil at the top), megaliths, and sacrificial posts (*e.g.*, the Vedic *yūpa*)—which are widespread throughout the primitive world—are also quite rudimentary. Altars, properly speaking, are set up either on sacrificial sites or in temples and may be either hollowed out in the earth or raised or constructed. Both of these categories are unknown in Africa and South America, where sacrifices are made on the ground or on a bed of sand. The first category includes the *vedi* ("altar") of Vedic rites, trenches, pits, and ditches dug in the earth. Some of the hollowed-out sites are used for a sacrificial fire and some for collecting victims' blood, as in Greece, pre-Sāsānid Iran, and pre-Islāmic Arabia. The altar is most often a table with one, three, four, or more legs. The top may be smooth, or it may be provided with drains for blood and liquid libations or with dishes to hold solid offerings, such as the firstfruits—*e.g.*, the *kernoi* (small sacrificial pots) of the pre-Hellenic Aegean civilization.

The altar may be round or oblong or may imitate other forms, such as the Indian Vedic altar, which was made in the form of a bird with spread wings. Altars are usually fixed in place and are made of various materials: clay (pre-Columbian religions of Central America); terra-cotta (*kernos*) and stucco-covered sun-baked bricks (religions of ancient Greece); fired bricks (Vedism in ancient India); wood (Buddhism and Shintō of Japan, primitive religions of Polynesia, and Christianity in Western and Nestorian—an Eastern independent church—churches until the 10th or 11th century); wood plated with metals, such as bronze and gold (the religions of the Hebrews and Byzantine Christians); and metals, such as iron (Germanic religion), bronze (ancient Near Eastern religions), and gold (5th- and 6th-century Byzantine Christianity). Most commonly, however, altars are made of stone slabs resting horizontally on legs, columns, or lateral supports, although the pre-Sāsānid Iranian slab altar (*ādōshi*) rested on a pedestal. The Christian altar is square or oblong; that used in Greek hero worship was rectangular, as was the altar of pre-Hellenistic Egypt, which was made of alabaster. Some altars, such as the marble Altar of the Earth at Peking, are cubical, and others, such as the Altar of Heaven at Peking and ancient Phoenician altars, are cylindrical. Occasionally, as in Greece, they are hollow and contain the ashes of burnt offerings. The Roman Catholic altar is required to contain a stone, no matter what the predominant material may be.

A throne may be a special form of altar and may be either a true piece of furniture fashioned in wood or metal or a seat carved out in rock. It also may surmount a stele, as in northern Vietnam and Bali.

Equipment for sacrifices

Sacrificial weapons, like the utensils, vary according to the nature of the sacrifice. The most common weapon is the knife, which is used to slit the throat of the human or animal victim, a practice observed, for example, by Semites, Muslims, and ancient Greeks. Sometimes the knife is cast into the sea after use. An ax involved in the Athenian Bouphonia ("Ox-Slaughtering Festival") was carried to the tribunal of the Prytaneum (the town hall, containing a community altar or hearth), inspected, and then submerged in the same way. Sometimes a poniard or dagger was used, such as in the Mithraic sacrifice of a bull; a ritual knife (*khadga*) shaped like a sickle, with the outer edge forming the cutting edge, is used in the sacrifice of black goats to Kālī (a Hindu goddess who is the consort of Śiva) in Calcutta. In the great imperial sacrifice of the horse (*aśvamedha*)of Vedic India, a gold-ornamented knife was used to sacrifice the horse, but knives of copper and iron were used for other animals. In the sacrificial rites of contemporary primitive peoples, a sword, which varies in size and form, generally is used. In ancient Iran the victim was slaughtered with a log or pestle. In all sacrificial rites, it should be noted that a flow of blood is always necessary, even when the victim is clubbed.

Sacrificial victims are also very frequently burned or else are cooked for a communal meal. Vessels for holding and maintaining the sacrificial fire may be used in such situations. Two such vessels have been well described in religious literature: the Vedic Indian vessel (*ukhā*) made of earth and fired in a pit on the sacrificial grounds and the urn (*ātash-dān*) of pre-Sāsānid Iranian fire altars. Sometimes the ashes were collected in cauldrons (the ancient Hebrews), and occasionally the viscera were placed separately in a gourd (Africa) or on a tray (pre-Hellenistic Egypt and contemporary Africa). When intoxicating beverages—such as the Avestan Iranian *haoma* and the Vedic Indian *soma*—are made at the same time as the sacrifice, the inventory of ritual objects necessarily includes the stones for pressing the plants, a wooden vat, a filter, and a libation cup at the fire.

Types of objects in libation rites

Three types of objects used in ablution and libation rites may be distinguished. First are the containers for storing liquids, such as water, fermented liquor, wine, and blood. A second type includes utensils—*e.g.*, spoons and ladles—used for drawing off liquids, which are fashioned out of pieces of wood of different, although ritualistically defined, varieties. The third type comprises the containers used directly for ablutions, libations, and oblations—*e.g.*, the ewers of Sumer, Egypt, and Vedic India; gold, silver, copper, or iron *pātra* of the Vedic and Brahmanic world; Hebrew goblets; cups of various forms, such as the Vedic and Tantric skull cup; the phial (bowl) and patera (shallow libation dish) of the Roman and early Christian worlds, made of gold, chased and engraved metal, semiprecious stones, or glass; the Australian bark *pitchi*; and the ciborium (covered container for the consecrated bread) and chalice (cup containing the consecrated wine) of Roman Catholic, Anglican, and Lutheran worship. The cup of the chalice must be made of gold, silver, or vermeil (gilded silver, bronze, or copper).

Other objects pertaining to sacrifice

The sickle for harvesting plants, a winnowing basket for preparing grain offerings, a reed broom for cleaning the sacrificial area, the scoop for collecting ashes used in Vedic India and by the Hebrews (who made it of gold or bronze), and baskets for presenting offerings of fruit or cakes are among the many other objects used in sacrificial rites. In order to consecrate such offerings, a priest of ancient Egypt touched them with a sceptre (*kherep*).

Ornaments used in sacrificial rites are of many different types. The adornment of the victim before sacrifice may take the form of gilding the horns, as in ancient Greece, or putting a necklace or garland of flowers on it. The priest may wear a breastplate, as in Egypt, Etruria, and Jerusalem, or a gold ornament—*e.g.*, the Vedic Indian *nikṣa*—around his neck. Divine statues also may be adorned with jewels, diadems, tiaras, and garments consisting of goldworked covers, a practice still observed in southern India, or with ceremonial apparel, a Christian practice observed in the veneration of saints, particularly in Czechoslovakia (Prague), Poland, and France (Brittany). Altars are permanently or occasionally decorated with incense burners, candelabra, and vases of flowers. Artificial flowers have been used on altars in Japan since the 7th century.

Finally, many sacrifices are accompanied by music, which may be viewed either as a protective measure or as an offering of sound. The musical instruments used in worship do not necessarily assume any special form, but they are often played by the priests themselves, as among Hindus, Tibetan Tantrists, and Hebrews, or are reserved for the accompaniment of particular rites. The silver

trumpets of the Hebrews and the conches of Indian-influenced countries are used in this way.

Objects used in temple, state, and private ceremonies. A large number of ordinary objects produced especially for the god have been used in the daily worship of divine statues. The most complete and best described rites were those practiced in ancient Assyria and Egypt and those still observed in the Vaiṣnavite temples of southeastern India. Such objects are identical in form to those ordinarily used by men, although the materials may vary: earthenware jars for "pure" water; table service, which may include plates, trays, bowls, cups, and pitchers; clothing; pots and flasks for salves and perfumes; jewels, ornaments, flower garlands, and metal mirrors; thrones and platforms; a swing; palanquins (enclosed litters), processional chariots, and boats for the god's journeys outside the temple; musical instruments, such as drums of all sizes, lutes, clarinets, and conches; and parasols, fans, flyswatters, standards, and oriflammes (banners).

The principal ceremony that pertains to the state is the coronation of the king or emperor. In addition to the pomp displayed on such occasions, the most significant objects generally are the containers used in baptizing or anointing the king, such as the sacred conches or antelope horns used for the lustral water in Indian-influenced countries and the Holy Ampulla (flask) for consecration oil, used particularly in France; the throne, which is the essential object of the ceremony in almost all civilizations; and the crown, the sceptre, the hand of justice, and the globe of the Byzantine, Iranian, and Western worlds.

Domestic rites were observed daily in ancient Rome, Brahmanic India, the Buddhist world, China, Japan, and other areas, as they still are in many places. The objects involved in such ceremonies are the same as those used in temple worship. Permanent altars, which are often placed near the entrance, contain statues, the tablets of the ancestors, and offerings of flowers, incense, fruits, and lights.

CONCLUSION

Ceremonial and ritual objects in past times have held and still hold, in many cases, a very important place in the civilizations of the world. From prehistoric times, they have played an integral part in the evolution of the various civilizations on two levels: (1) on the level of rites and rituals practiced in everyday life and (2) on the level of the more solemn and rare cultic and communal rites. From a merely functional standpoint, such objects serve sacred or symbolic purposes; their construction, forms, dimensions, and styles have been, from earliest times, codified. Some have been so closely associated with the divine or the sacred that they have been considered either a symbolic manifestation of the deity or an actual manifestation of the deity itself. In general, however, they lose in the course of time this particularistic characteristic. In this process, they generally survive only in a formal sense, and thus henceforth are devoid of any sacred power.

BIBLIOGRAPHY

General Works: JAMES HASTINGS (ed.), *Encyclopaedia of Religion and Ethics*, 13 vol. (1908–26, reprinted 1955), is the most complete source, although it is already outdated. See also the *Histoire générale des religions*, 2nd ed., 2 vol. (1960); *Symbolisme cosmique et monuments religieux*, 2 vol. (1953), texts and illustrations from an exhibit at the Musée Guimet, Paris; and *Le Symbolisme cosmique des monuments religieux* (1957), the proceedings of an international conference of the Istituto per il Medio ed Estremo-Oriente, Rome.

The Ancient period: CHARLES V. DAREMBERG and EDMOND SAGLIO (eds.), *Dictionnaire des antiquités grecques et romaines* . . ., 5 vol. (1877–1919), complemented by the work of PIERRE LAVEDAN, *Dictionnaire illustré de la mythologie et des antiquités grecques et romaines* (1931). MIRCEA ELIADE, *Le Mythe de l'éternel retour*, 5th ed. (1949; Eng. trans., *The Myth of the Eternal Return*, rev. ed., 1965).

The Holy Place: JEANNINE AUBOYER, *Introduction à l'étude de l'art de l'Inde* (1965), is a basic work. For the principal components of the Holy Place, see JAMES FERGUSSON, *Tree and Serpent Worship*, 2nd ed. (1873), which uses Indian facts as a base but makes many comparisons with data from antiquity. This work is complemented by ODETTE VIENNOT, *Le Culte de l'arbre dans l'Inde ancienne* (1954). JEANNINE AUBOYER, *Le Trône et son symbolisme dans l'Inde ancienne* (1949), makes many references to the role and to the morphology of the throne (royal and/or divine) in the different ancient and modern civilizations. D.R. SHASTRI, *Origin and Development of the Rituals of Ancestor Worship in India* (1963), is helpful. JEAN PRZYLUSKI, "Le Symbolisme du pilier de Sarnath," in *Mélanges d'Orientalisme*, vol. 2 (1932), deals with the gnomon and the cosmic pivot. See also LEOPOLD M. CADIERE, *Croyances et pratiques religieuses des Annamites dans les environs de Hue:* vol. 1, *Le Culte des arbres* (1918) and vol. 2, *Le Culte des pierres* (1919).

Architectural symbolism: GEORGE COEDES, *Pour mieux comprendre Angkor*, rev. 2nd ed. (1947; Eng. trans., *Angkor: An Introduction*, 1963), contains pertinent information in the chapters on temples and tombs and on architectural symbolism. ROLF A. STEIN, "Architecture et pensée religieuse en Extrême-Orient," *Arts Asiatiques*, 4:163–186 (1957), deals with tents used in Central Asia, especially Siberia and Rupestral temples, with their particular arrangements.

Icons and ritual symbols: See J.N. BANERJEA, *The Development of Hindu Iconography*, 2nd ed. (1956), particularly ch. 2, "The Antiquity of Image-Worship in India," ch. 5, "Deities and Their Emblems on Early Indian Seals," and 8, "Canons of Iconometry"; also GEORGE COEDES (*op. cit.*), ch. 3; and PIERRE FRANCASTEL (ed.), *Emblèmes, totems, blasons* (1964), an exhibition catalog of the Musée Guimet.

(1963); for Christianity, *Historia Religionum*, vol. 1, *Religions of the Past* (1969); and OSCAR CULLMANN, *Urchristentum und Gottesdienst*, 2nd ed. (1950; Eng. trans., *Early Christian Worship*, 1953); for Hinduism, *The Cultural Heritage of India*, vol. 1, *Vedic Rituals*, rev. ed. (1958); and PAUL E. DUMONT, *L'Aśvamedha: description du sacrifice solennel du cheval dans le culte védique* (1927); for Buddhism, *Hôbôgirin: Dictionnaire encyclopédique du Bouddhisme* . . ., 4 vol. to date (1937–67); and GEORGE P. MALALASEKERA (ed.), *Encyclopaedia of Buddhism*, 2 vol. to date (1961–68); for the Indian world, JAN GONDA, *Die Religionen Indiens*, 3 vol. (1960–64); for Indonesia, WALDEMAR STOEHR and PIET ZOETMULDER, *Die Religionen Indonesiens* (1965; French trans., 1968); for the Islāmic world, the *Encyclopaedia of Islam*, 5 vol. (1908–38; new ed., 1960–); for Tibet, ROBERT B. EKVALL, *Religious Observances in Tibet* (1964); HELMUT HOFFMANN, *Symbolik der tibetischen Religionen und des Schamanismus* (1967); ROLF A. STEIN, *La Civilisation tibétaine* (1962); and TURRELL WYLIE, "Apropos of Tibetan Religious Observances," *Journal of the American Oriental Society*, 86:39–45 (1966); and for Japan, WILLIAM G. ASHTON, *Shinto* (1905).

(J.Au.)

Cervantes, Miguel de

Miguel de Cervantes Saavedra was the outstanding genius and supreme innovator of Spanish literature. His *Don Quixote*, after the Bible the world's most widely translated book, is considered both the first and, by many, still the greatest of modern novels. A playwright and poet as well as a novelist, he was also the inventor of the psychological short story in Spain. His influence on the English novel—Fielding, Sterne, Smollett—was profound. His 68 years span the era of Spain's greatness and incipient decline. From the long record of struggle and achievement in the face of consistently hostile circumstance, he emerges as one of the noblest characters in his country's story.

He was born, the second son and fourth of seven children of Rodrigo de Cervantes and Leonor de Cortinas, at Alcalá de Henares, some 20 miles east of Madrid, which since 1510 had been the seat of Spain's second great university. His birthdate is not recorded, but the choice of name—Michael—suggests Michaelmas, September 29; he was baptized on October 9, 1547. Rodrigo's father had made a career in the law, serving as magistrate in various parts of Spain; but Rodrigo led the more precarious existence of an itinerant apothecary-surgeon. Known to have been in Valladolid in 1552–53, where he was imprisoned for debt, he moved his family to Madrid when Philip II established that still-small town as his capital in 1561. Miguel thus lost his chance of a university education; in its place he had early contracted a passion for reading, so that, as he tells, he would pick up scraps of

First literary interests

paper in the street to read. The self-educated man, later to become one of the best read and most intellectually curious Spaniards of his day, was already in the making; and in Madrid he had his chance of further schooling.

In 1569 Cervantes published his first known work in a volume of exequies to Philip's third wife, Elizabeth of Valois, the beautiful French princess whose early death on October 3, 1568, had plunged the nation into mourning. The editor, Juan López de Hoyos, Latin scholar and schoolmaster, included an elegy by Cervantes "composed in the name of the whole school" and twice referred to him as "my beloved pupil." As he was 21 at the time, it is assumed that Cervantes was a pupil-teacher, had studied earlier under López de Hoyos, and kept in touch with him. A link with the theatre is provided by Cervantes' reminiscence in 1615, a year before his death, of how as a boy he had seen Lope de Rueda, the author-actor-manager who, touring Spain with his troupe over the years 1551–65, did much to create a public for the nascent Spanish drama. From that experience doubtless stemmed the intense interest he displayed at the beginning and again at the end of his literary career in writing for the stage.

On September 15, 1569, a warrant was issued for the arrest of one Miguel de Cervantes, missing from the capital, against whom sentence had been pronounced of the loss of his right hand and ten years' exile "for wounds inflicted on Antonio de Sigura in Madrid." This, if the identity is accepted, would explain why he is next heard of in Italy, where territorial interest—the kingdom of Naples was then a patrimony of the Spanish crown—and, earlier, long involvement in the wars with France over Milan made a 16th-century Spaniard feel almost as much at home as in his own country. Much later he speaks of having served in the household in Rome of Cardinal Giulio Acquaviva, who had visited Madrid on a papal mission toward the end of 1568. It was presumably for this reason that Cervantes wrote from Rome to his father for certification of his *limpieza de sangre*, or untainted Christian descent, the criterion that played such a large role in social advancement in the Spain of the Inquisition. Backed by three witnesses, Rodrigo duly averred that neither he nor his wife, nor their parents nor grandparents, were or had been "Moors, Jews, converts or reconciled by the Holy Office of the Inquisition" but were old Christians of good stock and that Miguel was their legitimate son. The document is dated December 22, 1569.

Soldier and slave. Of his life in Rome, nothing more is known save that it was brief. But to have come at an impressionable age from the still-parochial Madrid to the hub of the Christian universe and a city whose surpassing beauty he treasured in memory for life proved a great enrichment of mind and all the senses. It proved a stimulus, too, to action. Spain's military concern to maintain its dominance in Italy and keep the French out was matched by an even more challenging naval rivalry with the Turks over control of the Mediterranean. The capture of Cyprus by Selim II, sultan of the Ottoman Empire, in 1570 —a sore blow to the pride and might of Venice—raised for Christendom as a whole the ugly spectre of a resurgent Islām. Pope Pius V, concerned for his own dominions, appealed to the powers to join in a holy league against the infidel. Only Venice and Spain responded, and the triple alliance was signed on May 20, 1571. Don John of Austria, half-brother of Philip II, was chosen as commander in chief. Recruiting had been under way since the previous summer, and Cervantes enlisted in a Spanish contingent in Rome that was ordered to Naples to await the arrival there of the main fighting force from Spain. It was a long wait. "Illustrious Naples," he was to write late in life, "whose streets I trod for over a year." Don John arrived on August 9 and three weeks later put to sea with 35 galleys for his rendezvous with the other fleets at Messina. The armada that sailed in search of the enemy on September 16 numbered 208 galleys, seven galleasses, and 24 sailing vessels, the largest Christian fleet the world had seen; the soldiery they carried totalled 26,000.

On October 7, 1571, the enemy was discovered drawn up in battle formation in the Gulf of Lepanto, at the entrance to the Bay of Corinth, and there ensued, in Cervantes' proud words, "the greatest occasion that past or present ages have witnessed or that the future can hope to witness." His ship, the "Marquesa," was in the thick of the battle, and none on the "Marquesa" or on any other —the testimony is cumulative and compelling—outshone him in bravery. Ill with fever, he refused to go below and, seeking out the most exposed position, was twice wounded in the chest, a third shot permanently maiming his left hand, "to the greater glory," as he says, "of the right." Of his part in the battle, Cervantes remained prouder throughout his life than of anything else. It was a crucial encounter for the West and was hailed as a mighty victory, although the threat from the East was far from laid: within the year a Turkish fleet would again be menacing the Adriatic.

Hero at Battle of Lepanto

Cervantes lay convalescing in a hospital in Messina until, deemed fit to rejoin the ranks, he was assigned in April 1572 to the regiment of Lope de Figueroa, one of the great commanders of the age, who had fought alongside Don John in Spain and at Lepanto. Joined now by his younger brother Rodrigo, Cervantes shared in Don John's second and, this time, inglorious expedition to the Levant in October 1572, one that failed to bring the Turks into action; in the capture of Tunis a year later; and, when that city was besieged in the fall of 1574, in the relief expedition that failed to prevent its recapture by the Turks. In between there were periods of garrison duty at Palermo and Naples. Wedded now, it seemed, to a military career but not yet halfway to the ten years' service normally required for a captaincy, Cervantes obtained permission to return to Spain and seek preferment from the King himself. Armed with letters of recommendation from Don John and the viceroy of Naples, he set sail from Naples, still accompanied by his brother, in the galley "Sol," one of several bound for Spain, on September 20, 1575. Much as he had already seen and experienced, his adventures were only beginning.

Off Marseilles six days later, the "Sol," having lost contact with the others, was attacked by three Turkish corsairs, and Cervantes and his brother were among those captured and taken to slavery in Algiers. This nest of piracy, won from the Moors in 1516 and administered from Constantinople under a dey—or governor—drew substantial revenue from the enslaving and holding for ransom of Christians. The letters he carried suggested that Cervantes was a person of consequence worth a high price, and he was closely guarded, manacled at first, and thrown into a dungeon. In 1576 he organized an attempt at escape, but a Moor whom he had engaged to guide him and others to Oran—then in Christian hands—deserted them after some days' march, and the fugitives had to return to Algiers, where Cervantes was again fettered and

Taken into slavery

treated with additional severity. Early in 1577, priests of the order of Mercy arrived with 300 crowns sent by his parents. This, rejected for Miguel, sufficed for the ransom of Rodrigo, who sailed to freedom in August charged with a more daring plan for his brother's release, a plan that two other captives of high rank commended in writing to the viceroys of Valencia and the Balearics. On the coast some three miles outside Algiers, a city magistrate had a country house and garden and in the garden a cave. With the connivance of the gardener, a captive from Navarre, Cervantes gradually smuggled 14 fellow captives and finally himself into the cave against the arrival of a frigate from Mallorca. The vessel arrived as planned during the night but was detected. The alarm was raised, and a Spanish fellow slave took fright and revealed everything to Hasan Paşa, the notoriously cruel dey. Under threat of torture and death, Cervantes maintained that he alone was responsible, so impressing the dey by his fortitude that the dey bought him for his own service. Cervantes, kept in fetters for five months, tried to escape again, smuggling an appeal for help this time to the governor of Oran in March 1578. The messenger, apprehended on the way, paid with his life. Cervantes was sentenced to 2,000 lashes, but once more the sentence was remitted.

Attempts at escape

His family continued its efforts. That same month, his father presented a petition to the King, setting forth his son's services. His mother obtained in 1579 a license authorizing the trading from Valencia to Algiers of goods to the value of 2,000 ducats. She raised a further 300 ducats toward his ransom, entrusting the money to two Trinitarian monks. Cervantes plotted on, this time in league with two Valencians trading in Algiers, to secure an armed frigate that might carry some 60 of his fellow slaves to freedom. The frigate was bought, and once again he was betrayed on the threshold of success and brought before the dey with hands bound and a rope round his neck. As before, he assumed total responsibility; and as before, the dey spared his life but consigned him to a further five months in chains, declaring that "so long as he had the maimed Spaniard in safe keeping, his Christians, ships and city were secure." The Trinitarians arrived in Algiers on May 29, 1580, just as Hasan's term of office ended. Their funds fell short of the 500 gold ducats he demanded, but Christian traders in the town made up the balance, and on September 19, when Cervantes—who was to follow Hasan to Constantinople as his slave—was already on board ship, he was declared free. Literature has rarely had a narrower escape. He sailed for Spain on October 24 and proceeded to Madrid.

Civil servant and writer. The letters of recommendation that had cost him so dearly in captivity availed him, if he still had them, little now. The brief campaign that in 1580 incorporated Portugal into the Spanish crown—uniting the peninsula once more for the next 60 years—was just over, and some minor mission took him to Tomar in Portugal in May 1581, and thence as king's messenger briefly back to Africa, to Oran. Returning to Madrid disillusioned in his hopes of official employment, he consorted with writers and turned his hand to the writing of plays. Much later he mentions "twenty or thirty" as "worthy of praise," which are ascribed to the years 1582–87: "but the one I esteem and pride myself on most was and is *La confusa*, which, with all respect to as many cloak-and-sword plays as have been put on the boards up to now, may well stand out as good among the best." Of these plays, all of which, he tells us, were acted, only *El trato de Argel* and *La Numancia* have survived, in manuscript copies discovered in 1784. Anxious to establish himself as a writer, he started out by following the popular taste, and in 1584 he obtained a license to print a pastoral novel, *La Galatea*. Published in Alcalá, his birthplace, in 1585 and twice reprinted during his lifetime, it remained his own favourite; and for over 30 years, and still on his deathbed, he kept promising a second part.

Return to Spain and marriage

On December 12, 1584, he married Catalina de Salazar y Palacios of Esquivias, a village not far from Madrid, a girl 18 years his junior and of good family—her parents did not highly esteem the match—who brought him as dowry some vineyards and an orchard, various items of furniture, four beehives, 45 hens and chickens, and one rooster. It was probably a year or two earlier that he had had a daughter, Isabel de Saavedra, by one Ana Franca de Rojas. By his wife he had no children, but Isabel figured disturbingly in his life in later years. His father's death in June 1585 doubtless increased his responsibilities as the man of a household of many women, including his sisters and a niece, and gave new urgency to the search for a livelihood that was not to be had from writing. The license to print *La Galatea* he had sold for 1,336 reals.

In 1587 he went to Seville, presumably alone, to seek employment in the provisioning of the Spanish Armada, the fleet that was to convoy an army to invade England. This mundane employment marked the beginning of a 15-year hiatus in his literary career. Excommunication for excessive zeal in requisitioning grain belonging to the dean and chapter of Seville at Ecija initiated a long chapter of mishaps and dire financial straits in this new role of naval quartermaster, in which he was retained after the defeat of the Armada. In May 1590 he petitioned the King for one of four posts then vacant in the Indies: an accountantship in New Granada (modern Colombia), the governorship of a province in Guatemala, the position of auditor to the galleys at Cartagena, and the chief magistracy in La Paz. But the petition, referred to the council for the Indies, was there annotated: "Let him look for something nearer home"; and he continued as quartermaster, still centred in Seville. The harassments of so uncongenial a task were much increased by constant difficulty in securing payment of his 12 reals a day, soon to be cut to ten. In November 1590 he had to borrow ten ducats to buy himself a suit of clothes; in August 1592 the sureties of this would-be auditor or accountant in the New World were called on to make good a deficit in his accounting.

Quartermaster for the navy

Meanwhile, he was still attracted by the stage, and on September 5, 1592, he contracted with one Rodrigo Osorio of Seville to write six plays at 50 ducats apiece, each to be put on the boards within 20 days of delivery and payment to be withheld were each not to prove, to Osorio's satifaction, "one of the best ever produced in Spain." Nothing came of the agreement. Within a fortnight Cervantes was for some days in prison at Castro del Río, again on charges of illegal requisitioning at Ecija. Difficulties with the exchequer led him into deeper and deeper water. But if he could not keep his books, he seemingly still kept the respect of his superiors. In 1594 his pay rose to 16 reals a day. In odd moments of leisure he still picked up his pen. A gloss submitted to a poetic competition in Zaragoza in May 1595 won the first prize, three silver spoons. In mid-1596 he entrusted to a banker in Seville 7,400 reals for payment to the treasury in Madrid. The banker absconded, and not until January 1597 was the money recovered. Eight months later, Cervantes was committed to Seville jail and held for three months for failure to guarantee compliance with an order that he present himself in Madrid within 20 days. With this incident, his official employment appears to have ended, although in 1599 and again in 1601 the government was still summoning him to Madrid to clear up his accounts. Still in Seville, direst poverty on occasion reduced him again to borrowing for food and clothes.

The years 1600–03 are a blank. The possibility that he may have rejoined his wife in the tranquil obscurity of Esquivias is reinforced by the only thing to be inferred with certainty of this period, that he was busily engaged in the writing of *Don Quixote*, conceived initially as an elaborate parody of the "false and absurd" romances of chivalry that for a century had exercised a hypnotic attraction on readers of all classes. In the writing it became much more, revealing not merely a richly creative imagination and an infinite humour but Cervantes' insights into the nature of reality and the meaning of life in general. Philip III had removed the capital to Valladolid in 1601, and when Cervantes reappeared there in mid-1604 it was to see to the publication of his manuscript. License to print was granted for Castile in September, and in January 1605 *El ingenioso hidalgo Don Quijote de la*

Mancha appeared, in Madrid, with a dedication to the Duque de Béjar that seems to have brought no return in patronage. The book had an immediate success: its deep philosophic implications were not fully appreciated until the present century, but none could doubt its entertainment value. "That man is either crazy or he is reading *Don Quixote*," Philip is said to have remarked of a student observed from the palace balcony to be in fits of laughter over a book; the story epitomizes what has been the world's verdict ever since. Within a few weeks of the authorized publication, three pirated editions were issued in Lisbon.

Success of *Don Quixote*

A second authorized edition, with minor revisions, was hurried out in Madrid with a license extending now to Aragon and Portugal, and two further reprints appeared in Valencia in the same year. It was reissued in Brussels (1607 and 1611), Madrid (1608), and Milan (1610). With the exception of Mateo Alemán's picaresque novel *Guzmán de Alfarache* of 1599, no Spanish book of the period achieved such success. Thomas Shelton's English version of 1612 was the earliest translation.

There was, for Cervantes, little money in all this; shortly after the book's appearance he was borrowing 450 reals from the printer. A stabbing affray outside his first-floor lodging in Valladolid in June 1605, which landed him and his womenfolk in jail for a week on suspicion, showed him to be still living in difficult circumstances. For three years thereafter, he is again lost to view, to reappear in 1608 in Madrid, now once more the capital. There he was much harassed by an interminable series of legal squabbles over financial matters involving his daughter and her second hubsand; and when in mid-1610 the Count of Lemos, known for his benevolent interest in men of letters, was appointed viceroy of Naples, Cervantes sought escape by aspiring to an appointment in his entourage. The hope did not materialize; but, in dedicating to the Count the second part of *Don Quixote*, Cervantes paid tribute to the generous support received in his last years from him. Earlier, in 1609, he had been received into the newly founded fraternity of Slaves of the Most Blessed Sacrament; about the same time his wife took the habit of the Third Order of St. Francis. In 1612 he joined the Academia Selvaje, a new literary club to which the dramatist Lope de Vega, the other literary giant of Spain's golden age and no friend to Cervantes, also belonged.

Novelas ejemplares and other works

A third and culminating period of intense creative activity now began. The 12 *Novelas ejemplares* appeared in 1613, likewise dedicated to the Count of Lemos, on whom he, famous now as the author of *Don Quixote*, could obviously count at long last for the patronage that was then the writer's only hope of material reward. The book itself brought him 1,600 reals and 24 copies. Five of the stories, cast in the Italianate vein of amorous intrigue, perilous adventure, and incredible coincidence, could have been written long before: they are separated by an abyss from the other seven, on which rests his proud double claim of originality—"I am the first to write short stories in Spanish"—and, for the light they throw on human nature, of "exemplariness." The prologue paints a candid self-portrait of the author, now aged 65:

> Features aquiline, hair chestnut, brow smooth and unfurrowed, merry eyes, curving well-proportioned nose, a silvery beard that twenty years ago was golden, long moustaches, small mouth, teeth under par for he only has six and they in poor state and worse distributed, not answering one to another, in build between the two extremes, neither tall nor short, complexion fresh, rather fair than dark, somewhat heavy-shouldered and not over-light on his feet.

There followed in 1614 the *Viaje del Parnaso*, a burlesque poem on the poets of the day with an admirably whimsical postscript, the *Adjunta al Parnaso*, in prose. He returned to his first enthusiasm with the *Ocho comedias, y ocho entremeses nuevos* (1615), genially admitting in the preface that these, written "some years previously," had found no favour with managers, whence his acceptance of an offer of publication from a bookseller. In the foreword to the *Novelas ejemplares*, Cervantes had promised speedy appearance of a sequel to *Don Quixote*. He was at work on the 59th chapter of the sequel when he learned of the publication at Tarragona, in 1614, of a spurious second part by one Alonso Fernández de Avellaneda of Tordesillas, pseudonym for a disgruntled dramatist who has never been identified. The book was not devoid of talent and robust humour. What stung most was an insolent preface taunting Cervantes with physical defects and moral infirmities. Cervantes hurried on with his own second part, allowing some bitterness against Avellaneda to creep in, and it appeared toward the end of 1615. It too was speedily reprinted, in Brussels and Valencia (both 1616) and in Lisbon (1617), with a first translation, into French, in 1618. From the Barcelona edition of 1617 onward, both parts appeared together.

With energy and inventiveness unabated, his mind shaping ever new projects, Cervantes grew conscious that time was running out. *Los trabajos de Persiles y Sigismunda*, his last work, he did not live to see in print; published in 1617, it ran through eight editions in two years, with two French translations in 1618 and one into English the following year. Of this long *historia setentrional* reflecting his increasing concern with religion, the defense of which had come to seem to him the noblest and most chivalrous enterprise of all, he boldly claimed that it would prove either the worst or the best work of imagination in the language. The brief dedication to his patron, a most moving and gallant leave-taking "with one foot in the stirrup for the next world," he penned on his deathbed on April 19, 1616. He had already received Extreme Unction, and on April 23, in his house in the Calle de León, he died. The next day he was buried in the Trinitarian convent; no stone marked his grave, and no will is known. His wife, who in a testament made in 1610 had borne witness to "the much love and good companionship we have had together," survived until 1626 and his daughter until 1652, when his line became extinct.

MAJOR WORKS

NOVELS: *La Galatea* (written 1583, published 1585; trans. in 1867 as *Galatea*, by G.W.J. Gyll); *El ingenioso hidalgo don Quijote de la Mancha* (Pt. 1 published 1605, pt. 2 published 1615; trans. as *The History of the Valorous and Wittie Knight-Errant, Don-Quixote of the Mancha*, 2 vol., by Thomas Shelton in 1612–20; as *The History of the Renown'd Don Quixote de la Mancha*, 4 vol., by Peter Motteux, 1700–12; as *The Life and Exploits of the Ingenious Gentleman Don Quixote de la Mancha*, 2 vol., by Charles Jarvis in 1742; as *The History and Adventures of the Renowned Don Quixote*, 2 vol., by Thomas Smollett in 1755; modern translations include John Ormsby's *The Ingenious Gentleman Don Quixote of la Mancha*, 4 vol., 1885, reprinted in 1952 in "Great Books of the Western World"; *The Adventures of Don Quixote* by J.M. Cohen for Penguin Books, 1950; and *The Ingenious Gentleman Don Quixote de la Mancha*, with a critical text based upon the first editions of 1605 and 1615, with variant readings, and an introduction by Samuel Putnam, 2 vol. (1953); *Novelas ejemplares* (1613; 12 short stories; trans. as *The Exemplary Novels of Miguel de Cervantes Saavedra* by Walter K. Kelly in 1855 and 1881, but previously published in small collections after 1640); *Los trabajos de Persiles e Sigismunda* (1617; trans. as *The Travels of Persiles and Sigismunda* by "H.L. for M.L." in 1619).

DRAMA: *La Numancia* (manuscript discovered in 1784; trans. as *Numantia: A Tragedy* by G.W.J. Gyll in 1870; and in the third volume of Eric Bentley's *The Classic Theatre*, as *The Siege of Numantia*, trans. by Roy Campbell, in 1959); *Ocho comedias, y ocho entremenses nuevos* (1615; trans. as *The Interludes of Cervantes* by S. Griswold Morley, 1948).

POETRY: *Viaje del Parnaso* (1614; trans. as *The Voyage to Parnassus*, 1870).

BIBLIOGRAPHY. L. RIUS, *Bibliografía crítica de las obras de Miguel de Cervantes Saavedra*, 3 vol. (1895–1905, reprinted 1967), is still fundamental on bibliographical matters, to be implemented for the modern period by J.D.M. FORD and R. LANSING (comps.), *Cervantes: A Tentative Bibliography* (1931); and R.L. GRISMER, *Cervantes: A Bibliography*, 2 vol. (1946–63). The standard edition of the *Obras completas*, with critical introductions, is that by R. SCHEVILL and A. BONILLA Y SAN MARTIN, 19 vol. (1914–41). J. BOWLES' annotated *Don Quixote*, 6 vol. (1781), marks impressively the start of a long tradition of textual scholarship culminating in the 10-volume edition of F. RODRIGUEZ MARIN (1947–49), who presents with equal authority the 7 significant *Novelas ejemplares*, 2 vol. (1914–17). The "Biblioteca Clásica" gives a

plain text of the *Teatro completo*, 3 vol. (1896–1927). In English translation the *Complete Works*, a cooperative project edited by J. FITZMAURICE-KELLY, remained unfinished, 7 vol. (1901–03). THOMAS SHELTON's version of *Don Quixote*, 2 vol. (1612–20), almost contemporary with the original, is notable for a rendering more spirited than faithful. Those of PETER MOTTEUX ("by several hands"), 4 vol. (1700–12); and CHARLES JARVIS, 2 vol. (1742), retain in numerous reprints a currency beyond their scholarly merits. Of modern translations by J.M. COHEN (1950), SAMUEL PUTNAM (1952), and W. STARKIE (abridged 1954), the first-named is perhaps the most satisfying. J. MABBE's version of six *Exemplary Novels* (1640), was staid and, in the choice, uncritical; WALTER K. KELLY did better by all 12 (1881). The *Interludes* found a spirited translator in S. GRISWOLD MORLEY (1948). For the life, F. FITZMAURICE-KELLY's minutely documented *Miguel de Cervantes Saavedra: A Memoir* (1913; in its fuller Spanish version, 1917), retains its authority. Much new evidence had been assembled by C. PEREZ PASTOR, *Documentos cervantinos*, 2 vol. (1897–1902); and F. RODRIGUEZ MARIN, *Nuevos documentos cervantinos* (1914). H.E. WATTS, lacking that knowledge, painted a more spacious canvas in his *Life of Miguel de Cervantes* (1891), and is still of value. R. SCHEVILL, *Cervantes* (1919), relates the man to his works; as S.J. ARBO, *Cervantes* (1951; Eng. trans., 1955), does to his age. A. CASTRO, *El pensamiento de Cervantes* (1925), remains the fountainhead of modern Cervantes criticism. S. DE MADARIAGA, *Don Quixote* (1935), is a stimulating essay in psychology. W.J. ENTWISTLE, *Cervantes* (1940), studies Cervantes the writer; and E.C. RILEY, *Cervantes's Theory of the Novel* (1962), exhaustively, his profound concern with literary theory.
